The occurrence of this case and the treatment pursued, while successful, does not convince us that it would in a similar case be at all proper or justifiable to rely entirely on the solution of dialysed iron as an efficient antidote, if not followed by the free use of sodium chloride; as we contend that where any doubt exists the patient should have the benefit of it, and, through the exhibition of other remedies, so multiply the chances of escape that death should ensue only from neglect of these.

NEW REACTION OF MORPHINE.*

BY G. PELLAGRI.

The suspected substance, evaporated at a gentle heat if necessary, is dissolved in concentrated hydrochloric acid, a small quantity of sulphuric acid is added, and the mixture evaporated on an oil-bath at a temperature of 100° to 120°. If morphine be present, the liquid acquires at its edges a purple colour, which is not masked by the carbonization of organic matter, and when all the hydrochloric acid has been driven off, the sulphuric acid remains of a red colour. This dissolves in concentrated hydrochloric acid, and becomes violet on neutralization with sodium bicarbonate. This colour is insoluble in ether, but if a few drops of hydriodic acid be added, it changes to green, and is now soluble in ether, colouring it purple. These colour changes are very delicate, and are common to apomorphine, into which the morphine is changed by the action of the acid. Codeine also gives the same reactions, but its solubility in ether serves to distinguish it from morphine. Brucine when treated in a similar manner gives a blue colour on neutralization with sodium bicarbonate, but the reaction is not delicate.

The Pharmaceutical Journal.

SATURDAY, JANUARY 19, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE IMPORTATION OF PHARMACEUTICAL PREPARATIONS INTO FRANCE.

WE learn from a French contemporary that the restrictions imposed upon the admission of foreign pharmaceutical preparations into France have recently been under the consideration of the Committee of Public Health attached to the department of the Minister of Agriculture and Commerce. The result has been the presentation of a report, in which the Committee recommends some relaxation of the conditions affecting the admission into France of foreign pharmaceutical preparations.

In order to render the subject clear to our readers, it may be well to state that according to the existing law the importation of all medicinal preparations, except distilled waters and extract of cinchona bark, is prohibited unless certain formalities are gone through with the object of obtaining admission. For this purpose it is necessary that the preparations in question should be recognized by the Ecole de Pharmacie as being "necessary or useful," and then they are passed by the Customs only on payment of a duty of twenty per cent.

These restrictions are considered to be too rigorous and to bear too much the character of protectionist principles that are out of date and otherwise undesirable. Another argument in favour of removing the barrier to the importation of foreign pharmaceutical preparations into France is afforded by the circumstance that similar preparations of French manufacture are very largely in demand in other countries where there are no such restrictions to bar their introduction to commerce. Moreover, reciprocity in regard to the importation of such articles seems desirable in order to secure a continuance of the free admission of French preparations into other countries, and it appears that the Italian Government has intimated that it is only under such conditions that the free importation of French medicinal preparations will be permitted.

All these arguments have been considered by the French Committee of Public Health, and it is admitted that in order to be entitled to the characteristic of being "useful," it is not indispensable that a preparation should possess new therapeutic properties; it may be sufficient for this purpose to modify the form of a preparation and thus to render its administration more easy by masking or disguising a repulsive smell or taste. Such means of overcoming the fancies of invalids are not without their utility and consequent importance.

In the report of the Committee it is remarked that while there exist in all civilized countries official pharmacopœias, or at least such as are in general use, by which the composition and preparation of medicines ordered by physicians are regulated, the formulæ of these pharmaceutical preparations often differ from those adopted in the French Codex. In regard to this it is added that since invalids attach great significance to the form in which medicine is administered, and generally judge of its therapeutic value by this character, there would be no advantage gained by disregarding this fact, although from a medical point of view it may only be indicative of a prejudice.

As regards medicines prepared in France the law considers public safety to be sufficiently protected when the responsibility for the pharmaceutical preparations administered to the sick rests conjointly upon the physician who prescribes and upon the pharmacist who supplies them. The Committee in its report expresses inability to discover any reasons for making greater demands in regard to medicines prepared in foreign countries, and it is considered that the protective influence of this double responsibility is quite independent of the circumstance that the preparations in question are of French or foreign origin.

In pursuance of these views the Committee has submitted to the Government the following suggestions:

1. That the restrictions imposed by the law of 1817 should not apply to compound medicines, the importation of which is demanded by a pharmacist, and that these medicines should be admissible subject to a duty of ten per cent. *ad valorem*; the value to be determined by the Ecole Supérieure de Pharmacie.

2. That the sale of foreign compound medicines admitted into France should be subject to the same regulations as the sale of similar products of French manufacture.

Acting upon these recommendations the Minister of Agriculture and Commerce has, in the draft of a bill presented by him last year to the French chamber in relation to the customs, proposed to allow the importation of such foreign pharmaceutical preparations as are comprised in the official pharmacopœias of other countries, subject to a duty of ten per cent., independently of a further compensatory duty in the case of medicines prepared with materials subject to customs or excise duty. As regards preparations that are not comprised in official pharmacopœias, however, it is still proposed to maintain the existing prohibitory restrictions. This bill was not discussed by the legislature during the late session, but it is likely to be soon brought forward.

THE CHEMISTS' BALL.

The Twelfth Annual Chemists' Ball took place on Wednesday last, and was as successful in point of numbers and in every other respect as any that has preceded it. As usual the only toast was "Success to the Chemists' Ball." This was proposed by the Chairman for the evening, Mr. George Webb Sandford, who said that when a few years ago it was proposed to have such a Ball, some of the older and more prudent doubted the advisability of making the attempt. But the younger friends were enthusiastic, and the result had been these twelve annual gatherings. Mr. Sandford added that he had many pleasant reminiscences of meetings in connection with pharmacy, but none were so perfectly unalloyed as those relating to the Chemists' Ball, where the company met by a kind of natural affinity that gave place to an elective affinity with no discordant elements to disturb it. The toast was heartily received, and followed by a cheer for the ladies. The enjoyment of the company was much enhanced by the admirable manner in which the arrangements were carried out by the Honorary Secretary, Mr. Walter Hills, and by Mr. T. C. W. Martin, who acted as M.C.

CULTIVATION OF THE CINCHONA IN THE UNITED STATES.

It would appear from the Report of the Commissioner of Agriculture that an attempt which has been made to introduce the cultivation of the cinchona into the United States has not up to the present time turned out very favourably. During the past ten years a continuous supply of young plants of several species of cinchona has been maintained by a yearly propagation of young plants equal to the numbers distributed. Plants have been sent to California and to several of the Southern States, mainly to Florida. The reports that have reached the department do not indicate success in their culture, owing to adverse climatic influences. Experiments here show that none of the species will stand the slightest frost without injury, and even in the equable atmosphere of the greenhouse their vitality is impaired when the temperature is below 50°. Whether or not the climatic conditions for the growth of cinchonas exist in any portion of the United States is a question not yet solved, but, so far as present knowledge warrants an opinion, further experiments should be confined to the locality of San Diego, California, as offering greater promise of success than any other point.

THE LONDON CHEMISTS' ASSISTANTS' ASSOCIATION.

We have received from the Secretary of the above Association a printed Calendar of Meetings to be held during the first session ending the 24th of April, 1878. From this we learn that on Wednesday next a paper will be read, entitled, "Dispensing Notes on Preparations of Phosphorus," by Mr. Glover.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

A meeting of the Glasgow Chemists and Druggists Association was held in the Andersonian College, George Street, on Wednesday evening, the 9th inst. In the absence of Mr. Frazer, President, the Vice-President (Mr. Fairlie) occupied the chair. The minutes of the previous meeting having been read and approved, Mr. J. Paton, F.L.S., Curator of the City Industrial Museum, was introduced, and delivered a lecture on Opium.

Mr. Paton divided his subject under the heads of history, geographical source, cultivation and commerce. Under the first head he sketched the history of the plant from three centuries B.C. up to the present, giving some very interesting facts concerning its use in ancient times, and stating that directly and indirectly it had been the cause of various national wars. The lecturer next observed that opium was one of the greatest producers of both pleasure and pain and the most remarkable drug in existance, standing unequalled and alone. He confined his remarks more especially to the plant cultivated in Asia Minor and Smyrna and in India, as being the most important sources, and described very minutely the commercial cultivation of the plant in both countries, from the sowing of the seed up to the final disposal of the opium in the marts of commerce. Interesting statistics were given as to quantity of seed sown per acre, the yield per acre, and the variable total crop; the passing of the opium from one trader on to another was also fully described. A collection of opium from various sources and products therefrom was exhibited.

On the motion of the chairman a hearty vote of thanks was awarded the lecturer.

Proceedings of Scientific Societies.

PATHOLOGICAL SOCIETY OF LONDON.*

Lactic Fermentation and its Bearings on Pathology.

BY JOSEPH LISTER, F.R.S.

(*Concluded from page* 558).

Now before I go further, I wish to make a confession. Next to the promulgation of new truth, the best thing I

* Address delivered Tuesday, December 18, 1877.

conceive that a man can do is the recantation of published error. Some years ago I published in the *Microscopical Journal* an account of the behaviour, as I supposed, of the bacterium lactis in different liquids. I described that, having obtained souring milk, I inoculated unboiled urine with a small drop, and the result was the development in the urine of a very different sort of organisms in appearance; instead of being small as these are, about $\frac{1}{20000}$ of an inch in length, and half that breadth, those were comparatively broad and exceedingly long and coiled organisms, spirillum-like. They were motionless like the bacterium lactis, but exceedingly different otherwise. Then from that I inoculated a second urine glass, and got the same appearance. From the second urine glass I inoculated a glass of Pasteur's solution, and now got an exceedingly different appearance. I got bacteria only in short pairs—and with exceedingly active movements. I then inoculated another urine glass from the Pasteur's solution, and got back my large coiled organisms; and, lastly, from this I inoculated a glass of boiled milk, and got the lactic fermentation back again as with the original milk. I had also taken the pains to examine a specimen from the Pasteur's solution mixed with urine in a glass garden, if I may so express it, in which I could see the organisms from time to time, and thought I had traced the transition of the one into the other. I was lately mentioning these facts to an eminent physiologist, who took the view that after all bacteria might be mere accidental concomitants of the fermentative changes. I mentioned these facts to him, and when I had finished my story, he said, "Well, I am convinced." I thought to myself, "Well, if I have convinced this eminent gentleman by these facts, they are worth proving more rigorously; I shall have a little time between giving up the surgeoncy in Edinburgh and going to London; I will reproduce the experiments, and this time I will do them more strictly; I will actually observe everything with the glass garden, and see from hour to hour what change does occur, and if the one organism does become transformed into the other." Accordingly I got some souring milk from the same dairy as before. I proceeded to inoculate a glass of unboiled uncontaminated urine, and also a glass of pure Pasteur's solution. The result in the urine was that, instead of getting the motionless organism, I got an actively moving double bacterium. In the Pasteur's solution, on the other hand, I got a motionless bacterium instead of the moving one.

Here, then, were the facts all wrong. What was the explanation of it? I had obviously got some accidental contamination, though I thought I had kept myself clear of the chance of such a thing. So I determined to try, if possible, to get rid of these accidental concomitants, and the way which occurred to me as a possible mode of doing this was to dilute the milk with so large a quantity of boiled, and therefore pure, water as to have on the average only one bacterium to every drop with which I might inoculate the boiled milk. If I did that, then, as the bacterium lactis was out of all proportion in enormously larger number than any other, the chances would be, so to speak, infinitely great that I should only have the bacterium lactis in every such drop, that I should exclude all others, such, for instance, as multitudes of organisms which could only develop when the bacterium lactis was excluded. Accordingly, I attempted to count the bacteria, and seemed to succeed, and, I believe, did succeed, in that particular specimen of souring milk. There happened to be two kinds of bacteria in every field. There was not only the motionless bacterium lactis, but there was also an actively moving kind of bacterium, but in much smaller proportion. I found it necessary to dilute with as much as a million parts of boiled water. Having done this, I inoculated five boiled milk glasses, and of those five only one was affected in any way. That was affected with the lactic fermentation. The others were not affected with any fermentation, nor did they show any bacteria. Therefore, presumably, we had now got the bacterium lactis pure and simple: we would work with it, and see how it would behave in other media. I accordingly inoculated urine with it, and here it is represented as it was found in the urine after two days' development, exactly like what it was in the milk. But if I had not had it by itself, I should not have noticed it at all. It grew with extreme slowness; and if I had had the other bacterium that I had before developing at the same time, this certainly would have escaped my notice, so scarce was it. After a time it came to develop still more slowly in the urine, and developed an exceedingly puny progeny, though still capable of producing the lactic fermentation.

Then I inoculated also Pasteur's solution. In doing so, I made use of a tube like this which I have called a separation tube—a little glass tube bent, with one leg shorter than the other, the shorter leg stuffed with moist cotton and purified by boiling, after which it is introduced into a pure liqueur glass. The liquid to be experimented on is then poured in not to so high a level as the top of the longer leg. The liquid finds its way through the cotton. It rises in the longer leg, and then if we inoculate the liquid in the longer leg with anything, that something will not be able to pass through the closely rammed cotton-wool, unless it be capable of development. If it be capable of development in the liquid, then it will work its way before long through the cotton-wool, closely rammed though it is. Thus we have the means of separating things which are living and capable of development in that particular liquid from things which are not living or not capable of developing there. I inoculated such a separation tube containing Pasteur's solution by introducing a little curdled soured milk—soured with pure ferment. There appeared to be for a long time no change at all. After a while, I thought the curd looked a little swollen. I took a piece of it out and examined it, and found that the curd seemed to have disappeared, and its place was occupied by small bacteria, having the characters of the bacterium lactis, showing that it had developed there; but it seemed to have developed only at the expense of the piece of curd; for, in the outside liquid, although it was kept for more than two weeks, no development whatever took place. The bacterium had not been able to make its way through the cotton. Not only so; but I inoculated directly another glass of Pasteur's solution from a glass containing the living bacterium lactis in urine. At the end of a fortnight, there was still absolutely no development. Therefore, it appears that, in Pasteur's solution, the bacterium lactis, though it is not destroyed by it, cannot develop; it has not the materials requisite for its nutrition. Therefore, I am bound to make this confession, that I appear to have been mistaken in my former experiments. Certain it is that, in these last experiments, where I took that drop from the souring milk and inoculated urine and got an actively moving bacterium, I got something accidentally concomitant with the bacterium lactis. Equally certain is it that, when I inoculated Pasteur's solution with the sour milk, I got an actively developing, though motionless, bacterium—an accidental bacterium. Now that we know from experiments how exceedingly numerous the organisms are which are liable to infest milk, we can easily understand how such contamination may have taken place.

Having got the bacterium lactis apparently pure and unmixed, I proceeded to the experiment which has been already described elsewhere. I ascertained how many bacteria existed on an average in every hundredth of a minim of milk. Having ascertained this, I knew how much boiled water I ought to add (of course, using the most scrupulous precautions against contamination) in order that every drop with which I should inoculate glasses of boiled milk should, on an average, contain one of the bacteria. Probably, there would not be absolute uniformity of distribution; therefore, some glasses would have more than one, and some would have none. I inoculated ten glasses with such drops. All of these you may say were in one sense infective drops; that is to say, drops taken from an infective liquid; but, of those drops, some only produce an effect; and, by a curious coincidence, it happened that, of the ten glasses, exactly five were affected with the lactic fermentation, and exactly five remained fluid. I have brought before the Society an example of one of the fluid glasses still remaining fluid at this long period, which, you will easily understand, must have been somewhat difficult to bring from Edinburgh here without contamination from spilling. It was, of course, very carefully nursed. There is under one of these microscopes a small drop from this glass. I examined it to-day for the first time since the examination before leaving Edinburgh. I had seen then that there were no bacteria, and I find to-day that there are none. The only alteration visible in the microscope is that the milk-globules are becoming some of them angular through the effect of drying. Here, again, is one of the glasses that underwent the lactic fermentation; and this is equally remarkable; because here, having got the lactic fermentation pure and simple, we have a pure white curd to this day just as if the milk had soured yesterday, whereas with ordinary souring milk, though we get a white curd to start with, we all know that it is soon followed up by other alterations. There is the bacterium that leads to butyric fermentation; there is the oïdium lactis that constitutes the yellow bloom upon a cream-cheese. Very likely the penicillium glaucum finds its way in, and in the course of time putrefaction takes place; but here we have the pure effect of one particular ferment, and you will perceive that, whatever little odour there is, it is a pure sour odour.

Although I have fully stated elsewhere the inference to be drawn from this experiment, its importance leads me to mention it before this Society. We have seen from the former experiments that in water the fermentative agency is in the form of suspended particles, not matter in solution; and the experiment I have just recorded with regard to souring milk proves the same with regard to that fermentation. All received equal sized drops; half only were affected with the fermentation. That shows that the ferment was not dissolved. It was, as in the case of the ferments in water, insoluble particles in suspension. Then, what are those particles? Let us assume, for the sake of argument, that it is possible that there might be chemical particles destitute of life, capable of multiplying as rapidly as the bacterium, which you may watch multiplying and see growing in souring milk, becoming doubled in the course of an hour—you can see them subdividing at that rate. Suppose, I say, for the sake of argument, you make what I believe to be an unwarrantable assumption altogether, viz.: that there might be chemical particles destitute of life, capable of self-multiplication like those bacteria—admit that as a mere hypothesis, and I say it would be inconceivable if those two sets of particles, the true ferment and the bacterium, were mere accidental concomitants; that they should be present in the same numbers; and, if you admitted that they were present in the same numbers, it would be equally inconceivable that they should always go in pairs. I went through the process of examining on the glasses; and I found that, wherever there was a glass affected with lactic fermentation, there was the bacterium lactis, and every glass that was not affected with lactic fermentation showed no bacterium whatever. Therefore, I believe it must be considered absolutely demonstrated that that special form of fermentation is due to that particular kind of bacterium.

If this be really demonstrated, it must be admitted to be a very important point. Of course, it only proves one instance; but the method, I conceive, can be applied in many other cases of fermentation.

With regard to the odour of sour milk, why should there be such a thing? The chemist would tell you that lactic acid is non-volatile, and so it is—lactic acid is absolutely odourless. If you take a specimen of milk like this, which is some of yesterday's milk from a dairy, kept near a fire to promote souring, you find a fine fragance of sour milk; but that is not the sort of odour you have from a lactic fermentation pure and simple. The smell of ordinary sour milk seems to be chiefly due to butyric acid, which is volatile; but what is it that causes the odour in our apparently pure lactic fermentation? Some other ingredient than the lactic acid. I have been at the pains to distil sour milk—soured under the influence of pure lactic ferment. I got a clear liquid, which had still more strongly the peculiar, pungent, sour odour, reminding one somewhat of acetic acid, different from ordinary souring milk; but, to my surprise this liquid had no acid taste, and did not affect litmus-paper in the least. Therefore, it was some form of ether, I suppose—some volatile substance—which, though having a sour smell is not acid. I must leave it to the chemists to investigate its nature. It has been shown by Pasteur that caramel and other substances exist as concomitants of the alcoholic fermentation of sugar; so it appears that this substance, whatever it is, exists as a concomitant of lactic fermentution.

I should like to allude, if I might, for a minute or two to this diagram, in which we have represented the bacterium lactis, after developing three days in milk diluted with twelve hundred parts of water. It will be observed that the bacterium lactis is here of extremely small size. These diagrams are all to scale, copied from camera lucida sketches. The magnifying power, as represented on the diagram, is about 300,000 diameters. You will imagine, therefore, how exceedingly minute these little particles must be. You could not well tell that they are bacteria, seeing that they are motionless, except under the circumstances in which they occur and their grouping; yet bacteria lactis undoubtedly they were. Let me compare them for a moment with this ferment, the torula cerevisiæ. What a huge organism is the one in comparison with the other. The small one is not so big in its individual elements as the mere granules in the torula cerevisiæ, yet it is an organism with the remarkable fermentative properties I have described. Now let us imagine what is surely not an improbable thing; that there may exist other organisms as much smaller than the bacterium lactis as these are smaller than the torula; and we at once get, by that very simple transition, so to speak, to ultra-microscopic organisms. This consideration bears upon pathology. It will not do for us to say that, because we do not find, for example, in erysipelas any visible organisms, there are none. There may be organisms as real, as distinct in structure as these little bacteria lactis, and producing as potent effects by their growth, though we do not happen to be able to see them with any microscope that we have, and are not likely to see them with any microscope that will ever be produced.

Then there is one other point. When the milk was diluted with 1200 parts of water, within three days the bacteria had produced this puny progeny, not half the size of those that occurred in souring milk; and I should observe that after three days the bacterium lactis in the souring milk is not so large as you see it in the first twenty-four hours. If you wish to see the bacterium lactis in the best condition, you should take a glass of boiled milk and dip into a glass of souring milk the point of a needle, and inoculate the side of the glass with it; then, within twenty-four hours, you will find the bacteria. You may search long before you find them; but, if you find one, it will be of a good size. In the course of the next twenty-four hours, they will become smaller and smaller, until at last the majority of them, affected apparently by the sour milk, become so small that you can scarcely recognize them, and they become so confused with the curd, entangled in the curd of the souring milk, as red corpuscles become entangled in the fibrine of coagulated blood, that you may sometimes fail to see them even after a prolonged search, as I fear some of you may fail in that specimen of curdled milk of some months ago, under one of the microscopes. In water, then, or rather in milk very much diluted with water, the bacteria became small. Now, that beautifully confirms an observation I made some years ago to this effect. I took tap-water and introduced it into a pure flask purified in the way I have described. I kept it forty-eight hours. At the end of forty-eight hours, when I took the flask into a dark room and put a candle on the other side, I could just discern a delicate bluish-white film, and, on examining it with a microscope, I found it consisted of closely packed motionless bacteria of extreme minuteness. They were really there in the stagnant water. Who could doubt, then, that they existed in the running water; that they existed not merely as germs in the running water, but as bacteria? Then call to mind the simple experiments with the subdivision of water into hundreds of a minim; and you remember that, in the tap-water, at least which I investigated, the fermentative particles only existed about one in every hundredth of a minim. Add to this that a hundredth of a minim, if spread out between two plates of glass, occupies a space equal to half of a square half-inch; and you will see that, if you were to search for a whole summer-day for such an individual bacterium, you would probaby fail to find it. I have gone through the experiment of actually mixing bacteria in such proportions with water, bacteria of full development and large size, and I have failed, with a patient search for hours, in discovering one of them. If to this you add that the bacteria that I saw in water were motionless and minute, I think it will be seen that to say that, because we cannot see in water existing bacteria, therefore, you must be forced to the conclusion that water contains germs of bacteria, ultra-microscopic objects, that we could not see at all even if we had them under our microscopes, is to make an unwarrantable assumption. I am aware that there are two instances, the bacillus anthracis and the bacillus subtilis, in which it is said that the actual germs of bacteria do exist. I have seen nucleated bacteria myself. I confess I have never seen things that resisted such treatment as these germs are said to have resisted in the hands of others. But even these germs are not ultra-microscopic. They are bright points that are seen—bright granules. There has never been evidence of any ultra-microscopic germ; and, as Dr. Roberts points out in his Manchester address, those two species are the only bacteria with regard to which there is anything like evidence that germs exist at all. For my own part, I think it extremely improbable that bacteria in general have germs. They are actually reproductive organs, constantly multiplied by segmentation; and, if there be any organism in existence that does not require germs, I should say it is the bacterium; but the facts that I have mentioned, on the one hand the scarcity of the fermentative particles in such water as I have examined, and on the other hand the small size the bacteria assume when they develop in water, seem to me sufficient to explain why we do not meet with them in microscopic examination. Thus I venture to say that, what appears to me to be at the present time a somewhat needless mystery in this matter, may be satisfactorily cleared away.

GLASGOW UNIVERSITY MEDICO-CHIRURGICAL SOCIETY.

The Relations of Pharmacy to Medical Students.*

BY JOHN EDMOND FAIRLIE.

In considering the history of the last hundred years, there is nothing which more surprises the reflective mind than the vast amount of scientific knowledge which has been gained in that, comparatively, short period. This indeed has been so great, that, utilized by what is known as the Arts and Manufactures and permeated as it is through the whole workings of society, it has produced changes which have been not only remarkable but revolutionary in the highest degree so as not only to completely remodel into a new era the manners and customs of life, but also to completely reorganize the whole scientific world.

There is no better example of this advancement and extension of human knowledge than is seen in that part of the great domain of science known as "Medicine." The consequence being that the "Medical Art," although of course still far from perfection, has become transformed and developed with such remarkable rapidity, that now it bears little or no resemblance to the mystified and grovelling art of the ancient physician.

As the amount of scientific knowledge increases, those subdivisions of science, or the so-called sciences, become multiplied with great rapidity; some of which spring into being from the study of subjects hitherto altogether overlooked, many originate in, and are evolutionized, as if it were, from the embryo of a mere trade, while others are formed as if by a process of germination from the further subdivision of other sciences. This also has been remarkably exemplified in the science of medicine, and there is no doubt but that as our knowledge extends, many further subdivisions in biological science will become necessary. In many of these cases, the subdivision is merely conventional, as no distinct line of demarcation can be drawn between them, for it is difficult to draw a dividing line between such sciences as Chemistry and Physics, Surgery and Practice of Medicine, or of Anatomy and Physiology; but the amount of matter to be treated of in each is so great, that separate and special study is an absolute necessity.

Hence, assuming an hypothetical line of separation, selecting from the great temple of science the truths necessary to illustrate the subject matter, and, searching out, both by reasoning and experiment, for new truth, we have what is in each case popularly termed a "science." In reality, the great field of science is so vast, and the span of a life so comparatively short, that, in order to unravel a little of the unknown, and to develop and improve a little of what has already been discovered, the student of science must devote an untiring lifetime to one subject alone.

In no case is this more true than in that of the great subject now treated of as "Materia Medica," in the which, even although discoveries have lately been made, which have almost entirely changed the whole system of prescribing, there has yet been all along so much vague speculation and utter contradiction among its very best authorities, that we are disposed to put the whole subject down as one comparatively crude and undeveloped. The reason of this I believe to be greatly owing to the fact that up to the present it has been overloaded with subject-matter, and its observations scattered over far too wide a field. This then may be a subject which, in the face of the rapid advance of science, demands a multiplication by branching. I hold that this is indeed necessary, and will now endeavour to point out how it could be divided into, at least, two distinct subjects. It has in reality been similarly divided, and that with great success, on the other side of the Atlantic, where, in the medical schools they have two chairs, each teaching a subject, drawn directly from the general subject of "Materia Medica," we mean those of Pharmacy and Therapeutics. Under the former I would include (1) Pharmacognosy, or the origin, properties, varieties, qualities, and the purity of medicinal substances; (2) Pharmacy itself, or the manufacture, collection, preparation of these substances, with a practical classification of their compounds and preparations. This would constitute the "Science and Art of Pharmacy," or in short, the science of "Pharmaceutics."

Under the latter I would include (1) "Pharmacodynamics," or the uses, effects, and administration in the removal, mitigation, or prevention of disease, with a classification of medicinal substances, on a clinicophy-

* Read January 4, 1878.

siological basis; (2) Toxicology, or the dangers, results of, and antidotes for an overdose of any of the more active substances; and (3) the dietetics, the hygiene, and certain mechanical operations which are most useful in treating disease. This would constitute the science and art of "Therapeutics."

It is true that the term "Materia Medica" applies equally to both these subjects as we have defined them, and a thorough knowledge of it is the basis of both. Yet I think that I have clearly shown that the practical distinction is as great as in many other cases.

Take the instance of anatomy and physiology. Here a knowledge of the animal structures is the real basis of both. Yet they are practically quite distinct, for although treating of the same materials it is under vastly different circumstances. The former (anatomy) treats of these structures in their inanimate form, the theories of their origin and development, their collection, preparation, preservation, and the handling and observing of them for the purpose of knowing them familiarly.

The latter science treats of these structures during the active performing of their functions, and all the circumstances which govern, sustain, or influence that function, whether by assisting or interfering with it in the least degree.

Similarly so is it with "Pharmaceutics" and "Therapeutics."

The former treats of medicines in their inanimate form, the theories of their origin and development, their collection, preparation, preservation, and the handling and observing of them for the purpose of knowing them familiarly; while the latter science treats of these materials during the active performing of their function on the living body, and all the circumstances which govern, sustain, or influence that function, whether by assisting or interfering with it in the least degree. The two cases may not be exactly analogous in every detail, but they are sufficiently so to show that medicinal substances, considered from a pharmaceutical point of view, on the one hand, and from a therapeutical on the other, are quite distinct.

Thus far I have endeavoured to define what we include under the term "Pharmacy," and in speaking of its relations to "medical students" I will consider, 1st. The importance and place of pharmaceutics in medical education; and 2nd. The relations of the two professions, viz., those of the physician and the pharmaceutist.

There can be no doubt but that a thorough knowledge of the materials at hand for the removal or mitigation of disease is an accomplishment both extremely useful and highly necessary to every physician. It may be true that cures have been made with coloured water, or bread pills, that the temperament of the patient has great influence in helping to remove a disease, and that belief is a great part of all cure. But if a patient is restored by any of these means alone, the affection must have been either very transitory, or existed only in his fretted imagination. In most cases where medical aid is desired, something materially has gone wrong with at least one function in the body. Now, the ideal of treatment would be to hit upon the quickest and easiest mode of restoring the order of that function. To do this successfully much more is required than the mere theory, or book knowledge, of the treatment of disease. For as in diagnosis, the more familiar we are with the structures of the body, the sooner shall we hit upon the exact one implicated; so in prescribing, the more familiar we are with the substances with which we have to deal, the sooner shall we hit upon the exact remedy indicated. Diagnosis may be the first, and certainly it is a vastly important feature in the treatment of disordered functions. But that of itself could never restore order. No matter therefore how elaborate, careful, and skilled, be our diagnosis, it availeth nothing if not accompanied by prompt, decided and efficacious treatment. I know of graduates of this university, who though passing through their classes with success and even graduating with honours, yet found the want of a practical knowledge of medicines an immense stumbling-block between them and a successful practice; while others, who though only taking a common stand in their classes, and passing for the degree with great difficulty, yet entered almost immediately into triumphant popularity, chiefly owing, as they themselves admit, to an intimate acquaintance with the nature and preparations of medicines. As in analytical chemistry the greater the practical familiarity with chemicals the greater the instinct which leads the chemist in the direction of the unknown, so in prescribing, the more of the practical knowledge of medicines that we possess the quicker will instinct lead us to the proper remedy.

Let us notice a few errors which the prescriber is apt to fall into (1) of giving nothing, (2) of giving too little, (3) of giving too much, (4) of missing the mark altogether, and (5) of giving erroneous and inelegant admixtures. Examples of these I have observed repeatedly, but I do not mention them in the least as a slight to the profession, for a man may make them all although well up in all the other parts of medical knowledge. In regard to giving the patient nothing (if it is supposed that nothing serious is wrong), it is a mistake; because as the patient believes that something is wrong he simply goes to some other doctor or resorts to some "quack medicines," whereas a little tincture of cardamoms or compound tincture of cinchona, by allaying the patient's apprehensions, might have performed a wonderful cure. In regard to giving too little it is evident that if there be a disease at all it not only does little or no good but often positive harm to prescribe too little even of the right medicine, for it only allows the disease to take its course and thus destroys the patient's faith in the physician. Many physicians while they do not openly espouse the doctrine of homœopathy, yet unconciously approach remarkably near the confines of that art. Take the following two examples, in which cases I know that the patients were decidely ill and had latterly to procure other aid. (1) For a lady about thirty was prescribed the following:—℞ Sodii Chloridi ʒvj, Aq. ad ℥vj. A dessertspoonful for a dose three times a day. (2) For a corpulent man who was disturbed with want of sleep was given—℞ Potassii Bromidi, ℈j, Aq. ad ℥x. M. sig. A tablespoonful at bedtime. In both these cases the whole bottle might have been given at once with comparatively little physiological effect. Regarding the giving of too much, this seldom happens, as it is the duty of the pharmacist to detect unusual doses, yet proof has often to be produced before the prescription is altered. This often happens from confounding the names of substances which are similar, or confounding the signs used in the writing of prescriptions. We have seen calomel prescribed as "Hydrargri Chloridi," a term which would also apply to corrosive sublimate; the dose of the latter being only one-twelfth of a grain, whereas that of the former is six grains. The sign for an ounce (℥) is often confounded with that for a drachm (ʒ), and the error of prescribing an ounce and a-half instead of a drachm and a-half of substances such as hydrocyanic acid has been made and corrected by the pharmacist. In regard to missing the mark we may reason *à priori* that it is a great blow to the success of any man, that is if the disease does not remove itself. This mistake may not only be of giving the wrong substance, but also of giving the right medicine in a form entirely unsuited in the particular case for which it is required, as it is a common occurrence for patients either to be unable to take, or have a horror for certain forms of medicine. Regarding the prescribing of erroneous mixtures I may say that this is exceedingly common. The effect of this is damaging to the interests of the physician, as I am convinced from what I have seen that a pleasant looking and elegant preparation will go a long way in helping its efficaciousness, and the apathy and disgust often evinced at the taking of ugly medicines must have a great counteracting effect upon their curative properties.

Among these I might mention nauseous oils and resinous juices not made into a proper emulsion; too large pills, powders, etc.; resinous tinctures mixed with water; substances which are incompatible, such as aromatic spirit of ammonia and syrup of squills; bringing an acid and an alkali together, and the mixing of substances which produce a disagreeable, muddy, dirty-looking precipitate, and necessitates the pharmacist sticking a label on instructing the patient to "shake the bottle," as if the harmless bottle had anything to do with the inelegant mixture,—I am disposed to suggest that the physician should get the shaking. Cases such as I have here mentioned cause the patient to loose confidence in the physician. He then takes off to some other, to some pretentious or unpardonable "quack," or what is exceedingly common, to the use of "patent medicines" or the study of 'Buchan,' or some equally ancient so-called "family doctor,'' all of which, whether by virtue of the substances used, or the captivating, highsounding, and alluring recommendations which are given with them, often perform in the eyes of the patient most wonderful cures. The failure of a number of our physicians to prescribe the "right thing in the right place" (not from want of medical knowledge, as a rule, but merely from a want of familiarity with the substances to be prescribed) has given a great incentive to, and keeps alive to some extent, the two bugbears of the medical profession at the present time, viz., prescribing by persons ignorant of the nature of disease, and that now alarmingly extensive, highly dangerous, and exceedingly ruinous system of respectable swindling, "patent medicine."

From what I have said it may be concluded that a good sound knowledge of pharmaceutics is a "talisman" of the greatest value to every physician.

In regard to the place of pharmaceutics in medical education I feel assured that it is destined to fill a higher place in the future than it has hitherto done. That place cannot be estimated at present owing to the rapid development of pharmaceutical knowledge. But there is not a doubt that it will very soon be one of the most popular of the practical classes in our whole curriculum.

The present system of an optional two months' course in summer or of taking three months in a chemist's shop, are totally inadequate and insufficient in view of the largeness of the subject.

I have had some experience of the sham of the latter arrangement, as the student knows about as much at the end as at the beginning of his term, and but that he bears away with him a certificate, which bears a lie on its face, his fee is worse than lost. Druggists have not the qualities nor experience of a teacher, and very few have time for teaching. The student is often left to find out things for himself, or is handed over to the care of the apprentice, with whom he often practises in the back shop the "noble art of self-defence," instead of hammering into his brain the details of the numerous preparations made from opium, cinchona, etc., while the medical student studying pharmacy behind the chemist's counter is often more an annoyance and a bore than anything else; further, very few of the pharmaceutical processes which are of real importance to the medical student are ever gone into in the average retail chemist's shop, such as the preparation of the alkaloids, the formation of salts, and the manufacture of substances having much intricacy in their manipulation. Our hope lies, on the one hand, in the examinations of the Pharmaceutical Society, for the elevation of the pharmacist. This Society has in the past done good service in London by establishing its School of Pharmacy, where the three branches, chemistry, botany, and materia medica, are taught to advantage; but the provinces have been neglected by this Society as well as by the various medical faculties throughout the country, and we must therefore look, on the other hand, to a systematic course of study being adopted, not only for those who have to present themselves to the pharmaceutical examinations, but also for medical students, and that in connection with every medical school in the country.

Referring to the Pharmaceutical Society, it is an examining body by law, but its students are allowed to find their education where they may. I have great faith in a systematic course of training, and I think that the medical faculties are standing in the way of true pharmaceutical progress in not endeavouring to have a chair of pharmacy established, and the attendance of the class made compulsory upon all medical students. In view of the new arrangement, now recommended for the medical curriculum in this college, of a five years' course, I think that one of the regulations ought to be that in the third year a regular winter's course of pharmacy, copiously illustrated by experiments and specimens, as a forerunner, and preparatory to the great and vital subject of "therapeutics," a course of which could be held in the fourth year. And in view of the then acquired clinical experience, and in the light of the knowledge of pharmaceutics, this universal and all-important subject might be studied with advantage and with an interest and appreciation which few medical students at the present time have any idea that it should possess for them.

Let us now consider shortly a few of the relations existing, or which ought to exist, between the physician and the pharmaceutist.

There are no apothecaries in Scotland, but in England and Ireland, the calling of the apothecaries—who were the druggists of the last century, and became fired no doubt with ambition and enthusiasm as time advanced by the numerous discoveries of modern science—has become exalted to the rank of an honourable profession. As an outcome, therefore, of the Pharmacy Act of 1868 and the standard of examinations now maintained by the Pharmaceutical Society, there is undoubtedly a glorious future in store for this new profession of pharmacy. But, as in the medical profession itself, it will be long before it will purge itself of old tradition and custom, free itself from the innovations of some of its empirical adherents, or defend the integrity of its constitution from the daring enterprises of some of its unruly and presumptuous members. In view of this state of matters, what are and what ought to be its relations to the profession of the physician, whose handmaid the pharmacist practically is? These are exceedingly delicate, and the elasticity which custom and the want of law gives to both demands an early and decided rectification. On the one hand the chemist, while he cannot ever be restricted from diffusing the knowledge he naturally acquires regarding the common action of simple medicines, or even their application in simple cases or in emergencies, is subject to a great temptation to fall into a custom of regular prescribing, simply from a desire not to refuse the requests of a good customer. This is especially the case in the poorer districts, and in the country, where the people are either too poor to pay a fee if it can be at all saved, or, ignorant of the real difference between a chemist and a doctor, they imagine the chemist to be a doctor who does not visit, who gives free advice, and yet knows as much, and in many cases gets credit for knowing more than the qualified professional man who goes about charging a fee. On the other hand the chemist has been encouraged in this, and has some ground of excuse, in the fact that there are about three doctors who keep open shop for every one chemist; this applies more particularly to Glasgow and the west of Scotland. The majority of doctors manage a shop by putting a boy or a girl in it, who knows little or nothing of the business, at a very small wage, for which reason, together with the fact that he generally has a fee in addition to his profit on the medicine, he undersells the chemist. There would not be so much room for complaint if the plan was generally adopted that is followed out by a very few, that is, simply to dispense their own medicines. But for professional men to bemean themselves, by encouraging the sale of all kinds of quack nostrums, is utterly *infra dig.*, and ought to be scouted down by all those who have the true interest of the medical profession and the good of the people at heart.

But the great bulk of surgeries, or so-called "Apothecary Halls," in this district contain a large stock of "sundries," and "patents," and the public may obtain any small quantity of medicine for the above reason, often cheaper than the chemist is able to supply them, and in many cases in these places free advice is given, charges being made merely for the price of the medicine, thus outdoing the chemist in every detail. So much so is this the case that I am confident that there is scarcely a chemist in the east end of the city, who derives more than a tenth of his income from the legitimate dispensing of prescriptions, the other nine-tenths being made up in despair by counter prescribing, pushing the sale of "patents," and the sale of common articles of stock. Some medical men, though above keeping open shop, find other ways and means of deriving a profit out of the medicine they prescribe, and I have been told that arrangements exist between some physicians and chemists whereby a percentage is allowed the doctor for every prescription sent. The physician presents the prescription to the patient in an envelope, with the chemist's name and address, remarking that that is the only shop where it can be properly made up, and even resorts to the writing of mythical prescriptions in terms which that chemist alone knows. Such prescriptions as the following are to be seen every day:—℞ Pess, No. 1, 2, 3, et 24. One as directed. ℞ Mist. Comp., ℥viii, a tablespoonful three times a day. ℞ Pil. alb. xii. The pills, etc. Such practices I would stamp as downright conspiracy against the public, and both doctor and chemist I think ought to be punished by the law. The system of counter prescribing when carried beyond ordinary bounds should be condemned with severe punishment. The system, so common in Scotland, of doctors having shops with only boys or girls in them, who cannot really have any understanding of the medicines, is so fret with danger to the general public that it also should be prohibited by law; while the system of the manufacturing and puffing in the newspapers of "patent medicines" now so enormously carried on, especially by the English chemists, is—as these are composed of nothing more nor less than the common articles of the materia medica which everybody knows—one of the best examples of respectable swindling, carried on, too, under the cloak of a christian government, ever introduced into a civilized country. I hold too that these malrelations neutralize the influence and retard the progress of both professions, and I am hopeful that the time is not far distant when purged from these evils they will live together peacefully, entwined together as elder and younger sisters, yet remaining each distinct in her own sphere. With the pharmaceutist abstaining completely from anything which would approach or in the least substitute medical advice; with the abolition of the doctor's shop and the surgery, unless when managed by a qualified chemist; with the annihilation of the whole trumpery of the so-called patent medicine, and with the members of both acting openly in the light, avoiding the darkness of conspiracy, they would rise accordingly in the honour and respect of the world; and each one performing his duty within his own sphere, with a faithfulness which is but the outcome of the truly noble soul, look far beyond the trivial opulence of mortal life for a far higher and more glorious reward.

Parliamentary and Law Proceedings.

The Angostura Bitters Trade Mark.

In the Chancery Division of the High Court of Justice, a case, Siegert *v.* Findlater, has been heard before Mr. Justice Fry, involving a trade-mark question of considerable peculiarity in its features, especially in the fact (at first sight surprising) that a part of the injunction asked for and obtained prevents the user in existing circumstances of a trade name adopted by Dr. Meinhard, the manufacturer of the offending goods, before it was taken by the plaintiffs.

The plaintiffs manufacture at Port of Spain, in the Island of Trinidad, an article which (as his Lordship held) has been for some years known and sold in England as "Angostura Bitters." The manufacture of this article is a trade secret invented by Dr. Siegert, the father of the plaintiffs, at a time when he lived at Ciudad Bolivar, on the Orinoco, the capital town of one of the federated states of Venezuela. The town was called Angostura till in 1846 it name was altered by the local legislature; the district is still known by that name, which the evidence showed, continues to be used in England and has not been erased from the plates of map publishers. Dr. Siegert, in consequence of the disturbed political state of the country, removed many years back to Trinidad, where he and his successors have ever since carried on the manufacture of their bitters in that island. Dr. Siegert's article was formerly called by the makers "Aromatic Bitters," but it acquired in England the appellation of "Angostura," and the plaintiffs now sell it in bottles of a particular size and shape in paper wrappers imprinted with advertisements and cautions against spurious imitations in four languages, and folded in a particular manner; it is designated on the wrappers as "Angostura Bitters." The present action was brought against Messrs. Findlater and Co. and Messrs. Ingliss and Wulff, who were employed by the general agent of Dr. Meinhard at Hamburg for the sale in England of bitters made by Dr. Meinhard at "Ciudad Bolivar," and sold in bottles of the same size with paper wrappers very like the plaintiffs', and folded in the same peculiar way. The action sought an injunction to prevent the sale in England so as to deceive the purchaser into believing that he was buying the plaintiffs' article. Messrs. Findlater had been dismissed the action, having at once ceased to sell, and the other defendants were defending under an indemnity from Dr. Meinhard. This is not the only litigation between the parties. An injunction was obtained in Trinidad to restrain the sale of "Aromatic Bitters" in imitation of the plaintiffs'; and, on the other hand, they failed in proceedings at Hamburg, not being able, it would appear, under the German law of trade-mark, to obtain protection for their paper wrappers.

Mr. Cookson, Q.C., and Mr. Fellows appeared for the plaintiffs; Mr. North, Q.C., and Mr. John Cutler for the defendants.

Mr. Justice Fry gave judgment at considerable length, in which he compared the points of resemblance between the rival articles as presented to the public, and came to the conclusion that, notwithstanding the names of the makers being impressed on the bottles and other slight differences, there was such a general resemblance in the "get-up" of the articles for the market that the similarity was likely to deceive a purchaser, and from that and the other evidence he must presume an intention on the part of Dr. Meinhard to obtain a sale of his goods as those of the plaintiffs. There was evidence of actual mistake. The plaintiffs' agent had discovered by taste that "Angostura Bitters" sold at the Criterion were not the plaintiffs', and the manager of that place in buying had himself been deceived. There was, he said, a question as to whether the injunction ought to extend to the use of the word "Angostura"; he was of opinion that the word had been adopted skilfully after judgment had been given against Dr. Meinhard in Trinidad to get the benefit of the use of a word under which the plaintiffs' article and no one else's was known in England. There would be an injunction to restrain, among other things, the use of that word in such a manner as to mislead; but it would not prevent Dr. Meinhard, if he discovered the plaintiffs' secret, from making an article exactly like theirs and selling it under that name; nor, if the name "Angostura Bitters" became of wider or different meaning in England, would the defendants be prevented from making and selling under that name an article properly so called.

POISONING BY STRYCHNINE.

At the Cambridge assizes on Tuesday, before Mr. Baron Huddleston, Samuel Shotliffe, a railway signalman, was charged with the wilful murder of Clara Jane Reddane, of Murrows, by inciting her to take strychnine. The deceased was sister of the prisoner's wife. She had had one illegitimate child, which was fourteen months old, and of which she alleged the prisoner was the father. Her brother-in-law stated that the prisoner had visited deceased at his house, and, according to his own version, pressed her to blame another man. She declined, and he said he was a ruined man, and she would not see him alive again. Thereupon, he said, she snatched a packet of strychnine which he held in his hand. He asked her to give it back to him, but she promised to burn it, and they parted. Shortly after deceased encountered the prisoner's wife, and there were words between them. Her death took place within four hours. In her dress pocket was found a packet, which was proved to contain nine grains of strychnine. It was proved that the same morning the prisoner purchased ten grains of strychnine, ostensibly for rat killing. He gave a fictitious name, and the chemist's daughter sold the drug without requiring him to be introduced by some one she knew. This drew forth severe remarks from the Judge, who hoped steps would be taken in that case, because had the laws been obeyed they would in all probability not have heard of this case. The prisoner said he originally purchased the strychnine with the intention of destroying himself, being overwhelmed with the disgrace which his conduct had brought upon a happy family. The jury found prisoner Not Guilty, and he was discharged.

Dispensing Memoranda.

[50]. EXT. ERGOTÆ LIQUID.—Mr. A. W. Gerrard, of University College Hospital, writes objecting to Mr. Langbeck's opinion that the crystalline deposit from fluid extract of ergot is potassium sulphate. He also states that—

"Two different deposits occur in this extract; the first is usually deposited within a month of its manufacture, consisting of distinct transparent crystals two or three lines thick, thus corresponding with the description of 'Young Pharmacist;' these crystals are soluble in water, have an acid reaction, and give all the characteristic reactions of phosphates.

"The second deposit is slower in its formation, and of a calcareous character, consisting mainly of phosphate of lime with a little sulphate; in this deposit, recently examined, minute traces only of potassium could be found, and judging from the solubility of Mr. Langbeck's barium precipitate in nitric acid, I think much lime must have been present in the form of phosphates.

"For further confirmation of my views, Flückiger and Hanbury state that the crystals found in ergot extract consist of acid phosphate of soda with a little sulphate; as to the acid they are correct, but the base is wrongly stated. Again Chevallier and Wiggers have separately analysed ergot, obtaining therefrom nearly 4½ per cent. of acid phosphate of potash, but they do not mention the sulphate."

[52]. I think Mr. H. Cumber can avoid dispensing anything so formidable as seven-grain pills. But to send out double the number ordered by a physician is unadvisable. If a patient had previously been told that twelve pills would be sent it would occasion surprise to receive twenty-four. Again, if at one house twelve large pills are supplied, and the prescription is subsequently handed to another dispenser, who sends twenty-four of a different size (and who quite possibly has no opportunity of explaining that he has only altered the form of dose), the uneasiness of the patient is naturally the result; and if the case were reversed the effect is the same. In this way confidence is lost, and too often not a little annoyance results both to dispenser and principal. If the prescription were in the first instance handed to me to be dispensed, and communication with the writer were practicable, I would ask him to write on the prescription that twenty-four pills should be made of the ingredients, and two of them be taken for a dose. That being done, each dispenser into whose hands the prescription might afterwards come would be in a fair position to merit the confidence of his principal's patron.

If, where practicable, the first dispenser of medicine having properties that raise the question of alteration in any manner would act as suggested above (though not for the first time so suggested), much trouble and annoyance would, I feel sure, be avoided.

In this instance, supposing access to the prescriber unattainable, or the prescription to have been previously dispensed, I would proceed as follows:—

℞ Ext. Hyoscyami . . . . gr. xxxvi.
Pulv. Pil. Rhei. Co. (*i.e.*, sine Theriacâ). gr. xxxii.

Make twelve pills. If well worked these are quite of presentable appearance, though smaller ones might be desirable.

S. H. P.

[54]. ℞ Creasoti . . . . ♏ ij.
Pil. Rhei Co. . . . . . . gr. ij.

This can be made into a pill not larger than a 4 gr. pill by the addition of 1 gr. of magn. calc. levis.

For ten pills:—

℞ Creasoti . . . . ♏ xx.
Magn. Calc. Levis. . . . . gr. x.
Pil. Rhei Co. . . . . gr. xx.

Rub the magnesia and creasote together, and set aside for three or four hours; it will then be hard enough to powder. Add the pil. rhei, work into a mass, and divide into ten pills.

W. WILKINSON.

263, *Cheetham Hill, Manchester.*

[54]. These pills can be easily made of a size not exceeding that of an ordinary five-grain pill. If half-a-dozen are wanted—

℞ Creasoti (by measure) . . . . . ♏. xii (12).
Pulv. Pil. Rhei. Co. (*i.e.*, sine Theriacâ) . . . . gr. viii (8).
Magnesiæ Levis . . . . ℈j.

Mix the pill and creasote well, add the magnesia, mix and roll out quickly.

S. H. P.

[54]. In answer to No. 54, I have found the following method for pills to make a nice pilular mass, and not too large.

℞ Creasote . . . . ♏ ij.
Pulv. pro Pil. Rhei Co. . . . gr. ij.
Excipt. Pulv. Tragac. Co. . . gr. iss.
Mica Panis . . . . gr. j.

Ft. pil. j.

C. W. BOTWOOD.

[54]. In answer to query No. 54 in last week's issue, "Aderyn" will find no difficulty in producing a good pill if he adds one grain each of cera flav. and pulv. glycyrrh., using an equivalent quantity of the pulv. pro pil. rhei co., instead of the mass.

A. E. C.

Scarborough.

[57]. Will any experienced dispenser kindly state the proper way to dispense the following prescription:—

℞ Tinct. Ferri Perchlor. . . . . ʒiij.
Tinct. Digitalis . . . . . . ʒij.
Aquæ Chloroformi . . . . . ʒij.
M. Cap. coch. parv. bis in die, ex semi cyath. aquæ.

Not knowing the physician or prescriber I dispensed it literally as it stands without the ad ℥ij; consequently making it ℥ij ʒv.. but I cannot think it was so intended.

BETA.

[58]. Can the following be made without effervescing, which causes inconvenience, so much so, that I have had a bottle or two burst soon after they were finished:—

℞ Potass. Iodid. . . . . ʒj.
Potass. Bicarbon. . . . . . . ʒij.
Ferri Ammon. Citrat. . . . . ʒij.
Aq. Flor. Aurant. . . . . . ad ℥iij.
M.

The quality of the chemicals cannot be doubted, as I obtained them from one of the best London houses to try to obviate the effervescing effect.

BETA.

Notes and Queries.

[574]. TRANSPARENT CEMENT.—Will some one kindly inform me how to make Transparent Diamond Cement? I have tried most of published forms, but find them all opaque.

AGGLUTINO.

[575]. CHERTIER'S COPPER.—I wish to inquire through the Journal what salt of copper is known as Chertier's Copper.

WALTER SLICER.

Obituary.

Notice has been received of the deaths of the following:—

On the 6th of December, 1877, Mr. John Priestley, Chemist and Druggist, Bradford. Aged 46 years.

On the 17th of December, 1877, Mr. Robert Lees, Chemist and Druggist, Edinburgh. Aged 74 years.

On the 19th of December, 1877, Mr. John Bennett, Chemist and Druggist, Clarence Parade, Cheltenham. Aged 61 years.

On the 20th of December, 1877, Mr. William R. Marsden Starks, Chemist and Druggist, North Shields. Aged 31 years.

On the 21st of December, 1877, Mr. James Paterson Roger, Chemist and Druggist, Rhynie, Aberdeenshire. Aged 42 years.

On the 23rd of December, 1877, Mr. Robert Robinson, Chemist and Druggist, Lockwood. Aged 75 years.

On the 27th of December, 1877, Mr. Patrick Milne, Chemist and Druggist, Arbroath. Aged 77 years. Mr. Milne had been a Member of the Pharmaceutical Society since 1870.

On the 30th of December, 1877, Mr. Philip Howman, Pharmaceutical Chemist, Winchcombe, Gloucestershire. Aged 63 years. Mr. Howman had been a Member of the Pharmaceutical Society since 1842.

On the 13th of January, 1878, Mr. Edmund Hewson Armitage, Pharmaceutical Chemist, Dartford. Aged 33 years. Mr. Armitage had been a Member of the Pharmaceutical Society since 1869.

Correspondence.

DEATH POINT OF BACTERIA.

Sir,—Mr. Willmott in his letter in last week's Journal claims to have determined for the first time the fact, "that bacteria and their germs were utterly destroyed when placed in a temperature of 150° Fahr. and upwards, providing that the heat were continuously applied for a period of from three to six days," and further states that "this was quite a new point in the inquiry."

I must correct Mr. Willmott with reference to this part of his subject. In 1874 a series of experiments was very carefully conducted by Leonid Bucholtz,* in the laboratory of Professor Dragendorff in Dorpat, and from the results obtained he arrived at the conclusion that bacteria were killed in a continued temperature of 60° C., equal to 140° Fahr. He kept up the temperature for three days, but states that if continued for twenty-four hours it is sufficient for the purpose.

Previously to this date no less an authority than Dr. Ferdinand Cohn had arrived at a similar conclusion, and published it in an article on bacteria in his 'Biologie der Pflanzen, 1872.'†

Whatever other merit the process may claim in destroying these obscure organisms and their germs, it lacks that of novelty.

THOMAS GREENISH.

20, *New Street, Dorset Square, Jan.* 16, 1878.

* Untersuchungen über den Einfluss der Temperatur auf Bakterienvegatum.

† Untersuchungen über Bakterien. Beitrage zur Biol, den pfl ii, 1872, s. 203, u ff.

W. Slicer.—Advertisements for this Journal should be sent to Messrs. Churchill, 11, New Burlington Street. The terms will be found in the advertising sheet.

R. E. Harrison.—Concerning chrysophanic acid ointment, see vol. vii., p. 528.

F. Shrivel.—(1) *Leucobryum glaucum* and *Hypnum cupressiforme;* (2) *Cladonia squamosa;* (3) *Cladonia uncialis;* (4) *Hypnum cupressiforme, β compressum;* (5) *Cladina rangiferina.*

"*Picrotoxin.*"—Piesse's 'Art of Perfumery.'

W. W. Morris.—Lafargue recommends to dissolve 3·6 grams of santonin in a little spirit and then add the solution to 500 grams of boiling simple syrup; 30 grams of syrup will contain about 20 centigrams of santonin.

Inferior Corks.—*W. J. F.* writes to complain of the inconvenience that results from the use of inferior corks by vendors of some of the private preparations that are required in the dispensing of prescriptions.

Mr. H. A. Thomas (Cannes).—We are much obliged to you for your communication, but you will see by a reference to the Journal for last week that the subject has already been fully dealt with.

Erratum.—On p. 559, in Dispensing Memorandum No. 53, for "Ess. Limonis ℥j" read "Ess. Limonis ʒj."

B. H.—Probably a variety of savin; we cannot tell without the fruit.

"*Student.*"—The second course of Lectures on Botany and Materia Medica commences in the first week in March and extends to the end of July. Apply at the School for a prospectus.

"*Inquirer.*"—A copy of the Regulations of the Board of Examiners may be had by applying to the Secretary, 17, Bloomsbury Square, W.C.

W. Jordan is thanked for his communication.

"*Chemist.*"—Chloral Hydrate and its preparations have been recently included in Part 2 of the Schedule of Poisons under the Pharmacy Act, 1868.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Walker, Mr. Murphy, Mr. Harrison, Occidens, Syrupus.

"THE MONTH."

The unusual mildness of the weather at this season of the year renders it a difficult task to inform our readers what they may expect to find in blossom. The winter jessamine, with its yellow scentless flowers and leafless branches, and the deliciously scented *Chimonanthus fragrans*, are sure to be seen in blossom, and possess some little botanical interest; the former on account of having generally six parts to the corolla, although it is an exogenous plant, while the other species of the genus have usually five or eight parts to the calyx and corolla, and the latter because the bracts, calyx, and corolla run so much one into the other that it is very difficult to distinguish between them, and because the wood has a microscopical structure similar to that of the magnoliaceæ. A figure and description of these plants may be seen in the *Gardeners' Chronicle* for January 19th.

The Christmas rose (*Helleborus niger*) is now in full perfection in the open air, while the orange may be seen in flower at Kew in the economic house. In the palm house a fine tree of *Cinnamomum Tamala*, one of the species from which the folia malabathri of old writers were obtained, is just coming into blossom, and a small plant of *Cassia Tora* is still in bloom.

In the country it is impossible to say what may not be found, for we find that a pharmaceutical chemist noticed at Looe about fifty wild plants in blossom on Christmas Day, among which was included the red poppy (*Papaver Rhœas*).

'Medicinal Plants' for this month contains figures of *Glycyrrhiza glabra*, *Capsicum fastigiatum*, *Andropogon Nardus*, and three British plants, viz. *Daucus Carota*, *Origanum vulgare*, *Matricaria Chamomilla*, and a double plate of *Papaver somniferum*. The figure of the white poppy is taken from a specimen of the large white-flowered form cultivated at Banbury. *Capsicum fastigiatum*, although such a well-known plant, has, according to the authors, only once before been figured by Wight, and of *Andropogon Nardus* no figure has hitherto been published. It is to be regretted that the *Matricaria Chamomilla* was not placed for the sake of comparison in part 22, in which the true camomile is figured.

In the *Comptes Rendus* for January 14, an interesting note appears from M. Jobert upon the preparation of the curare poison. He has seen it prepared by the Tecuna Indians, who, he states, compound it entirely of vegetable substances, the chief ingredients being "*Urari uva*," probably *Strychnos castelnæ*, Wed.; and *Taja*, a plant belonging to the aroideæ; a menispermaceous plant, three piperaceous, and one or two of other families complete the list. M. Jobert has already made some experiments upon the action of the plants administered separately, the results of which are not given, and intends to still further pursue his researches. Fortunately the plants used in preparing the poison have been photographed, and specimens of them will be brought to Europe by M. Jobert for exact determination.

According to the "Doctor," gurjon oil is being used with success in France for gonorrhœa. The dose recommended is not more than one drachm in twenty-four hours, emulsified by gum. It has the advantage of keeping the bowels open, in the above dose, of having a more rapid action than copaiba, and of not tainting the breath. The use of this drug for leprosy is already well known, and its use in gonorrhœa is by no means new, since it is official in the Indian Pharmacopœia for that purpose, and the reputation it has had in this country as an *adulterant* of copaiba is probably the reason why it has never been tried here as a substitute for it.

From the same journal we learn that iodoform is being used in very fine powder as an application to indolent ulcers and chancres, the powder being sprinkled over the sore, which is then covered with oil silk or gutta percha tissue. Unless the iodoform be finely powdered it is apt to irritate.

Condurango bark, which was long ago condemned as useless in this country, has been stated in the *Lyons Médicale*, by Dr. Freidreich, of Heidelberg, to have cured in his hands a case of cancer of the stomach.

In the *Philadelphia Medical Times*, Dr. Sansery recommends the use of ergotin in suppositories, four grains in each to be used, at first every night and morning, afterwards at night only. The extract known as Bonjean's ergotin is probably the ergotin here referred to.

Salicin has already found another application. Dr. Maclagan records that it has succeeded when given in large doses in cases of periodic neuralgia in which quinine has failed or could not be taken.

A singular case of poisoning of a child three years old, by bitter almonds, is recorded in the *Medical Times and Gazette*, and possesses considerable interest. Repeated vomiting was induced by means of inserting a finger in the throat after failure with sulphate of zinc; but a return to the comatose state took place after each vomiting until the whole of the almonds were ejected. As the hydrated mixed oxides of iron were administered, as well as brandy, it would seem that the relapses were due to the repeated formation of fresh hydrocyanic acid from the portion of almonds still in the stomach.

Only recently the preparation known as dialysed iron was found useful in a case of arsenical poisoning, and as it will probably take a place in pharmacy in future, and is likely to be always at hand in cases of emergency, a trial of it as a chemical antidote for prussic acid might be worth making. It may be questioned whether, in the above case of poisoning, the recovery was not largely due to the use of brandy, since all volatile poisons are eliminated chiefly through the lungs, and any means of stimulating the respiratory muscles is likely to prove the most successful antidote, for the oxidation of iron can only neutralize the portion of prussic acid which is not absorbed into the circulation and cannot influence the minute portion which by its action on the nervous system destroys life.

Dr. Squibb, at the last meeting of the King's County Pharmaceutical Society, made some remarks upon cod-liver oil, which may perhaps be of interest to some readers. He stated that he preferred the Norwegian oil to the Newfoundland oil, on account of the low temperature at which it was prepared, and also because only the very finest of that produced in Norway was exported. He further recommended the addition of ten drops of ether to two drachms of the oil as a stimulant to the flow of pancreatic fluid, which emulsifies, and thereby promotes the assimilation of the oil. He considered that one drachm of the oil three or four times a day was sufficient in the majority of cases. A five per cent. solution of gum arabic poured into a small medicine glass tended greatly to cover the taste, while some salt herring eaten just before taking the oil would render the taste imperceptible.

Chemists who have to powder podophyllin should be careful to cover the mortar in which they are powdering that resin, since in a recent number of the *Lancet*, Dr. Webster records four instances of chemists' assistants having suffered from severe inflammation of the eyes from this cause, and although treated with atropine and solution of borax the inflammation was not subdued for five days.

In the St. Petersburg *Medicinische Wochenschrift*, Dr. Sieven makes known a very simple remedy for preventing the development of boils. He states that if the skin be superficially scraped with a small knife, so that a drop or two of blood may be pressed through the epidermis as soon as the peculiar stabbing or pricking sensation and slight induration announce the commencement of the boil, it will not be further developed.

Sir Joseph Fayrer's recommendation in the *Medical Times and Gazette* of Indian bael at the present moment is singularly ill-timed. The fruit is unripe in the autumn, and therefore not procurable in that state at this time of year, nor is diarrhœa particularly prevalent at this season. Remedies for diarrhœa are numerous, but those for skin diseases comparatively few, and the fact that chrysophanic acid has met with success in this country is no reason why unripe Indian bael should do so.

Whooping cough, the dread and plague of childhood, has lately been successfully treated by Dr. Pattee, by the new remedy for asthma, *Grindelia robusta*. It is stated to have cured thirty cases after three or four days' treatment, ten drops or more being given every two hours. Thus another remedy has been added to the long list of those which have been found occasionally successful in this disease, although none of them can be said to have been invariably so.

Several medicines have been recently tried with a certain degree of success in epilepsy. Dr. Vallender, of Braunweiler, has found subcutaneous injections of apomorphia to prevent attacks, and bromide of zinc has been used successfully in France for the same purpose; while Dr. Gillman, in America, has found opium uniformly successful in the same disease.

A new therapeutical use for glycerine has been discovered by Dr. Young, of Florence, who administers doses of two teaspoonfuls in water, morning and evening, for hæmorrhoids.

Professor W. H. Thomson reports that one part of capsicum to three of quinine, or one part of ginger to one of quinine, increases the action of quinine by one half, with the additional effect, when capsicum is used, of sometimes purging violently.

Thymol appears to be attracting some notice, and the demand for it is increasing. For internal administration two, three or more tablespoonfuls a day are given of a solution containing 1 part in 2000, and afterwards of double the strength. For external use an aqueous solution of 1 part in 1000 is usually sufficient; but for offensive wounds a stronger alcoholic solution is recommended. The saturated aqueous solution is capable of arresting lactic fermentation, and arrests excessive secretion by mucous membranes.

Formic acid is also said to possess powerful preservative properties, exceeding, when added to acid solutions, even carbolic acid, and to be particularly suitable for adding to fruit juices; from one quarter to one half per cent. is the quantity requisite to preserve vinegar, fruit juices, glue, ink, etc.

In the *Répertoire de Pharmacie*, M. Catton reports meeting with samples of santonin containing 22·5 per cent. of boracic acid. After the accidents which have happened owing to the presence of strychnine in samples of this drug, it is not surprising that it should be carefully examined; but the appearance of so large an amount of another adulterant could hardly have been expected. It illustrates, however, the well-known fact that thieves often neglect the simplest precautions.

In the *Pharmaceutische Zeitung*, Prollius gives a very simple method for assaying opium. The drug is exhausted by water, the solution evaporated, and the residue dissolved in alcohol of 30 per cent. strength in such proportions that one part of opium is represented by ten parts of the solution. Fifty parts of this tincture, twenty-five of ether, and one of stronger solution of ammonia, are shaken briskly together, and allowed to stand for twenty-four hours. The liquids separate into two layers, the morphia collecting gradually at their line of contact in fine crystals, which coalesce into a crust, and sink to the bottom. The coloured liquids, containing narcotine, etc., are poured off, and the crystals washed with a very little dilute alcohol, dried and weighed. This process is not only one of the simplest yet proposed, but is said to give very good results.

The very much worked subject of the principles of ergot has evidently by no means been exhausted; Professor Dragendorff announces that the body which he named Sclerythrin, is not a simple body, but is resolvable into three bodies, sclerythrin, picrosclerotine, which is a bitter alkaloid, and fuscosclerotic acid, a yellowish brown substance.

A method of removing the disagreeable odour of petroleum has been published by Mr. E. Masson; 100 kilograms of petroleum are placed in a suitable vessel and 60 grams each of concentrated sulphuric and nitric acids poured into it through a long necked funnel, and finally 500 grams of alcohol are carefully poured on the top of the oil. As soon as the latter sinks to the bottom and comes into contact with the acids, it develops heat and causes effervescence from boiling. The petroleum assumes a yellowish colour, and after having remained in contact with the acids and alcohol for about an hour it is gently agitated with water, and after about ten hours decanted.

An ingenious idea has recently been carried out at Pesth. A deep artesian well has been sunk with the view of supplying the city with an unlimited supply of warm water for the public baths, etc. Already 175,000 gallons, at a temperature of 161° F. stream out daily from a depth of over 3000 feet, and rise to a height of 35 feet. It is intended to continue the boring until a temperature of 178° is obtained. Still more ingenious is the device of using the water rising from the well as a motive power, which drives the drills at a rate of speed double that previously obtained at the mouth of the well. The value of a supply of a water of this kind, not merely for baths, but in case of fires, cannot be over estimated.

In America a further proposed application of the heat contained in the earth is to use the hot air from mines as a means of warming houses and public buildings, the ventilation of the mine being accomplished at the same time.

Dr. Squibb, of Brooklyn, has recently published, in pamphlet form, his opinions concerning the practicability of a universal pharmacopœia. He has at last come to the conclusion that the design is premature, and for the present age impracticable. So far as an international pharmacopœia, which shall take the place of all other pharmacopœias and render them unnecessary, is concerned, it is quite possible to agree with him and to believe not only that the standard of medical education is not high enough to admit the radical changes which such a work would necessitate, but that it will never be.

The second idea of a universal pharmacopæia, which aims to embrace only the making of preparations or compound medicaments of a uniform strength and character, leaving the national pharmacopæias as necessary as ever, but in accord in regard to the strength and quality of the agents of certain classes of remedies that have been long and commonly used in different nations by the same or similar names, and to have them designated by the same name everywhere, is, he thinks, just as difficult to carry out. But the chief value of an international pharmacopœia would be to prevent accidents owing to variation in strength of powerful medicaments, such as hydrocyanic acid, tincture of opium, solution of strychnine, etc., and an international agreement as to the strength of all powerful medicines, the preparation of these being reduced in number, and the synonyms in various countries being appended to each, seems not only possible but probable.

The cultivators of science whose names and achievements will be recorded in 1878 are already at work, and they will have to work hard to ensure results that will compare favourably with all that was attained by the workers of the year that is now no more. The past year saw the discovery of certainly one new element, gallium, and the existence of another, davyum, was rendered probable, not to mention lavoisium, of which little has been heard since its rumoured discovery.

Then again, before the interest attaching to the radiometer had subsided, a new object of a deeper importance was discovered in the telephone, and while the admiration called forth by the development which has waited so promptly upon the discovery was at its height, chemists heard of the liquefaction of oxygen, hydrogen, and common air, thereby substantiating views long since maintained, and of late years more particularly supported by Andrews' experiments upon the continuity of the liquid and gaseous states. Big things have therefore been accomplished in the past year, but these must not be regarded from a too confined point of view. As the molecule is made up of atoms, and as oceans are but the accumulations of drops, so every important discovery is preceded by a number of newly discovered facts, every generalization and every law are but the expressions of perfected details previously ascertained. And fortunately for science, this persistent labour is continual and ever increasing, and to a large extent the scientist is not influenced by those changes which so materially affect most other avocations in life. It is true that to some extent war and revolution exercise a disturbing influence upon science and scientific men, and this may under circumstances become a large amount, but compared with the disturbance to which for instance commerce is subjected by such a state of things, it is after all insignificant. Here and there, in particular countries, science may suffer vastly, but commerce is liable to receive an universal check, something near to a complete stagnation.

While therefore the year which has just commenced may not witness the achievement of things so great in themselves as those of the past year, much may and will be done with what may be called brick-making, the making of those parts which, by a skilful hand or a cunning brain admit of the combination into huge structural generalizations and laws.

Since the last reference to the subject of the liquefaction of the gases, considerable progress has been made by Messrs. Cailletet and Pictet, the latter of whom has communicated to M. Dumas the information that he has succeeded in solidifying hydrogen. The result was no doubt especially agreeable to M. Dumas, who has always regarded hydrogen as a metal and who so long ago as the time when his 'Traité de Chimie' was first published, spoke of hydrogen as a gaseous metal.

The hydrogen employed by M. Pictet was prepared according to the method recommended by Berthelot, of decomposing potassium formate by caustic potash, which yields very pure hydrogen. The compression of the gas was commenced at 8·30 p.m. on the 9th inst., and gradually increased; in the space of rather more than half-an-hour the pressure was equal to 650 atmospheres; it then remained the same for a few seconds and on opening the stop-cock, the hydrogen escaped in the form of a liquid jet, having a steel blue colour. This jet suddenly became intermittent, and a hail of solid particles fell with a crackling noise upon the ground.

The stop-cock was then closed again and the pressure, amounting to 370 atmospheres, gradually fell to 215 atmospheres, remaining stationary at this point for a few minutes and then rising to 225. Upon opening the stop-cock, the jet was very intermittent, and in all probability this was due to the solidification of the hydrogen.

Another interesting result arrived at by M. Pictet is that relating to the density of liquid or solid oxygen, by which he confirms the views of M. Dumas, that it should be the same as the density of water.

In a lecture upon the coal tar colours, recently delivered at the London Institution, Professor Armstrong took occasion to recall the anticipation put forward by Professor Hofmann, in his report upon the chemical products in the Exhibition of 1862, where, in speaking of the inauguration of this industry in England, he remarked that this country "might before long send her coal-derived blues to indigo-growing India, her tar-distilled crimson to cochineal-producing Mexico, and her fossil substitutes for quercitron and safflower to China, Japan, and other countries whence these articles are now derived." There was, to some extent, ample ground for this anticipation, since the raw material from which these colours are derived is produced in far greater quantity in Great Britain than on the continent; but although the coal tar obtained from gas works in this country still constitutes, as it has hitherto done, the chief, if not quite the exclusive, source of the aniline colours, their manufacture has been to a great extent transferred to Germany and France. For some years past the benzol naphtha used in this manufacture has been exported from England to France and Germany, while the colours there produced from it have been brought back from thence to the markets of Manchester, Bradford, and Glasgow.

This fact stands in striking contrast to the statement of Professor Armstrong, that the manufacturers of England do not attempt to employ skilled chemists, and it is at the same time a practical satire upon their shortsightednesss.

The same result has been experienced in the artificial production of alizarine, another product of coal tar. Almost the whole of the anthracene from which this substance is produced comes from England, and the mode of producing it was discovered here at the same time as in Germany. Still the Germans buy English anthracene pretty well at their own price, they make it into alizarine, and are able to rule the English markets for it, as to quality and price.

Here are two remarkable illustrations of the decay of British Industry which are well deserving of consideration, since they may serve to explain how it is that similar tendencies are to be observed in other and more important branches of industry. How is it that the manufacture of the coal tar colours has drifted away from this country, notwithstanding the fact that English manufacturers had the command and almost a monopoly of the raw material as well as the advantage of such protection of the methods of production as the patent law affords ? Professor Armstrong suggests that the reason is that English manufacturers do not employ skilled chemists, and no doubt it must be admitted that this circumstance is an immediate reason why they are outstripped by German and French manufacturers. There must, however, be some more potent influence behind, for the inability to cope with foreign manufacturers is not even remedied by the employment of foreign chemists, and that it is not impossible to obtain skilled chemists at home has certainly been rendered unquestionable by the history of the very industry now referred to. Nicholson, Perkin, and Greville Williams have sufficiently demonstrated the capacity of Englishmen in that direction. But, says Professor Armstrong, there are so few chemists in England who have had the requisite training, and there is no school where instruction is given in the particular kind of chemical work that is required. Admirers of South Kensington and its works will not perhaps admit the latter statement if they do the former, and many others will still feel the want of a more satisfactory explanation of the evil now referred to than can be afforded by any assumed national defects in teaching power or learning capacity.

In regard to this subject, however, there is a difference between the classes engaged in productive industry in this country and in Germany especially. In the one case it is rare to meet either with masters or men who possess any scientific knowledge of the manufacture they are engaged in, while on the continent it is as rare to find a factory without the assistance of several persons well versed in those branches of science which relate to its particular industry. As a rule there is a wholesome appreciation of the value of science, not as a thing to be dallied with and admired at an evening gathering of idle folk, but as, in the case of chemistry for instance, being the mainspring and very essence of the power by which many technical operations are carried to a successful and profitable issue. Until those engaged in productive industry acquire such an appreciation of science and, in place of ignorant denunciation of what they term theory, they seek the aid of science in a proper spirit, it will be but natural that the training of the chemist should be lop-sided, that the majority of those who take to its study should run to seed in the vain pursuit of perfect structural formulæ and remain for ever destitute of any practical utility to manufacturers, whose business is slipping from them by reason of their deficient knowlege of the art by which they live. Whether, as suggested by Professor Armstrong, our universities are responsible for this state of things, and whether there be any ground for hoping they could mend it, are questions which would lead too far from the limits within which these pages must be confined.

Among publications to hand this month is one on the presence of certain metallic impurities in the materials employed in the manufacture of aërated waters, by W. Ivison Macadam. The author discusses the well-known fact that when the parts of the machinery employed with which the gas comes into contact are constructed of lead instead of pure tin, they become sources of lead contamination.

But Mr. Macadam dwells particularly upon the materials used in the compounding of lemonade, viz., tartaric acid, citric acid, sugar, and oil of lemons. He finds that many samples of tartaric acid contain lead, an average of four specimens showing the presence of 0·021 per cent. An average of four samples of citric acid showed the presence of 0·0045 per cent., while four specimens of soft sugar contained on the average 0·000255 per cent. of lead. Clear crystallized and loaf sugars showed the presence of much less lead, about ·0006 per cent. as a mean quantity. The oil of lemons derives its metallic impurities, including lead and copper, from the metal cases in which it arrives in this country, as long since pointed out in this Journal by Dr. Stevenson Macadam. The action is insignificant so long as the oil is pure, but by its contact with air, acetic acid is produced slowly, and this then acts rapidly upon the metals, thus introducing the deleterious ingredients.

From a table constructed by Mr. Macadam, it is shown that the use of quantities of the materials sufficient to yield one bottle of lemonade introduces into this aërated water no less than 0·00691 grain of lead, a quantity which he considers far too great to be taken with impunity. Of course, a great quantity of lemonade contains no lead at all, but it it liable to be contaminated with this poisonous metal when proper precautions are neglected and such materials are employed as have been described.

Some little time ago Messrs. W. M. Hamlet and C. B. Plowright called attention,* and gave furthur substantiation to a view previously held by some chemists to the effect that many fungi contain oxalic acid (in the form of hydropotassic oxalate or calcium oxalate) as a common constituent. They showed that various specimens of *Peziza venosa*, Pers., a large number of *Hymenomycetes*, *Lycoperda* and *Sphaeriæ* gave a strong acid reaction to litmus paper, and that *Fistulina hepatica* particularly exhibited the same reaction, and on analysis this last named specimen proved to contain 0·083 per cent. of free oxalic acid. Subsequently the presence of oxalic acid was detected in very many species of fungi.

More recently Messrs. A. Downes and T. P.

* *Chem. News*, xxxvi, p. 93.

Blunt* have pointed out that a solution of oxalic acid of decinormal strength when freely exposed to sunlight for some time is entirely destroyed, so that oxalic acid cannot be detected in the solution, and this observation is confirmed by Mr. W. N. Hartley† who states that in every such instance of decomposition he has found the mycelium of a fungus in the liquid, and hence he has attributed the change to some action exerted by the said fungus. Although Mr. Hartley's supposition is probably correct, the facts elicited by Messrs. Hamlet and Plowright, which have been above described, show that the subject is one well worthy of a further inquiry. It should be stated, however, that Messrs. Downes and Blunt do not share Mr. Hartley's view.

The *Philosophical Magazine* for the current month extracts an interesting article from the *Comptes Rendus*, by L. Cailletet. The author has collected the gases circulating in the hottest parts of the furnaces in which iron is worked, and the results of his analyses differ from those previously obtained by Ebelmen, who being unacquainted with the phenomena of dissociation did not take into consideration the influence towards re-combination presented by cooling of the gases

L. Cailletet's analysis is as follows:—

Oxygen	13·15
Carbonic Oxide	3·31
Carbonic Acid	1·04
Nitrogen (by difference)	82·50
	100·00

After cooling, by traversing a long flue in contact with the walls of boilers, the gas presented the following composition:—

Oxygen	7·65
Carbonic Oxide	3·21
Carbonic Acid	7·42
Nitrogen (by difference)	81·72
	100·00

The increase in carbonic anhydride is explained by the further combustion of a quantity of finely divided carbon, which is found in the atmosphere of the hearth furnace. Cailletet believes it is possible to utilize the large quantity of combustible material which ordinarily leaves the chimney with the cooled gases.

By placing iodine in contact with ozone at a temperature of 44° to 50°, Ogier‡ has obtained iodous acid, which is a pale yellow light powder, decomposable by water with the deposition of iodine. On the other hand iodic acid is apparently obtained when ozonized oxygen acts upon iodine vapour, or when a mixture of iodine vapour and oxygen is exposed to the silent electrical discharge. This iodic acid is a colourless body, and soluble in water without decomposition. It was accompanied by what appeared to be hypoiodic acid, a body less soluble in water and with characters reminding of the hypoiodic acid described by Millon.

It has been already noticed in this Journal that to avoid prosecutions for selling under strength, publicans are adopting the plan of labelling bottles containing spirits sold at their establishments, so as to show approximately the percentage of alcohol contained in them. It was reserved, however, for Mrs. Brown of Haydon Bridge to endeavour to protect her husband against the myrmidons of the law by protesting that the "grey hen" from which an inspector wished to have whisky (it was fifty-four under proof) was reserved for her husband's use to keep him sober! It is to be feared that Mrs. Brown is not improving upon acquaintance.

While treating of publicans (and sinners) attention may be drawn to a case of prosecution for alleged adulteration of beer with salt, reported in the *Brewers' Guardian* for the 8th inst. This case will be found particularly interesting not merely as regards the matter in question, but also as an exhibition of the way in which it is thereby shown analysts exhibit both ability and charity in the witness box.

The *Brewers' Guardian* also calls attention to the tenacity of life in bacteria, which are there said to be unaffected by tar, camphor, carbolic acid, chloroform, boiling heat and freezing cold. They may also rejoice for days in strong solutions of nux-vomica, opium, and chloral, and laugh sulphate of iron, mineral acids and chlorine to scorn.

In relation to this subject it may not be out of place to point out in connection with the recently lauded doctrine of contagium vivium, that it has been fairly well established by Panum, Burdon Sanderson, and others, that bacteria and other germs are innocuous so far as they are themselves concerned; they possess merely the power of initiating certain decompositions of albuminous and other substances under given conditions, which decompositions result in the production of septic poisons. The point may be deemed a fine one, but it is an all important one when viewed in connection with the subject of disinfection.

C. Neubauer* has made some interesting observations upon the concentration of wine must by means of cold. In certain of his experiments he exposed a sample of "Neroberg" must, of the year 1875, to the freezing action of Medinger's ice-machine. Before freezing it showed on analysis the following composition:—

Specfic gravity	1·0925
Sugar	18·34 per cent.
Extractive Matter	22·97 per cent.
Free Acid	0·735 per cent.
Nitrogen	0·0442 per cent.
Ash	0·322 per cent.

The following analyses exhibit the composition of wine obtained from the Neroberg must concentrated by cold (that is by the removal of ice), and of wine obtained from the thawed ice.

	Concentrated Wine.	Thawed Ice.
Specific gravity	1·0644	—
" " of the Wine without Alcohol	1·0785	—
Alcohol, per cent.	1·55	4·40
Free Acid, per cent.	8·13	0·45
Sugar, per cent.	13·94	·00
Extractive Matter, per cent.	18·33	1·456
Ash, per cent.	0·693	0·125

These results appear to indicate that the process of concentration by freezing and removal of ice might be profitably applied to vintages of a weak character.

* *Landw. Versuchs, stat.* xx, 105–112.

Latschinoff* has studied the oxidizing action of potassium permanganate upon cholesterine. This substance, which is ordinarily viewed as a monatomic alcohol ($C_{26}H_{43}HO$), occurs largely in brain-substance and biliary calculi, and it is also found in the fat extracted from the fleece of sheep. When heated with pentachloride of phosphorus it is known to yield the derivative $C_{26}H_{43}Cl$, and by oxidation with chromic acid oxycholic acid ($C_{26}H_{40}O_6$) is produced. Latschinoff describes three different acids whose salts he has separated by the use of different solvents; these acids are: cholesteric acid, $C_{26}H_{42}O_4$; oxycholesteric acid, $C_{26}H_{42}O_5$; and dioxycholesteric acid, $C_{26}H_{42}O_6$. These results require confirmation, and indeed the whole chemistry of cholesterin particularly calls for investigation, the more so on account of its well defined crystalline character and its apparent connection with biliary substances.

Dr. Zuelzer has shown that the chlorine in urine exists partially as chloride of potassium and not merely as chloride of sodium, and that under conditions of excitement of the system the quantity of sodium chloride is diminished while that of the potassium salt is augmented; under conditions of depression the reverse obtains.

Gorup-Besanez† has published a further research upon the juice of vetch germs. From his own previous work and that of other chemists it was rendered probable that during the germination of the vetch the albuminous substance forming the reserve-matter of the seed splits up into products of hydration, and among others leucine and asparagin had been detected. Gorup-Besanez now finds that these substances are accompanied, as was to be expected, with glutamic acid and probably tyrosin. The author prepared a blue crystalline glutamate of copper having a composition indicated by the formula $C_5H_7CuNO_4+2\frac{1}{2}H_2O$; the water of crystallization is lost at 140°.

Polyporic acid, with the empirical formula, $C_7H_9O_2$, is the new acid which Stahlschmidt‡ has obtained from several species of *Polyporus*. It is insoluble in water, and gives well-defined compounds with the alkalies forming purple-coloured solutions. By heating the potassium salt with zinc powder, benzene is produced.

Among recent American patents, one by Isaac Mayer of New York is of some interest, having for its object the obtaining of a superior machine tallow by a quick, cheap, and convenient process. This consists in cutting up raw animal fat into slices or blocks, which are treated in a wooden vat with dilute nitric acid of 2° Baume; after from 30 to 48 hours' standing, the liquor is poured off and the fat exposed to boiling in an iron vessel for about half an hour, stirring meanwhile. On then placing the fat under water, the fibrous parts deposit, while the layer of fatty matter is drawn off or otherwise removed. The deposit is said to constitute a good food for pigs, while the tallow is clearer and of a superior quality, and incidentally all obnoxious odours are avoided.

Domeyko§ has given the name Bolivite to an oxysulphide of bismuth which he has found in Bolivia; it is composed of the sulphide Bi_2S_2 and the oxide Bi_2O_3. He has also found Taznite, a chlorarsenate and chlorantimonate of bismuth, at Tazna in Bolivia.

§ *Comptes Rendus*, Nov. 19, 1877.

In reviewing the Dispensing Memoranda for the past year, it is satisfactory to note the increasing interest shown in the several subjects brought under discussion, and at the same time it is an agreeable duty to recognize the valuable assistance afforded by so many correspondents who, while freely giving their own experience, render considerable service by the suggestions offered.

No. 50 is the first number in rotation. The crystals found in some samples of Ext. Ergot. Liq. may be either acid phosphate of potassium or sodium, depending on the relative quantity of phosphoric acid to those bases existing in the ergot. That sodium and potassium are present in ergot is evident from the analyses which have been made, and this may account for the statements made on the one hand that the crystals are acid phosphate of potassium, and on the other that they are acid phosphate of sodium. In the tables of ash analyses by Dr. Wolff, there are two of ergot of rye, of which the following are copies—

	K_2O	Na_2O	CaO	MgO	Fe_2O_3	PO_5	SO_3	
Ergot from Rye	17·92	11·77	1·24	2·00	·70	58·66	—	in 10 part of ash.
Ergot from Rye	19·14	14·19	2·00	3·28	.70	53·88	—	

Probably the relative proportions of sodium and potassium would vary in accordance with variation in the constituents of the soil. The soil of one district where rye is grown may be more rich in potash than that of another, and some samples of ergot would in consequence have more or less potash accordingly. This view is borne out by a reference to twenty-three samples of ash analyses of rye, grown in different localities, quoted by Dr. Wolff, the relative quantities of potash and soda differing very greatly, whereas that of phosphoric acid is tolerably constant. Substantially the same results appear in tables given in Watts's 'Dictionary,' vol. i., under "Cereals."

It will be observed that in the analyses of the ash of ergot there is no sulphur, and in the ash of the rye the proportion of SO_3 varies from ·18 to 2·9 per cent. The crystals may therefore be acid phosphate of potassium in one sample, and that of sodium in another, or the two may be present in the same sample. Thus the statements of those who have examined crystals from various samples may be reconciled with some published statements apparently in contradiction. The ash of one sample of Ext. Ergot. Liq. examined yielded no trace of sulphate.

51. In this prescription the dose of Ext. Ergot. Liq. is called in question. The communication on the subject is not very clear. The physician when applied to is said to have stated that he very frequently gave the liquid extract in ℥j doses "as per prescription." The prescription very clearly states ℥ss of the liquid extract for a dose, and the question must be understood to apply to the prescription as written. Medical men attending cases of midwifery, often give ʒij of the liquid extract every quarter of an hour, to check that hæmorrhage which now and then follows labour, and there would be no hesitation in giving larger doses if the circumstances seem to demand it. ℥ss doses have been given in critical

cases—an emergency demands bold and prompt action. Accoucheurs generally take with them a supply of liquid extract of ergot, and large doses are therefore rarely met with in prescriptions although recognized in medical practice. It must be admitted however that a ℥ss dose is unusual in a prescription and it very properly attracted the attention of the dispenser.

52. The readers of the Journal are asked whether they would have sent out seven grain pills in a prescription. The prescription and its directions are clear and distinct (ft. pil. cap. j. h. s. s. mitte xij), with the exception of the last "s," which, being preceded by "cap." is unnecessary. Probably the prescriber had no idea of the size of a seven grain pill, and if convenient he should be referred to, if not, the pills may be made up seven grains each, and a note should be sent with them to the effect that the pills as written were larger than those usually prescribed, but if it were desired they could be divided so that two should represent the dose. Something to this effect would place the dispenser right in the patient's estimation, and at the same time would not compromise the medical man. Very large pills are sometimes made and sent out without a remark of any kind being thought necessary.

53. A lotion similar to this has been commented upon on a previous occasion. A separation will take place on the addition of the spirit of rosemary or any other spirit. If it were possible to make spirit of rosemary without spirit, probably the end in view would be accomplished, or if correctness be sacrificed to appearance by making the rosemary with a little oil of rosemary and water, such a separation will not take place. The first-class London house comes to the front again, but the dispenser may rest assured that if the lotion was sent out from such an establishment a separation did take place.

54. Creasote pills are very troublesome to make when the creasote is in excess and they require a little variation from the usual method of making pills with the ordinary ingredients. However, in this instance a very satisfactory pill may be readily made by adding half a grain of magnes. calc. to each minim of creasote, rubbing them together and allowing the magnesia and creasote thus mixed to stand in a mortar for a few hours, when the creasote and magnesia become a comparatively dry powder; the rhubarb pill may then be added and mixed as usual. A little time may thus very profitably be spent in determining the best proportion of magnesia to the creasote and the time necessary to accomplish its solidification.

55. It has been stated before in these columns that salicylic acid is nearly insoluble in water, a clear solution cannot be made with this prescription. There being only a small quantity of salicylic acid, probably the better plan would be to dissolve it by heat in half the quantity of water ordered in the prescription, and the chlorate of potash in the other half, mix them together, and add the spirit of juniper. Let the bottle be occasionally shaken, while the mixture is cooling, and again when it is cold, the recrystallized acid will be tolerably diffused, and there will be little difficulty with the divided doses.

56. Bread crumb is not a proper excipient for phosphorus, which oxidizes so rapidly that the mixture inflames. Perhaps the writer of the prescription may not have been aware of this difficulty, and the dispenser should bring it under his notice. Place the phosphorus in a mortar and dissolve in a few drops of bisulphide of carbon; when completely dissolved, add ℈j ol. theobromæ, rub this with the dissolved phosphorus, and when thoroughly mixed add ℈ij of bread crumb; manipulate quickly, and a very satisfactory pill will be the result. Bisulphide of carbon will be found the best solvent of phosphorus for pill masses, but care must be taken that the excipient is of a proper kind to prevent the oxidation of the phosphorus. For this purpose ol. theobromæ is very suitable.

57. It is difficult to determine what the writer of this prescription may mean, but what he writes is clear, and there being tr. digitalis as one of the ingredients, its presence suggests caution with regard to any alteration that may increase the dose of that ingredient. If the writer could be referred to, that course would be desirable, otherwise the prescription as written must be adhered to. Doubt may very properly be entertained as to whether the prescriber intended the tr. ferri perch. and tr. digitalis to be made up with aq. chlorof. to the ℥ij, or whether there should be ℥ij aq. chlorof. in addition to the ʒv of tincture. If the writer cannot be referred to, the dispenser has no safe alternative, he must make it up exactly as written, more especially as the error, if it be such, on the part of the writer leans towards the lesser dose.

58. If a reference be made to the characters and tests given in the formula for ferri am. cit. in the Brit. Ph. it will be seen that it should *feebly* redden litmus paper. Such an effervescence as described by this correspondent is inconsistent with ferri am. cit. B. P. standard.

A deviation from the B.P. standard lies at the root of the greater number of the difficulties which engage these columns. The excessive alkalinity on the one hand, or the extra acidity on the other, apparently trifles in themselves, when combined in a prescription disturb the balance and cause endless trouble. It cannot be too frequently repeated that it is incumbent on every pharmacist, whether he makes his own preparations or supplies himself from wholesale establishments, to see that they correspond to the characters and tests of the British Pharmacopeia.

An illustration will be found in the case reported on page 599, of the way in which persons with suicidal tendencies will evade the protective regulations of the Pharmacy Act and set at naught the care of the chemist.

BIRDS AND BERRIES.*

During the last few months certain trees have been observed covered with fruit, often in very large quantities. Many were early robbed of their produce, while others remain untouched even at the present time. The greedy way in which birds cleared off many varieties of the smaller native or hardy fruits and berries, to the total exclusion of others, although belonging to the same genus or species, is worthy of remark. This peculiarity was first observed during the autumn in the case of the berries of most of the varieties of the service or white beam trees. During September and October trees of all sizes were covered with fruit, which was rapidly taken off by blackbirds and thrushes, often before it was thoroughly ripe. Of one variety, however, viz., the *Sorbus torminalis*, which has brilliant crimson fruit, not one berry was meddled with till the end of December, and then only a few, as clusters of them are still plentiful on many of the trees.

* Read by Mr. James McNab before the Botanical Society of Edinburgh. From the *Garden* for Jan. 19, 1878.

The common red rowan tree berries were likewise cleared off in a few days during the month of September. At the present season, as well as all through December, the yew trees formed a great resort for birds, the red berries being greedily eaten by them, so much so, that besides passing a considerable quantity of pulp and seeds, which lay plentifully on the ground around, the branches were in many cases covered with ejected masses of crimson pulp. It seemed as if the berries were no sooner down the throats of the birds than they were immediately thrown up, always mixed with the small green nuts which are embedded at the end of the fruit. The Irish yews (*Taxus hibernica*) were this autumn loaded with fruit, and it was remarkable to see the manner in which the birds clung to their upright branches. While the yew berries last scarcely a holly or thorn seems to be meddled with.

Birds would appear to avoid certain fruits, the colours of which are different from those to which they have been accustomed. As I have stated, the rich crimson fruit of the *Sorbus torminalis* is avoided, although ripe at the same time as the other service tree berries, which are of a yellowish tinge, spotted with red, and these are eaten. The two varieties may even be seen side by side, the yellow bared, and the crimson untouched; but whether this is on account of the colour alone or because of a difference in flavour I am unable to say. The berries of both, however, are pleasant enough to the taste. This selection of certain fruits is also applicable to the fruit of the yellow-berried holly, which is found thick on the bushes during a severe winter when all the red berries are gone. Birds also seem to avoid the yellow-berried yew, yellow-berried mountain ash, and the black-fruited thorn, few of the fruits of these being touched till the common coloured kinds are gone. In this district of Scotland we have few ripe white berries on the mistleto this year, most being green, except in some very favourable situations. I find amongst the large bunches sent at this season from England, that although many berries are ripe and plump, numerous others are seen in the transition state from green to white. One can scarcely fancy that the mistleto berries are sought after by birds for the sake of food alone. It is evident that birds have an object to accomplish with regard to them. While eating the fruit, the extremely adhesive substance surrounding the seeds causes them to adhere firmly to the bills of the birds. In order to get rid of this foreign substance, recourse is had to rubbing their bills on the branches of neighbouring trees, and in this way the seeds are left sticking to the branches, where they afterwards take root and grow. This method of distributing mistleto seeds seems to be assigned to them by nature, as it is impossible for such seeds to grow in soil. We have just now several young mistleto plants growing on some out of the way branches, evidently two or three years old, in positions in which birds have taken refuge to get their bills cleared of the glutinous substance, and seeds adhering to them. A similar practice is adopted by cultivators when propagating the mistleto, viz., by bruising the adhesive pulp surrounding the green central germ with the fingers, and fixing it on the bark of a tree, to which it readily adheres. In order to prevent birds removing the green germ, which they frequently do, it is necessary at times to cover the germ with a piece of fine wire gauze netting or muslin, keeping the muslin tight over a piece of wire previously adjusted. The sea buckthorn (*Hippophæ rhamnoides*) is another indigenous fruit-bearing plant, which this year is fruiting in its native stations in the greatest abundance, the fruit clustering like that of the holly, but of an orange colour, the leaves being narrow and of a glaucous ash colour. This buckthorn it now very generally cultivated in many of the sandy districts of East Lothian. Perhaps the largest native tract of this plant is to be seen on the "Sandy Hint," at Tynningham Point, where a great extent of the ground is covered by a dense thicket of this shrub, varying from four feet to ten feet in height, and all in fruit-bearing condition, contrasting well with the hollies and thorns, which are also abundant in the district. I wrote to Mr. Lees, who was long gardener at Tynninghan, to ascertain if the berries of the buckthorn were eaten by birds, like those of the other native fruit-bearing plants. In answer to my question, he stated that he never saw them much frequented by birds till all the fruits of hollies and of thorns were exhausted. During the severe winter of 1860–61, when birds were sorely pressed for food, blackbirds, thrushes, and bullfinches might have been seen in flocks upon them; but although they ate the berries, he did not think they were very fond of them. Mr. Lees adds that it is rare to see the buckthorn fully covered with fruit two years in succession. Although the buckthorn succeeds in cultivation, it is rare to see more than one or two dozen berries on cultivated bushes in any one place away from the sea. While on this subject I may state that the distribution of many fruit-bearing plants, particularly in some districts of Scotland, is chiefly through the agency of birds, many such plants as yew, holly, thorn, elder, and mountain ash being found in quite inacessible places on the hill sides.

RHEUM PALMATUM, VAR. TANGUTICUM.*

BY PROFESSOR BALFOUR.

I have received from Mr. G. P. Regel, Director of the Botanic Garden at St. Petersburg, five young rhubarb plants, under the name of *Rheum palmatum*, var. *Tanguticum*. The plant was collected by Lieut-Col. N. Prejevalsky, on the north-western range of mountains of Mongolia, in the Tangut country and in the solitudes of Northern Thibet. It is rare in the environs of Chertinton, but is said to abound near the source of the Tatung and Etsina, further to the west. It is known to the Mongols as "Shara-moto," or yellow tree, and to the Tangutans as "Djumtsa." The leaves of the plant are described as large, sometimes two feet long by three feet broad, and resemble those of *Rheum palmatum*, which has been cultivated in the Botanic Garden since the time of Dr. John Hope, Professor of Botany in Edinburgh, and who read a paper on the subject to the Royal Society. The leaves, however, differ from those of *R. palmatum*, in being covered with longish and stiff hairs.

The flower stalk is said to attain a height of from seven to ten feet, with a thickness of half an inch near the ground. It does not branch, as in ordinary rhubarbs, but is more compact, the flowering branches coming off at a very acute angle, and running parallel to the stalk, as shown in the figure in the colonel's book. The root, when fully grown, is said to be about a foot long, and of the same thickness. The flowering time is the end of June or beginning of July, and the seeds ripen towards the end of August.

The Tangutans and Chinese dig it up in September and October. It is transported by land in winter and by boats in summer down the Hoang-ho to Pekin, Tientsin, and other ports, where the Europeans buy it, paying six or ten times more than its value at Sining.

The plant is quite distinct from *Rheum officinale*, which has lately been introduced into European gardens as the true rhubarb of commerce. According to Lieut.-Col. Prejevalsky, the plant yields the Kiakhta, or Khan-su rhubarb. Professor Maximovitch states that the dried roots (about 36 lbs.) brought home by the colonel, after having been carefully analysed and tested by Russian chemists and physicians, entirely agreed with the best Kiakhta rhubarb, both in internal structure and in the number of crystals of oxalate of lime, the quantity of extract obtained from the root, and in the medicinal effect of the powder, and other preparations.

* Read before the Botanical Society of Edinburgh. From the *Transactions*.

The Pharmaceutical Journal.

SATURDAY, JANUARY 26, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REGULATION OF PHARMACY IN VICTORIA.

IN April last,* we were enabled by the courtesy of a correspondent to place before our readers a *résumé* of two Acts that had been passed by the legislature of Victoria for the regulation of the practice of pharmacy, and the sale and dispensing of poisons in that colony. We have now received official copies of these Acts, which will be printed in an early number of this Journal for purposes of reference. With them have also come to hand the regulations of the Board of Examiners established under one of these Acts, and as this is the first legislation of the kind that has taken place in the Australian colonies, we have turned with some amount of curiosity and interest to see how these Regulations may compare with those of the Board of Examiners in Great Britain.

The control of the examinations is vested in the "Pharmacy Board of Victoria," consisting of a President and six other members, who are also to have the assistance of a Registrar. The members of the first Board were appointed by the Governor in Council without previous election, and are to continue in office three years; but the future members are to be themselves registered pharmaceutical chemists, and are to be elected by registered pharmaceutical chemists. The members of this Board are empowered to select three of their own number or three other suitable persons to act as examiners.

Only one title is created by the Act, that of "pharmaceutical chemist;" but the use of chemist and druggist, pharmacist, and other similar names by unregistered persons is prohibited. To obtain this title, except by those whose rights are preserved, it is necessary to pass the "Preliminary" examination, and others in materia medica, medical botany, practical chemistry, and practical pharmacy; to have served for not less than four years as an apprentice in the business of a registered pharmaceutical chemist, chemist and druggist, or homœopathic chemist, keeping open shop for the compounding and dispensing of prescriptions for legally qualified practitioners; and also to have attained the age of twenty-one years.

The subjects of the Preliminary examination are Latin, English and Arithmetic, and with respect to the first two the requirements are exactly the same as in the regulations for Great Britain. The arithmetic, however, goes no further than the first four rules, simple and compound, and vulgar and decimal fractions; while simple and compound proportion, and the metrical system of weights and measures, which occur in our syllabus, are omitted, though the metric system is included in the subsequent practical pharmacy examination.

The examinations in materia medica and medical botany and practical chemistry are not to be conducted by the Board, but are to be passed at the University of Melbourne, or at some school or college of pharmacy recognized by the Pharmacy Board, where the candidate must have attended at least one course of lectures. How far these examinations must be carried, and whether they will most resemble the corresponding portions of the Major or of the Minor is not defined, and must be left for inference.

The syllabus of the practical pharmacy examination is very similar in its terms to the portion of the Minor examination in this country included under the sections Prescriptions, Practical Dispensing, and Pharmacy. It includes, too, the more special portion of the chemistry section, so far as relates to the recognition of the ordinary chemicals used in medicine, the possession of a practical knowledge of the processes by which they are produced, the composition of such as are compound, and the ability to explain the decompositions that occur in their production and admixture. It is specially mentioned that the candidate must be able to spread plasters with dexterity and neatness, and he is also to be examined with regard to his knowledge of poisons and antidotes.

It will appear from the foregoing that the examinations properly carried out would be a test fairly equivalent to the Minor in this country, with the extra stringency of four years' apprenticeship, instead of three years' service as in this country, and the compulsory attendance at a course of lectures. We think the pharmacists of Victoria are to be congratulated that after a struggle prolonged through several years they have attained this measure of success and right heartily do we hope that the new Acts will be found to work beneficially. But we cannot help expressing the regret that the title "pharmaceutical chemist" has been again appropriated for use by persons passing an examination which must necessarily, however well conducted, be a test of the lowest measure of qualification considered to be consistent with the public safety. In Great Britain, the title of pharmaceutical chemist has come to mean more than this, and we believe that no inconvenience would have followed, whilst the highest interests of pharmacy would have been served, had the title been reserved in all English-speaking countries as a recognition of more than an ordinary amount of pharmaceutical knowledge and skill.

* See vol. vii. p. 859.

It will be remembered from our former *résumé* that the Pharmacy Board was authorized to issue licences to sell poisons to suitable persons living in places distant at least four miles from any city, town, or borough, and in which no registered pharmaceutical chemist resided. The Board, acting under its powers, has issued regulations as to the manner in which such persons are to conduct their business. The poisons are to be kept in a cupboard with sufficient shelves and divisions to keep each description of poison in a separate division. This cupboard, on which the word "poison" is to be conspicuously painted, is not to be allowed to remain open or unlocked, whilst the holder of the certificate is to keep the key in his own possession and is not to be allowed under any pretence to delegate the opening of the cupboard and the handling of the poisons to any other persons.

By the terms of the Act the Board is empowered to receive, in lieu of the examination, the certificates of the Pharmaceutical Society of Great Britain and of any college or board of pharmacy that it might decide to recognize. The recognition has now been extended to the Pharmaceutical Society of Ireland, the Schools of Pharmacy of France and Belgium, and the Colleges or Universities of Germany, Denmark, Sweden, Russia, Norway, and Austria.

THE MEDICAL ACT (1858) AMENDMENT BILL.

On the first night of the session, Dr. Lush gave notice of his intention to apply for leave to bring in a Bill to amend the Medical Act of 1858. This he did on the following evening, when the Bill was read a first time, and ordered to be printed. Although the Bill has not yet been issued among the Parliamentary Papers, we have been favoured with an inspection of a draft of it, and are able to say that it contains nothing to which chemists and druggists need raise any objection. It contains no clause similar to that in the first Bill, introduced under a similar name last session, as to the infliction of a penalty upon unregistered persons who should practise medicine or surgery for gain, which at that time created so much excitement amongst chemists and druggists, but it resembles more closely the second Bill, which was introduced after the withdrawal of the first. The second reading of the new Bill is fixed for the 20th of February.

EXAMINATION RESULTS IN GERMANY.

When referring to this subject in a recent number of the Journal, the remark was made that the comparatively small proportion of failures in the pharmaceutical examinations might be attributed to the candidates having, previously to an eighteen months' course of theoretical university lectures, served a three years' apprenticeship in a dispensary and its laboratory. An esteemed correspondent, Dr. Schacht, of Berlin, thinks that this is liable to mislead, as not stating the whole of the case, and he kindly supplies the following additional particulars:—

The young candidate for the honour of becoming a German pharmacist has first to show that he has the requisite scientific training and has passed two or three years of study at a German university; then to serve a three years' assistantship, half of which at least must be passed in a German pharmacy; then to attend the university during at least three semestres, the whole occupying from 6½ to 7½ years. Moreover, as every German is a soldier, the young pharmacist has also to serve one year under arms or as a pharmacist in a military hospital. So that practically a period of eight or nine years is taken up by a candidate in getting the education and scientific training requsite to enable him to pass the State examination.

FIRE AT A CHEMIST AND DRUGGIST'S.

A few days since, on the 8th inst., a fire broke out on the premises of Mr. Sadler, a chemist and druggist, living in George Street, Tamworth, which illustrates the great necessity that exists for the exercise of caution when dealing with some of the substances that find their way into a chemist's premises. A boy employed in the shop had poured out from the stock can a pint of benzoline required for a customer, and whilst attending to some other business, left it standing for a few moments upon the floor in a small tin. This, Mr. Sadler, entering the room just afterwards, kicked over, and the vapour of the liquid becoming ignited by the fire in a stove close by, a serious conflagration followed. We regret to say that Mr. Sadler was seriously burnt about the head and neck, and that probably some months will elapse before he will be able to return to business.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association will be held at 17, Bloomsbury Square, on Thursday evening, January 31, at 8 o'clock, when a paper will be read by Mr. J. G. Sangster on "Common Salt, its Manufacture and Uses."

CHEMISTS' ASSISTANTS' ASSOCIATION.

We are informed that by the kind permission of the Council of the Quebec Institute a Soirée in connection with the above Association will be held at 28, Baker Street, on Wednesday evening, February 27th. Further particulars will be announced shortly, and tickets will then be issued.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

A meeting of the Board of Examiners for England and Wales was held in London on Wednesday, January 23, 1878.

Present—Mr. Williams, President, Messrs. Allchin, Barnes, Carteighe, Gale, Martindale, Moss and Taylor.

The undermentioned Certificates were received in lieu of the Society's examination:—

Certificate of the College of Preceptors.

Morris, Henry W. G. ....Charlbury.

Certificate of the Royal College of Surgeons of England.

Greenwood, Samuel ....Sheffield.

Certificates of the University of Cambridge.

Callaway, George Frederic ......Ipswich.
Quiller, Charles Turner ....Kingston-on-Thames.
Wiggin, John Chinery............Ipswich.

Certificate of the University of Oxford.

Matthews, Henry Rouse.........London.

The report of the College of Preceptors on the examination held on January 7 was received.

Three hundred and thirteen candidates had presented themselves for examination, of whom *one hundred and ninety-two* had failed. The following *one hundred and twenty-one* passed, and the Registrar was authorized to place their names upon the register of Apprentices or Students:—

(Arranged alphabetically.)

Adams, Amos ....Barnstaple.
Adams, Henry George............Maidstone.

The Questions for examination were as follows:—

First or Preliminary Examination.

January 7th, 1877.

Time allowed: Three hours for the three subjects).

I. LATIN.

1. Translate into English:—Eodem die castra promovit et milibus passuum sex a Caesaris castris sub monte consedit. Postridie ejus diei praeter castra Caesaris suas copias transduxit et milibus passuum duobus ultra eum castra fecit, eo consilio uti frumento commeatuque, qui ex Sequanis et Aeduis supportaretur, Caesarem intercluderet. Ex eo die dies continuos quinque Caesar pro castris suas copias produxit et aciem instructam habuit, ut, si vellet Ariovistus proelio contendere, ei potestas non deesset. Ariovistus his omnibus diebus exercitum castris continuit, equestri proelio quotidie contendit.

2. Parse the words *die, castris, passuum, consilio, supportaretur, dies, aciem.*

3. Decline together—*id consilium, equestre proelium, acies instructa, idem dies.*

4. Write out in full the perfect and future indicative of the active voice of *duco, conclamo, habeo.*

5. Write out the declension of the relative pronoun, *qui;* and state the rule for the agreement of a relative pronoun with its antecedent.

II. ARITHMETIC.

6. Multiply 704745 by 615; and subtract the product from that obtained by multiplying 1174575 by 2214. Write down the answer in words.

7. What is the value of 2475 yards of cloth at 13*s*. 10½*d*. per yard? How many coins worth 1*s*. 6½*d*. each would pay for it?

8. What is the income corresponding to an income tax of £13 2*s*. 6*d*. at the rate of 7*d*. in the pound?

9. Simplify $\frac{4\frac{1}{7}-2\frac{1}{4}}{6\frac{1}{2}-2\frac{1}{7}}$.

10. Express £3 11*s*. 9¾*d*. as a decimal of £1, and also of £2 10*s*.

11. A room is 26 ft. by 35 ft. How much will it cost to cover it with carpet 2 ft. 4 in. wide, at 4*s*. 5*d*. a yard?

III. ENGLISH.

12. Name the parts of speech, and give a definition of each of them.

13. Which of the pronouns are declinable? Write out these in full.

14. Parse the following:—

"An idler is a watch that wants both hands,
As useless if it goes as when it stands."

15. Write a short composition on one of the following subjects:—Snow, music, travelling, competition, the Suez Canal.

NORTH BRITISH BRANCH.

The second meeting of the present session took place on the evening of the 17th inst., Mr. J. B. Stephenson, President of the Branch in the chair. The meeting was a very large one, many of those present being unable to find seats.

Dr. Andrew Wilson, of the Edinburgh Medical School and University of Glasgow, delivered a highly interesting lecture to the members on:—

The Beginnings and Relations of the Nervous System.

Dr. Wilson said, that the remembrance of the kindly welcome he obtained from the members of the Society on the occasion of his last lecture induced him to send an affirmative reply to the Secretary's request that he would lecture before them this session. He had chosen for his topic a subject which might in one sense be regarded as a continuation of his previous subject, and would invite their attention to the consideration of the questions, "How does the nervous system originate in animals?" and "Are the nervous acts of the lowest animals related to those of higher forms?" The nervous system, Dr. Wilson defined as that whereby the living being was brought into relation with its surroundings. When we touched a table, for example, we were enabled through the contact of our nerves with the object, to form ideas regarding its shape, size, hardness, etc. Even in the act of thought, exercised, it might be, apart from visible movement, we were bringing ourselves into relation with the world and our surroundings, either as regards the known past, the expectant present, or the unknown future. It was evident, the lecturer maintained, that the origin of a nervous system was only to be ascertained in quarters where nervous acts and other functions of life were to be seen and observed in their primitive simplicity of detail. The simplest acts of life were exhibited by the *Protozoa*, or lowest animals, whose bodies consisted of "protoplasm"—a term which, Dr. Wilson said, had given origin to not a few controversies that had ranged far afield into the domain of metaphysics, or into that of religion itself. An *Amœba*, or "Proteus Animalcule," occurring in stagnant water, or in infusions of organic substances, was a minute speck of protoplasm. It nevertheless fed itself, reproduced its species, and maintained relations with its surroundings as perfectly, when regarded in relation to the wants of its existence, as the highest animal. When a particle of food touched the margin of its body, the protoplasmic substance was stimulated in some fashion by the contact, and was protruded so as to engulph the food particle. Here, Dr. Wilson maintained, we had the beginnings of sensation. That the animalcule "felt" the contact, was an undoubted fact, and that it acted on "information received" was an equally plain inference, which the absence of "consciousness" did not invalidate in any way. Dr. Wilson described plainly and in a most interesting manner the nervous acts of a *Medusa,* or jelly-fish, as representing an animal of higher grade than the *Amœba*—the lecturer throughout the discourse illustrating his remarks by cleverly executed sketches on the blackboard. The *Medusa* had no demonstrable nervous system, but that impressions were conveyed in direct lines from the periphery or outer parts of the body to the central parts was evident from the motions of the central mouth. This mouth turned unerringly to the side of the body which was touched, and when the connection between the mouth and outer parts was partially destroyed, the mouth moved erratically in consequence, if the margin of the body was irritated. The insect's nervous axis was next described as leading to the idea of a defined nervous system, whereby impressions made on the outermost parts of the body were conducted in clearly marked channels—the nerves—from well-defined portions of the outer surface—sense organs—to internal parts. Proceeding to consider the question of the origin of the nervous system, Dr. Wilson maintained that it was not only conceivable but highly probable that the beginnings of nervous acts originated in impressions which were made on the outside parts of a living being of lowly grade, and which affected internal parts. The chief condition required to produce this result was that the body of the organism should consist of a highly contractile substance, capable of being stimulated by impressions from without. Such a substance was well exemplified by protoplasm. Suppose that a particle of food touches the periphery or margin of an amœba's body, contraction is seen to follow, and the food-particle is engulphed. This contraction and the subsequent act of nutrition are the direct results of the contact of the food-particle with the sensitive protoplasm of the body. If we imagine further that as development proceeded, these impressions became transmitted in definite lines from the periphery to the centre, we should reach the stage of the jelly fish, in which, although definite nervous tissues are unknown, nervous impressions travel in well-defined tracts. In these tracts in higher animals, nerves are developed. Similarly out of a still higher development of the relation between outward impressions and their mode of transmission internally, the defined nervous tissues of the highest of animals might be reasonably supposed to originate. In the protoplasm of plants, nervous impressions were transmitted slowly on account of the presence of cell walls—in other words, because of the discontinuous nature of the protoplasm. The proposition the lecturer submitted to his audience, was, that a nervous system originated from the interaction taking place between the contractile tissues of lowest organisms and impressions derived from the outer world; and in support of this proposition, Dr. Wilson asked his audience to study the development (1) of the eye, (2) of the ear, and (3) of the nervous system generally of vertebrata. The eye was formed by an ingrowth of the outer surface of the embryo, meeting with an outgrowth of the brain. The ear was formed in a similar manner, although some physiologists maintained that in the ear the nervous outgrowth was of much more limited extent than in the case of the eye. Thus the outer surface of the body participated in the development of both eye and ear; and if development, as every one believed, was to be taken as a clue to the origin of animal structures and of animals themselves, then it was clear that eye and ear alike simply represented modifications of an outer surface which had originally received impressions directly, and which, through development had come to assume complex relations with the interior and with the subsequently developed nervous system. Similarly, when we study the development of the chief nervous axis of vertebrata we find that the brain and spinal cord arise from the *epiblast* or outer layer of the embryo, part of which becomes folded inwards during development to form the great nerve centres. Thus, again we see how the outer surface, originally the receiving surface of impressions, becomes modified and related to internal parts. If part of the outer layer of protoplasm in the amœba became infolded, and still maintained connection with the exterior of the body, and if we further suppose that the infolded part assumed dominance over the actions of the animal, we should have imitated the action taking place in vertebrate development, and through which the originally sensitive outer layer of the vertebrate's ancestors became folded inwards to form the nervous system. Dr. Wilson concluded a lecture which was listened to with great interest, by an allusion to the deductions which might be drawn from his subject. He might, if he chose, lead his hearers into the domain of metaphysics and of theology by asking them to consider questions connected with free-will and necessity, and other matters bearing upon what he might call the "religion" of the nervous system. But he would only ask his hearers to regard one phase of the question before them, namely, that relating to automatism. This condition, Dr. Wilson held was the original state of the nervous system of man, as indeed it represented the sole condition of the nervous acts of most lower animals. Man had developed "consciousness," or the knowledge of self, how, Dr. Wilson would not profess to say; although he did not consider the development of consciousness a whit more extraordinary than the evolution of other and explicable phases of nervous action from lower states, lower nervous acts. And if his hearers objected to the doctrine of evolution as he had applied it to the explanation of the manner in which nerves arise, he would only say that in rejecting this doctrine they threw overboard the only feasible explanation of the origin of nervous acts that was known, or that was open to free and scientific discussion. A writer had well said that if evolution had shown us that man was descended from lower animals it was the duty of religion to point out that we were now different from these lower forms; and he commended that thought to the earnest consideration of his audience.

Dr. Stevenson Macadam, who was present, expressed his admiration of the clear, lucid, and eloquent lecture his colleague, Dr. Wilson, had delivered. Many might not wholly agree with the lecturer's statements; but all would agree that Dr. Wilson's remarks had opened up a suggestive train of thought.

On the motion of the President, a cordial vote of thanks was awarded to the lecturer.

Dr. Wilson in acknowledging the compliment remarked that he was pleased to see so large an attendance at these meetings of the profession in Edinburgh. He would not like to think that the large attendance was wholly due to Mr. W. L. Howie's paper on the "Telephone," but in any case he would commend the heads of the profession to influence their *employés* to attend these meetings, at which much information and instruction were presented to their notice. These meetings had his best wishes for their full success.

The Chairman then called upon Mr. W. L. Howie, who had promised to let the members hear something of the telephone.

Mr. Howie said that from allusions which had been made that evening, he was afraid that the expectation of the meeting had been raised too high, he simply contemplated bringing before them this wonderful instrument, a form of which he had constructed during the evening leisure of the Christmas holidays, and in a conversational way say a few words regarding its history and construction, and if the conditions were favourable, let each one in the room have an opportunity of hearing the telephone speak and sing. Mr. Howie then proceeded to describe the history and construction of the telephone as follows:—

The word "Telephone" indicates the use of the instrument, meaning literally far-sounder, or far-speaker, as the Germans have it, and I daresay that there is no one here so oblivious of recent scientific advancement as the old lady who thought a telephone was "a thing for sherpin rāāzors."

Although the speaking telephone is a recent invention, a Professor Page succeeded so long ago as 1837 in producing sounds at a distance by means of electricity; but to Philip Reiss, in 1861, belongs the honour of demonstrating that sounds of varying pitch—in other words, music—could, so to speak, be sent by telegraph. Reiss's instrument was not a speaking instrument, as you will be able to judge from the results to be obtained from a simple adaptation of Reiss's idea which I have here. Before showing it in operation, I would in a few words refer to the "thread telephone," which may be made from a couple of two-ounce willow boxes, the bottoms of which are replaced by gut-skin or parchment paper, stretched while wet, and held in position by the rim of the lid. A linen or other non-elastic thread connects the two diaphragms through a pin hole in the middle, and if these boxes be now taken apart till the thread is stretched, a whisper spoken into the one is distinctly heard in the other. This thread telephone is good for the distance the thread can hang free and straight, and the voice is reproduced quite distinctly; but the transmission of the sound is simply mechanical, the vibrations of the one membrane being communicated along the thread directly to the other. In this toy, sold in the streets for a penny, you have a striking illustration of the capacity of a vibrating membrane or diaphragm to reproduce articulate speech. A piano string when it vibrates produces a simple sound, whose pitch varies according to the speed with which it moves, the lowest note audible to the human ear being produced by sixteen vibrations per second of time, and from this we rise to very many thousands; but a diaphragm can not only give a simple sound, but chords, which are produced by two or more notes sounded simultaneously.

How this can be is not easily comprehended at first, but if I may liken the diaphragm to a placid pool of water into which a stone has been dropped, a wave circle is at once seen to spread over its surface, and if two stones are dropped in some distance apart, the waves from each cross and interlace and do not seem to interfere with each other, and so if a handful were cast in. The vibration of a diaphragm is not simply a to and fro motion, over its whole surface, but rather a succession of waves, and thus by the adoption of this form for the articulating part of the telephone, Professor Bell has produced an instrument capable of reproducing by the simplest means all the varying tones and qualities of the human voice. The speaking telephone invented by Professor A. Graham Bell, such as I hold in my hand, consists essentially of a vibrating disc, and a magnet and wire to communicate these vibrations. When the disc, which is of iron, vibrates or moves to and from the magnet an undulatory current of electricity is induced in the coil of wire which surrounds one end, this coil being connected by a line wire with the coil and magnet of a similar instrument. The current so disturbs the condition of the latter magnet, that it attracts and lets go its disc, causing it to vibrate in exact unison with the one first moved. Bell made the human ear his study, and the diaphragm of his first speaking telephone was membrane, with an iron armature attached, but this was in time discarded for the thin iron plate at present used.

The telephone is so simple in construction that any one with a small amount of mechanical ingenuity would have little difficulty in making an experimental pair. I would however warn you that they must not be put to practical use, as the invention is patented, and though a pair may be made for a few shillings, a complete set with call bells for short circuits costs £50. First, then, procure six pieces of mahogany 4 in. × 4 in. and $\frac{3}{8}$ inch thick. Screw four of these together, two and two, by means of a brass nail at each corner, then bore a 2-inch hole through the centre of each pair; take a couple of ferrotype plates and roughly cut them into 3-inch discs, which are to be placed between the pieces of mahogany just mentioned by undoing the screws and again tightening up. We have thus a pair of 2-inch diaphragms. Procure a pair of permanent bar magnets 4 inches long and $\frac{3}{8}$ inch diameter, with holes screwed into each end, and into one end of each fix a piece of $\frac{3}{8}$ inch soft iron rod, half-an-inch in length beyond the screwed piece—an ordinary sixpenny horse shoe magnet answers admirably instead of the bar form, but the soft iron core must then be 1 inch long and one-half of its length flattened so as to lie close to the flat magnet, to which it may be bound with twine; common thin tinned iron may also replace the ferrotype plates, though these and all other necessaries may readily be procured from any philosophical instrument maker. On this soft iron, slip, $\frac{3}{8}$ inch apart, two bone rings—as used for shields for feeding bottles, having enlarged the holes with a file so that the rings may fit tightly over the iron—then wind on the reels thus made, $\frac{1}{4}$ of an ounce of No. 36 silk covered copper wire, leaving some inches of each end hanging free, and cover the whole with a few rounds of knitting wool for protection. Now fix the magnets thus armed on the odd pieces of mahogany, by means of three screw nails, two screws on one side and one on the other, having first cut out of one end of the boards a semicircle to permit the reels to fall into; now fix the boards carrying the magnets to the diaphragm by means of a couple of brass screws, so that they will form the letter T—the magnet being the leg and the diaphragm the top piece. Take care to have the magnet in the centre of the disc and adjust it so as to be as close as possible without touching when the latter vibrates. The two free ends of the wire should now be fixed to the board by terminals or a couple of screw nails and the instruments are now complete. But they are improved by fixing outside of the diaphragm a mouth piece shaped like the aperture of a speaking tube, having an opening of about $\frac{5}{8}$ inch diameter near the plate. It is only necessary to take one out of ear shot and connect the two instruments together by a double line of wire, or if only one-line wire be used, both of the free terminals must be connected with the earth by a gas or water pipe to complete the circuit. In speaking to the telephone the articulation must be slow and distinct, high pitched voices suiting best, and it need not be very loud; but in listening, the instrument must be held close to the ear, and while perfect stillness is preserved, all attention must be given to catch the small voice.

For this reason public exhibitions of the telephone are usually disappointing; at large meetings after being described it is put in operation and handed to the chairman who listens and tells the audience that he has heard the voice, and with that they have to be satisfied. For such a meeting as the present it is better suited, but it is necessary to disabuse your mind of all the exaggerated accounts from American sources which flooded the newspapers some months ago. You must be very patient and very attentive, and I have no doubt all will in turn hear. I shall first let you hear the instrument sing aloud by a simple arrangement. Taking a ferrotype diaphragm mounted as just described for the telephone, having first removed the varnish from the highly polished side by laying it a couple of minutes on blotting paper soaked in chloroform, a wooden bridge is made over one side and a pointed brass screw nail driven through it and carefully adjusted so as to nearly touch the naked iron.

A piece of wire is soldered to the iron plate and another to the nail. If this "contact-breaker" is held before the mouth when singing, it will be found that the vibrating diaphragm strikes the nail point with a rapidity varying with the pitch of the note, producing a buzzing noise, and if this instrument and a one-cell battery are put into the circuit with a telephone, whatever is sung into the contact-breaker is transmitted to the telephone, which is now heard to sing loud enough to be audible over the whole room. There is here, however, no articulation, the "music" being akin to that produced by a speaking trumpet, and is of the same type as that which created such a stir and disappointment at the Queen's Theatre in London in August last.

The articulating telephone was then attached and handed among the audience, while messages were sent to and from the laboratory, where the other terminus was located, but from the difficulty of obtaining perfect silence in the crowded room, and the close and heated atmosphere the voice was not always distinctly audible to unaccustomed ears.

Dr. Stevenson Macadam (who had the advantage of hearing the instrument in the stillness of the laboratory), said that he had had experience in working Bell's telephone at the British Association meeting, and at Plymouth, and also at another meeting at Aberdeen, and knew what difficulties lay in the way of a public exhibition of such a delicate instrument; he was pleased to be able to say that Mr. Howie's instruments compared favourably with those he had heard. He believed there was a great future in store for the telephone, and that business men wishing to communicate with each other at a distance would soon be able to do so by the telephone: one would be shut up in a padded room at each end, and they could then at once open communication in their own voices.

Mr. Mackay, in moving a vote of thanks to Mr. Howie, alluded to the great interest taken in this instrument by all classes. The other day he had seen in a neighbouring street an itinerant vendor disposing of them in large numbers, assisted by a couple of street arabs at the ends of the thread as operators.

A vote of thanks was then awarded to Mr. Howie, who in acknowledging it referred to the pleasure with which he had listened to Dr. Wilson's lecture, which recalled a session of lectures on physiology he had attended many years ago in the "Andersonian," Glasgow, and made him wish to draw the attention of the younger members to the evening lectures on that subject delivered at the Watt Institute in Edinburgh. There was one lecture weekly, and the fee was only 5*s*. for the winter course.

After the lecture a number of gentlemen who remained behind obtained very favourable results in the now comparatively quiet room.

Mr. Mackay intimated that through the kindness of Professor Archer the next meeting would be held in the Museum of Science and Art, on the evening of Tuesday, 29th January, but billets would be issued in a few days.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fifth general meeting was held at the Royal Institution, December 6, 1877. The President, Mr. T. F. Abraham, in the chair.

The minutes of the previous meeting were read and signed.

The question-box was opened and the queries replied to by the President and members. One query asking for a reliable and correct method of testing the purity of cream of tartar elicited further information and discussion from Mr. Michael Conroy, F.C.S., Dr. Symes, and Mr. A. E. Tanner.

Dr. Symes said it would be remembered that the discussion arose at the previous meeting from the fact that cream of tartar had been found at Huddersfield and elsewhere to contain baryta in small quantities. It seemed clear that this could not have been added fraudulently as an adulterant, and yet no one could account for its accidental presence. Feeling that this was too serious a matter to remain in obscurity, he (Dr. Symes) had looked it up, with the following results:—In the *American Chemist* of 1873, Mr. J. Lawrence Smith proposed to prepare the tartrate from sulphate potassa by heating it with carbonate of baryta and then adding the requisite quantity of tartaric acid. This, however, was a laboratory process, for comparatively small quantities. In Hofmann's 'Juries' Report on the Chemical Products and Processes of the 1867 Exhibition,' he mentions a proposition by M. Kuhlman to use baryta instead of potassa for producing its tartrate for dyeing. But in this country, as early as 1856, Messrs. Pontifex and Ogston, of London, patented certain improvements in the manufacture of tartaric and citric acids, in which they treat crude tartar with carbonate of lime or sulphate of barium, and in the same year Mr. Pontifex patented a process for preparing citrates and tartrates from the mothor liquor left after crystallizing out citric and tartaric acids, and says, "if necessary letting any lime or baryta or other matter deposit." Thus it will be seen that some portion of the cream of tartar of commerce is made from the mother liquor of tartaric acid, which mother liquor may contain baryta. This, therefore, sufficiently accounts for its occasional if not frequent presence in minute quantities in that article as sold. He would mention to any one interested in the manufacture of these articles that there is a paper of considerable interest by Mr. Warrington in a recent volume of the *Chemical News*, which treats the subject most exhaustively in seventy octavo pages.

Dr. Symes also exhibited a specimen of artificial vanillin, which he presented to the museum, and detailed the method of its manufacture.

Other miscellaneous communications having been received, the meeting closed.

The sixth general meeting merged itself with the associated soirée of the literary, scientific, and art societies of Liverpool, which was held at St. George's Hall, December 14, 1877, under the presidency of his worship the Mayor of Liverpool, Mr. A. B. Forwood. The exhibits on the part of the Chemists' Association were numerous and highly attractive, consisting of drawings and models of the latest improvements in chemical plant; specimens of improved forms of chemical apparatus; specimens illustrative of the principal chemical manufactures and of fine and rare chemicals, acids, alkaloids, etc. Amongst the contributors of the objects were Messrs. Bowdler and Bickerdike, of Church, Dr. J. Campbell Brown, Liverpool, Messrs. Calvert and Co., Manchester, Mr. Alfred E. Fletcher, F.C.S., Mr. George Gordon, Liverpool, Messrs. Hargreaves and Robinson, Widnes, Messrs. John Hutchinson and Co., Widnes, Messrs. Hopkin and Williams, London, Messrs. Mottershead and Co., Manchester, and Mr. Peter Spence, F.C.S., etc., Manchester.

At half-past eight o'clock, in the Crown Court, Mr. Edward Davies, F.C.S., gave a short lecture on the subject of "Spontaneous Combustion." He described Homburg's pyrophorus made from alum and starch, and then alluded to the discovery of phosphorus and the intense interest which it excited at the time. The influence of a fine state of division in favouring spontaneous combustion was illustrated by a solution of phosphorus in bisulphide of carbon poured on filtering paper, also by reduced iron and lead reduced from the tartrate. The latter combustions being made in oxygen as well as in air. Spontaneously inflammable gases were next illustrated by phosphuretted hydrogen in air and in oxygen and siliciuretted hydrogen. Zinc ethyl poured into oxygen made a most brilliant illumination, and concluded the part illustrating spontaneous combustion arising from oxidation.

The lecturer spoke on the subject of spontaneous combustion in human beings, and expressed his disbelief in such occurrences. The human body contains nearly four-fifths of its weight of water, and the dry residue is not very inflammable, so that it is very difficult to imagine its taking fire by itself.

The lecture concluded with some examples of spontaneous combustion arising from chemical actions other than oxidation. Among these were antimony in chlorine and turpentine in the same gas.

The experiments were on a large scale and performed most successfully.

LEEDS CHEMISTS' ASSOCIATION.

Since the last report of the proceedings of this Association three general meetings have been held. On each occasion the chair was occupied by Mr. P. Jefferson, the President, and a vote of thanks cordially awarded to the lecturer.

"Colour and its Lessons" was the subject of the paper read by Mr. H. Pocklington, F.R.M.S., on Nov. 14, 1877. Treating the subject from the physical and physiological basis, he briefly touched upon the nature of light, explaining the undulatory theory and showing how completely it explained the varied colour phenomena met with in nature or brought about by scientific experiment. He then discussed, somewhat fully, the question as to how far the sense of colour-seeing was explained on the three nerve theory, expressing his own belief in the, at all events, approximate truth of the theory, which he thought was beautifully supported by the different results obtained by purely ocular analysis of coloured or white light and those obtained by prismatic analysis of the same light. He showed, for instance, that all the green lights of nature were impure and contained a large admixture of red and blue, and also that it was possible to obtain white light, which was sensibly pure white light to even the cultured eye, but which the spectroscope proved to be by no means the white light of the sun, which itself does not contain light of all the wave lengths comprised between the red and violet ends of the spectrum.

Mr. Thomas Fairley, F.C.S., contributed the paper for December 12, 1877, entitled "Spontaneous Combustion, and the Causes of Fires," with experiments. He showed that the term spontaneous combustion may be used either in a general or special sense. In the one it refers to all fires not due to the actual contact of hot bodies or the direct action of heat. In the other it is restricted to the combustion produced by the chemical action of bodies, originally cold, upon each other. He explained, and showed experimentally, numerous cases of spontaneous combustion due to the latter cause, more especially where the combustible bodies are finely divided, so as to expose a large surface to the action of the air or other gases acting upon them. Finely divided metals, such as lead, iron, zinc, take fire when exposed to the air. Recently fires had occured on board ship, due to the action of seawater on cargoes of zinc dust. The lecturer also instanced the class of nitro-compounds of which nitro-glycerine and gun cotton are best known; these, if impure, become still more liable to spontaneous combustion and explosion, as shown by the numerous accidents which have occurred. He referred to the Australian emigrant ship believed to have been lost by the explosion of badly prepared gun cotton, forming part of its cargo. Of fires due to other causes, he mentioned the numerous instances of buildings, trees, etc., set on fire by the electric discharge, and in particular the recent fire at Inverary Castle; also the fires caused by the heating of the bearings of machinery by friction or any kind of resistance to motion. Mr. Fairley next described the conditions under which ordinary materials—such as wet hay, sawdust, oily waste, etc.—tend to heat and fire spontaneously, illustrating these by experiments with readily inflammable substances. He described the mode of conducting experiments to ascertain the heating tendency of oils used in manufactures. In experiments undertaken for this purpose he found that cotton seed oil and similar drying oils applied to cotton wool and kept in a warm atmosphere took fire spontaneously in eight hours, or even a shorter time. Other causes of fire different from the preceding are those produced by dangerous substances, either on account of their low ignition point or because they cannot be extinguished by water, or because they give off an inflammable vapour at temperatures near the ordinary range of our climate. Sulphide of carbon is a material which is now extensively used for extracting fat from seeds, wool waste, etc., and for other purposes. It is also present, sometimes in considerable quantities, in ordinary coal gas. It is very inflammable, taking fire at a temperature not far above that of boiling water—300° Fahr. While ordinary combustibles can be readily extinguished by the application of water, petroleum and similar light oils which float on water cannot be extinguished by this means; in such cases sand, ashes, dry earth, etc., are the proper materials to throw on the fire. The Act of Parliament relating to petroleum requires that such liquids shall not be sold without a special label where they give off an inflammable vapour at temperatures below 100° Fah.; and the lecturer showed how the "flashing test" can be applied to distinguish such liquids. In concluding, he drew attention to the application of tungstate of soda to render muslin and other fabrics non-inflammable.

On January the 9th, "The Geographical Distribution of Plants" was the subject of a paper by Professor L. C. Miall, F.G.S., who referred to the different species of plants found in the tropics, temperate and arctic regions, pointing out that they were quite distinct in the majority of cases, although some, such as the leguminosæ, were indigenous to the temperate and torrid zones, yet in this country they rarely exceeded the size and character of a shrub, whilst in the tropical regions they assumed the proportions of large trees. Some plants in this country appeared to have their likes and dislikes, being found only on the tract of limestone, whilst others again preferred the sandstone grit, and were never found upon limestone soil. Another species is always found upon or near the sea coast, and rarely inland, except where there are salt marshes. Several European plants were quite cosmopolitan, being found in almost all parts of the world. How they were so widely dispersed was not easily understood. Some seeds were no doubt carried by the winds, others by migratory birds or merchandise; this was the case with seeds from many foreign parts, which came to this country in the ballast of ships, in bales of cotton, and various other ways. It was remarkable, however, how few of those imported into England were acclimatized, whilst those from this country, distributed no doubt by similar means, flourished with astonishing rapidity in America, Australia, and other countries. The mere compilation of the names and number of plants found in certain districts was not so useful as precise information of the soil, position, and circumstances in which they were met with.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, January 17th, Professor Odling, Vice-President, in the chair. After the confirmation of the minutes of the previous meeting, the reading of presents to the library, etc., the following certificates were read for the first time:—W. Hudson, G. S. Johnson, T. Lichtenstein, W. B. Lowe and L. T. Wright.

The chairman then announced that a ballot for the election of fellows would take place at the next meeting of the Society (February 7th).

The first paper was entitled—

On the Luminosity of Benzol when burnt with non-luminous Combustible Gases. By E. Frankland and L. T. Thorne.—It was pointed out by Dr. Frankland in

1852,* that hydrogen, carbonic oxide, and marsh gas practically contribute nothing to the luminosity of coal gas, and that the only constituents of value were benzol, ethylene, propylene, butylene and acetylene. The authors have endeavoured to determine the luminosity of benzol individually, and propose in further papers to make similar experiments on the other illuminating constituents of coal gas. Many attempts were made to burn benzol with a smokeless flame, and several lamps were constructed by Mr. Silber, but all the experiments yielded unsatisfactory results, and the authors had to limit their experiments to the determination of the luminosity of benzol vapour after dilution with hydrogen, carbonic oxide, and marsh gas. These three gases were severally prepared in the usual way, and were passed through a brass cylinder six and a-half inches long, three inches internal diameter, packed with sponge saturated with pure benzol, the whole being kept at a constant temperature by immersion in water. The quantity of benzol in the gas was determined by absorption with sulphuric acid. The authors obtained the following numbers:—

1 cubic foot of benzol vapour burnt with hydrogen in a fish-tail burner gave for one hour the light of 69·71 candles at the standard temperature and pressure.

1 cubic foot of benzol vapour burnt with carbonic oxide gave for one hour the light of 73·38 candles at the standard temperature and pressure.

1 cubic foot of benzol vapour burnt with marsh gas, first series, gave for one honr the light of 92·45 candles at the standard temperature and pressure.

1 cubic foot of benzol vapour burnt with marsh gas, second series, gave for one hour the light of 93·94 candles at the standard temperature and pressure.

Hence 1 lb. avoirdupois of benzol gives when burnt with hydrogen the light yielded by 5·793 lbs. of spermaceti.

1 lb. avoirdupois of benzol gives when burnt with carbonic oxide the light yielded by 6·100 lbs. of spermaceti.

1 lb. avoirdupois of benzol gives when burnt with marsh gas, first series, the light yielded by 7·682 lbs. of spermaceti.

1 lb. avoirdupois of benzol gives when burnt with marsh gas, second series, the light yielded by 7·803 lbs. of spermaceti.

Or, in other words, a given weight of benzol produces 5·3 per cent. more light when it is diluted with carbonic oxide, and between 32·6–34·7 per cent. more light when diluted with marsh gas, than when diffused in hydrogen. The authors point out that this difference is probably due, at all events in part, to the different pyrometric thermal effects of the gaseous mixtures.

In reply to the Chairman, Dr. Frankland stated that this increase in the illuminating power of benzol when mixed with marsh gas was not opposed to his former statement that marsh gas did not contribute materially to the illuminating power of coal gas, because in coal gas the principal hydrocarbons were ethylene, and members of that series, which would not raise the temperature to any considerable extent when burnt with marsh gas as compared with the effect produced by benzol vapour and marsh gas.

After the thanks of the Society had been given to the authors, Dr. Gilbert, Vice-President, took the chair.

The next paper was read by Mr. Perkin—

On the Action of Reducing Agents on Potassium Permanganate. By F. Jones.—Hydrogen in neutral solutions decomposes permanganate according to the following equation:—$2KMnO_4 + 8H = Mn_2O_3 + 2KHO + 3H_2O$, the reaction is hastened by raising the temperature. In solutions rendered acid by sulphuric acid, hydrogen produces a similar decomposition. In alkaline solutions a similar action takes place, but much more slowly, a manganate being first formed. Ammonia produces the decomposition—

$$8KMnO_4 + 8NH_3 = 4Mn_2O_3 + KNO_3 + KNO_2 + 6KHO + 9H_2O + 6N.$$

Phosphine when passed through a series of flasks containing solution of potassium permanganate forms sesquioxide of manganese. Phosphorus and phosphoric acids

$$6KMnO_4 + {}_4PH_3 = 3Mn_2O_3 + {}_2K_2HPO_3 + {}_2KH_2PO_3 + 3H_2O.$$

and $2KMnO_4 + PH_3 = Mn_2O_3 + K_2HPO_4 + H_2O$.

Arsine produces a similar reaction—

$$2KMnO_4 + As_3H_3 = Mn_2O_3 + K_2HAsSO_4 + H_2O.$$

The reaction with stibine is—

$$2KMnO_4 + SbH_3 = Mn_2O_3 + K_2HSbO_4 + H_2O.$$

The first action of oxalic acid on potassium permanganate results in the formation of manganese and potassium oxalates, water, and carbonic acid. A further addition of permanganate precipitates manganese sesquioxide, carbonic acid and oxygen being evolved and potassium carbonate formed. In the presence of sulphuric acid oxygen is given off. Oxygen is also evolved with carbonic acid when sulphuric acid acts on manganese dioxide in presence of an oxalate. When strong solutions of permanganate and manganese chloride are mixed sesquioxide of manganese separates out, whilst bubbles consisting of chlorine and and oxygen are evolved. By mixing dilute solutions oxygen, but no chlorine, is evolved. Solutions of ferrous and manganese sulphates similarly evolve oxygen when mixed with solutions of potassium permanganate.

Mr. D. Howard remarked that in the exhibition at Paris, 1867, a compound was exhibited which was said to be permanganate of ammonium; it exploded eventually with some violence. It was curious that such a compound could have been formed and sent to the exhibition, when according to the reaction in the above paper ammonia decomposes permanganate soon after the substances are mixed.

The next paper was read by Mr. Spencer Pickering—

On the Action of Sulphuric Acid on Copper.—According to the author, there are only two primary reactions, the first is represented by the equation $Cu + 2H_2SO_4 = CuSO_4 + SO_2 + 2H_2O$. The second $5Cu + 4H_2SO_4 = Cu_2S + 3CuSO_4 + 4H_2O$. Other products which may be formed are due to the subsequent decomposition of the subsulphide by sulphuric acid. Pure electrotype foil 0·15 mm thick was used. 3 grm. being acted on by 16·3 c.c. strong sulphuric acid, sp. gr. 1·843, for 30 minutes. The action commences at 19°, rapidly increasing as the temperature rises. But little gas is evolved until 130° is reached. No gas such as oxygen or hydrogen insoluble in water is given off, nor any sulphuretted hydrogen liberated during the reaction. The subsulphide formed seems to be deposited on the metal itself in a compact layer, it is not oxidized by exposure to air or by drying in a steam-bath at 100°C. Care was taken that some copper was always left undissolved at the end of the experiment. The author gives in a table the results of many experiments made at different temperatures. At 19°C. ·00015 per cent. Cu. dissolved in 30 seconds, at 100°C. ·052 per cent., at 150° 1·15 per cent., at 220° 70·57 per cent., at 270 nearly 100 per cent. in a few seconds. In two experiments the proportion of copper converted into sulphide to that converted into sulphate was found to be 2 : 2·914 and 2 : 2·964. At high temperatures but little sulphide is formed. The action of sulphuric acid on protosulphide is represented by the equation $2CuS + 4H_2SO_4 = S_2 + 2CuSO_4 + 4H_2O + 2SO_2$. The decomposition of the subsulphide by the equation $Cu_2S + 2H_2SO_4 = CuS + CuSO_4 + 2H_2O + SO_2$. The author thinks that the formation of the copper sulphide is due to the direct union of the copper with the sulphur in the acid, which opinion is supported by quantitative experiments and various theoretical considerations. The quantities of sulphuric acid actually used in the experiments, and the amount of sulphurous acid evolved were determined

* 'Memoirs, Manchester, Lit. and Phil. Soc.,' 2nd series, x, 71.

and found to agree with those required by the above equations. In some experiments a small sublimate of sulphur was observed round the neck of the flask in which the copper had been dissolved; this is probably due to the tendency of free sulphur to creep up the sides of the containing vessel. The effect of an electric current was tried: when the copper was rendered electro-positive it dissolved more rapidly and more sulphide was formed. When it was electro-negative more sulphate was produced and less sulphide. In some experiments the coating of sulphide protected the copper from the action of the acid to a notable extent. If the copper used be impure it dissolves more rapidly, and two sulphides are formed owing to the rapid formation of subsulphide, and its subsequent decomposition by the acid. The author suggests that the increased action of the acid on impure copper may be due to some sort of catalytic action of the impurities, analogous perhaps to the solution of alloys of platinum and silver in nitric acid. The action of dilute acids was also investigated. In conclusion, the author gave a *résumé* of the explanations which have been offered from time to time of the action of sulphuric acid on copper by previous experimenters, and criticized their results.

The next communication was—

On the Analysis of Sugar. By G. Jones.—The author proposes to estimate sucrose volumetrically by adding a 0·1 per cent. solution to a decinormal solution of permanganate, acidulated with sulphuric acid, until the dirty brown hydrated peroxide of manganese, which is at first formed, is reduced and dissolved. The solution, contained in a porcelain dish, is boiled after each addition of the saccharine liquid. No analyses are given, but the author states that in every case he obtained results which fully justify him in drawing attention to the process. The colouring matters in sugar do not seem to affect the value of the estimations.

Mr. Warington drew attention to the fact that this use of permanganate must be limited to cases in which the sugar was tolerably pure, and that it would be useless for determinations of the sugar present (*e.g.*) in the juice of the beet root, etc.

The last paper was—

On the Decomposition Products of Quinine. By W. Ramsay and J. Dobbie.—Five grms. of quinine were gently treated with 50 grms. of permanganate in solution. After complete reduction the alkaline liquid was filtered, neutralized with nitric acid, and precipitated with nitrate of lead. The precipitate was decomposed by sulphuretted hydrogen, and the new acid converted into a silver salt and the latter decomposed by sulphuretted hydrogen. The filtrate was evaporated *in vacuo*, and furnished needle-like crystals of a new acid, which proved to be dicarbopyridenic acid, identical with that obtained by Dewar from picoline. It gave 9·6 per cent. water, 3·16 per cent. H., and 44·56 per cent. C. Dicarbopyridenic acid contains 9·83 per cent. water, 3·00 per cent. H., and 50·30 per cent. C. The new acid contains nitrogen, melts 251—252°, gives a red colour with ferrous sulphate and a characteristic odour on heating. The silver salt gave 56·21 per cent. Ag, and behaves like mercury sulphocyanide; by titration the potassium salt contains 32·5 per cent. K, the soda salt 21·76 per cent. Na. The salts of dicarbopyridenic acid contain respectively 56·69 per cent. Ag, 32·15 per cent. K, and 21·80 per cent. Na. Besides the acid some quantity of a red deposit was obtained, the yield of this substance was diminished by effecting the reaction at 100°, whilst the yield of acid was increased. By oxidizing Marchand's quinetin with permanganate the authors obtained an acid identical with the one above described.

The Society then adjourned to February 7, when the following papers will be read:—

1. "Notes on the Tannins," by Dr. Paul and Mr. Kingzett. 2. "On a Method for the Determination of Boiling Points," by H. C. Jones. 3. "On the Alkaloids of the Aconite family; part ii., the Alkaloids of *Aconitum ferox*," by Dr. Wright and Mr. Luff. 4. "An Inquiry into the Action of the Copper-Zinc Couple on Alkaline Oxysalts," by Dr. Gladstone and Mr. Tribe. 5. "On the Estimation of Phosphorus in Iron and Steel," by C. Riley.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held at 17, Bloomsbury Square, on Thursday, Jan. 17, when a paper was read by Mr. Allen, on "Chemical Science some Two Hundred Years Ago." The author commenced by briefly tracing the history of chemical science up to the end of the seventeenth century, dwelling especially on the elementary principles held by different philosophers. The rise, progress, and decline of the alchemists were noticed, together with the chief objects of their study. Having alluded to some conjectures pointing to the present advance in chemistry, he proceeded, in the supposed words of one of the philosophers of two centuries ago, to compare some of the theories of that period with those of the present time. Having noticed what an easy task the pharmaceutical student had with only three anonymous elements to study he gave an instance of, what he was pleased to term, the "Atrocious, elongated, barbarous titles" of chemical compounds; the supposed merit of which seemed to him to consist in their containing the names of all their component elements.

A vote of thanks was unanimously awarded Mr. Allen for his paper, and the meeting then adjourned.

Parliamentary and Law Proceedings.

What is a Mineral Water.—The Sale of Pyretic Saline.

In the Court of Appeal of the Supreme Court of Judicature, before Lords Justices Bramwell, Brett, and Cotton, the case of Her Majesty's Attorney General *v.* Lamplough came on for hearing on Tuesday and Wednesday last. This was an appeal by the defendant from an order made on the Revenue side of the Exchequer Division, discharging a rule nisi to enter the verdict for the defendant. The case came before that Court under the following circumstances:—The Attorney-General had, on behalf of the Crown, laid an information charging the defendant, Mr. Henry Lamplough, that he did, in September, 1876, "expose and utter and vend a bottle of medicine containing a certain preparation to be used and applied as a medicine or medicament for the prevention, cure, and relief of disorders and complaints incidental to and affecting the human body, called Lamplough's Effervescing Pyretic Saline, wherein he had, or claimed to have, an occult secret or art for making and preparing the same," and that he did so sell it "without the cover, wrapper, or label provided by the Commissioners of Stamps for denoting the duty chargeable on such bottle." The information came on for trial before Mr. Baron Cleasby and a special jury, at Westminster, when certain evidence having been given, a verdict for a £10 penalty was taken by the Crown, subject to the opinion of the Court above on the point of law involved. The question accordingly came on for argument before the Lord Chief Baron and Barons Cleasby and Huddleston, on a motion to enter the verdict for the defendant, when the Court was divided in opinion, the Lord Chief Baron being of opinion that the preparation in question was not a medicine within the meaning of the statute under which it was sought to be taxed, while Barons Cleasby and Huddleston took a contrary view, and gave judgment for the Crown. From this decision the defendant now appealed to this Court. Mr. Herschell

Q.C., Mr. Ince, Q.C. (of the Chancery bar), and Mr. E. B. Cooper, were counsel for the appellant; and the Attorney-General, the Solicitor-General, and Mr. Dicey represented the Crown. The question involved depended on the construction which should be placed on certain acts of parliament. By the 44th Geo. III. stamp duties were chargeable on certain patent medicines which were specified in the schedule by name, and also by general words. That act was repealed by the 52nd Geo. III., c. 150, so far as regarded the schedule, and another schedule was enacted which set forth the articles to be taxed in alphabetical order, and under the heading "waters" appeared all artificial waters impregnated with soda, or mineral alkali, or carbonic acid gas, and all compositions in a liquid and solid state. "Lamplough's Pyretic Saline" is composed of tartaric acid, bicarbonate of soda, and a small quantity of chlorate of potash, and it was admitted that it formed an artificial mineral water when the ingredients sold in a solid state were mixed with water, and would as such be liable to be taxed but for the amending act—the 3rd and 4th William IV., c. 97, sec. 20—which altered the schedule of the 52nd Geo. III., and repealed the duties as regards artificial mineral waters. The question was whether the preparation in question was of this character, or whether it came within "the tail-end of the schedule" of the act as a medicament which a person had the right of selling under letters patent, or which he put forward by advertisement for the relief or cure of disease. For the defendant it was contended that Pyretic Saline was a beverage which was, in point of fact, an artificial mineral water, and therefore exempt from duty, and that if so charged Schweppe's soda water and lemonade, and all others of the same kind, would be chargeable; while for the Crown it was submitted that it did not come within the provisions of the repealing act as an artificial water, but the contrary, as its sale depended on its medicinal properties.

On the conclusion of the arguments their lordships delivered a unanimous judgment, holding that it was the intention of the legislature by the repealing act of William IV. "to exempt all these waters from taxation, even if the vendors held that they were beneficial for human ailments, and therefore that the Pyretic Saline was not chargeable with duty."

The judgment of the Court below was accordingly reversed, and the appeal allowed with costs.

Poisoning by Laudanum.

On Thursday, Jan. 17, an inquest was held before Mr. Rider, at the Leeds Town Hall, touching the death of Joseph Parsons, 46, draper, Leeds Street, Burmantofts. Deceased, who has recently been addicted to intemperate habits, after selling his home up went on the previous Tuesday evening to an eating-house, and asked for a bed. He was affected with liquor at the time. He went to bed, and on the landlady going to call him up at eleven o'clock he appeared ill and was groaning loudly. Mr. Hunt, surgeon, was sent for, and, after using the stomach-pump, ordered the man to be taken to the infirmary. On the dressing-table in the bedroom occupied by Parsons were three small empty bottles, labelled "Laudanum." The bottles bore the names of different chemists.

Mr. E. Jacob, physician at the infirmary, stated that when the deceased was admitted into that institution he appeared to be suffering from narcotic poisoning, and was unconscious. He died shortly after two o'clock on the following morning. He must have drunk over three-quarters of an ounce of laudanum.

It was stated that the deceased had previously made two attempts to commit suicide by drinking poison whilst suffering from depression of spirits consequent on heavy drinking.

The jury returned a verdict of "Suicide whilst in a state of temporary insanity produced by excessive drinking."—*Yorkshire Post.*

Dispensing Memoranda.

[50]. Ext. Ergotæ Liq.—Will you kindly permit me a last remark concerning Dispensing Memorandum No. 50, Extractum Ergotæ Liquidum.

My answers in Nos. 392 and 394 referred to the crystals found by "Young Pharmacist" sparingly or not at all soluble in water, not to those described by Mr. Gerrard in last number as being soluble in water.

The further statements of Mr. Gerrard induced me to make the following quantitative examination of the ash of extractum ergotæ liquidum.

10 grams of the liquid extract were evaporated, burnt to coal, the latter exhausted with diluted hydrochloric acid, again evaporated, heated in a platinum crucible to a dark red heat, and weighed:—

$$0{\cdot}15 = 1{\cdot}5 \text{ per cent.}$$

Re-dissolved in a little distilled water a salt remained,* which well dried weighed 0·0188, and subtracted from ash found left 0·1312 = 1·312 per cent. To the clear solution was added bichloride of platinum in excess, evaporated in a water-bath to dryness, then treated with spirit. rectif., which left the pot. platin. chlorid. undissolved. The latter collected in a well dried and weighed filter = 0·203:—

$$\begin{array}{lcll}
KCl, Pt\,Cl_2 & : & KO & \\
244{\cdot}4 & : & 47{\cdot}2 & = 0{\cdot}203 : x \\
x & = & 0{\cdot}0392 \text{ KO.} & \\
KCl, Pt\,Cl_2 & : & KCl. & \\
\text{or } 244{\cdot}4 & : & 47{\cdot}7 & = 0{\cdot}203 : x \\
x & = & 0{\cdot}062 \text{ KCl.} &
\end{array}$$

The same subtracted from soluble ash found = 0·1312; there remains 0·0692 = chloride of sodium.

The difference of climate and soil may account for the difference of inorganic matter found in the ergot.

The great demand of ergot for exportation, especially last year in Germany, may have induced people to collect the *Claviceps purpurea*, not only from *Secale cereale*, but also from *Alleopecurus pratensis*. Even *Claviceps microcephala* from *Phragmites communis*, *Claviceps pusilla* from *Andropogon Ischaemum*, and *Claviceps nigricans* from *Scirpus acustris*, may be sometimes found mixed mixed it.

H. W. Langbeck.

[52] The prescription quoted in No. 52 is open to another construction, viz., that the figure two by some misadventure was omitted after the words "fiat pil." and that it should stand thus—

℞ Ext. Hyoscyami . . . . . gr. iii.
Pil. Rhei Co. . . . . gr. iv.
Fiat Pil. ij. Cap. i h. s. Mitte xii.

This would make four different ways that the same receipt might be dispensed at four different establishments, and the same might occur with any other imperfect or doubtful prescription. Consequently I would supplement the memorandum of "S. H. P." by suggesting that (reference to the prescriber being impracticable) the first dispenser of such a prescription should make a rule of marking on the prescription the same memoranda that he makes in his own prescription book, showing how he has treated it, for the guidance of the next person that may be called upon to dispense it, thereby probably preventing annoyance to both a brother chemist and his customer.

J. C.

* The salt consisted of metaphosphate of lime ($CaOPO_5$ produced by heating the ash, which contained then acid phosphate of lime $(CaO \cdot 2\,HO) \cdot PO_5$. Besides I found traces of copper, the result of using a copper vessel in the preparation of the extract.

Professor Attfield found in extractum ergotæ (not the liquid) 3 per cent. of sulphate of potash. *Vide* Dorvault's 'L'Officine.'

[54].

℞	Kreosoti	♏ xxiv.
	Pil. Rhei Co. (sine Theriaca).	gr. xvj.
	Pulv. Saponis	gr. viij.
	Magnes. Calc.	gr. xij.

M. ft. pil. xij.

Mix the creasote with the soap, add the pil. rhei, and lastly the mag. calc. (previously made hot in a crucible); after standing for a short time in the mortar, the mass may be rolled into five grain pills.

JOHN COLEGROVE.

[57]. In answer to No. 57, I certainly think the intention of the prescriber would have been carried out if a ℥ij mixture only had been made. I have dispensed numerous prescriptions of a similar nature where the word "adde" has been omitted, and I know in several instances that the intentions of the prescribers were carried out by my so doing. If only a ℥ij mixture had been made ʒj would not be too much for a dose.

C. F. JAMES.

[57]. From the quantities ordered in this prescription, I should give it as my opinion that a ℥ij mixture was intended, and should accordingly have dispensed it as such. In cases of doubt, and where the prescriber cannot be communicated with, I think it is usual for the dispenser to use his own judgment. Why then did "Beta' act in opposition to his judgment?

A. E. C.

[58].

℞	Potass. Iodid.	ʒj.
	Potass. Bicarbon.	ʒij.
	Ferri Ammon. Citrat.	ʒij.
	Aq. Flor. Aurant.	℥viij.

M.

The above cannot be made so that it will not effervesce, or rather decompose. Any physician thoroughly up in chemistry would know better than to prescribe potass. bicarb. and ferri ammon. cit. together. In Squire's 'Companion to the British Pharmacopœia,' I find, under the head of "Ferri Ammonia Citras," "care must be taken not to put the salt of iron into the solution of bicarbonate of potash, because if it is, carbonic acid will be given off, and the bottle burst."

I am aware it is frequently done, but, as I have shown, injudiciously.

Edinburgh. NIL DESPERANDUM.

[58]. Had "Beta" referred to the "Characters and Tests" of ferri ammon. cit., given in the B. P., he would have discovered the cause of the effervescence in this mixture, and he would have been able to perceive that obtaining chemicals of unquestionable quality "from one of the best London houses" was the surest method of ensuring, instead of avoiding the effervescence.

This effervescence, however, is exceedingly slight, and all difficulty is easily obviated by leaving the bottle uncorked for a moment or two.

Scarborough. A. E. C.

Notes and Queries.

[576]. STINKING HELLEBORE.—I shall be obliged if any reader will tell me where I can obtain a little powdered Stinking Hellebore root (*H. fœtidus*). I want it for a customer who has been reading in the *Field* newspaper lately that it is an excellent vermifuge for dogs. My London patent medicine house has kindly sent round to all the principal wholesale drug houses and herbalists, but without success. One house sends me *H. niger* for it, another *H. viridis*, and the rest say they neither keep it nor know where it is kept.

PHARMACIST.

Correspondence.

EXTINCTION OF GERM LIFE.

Sir,—Mr. Greenish has hastened to correct me in what he assumes to be my position with regard to the above question; but he will, no doubt, remember the warning of Friar Lawrence, "They stumble who run fast."

If Mr. Greenish will do me the favour to read the articles he refers to with closer scrutiny, I think he will find that he has fallen into the very prevalent error (an error specially dwelt upon by Professor Tyndall) of confounding bacteria with bacteria germs. The distinction is imperative, and only, it would appear, to be fully appreciated by the practical worker. The new point in my inquiry consisted in the circumstance that highly putrescible and refractory liquids were sterilized of their germs, or fermentative particles, not that "bacteria were killed," as Mr. Greenish has put it—for this had already been pointed out by Dr. Bastian and others—by continuous exposure to a comparatively low temperature. In other words, it was not the destruction of bacteria, but the prevention of their development in nutritive fluids at a low degree of heat sustained over a given period that constituted the novelty set forth in this investigation. To "kill bacteria" is one thing, to sterilize infusions of their ferments, another. Clearly, therefore, Mr. Greenish has missed the mark, and consequently his well-intentioned, but by no means happily conceived, "correction" (for which, so far it goes, he needed no aid from foreign sources) does not apply. Presuming it did; presuming, for the sake of argument, that the inference he draws from the articles in question were shown to be correct; I would undertake absolutely, upon that interpretation, to prove the truth of spontaneous generation. But, obviously, such a controversy could not be carried on in the correspondence columns of the *Pharmaceutical Journal*.

May I, in addition, remind Mr. Greenish that at the dates he gives, viz., 1872 and 1874, bacteria germs, particulate ferments, desiccated organisms (call them what you will), as presented by the light of more recent research, were, in reality, outside the ken of philosophical investigators?

ELEMIC ACID—CONTRIBUTION TO THE CHEMISTRY OF ELEMI.

BY DR. EUGEN BURI.

It has been shown by Professor Flückiger* that in elemi there occurs a crystallized substance, bryoïdin $= (C_{10}H_{16})_2 + 3\,OH_2$. Some time ago I also devoted a paper† to another crystallizable principle, amyrin $(C_5H_8)_5OH_2$; and I have since succeeded in isolating a third crystallizable constituent of the same drug. Both bryoïdin and amyrin are devoid of an acid character, but the new substance is undoubtedly an acid, which may be termed *elemic acid.*

It was contained in the alcoholic mother liquor, from which crystallized amyrin was obtained. On evaporating this liquor an amorphous brown resin (R) remains, which with the same weight of petroleum spirit (60° C. boiling point) yields a clear solution; this, however, becomes turbid on addition of a large quantity of petroleum spirit. The mixture is then shaken with nearly the same volume of caustic lye (about 10 per cent. of KOH), when it separates in two liquid layers and a jelly. The latter can easily be collected and, on addition of water, forms an emulsion becoming quite clear by means of ether. The ethereal portion contains a little resin, the lower layer being chiefly a solution of elemate of potassium, from which *elemic acid* is precipitated by hydrochloric acid; it is still accompanied by an *amorphous resin* of an *acid character.*

The same crude elemic acid may also be obtained by the following process:—The above-mentioned resin (R) is dissolved in twice its weight of ether and the solution shaken with caustic lye; the potassium salts of elemic acid and the resinoid acid are formed but retained by the ether; on mixing it with much water an aqueous solution of these salts is formed, the indifferent resin remaining in the ether. It is advisable to use caustic lye containing about 10 per cent. KOH; a very weak lye, say of only 1 per cent., is not so well for producing an ethereal solution of the said salts. Elemic acid is then again precipitated, as above stated, by means of hydrochloric acid.

In order to purify the acid it is repeatedly recrystallized from hot alcohol, about 0·820 sp. gr., and the crystals must be washed with cold alcohol. It is by no means easy to get them absolutely clear and colourless; if so, they are very brilliant and much larger than those of both amyrin and bryoïdin. Although the finest crystals of elemic acid attain a length of several millimetres it has been found impossible to ascertain their crystallographic character, each of them being formed of very intimately aggregated individual crystals.‡

Elemic acid melts at 215° C., yielding on cooling an amorphous mass, which may again be obtained crystallized if dissolved in alcohol. Heated for some time, even without undergoing fusion, the acid turns brownish. It is readily soluble in ether, methylic, ethylic, or amylic alcohol; sparingly so in bisulphide of carbon; not at all in water. It requires, at 15° C., for solution, 17·55 parts of alcohol, 0·826 sp. gr., 0·6556 gram of acid having been afforded by evaporating 12·1619 grams of solution saturated at the said temperature. It is much more abundantly soluble in hot alcohol; oversaturated solutions are easily formed.

The alcoholic solution of elemic acid, especially when diluted with a little water, decidedly reddens litmus; alcoholic solutions of the salts of metals are not precipitated, all the elemates being readily soluble in alcohol. The solution of the acid is lævogyre; dissolved in ten parts of absolute alcohol it deviated the ray of polarized light 3·5° to the left (temperature 20°, length of the column of the liquid under examination=200 millimetres). The polaristrobometer of Wild and sodium light were used for this experiment.

In order to submit the acid to ultimate analysis its ethereal solution was shaken with dilute hydrochloric acid and washed with water. On evaporating the solution the elemic acid was obtained entirely free from inorganic matter; if not submitted to this treatment it always contains a small amount of calcium or potassium. The following figures have been obtained with the purified acid, viz.:—

			CO_2		OH_2
1. 0·2418 of	acid	yielded	0·6922	and	0·2279
2. 0·3041	„	„	0·8649	„	0·2847
3. 0·2993	„	„	0·8541	„	0·2803
4. 0·2959	„	„	0·8444	„	0·2768
5. 0·2919	„	„	0·8319	„	0·2726
6. 0·3141	„	„	0·8957	„	0·2943

or in percentages:

	I.	II.	III.	IV.	V.	VI.
C	78·07	77·57	77·83	77·83	77·73	77·77
H	10·47	10·40	10·40	10·39	10·38	10·41
O	11·46	12·03	11·77	11·78	11·89	11·82

This would answer to the formula $C_{35}H_{56}O_4$.

C_{35}	420	77·78
H_{56}	56	10·37
O_4	64	11·85
		100·00

By writing that formula as follows $(C_5H_8)_7O_4$, elemic acid is shown to be allied both with bryoïdin and amyrin, as well as with other derivatives of terpene C_5H_8.

Elemates.—If elemic acid and carbonate of sodium are gently warmed with dilute alcohol, sodic elemate is formed, but cannot be obtained in crystals. From the cold alcoholic solution of elemate of sodium elemic acid is precipitated by carbonic acid. *Elemate of potassium* can be prepared by gently warming the acid with caustic lye containing 10 per cent. of KOH, when at first a jelly is formed. Elemate of potassium, however, separates soon in the solid state from the liquid and can be dissolved in warm water; on cooling the liquid concretes nearly and consists then of needle-shaped crystals. They cannot be submitted to any further purification by recrystallization from either water, alcohol, or ether; all these solvents yield simply a greasy mass, but no distinct crystals. The crystals of elemate of potassium obtained as above stated must be separated from the mother lye by means of the water pump. The adhering trifling quantity of caustic potash is then converted into carbonate, from which it would be possible to separate the elemate by alcohol, but the elemate is then no longer obtainable in the crystallized state. It is decomposed by pure water, forming again a clear solution if very little potash is added

* *Pharm. Journ.*, Aug. 22, 1874, p. 142.

† *Pharm. Journ.*, vii. (Aug. 19, 1876), p. 157.

‡ The Pharmaceutical Society has been presented, by Professor Flückiger, with a specimen of crystallized elemic acid.

the salt is precipitated as soon as a somewhat larger amount of potash is present.

Elemate of potassium when dry is a perfectly white crystalline substance, which cannot be entirely deprived of water over concentrated sulphuric acid, but by heating it at a temperature of from 125° to 130° C. the water is eliminated. This, however, cannot be performed without decomposing the salt; it is, in fact, impossible to make a direct estimation of the water. It was calculated according to the following method:—The elemate being decomposed by warming it with very dilute hydrochloric acid, after cooling the elemic acid was collected in the filter, dried at 100° and weighed, whilst the filtered solution yielded the chloride of potassium.

1. 1·0092 gr. elemate, air-dried, yielded 0·5988 elemic acid $C_{35}H_{56}O_4$, corresponding to 0·5977 acid calculated according to formula $C_{35}H_{55}O_4$. At the same time 0·0856 chloride of potassium was produced. This gives 4·44 per cent. of potassium, combined with 59·22 per cent. of acid $C_{35}H_{55}O_4$.

2. 1·1885 gr. elemate of potassium yielded acid 0·7056 = 0·7043 = 59·26 per cent. of hypothetic acid $C_{35}H_{55}O_4$. On the other hand, 0·0998 KCl was produced = 0·0523 = 4·40 per cent. of potassium. The composition of elemate of potassium is accordingly as follows:—

	I. Analysis	II.		Calculated.	
$C_{35}H_{55}O_4$	59·22	59·26	$C_{35}H_{55}O_4$	539	59·75
K	4·44	4·40	K	39	4·33
18 OH_2	36·34	36·34	18 OH_2	324	35·92
				902	100·00

Elemate of sodium.—It has only been ascertained that is perfectly analogous to the potassium salt, yet seems not to be capable of crystallization.

Elemate of silver, $C_{35}H_{55}O_4Ag$, obtained by mixing an alcoholic solution of elemate of potassium with an aqueous solution of nitrate of silver. The gelatinous precipitate resembling hydroxide of aluminum, displayed a reddish hue; it was dried by pressing it between blotting paper and dissolved in ether, which left behind a very small amount of greyish matter. Elemate of silver as prepared ultimately by evaporating the ether, is white, very light, and on rubbing becoming electric; it is soluble in hot alcohol, but does not afford crystals from that solution. It is not easily altered on exposure to daylight. Before submitting it to analysis it was dried in a current of pure air, deprived of carbonic and hydrosulphuric acids. Its analysis furnished the following results:—

1. 0·5668 elemate of silver gave 0·0945 silver.
2. 0·5785 elemate of silver gave 0·0983 silver.
3. 0·2475 elemate of silver gave 0·0420 silver, 0·5850 CO_2, and 0·1906 OH_2.
4. 0 2282 elemate of silver gave 0·0388 silver, 0·5401 CO_2, and 0·1780 OH_2.

By means of the alcoholic solution of elemate of potassium other salts of elemic acid may be obtained; those of the metals are all amorphous. Elemic acid does not combine with ammonium; elemate of ammonium cannot be got in the solid form, although an alcoholic solution of elemic acid, which has become turbid by mixing it with water, is perfectly cleared by ammonia.

An *amorphous resin of acid character* having been mentioned above among the constituents of elemi, it may be pointed out that it appears to be a mixture of at least two substances, inasmuch as it is partly soluble in cold petroleum spirit. The residue dissolves readily in warm petroleum spirit. Neither the latter portion nor the former is able to form crystallizable salts.

In preparing elemic acid as above stated, the *indifferent amorphous resin* remains dissolved in ether. After the evaporation of the ether, a brownish brittle resin remains, which was ascertained to consist of a portion readily soluble in petroleum spirit, the residue being soluble in warm petroleum spirit. On cooling, a viscid mass separates, which when dry is a transparent slightly yellowish mass resembling colophony, but entirely differing from it by not being soluble in caustic lye. It has not been thought of any use to submit the amorphous resins to ultimate analysis, because it is evident that the means are as yet wanting for satisfactorily purifying them. It is scarcely necessary to state here that they form the prevailing amount of the drug as met with in the market, that is to say, the elemi of Manila. Amyrin also occurs in large amount in elemi; not so the acid principles to which the present paper is devoted.

Strassburg University School of Pharmacy,
Laboratory of Professor Flückiger.

AN OINTMENT OF THYMOL FOR RINGWORM.

BY BALMANNO SQUIRE, M.B. LOND.,
Surgeon to the British Hospital for Diseases of the Skin.

Thymol, which has recently been suggested as a more potent destroyer of germs than carbolic acid, seems to me to be capable of somewhat bolder use than it has yet been put to.

I desired quite recently to investigate what influence it might possibly possess as a destroyer of those particular vegetable germs (always so difficult to exterminate), which are the cause of the contagiousness and the persistency of ringworm.

It is not for the purpose of saying whether thymol be efficacious or not in ringworm that I now write; I have not yet arrived at any conclusion on that point. But as it is likely that other practitioners may investigate the properties of thymol as a possible means of treating ringworm, I have thought it may be of interest to pharmacists to know something as to the best mode of preparing an ointment of it.

I observe that in the *Pharmaceutical Journal* for January 26th of this year, a quotation occurs as to the strength in which thymol has been proposed as an external application, namely:—as an aqueous solution of 1 part of thymol in 1000. Now in the case of ringworm, an ointment is a far better form in which to apply the remedy. Then again, ringworm being a remarkably obstinate disease, the question arises, dare we apply the remedy in a stronger form than has been proposed? To this I reply that we unquestionably can do so. I have used thymol ointment containing 1 drachm of thymol to the ounce of lard, without producing irritation of the skin or any other evil effect.

Now as to the best mode of preparing the ointment, I find that the solid crystals of thymol melt at the temperature of a water-bath, and that the liquid thymol is miscible in all proportions with melted lard.

The formula then would stand thus:—

℞ Thymol . . . . ʒj.
Adipis . . . . ℥j.

Melt together at the temperature of a water-bath, stir the two together and allow to cool.

DITAIN.*

Ditaïn is the bitter active (uncrystallizable) principle contained in the bark of *Echites scholaris* (*Alstonia scholaris*, Brown), Apocynaceæ. This species grows wild quite abundantly in the central provinces of the island of Luzon (in the Philippines), where it has long been known and esteemed by the natives (under the name of "Dita") as a most efficient tonic and febrifuge. The people using it from times immemorial in decoction against malignant, intermittent, and remittent fevers with the happiest result, the attention of our leading physicians was excited, and the active principle, ditaïn, has now become a staple article, and *ranks equal* in therapeutical efficiency with the best imported sulphate quinine. Numberless instances of private and hospital practice, carried out by our best physicians, have demonstrated this fact. *Equal doses of ditaïn and of standard quinine sulphate have had the same medical effects;* besides leaving none of the disagreeable secondary symptoms, such as deafness, sleeplessness, and feverish excitement, which are the usual concomitants of large quinine doses, ditaïn attains its effects swiftly, surely, and infallibly.

(*a*) We use ditaïn generally internally, *i.e.*, in quantities of a half drachm (ʒss) daily for infants, and double the dose for adults, due allowance being made, of course, for age, sex, temperament, etc., as thought convenient by the respective medical practitioner. Given internally, our standard (Manila) formula is—

For Infants.

℞ Ditaïn . . . . ½ drachm.
Aq. Flor. Aurant. . . . 5 ounces.
Syr. Citri. . . . . 1 ounce.
S. One spoonful every hour.

For Adults.

Same mixture, but dissolving one drachm of ditaïn.

(*b*) Our medical practitioners use ditaïn as injections in the rectum. In this form experience has suggested—

For Infants.

Ditain . . . . 1 drachm.
Water . . . . 1 pound troy.
Dissolve. For three injections, one every three hours.

For Adults.

Same preparation, only instead of one use two drachms of ditain. Same intervals.

(*c*) We derive very beneficial effects from its use, too, under the form of poultices. Powdered dita bark, corn flour, each half a pound; hot water sufficient to make a paste. Spread on linen, and apply under the armpits, on the wrists and ankles, taking care to renew when nearly dry, and provided the desired effects should not have been obtained.

The extraction and preparation of ditaïn from the bark is analogous to that of quinine. Maceration with acidulated water and precipitation are its leading features. I have obtained from 100 parts of bark, 5 parts ditaïn, 0·85 parts sulphate of lime, and 10 parts extractive matter; the latter, however, of no medical virtue whatsoever.

As dita bark abounds in this country, and its manufacture is an inexpensive one, I hope to make its product acceptable and advantageous even in Europe. So far its cost of manufacture will enable me to lay it down in any part of the world at one-third the price of quinine sulphate, warranted invariably same strength and purity.

I beg now to present the following particulars as to the pharmacological characters, chemistry, etc., of the bark:—

The tree grows to a height of fifty feet or more, and can be peeled with impunity. The active principle therefrom obtained is a dark green powder, very hygroscopic, easily soluble in water, but not in absolute alcohol or ether. From the researches of Gorup-Besanez, it appears to contain a crystallizable substance, the alkaloid.

"The pieces of bark, as circulating in trade, are 0·04—0·06 met. long (0·025 metre = 1 inch Engl.), 0·015 m. broad, and 0·001—0·004 thick. They are bent irregularly, present on the exterior a thin leather-brown layer (kind of cork), and a good many longitudinal and transversal fissures, which make the bark look scaly. Very often the edges of the fissures are raised with the corky layer, and the transversal cracks themselves filled, whole or partially, with a colourless cellular tissue.

"The bark is of moderate hardness, and breaks easily, young bark giving fibrous, and old granular fragments.

"The interior of the bark is slightly indented, and presents the appearance of depressed meshes, sometimes longitudinally fibrous. The colour from leather-brown to dark grey, dotted very frequently with black specks and points. Lichen is quite seldom on it. When ground, the bark furnishes a yellow-grey powder, which is inodorous. In chewing it communicates only gradually to the palate a slightly bitter but not disagreeable taste. The cellular tissue of the bark shows, under the microscope, crystalline deposits (oxalate of lime).

"The aqueous extract is dark yellow, clear on cooling, pleasantly bitter, and suffers no alteration with ferruginous salts. Though sugar of lead throws down a precipitate from the decoction, there is another one formed in the filtered liquid through the addition of basic acetate of lead. This latter precipitate is copious and amorphous. After filtering and eliminating all the lead, the active bitter principle of the bark can be thrown down with phosphowolframic acid from the neutral solution.

"Ether, chloroform, and petroleum essence only withdraw from the bark indifferent extractive matter; boiling alcohol is the most efficient solvent. Potassic lye colours the bark yellow. Diluted muriatic acid, especially when heated, dissolves large amounts of oxalate of lime.

"Dried at 100° Cels., the bark loses 12·7 per cent. moisture, and incinerated leaves 10·4 per cent. of a white ash, chiefly lime.

"Treating the precipitate obtained by phosphowolframic acid with aq. barytæ in excess with ether and acetic acid, the analysts obtained an alkaloid which they called 'ditamin,' and which amounted to about 0·02 per cent. of the bark employed. It is a white amorphous powder, slightly bitter, easily soluble in ether, chloroform, benzine, and alcohol. From petroleum spirit, in which it seems to be less soluble, it may be obtained crystallized. Concentrated sulphuric acid dissolves it, cold, with reddish colour, warm, with violet. In concentrated nitric acid it is soluble, turning the solution yellow; and on heating the liquid it first grows dark green, afterwards orange, evolving red vapours. Heated in a capillary tube, it melts, forming at 75° a light yellowish, and at 130° a deep brownish-red liquid. Its alcoholic solution is alkaline and capable of neutralizing strong acids, thereby forming salts remarkable for their extreme bitterness. Its chlorhydrate leaves, on evaporation, a

* From the 'Report on Centennial Exhibition,' presented to the American Pharmaceutical Association ('Transactions,' 1877).

residue which, though amorphous, indicates some tendency to crystallization. Only once, under circumstances unknown to the operator, it formed nice colourless needles, which were easily soluble in alcohol and water. This last (aqueous) solution presented the following reaction: with—

"Chloride of platinum, $PlCl_3$, yellow amorphous precipitate, somewhat soluble on heating.

"Chloride of gold, Au_2Cl_3, dirty yellowish amorphous gelatinous precipitate, easily melting to a brown oily liquid.

"Bichloride of mercury, HgCl, white amorphous precipitate, soluble on heating in the supernatant liquid, and depositing, on cooling, in small watery groups.

"Double iodide of mercury and potassium, HgIKI, white amorphous precipitate, very little soluble in cold, but easily in hot water.

"Perchloride of iron, Fe_2Cl_3, no alteration.

"Iodide of potassium, KI, from concentrated solutions, produces an amorphous precipitate, easily soluble in water, and barely so in solution of iodide of potassium.

"Rhodanide of potassium, KCyS, from concentrated solutions, a white amorphous turbidity, which disappears on further dilution.

"Tannin, a white gelatinous precipitate.

"Phosphowolframic acid, abundant white precipitate.

"The ultimate organic analysis could not be undertaken, owing to lack of material.

"If the bark be digested with petroleum spirit, there results a resinous body, which, after having been purified, is but sparingly soluble in boiling alcohol, but easily so in chloroform, ether, petroleum spirit, and benzine. The analysts call this body 'echicaoutchin.' It is not acted upon by a potassic lye; if heated, it melts first, and then burns off easily and completely. Under tepid water it may be drawn out to long silky fibres. If the water be more than lukewarm, the substance loses its elasticity, but recovers it again at a lower temperature. The results of the ultimate analysis correspond with the formula, $C_{25}H_{40}O_2$.

"If the concentrated extract of the bark obtained with petroleum spirit (see above) be boiled with alcohol, there separates an oily liquid, which soon solidifies, and superincumbent there forms a copious layer of white crystals, which the analysts found to contain two new substances, viz., echicerin and echitin. Treating the former with sodium, they obtained its acid, analogous in composition, which they called echicerinic acid. Echitin is a neutral body, and crystallizes in tender white scales. Evaporating the alcoholic solution left over from echicerin and echitin, another neutral body, echiteïn, crystallizes out; bromine converts it in tribromechiteïn; and lastly the alcoholic mother liquors give a resinous substance called echiretin. Along with ditamin the analysts discovered another body, which is also precipitated by phosphowolframic acid, equally bitter, but offering in some respects only the essential qualities inherent to an alkaloid or vegetable base. A fuller investigation of this body could not be effected, through lack of material. The amount of all the resinous and oleo-resinous bodies, echicaoutchin, echicerin, $C_{30}H_{48}O_2$, echitin, $C_{32}H_{58}O_2$, echiteïn, $C_{42}H_{70}O_2$, and echiretin, $C_{35}H_{56}O_2$, along with another undetermined resin, is, together, 2·95 per cent. of the bark.

"Echiretin offers a great deal of similarity with a resin extracted by Heintz from the juice of the cow tree, another tree growing wild in the Guianas—*Tabernæmontana utilis*. In composition, but not in its properties, it is identical with lactucarin. The analysts are of opinion that it is isomerous with said body, as well as with camphor obtained from cubebs.

"It would appear that ditamin was also the body which Mr. De Gorup-Besanez obtained from ditaïn, but which he could not investigate further owing to lack of material. This much, however, seems to be certain, that the dita bark does not contain notable quantities of an alkaloid, properly so called, and that the febrifuge properties of the bark, as well as of the extract, can hardly be attributed to the very limited amount of alkaloid contained therein.

"In conclusion, we would say that the results arrived at by ditaïn in our Manila hospitals and private practice are simply marvellous. An octogenarian mestizo, suffering from typhoid fever, was cured by the application of six grams. A Spanish officer, subject for a long time back to persistent attacks of malarious fever, was treated six times a day with clysmas (injections in the rectum), each of 0·2 gram ditaïn; in three days he was well. Its tonic effects are unrivalled. In our military, hospital, and penitentiary practice, ditaïn has perfectly superseded quinine, and it is now being employed, with most satisfactory results, in the island of Mindanao, where malignant fevers are prevalent."

PREPARING PLASTER CASTS THAT CAN BE WASHED.*

The prize offered by the Prussian Minister of Commerce and Industry for a method of preparing plaster casts that permit of being washed was conferred upon Dr. W. Reissig, of Darmstadt. From Dr. Reissig's essay on the subject we abstract the following points:—

In preparing these casts it is not only desirable to obtain a surface which should not wash away, but also to include a simple process for preventing dust entering the pores and render them more easily cleansed. Laborious experiments convinced this gentleman that the only practical method of accomplishing this and retaining the sharpness of outline was to convert the sulphate of lime into (1) sulphate of baryta and caustic or carbonate of lime, or (2) into silicate of lime by means of silicate of potash.

Objects treated in this way are not affected by hot water or hot soap solutions, but, from the method of preparation, they remain porous, catch dust, etc., and when first put into water eagerly absorb all the impurities. To avoid this evil he subsequently coats the articles, now rendered waterproof, with an alcoholic soap solution, which penetrates more easily, deeper, and more freely into the pores than an aqueous solution. After the alcohol evaporates a layer of soap remains, which fills the pores, and when washed it is converted into a suds which removes the dust, without allowing it to penetrate.

1. *Process with Baryta Water.*—This is the simplest, easiest, and cheapest method. It depends upon the fact that gypsum, or sulphate of lime, is converted by baryta water into sulphate of baryta (which is totally insoluble), and caustic lime, which is converted by contact with the air into carbonate of lime. The practical method of carrying this out is as follows:—A large zinc vessel is required with a tight-fitting cover. In each vessel is a grating made of strips of zinc, resting on feet $1\frac{1}{4}$ in. high. This vessel is two-thirds filled with soft water at 54° to 77° Fah., and to every 25 gallons of water is added 8 lb. of fused or 14 lb. of crystallized, pure, hydrated oxide of barium, also 0·6 lb. of lime previously slaked in water. The solution stands about 4° Beck. As soon as the baryta water gets clear it is ready to receive the casts. They are wrapped in suitable places with cords, and, after removing the scum from the baryta bath, are dipped in as rapidly as possible, face first, and then allowed to rest upon the grating.

Hollow casts are first saturated by rapid motions, then filled with the solution and suspended in the bath with the open part upwards. After the cords are all secured above the surface of the liquid, the zinc vessel is covered. The casts are left in it from one to ten or more days, according to the thickness of the waterproof strata re-

* *Industrie Blatter*; reprinted from *Design and Work*, January 5, 1878

quired. After taking off the cover and removing the scum, the plaster casts are drawn up by the strings, rinsed off with lime water, allowed to drain, carefully wiped with white cotton or linen rags, and left to dry, without being touched by the hands, in a warm place free from dust. The same solution which has been used once can be used again by adding a little more baryta and lime.

Of course this process can only be applied to casts free from dust, smoke, dirt, coloured particles of water, resin and varnish, soap, animal glue from the moulds, or sweat from the hands. To prevent the casts getting dust upon them, they should be wrapped in paper when taken from the mould, and dried by artificial heat below 212° Fah. If, in spite of every precaution, the casts when finished show single yellow spots, they can be removed in this manner: The perfectly dry, barytated casts, saturated with carbonic acid, are painted over with water and oil of turpentine, then put in a glass case and exposed to the direct rays of the sun. All spots of an organic nature will then disappear; but of course rust, smoke, and mineral spots cannot be removed in this way.

In the place of cold baryta water the casts may be placed for half an hour in a concentrated solution of baryta heated at 104° to 122° Fah. This has the advantage that casts may be put in before drying. As the casts treated in this way are not hardened very deeply, and are still porous, it is well to place them subsequently in a cold bath for a longer time.

The casts are now ready, as soon as perfectly dry, for the soap solution. For cheapness a pure, good, hard soap is selected, shaved up, dried and dissolved in 50 or 60 per cent. alcohol; 10 or 12 parts of alcohol to one of soap. Such a solution of Marseilles soap, known as "spiritus saponatus," can be had at any drug store. The finest appearance, as well as a high degree of durability, is obtained by the use of a solution of stearate of soda in strong alcohol. Both the solution and cast should be warm, so that it may penetrate as perfectly and deeply as possible. It is no harm to repeat the operation several times, as long as the liquid is absorbed by the cast. When dry the cast is finished.

2. *Process with Silicate of Potash Solution.*—This process depends upon the conversion of the sulphate of lime into silicate of lime, an extremely hard, durable, insoluble compound, and is accomplished by the use of a dilute solution of silicate of potash containing free potash. To prepare this solution Dr. Kessig first makes a 10 per cent. solution of caustic potash in water, heats to boiling in a suitable vessel, and then adds pure silicic acid (free from iron) as long as it continues to dissolve. On standing, the cold solution usually throws down some highly silicated potash and alumina. It is left in well-stoppered glass vessels to settle. Just before using, it is well to throw in a few bits of pure potash, or to add 1 or 2 per cent. of the potash solution. If the plaster articles are very bulky, this solution can be diluted to one half with pure water.

The casts are silicated by dipping them (cold) for a few minutes into the solution, or applying the solution by means of a well-cleaned sponge, or throwing it upon them as a fine spray. When the chemical reaction, which takes place almost instantly, is finished, the excess of the solution is best removed with some warm soap water or a warm solution of stearin soap, and this finally removed with still warmer pure water.

The casts, which can be immersed or easily moved around, may be treated as above when warm; a very short time is required, but some experience is necessary. In every case it is easy to tell when the change is effected, from the smooth, dense appearance and by its feeling when scratched with the finger nail. It is not advisable to leave them too long in the potash solution, as it may injure them. A little practice renders it easy to hit the right point. The fresher and purer the gypsum, and the more porous the cast, the more necessary it is to work fast. Castings made with old and poor plaster of paris are useless for silicating. These silicated casts are treated with soap as above.

In washing plaster casts prepared by either method the author recommends the use of a clean soft sponge, carefully freed from all adherent sand and limestone, wet with lukewarm water and well soaped. They are afterwards washed with clean water. They cannot, of course, be washed until thoroughly dry and saturated with carbonic acid. The addition of some oil of turpentine to the soap is useful, as it bleaches the casts on standing. The use of hot or boiling soapsuds must be avoided.

NOTE ON MATÉ OR PARAQUAY TEA.*

(*Ilex Paraguayensis.*)

BY DR. H. BYASSON.

The author having been requested by Professor Gubler to examine a specimen of "maté" or "Paraguay tea," has recently presented to the Paris Academy of Medicine a note containing a *résumé* of the principal facts previously known respecting this product, together with some observations as to its chemical composition. The following is an abstract of this note.

Maté constitutes, throughout a great part of South America, the favourite drink of the inhabitants, who attribute to it innumerable virtues. The word "maté" originally designated the vessel in which the infusion was prepared; the maté tree is known as the *Arvore do Congonha.* The tea itself is sold under three different names, each indicating a commercial variety.

(1) *Caa-Cuyo* ("*caa*" signifies a leaf): consisting of buds scarcely expanded. It is consumed in the locality where gathered.

(2) *Caa-Miri*: prepared by the Jesuits from the dried leaves, carefully cleansed and powdered.

(3) *Caa-Gazu*: prepared by the natives from the leaves, roasted and coarsely powered. This was the variety examined; it contained also fragments of petioles and young shoots. The powder was greenish yellow, and had a slightly aromatic odour which was developed by contact with water.

The tree which yields the maté is the *Ilex Paraguayensis* or *Ilex Maté.* It was first described by A. Saint-Hilliare, who found the "*arvore do congonha,* or "*arvore do maté*" growing abundantly in woods near Carabita in Brazil. During his second voyage he established the identity of this Brazilian plant with the Paraguayan plant, he having met with the "*arvore do congonha*" in the quincunces of trees planted by the Jesuits in their ancient mission stations in Paraguay. Under the name *congonha,* however, have been also designated very different plants, belonging to the genera *Luxemburgia, Vochysia,* and *Trimeria.* The *Ilex Paraguayensis* grows in the wild state in the woods bordering the rivers and water-courses running into the Uruguay and Paraguay rivers. It there occurs as large as an apple tree, which it somewhat resembles in figure; but when cultivated and the leaves are regularly collected, the plant remains as a shrub. The trunk of the tree is as thick as a man's leg; the bark is whitish and shining, and the branches and all other parts of the plant have a velvety appearance. The leaves, which have a very short petiole, are simple, cuneiform, obovate or oblong-lanceolate, dentate, shining, coriaceous, and about 1 to $1\frac{1}{2}$ inches long. The flowers are white, as large as those of the common holly, grouped in a dichotomous and trichotomous axillary inflorescence. Each flower has a calyx with four suborbicular concave sepals, a corolla with four petals, and four stamens with very short filaments; the ovary is surmounted by a four-lobed stigma. The fruit is a red drupe the size of a peppercorn, containing four striated seeds.

* *Répertoire de Pharmacie et Journal de Chimie Medicale,* N.S., vol. i., p. 11.

The leaves are collected every two or three years, that interval being required for them to attain their full growth; the branches are cut off with their leaves and they are dried altogether over a large fire. The leaves are then detached, sorted, and placed in large baskets where their drying is finished. After about a month the leaves are powdered and are then ready for the market.

An infusion of the tea is prepared in a kind of cup (*maté*), made frequently of a calabash mounted with silver. Some persons add to the beverage a little burnt sugar or a few drops of lemon juice. The liquid is sucked up through a tube, called a "bombilla," at the lower part of which are several small holes, which do not allow the passage of the fragments of leaf. The leaves can be used three times, but the infusion alters rapidly.

After some qualitative experiments, M. Byasson proceeded with the analysis as follows: 100 grams of maté were intimately mixed into a paste with 25 grams of slaked lime, and the mixture was dried slowly in a stove at 75° C. It was then exhausted successively with (1) 600 c.c. of chloroform; (2) 600 c.c. of 95° alcohol; and (3) sufficient distilled water to remove the alcohol as much as possible. The chloroform solution, of a green colour, was distilled; the dried residue, which was brown and contained crystalline needles visible to the naked eye, was treated several times with distilled water, upon slow evaporation of which a yellowish white substance was obtained that, redissolved in alcohol, gave after evaporation and cooling a nearly white crystalline mass. Previous experiments had indicated that this was caffeine and the product was sublimed to obtain a better crystallization. The caffeine obtained from the 100 grams of maté weighed, after crystallization from alcohol, 1·850 gram; after sublimation, 1·734 gram, a small quantity being destroyed by sublimation.

The residue from which the caffeine had been extracted was dried over sulphuric acid. It formed a greenish brown substance, resembling in consistence the birdlime extracted from the common holly, but less elastic and darker in colour. This glutinous substance dissolves in all proportions in ether; it becomes nearly liquid at 80°, and it burns with a white fuliginous flame. Strong solution of potash attacks it with difficulty. Attempts to purify it and determine its chemical character were not successful on account of the small quantity operated upon and especially the difficulty in removing the green colouring matter with which it is impregnated. The following experiment indicates that it must be considered to be a fatty body or compound ether, the alcohol of which would be near to cholesterine. Two grams were submitted to the prolonged action of a hot alcoholic solution of potash, care being taken to replace the alcohol evaporated. After two hours the glutinous matter appeared to be completely transformed and yellowish white flocks floated in the liquor. The alcohol having been driven off by evaporation and the residue taken up with ether, the ethereal solution left upon evaporation a nearly white substance in crystalline scales, resembling but without being identical with those of cholesterine. The portion insoluble in ether, treated with water acidulated with hydrochloric acid, gave a white fusible substance, soluble in alcohol and in alkaline solutions.

The alcoholic liquor, which was of a slightly greenish yellow colour, was distilled to remove the alcohol and the residue treated with distilled water. A yellowish white substance that floated to the surface of the liquid was separated on a filter, washed with water, and redissolved in absolute alcohol. It presented all the characters of a resin; it had neither taste nor odour, and by dry heating it yielded a spongy charcoal, and a small quantity of brown acid liquid, having an acrid taste. The evaporation of the water left a substance difficult to dry completely and not showing any trace of crystals. Again treated with absolute alcohol it dissolved completely. The alcohol deposited an amorphous substance, nearly white, with an aromatic odour recalling that of the plant and a scarcely acid reaction, but presenting none of the characters attributed to caffetannic acid and noticed in maté by Rochleder. Caffetannic acid was also sought for by precipitating an aqueous infusion of maté with acetate of lead, but the result was negative. The preceding substance boiled in water, slightly acidulated with sulphuric acid, developed the markedly aromatic odour of the plant, whilst the solution reduced the cupro-potassic liquor freely. After some hours it became strongly coloured, and deposited brown flocks.

The aqueous infusion of 100 grams of maté, slightly acidulated with sulphuric acid, heated and then decolorized by acetate of lead, was dextrogyre.

These characters proved that the substance isolated was a complex glucoside, the decomposition of which yielded glucose and a compound to which the plant owes its characteristic odour.

100 grams of maté exhausted by a litre of boiling distilled water yielded 24 grams of dry extract. The precipitate produced in aqueous infusions by basic lead acetate was washed with cold water and redissolved in boiling water. The filtered solution deposited upon cooling slender crystals of a salt presenting all the characters of malate of lead; particularly those of fusion and of yielding a pitchy mass by the action of a quantity of water insufficient to dissolve it. The tests for tannin gave negative results.

Incineration of the extract yielded a proportion of ash equal to 3·92 per cent. of the maté used. The ash contained carbonate of potash; it was rich in sulphuric acid, and iron was present in weighable quantity.

The 100 grams of maté yielded—

Caffeine	1·850 grams.
Glutinous substance, or peculiar fatty matter and colouring matter . . .	3·870 ,,
Complex glucoside . . .	2·380 ,,
Resin	0·630 ,,
Inorganic salts, including iron	3·920 ,,
Malic acid	Not estimated.

The relative proportions of caffeine or theine contained in different sorts of coffee or tea (*Thea Chinensis*) determined by Stenhouse amounted to 1·37 per cent. in the richest tea, 0·20 per cent. in coffee, and a still smaller proportion in maté. These figures do not agree with those obtained by Robiquet, Payen and Mulder, and agreement is scarcely possible with specimens from different sources analysed by different methods. But Paraguay tea analysed by the author as described contained an amount of caffeine comparable with that in the kinds of coffee and tea richest in that alkaloid.

PURIFICATION OF VALERIANIC ACID.*

According to Lescœur, valerianic acid prepared from fusel oil is frequently contaminated with homologous acids, as well as with amyl valerianate. To remove these, the author recommends to dissolve in two equivalents of the crude acid, one equivalent of neutral sodium valerianate, by gentle heat. On standing in a cool place, the solution deposits crystals of sodium tri-valerianate, which are dried upon porous plates, and finally by pressing between blotting-paper. These yield, on distillation with sulphuric acid, a perfectly pure valerianic acid, provided that anything which distils over below 260° and over 280° F. is rejected.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 2, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE MUSEUM OF THE PHARMACEUTICAL SOCIETY.

THE appearance of a Catalogue, numbering three hundred pages, of the Collections in the Museum of the Pharmaceutical Society of Great Britain, affords an opportunity for referring specially to the past history and present position of one of the most important and interesting aids to the study of materia medica existing in this or any other country. Probably only a small proportion even of the members of the Society have an adequate conception of the results that have followed the work of a comparatively short time in collecting and arranging specimens of substances used in medicine from all parts of the globe.

It is just thirty-six years since the Museum was first described, rather quaintly, in this Journal. It was then a front room on the ground floor, containing not a vestige of furniture. The bare boards were well scoured, the ceiling and walls were in a perfect state of repair, but there was not in it even a chair or a table. On the floor, in one corner was a small heap of brown paper parcels, containing a few donations from two or three members, and on the mantelshelf were about a dozen glasses and bottles in which were sundry crystals, roots, and other substances. But these formed the nucleus of what is now perhaps the finest and most complete collection of materia medica in the world. Four months afterwards, at the first Annual Meeting of the Society, the Council was able in its Report to state that two cases for the Museum were in course of erection. It was not, however, until August, 1842, that the announcement was made that glass cases and jars were ready for the reception of specimens, and the first list of donations was published in the October following. The list was a long one, and amongst the donors were men whose names will be long held in reverence among British pharmacists.

The original proposal was that the Museum should contain a specimen of every substance contained in the materia medica, which is capable of preservation, in the highest possible state of perfection and purity, and by the side of this was to be placed a specimen of inferior quality, in order that the student might learn to exercise his judgment in the choice of drugs. This plan has not been since uniformly adhered to, but its importance in the eyes of the early managers of the collection may be inferred from a curious statement published the following month, that the most acceptable donations to the Museum would then be specimens of drugs of inferior quality to exhibit in contrast with the fine specimens already received. At the Second Annual Meeting the Council was able to report that the Museum contained eight hundred and fifty specimens, more than five hundred of which had been presented to the Society. Since that time the history of the Museum has been one of steady progress, continual additions of specimens being made by gift or by purchase; but we feel warranted in saying that at no period has its advance been more marked than since it has been under the management of its present able and energetic curator, Mr. HOLMES, to whose labours we are mainly indebted for the catalogue now published.

Perhaps these columns would hardly be the place to enter into any elaborate eulogy of this publication, but it may be remarked that it is a great deal more than its title implies. It is not only a systematic catalogue of all the substances exhibited in the principal collections in the Museum, but it is interspersed with numerous short though valuable notes, which also contain a considerable number of bibliographical references. A copious index of names and synonyms is added, so that in seeking for information respecting any particular substance not only will its place in the Museum be ascertained by an easy process of reference, but appended to the entry will be frequently found some useful practical information respecting it, as well as indications as to where fuller details may be looked for. The Catalogue is divided into three sections, the Vegetable Materia Medica, the Chemicals, and the Animal Materia Medica. The first section is grouped under natural orders, following the arrangement adopted in BENTLEY'S 'Manual of Botany.' The Chemicals are grouped as Inorganic and Organic Compounds, and again suitably subdivided. In the Animal Materia Medica the classification generally accepted in this country is adopted. It is, we understand, intended to number all the specimens to correspond with the numbers in the Catalogue, and to indicate those of them that are official.

It may be useful to state that the principal general collection, to which this Catalogue alone refers, is intended to represent every substance that is official in the British, United States, and Indian Pharmacopœias, and also such as have been the subjects of papers contributed to this Journal. There are, however, besides these several special collections, which it is intended to catalogue at a future time. Of these may be mentioned the HANBURY Collection and Herbarium, a Collection of Old English Drugs, one of Indian Drugs, including those presented by Professor DYMOCK, as well as others of Australian, South American, North American, African, and Chinese Drugs. There is also a very complete collection of barks. Lastly, there is a general herbarium. All these collections are continually, and often profitably, consulted by persons who have proved their value, but not by so large a number as would probably avail themselves of the advantage were their existence and nature more generally understood amongst pharmacists. We hope, therefore, and we have little doubt, that the publication of the new Catalogue will exercise a salutary influence in this direction.

We suppose the issue of the Catalogue will come under the consideration of the Council at its next meeting, and that in a few days we shall be in a position to state what are the terms upon which it will be supplied to those who desire to possess copies.

THE FIRE AT A CHEMIST AND DRUGGIST'S.

We regret to announce that Mr. Frederick Sadler who, as was mentioned in these columns last week, was severely burnt while endeavouring to extinguish the fire which occurred at his shop, in George Street, Tamworth, died from the effects of his injuries on the 22nd. Mr. Sadler was well known in Tamworth and neighbourhood, where he had won the respect and high estimation of all classes, and universal regret was felt when it became known that his injuries had resulted fatally. The deceased leaves a widow and four children.

DEATHS OF MM. REGNAULT AND BECQUEREL.

France has within a few days lost two of her most eminent men of science, Antoine-César Becquerel and Victor Regnault, who died, the former on the 18th, and the latter on the 19th of January. M. Becquerel was the Professor of Physics at the Jardin des Plantes, and was well known by his investigations in the science of electricity, especially in that branch of it which he called "*électrochimie*," for which in 1837 he was awarded the Copley medal by the Royal Society of London. At the time of his death he was just ninety years of age, and in 1874 he was presented with a medal to commemorate the completion of fifty years of membership of the Academy of Sciences. M. Regnault was also best known as a physicist, but the earlier part of his career was devoted to chemistry, and for some time he was Professor of Chemistry at the Polytechnic School, during which period he published his well-known *Traité de Chimie*. He subsequently became Professor of Physics in the College of France, and eventually Director of the manufactory at Sèvres. M. Regnault died after a long illness at the age of sixty-eight. Upon the announcement of the death of these eminent men at the succeeding meeting of the Academy of Sciences the sitting was immediately adjourned as a mark of respect to their memory.

THE EVENING MEETING.

An Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, February 6th, at 17, Bloomsbury Square, when the following papers will be read:—"On the Progress of Cinchona Cultivation and Alkaloid Production in Bengal," by Mr. C. H. Wood; "Examination of Commercial Oil of Tuyme," and "Thymol and its Pharmacy," by Mr. A. W. Gerrard; and "A Spurious Balsam of Tolu," by Mr. W. A. H. Naylor.

Provincial Transactions.

COVENTRY AND WARWICKSHIRE PHARMACEUTICAL ASSOCIATION.

The opening meeting of the above Association took place on the evening of the 9th inst. in the Assembly Room, Agricultural Hall, Coventry. The President (Mr. Councillor Wyley) occupied the chair, and there were present about one hundred and twenty gentlemen connected with the medical, pharmaceutical, and scientific professions. Along the sides of the large room were placed tables, upon which were tastefully arranged specimens of new drugs, rare chemicals and alkaloids, pharmaceutical apparatus, microscopes, radiometers, materia medica cabinets, geological specimens, etc., the principal exhibitors being Messrs. Hopkin and Williams, Gerrard, Evans, Lescher and Evans, Pfleiderer, Silverlock, Davis, Hinds, etc.

The President having briefly opened the meeting, the minutes of the introductory meeting establishing the Association were read and confirmed; the rules as amended by the Council were approved of and ordered to be printed for circulation.

The Hon. Secretary then read the following list of donations:—Mr. Thomas Hyde Hills, five guineas; Messrs. Wyleys and Co., five guineas; Mr. Henry Silverlock, five guineas; Messrs. Burgoyne, Burbidges and Co., two pounds; Messrs. Alderman Bates, Councillors Sellors, Bird, Jenkins, Hiscock, Barton, Welton, Clarke, Williamson, Whiting, Fletcher, Wisher, and Barrett, one guinea each; the Pharmaceutical Society, current copies of the *Pharmaceutical Journal* and the 'Calendar' and 'Register;' Mr. John Williams (President of the Pharmaceutical Society), an excellent Portrait of himself for the Library, Bloxam's 'Chemistry,' and Royle's 'Materia Medica;' Mr. T. Hyde Hills, valuable Framed Portraits of John and Jacob Bell, William Allan, and Dr. Pereira; Mr. S. U. Jones, (President of the Trade Association), his Portrait and Attfield's 'Chemistry;' Professor Attfield, Attfield's 'Chemistry;' Professor Balfour, 'Manual of Botany;' Professor Bentley, 'Manual of Botany;' Professor Frankland, 'Lecture Notes to Chemical Students,' vol. ii.; Professor Odling, 'Animal Chemistry,' 'Outlines of Chemistry,' and Odling's 'Chemistry;' Professor Tuson, 'Veterinary Pharmacopœia;' Messrs. Howard and Son, a Collection of excellent Specimens of East Indian Red Cinchona Bark in Glass Jars; Dr. John Muter, F.C.S. (Director of the South London School of Pharmacy), 'Elements of Chemistry;' Dr. Morel Mackenzie, 'Throat Hospital Pharmacopœia;' Dr. Tilden, F.C.S., 'Chemical Philosophy;' Dr. Thorowgood, 'Notes on Asthma;' Dr. Stevenson, Naquet's 'Modern Chemistry;' Messrs. Evans, Lescher and Evans, a Cabinet of Materia Medica Specimens; Messrs. Southall, Brothers and Barclay, a Cabinet of Materia Medica Specimens and Vegetable Materia Medica; Messrs. Burgoyne, Burbidges and Co., the *Monthly Magazine of Pharmacy*, etc.; Messrs. Barnard Proctor, 'Practical Pharmacy;' F. Harwood Lescher, 'Elements of Pharmacy;' G. S. V. Wills (Principal of Westminster College), 'Elements of Pharmacy' and 'Elements of Materia Medica;' J. Tully, Six Pamphlets on Examination Topics and an Herbarium; W. Southall, Materia Medica; E. Kensington, 'Food Analysis;' Bird, Books; Bambridge, Collection of Fossils and two Ancient Pharmacopœias, etc.

Votes of thanks having been very heartily passed to the several donors, the Hon. Sec. (Mr. F. J. Barrett, F.C.S.) proceeded to give a short statement of the affairs of the new Association. He said that it was a matter of congratulation to the Council that their project had been so warmly taken up. Mr. Whiting (the Deputy Treasurer) had very kindly canvassed the chemists of Coventry and immediate neighbourhood, and he was pleased to say he had not met with a single refusal. He had also been to several of the adjacent towns, and with but few exceptions the formation of their society was applauded and numerous promises of help had been received. He saw no reason why they should not have very successful evening meetings in Leamington, Warwick, Rugby, and other towns, so that the Association, with head-quarters in Coventry, should really be a county affair. The Council had not yet secured suitable central rooms, but they hoped in the course of a few days to be able to announce having done so. The classes for the "Preliminary" and "Minor" examinations were in process of formation, several gentlemen, including three passed pharmaceutical students, had volunteered to conduct the latter classes, and an efficient master would be engaged for the former as soon as suitable rooms could be obtained and a sufficient number of students had entered. Special instruction would also be given to those preparing for the higher examination. With regard to the evening meetings, he had the pleasure of announcing that Mr. Stokes Dewson had promised to give them a lecture in February; Dr. Iliffe would address them in March on "Contagion"; Mr. Bambridge and Mr. Axford would also read papers on "Tobacco" and "Oleic Acid and its Combinations," at some future time, particulars of which would be given in due course. He then announced that the Hon. Sec. of the Midland Counties Association had written to invite members to the *soirée* on the 23rd inst, and he hoped that as many as possible would make it convienent to attend. It was with great regret that he had to announce that two of the members of the Council, elected at their opening meeting (Messrs. Phillips and Hinds) had, on account of business engagements, been compelled to withdraw, but they had both written expressing their willingness to assist in every possible way in forwarding the objects the Council had in view. At the close of the Secretary's report, Messrs. Barton (Kenilworth) and Davis (Leamington) were unanimously elected to fill the vacant seats.

The opening address was then delivered by the President (Mr. Counciller Wyley). He commenced by stating that he could not, owing to the very recent establishment, refer to the work that had been accomplished by them during the past year, but he would instead briefly glance at recent pharmaceutical introductions, and speculate upon the duties to be accomplished in the future. Mr. Wyley then referred to the good that had been done by the recent formation of an organized fellowship of chemists for their defence against unjust and vexatious legislation, under the name of the Chemists' Defence Association.

Humorously alluding to the break-down of the absurd milk of sulphur prosecutions, Mr. Wyley warmly commented upon the action of certain official analysts in recommending such paltry prosecutions, and in a few cases misleading the adjudicating magistrates by the use of "sensational" terms; instancing the "Sweet Nitre," "Citrate of Magnesia," Scammony, and Copaiba cases. He said that in many instances the evidence of the food analyst disclosed his utter ignorance of the ordinary mode of testing drugs for impurities, showing his incapability of filling a position that should be occupied by highly and specially trained pharmaceutists. Such actions were grave scandals against the satisfactory working of an important and necessary Act of Parliament. It was no light matter for an upright chemist to be dragged before a bench of magistrates and branded as a dishonest tradesman and a cheat. The chemists of Great Britain stood high in the scale of trade morality and it was incumbent upon them all to guard with jealous care any action which would tend to lessen the status of their profession.

Mr. Wyley then reviewed the vexed question of "counter prescribing," and said that although they could have no sympathy with the man, who, for purposes of mere gain, would undertake the treatment of complicated diseases or even simple disorders, the character of which he did not understand, still it would be an insult to common sense to forbid the dispensing chemist to give suitable mixtures for such trifling ailments as a cough, or cold, or temporary indigestion. Such action would be a grave injustice to the working man or petty tradesman who depended upon the chemist for advice in small matters, and called in the doctor when it was necessary. It would be simply opening the door to uneducated quacks who could legally vend their patent medicines under government patronage, or would tend to pauperize him, and insult his dignity by forcing him to apply at the hospital for gratuitious advice.

The speaker then, in an able *résumé*, commented upon the recent scientific and pharmaceutical introductions to materia medica. Guarana, jaborandi, carnauba root, caroba leaves, "yerba santa," damiana, tayuya, grindelia robusta, boldo, coca leaves, coto bark, hamamelis root, "yellow jasmin," eucalyptus, xanthium spinosum, and curara were described and their preparations fully spoken of. The mode of manufacture of hydrobromic acid, dialysed iron, carbolated camphor and iodine, vaseline and its rivals cosmoline and unguentum petrolei, salicylic acid and preparations, monobromated camphor and many other pharmaceutical introductions were noticed and their composition and mode of preparation explained. The President said that these were some of the new weapons added to the armoury of materia medica, and that as faithful superintendents of this armoury it was their duty always to be in readiness to assist those who defended them from the invasion of death and disease, the members of the most noble professions on earth, medicine and surgery.

Mr. Wyley then continued. In conclusion, a few words with reference to the future of our newly-formed Association. You have done me the honour of making me its first president, and I shall feel it not less a duty than a high privilege to use every effort to ensure its success, and make it a means of promoting the education and scientific advancement of its members.

To you younger members of the Association—the Pharmacists of the future—I would specially point out the necessity of taking advantage of the means of improvement which are now offered to you.

If you would make your mark in the profession to which you belong, it is specially needful that you keep abreast of the times in pharmaceutical knowledge. A Spanish proverb tells us, in the kingdom of the blind the one-eyed man is king, but now-a-days there are fewer and fewer blind pharmacists, hence he who would reach regal rank must have eyes, and more than this, have learnt the power of using them. A little knowledge, perhaps, now more than ever, is a dangerous thing. He is an unwise tradesman who places all his stock in the shop windows, and the same epithet belongs to the student who, by means of cram, manages to obtain just sufficient information to pass his examinations, but has no surplus stores of knowledge to fall back upon. Put all your energies and strength, in fact, put yourselves into your daily work, and cast away the mistaken notion that doing your duty can ever be degrading, thus only can—

"Work be made worship
And e'en drudgery divine."

And if we all in such a spirit as this, whether senior or junior members, are able to enter thoroughly into the means of improvement which will now be within our reach, we shall assuredly have no reason to regret the evenings we have spent under the auspices of the Coventry and Warwickshire Pharmaceutical Association.

Mr. Alderman Betts, Mr. Councillor Sellers, Dr. Iliffe, and other gentlemen having spoken, a very hearty vote of thanks was passed to the lecturer who in accordance with the expressed desire of the members, consented to have his address printed for distribution.

Mr. L. Aviss then gave an experimental demonstration of the manufacture of cigars, etc. He explained that he was present at the invitation of the Secretary, who thought that some interesting practical demonstration of the method of preparing cigars and tobacco would render their first meeting more attractive. Mr. Aviss then called attention to the various tobacco leaves he had before him, and explained the various growths, the most valuable kinds appearing to be the leaves from Manilla and Havanah. He contended that there was not the slightest reason why cigars made in England from genuine leaves should not equal in quality the more expensive foreign brands. An explanation of the growth, gathering, drying, and fermenting of the tobacco was then made; and Mr. Aviss concluded with an interesting account of the penalties to which tobacco adulterators were liable, the immense revenue derived from the importation, etc. At the close of the address, cigars were made and rapidly distributed amongst the audience, who were thus practically able to test and confirm the truth of Mr. Aviss's remarks upon the quality of British-made cigars.

The President then gave an explanation of the construction, probable uses, history, etc., of the Articulating Telephone, illustrating his remarks by conversing freely with a gentleman in the Corn Exchange.

Votes of thanks to the Chairman for presiding, and to the Deputy-Treasurer (Mr. Whiting), and the Honorary Secretary for their energetic endeavours, which had conduced to make the first general meeting so great a success, brought a pleasant evening to a close.

The lecture of the Chairman was abundantly illustrated by a collection of crude drugs and preparations, contributed by Messrs. Wyleys and Company, of Coventry and London, Messrs. Hopkin and Williams and Mr. Gerrard, of London.

The next meeting will take place on the 7th inst.

LIVERPOOL CHEMISTS' ASSOCIATION.

The seventh general meeting was held at the Royal Institution, Jan. 17, 1878. The President, Mr. T. Fell Abraham, in the chair.

The minutes of the previous meeting were read and confirmed. The donations to the library were duly acknowledged. Mr. T. Farmer was unanimously elected a member.

Dr. Charles Symes said he would occupy a few minutes of the meeting to explain the construction and exhibit practically the use of the telephone. He had four complete instruments on the table and two that had been taken to pieces in order to more readily demonstrate the component parts.

The telephone he described as consisting essentially of a wood or metal case, a magnet, helix of insulated fine copper wire, and a disc of thin sheet iron. The human voice (or any other sound) causes the sheet iron disc to vibrate, and thus affects the condition of the magnet, the latter in its turn disturbs the electric condition of the helix of wire which surrounds it, and by a wire communication reacts in the opposite direction on a telephone placed at the other end, where the voice is distinctly reproduced. It was a marvellous instrument, although so simple, and whilst a large amount of credit is due to Professor Bell for the invention, neither were the labours of several of our own countrymen to be forgotten, notably those of Faraday and Wollaston, the latter having as early as 1840 reproduced most distinctly the ticking of a clock through several miles of electric wire. Dr. Symes remarked that the *Pharmaceutical Journal* of Jan. 12 contained a very correct description of the instrument, but some of the remarks concerning it were in his opinion clearly not the result of experience. The experiments referred to between Liverpool and Manchester, for example, were practically a failure, not so much from any imperfection in the instrument as from the fact that the wire used was one of a bundle of telegraph wires laid for telegraphic and not for telephonic purposes; hence the induction was so great that scarcely a distinct sound could be heard. Dr. Symes placed his telephones in practical use and conversed from a distant room with the President and members with the greatest ease and success.

Mr. A. C. Abraham called attention to an error in the Pharmacopœia occurring on page 404 of the 1867 edition. At the top of the page it is stated that—

1 pound	=	453·5925 grams.
1 ounce	=	28·3495 „

These he believed to be correct, and were presumably calculated direct from the equivalent of the gram, viz., 15·4323487 grains. Lower down, however, on the same page, 1 gallon is stated to be equal to 4·543487 litres, whereas it should be of course ten times the pound, or 4·535925 litres. The error is carried through the whole series, which should be as follows:—

1 gallon	=	4·535926 litres.
1 pint	=	·56699 „
1 fl. ounce	=	·0283495 „
1 fl. drachm	=	·0035437 „
1 minim	=	·000059 „

As this error has been overlooked in the third reprint, he thought it as well to call the members' attention to it.

Mr. Alfred E. Tanner read the following paper:—

ON ERGOT.

The peculiar external appearance of the substance known in medicine as ergot or spurred rye is well known to all engaged in pharmacy, but perhaps its internal structure and its mode of formation are not equally well-known except to those who have given special attention to the subject. It is not a little curious that a substance presenting such a singular appearance as ergot should have escaped the notice of writers of antiquity, yet such is the fact, for we find it nowhere mentioned in the writings of the ancient classical authors. Apparently the first undoubted description of it occurs in the writings of Adam Loncier of Frankfort, who towards the middle of the sixteenth century describes its appearance in the ears of rye, and mentions also its use in obstetrical cases, adding that it is regarded by women to be of remarkable and certain efficacy. Johannes Thallius, who lived in 1588, speaks of it also as used "*ad sistendum sanguinem*," thus clearly indicating its hæmostatic virtues, and although its power of arresting hæmorrhage was thus early known and appreciated, yet the action of ergot seems, until comparatively lately, to have been associated entirely with its special effect on a certain organ (the uterus) rather than upon the whole system. No mention of ergot appears in that repository of curious information, *Gerard's Herbal*, although many other rare and curious products used in medicine and pharmacy are there described. Caspar Bauhin, in the next century (1623), notices it, and terms it *Secale luxurians*, and later on in this country it is well described by our own countryman, Ray, who was a famous botanist, and who also alludes to its medicinal properties. The Dutch accoucheurs in 1747 were in the habit of employing ergot; and thirty years later it was employed with success by Desgranges of Lyons. Still the effects ascribed to it were open to grave doubts by many, and its use hardly became general and established until the commencement of the present century, when Dr. Stearns, an American, fully recognized its importance, and placed beyond doubt its therapeutic value. It is very probable that the disrepute and ill-success met with by previous experiments may be referred to the use of ergot which was either immature, or had become damaged and inert by age or other similar cause, for no substance appears to undergo change with such facility as ergot, if great care is not exercised in keeping it. It is somewhat remarkable that although so long in use, its introduction into the London Pharmacopœia did not take place until the year 1836, presenting a considerable contrast to the case of chloral hydrate and some other recently discovered substances which seem to have gained for themselves a reputation and recognition in an infinitely shorter time, although their effects cannot be said to be more definite or specific than the substance we are at present considering. Probably the powerful effects that ergot is capable of producing were first noticed to arise from the use of flour made from ergotized grain, which is well-known to be is capable of giving rise to a very formidable disease in those who are unfortunate enough to partake of it. This disease, which is known in modern medicine by the name of ergotism, was in early time distinguished by various appellations, chiefly derived from the most prominent symptoms exhibited by those who were attacked, such as morbus spasmodicus, morbus convulsivus, malignus, etc., also convulsio raphania, and ignis Sancti Antonii. There is little doubt that some of the malignant epidemics which ravaged Europe in the middle ages, and which appeared after seasons of excessive rain and scarcity, were due more or less to the use of ergotized grain; especially may be mentioned that which prevailed in France during the tenth, and in Spain during the twelfth centuries. The medical faculty of Marburg attributed to the use of cereals containing ergot the frightful pestilence which in 1596 ravaged Hesse and the adjoining regions. So far as Europe is concerned the last epidemic which appears to have taken place was in 1816, after a season of great rain, and its ravages were principally felt in Lorraine and Burgundy, the poorer class suffering most severely. The mode of formation of ergot was long a matter of speculation and great diversity of opinion. At one time it was thought to be merely the seed altered by disease, the morbid condition being ascribed by some to the agency of an insect, as in oak galls; by others the change was thought to be produced by excess of heat and moisture. Another opinion was that it was a parasitic fungus occupying the place of the seed; this opinion was that of De Candolle who named the particular fungus *Sclerotium clavus*. A third supposition, and intermediate between the other two, was that the ergot is the seed, diseased and entirely perverted in its nature by the presence of a parasitic fungus attached to it from the very beginning of its development; this is the view put forward by M. Léveillé, and published in the annals of the Linnean Society of Paris for the year 1826. The supposed fungus he calls *Sphacelia segetum*, and until within the last few years, the credit was ascribed to the late Mr. E. J. Queckett of having fully investigated this subject and established the last mentioned view of the nature of ergot. All these views were, however, to a greater or lesser extent erroneous, and it was not until 1853 that the true nature and mode of formation of ergot was finally set at rest by the laborious and painstaking researches of M. Tulasne, who has clearly demonstrated that ergot is the immature form of a particular fungus, which he calls *Claviceps purpurea*, a fungus belonging to the order Pyrenomycetes, which if kept under favourable conditions will develop into the perfect fungus of which ergot is the sclerotium (the British Pharmacopœia calls it the compact mycelium or spawn), which definition will perhaps convey a better idea of its nature; it is in reality a mushroom, and there are three successive stages, in each of which this fungus presents a peculiar form. It begins with a structure, which M. Tulasne calls the sphacelia; this appears on the outside of the ovary of the flower, and is intimately attached to it. Its development commences with that of the pistil, which really serves as a soil for it. The ovary of the rye consists of a cellular membrane of two coats, the outer of which has a thick parenchyma, white and gorged with juice, the inner is very delicate and green. The sphacelia, when it takes possession of the ovary, identifies itself with the outer parenchyma, and in some measure replaces it, being as it were borne by the inner membrane. It rapidly increases taking the form of the ovary, and almost obliterating its cavity. For some time the parasite is represented entirely by the sphacelia, which is an oblong fungous mass, almost homogeneous, soft and tender, marked on its surface by numerous furrows, and having within many irregular cavities, which, as well as the outer coat, are uniformly covered with linear parallel cells. From the summits of these cells issue oval corpuscles, which are a kind of reproductive cells called conidia; these are common to many fungi long before the perfect plant is developed. At the base of the sphacelia is produced a compact body, violet black without and white within, which is the ergot in a rudimentary stage. With this body commences the second stage in the development of the fungus. The young ergot is everywhere invested by the tissue of the sphacelia (which Tulasne calls "spermagonia" from its office); but as it increases, it seems to be placed below the spermatopherous apparatus, and raises it steadily out of the floral bracts which concealed it, ending by supporting it wholly at its summit. Sometimes the atrophied ovary and some remains of the stigmas are carried with it, and may even continue to be visible after the ergot is gathered, but more usually they become detached by drying and packing.

The time required for the full development of the sphacelia and the ergot or sclerotium has been variously estimated, and a rapidity of growth claimed for it which the truth will not warrant. Some observers state that all this takes place in about three days, but the more reliable and accurate researches of M. Tulasne, seem to indicate that about a month is necessary from the appearance of the sphacelia to the full development of the ergot or sclerotium.

Apart from any obscure resemblance to the seed of the plant supporting it, the ergot has absolutely nothing in common with the normal grain, and it is surprising that it should ever have been considered as the hypertrophied grain, to which it bears very little resemblance when closely examined. The anatomical structure and all the physical characters of ergot, are those of the mushroom; no one who has prepared the fluid extract of the Pharmacopœia could fail being struck with the mushroom-like odour which is evolved by the heat during evaporation. The germination of the ergot and the growth of a minute mushroom are the last stage in its development. Falling to the ground, in its natural course, the ergot in the soil germinates and produces mushrooms, the spores of which, carried up with the juices of the rye, become lodged in the ovary, where they begin anew the course of life and progress which I have attempted to delineate.

The ergot should not be collected until some days after it has begun to form, as, according to M. Bonjean, if gathered on the first day of its formation it does not possess the poisonous properties which it exhibits when taken on the sixth day.

The ergot fungus then, or *Claviceps purpurea*, passes through three distinct stages: (1) The mycelium and sphacelia; (2) the sclerotium, or ergot; and (3) the fruit-bearing heads, or mushrooms; the middle stage being the one with which we are particularly concerned, and which is the special state of rest of these plants. In the fully developed ergots no organs can be distinguished by the microscope. They consist of a densely felted tissue of short and somewhat thick walled cells, containing numerous drops of oil, but neither starch nor crystals.

Numerous analyses of ergot have been published, which present among themselves a curious diversity. The most elaborate is that of M. Legrip, which, however, affords little information as to its active constituents, and is, moreover, erroneous in stating starch to be one of its constituents; it is as follows:—

Fixed Oil	34·50
Starch	2·75
Albumen	1·00
Inulin	2·25
Gum	2·50
Sugar	1·25

Brown Resin	2·75
Fungin	3·50
Vegeto-Animal Matter	13·50
Osmazome	·75
A Fatty Acid	·50
Lignin	24·50
Colouring Principles	·50
Potassium Fungate	2·25
Sodium Chloride	·50
Sulphate and Magnesium, etc., Calcium	·50
Subphosphate of Calcium	1·25
Oxide of Iron	·25
Silica	·15
Water	2·50
Loss	2·35
	100·00

This is a curiosity in its way, and seems framed more for mystification than for elucidation. On few substances has so much chemical research been expended with such discordant results. No sooner has one observer announced the discovery of its active principle or principles than another publishes observations which entirely negative the conclusions of the first. Dr. Wright supposed the virtues of ergot to reside in the fixed oil, which constitutes about 30 per cent. of this drug. Wiggers subsequently announced the discovery of what he called ergotin, which has been since proved to be merely resinous matter, and which, as in the case of the oil, has been proved to have little or no effect. Bonjean, a pharmacien of Chambère, in 1843, was the first to prepare a really active form of ergot; this he calls ergotine, or hemostatic extract. A few years since, W. T. Wenzell, of Wisconsin, announced the discovery of two alkaloids in ergot, which he named respectively ecboline and ergotine; to the former he ascribes very powerful effects, and states that it possesses in a high degree the special medicinal properties of the ergot; in the latter, viz., the ergotine, little effect was found. The whole subject of the chemical constituents of ergot has been recently very carefully gone over, with the view of determining with some degree of certainty to what bodies it owes its peculiar action. This has been undertaken by Professor Dragendorff, of Dorpat, and Herr Podwissotzky, with the result that ergot owes the greater part of its activity to a principle called sclerotic or sclerotinic acid, which is present to the extent of about 4 per cent., and which is obtained by a tedious process from the ergot exhausted with water and precipitated by absolute alcohol. I have a small sample of this substance here, and I had hoped to have brought with me a much larger specimen, but found I could not complete it in time. It has been extensively used hypodermically in Germany by Professor Von Holst, and seems possessed of a very high degree of activity, four to five centigrams being the usual dose. It certainly has the merit that whereas the substances formerly announced as being active principles were prepared by means of powerful chemical agents, and therefore presumably more or less altered or actually formed during the process, this one, viz., the sclerotic acid, has been separated entirely by means of alcohol, and therefore not exposed to powerful chemical action, a most undesirable proceeding with a substance so prone to change as ergot. The whole paper is a most interesting one, and will well merit careful study—and it will be found in the *Pharmaceutical Journal* for June 17, 1876. There is no doubt, should further trial prove the efficacy of sclerotic acid, that it will be found far superior as an agent for hypodermic use than the so-called ergotins at present used, all of which, however carefully purified, cause much pain and inconvenience in use, and are besides very prone to decomposition. The administration of medicines hypodermically is now much in vogue; they are found to act with much greater rapidity, with less constitutional disturbance, and in smaller doses than when administered by the stomach. The cases in which ergot is now employed are much more numerous than formerly. Its action is chiefly confined to unstriped or involuntary muscular fibre, such as the middle coat of the arteries, the uterus, etc., causing powerful contraction and thus arresting hæmorrhage, which it does most promptly; it has also been used for months together in the treatment of fibroid tumours of the uterus, aneurisms, etc. Its use seems indicated in some of the most terrible maladies which affect mankind; its investigation, therefore, is all the more important.

A discussion on the paper took place, to which the author replied; and with a cordial vote of thanks to the members for their miscellaneous communications, and to Mr. Tanner for his able paper, the meeting terminated.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION SOIREE.

The annual *soirée* of the Midland Counties Chemists' Association took place on Wednesday evening, January 23, at the Town Hall, Birmingham, and was a most enjoyable and successful reunion.

The *soirée* was well attended, visitors being present from London, Manchester, Liverpool, and most of the towns in the surrounding district.

The proceedings began with an organ recital by Mr. Stimpson, who played a choice selection of music, and the interval between the organ performance and the commencement of dancing was filled up by an inspection of the exhibition.

In the basement of the hall Messrs. F. S. Cleaver and Sons, of Red Lion Street, Holborn, illustrated the manufacture of fancy toilet soaps by a new and interesting method. The ordinary mode of manufacturing toilet soap is by boiling, the scent being put in whilst the material is in a liquid state; the consequence is that a considerable amount of the scent evaporates. By the process adopted by Messrs. Cleaver, the soap is first cut into shavings and dried artificially until all the superfluous moisture is extracted. The shavings are then passed through rollers, and are ultimately discharged in long strips something like ribbon. This is done three times, and whilst the operation is going on the scent and colour are added, so that none of the former is lost by evaporation, being well mixed with the soap, and there is afterwards no shrinking and consequent loss of weight and appearance. The next process is to place the shavings in a machine in which there is a large cone-shaped screw cylinder. The soap is worked along from the large to the small end of the cylinder by the revolutions, and thereby compressed; it is then forced through a grating into what is termed a mouthpiece, around which there is hot water, the water being kept at a temperature of about 100° by a lamp underneath. The soap passes out of the mouthpiece in bars, and another apparatus cuts them into tablets, which are then stamped and wrapped up. The process attracted much attention from the visitors, and it was rendered additionally interesting by ladies themselves stamping the tablets, which bore an inscription stating that they had been presented by F. S. Cleaver and Sons. Messrs. Cleaver also exhibited their mode of filling and closing collapsible tubes for perfume. The tubes are filled from the bottom, and they are then placed in sockets with the tops downward, the machine holding about two dozen. A cam action takes along the frame, in which the tubes are placed by steps, and each tube passes through a series of "jaws" and tunnels—the former pinching the metal together, and the latter lapping over a small portion of the end, so that it comes out beautifully fitted up. The machine closes about two dozen tubes a minute. The machinery was worked by the "Otto" silent gas engine, which had been lent for the occasion by Messrs. Wright and Co., of Broad Street.

The manufacture of porcelain was exhibited and carried on in the east corridor by the Worcester Royal Porcelain Company, under the direction of Mr. Binns. Bolton's potter's wheel was especially obtained by the company and fitted up for the purpose of illustrating the process of "throwing." The motive power of the wheel is given by two cones, which are regulated by a lever, so that a fast or slow motion can be obtained at the will of the operator. On receiving a ball of clay, the thrower places it upon the head of a wheel or horizontal lathe before him and presses it with both hands; the rotary movement causes the clay to rise in the form of a stalk or cone, which he then depresses and again allows to rise. When the clay is thus made ready he inserts his thumb into the mass, moulding and fashioning the outsides with the other hand. In this ways cups, bowls, and all circular articles are formed, the correctness of outline depending entirely on the manipulation of the thrower. Another process exhibited was figure-making and casting. For this purpose moulds are used, and the china employed is a liquid "slip," like cream. This is poured into the orifice of the mould left for that purpose, and then allowed to stand for a short time. When sufficient slip has adhered to the mould the remainder is poured back into the casting jug. The moulds being porous the water is absorbed, leaving the inside of the article hollow, and the slip soon becomes solid enough to enable the workman to handle it. He next arranges all the pieces, trims off the superfluous clay, makes a perfect joint, and each part is fitted to its proper place until the whole figure is built up as required. For some huge figures as many as ninety-seven different moulds are required, and even the very smallest are represented by eight or ten separate parts. The subsequent processes of baking and glazing were explained; but it was, of course, not possible to illustrate them practically. Another very interesting operation, however, was exhibited, namely the decoration of porcelain. The mode of painting the beautiful colours and objects for which the Worcester china is so noted, was intelligently described by an artist, whose manipulation of the finely-executed patterns and explanation of the various stages through which the work advances and the gilding process attracted the utmost attention, and afforded no little interest. The crude materials of which the porcelain is composed were also exhibited, and beautiful samples of finished work, in Japanese and other patterns, as well as examples of hand-painting, were shown by the company.

In the great gallery there was a microscopical exhibition, under the superintendence of Mr. W. Wright Wilson, F.L.S., assisted by members of the Natural History Society and others. About thirty microscopes were exhibited by Mr. Bolton, of Stourbridge. The crystals of various drugs were shown, illustrating the different forms of crystallography, and electrical and other apparatus were lent by Messrs. P. Harris and Co., also, a collection of new fluorescent solutions; and a set of Bohemian glass, illustrating the various forms of crystals. Here, too, Messrs. Southall Brothers and Barclay displayed a number of specimens illustrating the production of alkaloids. Quinine was shown in snow-white masses of delicate needle-like crystals, and the impure article in various stages of purification, together with the other products of the bark. Morphine came next, with samples of exhausted opium liquor containing the morphia, and various precipitates more or less pure. Strychnine, from nux vomica, was illustrated by a similar series of preparations; as well as emetine, atropine and aconitine, displayed with similar illustrations. The process of distilling artificial fruit essences was shown by means of a model furnace and sand-bath. A collection of the articles employed showed that, by manipulating *secundum artem* certain proportions of decayed cheese, chalk, and fusel oil, a product could be obtained having the delicate odour and flavour of the choicest pine-apple. From similar apparently unlikely materials were also produced liquids smelling strongly of apples, pears, the flowers of meadow sweet, wintergreen oil, bitter almonds, etc. The same firm also exhibited a fine and most interesting collection of specimens illustrating the chemical composition of many articles of food and drink, showing by analysis the several constituents and relative value of each kind of food. Close by these specimens Mr. H. W. Jones, F.R.M.S., exhibited an ingenious apparatus for analysing tobacco smoke.

In the west corridor Messrs. Southall Brothers and Barclay also exhibited specimens of the various plasters. By means of a large copper pan, heated for the occasion by gas, the production of lead plaster, the basis of the plasters exhibited, was shown.

Among the other exhibits was an arrangement for pin-papering in operation, sent by Mr. Councillor Cook; Messrs. W. F. Hunt and Co., of Oxford Street, London, exhibited in operation a machine for making plaited paper bottle caps stronger than ordinary capping paper, which neither crack nor shrivel and require no wetting, trimming, or skill in fixing. Scientific apparatus and experiments of considerable interest were shown by Mr. C. J. Woodward. Mr. Russell, of the Midland Institute, also contributed some novel and interesting experiments in physics. Rare drugs and pharmaceutical preparations were lent by Messrs. Hopkin and Williams, and Mr. Gerrard, of London, and new remedies and their preparations by Messrs. Wyleys and Co., of Coventry. An apparatus kindly lent by the Midland Institute, showing beautiful figures produced by coloured solutions diffused through two alcoholic liquids of different densities was exhibited by Mr. Marlow and Mr. Josiah Austin. The manufacture of confectionery, lozenges and crèmes was illustrated by Messrs. Gammon, Marrian, and Co. of Birmingham. The telephone was practically demonstrated with a short lecture by Mr. W. J. Lancaster. Mr. Ballard, of Ledbury, showed a new and improved pendulum apparatus with a rotating pen. Mr. Josiah Pumphrey exhibited autographic printing, type writing, etc. Messrs. Silverlock of London, sent some excellent specimens of medical and chemical labels for dispensing, etc. Messrs. Philip Harris and Co., E. Morand and Wright Wilson provided a joint display of the various effects produced by the electric fluid, amongst which may be enumerated the gorgeous effects of the electric spark passed through a vacuum tube containing a fluorescent fluid; a three-inch spark from a powerful coil, made by Mons. Morand; the heating effects of the current on platinum wire and a leyden jar, which gave a fairly good imitation of lightning. In one of the corridors Mr. Wright Wilson gave an interesting exhibition of the effects of various coloured lights upon flowers, coloured dresses, etc. Contrasting this with the effects of the colours produced by the lime-light after being passed through a prism, the effects were marvellous. A red camellia or pink scarf was black or pale green by sodium light, but the natural colours were re-established by the lime-light. Mr. E. Robotham, of the Great Western Arcade, exhibited a collection of his specialities, viz., show cases, glass stands, and shop fixtures; also the various productions of Messrs. Francis M. Farina of Cologne, consisting of their gold medal Cologne, prize soaps, perfumes, etc. The Terra Cotta Company of Torquay showed some of their handicraft, one specimen of which is well worthy of notice, viz., "Sunshine," an original study by one of the company's own artists. Some magnificent specimens of wood carving were also shown by the same firm. Great credit is due to Mr. F. W. Kimberley, for his great labour in carrying out the arrangements for the *soirée.*

A full military band was in attendance, and dancing was engaged in until an early hour.

ABERDEEN SOCIETY OF CHEMISTS AND DRUGGISTS.

The second of the course of lectures in connection with the above Society was delivered in the rooms, St. Nicholas Lane, on the evening of Thurdsay the 18th

Jan., by Mr. George Miller, of John Miller and Sons, Sandilands Chemical Works.

Mr. D. Reid, of George Reid and Sons, occupied the chair, and in introducing the lecturer complimented the Society as to having taken a step in the right direction. These meetings brought to his mind many pleasant recollections of forty years ago; and though many of the then members were off the stage, still there were younger ones growing up to tread in their footsteps. He then urged on the younger portion of his audience the necessity of using the present opportunities for study, so as to enable them to combat successfully with the examinations of the Pharmaceutical Society, as well as to lay a sure foundation whereon to build a store fit for future use.

Mr. Miller then delivered a very able and interesting lecture on "Artificial Light." The lecturer described very minutely the lights of past ages, giving as illustrations the primitive oil lamps with rush wicks, tallow dips, and composite candles. He then passed on to more recent times, the lights of which were illustrated by naphtha, paraffin, and benzine, as well as paraffin and ozokerite candles. Some duplicate lamps were burning (which were filled with oil of a different quality from the above) merely for the sake of showing the different illuminating powers. He then gave in detail the various sources of earth oil, describing the countries, the methods of boring and procuring the oil from the wells.

As time would not permit, the second part of the lecture, which relates principally to the coal tar products, was left over for another evening.

The lecture was listened to with marked attention, and at the close a hearty vote of thanks was given to the lecturer and chairman, after which the greater part of those present took the opportunity of inspecting the various samples of oil, etc., in their various stages of refinement.

The next lecture is expected to be delivered on Thursday, 14th February, by Mr. George Edward.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.—ASSISTANTS' SECTION.

The third meeting of the present session was held in the Andersonian College, on Wednesday the 16th ult. Mr. William Simpson, President, in the chair.

The minutes of the last meeting having been read and confirmed, Mr. Simpson read a paper on Iodine, in which he gave a sketch of its discovery by Courtois, in 1812, and described the preparation of kelp, and the processes employed by manufacturers, more especially those of Glasgow, in isolating the iodine from it. He also mentioned the close analogy of iodine to chlorine and bromine, and mentioned the reagents by which its presence, either in a free state or in combination, might be confirmed. After a few remarks by some of the members, a cordial vote of thanks was awarded to the reader of the paper.

The festival committee gave in their report, after which a few new members were elected and the meeting brought to a close.

Parliamentary and Law Proceedings.

A Bill to Amend the Medical Act, 1858.

The following is a copy of the Bill introduced by Dr. Lush:—

"Whereas an Act was passed in the twenty-first and twenty-second years of the reign of Her Majesty 'to regulate the qualifications of practitioners in medicine and surgery;' and whereas it is expedient to amend the said Act:

"Be it therefore enacted by the Queen's most excellent Majesty, by and with the advice and consent of the lords spiritual and temporal, and commons, in this present parliament assembled, and by the authority of the same, as follows:—

"1. Section forty of the said recited Act is hereby repealed; and in lieu thereof it is enacted: Any person who for the purpose of gain shall take or use the name or title of physician, doctor of medicine, licentiate in medicine, licentiate in surgery, bachelor of medicine, surgeon, general practitioner, apothecary, or any other medical or surgical name, title, or description purporting to authorize the practice of medicine or surgery, unless such person holds a qualification or qualifications entitling him to take or use such name, title or description, and such qualification or qualifications be also registered under the said recited Act, shall, upon summary conviction for either or any such offence pay a sum of twenty pounds.

"Any person who for the purpose of procuring the registration of the cause of death of any deceased person shall make, fill up, or sign any medical certificate of the cause of such death, unless he personally attended such deceased person during his or her last illness, and holds a qualification in medicine or surgery duly registered under the said recited Act, shall upon summary conviction for either or any such offence pay a sum of twenty pounds.

"If any person shows that he is not a British subject and not ordinarily resident in the United Kingdom, and holds a medical diploma, degree, or title from some university, college, or body in any British possession or foreign country entitled to grant the same, such person shall not be liable to any penalty under this section.

"2. To section forty-two of the said recited Act the following words shall be added, viz., anything to the contrary in any Act passed before the passing of this Act notwithstanding.

"3. To schedule A of the said recited Act this section shall be added: When the General Medical Council are satisfied that any medical diploma, degree, or title granted by any university, college, or body in any British possession or in any foreign country is granted in respect of a degree of knowledge in both medicine and surgery equal to that required for obtaining a licence in both medicine and surgery under the said recited Act, they may from time to time, if they think fit so to do, place such diploma, degree, or title upon the medical register, and if at any time any such medical diploma, degree, or title ceases to be granted in respect of such degree of knowledge as aforesaid they may remove the same from such register.

"4. This Act to be read with and form part of the said recited Act.

"5. This Act may be recited for all purposes as the Medical Acts Amendment Act, 1878."

The Practice of Using Old Mineral Water Bottles.

A question of considerable interest to mineral water makers came on this week in Chancery Division of the High Court of Justice, before Sir R. Malins, in the suit of Bratby *v.* Mather. This was a motion to restrain the defendant from selling mineral waters in bottles bearing the name of the plaintiff. Both parties carried on business in Manchester as vendors of aerated and mineral waters. The plaintiff stated that the defendant was in the habit of filling up with his own mineral waters and affixing his own labels to empty bottles bearing the name of the plaintiff stamped on the bottles in raised glass letters. The defendant did not deny the facts, but stated by way of defence that he only filled up bottles that had been returned amongst his own empties by his own customers, and that this was a usual custom. A statement in the defendant's affidavit that such custom was "a bad practice, though difficult to avoid," caused some amusement in the court.—Mr. Pearson, Q.C., and Mr. A. J. Pound appeared for the plaintiff; Mr. Higgins, Q.C., and Mr. Henderson for the defence.—The motion was ordered to stand over until the hearing of the cause.—*Standard.*

Poisoning by Carbolic Acid.

At the Liverpool Coroner's Court, on Saturday, Jan. 26, Mr. Clarke Aspinall held an inquest upon the body of Elizabeth Lavell, forty-two years of age, wife of Wm. Lavell, stevedore, of 22, Duke Street. The deceased who was said to be addicted to drunkenness, and to have been in liquor at the time, drank some carbolic acid from a cup on Thursday evening, saying, "Now I have done it," and died from the effects of the poison next morning. A verdict to the effect that the deceased had committed suicide while labouring under temporary insanity was returned.

The Regulation of Pharmacy in Victoria.

The following are the Acts passed by the legislature of Victoria referred to in the last number of this Journal:—

AN ACT TO ESTABLISH A BOARD OF PHARMACY IN VICTORIA.

[22*nd December*, 1876.

Be it enacted by the Queen's Most Excellent Majesty by and with the advice and consent of the Legislative Council and the Legislative Assembly of Victoria in this present Parliament assembled and by the authority of the same as follows:—

1. This Act shall come into operation on the first day of January One thousand eight hundred and seventy-seven, and shall be called and may be cited as the "*Pharmacy Act* 1876."

It is divided into parts as follows:—

Part I.—The Pharmacy Board of Victoria, ss. 3–10.

Part II.—The Pharmaceutical Register of Victoria, ss. 11–17.

Part III.—Registered Pharmaceutical Chemists, ss. 18–21.

Part IV.—Miscellaneous, ss. 22–26.

2. Chemists and Druggists within the meaning of this Act shall consist of all persons who at any time before the passing of this Act have carried on in Victoria the business of a chemist and druggist in the keeping of open shop for the compounding of the prescriptions of duly qualified medical practitioners and also of all such persons as may be duly registered under this Act.

Part I.—Pharmacy Board of Victoria.

3. Subject to the provisions of this Part of this Act the Governor in Council may appoint a Board consisting of a president and six other members, under the style of "The Pharmacy Board of Victoria," hereinafter in this Act termed "The Board."

4. No person shall be elected or appointed president or member for more than three years, but shall be eligible for re-election or re-appointment, and the Governor in Council may from time to time remove the president or any other member of the Board.

5. The first president and other six members of the Board shall be appointed by the Governor in Council without previous election, provided that no person shall be so appointed who does not appear to be eligible for registration as a registered pharmaceutical chemist; such president and members shall be appointed for a period of three years; if any vacancy occur in the Board during such period the Governor in Council may appoint thereto without previous election any registered pharmaceutical chemist, and the person so appointed shall hold office until the expiration of three years from the date of the appointment of the first members of the Board under this Act and no longer.

6. At the expiration of the period for which the first president and members of the Board shall be appointed to hold office no person shall be a member of the Board unless he be a registered pharmaceutical chemist, and unless he shall have been elected to act as a member of the Board by the registered pharmaceutical chemists of Victoria; and no person shall be appointed as president unless he be a member of the Board and shall have been elected by the other members to act as president. Every election shall be held in manner prescribed by regulations to be made by the Board subject to the approval of the Governor in Council.

7. A quorum of the Board shall consist of not less than three members thereof, and in the absence of the president from any meeting of the Board one of the members present shall be elected chairman of that meeting.

8. The Board may from time to time appoint a registrar and any other officers, whom they may require for the purposes of this Act, and shall have power to remove the same at any time.

9. The Board may from time to time make alter or rescind regulations for the purpose of carrying this Act into effect. Such regulations shall not have any effect if they be repugnant to any law in force in Victoria or to the provisions of this Act nor until they shall have been confirmed by the Governor in Council and published in the *Government Gazette.*

10. The Board may question any person who may attend before the Board and any witness who may be produced before the Board and may examine any persons upon oath or take a solemn declaration from such persons, and if any person shall wilfully knowingly or corruptly make any false statement upon such examination or in such declaration or shall utter or attempt to utter or put off as true before the Board any false forged or counterfeit diploma degree license certificate or other document or writing he shall be guilty of a misdemeanor and being thereof duly convicted he shall be liable to be imprisoned for any period not exceeding one year.

Part II.—The Pharmaceutical Register of Victoria.

11. The Board shall from time to time cause the names of all persons certified by the Board as duly qualified for registration as registered pharmaceutical chemists to be registered with their residences and qualifications in a book to be kept by the Board for that purpose in the form in the First Schedule to this Act or to the like effect; and such register shall be called "The Pharmaceutical Register of Victoria." All persons so long as their names continue to be enrolled in such register may be described in this or any other Act or any regulations as "registered pharmaceutical chemists."

12. Previously to registration or examination under this Act such fees shall be payable as are set out in the Second Schedule to this Act or such other fees as may from time to time be fixed and determined by any regulation hereafter made by the Board in accordance with this Act, and the said fees shall be paid to the registrar of the Board for the purposes of this Act.

13. The Board may from time to time make the necessary alterations in the registration of the qualifications and addresses of the persons registered under this Act, and may from time to time write or cause to be written a letter to any registered pharmaceutical chemist addressed to him according to his last known address to enquire whether he has changed his residence, and if no answer be returned to such letter within the period of six months from the sending thereof the Board may erase the name of such person from the Pharmaceutical Register and may restore the same to such register upon the personal application of such person and production of his certificate or satisfactory proof of his former registration.

14. Every registered pharmaceutical chemist on changing his residence shall intimate the same to the Board and every deputy registrar in Victoria on receiving information of the death of any registered pharmaceutical chemist shall forthwith transmit notice thereof by post to the president of the Pharmacy Board in Melbourne, and on receipt of such notice the Board shall erase the name of such chemist from the Pharmaceutical Register of Victoria.

15. If any registered pharmaceutical chemist be convicted of any offence under this Act which in the opinion

of the Board renders him unfit to be on the Pharmaceutical Register of Victoria the Board may subject to the approval of the Governor in Council order the name of such person to be erased from such register, and such erasure shall be a disqualification as a registered pharmaceutical chemist within the meaning of this Act, and it shall be the duty of the Board to erase such name accordingly.

16. The Board shall in the month of January in each year cause to be printed published and sold a correct register of the names of all registered pharmaceutical chemists, and in such registers respectively the names shall be in alphabetical order according to the surnames with the respective residences of such chemists, and such printed register shall be called "The Pharmaceutical Register of Victoria for 1877" and for every succeeding year.

17. A printed copy of such register for the time being purporting to be so printed and published as aforesaid, or a copy of the *Government Gazette* purporting to contain any regulation made by the Board shall be *primâ facie* evidence in all courts of justice and in all legal proceedings whatsoever that the persons specified in such printed register are registered according to the provisions of this Act, or that such regulation is duly made; and the absence of the name of any person from such printed register for the time being shall be evidence until the contrary shall be made to appear that such person is not a registered pharmaceutical chemist.

Part III.—Registered Pharmaceutical Chemists.

18. No person shall receive from the Board a certificate that he is duly qualified for registration as a registered pharmaceutical chemist unless he shall have attained the age of twenty-one years, and unless—

(I). At any time before the date of the commencement of this Act he shall for not less than two months have carried on the business of a chemist and druggist or homœopathic chemist in the keeping of an open shop for the compounding and dispensing of the prescriptions of legally qualified medical practitioners, or unless

(II). At any time before the date of the commencement of this Act he shall for not less than three months have been employed as a dispensing assistant in an open shop for the compounding and dispensing of the prescriptions of legally qualified medical practitioners, or until he shall have been for not less than three years employed as a dispensing chemist in an hospital benevolent asylum or other public institution or unless

(III). He hold a certificate or diploma of competency as a pharmaceutical chemist or as a chemist and druggist or homœopathic chemist from the Pharmaceutical Society of Great Britain or any college or board of pharmacy recognized by the Board under any regulations made under this Act, or unless

(IV). He shall have served for not less than four years as an apprentice in the business of a registered pharmaceutical chemist or chemist and druggist or homœopathic chemist keeping open shop for the compounding and dispensing of the prescriptions of legally qualified medical practitioners, and shall also have attended one course of lectures and passed examinations in each of the following subjects at the University of Melbourne, or some school or college of pharmacy recognized by the board:—Materia medica, and medical botany, and practical chemistry; and shall have passed examinations before the board as hereinafter provided in the subject of practical pharmacy and any subject that may be prescribed by the Board with the approval of the Governor in Council. Provided always that any person having served or serving in Victoria a period of not less than three years' apprenticeship whose period of apprenticeship shall have commenced three months at least before the date of the commencement of this Act either with a chemist and druggist or with a recognized licentiate apothecary or in a public hospital shall be required to pass such modified examination only as the Board may prescribe.

A certificate of qualification in the form in the Third Schedule hereto shall entitle the person named therein on payment of the proper fee to be registered under this Act at any time within six months after the date of such certificate.

19. The Board shall permit any officer or person appointed by the Governor in Council to be present during the progress of any examination conducted by the Board.

No person shall be examined by the Board as directed by the next following section until he furnish a statutory declaration by a master chemist in the form in the Seventh Schedule hereto or to the like effect of his having served the apprenticeship and where necessary certificates of his having attended one course of lectures and passed the examinations directed in the last sub-division of section eighteen.

20. The Board shall have power to control and direct all examinations in practical pharmacy and such other subjects as may from time to time be approved by the Governor in Council and published in the regulations of the Board. Such examinations shall not include the theory and practice of medicine surgery or midwifery. The Board may grant or refuse to such persons certificates of competency skill knowledge and qualification to exercise the business or calling of a pharmaceutical chemist. In the case of rejection a rejected candidate may present himself for re-examination after a period of six months.

21. Every person who desires a certificate of qualification for registration under this Act or to be examined by the Board shall furnish the Board with a statutory declaration according to the Fourth or Fifth Schedule or to the like effect.

Where a person applies for such certificate under subdivision one of section eighteen his declaration must be accompanied by the statutory declaration of a justice or legally qualified medical practitioner in the form in the Sixth Schedule or to the like effect that such justice or practitioner from his own knowledge believes the statement of the applicant to be correct and true.

Where a person applies for such certificate under subdivision two of section eighteen his declaration must be accompanied by a statutory declaration in the form in the Seventh Schedule or to the like effect of the person in whose shop he was employed that the statement of the applicant is correct and true.

Where a person applies for such certificate under subdivision three of section eighteen his declaration must be accompanied by the certificates or diplomas on which he bases his application. Such certificates or diplomas shall be returned to the applicant by the Board.

Part IV.—Miscellaneous.

22. The provisions of Part II. of the "*Public Health Statute* 1865," shall extend to all articles usually taken and sold as medicines, and every adulteration of any such article shall be deemed an admixture deleterious to health, and any person whether registered under this Act or not who sells any such article adulterated shall unless the contrary be proved be deemed to have knowledge of such adulteration.

23. Nothing herein contained shall extend to or interfere with the business or with any rights and privileges of any legally qualified medical practitioner or of any member of the Royal College of Veterinary Surgeons of Great Britain nor with the business of wholesale dealers in supplying drugs and chemicals in the ordinary course of wholesale dealing; and upon the decease of any registered pharmaceutical chemist actually in business at the time of his death it shall be lawful for any executor

administrator or trustee of the estate of such pharmaceutical chemist to continue such business for a period of twelve months and no longer unless by permission of the Board of Pharmacy of Victoria if and so long only as such business is *bonâ fide* conducted by a registered pharmaceutical chemist.

24. Any deputy registrar or other person who shall wilfully make or cause to be made any falsification in any matter relating to the Pharmaceutical Register of Victoria or the Pharmaceutical Register of Victoria for any year, and any person who shall wilfully procure or attempt to procure himself to be registered under this Act by making or producing or causing to be made or produced any false or fraudulent representation or declaration either verbally or in writing and any one aiding or assisting therein shall be deemed guilty of a misdemeanor punishable by fine or imprisonment, and shall on conviction be liable to a penalty not exceeding Twenty pounds or to imprisonment for any term not exceeding twelve months.

25. From and after six months after the date of the first appointment of the Board any person who commits in Victoria any of the following offences shall on conviction thereof be liable to a penalty of not exceeding Ten pounds for each offence, and may also be committed to prison for any period not exceeding six months.

(I). Any person not being a registered pharmaceutical chemist who carries on or attempts to carry on business as a chemist and druggist or homœopathic chemist or either.

(II). Any person not being a registered pharmaceutical chemist who takes uses or exhibits the name or title of or who pretends to be a registered pharmaceutical chemist, chemist and druggist, chemist, druggist, pharmacist, pharmaceutist, pharmaceutical chemist, homœopathic chemist, dispensing chemist, or dispensing druggist.

(IV). Every registered pharmaceutical chemist or person in the employ of such chemist who prescribes or practices medicine or surgery except in accordance with any rights and privileges hitherto enjoyed by chemists and druggists in their open shops.

(V). Any person who fails to comply with the provisions of this Act or any regulations made hereunder.

Nothing in this Act shall prevent any person from being liable to any other penalty damages or punishment to which he would have been liable if this Act had not been passed.

26. All offences under this Act shall be heard and determined and all penalties imposed by this Act shall be recovered in a summary manner before two justices of the peace in petty sessions, and all penalties when recovered shall be paid to the Board to be applied towards the expenses of carrying this Act into effect.

Second Schedule.

Fees Payable under Pharmacy Act 1876.

	£	s.	d.
For every examination before the Board under section 18	3	3	0
On registration as a pharmaceutical chemist without examination (sect. 18, subdivisions 1, 2, and 3)	2	2	0
On registration in every other case	1	1	0

AN ACT FOR REGULATING THE SALE AND USE OF POISONS.

[*22nd December*, 1876.

Whereas the unrestricted sale of poisons often leads to fatal accidents and the commission of crime: And whereas large quantities of arsenic, strychnine, and other poisons, are used in the colony for pastoral, agricultural, and other purposes and fatal accidents occur by reason of the careless custody and use of such poisons by the owners thereof or persons in their employ: And whereas it is expedient for the safety of the public to regulate the sale of poisons and to make provisions for the exercise of proper precautions in the use of the same: Be it therefore enacted by the Queen's Most Excellent Majesty by and with the advice and consent of the Legislative Council and Legislative Assembly of Victoria in this present Parliament assembled and by the authority of the same as follows (that is to say):—

1. This Act may be cited as the "*Sale and use of Poisons Act* 1876."

2. The several articles mentioned in the First Schedule hereto shall be deemed poisons within the meaning of this Act; and on the recommendation of the Pharmacy Board of Victoria the Governor in Council may by proclamation duly published in the *Government Gazette* from time to time declare that any other article specified in such proclamation shall be deemed a poison within the meaning of this Act.

3. Every person other than a legally qualified medical practitioner or a registered pharmaceutical chemist who shall sell any poison shall unless he hold a certificate from the Pharmacy Board of Victoria that he is a fit and proper person to sell poisons be liable to a penalty not exceeding Twenty pounds.

4. In places distant at least four miles from any city town or borough and in which no registered pharmaceutical chemist has an open shop any person who shall produce a certificate from a legally qualified medical practitioner and a police magistrate that he is a fit and proper person to be allowed to sell poisons in such place shall receive from the Pharmacy Board of Victoria a certificate as a dealer in poisons on payment of a fee of Twenty shillings per annum to such Board.

Every dealer in poisons shall keep all poisons in a cupboard of such dimensions and containing such shelves as the Pharmacy Board of Victoria may direct. The word "poisons" shall be conspicuously painted or written on such cupboard, and no articles other than such poisons shall be placed or kept therein.

5. Every person who shall sell any poison specified in the first part of the First Schedule hereto shall before the delivery thereof to the purchaser inquire his name, place of abode and occupation, and the purpose for which such poison is required or stated to be required, and shall thereupon make a faithful entry of such sale, specifying the poison and the quantity thereof and all such particulars so given by the purchaser, together with the day of the month and year of such sale, in a book to be kept by the vendor for that purpose in the form set forth in the Second Schedule hereto; and every such entry shall be signed by the person making the same and also by the purchaser unless he shall declare himself unable to write (in which case the person making the entry shall add thereto the words "purchaser cannot write"); and whenever a witness to the sale is required by this Act such entry shall be signed by such witness together with his place of abode. When sales and purchases of poisons are made by correspondence the letter ordering the same shall be preserved by the vendor and a memorandum of the date of the said letter by whom it was written and the quantity and particulars of the poison therein ordered shall be entered in the said book; and no person shall sell poison so ordered to any person with whose signature he is not acquainted unless such signature shall have been witnessed or purport to have been witnessed by a justice clergymen or public officer or be authenticated by some person known to the vendor.

6. No person shall sell any poison either by wholesale or retail unless the bottle or other vessel, wrapper or cover, box or case immediately containing the same bears thereon the word "poison" printed conspicuously together with the name of the article and the name and address of the seller thereof.

7. No person shall sell any arsenic or strychnine or any preparation of the same respectively, unless in the case of arsenic and any uncoloured preparation of the

same such poison shall be mixed before the sale or delivery thereof with soot in the proportion of one ounce of soot at least to one pound of arsenic, and so in proportion for any greater or less quantity; and unless in the case of strychnine or any uncoloured preparation of the same such poison shall be coloured with Armenian bole or other red colouring matter before the sale or delivery thereof: Provided always that whenever the purchaser states that such arsenic or strychnine or any preparation thereof respectively is required not for any pastoral or agricultural use but for some other purpose for which such admixture would according to the representation of the purchaser render it unfit such poison may be sold without the admixture hereinbefore specified.

8. No person shall sell any poison specified in the first part of the First Schedule hereto to any person who is under eighteen years of age or who is unknown to the vendor unless the sale be made in the presence of some witness who is known to the vendor and to whom the purchaser is known, and which witness signs his name together with his place of abode to the required entry before the delivery of the poison to the purchaser.

9. Any owner or other person whatsoever in charge or possession of any poison who shall leave it in any place (whether the same be ordinarily accessible to others or not) unless the bottle or package of whatever kind in which such poison may be contained shall be marked as "poison" and be otherwise duly labelled in the manner provided by section six shall be liable on summary conviction thereof before any two justices to a penalty not exceeding Twenty pounds.

10. If any person shall sell any poison contrary to the provisions of this Act, or if on any sale thereof he shall deliver the same without having made and signed the entry required by this Act on such sale, or without having obtained such signature to such entry as required by this Act, or if any person purchasing such poison shall give false information in answer to inquiries to the person selling the same in relation to the particulars which he is by this Act authorized to inquire into of such purchaser, or if any person shall sign his name as a witness to the sale of any such poison to a person unknown to such witness, or if any person fail to comply with any of the provisions of this Act for offending against which no specific penalty is provided, every such person so offending shall for every such offence upon summary conviction thereof before two justices be liable to a penalty not exceeding Ten pounds.

For the purpose of this section the person on whose behalf any sale is made by an assistant or apprentice shall be deemed to be the person who shall sell, and such assistant or apprentice shall be liable to the like penalties as the person on whose behalf he makes any sale.

11. The Governor in Council may on the recommendation of the Pharmacy Board of Victoria by order direct the cancellation of the certificate as a dealer in poisons held by any person who is convicted of any offence against this Act which renders him unfit or who shall be deemed unfit through habitual intoxication or otherwise to continue to sell poisons.

12. The Governor in Council may on the recommendation of the Pharmacy Board of Victoria from time to time make any regulations as to the colouring of any poisons or as to the sale or custody of the same or otherwise as to carrying into effect the objects of this Act. Such regulations after publication in the *Government Gazette* shall have the same force and validity as if the same formed part of this Act, and a copy of the same shall be laid before both Houses of Parliament without unnecessary delay.

13. This Act shall not extend to the sale of any poison when made up or compounded as a medicine according to the prescription of a legally qualified medical practitioner or in the form of homœopathic medicine unless in the crude state mother tincture of a greater strength than the third decimal potency; nor to the sale of patent or proprietary medicines; nor to the sale of photographic materials for the purpose of photography; nor to the sale of medicines dispensed by veterinary surgeons for animals under their treatment; nor to the sale of fly poison papers or packets of poisonous mixtures save and except poisoned seed for the destruction of vermin when duly marked as such; nor shall it extend to any sales by wholesale dealers in the ordinary course of wholesale dealing if an order in writing signed by the purchaser shall be given for the supply of the same: Provided that all such sales shall be entered in a book and that the bottle or other vessel wrapper or cover box or case immediately containing the poison be labelled as required by this Act.

SCHEDULES.

First Schedule.

LIST OF POISONS.

1st Part.

Arsenic and its preparations.
Prussic Acid and its preparations.
Strychnine and its preparations.
Savin and its Oil.
Ergot of Rye and its preparations.
Chloral Hydrate.
All poisonous Vegetable Alkaloids and their Salts.
Aconite and its preparations.
Tartar Emetic.
Corrosive Sublimate.
Cantharides.

2nd Part.

Cyanide of Potassium and all Metallic Cyanides.
Oxalic Acid.
Chloroform.
Belladonna and its preparations.
Laudanum.
Opium and all preparations of Opium or of Poppies.
Arsenical preparations except Green and other coloured Paints and Pigments.
Essential Oil of Almonds, unless deprived of its Prussic Acid.

Reviews.

THE MATERIA MEDICA OF THE HINDUS, compiled from Sanskrit Medical Works, by UDOY CHAND DUTT; with a GLOSSARY OF INDIAN PLANTS, by GEORGE KING, M.B., F.L.S., and the Author. Calcutta: Thacker, Spink and Co. 1877.

This work appears to have been written partly to show the extent of knowledge obtained up to the present time by Hindu physicians from their own practice and observation, and partly to enable European medical men to get some idea of the nature and composition of the medicines of which they hear only the native name, for it often happens in India that an European doctor is called in to see a patient who has already been treated by a native practitioner before coming under his care.

In the somewhat lengthy but very interesting preface, the author gives a sketch of the history of Hindu medicine and of the more important native works on the subject. An introduction follows which gives information as to weights and measures and the various ways in which medicines are applied or administered by the Hindus. The materia medica portion is arranged in the usual manner, the inorganic substances being first treated of and then those derived from the vegetable kingdom.

Although the author modestly describes the book as a compilation from standard Sanskrit medical works, he has evidently brought very considerable personal knowledge to bear upon it, availed himself of all possible sources of information, and exercised great discrimination in distinguishing between the practical uses of the drugs and those which are only occasional, or in many cases only theoretical. The author has evidently taken great pains also to make the work as trustworthy as possible, having given the original Sanskrit text in foot notes, so that the reader may be able to compare it with the translations given.

The articles of vegetable materia medica have been carefully identified by having authenticated specimens from native physicians compared with plants in the Royal Botanical Gardens at Calcutta, under the able superintendence of Dr. King. So carefully has this work been done that some plants, the identification of which was doubtful, have been omitted from the list. The characters of the drugs themselves are not described, but full details are given of the method of preparing them and of the way in which they are used. The absence of descriptions by means of which the various substance might be identified is the only thing wanted to make the work as complete as possible, since the same native name is often applied to several distinct drugs having the same leading characteristic property. Dr. Dymock's recent papers in this Journal will, however, amply make up for this deficiency.

Much interesting information will be found scattered throughout the book; the general tenor of it shows that the Hindus are far in advance of many other Asiatic peoples in their knowledge of the properties of medicine, and that they use with boldness and skill many powerful medicines, such as arsenic, aconite, mercury, etc.

A very comprehensive glossary of the native names of Indian plants in Sanskrit and the vernacular, with their scientific equivalents, and a good index, conclude a work which should be in the hands of every European physician in India, and which from its intrinsic value should find a place in every medical and pharmaceutical library.

Elements of Dental Materia Medica and Therapeutics, with Pharmacopœia. By James Stocken. London: J. and A. Churchill. 1877.

This little work was first compiled for hospital use, at the request of the medical staff of the National Dental Hospital and afterwards published in sections in the *Monthly Review of Dental Surgery*. It now appears in a revised form before the public. The materia medica occupies the larger portion of the book and comprises nearly a hundred subtances, the remainder being occupied with the dental pharmacopœia and numerous tables. The latter enumerate the number of drops of different liquids equal to one drachm of water; the proportionate doses of medicine for children and adults; the normal respiration and pulsation at different ages; antidotes for poisons, and a glossary of terms used, etc. The index is very complete and gives also the doses of each remedy. The work is evidently very carefully compiled and is brought quite up to the most recent advances in dental science; thus monobromo-camphor, gelsemium, croton-chloral hydrate, amyl nitrite, phenate of soda, and thymol are found amongst the materia medica, and the chapter upon nitrous oxide, in particular, occupies several pages, and is replete with valuable information. The remarks under the articles of materia medica include the chemical formulæ, physical and chemical characters, mode of preparation, therapeutical effects, and uses and doses, and while briefly and clearly put, comprise all that is necessary for practical purposes. There are one or two trifling omissions which will perhaps be noticed. Thus, croton chloral is still retained under its old name, although it is now known to be butyl chloral; for antidotes to aconite the reader is referred to the table of antidotes, where that drug is not mentioned; calendula is mentioned in the pharmacopœia but not in the materia medica. In the table of approximate measurements a teaspoon is supposed to hold one drachm, and a tablespoon half a fluid ounce, without any remark being made upon the well-known fact that modern spoons hold nearly double those quantities. The term gelsemin is applied by the author to the crude drug instead of gelsemium, although the former name properly belongs to a so-called resinous principle, obtained from the root and used by the Eclectics in the United States. With these exceptions, however, the book appears to be as perfect as possible, and will, we feel sure, speedily reach a second edition. The formulæ in the pharmacopœia will doubtless be found very useful to chemists, and no dentist ought to be without this admirable little treatise.

Notes and Queries.

[574]. Transparent Cement. (From the *Polytechnisches Notizblatt*. Best transparent gelatine cut small and warmed in a china dish with a little acetic acid until fluid, will make a good cement.

In using it the pieces to be cemented must be warmed and painted by means of a camel hair pencil with the warmed cement, and allowed to dry for twelve to twenty-four hours.

Hugo W. Langbeck.

---

[575]. CHERTIER'S COPPER.—In answer to Mr. Walter Slicer, Chertier's Copper is a compound used in pyrotechny, and bears the name of its inventor; a formula for its preparation may be found in a work on the 'Pyrotechnic Art,' by that author. I, however, give one below:—

Sulphate of Copper in fine powder	. .	7 lbs.
Chlorate of Potash ,,	. .	7 ,,
Solution of Ammonia, sp. gr. ·880	. .	2 ,,

To the powders intimately mixed, the ammonia is added, and the pasty mass thus formed is to be dried with a gentle heat (about 120° Fahr.); for if a much greater heat is employed, the compound is liable to spontaneous combustion, occurring in the first instance, by the appearance of brownish-black spots, which shortly kindle into a smouldering fire.

Peckham Rye. Henry Child, F.C.S.

A similar answer has been received from Mr. C. J. H. Saunders, Mr. R. Knowles, Mr. Princep, and from Mr. Baxter.

Dispensing Memoranda.

[54]. Creasote Pills.—I have waited to see the result of the replies to this query with some interest, but seeing the summing-up in "The Month" in favour of light magnesia, I cannot let it pass without expressing my very strong objection to it. I have made creasote pills both with light magnesia and with slaked lime, but in either case the creasote is almost entirely combined, and pills made with either excipient are as insoluble as marbles; I have boiled them or some time with water without altering their shape. With bees' wax, the results are not much better. I have found the best results are obtained from powdered animal soap, B.P. Mix in a stoppered bottle and digest in a water-bath equal parts of creasote and the soap. This on cooling makes a suitable plastic mass for forming pills, and mixed with an equivalent quantity of the species for compound rhubarb pills readily forms the pill—not a bolus—referred to. This will be readily soluble, and the creasote will exist as creasote in the pill—what the prescriber intends.

Wm. Martindale.

---

[58] I have made the mixture referred to by "Beta," without any inconvenience, by dissolving Pot. Iod. and Pot. Bic. in a little water, and the Ferr. Amm. Citr. separately in a mortar, then mixing the two solutions together, allowing them to remain for a short time, when

all effervescence will have ceased. The mixture made thus has stood upon the counter for several days without any alteration.

I can hardly agree with "Nil Desperandum," because physicians of the present day are as a rule well up in chemistry, and would not prescribe such ingredients without knowing the result.

Bristol. VERITE SANS PEUR.

Correspondence.

DEATH POINT OF BACTERIA.

Sir,—Mr. Willmott heads his first letter "Death Point of Bacteria," and in that letter states that, "Bacteria and their germs were utterly destroyed when placed in a temperature of 150° F. and upwards, providing that the heat were constantly applied for a period of from three to six days," and this he claimed as his "new point in the inquiry." In the *Pharmaceutical Journal* of the following week I called in question the novelty of this process for the destruction of bacteria. In Mr. Willmott's reply of last week he adopts a totally different title to that of his former letter, and no longer calls it the "Death Point of Bacteria," but the "Extinction of Germ Life," and, moreover, states that it is a common error to confound bacteria with bacterian germs. The error in this instance is his own. I have quoted his words, the "death point of bacteria," and though he mentions germs the prominence is given to bacterian life. It will be seen how the matter now stands if I give the exact words of his last communication:—

"It was not the destruction of bacteria but the prevention of their development in nutritive fluids at a low degree of heat sustained over a given period that constituted the novelty set forth in these investigations."

This, then, must be accepted as the correct definition of what is claimed as new, although it differs materially from the former one. The prevention of bacterian life is one thing, the destruction of that life after its appearance quite another.

I shall confine myself to the results obtained by the same two authors I quoted on a former occasion, but shall confine myself mainly to Bucholtz.

In the investigations of Leonid Bucholtz on the "Influence of temperature on bacterian vegetation," he used six flasks, and placed in each fluid suitable for the development of bacterian life. Two of these flasks were subjected to a temperature of 60° C. (140° F.) continued for three days. The fluid showed no signs of bacterian development, and continued in the same state several days. The other flasks, subjected to lower temperatures, gave evidence of active bacterian development.

Cohn, as the result of careful examination, states that in a suitable fluid which had been subjected to a temperature of 60°—62° C. (140—143° F.) no bacteria developed themselves.

Do not these experiments on bacterian life show the "prevention of their development in nutritive fluids at a low degree of heat sustained over a given period"? If so, do they not cover the ground occupied by Mr. Willmott in the process which he considers a novelty?

Mr. Willmott gives evidence of confusion in his own mind with regard to this subject, and he has yet to prove whether the non-development of bacteria in a suitable fluid be due to the destruction of bacterian germs by heat or to the fluid being rendered by that heat unsuitable for the development of bacterian germs.

If Mr. Willmott's object be the elucidation of truth, personal matter is out of place. It can but weaken an argument used or supply the place of an absent one.

A writer is at perfect liberty to quote from any author, home or foreign, and in referring to the published works of Dr. F. Cohn I refer to those of a man of European reputation on infusoria and the biology of plant life. Leonid Bucholtz was a student of medicine in the Dorpat university. He undertook a series of experiments with the view of determining the influence of temperature on bacterian life.

I have now said my last say on this subject, and I think it is sufficient to prove that "whatever other merit the process may claim it lacks that of novelty."

THOMAS GREENISH.

AN ASSISTANTS' SECTION.

Sir,—Some time ago the Council of the Society very generously gave permission for a meeting to be held in the Lecture Theatre for the purpose of inaugurating a chemists' assistants' association.

As a quiet observer, and in common with very many others, it has, I am sure, afforded me and all the well-wishers of the assistants' section much pleasure to witness its progress.

But the question has, I think, now assumed rather a wider range, and in a recent number of the Journal a valuable suggestion came from Edinburgh, asking whether it was not possible to establish an association for the entire body of chemists' assistants. Our Edinburgh and Glasgow friends have shown, as usual, that they are always to the front on educational and all other subjects relating to the welfare of pharmacy, and the establishment of an annual supper for assistants is no mean contribution to the social and friendly co-operation which all such gatherings must help on and develop.

But the question has arisen with me to know whether it would not be possible to establish a federation of all the local associations into what I am disposed to believe would work best as an Assistants' Section of the Pharmaceutical Society. In which case I presume the whole thing should be worked by assistants, with the head centres in London and Edinburgh, when no doubt it would be necessary to have permanent secretaries, with an assistant secretary, *pro tem.*, and local secretaries in all towns sufficiently large to organize a local association affiliated with the parent societies.

There might be one annual subscription, and in case of an assistant who may be a member of any local association removing from that to any other town, or coming up to London, he should, on producing his ticket of membership, be admitted without further payment for the current year to the association in the town or city to which he is a new comer.

Surely, sir, there is abundant material, if rightly fitted together, to build up and found an assistants' section on the bulwarks of the Pharmaceutical Society.

This object would probably be best attained if all interested in the subject throughout Great Britain would contribute to your pages the various ideas which may be passing in their minds on this subject; and permit me, sir, especially to commend it to the consideration of those gentlemen of the Council, and our esteemed President, who are so well and so widely known for their desire to promote all schemes having for their object the advancement of the young men, assistants in pharmacy. *Apropos* of this subject, I am glad to learn that the London chemists' assistants' association intend giving a *soirée* in February of a scientific and social character.

"This is good news for the new year."

J. Higgins.—The book is in the Library of the Pharmaceutical Society. The proportions vary so with the wood employed that to give a figure as representing the average would be misleading.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Ivatts, Mr. Durrant, Mr. Lauria, Mr. Abraham, Mr. Bennett, Mr. Bates, Mr. Taylor, Mr. Bunker, Emplastrum, W. W. B., C. J. B., F. H. J., A. P. S.

THE PROGRESS OF CINCHONA CULTIVATION AND ALKALOID PRODUCTION IN BENGAL.*

BY C. H. WOOD, F.C.S.,

Professor of Chemistry, Medical College, Calcutta; Quinologist and Chemical Examiner to Government of Bengal.

At the request of the officers of this Society, I have undertaken to bring before you to-night some account of the progress that has been made in the cultivation and utilization of the cinchona species in Bengal. In fulfilling this engagement, however, I am unable to do more than summarize information that has been already to some extent published in the reports to the Indian Government. But as the questions that have been thus brought under official consideration have involved some points of considerable pharmaceutical interest, they may furnish a few points worthy of discussion at this meeting.

The first attempts at the cultivation of cinchona in Bengal were made by Dr. Anderson, the Superintendent of the Botanical Gardens, Calcutta, in the year 1861, with some seed received from Kew.† Thirty-one plants were thus obtained. In the same year Dr. Anderson was sent to Java to study the system of cultivation adopted there, and to convey some plants from that colony to India. Part of these Java plants were afterwards taken by Dr. Anderson to Ootacamund in the Madras Presidency, where cinchona cultivation was already progressing under Mr. MacIvor, and were exchanged for plants of other species. The total number of plants thus collected and reared in Calcutta from these different sources amounted at the commencement of 1862 to 289 plants, comprising of course several species. The permission of Government was then obtained for the removal of these plants to Sikkim for the purpose of establishing a permanent plantation on the slopes of the Himalayas. Here Dr. Anderson laboured untiringly for a considerable time towards the accomplishment of his object, and after encountering many obstacles ultimately succeeded in finding a suitable locality in the valley of Rungbee, twelve miles distant from Darjeeling. The first little patch of 500 cinchonas was planted on this site during the latter half of 1864. At that time the valley was a dense and little known forest, utterly without roads, and only approached by cutting a path for miles through an impenetrable mass of vegetation. Moreover appliances of every kind necessary for plant cultivation had to be brought up from Calcutta, involving frequent and vexatious delays, the time usually occupied in the transit being a couple of months. All these early difficulties were mastered by the energy of Dr. Anderson, ably seconded by his assistant, Mr. Jaffray. Since 1866 the executive charge of the undertaking has been in the hands of Mr. J. Gammie, and to his great practical skill under the scientific direction of the Superintendent of the Botanical Gardens, the rapid development of these plantations is mainly attributable. At the present time the total number of cinchona trees growing is in round numbers 3,000,000, covering a total area of about 1900 acres.

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, Feb. 6, 1878.

† The history of cinchona cultivation in Madras and Bengal has been admirably told by Dr. King in his 'Manual of Cinchona Cultivation' published by the Indian Government, from which I have taken these dates.

The earliest species of cinchona placed under cultivation at Rungbee were the *Pahudiana*, *Officinalis*, *Micrantha*, *Succirubra* and *Calisaya*. The bark of the *Pahudiana* was ultimately proved to be comparatively worthless, and the cultivation of this species therefore has been long since abandoned. The *Officinalis* was well known to furnish one of the most valuable quinine yielding barks, and its propagation was carried on vigorously for some time, but the result showed that the plant would not thrive under the climatic conditions of Sikkim. Experiments were also tried with some plants of *C. Pitayensis*, but failed, and attempts at the cultivation of both these species had to be discontinued. The *Micrantha* species and its allies yielded a bark rich only in cinchonine, which is certainly the cheapest and reputedly the least efficacious of the cinchona alkaloids. There was no sufficient inducement therefore to extend its cultivation.

The *Succirubra* has been deemed a really useful species, and its cultivation in Sikkim has proved a decided success. It is hardy, growing well under a sufficiently wide range of conditions, it seeds freely, and from its little disposition to run into varieties, it can be easily propagated. Thus the extension of succirubra in Sikkim has gone on rapidly.

Cinchona Calisaya, from its yielding a bark rich in quinine and containing but a small proportion of other alkaloids, is undoubtedly the most valuable species for cultivation in Bengal. But it grows under more limited conditions than succirubra, is more difficult to propagate, and has therefore not made anything like the same progress. Unlike succirubra it displays a great tendency to furnish a number of varieties, and these do not yield bark of equal value.

Analyses of the bark from six of the leading varieties in 1874 gave the following results:—

Cinchona Calisaya Varieties.	1	2	3	4	5	6
Total Alkaloid	1·6	6·1	5·57	7·1	5·75	7·4
Alkaloid soluble in Ether	0·82	5·9	5·21	6·93	5·75	7·4
Crystallized Sulphate of Quinine	None.	4·53	4·6	6·92	5·34	6·2

It is obvious that the bark from the best of these varieties would be admirably adapted for the manufacture of a pure sulphate of quinine by a simple process, and if it could be produced in sufficient quantities, all that the Government of India desire could be readily accomplished. Steady attention, therefore, is now being given, under the able direction of Dr. King and the personal superintendence of Mr. Gammie, to the propagation and extension of the good varieties of calisaya; it is too soon yet to form an opinion on the measure of success likely to be obtained, but there is reason to hope that in the hands of these highly skilled officers the difficulties of cultivation will be overcome, and that large areas of good calisayas will ultimately reward their efforts. In any case, however, several years must elapse before the bark of this species can be obtained in sufficient quantity for practical utilization on the large scale; meanwhile, therefore, the produce of *succirubra* is the only bark really available for economical application.

This species, as I have already stated, has made the most rapid progress from its hardy character and the ease with which it can be propagated.

The total number of succirubra trees growing is estimated in round numbers at 2,500,000. In the progress of cultivation a certain amount of bark was annually obtained from these by the necessary processes of pruning and thinning; and in 1875-76, in addition to that got by such means, a crop of bark was taken by cutting down and stripping a large number of trees. The following table shows the total amount of dry succirubra bark yielded by these plantations up to the end of March, 1876:—

		lbs.
Collected by pruning and thinning during	1869-70—	2,400
,, ,, ,,	1870-71—	12,500
,, ,, ,,	1871-72—	39,000
,, ,, ,,	1872-73—	*nil.*
,, ,, ,,	1873-74—	16,000
,, ,, ,,	1874-75—	39,405
Crop of 1875-76	—	211,931
	Total—	321,236

During the end of 1874 and the beginning of 1875, a number of experiments were conducted with a view of determining somewhat accurately the amount of succirubra bark that could be annually harvested without injuring the plantations. For this purpose a large number of trees of different ages were cut down, and the bark stripped from each separately weighed in the green state. Every precaution was taken that the trees selected should fairly represent the whole. The results are given in detail in the Quinologist's report, May 24, 1875, from which I will simply extract the following table:—

AVERAGE WEIGHT OF DRY BARK PER TREE, AT DIFFERENT AGES.

	Bark peeled from stem and large branches	Bark scraped from small branches.	Total.
Trees planted in 1866	2·52 lbs.	0·41 lbs.	2·93 lbs.
,, ,, 1866	2·06 ,,	0·38 ,,	2·44 ,,
,, ,, 1867	2·27 ,,	0·33 ,,	2·60 ,,
,, ,, 1868	1·05 ,,	0·34 ,,	1·39 ,,
,, ,, 1869	1·01 ,,	0·33 ,,	1·34 ,,
,, ,, 1870	0·92 ,,	0·39 ,,	1·31 ,,
,, ,, 1871	0·34 ,,	0·12 ,,	0·46 ,,
,, ,, 1872	0·26 ,,	0.12 ,,	0·38 ,,

The bark of the roots was not taken in these experiments. This table shows, therefore, the *average* weight of dry stem and branch bark yielded per tree of each successive year's planting; but this average includes a very wide range. Thus, taking the trees of 1866 at Rishap (of which 389 were cut for experiment), 2·32 per cent. yielded from 5 to 6 lbs. of peeled bark each; 41·9 per cent. yielded from $1\frac{1}{2}$ to $2\frac{1}{2}$ lbs. each; and 12·85 per cent. furnished only 6 to 12 ounces each. It should be remembered that a small addition has to be made to these figures for the amount of bark that has been already taken from trees of seven or eight years' growth, by occasional pruning. This probably does not exceed 2 or 3 ounces per tree. From the data thus collected, after making liberal allowances in different directions, it was estimated that if all the trees were regularly cut at the completion of their seventh or eighth year (a corresponding proportion being at the same time planted out), an annual crop of 366,000 lbs. of bark could be safely taken without diminishing the permanent value of the plantation. Some independent observations since made by Dr. King, in a different manner, have corroborated these results.

The bark crop has been hitherto taken either by coppicing or by the entire uprooting of the trees. In the latter case, the bark of the root is obtained as well as that of the stem and branches, with the further advantage that by the digging up of the roots the ground is very thoroughly broken and turned over, thereby probably rendering it more suitable for fresh planting. In coppicing, the trees are cut down pretty close to the ground, when new shoots are thrown up from the old roots, and under suitable treatment, these ultimately thicken into good stems. Much of course has yet to be learnt respecting the relative economy of these methods, and both admit of several variations. Many years must probably elapse before the most advantageous plan of harvesting is decisively known.

The quality of the succirubra bark thus obtainable has also been made the subject of considerable investigation, of which I can only indicate the general result. Samples of bark taken from the lower part of the stems of the finest trees of different ages have yielded the following percentages of total alkaloids:—

		Total Alkaloid.
No. 1 trees planted in	1866 . .	6·7 per cent.
,, 2 ,,	1867 . .	7·3 ,,
,, 3 ,,	1868 . .	6·8 ,,
,, 4 ,,	1869 . .	6·6 ,,
,, 5 ,,	1870 . .	6·6 ,,
,, 6 ,,	1871 . .	6·0 ,,
,, 7 ,,	1872 . .	7·7 ,,

The total alkaloid from Nos. 1, 6 and 7 of these, yielded the following products:—

From 100 parts of Dry Bark:—	No. 1 (1866)	No. 6 (1871)	No. 7 (1872)
Total Alkaloid	6 7	6·04	7·68
Alkaloid Soluble in Ether . . .	2·4	2·73	2 17
Cinchonidine	1·9	1·99	2·95
Cinchonine	2·4	1·31	2·56
Crystallized Sulphate of Quinine	1·3	1·35	0·82

Experiment, however, has shown that the proportion of total alkaloid is greatest in the bark of the root, and diminishes as we go up the stem to the branches. The composition of the total alkaloid also varies appreciably, according to the part of the tree from which the bark is taken. Our observations on these points closely confirm some results recently published by Mr. David Howard in the Journal, and I need not therefore dwell further upon them. It follows from such observations, however, that we cannot expect the entire bark crop to furnish the amounts of alkaloids just given. Numerous analyses of samples taken from bark actually harvested indicate that the average yield of the plantations contains from 4 to 5 per cent. of total alkaloids the average composition of which may be represented as follows:—

Quinine	16·31
Cinchonidine	30·53
Cinchonine	35·26
Amorphous Alkaloid	17·90
	100·00

From all the facts that have been thus collected then it results that these plantations are now capable of annually yielding 366,000 lbs. of dry succirubra bark containing an average of 4 per cent. of total alkaloid.

The Government of India having determined to employ this bark in the preparation of a cheap medicine for the use of the fever-stricken population, experiments on a large scale have been in progress for the past three years to determine the best and most economical form of febrifuge obtainable from it. It is seen that the bark of succirubra yields several different alkaloids in nearly equal proportions. It has been clearly proved that all the cinchona alkaloids possess, in a greater or less degree the febrifugal properties of quinine. It was reasonable to infer, therefore, that if the alkaloids of succirubra were extracted as a whole and issued in some convenient form, they would be likely to constitute a valuable and efficient remedy. It was obvious that if such an aggregate of alkaloids possessed anything like the febrifugal powers of quinine it would be the most economical product obtainable from the bark in hand. A similar preparation had been for some time made in Madras from the surplus bark of the Nilghiri plantations, but, chiefly from causes dependent on the process adopted for its production, it had not been deemed economical or convenient, and the manufacture had been stopped. In presence of this experience it will be understood that a fresh attempt in the same direction was not made without mature deliberation based on a considerable series of experiments. But it was found that by employing an entirely different mode of procedure, more convenient physical properties could be given to the product with less cost in manufacture. Without entering into details, I may at once state that the general nature of the process provisionally adopted is to exhaust the dry bark by successive treatment with dilute hydrochloric acid and to precipitate the resulting liquor with an excess of caustic soda. The precipitated alkaloids are collected on filters, washed, dried and powdered. This product is then dissolved in a quantity of acid just sufficient to take up the alkaloids, filtered from some insoluble colouring matter, and the solution again precipitated. After washing, drying, and grinding, a fine white powder is obtained, which, however, acquires a slight buff tint by keeping. It never agglutinates in any way, even in the trying climate of India. It is freely soluble in weak acids, and is readily taken up by lemon juice, which constitutes a pleasant vehicle for its administration.

This preparation, under the name of "cinchona febrifuge," was first issued to the hospitals of Calcutta for trial, and a considerable quantity was also sent to Burdwan. The reports received from Drs. Chevers, Ewart, Bird, and French clearly showed that in their opinion it possesses to very nearly the same extent the antiperiodic properties of quinine, and might be safely substituted for the latter in the treatment of ordinary fever and ague. Since then it has been extensively distributed among the medical officers of Bengal, and a preponderating mass of testimony in its favour has been received. But, as must necessarily happen in such cases, adverse opinions have been also expressed. These in some cases have clearly arisen from misapprehension or want of pharmaceutical knowledge. Some of the objections that have been urged against it, however, are now under investigation, and experiments are still in progress for the purpose of determining whether these alleged objectionable qualities are really dependent on the composition of the product or are attributable to the methods of administration. I believe it is now the general opinion of those who have used it largely that it should not be given in larger doses than would be administered of quinine. The Surgeon-General of Bengal, after a long and careful examination of the medical reports on its efficacy, has declared it to be a valuable efficient febrifuge, and has ordered it to be used in all the Government hospitals and dispensaries under his control. About 5000 lbs. have been already made and issued; it is now being manufactured at the rate of 4000 lbs. a year, but the current demand is rapidly overtaking this scale of production, and a further extension will soon be necessary. As yet only temporary means are employed in its manufacture, and the full measure of economy has therefore not been attained. Its cost price at the present time is one rupee per ounce (1*s.* 9*d.*).

In forming an opinion of the value of this preparation it should be regarded as a pharmaceutical preparation rather than as a chemical product. It contains all the required medicinal properties of the crude drug in a concentrated and convenient form for administration. The attainment of this object is, as I understand it, the true aim of pharmacy. The cinchona febrifuge is not intended to be a substitute for quinine but a supplement to it. Pure quinine is undoubtedly the best known, and, for that reason, the most trustworthy specific against fever. But quinine is simply unattainable in quantities sufficient to alleviate a tithe of the suffering that results from fever in India.

On this point I would quote the following words from Dr. King:—"It is probable that for very severe and critical cases of malarious fever, especially amongst Europeans, sulphate of quinine will long remain in the estimation of the medical profession the best remedy; but every one who has had much experience of India knows that bad cases of fever are more the exception than the rule, and that there is simply an incalculable amount of fever prevalent amongst the natives of the country which rarely takes the form of a violent or fatal attack, but which expends itself in a succession of attacks, each sufficient to incapacitate the sufferer from work for a time, and a repetition of which too often ultimately induces malarious cachexia and disease of the spleen. There appears to be ample medical evidence for believing that, for malarious fever of this ordinary type, the 'cinchona febrifuge' is a most efficient remedy. Everybody who knows much of rural life in this country must also be aware that at present the great majority of such attacks of fever receive no medical treatment whatever, or at least none of an efficient kind, and for the simple reason that no febrifuge is accessible to the sufferers. Quinine is a costly drug, quite beyond the means of a large proportion of the population. Moreover it is not to be had except at dispensaries and in large bazaars in neighbourhoods where Europeans happen to be settled. It is no exaggeration whatever to say that, to three-fourths of the population of India, quinine is simply unobtainable even by purchase."

I have already shown that our efforts are being directed to the extension of calisaya with a view to provide a more abundant supply of this alkaloid. In the meantime, from 10,000 to 12,000 lbs. of the succirubra febrifuge can be annually issued, which there is every reason to believe is quite powerful enough to arrest the ordinary fever and ague of the country.

[*The discussion on this paper is printed at p.* 638.]

A SPURIOUS BALSAM OF TOLU.*

BY W. A. H. NAYLOR.

A few months ago Mr. Holmes had sent to him a viscid resinous-looking body, accompanied by a note. This communication explained that the sample forwarded had been supplied by a wholesale firm as balsam of tolu. The purchaser suspecting it was not genuine, wrote to the firm to apprise them of their mistake, when to his great astonishment he received a reply assuring him that the article referred to was genuine balsam. At first, a study of the physical characters of this suspected balsam alone was made, but as these afforded no clue to its recognition, a chemical examination was deemed a necessary supplement. For this purpose it was handed over to me, and having pursued the inquiry to a fixed point I now submit the results. This spurious balsam when seen in bulk is yellowish-brown in colour; in thin layers it is perfectly transparent and of a golden yellow. It is extremely viscid, in this respect bearing some resemblance to bird-lime, from which, however, it differs in not possessing the properties of caoutchouc. By keeping it hardens but little, and does not become brittle when exposed for some days to a temperature of 100° C. Its odour is not balsamic but reminds one rather of glue, and becomes more strongly developed upon warming. Its taste is not perceptible at first, but when chewed a few seconds, it produces a sensation of warmth and acridity. A thin layer examined under the microscope after it had been exposed for three or four hours to a temperature of 90° C., showed no crystalline matter after standing some time. It is completely soluble in carbon bisulphide, benzol, chloroform, and ether; glacial acetic acid and potash solution act as partial solvents. Boiling alcohol of 90 per cent. dissolves it entirely, but the solution deposits upon cooling. The ethereal and alcoholic solutions have a distinctly acid reaction. The balsam melts at 58° C. Strong hydrochloric and nitric acids produce no apparent effect upon it in the cold; strong sulphuric acid develops a cherry-red colour. When treated repeatedly with boiling water, filtered while hot, the filtrate remained clear, had a neutral reaction, and when evaporated left no residue.

Distilled with a mixture of bichromate of potash and sulphuric acid, no oily liquid passed over, and no odour of bitter almonds was evolved. It contains no constituents volatile at a temperature of 160° C. Boiled for some hours with a strong solution of caustic potash it saponifies. If the soap is salted out repeatedly until free from excess of alkali, then decomposed by sulphuric acid, no oil globules can be seen, nor does the separated resin leave a grease spot when applied to bibulous paper. If it is shaken up with weak ammonia solution, filtered, and the filtrate slightly acidified with dilute sulphuric acid, a light pink colour quickly develops. If potash is used in place of ammonia, or free dilute acid alone, the colour is not produced. In this particular it corresponds with balsam of tolu, but it differs in that no colour is developed in the true balsam, if it is first well washed with hot water. Digested for two days in weak spirit, the clear liquor removed by a pipette, the insoluble portion kneaded, then treated with hot alcohol and exposed in a cool place for twenty-four hours; the deposit examined under the microscope, presented no crystalline appearance. These are conditions under which colophony readily assumes the crystalline condition. The absence of organic acids, volatile and fixed oils, together with the difficulty of effecting crystallization, suggested the advisability of attempting a separation of the resins, provided the body was not a simple one. A few preliminary experiments with weak potash solution, spirituous solutions of acetate of lead and copper, sufficed to show the complex character of the resin and to indicate a probable method of fractionation. That acid and indifferent resins were both present was ascertained by kneading with a glass rod a portion of the balsam with weak ammonia solution, adding repeated solutions of chloride of sodium, and filtering; the filtrate, when acidified with an acid, became turbid through the separation of resin particles, the alcoholic solution of which had a distinctly acid reaction. This mode of separating the acid from the indifferent resins was not followed on account of the inconveniently large quantity of chloride of sodium solution required to precipitate completely the neutral resins. Filtration without the salting process was impracticable—so perfect an emulsion was formed, that after standing three days there were no signs of a deposit. To effect this separation, advantage was taken of the solubility of the lead compound of the acid resins in cold alcohol of 90 per cent. From this solution, the mixture of acids was obtained in a free condition by decomposition with sulphuretted hydrogen. The mixture of acid resins thus obtained was precipitated by a spirituous solution of acetate of copper, the copper compound decomposed by sulphuretted hydrogen, filtered, and half the quantity of copper acetate solution necessary for complete precipitation added to the filtrate. It was allowed to stand, filtered, and the remainder of the copper acetate solution added to the filtrate. The respective compounds were decomposed by sulphuretted hydrogen, their solutions evaporated, and the melting points of the corresponding resins ascertained. The indifferent resins were fractionated in a similar manner. Operating in this way until accordant results were obtained, two acid resins were separated, one melting at 55° C.; the melting point of the other could not be accurately determined, on account of its want of uniformity. In addition to these an indifferent resin separated melting at 63° C. None of the fractions separated emitted a terebinthinate odour when warmed. The portion of balsam insoluble in cold alcohol was too small in quantity to admit of further examination.

Every attempt was made to identify this spurious balsam, by comparing it with resinous bodies known to be employed in medicine or the arts, but without success. That it is not a commixture of two or more resinous substances, artificially prepared, may be inferred from its uniform behaviour towards solvents, the persistent and unchangeable character of its odour when heated, and the constancy of the melting points of the fractions. That it is not balsam of tolu is certain. The author therefore ventures to suggest the probability that this substance is a natural product of new importation, and not a tampered or manufactured article.

The circumstances under which this spurious balsam was vended are such as may occur again; to caution pharmacists, therefore, against making a false purchase, as well as to supply means of distinguishing between the genuine and a substitute, is the object of this note. I cannot conclude without expressing my obligations to Messrs. Corbyn, Stacey and Co., in whose laboratory this examination has been made.

THE PRELIMINARY EXAMINATION.

WE have for some time past entertained the belief that any one who reads through the questions put to candidates presenting themselves for the Preliminary examination might reasonably be expected to recognize an absence of anything that could be regarded as superfluous and calling for a higher degree of scholastic teaching than is consistent with very moderate views as to the requisite qualifications of a youth entering upon the business of a pharmacist. The recent transfer of the conduct of the Preliminary examination to the College of Preceptors has also contributed to strengthen this belief; for since the subjects dealt with are essentially scholastic, it may fairly be inferred that those who are actively and habitually engaged with scholastic duties would be better fitted to conduct the examination than persons who had not that opportunity of appreciating the acquirements of school boys and making due allowance for their deficiences.

To judge, however, from some letters we have received in reference to the failures in the Preliminary examination, it appears that in some quarters very different views prevail. One of our correspondents, referring to the preponderance of failures, expresses his "astonishment that this state of matters should have so long been allowed to exist, without any apparent remedy being attempted," and though he does not advocate a lowering of the standard, he suggests that the Pharmaceutical Society might institute a system of classes specially preparatory for the examination, at least in the more important, if not in all, the centres where it is held.

Another correspondent, referring to the fact that out of 313 candidates who presented themselves at the last examination, 192 failed to pass, goes so far as to ask whether the examination has been a fair and honest one, whether the papers have been judged on their general merits, or whether some catch question has been the rule and guide of one or more of the examiners. He also expresses the opinion that many will incline to this latter view, and he candidly confesses himself to be among the number.

This subject was brought before the Council last Wednesday, and some facts were elicited which, together with a consideration of the questions* put at the examination referred to, will enable our readers to judge how far there is any foundation for the opinions expressed in the letters above-quoted from, and whether there is any adequate reason for regarding the number of rejections as being an injury to the trade or even a hardship to the rejected candidates.

It appears from the data furnished by the Secretary, that out of the 192 who failed, 41 did not obtain the pass number in Latin, 101 failed in English, and 167 failed in arithmetic, while 23 of these latter did not obtain a single mark in that subject. Since the failures in the Preliminary examination have been lately made a ground of remonstrance by the Glasgow Association, it will not be out of place to mention that out of 42 candidates in Scotland, not less than 31 failed to pass the Preliminary examination, and as pointed out by the President, the deficiences in regard to arithmetic were even greater in the North than in the South. This result is nothing exceptional, for it appears from the examination report for October, 1876, that on that occasion the report of the examiner stated that the Latin translation was moderate, the grammar generally pretty good, the English satisfactory, and the spelling correct, while in arithmetic there was more deficiency.

As regards the questions, it can scarcely be contended that they furnish any justification for the idea that they are in any way extraordinary, or that the examination is so strict as to create any difficulty in securing desirable apprentices, neither can we conceive that there is any room for the suspicion of unfairness in judging the candidates' papers. On the contrary, the only reasonable and even possible inference seems to be that the rejected candidates did not possess that moderate acquaintance with their own language, and with the simple rules of arithmetic, which is demanded by even the most modest estimate of a pharmaceutical pupil's qualifications. We are inclined therefore to regard these rejections —however much they may be regretted for the sake of the individuals—as operating to the advantage of the general body rather than the reverse. It is, we believe, only by the maintenance of the examination standard that the practice of taking as apprentices lads of deficient education can be done away with, and whether the failures in the Preliminary examination are due to the prevalence of this practice or to the generally defective nature of our middle class education we cannot perceive that as regards the well-being of the trade there is any reason for the lamentations which are from time to time heard on the subject.

* See before, p. 592.

A DENTAL PRACTITIONERS' BILL.

ON Wednesday week a Bill was introduced into the House of Commons by Sir JOHN LUBBOCK, and read a first time, which deals with a subject of considerable interest to many chemists and druggists, as it shadows forth an important alteration in the law relating to the practice of dentistry.

The Bill provides for the compilation and keeping of a "Register of Dentists," and restricts to persons registered the use of the title of "dentist" "dental surgeon," "dental practitioner," or any title or description implying that the person using it is specially qualified to practise dentistry, the penalty for an offence, after the 1st of August, 1879, being a fine not exceeding £20. After that date also fees for dental operations or advice are not to be recoverable except by registered persons.

The qualification for registration proposed is the licentiateship in dental surgery or dentistry of any Royal College of Surgeons in England and Wales, or of the Faculty of Physicians and Surgeons of Glasgow; or the being *bonâ fide* engaged at the time of the Act passing in the practice of dentistry, either "*separately* or in conjunction with the practice of medicine or surgery," and furnishing satisfactory evidence of the fact before the 1st of August, 1879. It may be remarked *en passant*, that the words between inverted commas, especially the first, are very ambiguous, and might be construed most disadvantageously to many who practise dentistry but do not carry it on as a separate profession or in conjunction with medicine or surgery.

Registration is to be made by local registrars appointed by the General Council of Medical Education and Registration, established under the Medical Act, 1858, and such registrars are to be empowered to demand and receive a fee not exceeding £2 in respect of the registration of any person applying before the 1st of January, 1879, and a fee not exceeding £5 in respect to the registration of any person applying after that date. The local registrars are to make the alterations and erasures necessary to keep their respective registers correct, with powers in this respect similar to those conferred upon the registrar under the Pharmacy Act, but they are promptly to transmit certified copies of all registrations, alterations and erasures to the registrar of the General Medical Council, and there is also to be a power of appeal from the decisions of the local registrars to this Council. With the assistance indicated the registrar of the Medical Council is to compile and keep a general register, to be called a "Register of Dentists," copies of which are to be printed and sold in the month of January in every year.

Other clauses of the Bill deal with the arrangements for conducting the examinations by the Royal College of Surgeons of England, Scotland, and Ireland, and the Faculty of Physicians and Surgeons in Glasgow, under the general supervision of the Medical Council, with a final reference to the Privy Council. One clause provides for the exemption of registered dentists from service upon juries, in corporate or parochial offices, or in the militia.

THE CATALOGUE OF THE MUSEUM.

As will be seen by a statement upon another page, the Council has decided that a copy of the Catalogue of the Collections in the Society's Museum shall be supplied gratis to each Member and Associate in Business who makes application for one to the Secretary.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, February 6, 1878.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atkins, Betty, Bottle, Churchill, Cracknell, Gostling, Greenish, Hampson, Hanbury, Hills, Owen, Rimmington, Robbins, Sandford, Schacht and Shaw.

The minutes of the previous meeting were read and confirmed.

Mr. HAMPSON asked leave to put a question, with regard to the report of the proceedings of the last Council meeting. If he remembered rightly, the Council was in Committee when a communication from the Solicitor of the Apothecaries' Company was read, and it was clearly understood that no report should be made of what took place. He was therefore astonished to find not only a statement of what had taken place, giving the views of the Apothecaries' Company, but also a paragraph in the *résumé* of the year, by the editor, dealing with the same subject. He was much disappointed at this, which he thought showed a weakness in the system of reporting. It was evident that either there was some error in the filtration of the report, and that some foreign matter had crept in, or some one had injudiciously broken the medium of filtration. He thought it very undesirable when the Council was in Committee that its proceedings should be reported.

The PRESIDENT was very sorry Mr. Hampson had raised this question, but he must say he (the President) was entirely responsible for what had taken place. The report, as it came from the reporter, contained no allusion to the business before the Committee, but he thought it so outrageous a thing to send out a professed report of the meeting of the Council, and leave out all allusion to the most important matter which had come before it, that he took upon himself, though not without consultation with others, to insert the paragraph now complained of. He did not consider, although the Council was in Committee, that it followed the business before the Committee could not be mentioned, or a statement made of what the Council was doing. The question was a most interesting one to all the trade, and he did not think the report of the Council meeting ought to have gone forth containing no reference to it. He did not consider the paragraph inserted was any breach of confidence, and he was astonished to find that gentlemen who generally were in favour of the utmost publicity should take exception to what he considered a step in the right direction, for he, personally, should like the reports of the Council meetings to be much fuller than they usually were.

Mr. HAMPSON said the President's explanation was very clear, but he altogether took exception to any person amending the report.

The PRESIDENT said he could hardly be considered in his official capacity "any person." He considered it his duty, when he found a report to be inaccurate to set it right.

Mr. HAMPSON begged to call the attention of the President to the fact that there was a discussion as to whether any report should appear, and it was distinctly understood by the Council that for the present the information should remain with themselves. He thought it a mistake to publish that report for this special reason, that if any report were given the means by which the Council had arrived at that position should also be stated.

The PRESIDENT said anything like a detailed report would have been a breach of privilege, but he did not consider any had been committed.

Mr. SANDFORD could not help thinking that Mr. Hampson had rather over-stated the understanding, for there was no resolution of the Council not to publish anything with regard to the interview referred to. The Council was in Committee, and of course the proceedings could not be reported, but the real question considered, and decided in the negative, was whether Mr. Upton's letter should be published, and he remembered that at the close of the meeting Mr. Hampson requested to have a copy of it, to communicate to the Chemists and Druggists' Trade Association. The objection to that was that the Council could not, having agreed not to publish the letter, give a copy of it for the use of another society, but it was distinctly understood that there would be no objection whatever to any member of the Council giving a summary of that letter to his friends outside. He therefore thought the President had done quite right.

The VICE-PRESIDENT said a certain amount of discretion ought to be placed in the hands of the President. At the same time he could not lose sight of the fact that it was thought undesirable to publish the communication, inasmuch as it was scarcely official, being only a report of a Committee.

Mr. BETTY thought, with all due respect to the President, that it was unfortunate that this notice of the Council proceedings had been published in the semi-official way in which it had been done. There was no need for the members of the Council to exculpate themselves before their constituents, since no accusation had been made against them, and he thought the matter might have stood over for another month, when they could have stated what the letter actually contained. It was a precedent which he hoped would be followed with great caution. He did not quite agree that the main point of discussion was whether Mr. Upton's letter should be published, his impression being that the question was whether the proceedings should be published at all.

The PRESIDENT said he had done what he did with due deliberation, and he should certainly do the same again.

Mr. SCHACHT not having been present at the last meeting was not in a position to argue the whole matter, but he must say that at the December meeting, although the proceedings were in Committee there was a distinct resolution carried that there should be a notice in the report conveying to the outside world that this subject was being thoroughly handled by the Council. He could not help thinking therefore that the President was acting in accordance with the spirit of the resolution passed in December.

Mr. SHAW agreed with Mr. Schacht, and could not see any substantial difference between the report of the December meeting and that of the January. He thought some discretion should be left with the President in such matters.

Mr. HILLS felt much obliged to the President, who had acted, in his opinion, quite correctly.

Mr. BOTTLE also said he felt much indebted to the President for having conveyed the information. Not having been present at the last meeting, he should have been much disappointed if he had not seen that the subject had been receiving attention. He was utterly at a loss to see how members of Council could reconcile to themselves the privilege of taking away memoranda for the use of other societies, and yet say that the members of this Society were not to know what was going on.

Mr. OWEN agreed with Mr. Bottle.

Mr. ROBBINS also approved of the report which had been issued.

Mr. GOSTLING thought the paragraph was perfectly in harmony with the resolution come to at the previous meeting.

Mr. ATKINS had no doubt that if the President required a vote of confidence, it would be cheerfully passed. It was very desirable that those who could not attend the Board should see as full a report of the proceedings as possible.

Mr. HAMPSON wished to explain that any information he had ever obtained was always considered to be given, and was always used, confidentially, and he did not see therefore that the remarks which had been made were at all called for. He disavowed any personal feeling in the matter, and was anxious to have the best possible report of the proceedings, but he thought it should come from the reporter and not from the President.

The PRESIDENT said he could not quite take that view.

The subject then dropped.

MEMBERS OF COUNCIL WHO RETIRE.

The lot being taken in the usual manner for the seven members of the Council who should retire in May next, the following names were drawn :—

Atherton	Gostling	Hampson
Betty	Greenish	Williams
Brown		

The following who remained in by lot last year now retire by rotation :—

Atkins	Owen	Savage
Hills	Sandford	Schacht
Mackay		

The following remain in office for another year :—

Bottle	Hanbury	Robbins
Churchill	Rimmington	Shaw
Cracknell		

ELECTIONS.

MEMBERS.

Chemists and Druggists.

Brownridge, Peter Fallows......Openshaw.
Eagle, John ....London.
Van, Frederick W. Stephen ...Barking.

ASSOCIATES IN BUSINESS.

The following having passed their respective examinations, being in business on their own account and having tendered their subscriptions for the current year were elected "Associates in Business" of the Society.

Minor.

Allis, William ....Alford.
Baker, Matthias ....Nuneaton.
Bate, Joseph William ....Walsall.
Cumine, Rupert Henry ....Farningham.
Davies, Thomas Morris ....Rhyl.
Evans, Richard.......................Liverpool.
Lakeman, Jasper James ....Leytonstone.
Lakeman, Stephen ....Chertsey.
Loggin, Chas. Frederick, jun.Stratford-upon-Avon.
Marshall, George Thomas ... ..Morpeth.
Peacock, Percy... ....Poplar.
Schofield, Frederick Elston......Morpeth.
Shepherd, John William.........Settle.
Smith, Arthur John.......... ...Taunton.
Strawson, George ....Bishop's Castle.
Walker, George ....Dewsbury.
Yates, Ebenezer ....Swinton.

Modified.

Brodie, Robert ....Glasgow.
Chapman, Henry ....Scarborough.
Holmes, Frederick George ......Brill.
Macfarlane, James ....Glasgow.

ASSOCIATES.

The following having passed their respective examinations and tendered their subscriptions for the current year were elected "Associates" of the Society:—

Minor.

Austin, Josiah ....Birmingham.
Bathe, William.......................Chippenham.
Bowden, Thomas Lemon ......Barnstaple.
Eardley, James Furnival ......Manchester.
Heywood, John Henry ....Lincoln.
Johnson, Samuel ....Barnard Castle.
Lacey, James ....Clifton.
Lister, Charles Edward ....Manchester.

Wimpenny, John McMillan ...Waterloo.
Young, Edward Herbert... .....Tring.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The name of Robert Jones, of 3, Turf Square, Carnarvon, was restored to the Register of Chemists and Druggists.

The REGISTRAR presented the report of the state of the Society, and drew attention to the decrease in the number of members, both pharmaceutical chemists and chemists and druggists. This report is printed on pages 630 and 631.

The VICE PRESIDENT said great thanks were due to the Registrar for the able and clear manner in which he had presented the figures. He could not help noticing the contrast between the percentage of failures in the Minor examination in England and that in Scotland, being 48 per cent. in England and only 25 in Scotland.

Mr. HILLS asked if the Secretary could say how many of the chemists and druggists on the register had passed an examination. The total number was 11,013.

The SECRETARY could not give the exact figures, but the numbers were about 3400 examined and nearly 7800 not examined.

Mr. GREENISH wished to draw attention to the point already alluded to by the Vice-President. In the Major examination the percentage of failures was 46·8 in England and 25·0 in Scotland; in the Minor, 48·19 in England, 25·53 in Scotland; in the Modified they were very nearly alike. This seemed to show that there must be very important differences in the examinations. He had on more than one occasion requested that the Council should have a report from the examiners stating in what subjects young men were most generally deficient. There was probably one or more subjects in which the majority failed; he believed it was botany. No doubt the information could be got from the office, but it would not be so satisfactory as if it came from the examiners, because many candidates were sent away for having failed hopelessly in one or two subjects.

The PRESIDENT reminded the Council that it had agreed to send a deputation from the Board of Examiners to attend the examination at Edinburgh this month. The member of that deputation would no doubt consult with their colleagues as to the reason for this large discrepancy, and arrive at some understanding.

Mr. HAMPSON said the Council was responsible for the examinations, and he thought it could scarcely allow statistics of this character to pass without observation. There was a marked difference in the percentage of failures; it might be that the Scotch Board was not strict enough, or that the English Board was too strict;

but whichever it was there ought to be a greater similarity in the average attained.

PRELIMINARY EXAMINATION.

Mr. GREENISH wished to draw attention to the last Preliminary examination, where 192 failed out of 313. The questions were very simple, and he could not help thinking that a lad taken from one of the national schools would answer the questions in arithmetic in the January examination paper, but he understood that this was a subject in which a very large number of failures took place. It appeared to show that middle class education was grossly deficient. He had mentioned to the Secretary his intention to refer to this question, and he would now ask whether any information could be given as to the number of cases under each subject in which the unsuccessful candidates failed to obtain the requisite number of marks at the Preliminary examination held last month.

The SECRETARY said he had ascertained the following details with regard to the Preliminary examination:—The total number of failures was 192; in Latin 41 failed to obtain the pass number; in arithmetic 167 failed; and in English 101. It was to be remarked that of the 167 who failed to obtain the pass number in arithmetic 23 did not obtain a single mark in that subject.

The PRESIDENT added that the answers which came from the north were more deficient in regard to arithmetic than those which came from the south.

Mr. GREENISH asked if the same details could not be given with regard to the other examinations as were given in the case of the Preliminary.

The PRESIDENT said it was a very different thing with the other examinations, and it could not be done unless the examiners could be compelled to test each candidate in all subjects and find out where he failed, whereas the practice was that where a man failed hopelessly in one subject in examination was not further proceeded with.

Mr. OWEN thought that was hardly fair, as young men were nervous when they first came forward, and they became more self possessed afterwards.

Mr. SHAW wished to ask what proportion of those who passed the Major examination had become united with the Society during the past year. This was important, seeing that the Council and the Board of Examiners must in future be composed of pharmaceutical chemists.

The PRESIDENT said, during the past year 53 had passed the Major examination and 56 members had been elected.

Mr. SHAW said in 1875 there were 1248 examined pharmaceutical chemists members; in 1876, 1281; being an increase of 33. He wished to know what was the increase during the past year.

The PRESIDENT said when a member was elected no inquiry was made as to whether he had passed this examination during the same year.

Mr. ATKINS was glad the question had been asked with regard to the Preliminary examinations, and suggested that the weak points might be published. The Council wanted to be able to inform the educating body what were the special points in which failure took place. As a member of the local committee for the university local examinations, he might say that at Salisbury they had made a great point of getting at that information, and found that in the case of girls especially the weak point was arithmetic. One of the examiners, however, a fellow of a college at Cambridge, had most generously endeavoured to repair that special weakness by giving instruction in one or two schools in arithmetic, and at the last examination those schools which he had assisted passed a large number of girls successfully in this subject. Another remark to be made was that 23 candidates had failed to obtain any marks whatever in arithmetic. Now he had frequently found, as a superintendent, that a young man would select out of his subjects those he knew something about and reserve the others till the last, and would sometimes actually drive himself up to the last moment and have no time left in which to deal with them. He always cautioned candidates before beginning to look at the work to see how many subjects there were and how long it would take them to do each. On the last occasion on which he gave that advice he found that at five minutes before the expiration of the time allowed one candidate had not done a single line of his English essay. Whether the candidate failed to pass on that account he could not, of course, say. He believed a great many failed in arithmetic because they presented themselves at, perhaps, the age of nineteen, when they had forgotten the technicalities which were familiar to them on leaving school.

The PRESIDENT said a great deal depended on the superintendents, and if they paid more attention to their duties no doubt the examinations would go on much better.

Mr. SCHACHT said the observations of Mr. Atkins showed what difficulties surrounded this subject. Mr. Greenish had said that this large number of failures pointed to an imperfect system of middle class education, but he could not help thinking that although chemists and druggists desired to get their apprentices from the middle classes, in very many instances apprentices were obtained from a lower class. He knew of cases where boys who almost might be called charity boys were introduced into the business, and, of course, such attempts must result in failure. He had always felt greatly interested in these examinations, and might mention in reference to a suggestion he had heard that copying might take place, that such an idea must be very cautiously admitted from an apparent similarity of answers. He well remembered a lot of papers being put into his own hands when it was supposed that the candidates must have copied from one another, as the same phrase occurred in a great many papers; but he happened to know that it was not so; that it was simply the result of a favourite phrase of the teacher, which had impressed itself on the minds of several of the candidates, and the same words were used in many of the papers because one of the questions happened to touch upon a subject about which the teacher had used his favourite phrase.

Mr. CRACKNELL said he was surprised at the result of the last examination, especially as the questions on the whole were easier than they were formerly. It only showed the necessity for the Preliminary examination. He should like to know something about the age of the candidates, and whether they were apprenticed.

The SECRETARY said they were mostly young men; he thought the average age would be about seventeen. He could not say whether they were apprentices or not.

Mr. CRACKNELL said it would be very desirable if the Council could prevent apprentices being taken until they had passed the Preliminary examination.

Mr. RIMMINGTON could quite confirm the complaints Mr. Schacht had made about apprentices being taken from the lower stratum of the middle class. In all large towns there were a great number of small chemists who were unable to pay assistants or to get apprentices from the respectable middle class, consequently they took youths who were both unfitted for the business and imperfectly educated, and they had to cram up as well as they could to try and get through the examinations. He did not see how the Council could remedy this, because it could not say a man should not take an apprentice if his parents were willing.

Mr. ATKINS was very glad this matter had been mentioned. There were no doubt a number of lads being apprenticed whom it was positively cruel to introduce into the business considering the examinations which had to be passed. He believed it arose in great measure from

THE REGISTERS OF PHARMACEUTICAL CHEMISTS AND CHEMISTS AND DRUGGISTS, 1877.

Additions during the year:—	
Number of persons who have passed the Modified Examination	15
Minor „	299
Major „ 53*	
Number of persons registered on payment of the Registration Fee, having been in business before August 1, 1868........	34
Number of persons restored to the Register on payment of a fine	22
Placed on the Register by virtue of restoration to membership—Pharmaceutical Chemists	3
An Associate of the Society before July 1842, restored	1
An Associate of the Society before July 1842, restored and elected a Member—Pharmaceutical Chemist	1
	375

* These having already been included in the number who passed the Minor, do not increase the numbers on the Register.

Erasures during the year:—	
Deaths:—	
Notices from Registrars	173
Other sources	57
Erased at the request of registered persons themselves........	2
Erased by order of the Council	1
Increase of numbers on the Register	**142**
	375

Number of Pharmaceutical Chemists on the Register, December 31st, 1877	2,307	
„ „ Chemists and Druggists	11,013	
		13,320

the custom now growing up of taking outdoor apprentices, because when this was the case the chemist not only took less premium, but the apprentice did not associate with the family, and therefore the master was not so particular as to his social standing. He hoped that would be deprecated as far as possible; at the same time he felt that the mischief lay rather in another direction, that in middle class education they had no test of what results were got for the money spent. Mr. Lowe had introduced the celebrated phrase "payment by results;" but in middle class society there were very large sums paid for education as to which no test whatever was applied.

Mr. Greenish said that Mr. Schacht's remarks were no doubt important, but he must draw attention to the fact that so few failed in Latin, and comparatively few in English, whilst the great number of failures occurred in arithmetic. This went to show that the young men could not have been taken from what was called the lower stratum of society.

The President reminded Mr. Atkins that in Scotland and the North it was the almost universal practice to take outdoor apprentices, so that it would not do for the Council to attempt in any way to interfere with that practice.

Mr. Hampson said it was currently discussed, and to a certain extent credited, that the examinations held in England were too strict, and that the questions asked were sometimes of a rather extraordinary kind. He hoped therefore that the members of the deputation from the examiners in their conference with their Scottish brethren would come to something like a fair understanding on this matter.

Mr. Hills said he believed there was about the same percentage of failures in the Preliminary examinations for the College of Surgeons and for the College of Physicians and Apothecaries. Certain remarks had been made as to where the young men came from, but he was rather inclined to think that whatever stratum of society a young man came from he might make himself a gentleman and take any position. It was important that he should pass the Preliminary examination before he entered the business. If he did so, and then complied with the other regulations, he was eligible to be become President of the Society, or attain any other position.

Reports of Committees.

Finance.

The report of this Committee was read and adopted, and various accounts ordered to be paid.

Benevolent Fund.

The report of this Committee included a recommendation of the following grants :—

£15 to the widow, aged 60, of a pharmaceutical chemist, and formerly a local secretary.

£15 to the widow, aged 57, of a member.

£10 to a registered chemist and druggist, aged 68, suffering from incurable disease. Applicant had received two previous grants of £10 and £5 respectively.

£10 to the daughter of a chemist who has had ten previous grants of like amount.

£10 to a former member, in reduced circumstances to enable him to apprentice his son.

Several other cases had been before the Committee, but their further consideration had been deferred for more complete information, and in one instance the Committee had declined to recommend any grant.

The report and recommendations of the Committee were unanimously adopted.

The Secretary presented the following statement, showing the amount of annuities and of temporary assistance given from the Benevolent Fund during the past year, and who were the recipients; also a table showing the number of subscribers and donors to the Fund, and the amount contributed by each :—

A Proposed Grant to the Benevolent Fund.

Mr. Sandford then moved the resolution of which he had given notice :—

"That the sum of £500 be transferred from the General Fund to the Benevolent Fund."

He said it was some years since the Council had granted anything to the Benevolent Fund. Two months ago when £2000 was invested, he was told by some friends that the Council had no business to accumulate money, and he thought it could not do better than give £500 to the Benevolent Fund; all members and associates had the right of voting for annuitants, and therefore the Society should contribute to the maintenance of the Fund. When he first proposed this in December, Mr. Hills had promised to second the motion, but had now withdrawn, and he therefore asked if any other member of Council would second it.

Mr. Gostling said he would second the motion, as he thought it very important that the permanent fund for benevolent purposes should be increased without trenching on the annual subscriptions.

Mr. Betty suggested that any discussion on this motion should take place in Committee.

Mr. Hanbury thought it was a very important question and not desirable to be publicly discussed in the first instance. If there were any pressure on the Benevolent Fund, or inability to pay the annuitants he should then think it proper to make such a grant, but when the Fund was flourishing the proposal to transfer a large sum from the funds of the Society to the Benevolent Fund was a matter which took him by surprise, and, under the circumstances, he thought the Council would do well not to publish the discussion which might take place upon the question.

Mr. Hills thought it would be well to go into Committee on the matter.

Mr. Hampson asked for the reasons for so doing.

Mr. Betty having stated shortly the reasons why he thought it desirable to do so,

Mr. Hampson said he thought if the Council could not discuss a question on the Benevolent Fund without going into Committee things had come to a very strange pass. He thought the Benevolent Fund would stand fair discussion, and that it would be to their advantage that the members of Council should speak with such deliberation as would be necessary if they spoke openly.

The question of going into Committee was then put to the vote, and it was decided by a majority of one that the discussion should take place openly.

Mr. Bottle said he had already asked Mr. Sandford to withdraw the motion. The return now put into their hands showed that of 13,320 chemists and druggists on the Register 2189 only subscribed to the Benevolent Fund. The Secretary had just sent out a petition on behalf of the Fund, and he would ask Mr. Sandford, if he did not entirely drop this proposition to, at any rate, defer it to a later period of the year.

The Secretary said he had already received several satisfactory returns to the circular.

Mr. Robbins also feared that if this amount were given to increase the funded capital it would have a tendency to lessen the subscriptions. He would much rather keep the £500 in hand, and if the Fund at any time required it he would vote it willingly. At present the money could be used for any purpose to benefit the Society, but if once it were drafted to the Benevolent Fund it was tied up, and could be used for that one purpose only.

Mr. Hampson said he should like to satisfy himself that it was a right thing to vote £500, subscribed by members and associates, for the benefit of all chemists and druggists as well as members.

Mr. Bottle said that was quite within the power of the Council by the Act of Parliament.

Mr. Hampson thought it would be wise to withdraw the motion for the present. The Fund was not languishing, and there was every prospect that members would subscribe in the future perhaps more than in the past.

Mr. Betty appealed to Mr. Sandford not only to withdraw his motion, but not to bring it forward again. He could not help thinking that in the present state of things the Benevolent Fund was suffering from too many doctors. Two or three years ago the members of the Council had "Dr." Robbins telling the Committee that the administration of the Fund had been very injudicious from the beginning, because it had been too timid in the distribution, that it accumulated money to save the pockets of posterity. This view had been adopted by the Council; it had relied on the active benevolence of those whom it concerned; this was its guiding principle. Now a second "doctor" came forward and wished them to reverse that policy and supplement the Fund with this fictitious aid from the moneys of a public institution. One or other of these principles must be wrong. The evil would not be so much in tying up the £500 as in departing from those accepted principles of liberality and charity which were now relied upon. He must be a bold man who would jeopardize the present successful mode of carrying on the Society's benevolent operations, but if it were known that the Council entertained the idea of voting large sums of money it would remove a great incentive to charity. The Fund would be looked upon as independent of popular aid; it would be thought there was a certain power at its back to aid it in case of emergency, and this would not at all contribute to its successful operation.

Mr. Sandford said he could not accede to either of the requests which had been made. When Mr. Betty talked about a new system, he thought he could hardly remember what had taken place before, because the charter plainly stated that one of the objects of the Society was to provide a fund for the relief of distressed members, their widows and orphans.

Mr. Hampson said it did not say anything about chemists and druggists outside the Society.

Mr. Sandford said that was subsequently added by the Act of 1868, when the Council got power to relieve men who were not actually connected with the Society, and this had been a great benefit to many who were not members. He believed every one there had felt a pleasure in administering relief to those who needed, although they had not subscribed to the Society. It was not a fictitious grant in any way, and as far as the prosperity of the Fund was concerned, it always struck him that people liked to subscribe to a rich fund rather than a poor one. The Council was now voting large sums in relief, £60 that morning, and therefore funds were required. He had always held there should be enough invested capital to furnish sufficient money to pay the annuitants. He should be sorry, however, to raise any discussion which would be injurious to the Fund, and therefore he hoped the question would be put to the vote.

Mr. Betty was quite aware the Council had voted money before, but it was under totally different circumstances.

Mr. Owen hoped the members present would oppose the vote. The Benevolent Fund had never been in such a flourishing state, and therefore it would be wiser to trust to the generosity of members of the trade.

The President said he should be sorry to oppose aiding the Benevolent Fund if he thought such assistance was wise, but on this occasion he was of a different opinion. There was no doubt the Council had power to make a grant to the Benevolent Fund if it were necessary, and the time might come when it would be wise to do so, though he hoped it would not. The Fund ought to be self-supporting.

Mr. Atkins joined in the appeal to Mr. Sandford to withdraw the motion for the present. He thought the Council ought to look forward some day to the Society having premises of its own, for which a large accumulated capital would be required.

Mr. Sandford having referred to the passages in the Charter and the Act of 1868 which authorized the proposed course, a vote was taken upon the motion with the following result:—

For—Messrs. Churchill, Gostling, and Sandford.

Against—Messrs. Atkins, Betty, Bottle, Cracknell, Greenish, Hills, Hanbury, Hampson, Owen, Rimmington, Robbins, Schacht, Shaw, Savage and Williams.

The Casual Fund.

The Vice-President then moved, pursuant to notice—

"That the sum of £20 from the Benevolent Fund be placed in the hands of the Secretary for the relief of such temporary pressing claims as he may think desirable, and that he be required to produce a statement to the Committee of its disbursement."

He said it was well known that the Secretary had small amounts placed at his disposal by private members for the purpose of rendering assistance to those who were in immediate want. It occurred to him that it would be very desirable that such a sum as he proposed should be in his hands which might help to prevent the President and other members being imposed upon, as the Secretary would be more likely to take pains in inquiring into the character of applicants than private persons who had not the time or opportunity to do so.

The PRESIDENT said the subject had been discussed in Committee, and it had been considered that some small sum should be placed in the Secretary's hands from the Benevolent Fund.

Mr. SHAW raised the question of the legality of this proceeding. He understood that the Secretary gave from this casual relief fund assistance to persons who were precluded by the regulations from obtaining assistance from the Benevolent Fund direct. It appeared to him rather irregular that money should be taken from the Benevolent Fund and handed to a second party to do that which the Committee had not apparently power to do. He thought it would be more legitimate to give the money from the General Fund.

Mr. OWEN thought it very desirable that the motion should be carried.

Mr. ATKINS thought if the Council could not do this it was very absurd. The Benevolent Fund did not exist for chronic cases only.

Mr HAMPSON suggested the matter should be referred to the Committee.

Mr. GREENISH said it had been already considered by the Committee, which was unanimous in its favour.

The motion was then put to the vote, and carried unanimously.

COUNTER PRACTICE.

The Council then went into Committee to receive a communication from the Solicitor with regard to his communications with the Society of Apothecaries, and it was afterwards resolved that the following correspondence be published:—

"20, Austin Friars, London,
"1st January, 1878.

"Dear Sir,

"I placed the subject of our discussion before the Act of Parliament Committee of my Society.

"It was their intention to have referred the decision of that Committee to the full Court of the Society, which sat the same day at a later hour, but the Court was so much occupied with other business that the decision of the Act of Parliament Committee could not be brought before them.

"The communication therefore which I make to you has not that official sanction which it would have if it were a resolution of the Court of the Society, instead of the decision of a Committee formed out of that Court.

"But as that Court is constituted of all the leading members of the Society, I have no reason to doubt but that the decision which they have come to will be accepted without alteration by the Court.

"Their decision was 'That having regard to the statement laid before them by Mr. Upton, this Committee was unable to discover any case where the sanction of the Society had been given to a prosecution on a pure and simple case of counter practice and that while this Committee expresses no opinion as to whether cases of counter practice come within the Act of 1815, or whether the persons prosecuted in respect of such practice are liable to the penalty imposed by that Act (although the decided cases appear to be in favour of such practice being within the Act), it is not desirable that the sanction of the Society should be given to prosecution where counter practice is *alone* involved.'

"I think it right to add that in nearly all cases of prosecutions by the Society, there is a double offence alleged to have been committed, viz., visiting and counter practice, and that it is impossible for the Society in giving their sanction to a prosecution to limit it to *one* of the alleged offences.

"If the person who is alleged to be guilty of visiting patients is also guilty of counter practising it is impossible to withdraw the consideration of the latter question from the tribunal before which the case comes.

"Under these circumstances (subject to the official sanction of the Court to which I have above referred), it is unlikely that the Court will accept the suggestion which was made by yourself to me.

"Yours faithfully,
"(Signed) JAMES R. UPTON.

"W. Flux, Esq."

"3, East India Avenue, London,
"2nd January, 1878.

"Dear Sir,

"Referring to your letter of yesterday, will you oblige me with a line saying whether it may be regarded as a formal communication to be used without reserve?

"Or whether I am to regard and use the same to any and what extent as confidential and private?

"Sincerely yours,
"(Signed) WILLIAM FLUX.

"Jas. R. Upton, Esq."

"20, Austin Friars, London,
"2nd January, 1878.

"Dear Sir,

"In reply to your letter there is nothing private in the communication I sent you yesterday.

"Yours faithfully,
"(Signed) JAMES RICHARD UPTON.

"W. Flux, Esq."

3, East India Avenue, London,
"10th January, 1878.

"Jas. R. Upton, Esq., *Solicitor*,
"20, Austin Friars.

"Dear Sir,

"As my clients' Council Meeting took place on on the morning when your esteemed favour dated the 1st inst. arrived, time did not permit of my looking into and reporting fully to the Council upon sundry materials bearing upon the considerations suggested by the letter, therefore I submitted to the Council the letter as received and made a short oral statement that the suggestion of mine to which your concluding sentence referred was to the purport that if your clients really desired to question the legality of counter practice by chemists and druggists the matter should be openly and fairly tried in a test case to be arranged for by your clients on the one hand and my clients on the other, and conducted by the solicitors of the Societies; so that the precise point should be satisfactorily arranged for trial by my finding a respectable chemist and druggist to perform the acts of counter practice which you may think necessary for raising the point to be the subject of decision; and so also that cessation of sundry cases might result. I also mentioned having stated to you that my clients, whilst regarding counter practice as a public and trade necessity protected by the 21st section of the Apothecaries Act, 1815, did not encourage, and had no intention at variance with discouraging its exercise further than unavoidable.

"In Committee of the whole Council, the letters were considered so far as time would permit of and a resolution was passed in words as follows:—

"'That the letters of the 1st and 2nd January instant, received by Mr. Flux from Mr. James Richard Upton, the Solicitor of the Society of Apothecaries, be entered on the minutes. That the consideration of them be proceeded with at the next Council, and that in the meantime Mr. Flux do ask Mr. Upton to inform him when the resolution of the Act of Parliament Committee referred to in the letters has been considered by the Court of the Society, and also to say distinctly whether this Council may feel free to publish the letters in their discretion or to use them in any general meeting of this Society.'

"I feel at liberty to mention that the tenor of the resolution passed by the Act of Parliament Committee of your Society was regarded as satisfactory to a point, but that doubts existed as to whether it was sufficiently conclusive and satisfactory, regard being had to the actual course which the litigation authorized by your Society has taken and appears likely to take if not controlled by you.

"As it appears that the litigation has not been conducted by your Society, but by prosecutors who have obtained the sanction of your Society, on allegations concerning alleged acts, other than counter practice, I have been careful to refer to the printed reports which have appeared of the cases before the Courts, and have not found that the Apothecaries' Society (or rather those representing it) have given evidence of acts outside of the shops of the defendant chemists and druggists.

"To me it appears that whatever may have been the statements upon which parties obtained the sanction of the Apothecaries' Society to proceedings that sanction has been used for the purpose of raising issues as to and only as to counter practice, and I cannot trace materials for advising with confidence that in each and every of the cases now in issue, or in any future case they can rely upon the legality of counter practice not becoming the subject of the issue on which the case will turn.

"It certainly would be more satisfactory to my clients if I could convey to them an assurance that the powers of suing for penalties reposed by statute in the Apothecaries' Company will henceforth be exercised by and only by the Society acting by its own solicitor.

"My clients never have delegated the powers of suing entrusted to them, and the preservation of that good understanding between the Societies which hitherto has prevailed will be less in peril if the practice of your Society in regard to litigation be placed and preserved on a similar footing.

"The next Council of my Society will take place on Wednesday, the 6th February.

"I am, dear sir, yours truly
"(Signed) Wm. Flux."

"20, Austin Friars, London,
"5th February, 1878.

"My dear Sir,

"In reply to your letter of the 10th ult., I am authorized to state that your clients may make any use of my letter to you of the 1st ult., which they may think right to do.

"If you again refer to my letter of the 1st ult., you will I think find that there is really nothing inconsistent between what I there stated and what you say is the result of your perusal of the evidence in various cases to which you have referred.

"I am prepared again to affirm that in the few years during which I have acted as the solicitor to the Society, I have not authorized any prosecution in a case of pure and simple counter practice, and that I shall not do so, so long as I have the honour to hold that office, and I think you may accept this, not only as the course which I should personally pursue, but as the policy of the Society.

"Under these circumstances I must ask you to let the matter rest between us where it is.

"As regards the Society taking upon themselves the conduct of prosecutions, the reasons are so numerous, and (I may almost add) obvious, why they should not do so, that I do not think it necessary to go into this part of the question, but I may add that if they were to do so I am satisfied that the result would be exactly the reverse of what your clients suppose would happen.

"Yours faithfully,
"(Signed) James Richard Upton.

"W. Flux, Esq."

Library, Museum, and Laboratory.

The report of the Committee included the Librarian's report as follows:—Average attendance for the previous month, day, 15; evening, 8. Circulation of books, town, 102; country (20 places), 32; carriage paid 8s. 1½d. Circulation of books for 1877:—No. of entries 2014, being about 1600 in town, and 400 in the country. Total number of attendances during the year, day, 5255; evening, 2050. Highest attendance during the year, day, 37; evening, 25. Average attendance for the year, day, 17; evening, 10. No. of books and pamphlets added during the year, nearly 300. No. now in the library, 5050.

The Committee recommended the purchase of Burbidge's 'Horticulture.'

The following donations to the library were reported:—

'Das Nördlinger Register.'

'Note sur la racine de Violette de Vérone.'

'Notizen über das Saponin der Sarsaparilla.' From Professor Flückiger.

'Year-Book of Pharmacy 1877.' From the British Pharmaceutical Conference.

'Die Herbstzeitlose im Bier.'

'Beiträge zur Kenntniss der Veratrum-Alkaloide, von A. Tobien.' From Professor Dragendorff.

'A Universal Pharmacopœia.' From Dr. E. R. Squibb (author).

'Etude sur les propriétés de la Conicine.' From M. A. Petit (author).

'Chemical Composition of Foods,' etc. From Mr. E. T. Kensington (compiler).

'On the Geology of the Eastern Portion of the Banbury and Cheltenham Direct Railway.' From Mr. T. Beesley (author).

The Curator had reported the average attendance for for the previous month in the Museum as follows:—Day, 13; evening, 4. Also that the specimens of drugs asked for had been sent to Leicester, with a few exceptions, in cases where there were no duplicates. The list of duplicate specimens was in progress.

A letter had been received from the Philadelphia College of Pharmacy saying that in re-arranging the museum, duplicate collections of American drugs were being made, of which lists would be prepared with a view to presenting them to foreign pharmaceutical societies, and that if agreeable a list should be sent to the Pharmaceutical Society of Great Britain; also that should the Society specially desire any drug or preparation of North American origin the Committee would endeavour to procure it.

The Committee had requested the Secretary to write and thank the College for its kind offer, and to state that the Society would gladly accept the proposed presentation of American drugs.

The Professors had attended and reported favourably of their respective classes.

The following special evening lectures were stated to be arranged for—

Wednesday, February 20, Professor Redwood, on "Spectrum Analysis," illustrated with the electric light.

Wednesday, April 17, Professer Bentley, on the "Properties and Uses of the Eucalyptus Globulus.

The Chair to be taken at 8.30 on each occasion.

The report and recommendations of the Committee were received and adopted.

Catalogue of the Museum.

The President drew attention to the catalogue of the Museum which had just been completed. He said he thought it was important that it should be distributed as freely and liberally as possible, and the resolution he had to propose was that a copy be sent to each local secretary, and he would add to all local associations.

Mr. Schacht asked what would be the expense of sending a copy to every member.

The Secretary said this would involve a very heavy expense, and there were not in fact sufficient copies printed.

Mr. SCHACHT said it was one of the most useful things that had emanated from the house for a long time.

The PRESIDENT said it had already been agreed by the Committee to recommend that a copy should be supplied to every member and every associate in business who chose to apply for it. It would probably prove too much trouble to the majority to apply, but he did not think the Society should go to the expense of sending copies unless they were applied for. He would also suggest that learned societies at all concerned in the sciences allied to pharmacy and also public hospitals should have a copy.

Mr. RIMMINGTON thought the President's proposition was quite wide enough. More than half the members would not care about having a copy.

Mr. HAMPSON suggested that editors of medical journals should have copies.

The SECRETARY said they would of course have copies.

Mr. GREENISH proposed that the matter be referred to the Library Committee who should report to the Council at the next meeting. Of course, copies might be sent to local secretaries at once, but he wanted about forty or fifty copies to go to persons who had contributed and were willing to contribute to the museum.

Mr. GOSTLING suggested there should be a prominent announcement on the outer page of the Journal of the proposition that members should have a copy on application.

The motion to send a copy to each local secretary was then agreed to, as was also a vote of thanks to Mr. Holmes, the Curator, for the preparation of the catalogue, and a similar compliment to those members of the Committee who had assisted him.

DEPUTATION TO THE BOARD OF EXAMINERS IN SCOTLAND.

Mr. BOTTLE said that some years ago he accompanied a deputation to Edinburgh when there was some little discrepancy between the results of the examination in England and Scotland, although nothing approaching that shown by the present returns. It now appeared that the percentage of rejections for the Major examination was in England, 46·8; in Scotland, 25; for the Minor, England, 48·19; in Scotland, 25·53; for the Modified it was 45 in London, and 50 in Scotland, being a very near approximation, but he must say the variations in the Major and Minor results literally astonished him. When he visited the Scotch examination some few years ago he could not detect any difference between the examinations in Scotland and those carried on in England, and if there was any difference his impression was that the Scotch Board was really firmer in its determinations than the English. He had been trying to make up his mind as to what was the cause of the difference, and was inclined to believe that those who passed the Preliminary in Scotland were better educated than those who did so in England, and that might be a reason why a larger number of them were more successful in coming up and passing the Minor and Major afterwards. But it was now found that the reverse was the case, so that could not be the explanation. Then it had occurred to him that in Scotland a young man might have shorter hours of work, as many of them were out-door apprentices, and thus they might have more time and opportunity for study; but at any rate it was very important that some greater approximation to uniformity should be made, and he therefore proposed that the President, Mr. Sandford, and two members of the Board of Examiners, with the Assistant Secretary, attend the examination in Edinburgh on the 26th and 27th inst.

Mr. ROBBINS seconded the motion, and hoped the deputation would make a special point of inquiring into this matter.

Mr. BETTY supported the motion although he had not great hopes of a two days' visit being sufficient to enable the deputation to remedy the discrepancy which appeared in the returns.

Mr. SANDFORD hoped that some one would be appointed in place of himself.

Mr. SCHACHT said the object was to assimilate the examinations in England and Scotland, and he therefore suggested whether it would not be better for the deputation to consist exclusively of members of the Board of Examiners. If they could have two of the Scottish members attending a London examination and two London examiners attending the one in Edinburgh, and if that process were continued from time to time, there would grow up a more intimate knowledge of the course adopted by each Board, and he thought that would lead to more practical good than these formal visits of inspection.

Mr. GREENISH suggested that the Curator should attend the deputation.

Mr. BETTY supported the proposal of Mr. Schacht which he thought if carried out would go to the root of the matter, and he hoped at some future time it would be adopted.

Mr. BOTTLE said Mr. Schacht's suggestion was very good, and he quite agreed in it, but the 10th section of the byelaws provided that certain parties should be examiners in England and Wales and others in Scotland, so that he thought there was a practical difficulty in carrying it out.

Mr. BETTY remarked that at the next election they might appoint two Englishmen to the Scottish Board and two Scotchmen to the English Board.

The SECRETARY said that in that case they would only be conversant with the practice of the Board to which they belonged.

After some further discussion the motion was unanimously agreed to.

HOUSE.

The Report of this Committee was read and adopted. It recommended that certain alterations be made to improve the ventilation in Professor Redwood's room.

LAW AND PARLIAMENTARY.

This Committee reported that at its meeting a long letter had been read from Mr. Von Cavania, whose name has lately been removed from the Register, giving details of his business, and stating that he was prepared to prove his title to registration. The Secretary had been requested to write to him, saying that his registration had become invalid, but that any future application he might make, supported by proper evidence, would be considered.

Recovery of a Penalty.

The report of the Solicitor included a statement of the proceedings taken against Mr. William Mackness, of 113, Tottenham Court Road, grocer, for carrying on the business of a chemist and druggist under the style of The London and Provincial Supply Association, he being unregistered. The result was that Mr. Mackness had paid the penalty of £5 and costs. It had also been intimated that the defendant was taking steps to terminate any violation of the law. A letter had since been received saying that Mr. Mackness had sold his business to the "London and Provincial Supply Association, Limited."

The report included details of several other matters connected with infringements of the law.

Weights and Measures.

The following communication had been received:—

"Board of Trade
"(Standards Department),
"22nd January, 1878.

"Sir,

"I have the honour to inform you that the Board of Trade are preparing a Bill to consolidate the laws relating to weights and measures.

"By the Medical Practitioners' Act, 1858, it is provided that the General Council of Medical Education shall cause to be published in the British Pharmacopœia a list of medicines, etc., together 'with the true weights and measures by which they are to be prepared and mixed.'

"The Weights and Measures Act, 1835 (5 and 6 William IV., cap. 63, section 10), provides, however, that drugs may be sold retail by 'apothecaries' weight.'

"The Board of Trade would be glad therefore to be informed whether in the opinion of the Pharmaceutical Society there would be any objection to the repeal of so much of section 10 of the Act of 1835 as relates to 'apothecaries' weight,' as avoirdupois weight appears now to be used in the preparation as well as in the retail sale of drugs. "I have the honour to be, sir,

"Your obedient servant,

"T. H. Farrer.

"The President of the
Pharmaceutical Society of Great Britain."

When the subject was under consideration, Professor Redwood had attended the Committee, and stated that the Medical Council had received a similar communication.

After due consideration the Committee decided that it could not recommend the repeal of the clause referred to, because many drugs are required to be sold in quantities smaller than are represented by any denomination of avoirdupois weight, and in the event of such repeal there would be no other weight than the avoirdupois that could be legally used. A copy of this resolution was directed to be sent to the Medical Council.

Mr. Shaw did not see what difficulty there was in agreeing to the proposal of the Government with respect to weights and measures that the use of the apothecaries' weight should be given up.

The President said the question was not as to the use, but whether the practice of selling things by apothecaries' weight should be made illegal. If a person came in for a drachm or half a drachm of quinine the pharmacist would not be allowed to sell it under that name if this alteration took place.

Mr. Shaw thought the Council should assist the Government in the effort at uniformity in weights and measures. He did not see any difficulty in making use of the avoirdupois weight. It was now adopted and used by the Pharmacopœia Committee.

The President said the Committee had had the privilege of Dr. Redwood's assistance, and it appeared that the Medical Council in authorizing the alteration to avoirdupois weight did it from the idea that it would be consulting the convenience of pharmacists. It reasoned in this way, that when preparations of the Pharmacopœia were written in apothecaries' weight they often had to be calculated by the pharmacist into avoirdupois weight, because he generally wanted to make up a larger quantity than that mentioned; but the Medical Council had no idea of doing away with apothecaries' weight, either in prescribing or dispensing, or its ordinary use for small weights. You could not use an ounce of 437½ grains, and divide it into small quantities. Therefore, although avoirdupois weight was convenient for large quantities it was never supposed by the Medical Council it was going to do away in dispensing with the most convenient system of weights—the apothecaries' weight.

The Vice-President added that if chemists and druggists agreed to this proposal they could not claim payment for any article which they sold by the drachm; it would be illegal. It was very desirable to retain the present weights, and he saw no advantage for getting rid of them.

The report and recommendations of the Committee were then agreed to.

Medical Act Amendment Bill.

Mr. Atkins drew attention to the Medical Act Amendment Bill, recently introduced by Dr. Lush, of which he had seen a rough draft, and was happy to say it contained nothing in it whatever affecting the interests of pharmacists. It was a very short Bill, only dealing with questions of medicine and surgery.

Report of the Board of Examiners.

Report of Preliminary Examination.

January, 1878.

Candidates.		
Examined.	Passed.	Failed.
313	121	192

Certificates received in lieu of examination:—

1 Royal College of Surgeons.
1 College of Preceptors.
3 University of Cambridge.
1 University of Oxford.

The Secretary reported that two candidates at the recent Preliminary examination had been disqualified owing to a report from the College of Preceptors that their papers had evidently been copied one from the other.

Some conversation took place with regard to this matter, and a very strong opinion was expressed as to the neglect of duty on the part of the superintendent in allowing such a thing to take place.

Chemists' Assistants' Association.

A letter was read from this Society asking for the loan of a few materia medica specimens for exhibition at a conversazione to be held this month. The matter was referred to the Library Committee with power to deal with it as it thought right.

PHARMACEUTICAL MEETING.

Wednesday, February 6, 1878.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting having been read and confirmed—

Mr. Holmes described several specimens which were exhibited on the table. Among these were some very magnificent crystals which were prepared some years ago by Mr. Copney, and lately presented to the museum. One was a crystal of common alum and chrome alum crystallized together so as to show that they were perfectly isomorphous. There were very fine specimens of Mogador colocynth, which had lately been very rare in the market. The specimen of absolute phenol was presented by Messrs. Bowdler and Bickerdike. He believed the substance had been before the meeting on a former occasion, but he should be very glad to hear from any of the gentlemen present whether it really was deliquescent or not. He had a specimen in his room for some time, and it seemed to cohere. The specimens of monochloride of iodine and trichloride of iodine had been prepared by Mr. W. R. Dunstan, one of the students in the laboratory, but they were of purely chemical interest. The specimen of dragon wood had somewhat of the appearance of sanders wood, but whether it was identical with that substance he could not state. The specimen of oil of rose geranium was of some interest, from having been prepared artificially from one of the andropogon oils. The specimen of salicylic acid and of salicylate of soda, prepared from oil of wintergreen had been presented by the President. The specimen of a stem of *Scorodosma fœtidum* was obtained from a plant which had a very different appearance from the *Narthex Fœtida* plant when growing. The narthex had very large leaf-sheath and numerous branches. This, on the contrary, was almost bare of branches and had very few leaves, and these leaves had not the leaf sheaths. The vittæ of the fruit were also less distinct.

The President read a letter from Mr. Howard, accompanying some specimens of cinchona in flower.

Professor BENTLEY said that there was a specimen of Chinese opium which had been sent by an old student of the School of Pharmacy, Mr. Thirlby, who was now residing at Shanghai. Along with the specimen Mr. Thirlby had sent the capsule of the poppy from which the opium had been extracted. It was known that ordinarily the capsules of the poppy were incised in different ways—both vertically and transversely. This specimen of Chinese opium came from the port of Winchow, which had recently been opened, and was much south of Shanghai. It appeared that in China, instead of the capsules being incised, they were punctured. The juice exuded and was collected in the ordinary way after a day or a day and a half. Mr. Thirlby described the specimen of Chinese opium which he had examined as being very moist. In point of fact, the Chinese simply scraped it from the capsules and put it into jars. The specimen on the table had been subjected to a process of drying, but even the drying was so imperfect that the opium was quite musty. Still, there was a decided opium odour about it. Chinese opium was particularly interesting, because, as might be known by some of the members, opium was now being obtained in various parts of China in large quantities. The amount of morphia obtained from it had been variously estimated, and some reports had been published by the Apothecaries' Company and by others, and he (Professor Bentley) was informed that in some specimens as much as from 15 to 17 per cent. of morphia had been found. The specimen which had been examined by Mr. Thirlby had been found by him to contain 7·75 per cent. of morphia, and 6·75 per cent. of narcotine. The Chinese opium which he (Professor Bentley) had seen, he should say, was altogether inferior to Smyrna opium, although he had heard statements made to the contrary. He would also call attention to some flowers that were upon the table. Mr. Lockwood, of the Bengal Civil Service, who had recently returned from India, had brought home with him a large consignment of these flowers. They were produced by a plant of which there were millions of trees in India. The flowers were called *matura* flowers. They were like fruits on a superficial examination, but were really the corollas of a plant known as *Bassia latifolia*. Mr. Holmes had also obtained some specimens from Mr. Christy. If these flowers were put into water it would be seen that they were flowers and not fruits, for the stamens would be seen inside the corolla. In some parts of India they were very largely used for food, not only by birds and other animals, but also by human beings. They had a decidedly saccharine smell, and contained a large quantity of sugar. It was proposed to use them for the distillation of a kind of spirit very much like whisky. When the spirit obtained from them was new it had much the effect of new rum, and was very injurious, and there appeared to be a difficulty in freeing the spirit from its disagreeable qualities; but when it was old it got better. Several tons of the flowers were coming into the English market to be used in distillation.

Dr. DE VRIJ objected to the use of the term "artificial oil of geranium" to designate an oil which was not in reality an oil of geranium, but was obtained from a species of *Andropogon*. He said that the use of such a term would cause great confusion.

Mr. UMNEY said that he should be glad to learn by what process the artificial specimens on the table had been prepared.

The PRESIDENT said that they would not suppose an artificial oil to be a thing produced by nature at all, but they would understand that the word "artificial" indicated that the oil was produced by chemical means.

Professor BENTLEY said that "oil of geranium" was a term which was well understood in this country. It was unfortunate that there should be a confusion of terms. There was a true oil of geranium obtained from one or more species of Pelargonium.

A paper was then read on

THE PROGRESS OF CINCHONA CULTIVATION AND ALKALOID PRODUCTION IN BENGAL.

BY C. H. WOOD, F.C.S.

The paper is printed at p. 621, and gave rise to the following discussion:—

Dr. DE VRIJ said that he was deeply interested in this subject, as might be inferred by the meeting when he said that he had left his own country on the previous afternoon in order to be present at that meeting. He congratulated Mr. Wood that he had met with the great success that he had so long desired. The subject of cinchona cultivation was a hobby of his (Dr. De Virj's). The speaker quoted several passages from Mr. Wood's paper, and expressed a general agreement with what had been put forward by Mr. Wood. He admitted that the calisaya was a very valuable bark, but he wished to direct the attention of Mr. Wood to the bark from *C. pubescens*. According to the latest information he had obtained from Mr. McIvor this species grows very rapidly, even faster than the succirubra, and the bark was a very good one. From specimens of the first renewal he had obtained 9 per cent. of total alkaloids, which yielded 7·2 per cent. of quinine sulphate. He said that there had been a question between various gentlemen as to whether the mossing or renewal process, or the process of coppicing was the better mode. Mr. McIvor was a great advocate of the mossing process. At the meeting of the Quinological Congress in Amsterdam in April last, at which Messrs. Weddell, Planchon, Howard, and other eminent quinologists were present, the question was debated, and it was decided that the process adopted by Mr. McIvor produced the best and richest bark, and that that was the future of cinchona cultivation. His own personal experience was that the bark produced by coppicing was much poorer than that produced by renewal. The renewed bark of succirubra contained three times as much quinine as the original bark. He was happy to hear the statement of Mr. Wood as to the relative richness of the root bark in alkaloids, as compared with the bark of the stem and branches, because it confirmed what he had himself stated in 1864, as was published in the *Pharmaceutical Journal*, although at that time the fact was doubted by the eminent quinologist, Mr. John Eliot Howard. In the *Pharmaceutical Journal* of December 1876, there was a report by Surgeon-General Smith of the Indian Medical Department who there spoke against the preparation made by Mr. Wood. It was interesting to see how pharmacists were often condemned by medical gentlemen who did not understand the subject. Dr. Smith reported that in an experiment made in his presence, three drachms of dilute hydrochloric acid failed to dissolve one drachm of powder in two ounces of water. This sparing solubility Dr. Smith considered to be very objectionable. If it had been true, of course it would have been very objectionable, but it was not true. He (Dr. De Vrij) must confess that he was angry when he read this statement, for he was a great advocate of cinchona febrifuge. It was a great boon to procure a cheap medicine like that. He regretted that the able editor of the *Pharmaceutical Journal* had not made any remark in reply to Dr. Smith, for he was more than competent to do so. It was well known that 324 parts of quinine required 36·5 parts of pure HCl, and that 308 parts of cinchonine or cinchonidine required the same quantity. Now if this were true of the individual alkaloids it must also be true of the mixture, and therefore if Mr. Wood had done his business well, the statement of Surgeon-General Smith could not be correct. He (Dr. De Vrij) had examined a sample of this febrifuge, forwarded to him by Mr. Markham, and had satisfied himself that it was soluble and that Mr. Wood had proved himself to be the right man in the right place. He (Dr. De Vrij) would suggest that the preparation should be called "quinetum" instead of "cinchona febrifuge." The termination, *etum* was the Latin for a collection. "Arboretum" was a collection of trees, and "quinetum" might be used to designate a collection of *quina* alkaloids, such as this substance contained. He agreed with Mr. Wood in the statement that the febrifuge should not be given in larger quantities than quinine. All barks contained a certain amount of amorphous alkaloid, and he had found that the Darjeeling bark contained more than other barks. Professor Binz of Bonn had proved by physiological experiments upon rabbits, etc., that the amorphous alkaloid was much more toxic than quinine, so that persons might be injured by a certain dose of the amorphous alkaloid, while they would be able to bear an equal dose of quinine. He agreed also with Mr. Wood that "in forming an opinion of the value of this preparation it should be regarded as a pharmaceutical preparation rather than as a chemical product." In making that remark, Mr. Wood showed that he was a real pharmacist. Cinchona febrifuge was not a chemical compound, but it was a very good pharmaceutical preparation.

Mr. PHILLIPS, in speaking with regard to the commercial aspect of the question, said that year by year the quantities of the Indian bark sold in this country had increased, and the price obtained had increased also. Last year he obtained a very high price for the article in consequence of the small stock of barks that were in in hand, the quantity having been reduced in consequence of the disturbances in Columbia and Ecuador. As Dr. De Vrij had said the bark from Darjeeling was very much inferior. There was no doubt that Indian bark would be the principal bark which in future came to this country. The bark coming from Columbia had been very much mixed with inferior barks of late years, and could not be depended upon. The bark from Java always went to Amsterdam, and he never saw it.

Dr. PAUL said that he had very little to say except with regard to one remark which had fallen from Dr. De Vrij. He gathered that Dr. De Vrij referred to an article in the *Pharmaceutical Journal* where reference was made to the preparation of bark known by the name of cinchona febrifuge, which was being tried in India with various results. He believed that Dr. De Vrij expressed his opinion that in publishing the statement which had appeared in the Journal* on the authority of Surgeon-General Smith, he had failed to do something which he ought to have done. He objected to that opinion, for his business as Editor did not require him to do more than furnish information, so that the readers of the Journal might have an opportunity of knowing what was being done and said in India about this preparation. He left it for those who were more personally interested to make any comment or criticism which they thought desirable. Dr. De Vrij, being the rider of this hobby horse, if he found a fence in front of him was the man to take the horse over it. He (Dr. Paul) had merely put forward what was stated officially by a gentleman of position and authority. No comment was made upon the statement, and no contradiction had been offered; and therefore they were bound to take the statement for what it was worth. It was too late now for Dr. De Vrij to come forward and criticize the statement, and say that he (Dr. Paul) ought to have done what was really Dr. De Vrij's work. Surgeon-General Smith stated that one of the objections to the cinchona febrifuge was its insolubility. The whole report was of a vague character, and the account given of the preparation referred to was not at all definite. No indication was given as to the strength of the acid used. There were several other objections which had been raised against the preparation, and they might have contributed to the distaste with which the article in the Journal was received by Dr. De Vrij. One of those objections was that patients of the hospitals after having had one dose given to them had disappeared by the next morning, for fear of having to take a second dose.

Dr. DE VRIJ said that Mr. Wood was not an unknown man. He was the editor of the pharmaceutical 'Year Book,' and if such a gentleman was accused of putting forth a preparation as soluble while it was not soluble, the accusation was a very important one, and therefore he (Dr. De Vrij) thought that a chemist like Dr. Paul might have said, in a couple of lines, that the statement made by Dr. Smith that the preparation was insoluble was not correct.

The PRESIDENT thought that the solubility of this quinine mixture would very much depend upon its absolute purity. If it was a very rough article, and contained much of the natural tannin of the bark, it would be so much less soluble.

Mr. MOSS said that he did not think that the word "quinetum" would be a very good name for the substance in question, for such a word would rather indicate that it was a collection of quinines instead of a mixture of alkaloids. The word "cinchonetum," which perhaps might be a better word, would be out of the question, because it would indicate a collection of cinchona barks, or, perhaps a collection of cinchona trees in a garden, and when we came to such words as "cinchonalkaletum," more descriptive still, we get a word as unmanageable in a prescription as the name "cinchona febrifuge," which Dr. De Vrij deprecates. Another objection to the term "quinetum" was that it was already applied to a trade article, which, according to the fashion of the day, might or might not be registered.

Dr. DE VRIJ said that he had not derived the name "quinetum" from "quinine," but from "quina."

Dr. PAUL asked to be allowed to offer two or three more remarks. He would say with great deference to Dr. De Vrij, compared with whom he (Dr. Paul) was a novice in the matter, that it appeared to him the question as to the subject before them was an exceedingly simple one, and was not to be judged from the hobby-horse point of view, but from a dry regard to matters of fact. The Government of India had bestowed great pains in introducing the cultivation of cinchona trees into two, or he might say three parts of India, viz., Madras, Bengal, and Ceylon. In Madras, the cultivation had been fairly successful, and in some cases eminently so. In Ceylon it had also been very successful. In both those places success had been obtained in producing cinchona trees which yielded bark very rich in quinine, the alkaloid which still bore the highest repute amongst medical men. In the province of Bengal, however, the Government had introduced a tree which did not yield quinine, or which yielded it to such an insignificant extent that it was practically valueless for the purposes of quinine manufacture. The bark of this tree did not yield, on the average, more than from 1 to $1\frac{1}{2}$ per cent. of quinine; and the greater part of the alkaloid contained in it consisted of cinchonidine and cinchonine. The consequence was that this bark was valueless in the English market for the main purpose for which bark was sold, viz., the manufacture of quinine. As there were immense plantations of this tree in Bengal, it became a question what should be done with the bark, since it could not be sold for quinine making, and it was more than sufficient to supply the wants of druggists for galenical preparations. In this extremity the Government of India had turned its attention to the manufacture of a preparation which, as Mr. Wood very fairly put it in his paper, was a pharmaceutical preparation more than a chemical one, and contained the total alkaloids mixed together in much the same condition as they would be met with in the liquid extract of bark. This product, consisting of a mixture of the alkaloids present in red bark, had been prepared not only in India where the Government had the advantage of the skill and experience which Mr. Wood had brought to bear with so much effect, but it had been made by a gentleman in this country, Mr. Whiffin, who had introduced it under the name quinetum. And no doubt the preparation of this substance was a good mode of using up the succirubra bark of Bengal which was

* See *Pharm. Journ.*, vii., p. 499.

otherwise comparatively valueless, and of placing in the hands of the medical practitioner a cheap material possessing the virtues which resided in cinchona bark. But we still come to the question whether the quinetum as made at Battersea, or the cinchona febrifuge, as made in Bengal, however skilfully prepared and carefully administered, would compete with the pure alkaloids; whether it would even be able to stand against the sulphate of cinchonidine, for that was a definite substance, while this preparation might be one thing to-day and another thing to-morrow, according to the material which was operated upon, and the skill or perhaps in the case of India the ignorance, of the natives who might be deputed to carry out the details of the process. All this was a matter of chance and accident, and there was no guarantee that this preparation would contain to-day, as it had done hitherto, 15 or 20 per cent. of quinine. It might be merely a *misch masch* of an indefinite value, containing mainly the red substance which any one who was conversant with the working of red bark knew it was so easy to introduce into his products. Whatever, therefore, might be the advantage of using up the bark in the preparation of the substance in question, it was still a question whether it would be possible for either quinetum or the cinchona febrifuge to stand against the preparations of the pure alkaloids as prepared and delivered in this market.

Dr. De Vrij made a few observations in reply to Dr. Paul.

Mr. Wood then replied upon the discussion. He said that he would, in the first place, offer his thanks to Dr. De Vrij for the very kind manner in which he had come forward upon this question. That gentleman was so well known as an eminent worker in this subject, that anything falling from him would necessarily be entitled to considerable respect. The discussion generally had been somewhat discursive, but there had been a tendency on the part of some of the speakers to introduce a comparison between the plantations of Bengal, and those of Madras and of Ceylon, and possibly of South America. There seemed to have been a general comparison of barks for the purpose of putting down the Bengal bark as the very worst. He was not at all afraid to have such a comparison, provided that the substances were judged of fairly upon their merits. He believed that they could produce an extremely useful and valuable bark in Darjeeling, and at a very low price. Although a scientific society such as the present was interested in the chemical aspect of the question, rather than the economical aspect, still the prime cost of producing a bark was an important element in judging of what profit it would be when it was sold. The barks of which he had spoken had been grown at Sikkim at a very cheap rate, but they could not make a comparison of them with the barks from Madras and other districts until they knew what all these barks would cost to produce. Dr. De Vrij had suggested the *Cinchona pubescens* as a bark which they should cultivate in India, and that gentleman had also a prejudice in favour of Madras bark. He (Mr. Wood) would remind Dr. De Vrij that in Madras they had had a great deal of scientific assistance and a long start in the cultivation of the cinchona tree before it was introduced into Bengal. He believed that they could claim that in a little time Bengal would be able to produce barks which were equal to the *Cinchona pubescens* which had met with so much approbation from Dr. De Vrij. They had on the Bengal plantations trees which would yield bark of very high quality, and containing large amounts of quinine and other alkaloids; but he had omitted from the paper any reference to them, because they were not yet in a position to affect the practical aspect of the question. They could put forward specimens of calisaya bark which were equal to some, though perhaps not the best of the Ledgeriana bark of Java, and these were the varieties the cultivation of which they were using their efforts to extend. The officinalis bark grew well in Madras, but it did not grow well in Bengal; but it was possible that the calisaya would grow better in Bengal than in Madras. The conditions of growth were not the same in both cases. With regard to the question of taking the bark the advantage had been given to Madras, because their method of mossing had produced a very magnificent and rich bark. But that, again, was a question which to judge fairly required the economy of the process to be taken into consideration, and it was open to discussion whether the process of mossing in Madras was economical, notwithstanding the high price which the bark fetched. But certain it was that whether the process of mossing was economical or not, it had failed in Bengal. Insects and more especially the ant, got beneath the moss, and destroyed the new bark as soon as it was deposited. As to the solubility of the product which had led to a little controversy between Dr. Paul and Dr. De Vrij, he (Mr. Wood) thought that it was quite unnecessary to discuss it. Anybody who wished to satisfy himself upon that point could try an experiment; and it was so obvious that Dr. Smith had made a mistake in what he had written about it that it was unnecessary to take any further steps to refute his statement. But he would point out that Dr. Smith was the Surgeon-General of Madras, and that Madras had produced a similar preparation from its plantations, and that this preparation had failed, and had been abolished because the Madras people could not make it pay. When the same kind of preparation was sent to Madras from Bengal it was in human nature that the Madras people should be prepared to find all the fault with it that they could. The substance went to Madras without any information accompanying it, and it was almost unlabelled, and it was very probable therefore that they knew very little about it, or about how it was to be dispensed, and they might have fallen into some errors with regard to it. Then the question of the name had been brought forward by Dr. De Vrij who had recommended that the substance should be called quinetum. He (Mr. Wood) had carefully considered all the names that had been brought forward, and he confessed that up to the present time he had not come across one that was thoroughly satisfactory to him. He had called it "cinchona febrifuge" in desperation. He had looked at the word "quinetum" in several lights. Upon turning to a Latin grammar, he found that the termination *etum* did not mean merely a collection of things, but it meant specifically a collection of plants and flowers, and, as far as he could find, was only used for plantations. We had the words "*vinetum*," for a vinery, and "*arboretum*" for a collection of trees. It seemed to him rather an odd thing to call a powder a collection of trees, or a plantation. He inferred that Dr. De Vrij meant the name to be significant of cinchona plantations, and that by labelling the substance "quinetum," which, as he (Mr. Wood) translated it, meant a plantation of quina trees, Dr. De Vrij intended to signify that this preparation was from such a plantation. But the derivation of the word "quinetum" was not the main cause of his (Mr. Wood's) reluctance to adopt the name. The consideration which mainly influenced him was that it was a Latin word, and that apart from the mistakes which it might lead to with regard to its being a new alkaloid or anything of that description, a Latin name was inconvenient for use in India. Dr. De Vrij had asked, "Suppose I wanted to write a prescription, how should I represent this thing?" That was a perfectly fair question, and for the name of the article in this country, such a Latin name would be most convenient. But for the purposes for which this preparation was intended to be used in India, that prescription would never be written. There was not in India, as in this country, a class of physicians, and a class of highly skilled pharmacists to dispense what the physicians wrote. This stuff was intended to go into the villages of Bengal, and to be given to the people themselves to take in their own fashion. Probably it would never fall into the hands of pharmacists, or, at all events, it would do so to only a very slight extent. It was intended to go directly to the masses of the people, and they would make up their own little pills, or take it in powder stirred in water, according to their own notions. For such a purpose a word was wanted which could be easily translated into the vernacular. The word "quinetum" did not seem to meet that requirement at all. It was true that the natives of India had learned to understand the name "quinine," and to highly appreciate the substance; but if the cinchona febrifuge was given to them under the name of "quinetum," they might be led to think that it was some kind of quinine or other, and it did not seem to be strictly fair to produce that impression. Pharmacists did not want them to regard this thing as quinine, but they wanted them to regard it as a distinct febrifuge. It so happened that the word febrifuge could be very readily translated into several of the native languages. There was, for example, a Bengalee word which exactly corresponded with it, and signified "fever-killer." That was the main reason why he still clung to the title "cinchona febrifuge," although he admitted that it was not a name which was perfect in all respects. Then he came to some remarks which had been made by a gentleman who had worked upon the subject of quinine to some extent, and who had treated this subject in what he regretted to say was a somewhat hostile spirit. He referred to the remarks of Dr. Paul. Having heard Dr. Paul's later observations, he (Mr. Wood) could understand why Dr. Paul had selected for publication in the *Pharmaceutical Journal* all those extracts from Indian papers which bore against the febrifuge, and had most remarkably overlooked all the medical and other reports which told in its favour. It had certainly been a matter of comment in India that the *Pharmaceutical Journal*, which was supposed to be well-informed on all these subjects, should, after a mass of matter had been written and published on this preparation, have been able to select only one small passage from a report of Dr. Smith, the Surgeon-General of Madras. He thought, on the whole, that it would have been better to omit the subject altogether than to produce one small, miserable extract, and to pretend that that represented the general results that were being obtained in India.* But as Dr. Paul proceeded to develop his ideas upon this subject, he (Mr. Wood) was led to understand why he should persistently overlook all that was favourable to it, because he found him so reduced for chemical definitions as to invent such a term as "misch-masch." He (Mr. Wood) confessed that up to the present time he had not met with such compounds, and he did not know what they were. He was not, therefore, in a position to judge of, or to reply to, any observations upon terms of that description, but he thought that Dr. Paul went even farther, and if he understood that gentleman rightly, he deprecated the idea of using a preparation, the composition of which was "dependent upon the ignorance of the manufacturers, and the chance and accident which they would bring to bear upon it." He did not know how far he was to understand that observation, and he should like to ask Dr. Paul whether he was really correctly quoting his words. Of course, if Dr. Paul imputed that this preparation was to be distrusted on account of the ignorance of the manufacturer, he (Mr. Wood), being mainly responsible for the quality of the product, was scarcely in a position to retort upon Dr. Paul. He had no wish, at any rate, to degrade the discussion into bandying words of abuse, when he thought that the ordinary courtesy which obtained between scientific men ought to have prevented such words being originated.

Mr. Passmore said that he was afraid that in consequence of deafness resulting from a cold, Dr. Paul had failed to hear the greater part of what had been said by Mr. Wood. He (Mr. Passmore) was not concerned to dive into a discussion as to the ulterior motives which might have guided Dr. Paul in selecting and putting into the Journal certain extracts, but there was one subject to which reference had been made upon which he felt warranted in speaking. Up to the present time there had been received at the editorial office information with respect to the result obtained with the "cinchona febrifuge" preparation from two sources only: one was an Indian newspaper, which was quoted as the authority in the article to which Dr. De Vrij had referred; and another was Dr. King's Report and his 'Manual of Cinchona Cultivation,' an appendix to which contained three or four favourable testimonials from medical men. These also had been quoted in the Journal, and they constituted all the information that had reached the Journal on the subject. He might remind Mr. Wood that it was only two or three days ago that he (Mr. Passmore) was complaining to him that the *Pharmaceutical Journal* was not kept supplied with information respecting this interesting subject, and he asked Mr. Wood whether he could suggest any way by which the information could be obtained. Mr. Wood told him—what he (Mr. Passmore) knew before pretty well—that very few copies of the reports were printed, and those that reached England were soon distributed. The reports, in fact, were very difficult to get hold of; and he had half suggested to Mr. Wood that the *Pharmaceutical Journal* might be furnished with copies. The remark which Mr. Wood made to him was that he did not think it advisable that such information should be furnished; or, at any rate, Mr. Wood went so far as to say that he thought that the less that was said in the discussion of these matters the better, giving reasons which need not then be mentioned.

Mr. Wood: May I ask Mr. Passmore whether the *Indian Medical Gazette* is a publication quite out of the reach of the Journal?

Mr. Passmore: It does not reach us.

Mr. Wood: It is a publication which is known in India, and it gives full information.

Mr. Passmore: But we are in London.

The President, in closing the discussion, said that it was perfectly certain that the Pharmaceutical Society, and the staff of the Journal, could not possess all the newspapers and all the information which the world produced, and if their friends in India would only send the information, and the journals which contained the information, to the Pharmaceutical Society, the Journal would fairly represent all sides. He believed that it was merely through the accident of only getting one side of the question that the Journal had presented only one side to the public, if such was the case. However, he had no doubt that the remarks which Mr. Wood had made on the subject would be of great value, and would be attended to hereafter. He was sure that they were all very much obliged to Mr. Wood, and also to Dr. De Vrij, and the other gentlemen who had taken part in the discussion. There were three more papers down for reading that evening, but as the hour was late he would ask the meeting to take them as read, and then they would appear in the Journal. One of these papers, on a Spurious Balsam of Tolu, by Mr. Naylor, is printed on p. 624; the other two, by Mr. Gerrard, on Thymol, will appear next week.

It was then announced by the President that on Wednesday, the 20th instant, Professor Redwood would deliver a lecture on Spectrum Analysis, illustrated by the electric light.

* For evidence of the totally unfounded nature of Mr. Wood's statements and inferences, the readers of the Journal are referred to *Pharmaceutical Journal* (3), vi., pp. 223, 367, 411, 566, 570, 772; vii., pp. 537, 807. It must, however, be admitted that Mr. Wood is so far correct that the application of the term "misch-masch" is consistent with the principles of what is known as "abusive nomenclature," inasmuch as the term in question signalizes the chief characteristic of "cinchona febrifuge," as will be seen by reference to Flügel's German Dictionary, where "medley" and "hodge podge" are given as the English equivalents of that term.—B. H. P.

NORTH BRITISH BRANCH, EDINBURGH.

The third meeting of the present session was held in the Museum of Science and Art, on the evening of Tuesday, 29th ult. By the kindness of Professor Archer, billets were issued asking the attendance of those connected with the Society at the Museum.

There was a good attendance, and the chair was taken by the President of the Branch, Mr. J. B. Stephenson, who, on introducing the Professor, remarked how much indebted the Society was to him for the present as well as for past kindness, and he felt certain that what Professor Archer had now to say would interest the meeting, the subject being one of considerable importance to all present.

In commencing his remarks, Professor Archer said that the great object to be kept in view in the arrangement now about to be submitted was one by which the student might be taught without other aid than that of having the specimens plainly before him, so that the eye might easily comprehend the various characters of the drug under observation. Professor Archer then proceeded to describe to the meeting a new arrangement which he had made for protecting and showing articles for museum and class purposes. The members of the Society would, he said, be aware of the great difficulty which was experienced in arranging materia medica specimens in such a way that they could be fully and fairly consulted by the student and yet be preserved. All the arrangements which he had seen had failed in achieving this double object. Either the specimens were not placed before the eyes so that the student could readily examine them, or if the student was allowed to handle the specimens these had in a short time to be replaced. But if they had very choice specimens, as they ought to have, it became a very difficult, as well as a very expensive matter to replace them. It had surprised him very much to observe that the materia medica part of the museum was perhaps more frequented than any other, except that of natural history, and until lately not excepting even that. He had, then, naturally had an extreme desire to provide for students of pharmacy every possible means to enable them to carry out their studies, and he thought he had hit upon a plan which would meet the purpose. So far as he had yet gone he had confined his arrangement to the vegetable portion of the British Pharmacopœia, or drugs, because he felt that it would be a difficult thing to arrange the chemical portion in such a way as to enable the different specimens to be recognized without their being handled and tested. The plan adopted was to have a series of upright cases, each occupying an exceedingly small place, in which were placed, under drawings of the particular plants, small glass boxes containing specimens of the drugs obtained from these plants. These glass boxes were, he said, a great improvement upon the glass bottles into which specimens had been hitherto thrust, inasmuch as they received the plant without crushing it. The idea of their use he had gained when he was in St. Petersburg; and he now explained to the Society an ingenious and simple method of manufacturing them with ease and at trifling cost. The Professor took occasion to point out that the museum collection of the pharmaceutical products of foreign countries was probably the best to be found in the world, and was largely consulted, not, he was sorry to say, by Edinburgh students, but by persons from London and other places. In illustrating the manufacture of the boxes, the Professor remarked that on the continent great difficulty had been found in making them, for the sides were no sooner put together than they gave way; but by the manner adopted in the museum the sides were kept in position by outer bars of wood and an inner block, so that when strong paste was used in making the attachments, the box was completed in a very short space of time. So convenient were these boxes as regards space that four cases of about $5\frac{1}{2}$ feet high, 2 feet broad, and 10 inches deep, with 12 glass shelves in each, have all the specimens of the British Pharmacopœia. The foreign collection already referred to was also examined with considerable interest.

The coloured drawings used for the purpose of illustrating each specimen were those from the well known work of Bentley and Trimen, and even the placing of the drawings showed some ingenuity, for they were put upon strong brown paper and the glass face bound in its position by strips of pasted ribbon, so that at any time the drawing could be removed without the slightest injury.

After having spent a pleasant and interesting evening, the President proposed a very hearty vote of thanks to Professor Archer for his kindness in inviting those connected with the Society to visit the museum as they had done that evening. The museum of Science and Art, as a whole, was to him one of the things in Edinburgh of which all might be proud, and well might the delay in Government still hesitating to make additional grants for the extension and completion of such a noble institution cause surprise not unmingled with a feeling somewhat stronger.

Dr. Craig, in seconding the vote of thanks, said that as a lecturer on materia medica he had been very much gratified indeed at the perfect manner in which the manufacture of such useful receptacles for specimens of materia medica had been explained. Among other advantages these boxes possessed, Dr. Craig thought one great recommendation was, that in event of specimen being put aside during the interval between a winter and summer course, from their shape and occupying so little space, the room required, as compared with bottles and jars, would be much lessened. The only suggestion he (Dr. Craig) could offer as to the completeness of the arrangement was, that the doses might be added to the drawings and names of the plants, so that those viewing them might have this information at hand.

Professor Archer, in acknowledging the vote of thanks, thought that the kindness was all the other way, and that he was exceedingly glad to see so many connected with the Pharmaceutical Society present. He did not agree, however, with Dr. Craig's suggestions about the doses, because he thought any one coming to see the specimens for the purpose of really gaining information ought to be a student in the strict sense of the term, and come prepared to study, by having a book with him, from which he could gather all the particulars which it was necessary for him to know on the subject.

The meeting then adjourned.

Proceedings of Scientific Societies.

THE INSTITUTE OF CHEMISTRY.

The first general meeting of this Institute was held on Friday, Feb. 1, at the rooms of the Chemical Society, Burlington House. Dr. Frankland occupied the chair, and there was a very good attendance.

The Chairman opened the proceedings by reading an address referring to the rapid advance made in the science of chemistry during late years, the first impulse to which he ascribed to the establishment of the first practical laboratory for instructing students, by Liebig at Giessen. Amongst the students at that laboratory were several Englishmen, who on their return home endeavoured to follow out the same system. In 1845, however, when he himself was searching for a laboratory in which he could obtain practical instruction in chemical analysis, he could only hear of one, viz., that under the direction of Dr. Lyon Playfair, then carried on in the cellar of the Royal Institution, at Manchester, but which was afterwards promoted to a back kitchen in Duke Street, Westminster. About the same time the College of Chemistry, under Dr. Hofmann, was established, and from it and one or two other laboratories there soon issued an army of chemists who promulgated sound practical teaching throughout the land, and the science soon became a recognized subject in universities, colleges, and even in schools. Thus in 1856 there were in connection with the Science and Art Department alone no less than 115 chemical laboratories, in which 2400 pupils received instruction. Many of these, no doubt, were on a very moderate scale, but their number showed the desire for technical training and the efforts made to meet it. The continual application of analytical chemistry to industrial and domestic life led to the necessity for an organization of those practising it, he having thrown out the idea in 1872 at a dinner given to Professor Cannizaro on his appointment as Faraday lecturer. It did not at first receive much support, but it was resuscitated in 1876, when an attempt was made to originate a scheme of the kind originally contemplated, and it was hoped that it might be carried out in connection with the Chemical Society. A committee was appointed and a report drawn up, but it was ultimately decided, at a meeting held in November, 1876, to found a new society and to get it legally incorporated. The remainder of the address was mainly occupied by a recital of the difficulties which had to be encountered and overcome, including the temporary opposition of the Pharmaceutical Society to the articles of association as originally drawn; and also the further obstacles thrown in the way of the new society by the Privy Council, based on the words of the Pharmacy Act, 1868, which rendered any person calling himself a chemist, who had not passed the examination of the Pharmaceutical Society, liable to a penalty of £5. The committee had ultimately modified the articles so as to obtain the approval of the Board of Trade, but it still intended to institute a system of examinations such as was imposed by no other body and which would have the effect of thoroughly testing the qualifications of future candidates for membership.

Dr. Odling moved a vote of thanks to the Chairman for his interesting and useful address, and also that it be printed and circulated amongst the members. Reference had been made in the address both to the Chemical Society and to the Pharmaceutical Society, of both of which he was a member. The latter was placed in a very awkward position, and he was sure any difficulties which had arisen would have been removed by a little explanation between the two bodies. He was an old student of the College of Chemistry, but he believed that was not the first practical laboratory founded in England. If he remembered rightly, the Birkbeck Laboratory, in King's College, was founded somewhat earlier, under the direction of Professor Fownes.

Professor Attfield seconded the resolution, and mentioned that as early as 1842 a laboratory for instruction in practical chemistry was suggested at the Pharmaceutical Society, and in 1844 steps were actually instituted, and many gentlemen who were now no longer connected with pharmacy, but were ornaments to the science of chemistry in this country received their education there. With regard to the action of the Pharmaceutical Society in 1868 in reserving for its members the title of chemists, he thought on the whole the profession of chemistry was under a deep debt of obligation to the Society for having at that time rescued the name chemist, and provided that in all future time no one but he who had some special education in chemistry should be allowed to take it. Up to 1868, any shopkeeper or huckster could call himself a chemist, but since then no such individual could take the title. Nothing showed more the need of such an organization as had now been founded than the fact that in 1868 no opposition was made to the Pharmacy Bill by any gentleman calling himself a scientific or analytical chemist. Such a bill if introduced now could not be passed. With respect to the action recently taken by the Pharmaceutical Society, he thought it was pretty well known by this time that that Society was really urged to it by the Privy Council.

The resolution having been carried unanimously, the Chairman thanked the meeting or the kind way in which his remarks had been received, and also Dr. Odling for reminding him of the existence of other laboratories. He was aware of the existence of the Birkbeck laboratory, but did not know that it was in operation earlier than the College of Chemistry. With regard to the Pharmaceutical Society he hoped nothing which had fallen from him would be taken as in any way showing hostility towards that Society, which had treated them throughout all the negotiations on this matter with the greatest courtesy. That Sociey had no doubt obtained this Act of Parliament and the title to the exclusive use of the name of chemist, and had therefore a fair ground of complaint at a new body of gentlemen calling themselves professional chemists. He thought the members of the Pharmaceutical Society might with very great propriety term themselves professional chemists, and therefore it was perhaps rather unwise to attempt to take that title without limitation. Still he hoped some mode would be devised by which this title might be shared with the pharmacists, so that the term chemist would not in this country be exclusively devoted to pharmaceutical chemists.

Some further conversation took place with regard to early practical laboratories in London, in which Mr. Dugald Campbell, Mr. Bell, Dr. Gilbert, Mr. James Young and others took part. The Chairman said his remarks only referred to his own experience, but he would take care to correct any inaccuracies on this point before his address was printed.

The Secretary then read the report of the Council, which stated that the most important business since the incorporation of the Institute had been the development of the organization by providing for the admission of all competent chemists. In order to form a nucleus of the society, it was deemed advisable in the first place to invite all chemists of standing in the profession, who were known to the Council, either personally or by reputation, to join. Those having been elected, a Committee was appointed to examine into the qualifications of those seeking admission. Over 150 persons had made inquiries, and 93 had already become candidates for fellowship or associateship, sending in certificates. The Nomination Committee had carefully considered the qualifications required, and had advised that the qualification for a fellowship should be, that the candidate should be not less than 24 years of age, that he had passed through a course of three years' training in theoretical and analytical chemistry, and physics, and had subsequently been engaged for three years, either as assistant to a chemist of repute, or as an assistant or demonstrator in some public institution, or had conducted and published an original research of sufficient merit in the opinion of the Council, on some chemical subject necessitating practical work, or that he had been trained and qualified in some other way which the Committee might deem equivalent. With regard to associates it was required that their age should be not less than 21, that they should have passed through a three years' course of study in analytical chemistry, physics, and elementary mathematics. In very few instances only had the Council found it necessary to depart from this rule. Where candidates were not actually proposed by members of the Council they were required to produce certificates or other documentary evidence that their statements were correct, and it was satisfactory to note that with regard te the associates, such was the satisfactory character of their attainments, that many of them were only debarred from claiming fellowship on account of their age. The object of the Institute had been favourably received by almost all. Of those invited to join at the first meeting, 153 had already accepted, and since then, 160 fellows and 43 associates had been proposed and elected, and 65 had accepted membership. As, however, a very short time had elapsed since the foundation of the society, no accurate estimate could be made of how many would eventually join. At present 225 fellows had joined; 142 had been elected, but not yet formally admitted. The Council was of opinion that a high standard should be fixed not only in chemistry, but in physics, and elementary mathematics, and that such could only be ensured by a carefully arranged system of examination, and a committee had therefore been appointed to draw up an examination scheme. A complete list of fellows and associates would soon be published, and Dr. Frankland had very kindly offered two prizes of £50 each, to be awarded by the Council for the two best original investigations involving gas analysis, conducted by associates of the Institute. In conclusion the Council begged to thank the President and Council of the Chemical Society for their kindness in allowing the use of their rooms.

Mr. Thorpe having moved the adoption of the report;

Mr. Riley thought before it was adopted, they ought to have some explanation of one of the rules which appeared to him ambiguous, and in fact the Secretary had admitted it was ambiguous when he had written to him on the subject. The ambiguity was as to what was a member, and what was a fellow. It appeared to him from the explanation given that there might be fellows who were not members, and he thought that applied to honorary fellows, but then it appeared by another rule that every fellow had to subscribe two guineas, and it did not seem right that gentlemen should be called upon to subscribe who did not receive a copy of the report and balance sheet; nor did he see how an honorary fellow could be elected, and then made to pay for it.

Dr. Tidy said he had not heard anything of this Institute until November, and he considered that it had been got up in what appeared to be somewhat a hole and corner manner. As a teacher of chemistry at one of the large hospitals, he rather wondered that he had not been made acquainted with it, and he knew several who were in the same position. He never heard anything of the matter until he received a paper saying he had been elected a fellow of the Institute.

The Chairman said he feared Dr. Tidy did not read the *Chemical News*.

Dr. Tidy said in reply that he did not mean that he had not seen it in the *Chemical News*, but had never been informed of it officially. He also had a difficulty in understanding the difference between a member and a fellow.

The Chairman suggested that the matter should be explained by the solicitor. He might add, however, that up to the present time no fellows had been elected who were not also members.

The Solicitor said it had been considered desirable that the benefits of legal incorporation should be obtained, but this could only be done in three ways, either by a special Act of Parliament, by a Royal Charter, or by registration under the Companies Act of 1867; and the latter method was chosen. Under that Act, the incorporation had to receive the sanction of the Board of Trade; and under it, also, members only were recognized, not fellows. Consequently all persons belonging to the Association were in the eye of the law members. The term fellow had been used contrary to his advice, because some gentlemen in the profession deemed it better that members of this association should be called Fellows of the Institute of Chemistry, rather than members, but the term throughout the articles of association was member. Clause 55 was inserted for the express purpose of giving the Council power to confer the title of Honorary Felllow on persons who should not be members, and he thought the only mistake was in saying that honorary fellows should pay a subscription. In reality the terms fellow and member were interchangeable, except with regard to persons resident abroad.

Mr. Riley suggested that some minutes should be made which would meet the facts of the case, and a somewhat lengthy discussion ensued upon the same point.

Dr. Odling suggested that it would be much better if they were to call themselves members, and drop the term fellows altogether.

Mr. J. Denham Smith moved that this be done, which was seconded by another member.

Dr. Tidy said there was a very definite distinction between fellow and member.

Dr. Odling doubted whether it would be possible at the present moment to make the alteration.

The Solicitor said they could resolve to use the term member in preference to fellow, but they could not alter the regulations except on notice.

Dr. Hake suggested that if the word fellow were omitted there would be only one class of members, including associates.

The Solicitor pointed out that throughout the articles a distinction was drawn between associates and members.

Mr. Carteighe said he objected to dropping the word fellow.

It was then moved by Mr. Denham Smith and carried that the question of the distinction between the term member and fellow be referred to the Council.

Mr. Riley then seconded Mr. Thorpe's motion, and it was carried unanimously.

The Treasurer (Dr. Wright) then read the balance sheet as made up and audited to December 31st, showing receipts from 92 members' admission fees £193 4*s*., 79 members' subscriptions for 1878 £165 18*s*., 8 members' life subscriptions £168, and 2 associates' subscriptions for 1878 £2 2*s*., making a total of £529 4*s*., out of which had been paid, printing, postage, etc., £23 7*s*., and petty cash disbursements 19*s*. 11*d*., leaving a balance of £501 7*s*. 1*d*. The Treasurer added a further statement up to 12 o'clock of that day, to the following effect: 222 entrance fees had been paid in, 201 members' subscriptions for 1878, 18 life subscriptions and 17 associates' subscriptions. The total receipts since the formation of the Institute being £1273 13*s*. 7*d*. Out of this there had been a certain amount of expenditure, namely, £69 5*s*. for printing, etc., £7 19*s*. 6*d*. for office furniture, £143 19*s*. for law expenditure, and £22 3*s*. 1*d*. petty cash disbursements, leaving a balance in hand of £1034 3*s*.

The Chairman said the only remaining business was that of electing four censors in accordance with section 47 of the Articles of Association.

The Council had nominated nine gentlemen whose names were read, and on scrutineers being appointed and a ballot taken, the following four gentlemen were elected:—Dr. Odling, Professor Abel, Dr. Delarue, and Professor Roscoe.

This terminated the proceedings.

Correspondence.

C. Jones is thanked for his communication.

E. B. Vizer.—All such information, so far as it is available, is given already. We are not in a position, neither would the columns of the Journal be the place, to give details as to the preparations of particular manufacturers.

E. B. Ivatts.—We are much obliged to you for your kind offer, but we fear that satisfactory results could not be obtained from the examination of a small quantity.

"*An Inquirer*."—(1) We think this question had better be put to the maker or seller of the foot warmer. (2) A full account has already appeared in this Journal on several occasions. See especially vol. i. (present series), p. 43, and vol. vi., pp. 823 and 946. (3) Glycerine of tragacanth.

C. Griffith.—*Petasites fragrans*. See "The Month" for January, 1877.

C. J. B.—At present we are not acquainted with a process for the assay of opium that will give satisfactory results in all cases. See the papers read before the Pharmaceutical Conference at Glasgow in 1876, reported in vol. vi. of this Journal.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Mackay, Dr. De Vrij, Professor Fluckiger, Mr. Summers, Mr. Jackson, Mr. Barnes, Mr. Taylor, Mr. Jackson, Mr. Jones, Mr. Walker, Mr. Naylor, Mr. Talbot, Inquirer, Veritas, Major, X. Y. Z., L., R. C. B.

THYMOL, AND ITS PHARMACY.*

BY A. W. GERRARD, F.C.S.,

Teacher of Pharmacy at University College Hospital.

At present the attention of the medical profession and others is being directed towards the substance known as thymol or thymic acid, and much experimental work thereon is being carried out in several of the London hospitals, with the view to extending our knowledge of its remedial and antiseptic value. For the past six months I have had much to do with this drug, and made a number of experiments thereon which have developed a few novel facts concerning it, and of a character likely to prove useful to the pharmacist.

Thymol is a homologue of the phenol series, and represented by the formula $C_{10}H_{14}O$. Several plants of the order Labiatæ are known to yield it, the principal of which are the common thyme, *Thymus vulgaris*, and horse mint, *Monarda punctata*; it is also obtainable from a plant of the order umbelliferæ, called *Ptychotis ajowan*, an East Indian drug. It is from the essential oils of these plants that the thymol is finally extracted.

The separation of thymol from oil of thyme can be effected by two processes, both of which are of a simple character. Thus, when oil of thyme is treated with an equal volume of caustic soda solution, 1 in 5, and well shaken, the thymol only is dissolved by the alkali and, after standing for a few moments, forms a separate layer; this upon withdrawal and neutralization with hydrochloric acid, liberates the thymol which rises to the surface; it should be further distilled from water. Prepared in this manner it is an oily liquid, said to be incapable of crystallization. The second and best process is to submit oil of thyme to a low temperature for a few days, when the thymol separates in the crystalline state. Flückiger and Hanbury made thymol by submitting oil of ajowan to a temperature of °O C., and obtained 35 per cent. in superb tabular crystals. Oil of thyme is stated to yield 50 per cent. of thymol.

As found in commerce, thymol consists of irregular broken crystals, nearly transparent and colourless; the taste is burning and aromatic; sp. gr. 1·028, but lighter than water when fused; its melting point is about 44° C. When once completely fused and allowed to cool to the ordinary temperature it will maintain itself in the fluid condition for several days, but the contact of a crystal will at once cause it to crystallize. It is freely soluble in alcohol, ether, chloroform, benzol, carbon bisulphide, fats and oils, and but sparingly in water and glycerine. The alkaline hydrates of potash and soda are powerful solvents of thymol; ammonia dissolves it but sparingly. The potash and soda solutions are spoken of by some authors as chemical combinations, but the following test will demonstrate them otherwise. When shaken with ether, the thymol can be entirely removed and obtained as a neutral volatile residue.

The principal property ascribed to thymol is that of a powerful antiseptic, superior even to carbolic acid. Some experiments of S. Leon, were published in the 'Year-Book of Pharmacy,' 1876, p. 279, on the antiseptic properties of thymol compared with carbolic and salicylic acids. The author found that thymol possessed much greater power than either in arresting the fermentation of sugar and the decomposition of albumen and milk. Bucholz has also published the following table of comparative values of antiseptics, giving to thymol ten times the power of carbolic acid.

TABLE OF COMPARATIVE VALUE OF ANTISEPTICS.
BUCHOLZ.

Name.	Colytic.	Destructive.
Chlorine	—	2·5
Thymol	200	20
Sulphurous Anhydride	—	66
Salicylic Acid	66	31
Carbolic Acid	20	25
Alcohol	5	0·5

My first association with thymol is due to Dr. Radcliffe Crocker, Assistant Physician in the Skin Department of University College Hospital, who conceived the idea that it might prove of value in treating the diseases of his department, and for the past six months he has used it extensively and successfully. His results, which are of interest to the medical profession, will shortly be published in the *British Medical Journal.*

A relation of the behaviour of thymol towards various solvents under the varying conditions of heat and cold, may be termed its pharmacy, and I will now give my experience in this respect. Of the solvents of thymol already mentioned, I shall consider only the following, as being the best adapted to the various uses to which it may be medicinally applied, viz., water, rectified spirit, glycerine, fats, and alkalies.

The strongest aqueous solution of thymol obtainable, using cold water, is 1 in 1200, but with hot water 1 in 1000 can be dissolved; a solution of 1 in 900 which I prepared with hot water remained clear for twenty-four hours, and then began to deposit crystalline needles, mingled with prismatic plates throwing off beautiful coloured reflections. This then shows that the strongest permanent watery solution of thymol available is 1 in 1000; a solution of this strength applied in the form of spray was found by M. le Baron de Watteville to be of especial value in destroying the fetor of a carious nasal bone, and he preferred it to a solution of permanganate of potash of the same strength.

Rectified spirit will dissolve its own weight of thymol, but on dilution with water most of the thymol is separated; the strongest spirituous solution miscible with water in any proportion without turbidity is one of 4 grains in the fluid ounce.

The power of glycerine as a solvent of thymol is not great; cold glycerine dissolves it but sparingly, hot glycerine more readily. I find 1 grain dissolves in two fluid drachms of heated glycerine, and on cooling deposit s no crystals. If this glycerole of thymol be added to water in equal parts, turbidity is produced, and continues till 4 volumes of. water are reached; thus then 1 of thymol is soluble in 120 of glycerine, and can be reduced with water to 600 parts, forming a clear solution. This glycerine solution possesses, according to Dr. Crocker's statement, special advantages for preparing lotions, the presence of the glycerine obviating the drying effect upon the skin produced by aqueous or spirituous solutions of thymol alone.

Fats and oils, and with these I include vaseline,

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, Feb. 6, 1878.

are excellent solvents of thymol, but require to be heated with the drug to ensure perfect solution and diffusion, and unless particular attention be paid to this, much irritation may be caused a patient by minute undissolved particles of thymol being present in an ointment. The process I prefer in making ointments is to dissolve the thymol in a few drops of spirit, and then mix in the basis. Two strengths of ointment have been principally used in our hospitals, containing respectively 1 and 5 per cent. of thymol, with vaseline as the basis. Unless elegance be desired I see no important advantage in vaseline over lard.

With reference to vaseline as a solvent of thymol, I have found since making these notes that a 5 per cent. solution prepared by heat has, in four days, its surface covered with minute crystals of thymol, so that vaseline can scarcely be considered an eligible basis, unless the thymol be admixed as a spirituous solution.

The caustic alkalies, potash and soda, dissolve thymol readily; 70 grains are dissolved by 22 grains of caustic soda, or in simpler numbers for practical adoption, 1 grain of caustic soda dissolves 3 grains of thymol. Of caustic potash 1 grain dissolves $2\frac{1}{3}$ grains of thymol. These alkaline solutions may be diluted with water in any proportion without separation, and are likely to prove the most useful and economical of any of the preparations of this drug, especially where a strong solution is desired.

In a comparison of the commercial values of thymol and carbolic acid, the thymol is at a disadvantage, being as much per ounce as the latter is per pound, but valued as antiseptics by the statement of Bucholz that 1 of thymol is equal to 10 of carbolic acid, then the difference is not so great.

With reference to the supply of this drug, should the demand be large, I believe some difficulty would at first be experienced in meeting it, but eventually I think the supply could be made to meet the demand, for I have recently been informed by a medical gentleman, native of Calcutta, that the Ajowan is a most abundant production of the Indian Empire, growing as a weed over immense tracts of country; therefore then it is from this source we may suppose our future supplies would be drawn.

In conclusion I may say in favour of thymol that all experimenters with it, so far as I am acquainted, are unanimous in their opinions of its high value, giving it a position above any other body of its class we have at our command. Its pleasant odour and non-poisonous property are also very important features of which few antiseptics can boast.

EXAMINATION OF COMMERCIAL OIL [OF THYME (SO CALLED ORIGANUM).*

BY A. W. GERRARD,

Teacher of Pharmacy at University College Hospital.

Judging from the published statements, that oil of thyme contained 50 per cent. of thymol, and the simple method for its extraction, I imagined I should be able to prepare my own thymol as a paying operation, oil of thyme being 2*s.* 6*d.* per pound, and thymol as much per ounce.

The first sample of oil of thyme I purchased, to my surprise after proper treatment yielded not a particle of thymol. Eight more samples were then obtained, four of the *huile rouge de thym*, or red oil of thyme, and four of the *huile blanche de thym*, or white oil of thyme. They were examined first by shaking in a graduated test tube with an equal volume of caustic soda solution one in five, and on separation the increase in volume of the alkaline layer was observed, and only in one instance was an appreciable increase apparent, and that to the extent of 12 per cent. In each case the alkaline solution was removed and neutralized with hydrochloric acid; in all of them turbidity was obtained, but in one case only in sufficient quantity to be estimated; the separated oily matter in this one case formed nearly 12 per cent. of the oil from which it was extracted. Upon examination it differed in colour, odour and taste from thymol, and I would not pronounce it as such.

The same samples were now surrounded with loose ice for three days, when it was found that not the slightest trace of crystalline or other matter had separated.

These results then are entirely of a negative character, and show that thymol is not present in the oils of thyme of English commerce, and lead us to the inference that it must be extracted in the countries of its production, the residual cymene and thymene being sold us as oil of thyme.

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, Feb. 6, 1878.

THE USES OF SOME OF THE INDIAN SPECIES OF BASSIA.

BY JOHN R. JACKSON, A.L.S.,

Curator of Museums, Royal Gardens, Kew.

The characteristic properties of the Sapotaceæ are, as is well known, of an oleaginous nature, and this principle is, perhaps, more fully represented in the genus *Bassia* than in any other. The best known species is the shea butter tree which, though described by Don as *Bassia Parkii*, has by modern botanists been put in the genus *Butyrospermum*. It is an African tree and is well known on account of the accurate description which is recorded of it in Mungo Park's travels; the concrete oil he describes as being, when fresh, equal to good butter from cow's milk. The fat is extracted from the seeds by boiling. When fresh it is of a white colour and of a bland agreeable taste; with age, however, it turns yellowish and becomes somewhat rancid. It is much used by the people in the countries where the plant grows, and is an article of trade at Sierra Leone.

Three species of Bassia are well known in India: —*Bassia butyracea*, Roxb., *B. longifolia*, Willd., and *B. latifolia*, Roxb. The first is known as the Indian butter tree or "Phulwa," and grows to a height of from forty to fifty feet with a straight trunk five or six feet in circumference. A soft but solid white fat about the consistence of fine lard is extracted from the seeds by a system of bruising and pressing somewhat in the following manner:—After being beaten till they are about the thickness of cream the mass is put into a cloth bag, upon which a heavy weight is placed, and left to stand till all the oil or fat is expressed. This fat or butter has the reputation of being a valuable preservative for the hair, and when mixed with sweet scented oils is thus used by the native population and is also exported. Scented or perfumed with attar of rose or cloves it forms an ointment which has a great reputation in rheumatic and similar affections

The fat may be kept for a very long time without deteriorating, and when pure it is said to burn well with a bright light, without smoke or smell. It also makes excellent soap. The cake left after the expression of the oil is eaten as food. The pulp of the fruit has a sweet, insipid taste, but is nevertheless eaten by the people. A sweetish juice is sometimes extracted from the flowers and made into sugar, and sold in the bazaars, and is described as being very similar in all respects to date sugar. The flowers, unlike those of the other species, are not eaten.

Bassia longifolia, Willd., known as the "Illupi," is a tree growing to a height of some forty feet, and common in the forests of Western Mysore, Malabar, and the Circars. The seeds yield an oil in plenty, but of a quality inferior to that from the other species. It retains its solidity at a moderate temperature, but it is said to keep good in the warm season only for a fortnight or three weeks, when it becomes so rancid as to give off a very disagreeable smell. In cold weather, however, and if it is well secured from contact with the air, it will keep good for months. The oil cake or residue left after the expression of the oil is used for preparing a head wash. From the bark a viscid gummy juice exudes which was formerly used in rheumatic affections, and from the leaves was also obtained a similar juice. From the bark is prepared a decoction which is used as an astringent and emollient. The flowers themselves are roasted and eaten, and are also bruised and boiled till they form a jelly.

Bassia latifolia, Roxb., is perhaps the most important of the Indian species, not so much on account of the oil which it yields, as for the flowers. The tree is commonly known as the "Mahwa," and grows to a height of sixty feet, the trunk often measuring six to seven feet in circumference. Dr. Brandis, in his 'Forest Flora,' describes it as being cultivated, propagating itself by self-sown seedlings, and protected in most parts of India. In the Punjab it is grown in the sub-Himalayan tract and the outer valleys as far as the Ravi, but not commonly in the plains. It is abundant in all parts of Central India from Guzerat to Behar. There seems no doubt that the tree is indigenous in the forests of the Satpura range of Western India above Ghat, and perhaps also of Eastern Kumaon. It thrives in dry stony ground. The old leaves are shed gradually from February to April, the fresh leaves opening out immediately afterwards. The flowers generally appear before the new leaves, in March and April, and after the corollas have dropped the leaf buds above the flowers expand. The fruit is eaten both in the ripe and unripe states. The seeds contain a quantity of oil, which is obtained from them by expression. It is at first quite fluid, and of a greenish colour; but while it keeps limpid and sweet for a length of time in a cool climate, in the heat of India it soon turns rancid, assuming a bitterish taste and a brown colour, the heavy oil separating from the fluid portion and sinking to the bottom of the vessel. The cake, after the expression of the oil, is used to poison fish, and it is also used as an emetic. The smoke that arises from the burning of this oil cake is said to be fatal to rats and various insects. A gum exudes from the bark; and the wood, which is close and even grained, is sometimes used for railway sleepers. It is, however, for the flowers that the tree is most valued. These flowers are very fleshy or succulent, and fall from the trees in vast quantities during the night. They are eaten in very large quantities, both raw and cooked, sometimes with grain and sometimes as sweetmeats. They have a sickly sweetish taste, and a sweet, somewhat spirituous smell, more especially after being enclosed in a box or closed jar. Dr. Gibson writing, many years since, of this plant in Guzerat and Rajpootana says:—"This flower is collected in the hot season by Bheels and others from the forests, also from the planted trees which are most abundant in the more open parts of Guzerat and Rajwarra. The ripe flower has a sickly sweet taste resembling manna. Being very deciduous it is found in large quantities under the trees every morning during the season. A single tree will afford from 200 to 400 lbs. of flowers. The seeds afford a great quantity of concrete oil used in the manufacture of soap. The forest or Bheel population also store great quantities of the dried flowers as a staple article of food, and hence in expeditions undertaken for the punishment or subjection of those tribes when unruly, their bassia trees are threatened to be cut down by the invading force, and the threat most commonly ensures the submission of the tribes. In Guzerat and Rajpootana every village has its spirit shop for the sale of the distilled liquor from the flowers; in the island of Caranja, opposite to Bombay, the Government duty on the spirits distilled (chiefly from this flower) amounts to at least £60,000 per annum. I rather think that £80,000 is most generally the sum. The Parsees are the great distillers and sellers of it in all the country between Surat and Bombay, and they usually push their distilleries and shops into the heart of the forest which lines the eastern border and hills of those countries. The spirit produced from the bassia is, when carefully distilled, much like good Irish whisky, having a strong smoky and rather fetid flavour; this latter disappears with age. The fresh spirit is, owing to the quantity of aromatic or empyreumatic oil which it contains, very deleterious, and to the European troops stationed in Guzerat, some thirty years ago, appeared to be quite as poisonous as the worst new rum of the West Indies has generally proved to our soldiers. It excited immediately gastric irritation, and on this supervened the malarious fever so common in those countries."

It is remarkable that these flowers, so well known in India, should not before this have been introduced as a commercial article into this country. We understand, however, that experiments have been made with them quite recently in England, both in distilling and also for cattle feeding; in the former 6·16 gallons of proof spirit were obtained per cwt., and this spirit was of a very superior quality. For feeding cattle these flowers are also said to be very efficacious, the flesh of pigs and other animals fed upon them is said to be very much improved, and of a delicate flavour.

If these are facts that can be borne out by practice, and of this there seems no reason to doubt when it is known how abundant the trees are in India, and how prolific they are in flowering, there is apparently good cause to suppose that mahwa flowers may ere long become a recognized article of commerce, for we are reminded that the cost of production is almost *nil*, for they have only to be swept up from the ground and shovelled into sacks or boxes, when they are ready for immediate exportation. It is said that a bad mahwa harvest has never yet been known in India, so that there is the certainty of a constant and unlimited supply. The flowers will keep for almost any length of time, and considering the abundance of sugar they contain their application may yet be further developed. The principal cost would of course be in the freight, but if the importation were taken up in earnest new applications would soon develop themselves, and the uses we have mentioned would also be perfected.

NOTE UPON PAO-PEREIRO BARK.*

BY O. HESSE.

The presence of an alkaloid in Pereiro bark, also called Pingnaciba and Canudo amargoso, which in Brazil has a reputation as a febrifuge, was announced by Correa dos Santos, and its occurrence was confirmed by Goos† in 1838. Goos described it as amorphous, but subsequently Peretti‡ observed that it was capable of separating from ether or alcohol in granules, and consequently probably of crystallization. Bochefontaine and De Freitas§ have recently studied the action of this alkaloid upon different animals and found that it has considerable toxic power. In these experiments the alkaloid was used partly dissolved in water (!) and partly in alcohol. The latter authors also suggested that the name "pereirine" at present used for the alkaloid in question should be changed to "geissospermine," in order to recall the origin of the alkaloid. According to Peckholt the tree yielding pao-pereiro bark (not pao-pereir*a* as it is usually erroneously spelt) is the *Geissospermum Vellosii,* and according to Baillon the *Geissospermum læve*, consequently it is one of the Apocynaceæ.

I have myself also been engaged in the investigation of this subject, and last June I informed Professor Wiggers, to whom I was indebted for a considerable quantity of bark and leaves of pao-pereiro, that the bark contained several alkaloids, one of which was distinguished from the others by its difficult solubility in ether. This alkaloid I have named "geissospermine."

Geissospermine forms small white prisms, truncated at both ends. It dissolves readily in alcohol, but is nearly insoluble in water and in ether. It is freely soluble in dilute acids, and from such solutions it is again precipitated by an excess of ammonia or sodium hydrate. The precipitate at first consists of amorphous white flocks, which are quickly transformed into small crystals.

The hydrochloric solution of geissospermine gives with platinic chloride a pale yellow amorphous precipitate; with gold chloride it gives a brown yellow precipitate, no reduction of the metal taking place in this case.

Concentrated nitric acid dissolves geissospermine with a purple red colour, which at the ordinary temperature continues for a considerable time; but after heating the colour immediately disappears, passing into orange yellow. Pure concentrated sulphuric acid dissolves the alkaloid colourless; but after a few seconds the solution becomes bluish, afterwards blue, and at last again pale. Ordinary concentrated sulphuric or acid containing oxide of iron also dissolves the alkaloid with a more or less intense blue colour, which eventually becomes pale. Sulphuric acid containing molybdic acid on the other hand dissolves it with a dark blue colour which retains the same intensity as at first, even after twenty-four hours. Concentrated hydrochloric acid produces no colour reaction with geissospermine. When heated with a little soda lime, geissospermine yields a substance that sublimes in light yellow delicate scales, which are freely soluble in ether, and dissolve without colour in concentrated nitric acid, but with a beautiful blue colour in sulphuric acid containing molybdic acid.

The crystalline geissospermine contains water of crystallization which passes off at 100° C., the substance then becoming coloured faintly yellow. At a higher temperature the alkaloid becomes more coloured and melts at 160°, forming a brown liquid that solidifies amorphous upon cooling.

The alkaloid deviates the plane of polarized light to the left; amounting for the hydrate dissolved in 97 per cent. alcohol, with $p=1{\cdot}5$ and $t=15°$ C. to $(\alpha)_D = -93{\cdot}37°$.

Finally, the formula of anhydrous geissospermine, dried at 100° C., is $C_{19}H_{24}N_2O_2$; that of the hydrate, or the crystalline air-dried alkaloid is $C_{19}H_{24}N_2O_2 + H_2O$; and that of the platinum salt dried at 130° C. is $(C_{19}H_{24}N_2O_2 \cdot HCl)_2 + PtCl_4$.

A second alkaloid from pereiro bark forms a greyish white amorphous powder, very easily soluble in ether. It is coloured blood red by concentrated nitric acid, and violet red by pure sulphuric acid. It corresponds best with the notices of Goos and others respecting pereirine, which name should therefore be retained for it. This alkaloid is apparently contained in the bark in preponderating proportions.

I intend further to investigate both these alkaloids and especially to ascertain whether they are contained in the leaves of pao-pereiro, which Wiggers has received from Rio Janeiro, under the name of Folia Carobæ.

HANDY ANTIDOTES.*

The French medical profession have frequently occupied themselves with the endeavour to add to their pharmacopœia an antidote which would answer the purpose in the majority of accidental poisonings, and which could always be kept at hand, so that it might be administered at once, before more special indications had the time to develop themselves, either according to information and anamnestics, which are often wanting in cases of accident, or according to symptoms noted by observation of the patient. M. Mialhe has highly recommended, for this purpose, hydrated sulphate of iron mixed with calcined magnesia. This is a good antidote for the metallic salts, which it deoxidizes and changes into harmless sulphurets. But this antidote has the disadvantage of disengaging sulphydric acid in the presence of acids. It requires great nicety in preparation, and is difficult to keep. M. Dorvault has proposed, in cases of alkaloid, cyanic, and metallic poisonings, an antidote composed of equal parts of calcined magnesia, peroxide of iron, and washed powder of animal charcoal. This mixture also, however, changes if it be kept some time. M. Jeannel proposes to keep separately—1, a solution of sulphate of iron; and 2, a mixture of 80 grams of calcined magnesia and 40 grams of animal charcoal in 800 grams of distilled water. This mixture, added at the moment of using to the solution No. 1, forms the antidote, which is to be administered in successive doses of from 50 to 100 grams (about 1¾ to 3½ ounces). This antidote renders preparations of arsenic, zinc, and digitalis insoluble. It completely saturates free acid, and only acts partially on the alkaline hypochlorites and the oxide of copper. It also leaves in solution a small amount of morphia and strychnia, and the oxide of mercury in notable quantity. Professor Ranieri Bellini has made a communication to the Medico-Physical Society of Florence on the iodide of starch, which MM. Bouchardat and Quesneville were the first to introduce into therapeutics, and frequently employed in cases which required an active alterative medication, when the stomach refused to tolerate iodine in any other form. The iodide of starch is a chemical antidote which is specially appropriate to poisoning by sulphur, by the alkaline or earthy sulphurets, by caustic alkalies, ammonia, or any of the

* From *The British Medical Journal* for December 22, 1877.

alkaloids. It is also an eliminating agent, very useful in the treatment of long-standing metallic poisonings, especially those resulting from lead or mercury. Dr. Bellini advises that the patient should always be made to vomit soon after the administration of the antidote, to rid him of the chemical products which result from the decomposition of the toxic agent, which in their turn might likewise become decomposed.

THE CHARACTERS OF CONICINE.*

BY A. PETIT.

The author having had occasion to prepare a large quantity of conicine according to the process of the Codex has taken the opportunity of studying the properties of this alkaloid. The results that he has obtained as to the boiling-point, density, and rotatory power differ considerably from those of other authors. He has also arrived at the conclusion that the rotatory power cannot be depended upon as an indication of the purity of the alkaloid, or of the degree of dilution when it is diluted. Commercial conicine is not as a rule diluted except by a mixture of water and alcohol. Specimens examined contained only slight traces of methyl-conicine; whilst the rotatory power of conhydrine differs but little from that of conicine.

The product from a large operation was distilled in a current of hydrogen. Three liquids were separated: (A) passing over between 130° and 140° C.; (B) passing over between 160° and 170°; and (C), the greater portion, passing over at 170°. The operation was stopped at 172° at which point conhydrine began to distil over. The third portion (C), consisted of pure conicine, the hydrochlorate and sulphate giving very closely the theoretical quantity of chlorine and sulphuric acid respectively; it was therefore used in the subsequent experiments.

The boiling point of pure conicine, at the ordinary pressure, according to the author, is 170° C. Other experimenters have attributed to it figures ranging between 136·5° (Wertheim); and 212° C. (Ortigosa), the latter being the boiling point given in the Codex and by most authors. Blyth, however, has placed it between 168° and 171° C.

The density attributed to conicine by Gerhardt, Pelouze, and Wurtz was 0·878, and by Berthelot and Dragendorff 0·89. The following were the results obtained by the author, operating at a temperature of 12° C.:—

Product A	0·869.
„ B	0·850.
„ C (pure conicine) . . .	0·846.

Examined with the sodium light the rotatory power of pure conicine freshly prepared was found to equal +20·7°; but after keeping the preparation eight days this had diminished to equal +10·36. Chloroform, used as a solvent, diminished the rotatory power of conicine, but to a much less degree than alcohol. Ether, oil, and benzol are without action in this respect.

Pure conicine (product C) can be preserved a long time without alteration. Combined directly with hydrobromic acid or hydrochloric acid it forms with the greatest facility very stable salts that remain unaltered at 100° C. or even 120° C. The best method of preparing them is to employ the conicine distilled in a current of hydrogen and colourless, and add to it a very slight excess of hydrobromic or hydrochloric acid. Upon evaporating slowly over a water-bath, fine perfectly white crystals of the hydrobromate or hydrochlorate are obtained. The insoluble modification of hybrobromate of conicine, noticed by Mourrut as being formed when the temperature was raised above 60°, was not observed by the author to more than a most trifling extent. Crystals of hydrobromate of conicine dissolved in distilled water formed a clear colourless solution, which when heated during half an hour to 100° gave no precipitate. Both the hydrobromate and the hydrochlorate of conicine are anhydrous.

The hydrobromate of conicine is soluble in two parts of water, the hydrochlorate is a little more soluble. The hydrobromate is soluble in two parts of alcohol, and the hydrochlorate in three parts.

A specimen of conicine obtained from a German source was found by the author to agree with pure conicine prepared by himself as to the boiling point and density, but differed considerably in rotatory power, which equalled +15·79°. The author suggests whether this variation between +10·36° and +15·79° in the rotatory power of substances, presenting otherwise identical characters, may not be indicative that conicine extracted from conium fruit is a mixture in variable proportions of conicine active and inactive upon polarized light.

* *Journal de Pharmacie* [4], vol. xxvi. p. 200.

COLCHICUM AND ITS PREPARATIONS.*

BY DR. FRANZ MOLS, PHARMACEUTIST.

There is perhaps not a single drug that has played so conspicuous a part in materia medica as *Colchicum autumnale* (*meadow saffron, Herbst Zeitlose*) and its various preparations, such as extractum colchici aceticum, extractum colchici seminis fluidum, extractum colchici radicis fluidum, tinctura colchici seminis, tinctura colchici radicis, acetum colchici.

To this list has most recently been added *colchicine*, but it has not proved a great favourite in therapeutic practice on account of its exceedingly dangerous application, and physicians have turned to new preparations, such as iodide of potassium, propylamine, and salicylic acid, in order to overcome certain diseases in which preparations of colchicum had formerly been used. Many practitioners have abandoned these newer preparations and have returned to colchicum, but frequently have arrived at no satisfactory results therefrom.

The main cause of these unsatisfactory results of the use of colchicum in medical practice is twofold, and may be looked for partly in the unfitness of the raw material used in pharmaceutical laboratories, and on the other hand in the manner of its preparation, and this latter defect, again, caused by impractical formulas in most of the pharmacopœias as well as the thoughtless following of the same by the preparing pharmaceutists themselves.

The most effective constituent principle of *Colchicum autumnale* is without doubt found in the alkaloid—colchicine—and this is said without denying all the effectiveness of the extractive substances which are soluble in water.

According to the assertions of the most prominent chemists of our time it has been established that the seed of the colchicum, after it is over a year old, contains very little, if any, colchicine, and this is the case with the root or bulb after having been gathered a few months. The last editions of the 'Pharmacopœia Borussica' as well as the 'Pharmacopœa Germanica' permit only the use of colchicum seed which is not over a year old.

Now it will be admitted by any practical pharmaceutist that the supply of several pounds of colchicum seed, which always has been taken from a wholesale house, is sufficient to make all preparations of colchicum for several years, even in a thriving business, and it may be safely stated that the colchicum bulb or seed found in most of the drug stores contains no colchicine at all. The other causes of the real ineffectiveness of these preparations are some of the formulas of the pharmacopœias. According to the researches of the most prominent chemists of our time who have made the preparation of colchicine a specialty, such as Huebler, Aschoff, Bley, Pfeiffer, Maisch, Walz, Schoenbroodt, Burmeister, and Geiger, colchicine is extractible from the root or seed of colchicum *only by the medium of heated or acidiferous alcohol of* 90 *per cent.*, while the pharmacopœias invariably dictate *diluted* alcohol, and in the cases of vinous preparations prescribe it *more diluted* yet. By such method it is impossible to gain any colchicine, even if the natural raw material used really contained it.

* From the *Druggists' Advertiser* for January.

In order to meet this dilemma, I have taken pains, first, to be in receipt every fall of a fresh consignment of colchicum seeds; and, secondly, I have prepared a formula, according to which a preparation may be made which contains all and every effective particle in the colchicum. This preparation is available alike to the physician and the druggist, because it is in the shape of a *fluid extract,* and therefore applicable to the preparation of the tincture as well as the wine.

I have the colchicum seed gathered in Germany (on the banks of the Neckar near Heidelberg) in the month of July, have it slightly dried, sprinkled with alcohol, and then sent to me in hermetically sealed packages.

I here give my manner of preparation :

Colchicum seed, which has been gathered in July, is first dried, then ground, and moistened with alcohol of 90 per cent. After twenty-four hours digest for further twenty-four hours on a steam-bath with 90 per cent. alcohol four times the weight of the seed used. (This procedure is best done in the still of Wolff's or Mohr's steam distilling apparatus, whereby the over-distilled alcohol may be saved and returned in to the still). When cold strain the contents of the alembic through linen and distil off the liquid until there remains but one-half the weight of the seeds originally used, and place aside.

Macerate the strained seed again, but this time with hot distilled water, during twenty-four hours, pack it in a glass percolator and exhaust with hot distilled water as long as the liquid retains a bitter taste; then evaporate by the steam-bath until but half of the original weight of the seeds used remains. Then mix both extracts—the alcoholic with the aqueous—and keep the product four or five days in narrow vessels (for which I find tall and narrow glass bottles are best adapted). The dark green oil (*Oleum Colchici seminis pingue*), which was dissolved in the alcohol, will have accumulated on top, and is to be removed by decantation.

For this fat green oil there has not been found any use as yet. One troy ounce of this fluid extract represents one troy ounce of colchicum seed.

I have convinced myself of the presence of colchicine in an extract prepared as above, as I gained 15 grains of colchicine from a pound of extract, while with even the greatest possible accuracy in analysis I could not detect the least trace of colchicine in five samples of extract that I had procured from several large establishments of so-called respectable manufacturing chemists.

THE NUTRITION OF DROSERA.

An objection is frequently raised to the modern view of the "carnivorous" habits of the sundew and of some other plants, on the ground that they do not benefit by this habit, but appear to carry on quite as healthy and vigorous an existence when deprived of this source of food. According to the Darwinian theory of natural selection no habit can be acquired by an organism unless it is of some benefit to it. In a paper recently read before the Linnean Society, Mr. Francis Darwin pointed out that the statements that animal food supplied to the leaves of *Drosera* is not advantageous to it, rest on vague or unreliable data, and he described a series of careful and elaborate experiments, from which he appears to have proved that it is distinctly advantageous.

For this purpose about 200 plants of *Drosera rotundifolia* were transplanted on June 12th, 1877, and cultivated in soup-plates filled with moss during the rest of the summer. Each plate was divided in half by a low wooden partition, the plants on one side of the partition being fed by supplying each leaf with one or two bits of roast meat, each weighing about $\frac{1}{50}$ grain, while the plants in the other half were "starved." The feeding was performed at intervals of a few days from the beginning of July till the early part of September. The benefit of the feeding on the plants in one half of each plate was soon apparent. By July 17th the leaves were evidently of a brighter green, showing that the increased supply of nitrogen had allowed a more active formation of chlorophyll grains to take place; and from this time the flower stems on these plants were distinctly taller and stouter. On August 7, the ratio between the number of "starved" and "fed" flower-stems was as 100 to 149·1, and by the middle of August the proportion of leaves on the two sides was as 100 to 136·9. At the beginning of September, the seeds being ripe, all the flower stems were gathered, and the following comparisons were arrived at as the result of counting, measuring, and weighing the various parts of the two sets of plants :—

Ratio between the number of starved and fed plants	as 100 to	101·2
Ratio between the weights of the plants exclusive of flower-stems . . .	as 100 to	121·5
Total number of flower-stems . .	„	164·9
Sum of the heights of the flower-stems	„	159·9
Total weight of flower-stems. . .	„	231·9
Total number of capsules	„	194·4
Average number of seeds per capsule	„	122·7
Average weight per seed	„	157·3
Total calculated number of seeds produced	„	241·5
Total calculated weight of seeds produced	„	379·7

The most important feature in the general result is that the advantage gained by the fed plants is far more conspicuously shown in all that relates to the seeds and flower-stems, than in any other part. Thus, the ratio between the weights of the plants, exclusive of flower-stems, is as 100 to 121·5; while the weights of the flower-stems, including seeds and capsules, were in the proportion of 100 to 231·9. The highest ratio is seen to be between the total weights of seeds produced, viz., 100 to 379·7; and this is intelligible, says Mr. Darwin, because a source of nitrogen is laid by in the albuminous seeds. Another point is that the difference between the starved and fed plants is more clearly shown in the comparison of weights than in that of numbers or heights. It is clear that increase of weight is a better proof of increased assimilation than any other character.

It may fairly be said that the above experiments prove beyond a doubt that insectivorous plants are largely benefited by a supply of animal food, and it can no longer be doubted that a similar benefit is gained in a state of nature by the capture of insects.

SELF-FERTILIZATION OF PLANTS.

At a recent meeting of the Linnean Society, the Rev. G. Henslow gave an account of a series of experiments on this subject, the results of which are not altogether in harmony with those at which Mr. Darwin has arrived. These results may be summed up, according to Mr. Henslow, in the following statements :—1. The majority of flowering plants are self-fertile. 2. Very few are known to be physiologically self-sterile. 3. Many are morphologically self-sterile. 4. Self-sterile plants become self-fertile by (*a*) withering of the corolla, (*b*) its excision, (*c*) loss of colour, (*d*) closing, (*e*) not opening, (*f*) absence of insects, (*g*) reduction of temperature, (*h*) transportation. 5. Highly self-fertile flowers may arise under cultivation. 6. Special adaptations occur for self-fertilization. 7. Inconspicuous flowers are highly self-fertile. 8. Cleistogamous flowers are always self-fertilized. 9. Conservation of energy in the reduction of pollen. 10. Relative fertility may equal or surpass that of crossed plants. 11. It does not decrease in successive generations. 12. It may increase. 13. Free from competition, self-fertilized plants equal the intercrossed, (*a*) as seedlings, (*b*) planted in open ground. 14. They may gain no benefit from a cross from the same or a different stock. 15. They are as healthy as the intercrossed. 16. They may be much more productive than flowers dependent upon insects. 17. Naturalized abroad, they gain great vigour. 18. They are under these circumstances the fitter to survive in the struggle for life.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 16, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REGISTRAR'S STATISTICS.

AT the meeting of the Council last week, the Registrar presented his usual statistical report on the Register of Chemists and Druggists and the numerical strength of the Society, by which we are enabled once more to take a brief glance at the relations they bear to each other and to those of former years. The subject-matter of that portion of the Registrar's report which is included under the heading "Analysis of Examinations" has already been dealt with in our recent review of the past year, and therefore calls for no further notice here beyond the remark that the fuller details now presented disclose an apparent incompatibility in the results obtained by the two Boards which is occupying the attention of the Council.

The number of persons who passed the Minor examination last year and thus became qualified for registration as chemists and druggists was 299. To these must be added 15 persons who passed the Modified examination and no less than 34 who have been registered upon payment of the registration fee, after having given statutory evidence that they were in business on their own account before the date of the passing of the Pharmacy Act, 1868, and 27 whose names have been restored to the Register. These make a gross total of 375. On the other hand there have been 230 erasures from deaths and 3 from other causes. The net result is that the Register for 1878 will contain 13,320 names, or 142 more than that for 1877. Probably, however, these figures give the increase in a somewhat exaggerated form, and that it is more truly shown by the difference between the number of persons passing the qualifying examinations, 314, and the number of erasures, 233. The other principal source of increase is accidental and must soon become exhausted. Moreover, if we may judge from past experience, which has proved that the Register becomes cumbered at the rate of about 100 a year with names that require erasure, but concerning which information has not yet reached the Registrar, some allowance requires to be made in this respect. It is evident therefore that for a more exact estimate of the relative strength of the Register we must wait until the Registrar finds another opportunity for the exercise of his expurgatory powers.

Before leaving the subject of the Register we may remark that on the same day the Registrar presented another series of statistics relating to the Benevolent Fund. From these we gather the surprising fact that although a subscription of 2*s.* 6*d.* now entitles the giver to a vote at the next election of annuitants, only 2189, or a little more than 16 per cent., of the 13,320 persons on the register of chemists and druggists subscribe to the Fund.

In the comparative statement of the numerical strength of the Society we have satisfactory evidence that, notwithstanding certain vaticinations, the Pharmaceutical Society continues to make a steady advance, the number of registered chemists and druggists who now belong to it as Members or Associates being 4510, or more than at any previous time, and 89 in excess of the number stated in the report last year. It is true that there has been a decrease in two important classes, and the decrease in the class of pharmaceutical chemists has been the subject of deserved regret. But, as has before been pointed out, until the stage has been arrived at where the number of candidates passing the Major examination equals the number of deaths of unexamined as well as examined men on the Register of Pharmaceutical Chemists, decrease must be expected. During the past year it has amounted to 14 on the entire Register, while the decrease in the number of pharmaceutical members of the Society is nearly as many again, viz., 27; but this difference may find a partial explanation in the fact that naturally the death rate becomes relatively greater year by year among the unexamined men, who must have all been placed on the register before 1853, or a quarter of a century since, and that these are all members of the Pharmaceutical Society. Nevertheless, whilst recognizing these causes that necessarily affect the numbers unfavourably, all who have the interests of British pharmacy at heart will hope they are temporary, and would be glad to know that sufficient men were passing the Major to keep the Register up to at least its present standard. With regard to the chemist and druggist members of the Society it was pointed out last year that probably the turning point had been reached, and that from that time the numbers would diminish. This expectation has been verified in a decrease of 9, and it is evident that this must go on in a gradually increasing ratio.

When we come to the two classes of Associates, however, the facts are of a very different order, the return showing that there were 108 Associates in Business and 18 Associates not in business more at the end of 1877 than there were at the end of 1876. From these figures it would appear that a number of persons equal to, if not exceeding, the total number entering the business by passing the Minor examination have joined the Pharmaceutical Society during the year just past.

Another interesting feature of the report, and one of good omen for the future of the Society, is that there has again been a very large increase, amounting to 120, in the apprentices or students of the Society, this class now numbering 1054.

According to our usual practice we throw these figures into a tabular form, in order that they may be conveniently compared with those of former years:—

	1877.		1878.	
	No.	Per cent. of whole.	No.	Per cent. of whole.
Pharmaceutical Chemists, Members of the Society	2062	88·84	2035	88·21
Other Registered Chemists and Druggists connected with the Pharmaceutical Society	2359	—	2475	—
Total Number of Registered Chemists and Druggists connected with the Pharmaceutical Society	4421	33·55	4510	33·86
Registered Apprentices subscribing to the Society	934	—	1054	—

THE NEW READING OF THE SALE OF FOOD AND DRUGS ACT.

In the House of Commons, on Tuesday, Mr. Anderson called attention to a recent decision of the High Court of Justiciary, Scotland, to the effect that the adulteration of an article of food or drink purchased for the purpose of analysis under the Sale of Food and Drugs Act is not to the prejudice of the purchaser, and asked the President of the Local Government Board whether he purposed taking any steps to prevent the Act becoming a dead letter. It has also been held by two Scotch judges that the sixth section does not prevent tampering with an article to the deterioration of its quality, if without the addition of extraneous matter. The President of the Local Government Board replied that in all cases in England where this objection had been raised it had been overruled, a view in which he himself concurred, and he could not believe that the High Court of Justice, if appealed to, would come to any other decision. He did not think it necessary, therefore, to introduce an amending Bill at present.

CHLORAL HYDRATE.

It would appear from a report on another page that a coroner's jury, through its ignorance—which was shared by the coroner and the medical witness—of the fact that chloral hydrate is now included in the schedule of poisons, has decided to forward a memorial on the subject to the Board of Trade. It appears very desirable that such anachronisms should be avoided by the Home Office making coroners acquainted with any alterations that may take place in the poison schedule. The Pharmaceutical Society is at least doing its part, at a considerable expense, in forwarding information to every chemist and druggist on the Register of the recent addition of chloral hydrate to the schedule.

TOXICOLOGY IN THE POLICE FORCE.

A Coroner's inquest in a case of alleged poisoning is referred to on p. 661, which, as the report at present stands, seems to have resulted in a most unsatisfactory verdict. A woman of dissolute habits died rather suddenly; a bottle that had contained tincture of iodine, supplied to her for outward application, being found upon her empty, the inference drawn was that she had swallowed the tincture, although nothing is said of any discoloration of the mouth being noticed or any symptom that would be expected to follow the ingestion of an overdose of iodine. Add to this that a policeman stated in evidence that a drachm of tincture of iodine was more than sufficient to cause death, and apparently without any other medical evidence or *post mortem* examination, a Staffordshire jury saw sufficient to warrant it in returning a verdict of death from poisoning by iodine. Now a drachm of tincture of iodine, B.P., contains about $1\frac{1}{3}$ grains of iodine, and half as much potassium iodide. This quantity is considerably in excess of the official dose, and may or may not be sufficient to cause death if swallowed, but we think medical evidence should have been required upon this point and as to the symptoms that might have been expected. Certainly the decision should not have depended upon the *ipse dixit* of a police constable. It may be mentioned that Taylor, in his work 'On Poisons,' only quotes two cases of poisoning by iodine, the smaller dose having been half a drachm dissolved in an ounce of spirit, and in that case the patient recovered.

PROFESSOR REDWOOD'S LECTURE.

We would remind our readers that at a Special Evening Meeting of the Pharmaceutical Society, to be held on Wednesday next, Professor Redwood will deliver a lecture on "Spectrum Analysis," and in doing so we take the opportunity of saying that the lecture will not be a repetition of that delivered last year by the learned Professor on the same subject, but a continuation of it. As on the previous occasion the lecture will be illustrated with the electric light.

We understand that in order to give the members of the Chemists' Assistants' Association an opportunity of attending this lecture, no meeting of that Association will be held on Wednesday next.

BRISTOL PHARMACEUTICAL ASSOCIATION.

It has been arranged that the following lectures shall be delivered in connection with the above Association, at the Museum and Library, Queen's Road. On Monday evening, February 18th, on "The Artificial Production of Cold," by Mr. S. P. Thompson, of University College, Bristol, and on Friday, March 29th, on "Specific Gravity and its Applications in Pharmacy," by Mr. W. W. Stoddart.

Provincial Transactions.

OLDHAM CHEMISTS AND DRUGGISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The annual meeting of the above Association was held in the room at the Church Institute, on the 29th ult.; Mr. Wood, President, in the chair.

After the usual preliminary business, the Honorary Secretary, Mr. J. Naylor, read his report for the past year. He said he was glad to be able to state that the Association had been gradually improving, and had therefore attained a higher state of perfection since he presented his last annual report. This statement he was sure could not fail to give general satisfaction. In speaking of the improvement he alluded not only to the financial position of the Association, but also to the increase of ordinary members; on the other hand, he regretted to have to state that there had been a slight decrease in the number of honorary members, owing chiefly to changes in the drug business; the Association had also become possessed of additional books during the year (for which it was indebted to the Pharmaceutical Society for a grant of money), thereby rendering it replete with every requirement for pharmaceutical students as regards books, botanical specimens, specimens of the British Pharmacopœia and chemical apparatus for experimental purposes. The Association was also greatly indebted to the Pharmaceutical Society for the weekly issue of the Journal, also to Professor Attfield of the Pharmaceutical Conference, for the 'Year-Book of Pharmacy.' Lectures, essays, papers, etc., have been given on the following subjects:—"Theoretical Review of the British Pharmacopœia," "Practical Review of the British Pharmacopœia," "The Acids," "Dispensing Chemicals," "The Gases," and "The Laws of Chemistry and the Atomic Weights," by Mr. Wood; "Trade, Past and Present," and "Natural Facts," by Mr. Hurst; "Sciences, and a few Scientific Men," and "The Use of Tobacco," by Mr. Naylor; "Pharmacopœial Preparations," and "Silver," by Mr. Critchlow; "Purgatives," by Mr. Thatcher; and "The Natural Orders of Plants," by Mr. Jones. In addition to these, numerous examinations have been conducted and private classes held. In concluding, he remarked that the Association had suffered a rather severe blow during the last year in losing its late President, Mr. Taylor, who for a considerable number of years presided over the Association, during which time his manner towards the members bore the unmistakeable impress of a kindly feeling, with a strong desire to see the business of the Association carried to a successful issue; he trusted this essential quality might be the predominating one with the present members, and that by working harmoniously and energetically together the Association might attain a position surpassed by none.

The Treasurer, Mr. Hurst, then made his financial statement, which showed the Association to be in a most satisfactory position, it having a surplus of £7 1*s.* 8*d.* in hand, including a part of the Pharmaceutical Society's grant; the latter to be expended in books.

A hearty vote of thanks having been awarded to the retiring officers, the election of officers for the ensuing year was proceeded with, which resulted as follows;—President, Mr. J. Wood; Vice-President, Mr. Critchlow; Treasurer, Mr. T. G. Hunt; Librarian and Curator, Mr. R. Thatcher; Hon. Secretary, Mr. J. Naylor.

The President then delivered his inaugural address as follows:—

Gentlemen,—Allow me to thank you for the honour you have conferred upon me this evening in electing me President of this Association. It affords me great pleasure when I look back to the time of my election last year, and this evening you have shown to me your unabated confidence. I also tender to you my warmest thanks for having chosen me as the head of your various classes, and I am sure it will afford me very great pleasure to give you any assistance I can in the future. Allow me to congratulate you on the financial position of the Association, as I can say with certainty that it has never been in such a prosperous state as at present. I must also state that this Association has been of immense value, both to the masters, assistants, and apprentices of Oldham. I may say to those who do not know the history of the Association, and I believe I am the only one left who took part in it at the commencement, that there have been many difficulties to surmount. It has also been a great benefit to us as regards early closing, as we have through this Association succeeded in getting eight hours per week less. Another advantage is the one offered to students preparing for the various pharmaceutical examinations, and I do candidly say that if a student got a fair examination he would be able to pass without going through a course of study in London. We have also the opportunity of meeting together for social intercourse respecting business matters and the best mode of making our various preparations. It may also be interesting to new members to give a short account of its early life. First, there was an advertisement inserted in the Oldham papers calling a meeting of assistants and apprentices at the Waverley Temperance Hotel, for the purpose of taking into consideration the formation of an Association, at which officers were elected, and a deputation appointed to wait upon the masters, asking them to close their shops at 8·30 p.m., and Saturdays at 11 o'clock. We afterwards removed to two other temperance hotels, and the year following we went to the room of the Young Men's Christian Association, but only for a short time. A Latin class was then commenced, and continued for a time at the Lyceum, under the mastership of the Rev. A. Peaton. After a time we had, however, to give this room up in consequence of it being let to the School Board. During this time we received presents from the various wholesale drug houses. Afterwards we had a room in this Institute for one night a week, which lasted only for a short period, when the Association collapsed. In about two and a half years afterwards it was re-organized, the meetings being held once a week in the same room for nearly twelve months; thereupon the members determined to have a room for their entire use, which by their united efforts they succeeded in getting, it being the one we are now in, and I may also say, with all deference to the present members, that during the last year we lost two of our best members, namely, Messrs. Taylor and Burrows. After giving you this short history you will see that we have had to struggle hard. And now let me beg of you all in the forthcoming year to pay more attention than during the last, and also to press on you to give your minds to the different branches of study required, for which we have now every convenience, and the pharmaceutical examinations do certainly get more difficult every year, therefore it requires all our spare time to prepare for them. I, myself, think the examinations too severe for chemists in this part; they may suit the London chemists. Look, for instance, at the number of hours we have to be in the shop every week, no less than seventy-six hours, and then to commence studying for an examination; it is most unreasonable. My opinion is that we should have a board of examiners who understand what a drug business is in these large manufacturing towns. I should think, I may say, without fear of contradiction, that most of the important chemists in London get as many prescriptions in a day as all the chemists in Oldham get in a week. It would afford me very great pleasure to see a board of examiners in Manchester. I trust this may be taken up by the chemists of the district.

A hearty vote of thanks to the President for his address brought the meeting to a close.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The annual supper of the members of this Association was held at the Flying Horse Hotel, on Tuesday evening, January 29th, when thirty gentlemen sat down to an excellent repast. In the absence of the President, Mr. J. H. Atherton, F.C.S., through indisposition, the chair was ably occupied by the Vice-President, Mr. R. Fitz-Hugh, F.C.S., who was supported by the Treasurer, Mr. Rayner, and the Hon. Secretary, Mr. R. Jackson, and most of the members of the council.

After the usual loyal toasts had been given from the chair and duly honoured, Mr. Rayner proposed in complimentary terms, "The Pharmaceutical Society," which was heartily drunk, great regret being felt that the President was not able to be present and respond as usual to the toast.

Mr. Rivers Langton then proposed the toast of the evening, "Success to the Nottingham and Notts Chemists' Association." He eulogized the educational work of such associations, and spoke of the great benefit they were to members of the trade generally in promoting friendly feelings and rubbing off rough corners. He concluded by coupling with the toast the name of the Vice-President, who responded and mentioned with great satisfaction the testimony which had been borne to the value of the Association by some of the former students, who were now conducting some improvement classes for the benefit of the associates.

Mr. Warriner next proposed "The Medical Profession," which was responded to by Dr. Lill, who assured the company that the great majority of medical men did not wish at all to interfere with the chemists in the legitimate exercise of counter prescribing, but only wished to put a stop to chemists treating patients in serious cases.

Mr. Pearson then proposed "The Executive," and eulogized the officers and council for the energetic and hearty way in which they worked for the Association; he coupled with the toast the names of Treasurer and Secretary, who both suitably responded. The remaining toasts were "The Visitors," proposed by Mr. Bolton and responded to by Mr. J. J. Harvey; "The Vice Chairman," by Mr. W. H. Parker, acknowledged by Mr. J. Lewis; and "The Ladies," proposed by Mr. Ward, and responded to by Mr. W. Widdowson. The proceedings were agreeably diversified by a capital selection of songs and duets, with some choice music, and a very pleasant evening was spent.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The fourth meeting of the session was held in Anderson's College, on Wednesday evening, 30th ult. Mr. Kinninmont (Ex-Vice-President), in absence of the President and Vice-President, occupied the chair.

After the minutes of the last meeting had been read, Mr. Dougald Clerk, F.C.S., late of Anderson's College, was introduced, and delivered a lecture on "Continuity in Chemical Action," which was very fully illustrated throughout with experiments.

Continuity in Chemical Action.

In the chemical world there exists at present a growing antipathy to the atomic theory and its explanations of chemical phenomena. This antipathy may be traced, I think, to the abuse of that theory by its most ardent supporters, in the construction of that vast superstructure of so-called graphic formulæ, which serves principally to bewilder students and give false notions of the accuracy of our knowledge regarding the compounds whose *constitution* they are supposed to represent. The workers in organic chemistry are more especially to blame for this. In the ardent desire to discover new bodies, they have gone on adding compound after compound until now chemists are saddled with a host, where units may be reckoned in scores of thousands, and of this host our knowledge is but fragmentary; of each member the discoverer has probably determined the boiling point, the vapour density, and the percentage composition by ultimate analyses; a few of its reactions in most cases complete the test. Now it seems to me that although our knowledge is certainly extended in one way by this method of work, yet it would be more to the advantage of chemical science if fewer new compounds were formed and greater attention paid to the examination, thorough and accurate, of those compounds with which we are already acquainted. Chemistry is still very far behind the physical sciences in this, that in other sciences, given certain conditions, and the event may be predicted. So little, however, is known of the laws of chemical action, that we cannot as yet predict the result of any given action between bodies with which we are quite familiar. Very early in the history of the science efforts have been made to formulate chemical affinities; in the older books in the science, you have all observed tables of affinity, in which the supposed relations of a series of elements to one element with which they all combine is shown; these relations held for but a short time, new discoveries proved given actions capable of complete reversal under changed conditions. To take an example, I have here solutions of silver, mercurous, cupric and plumbic nitrates. Into the first solution I introduce metallic mercury, second copper, to the others in their order, lead and zinc, the result being, as you see, the precipitation of metals contained in solution, and the partial solution of the free metal added. Now at one time, these reactions would be supposed to prove that the affinity of mercury, copper, lead and zinc, for the acid radicle, was greater than that of the metals existing in solution; but Dr. Odling* has shown that in all these cases with the exception of the last, the order of precipitation may be reversed.

Tables of affinity, constructed in this way, cannot express completely the relations of the combining bodies.

Berthelot very early recognized the necessity of knowing more of a chemical change than its ultimate result; he enunciated a law which, from *à priori* reasonings, he supposed to regulate chemical combinations, but his researches were not experimental, and his law does not express correctly what occurs in any chemical action.

Gladstone's investigation "On Circumstances modifying the Action of Chemical Affinity" (*Phil. Trans.*, 1855, p. 179) was the first noteworthy step in the direction of definite study of the conditions of a chemical reaction. He succeeded in proving that in some cases alteration in the relative masses of the acting bodies causes proportionate change in the chemical action taking place. From 1855 to the present time many investigators have wrought at this subject, among whom may be mentioned Bunsen, Debus, Harcourt and Essen, Brodie, Berthelot, Guldberg and Wage, etc.; it is my object to-night to examine their results and place before you as briefly as possible the methods of investigation. Let us begin with Gladstone. When certain ferric salts in aqueous solution are brought in contact with potassic sulphocyanide, ferric sulphocyanide is formed of a deep blood red colour, in the case of ferric chloride

$$Fe_2Cl_6 + 6KCNS = 6KCl + Fe_26CNS$$

this reaction would occur if the double decomposition were complete. But Gladstone found that when one equivalent of potassic sulphocyanide was added to one equivalent of ferric salt, the double decomposition was not complete; instead of one equivalent of ferric sulphocyanide being formed, in no case did the amount equal ·2 equivalent, but that on further addition of sulphocyanide of potash, the colour went on increasing, and was still perceptibly increasing with the addition of the 700th equivalent. By preparing a standard solution of ferric sulphocyanide, and comparing the colour produced by successive

* "On the Reciprocal Precipitation of the Metals."—Odling, *Chem. Soc. Journal*, vol. ix., 144.

additions of alkaline sulphocyanide to a solution containing a known amount of ferric salt, Gladstone was able to trace the amount of ferric sulphocyanide, formed by each successive addition. He found this increase to be perfectly continuous, and capable of being represented by a curve, but he was unable to enunciate any law governing this change. Many similar reactions were examined, among others, that of hydrochloric acid and cupric sulphate. An aqueous solution of cupric sulphate is blue, and on the addition of hydrochloric acid, it becomes green, showing the formation of cupric chloride; this green colour increases in depth with the amount of hydrochloric acid added. When to a solution of ferrous sulphate is added tannic acid, ferrous tannate is formed of a black colour; increase of tannic acid or of ferrous sulphate produces increasing depth of tint; the red solution of auric bromide when treated with sodic chloride becomes yellow, showing formation of auric chloride. All these reactions, Gladstone found to behave in the same manner as that first mentioned. It was then considered proved, that when any two salts are brought together in aqueous solution, which do not form any insoluble salt by double decomposition, the salts invariably partially decompose each other, forming four salts, the relative proportion of which, depends on the excess of the original salts. Harcourt* and Essen, in 1866, attacked this question in a different way. When hydriodic acid is brought in contact with hydrogen dioxide, double decomposition takes place and iodine is liberated,

$$H_2O_2 + 2HI = 2H_2O + I_2.$$

In dilute solutions this reaction is found to take a considerable time. The object of the investigation was, taking a constant amount of hydrochloric acid in a given solution, and varying quantities of H_2O_2, find the time required to expel the iodine from this hydriodic acid. A solution was made containing H_2O_2 and HI together with starch which served as an indicator; to this solution was added one drop of strong solution of sodic thiosulphate; the free iodine attacked the thiosulphate, converting it into tetrathionate

$$2\ H_2S_2H_2O_4 + I_2 = H_2S_4O_6 + 2HI + 2H_2O.$$

As long as any thiosulphate was present in solution no blue colour could appear; the iodine as fast as it was liberated from the hydrochloric acid by the hydrogen dioxide was reconverted by the thiosulphate. Adding then equal amounts of thiosulphate to the solution, and noting successively the time required for the reappearance of the blue colour denoting excess of iodine, a definite relation is found between the diminution of hydrogen dioxide present in the solution and the increased time taken to perform equal amounts of chemical work. When the amount of hydrogen dioxide present in the solution decreases by equal intervals, the time taken for the diminished amount to liberate a given quantity of iodine from hydriodic acid increases in constant geometric rates.

It was found by experiment that the presence of tetrathionate did not influence the reaction in any way, and that the thiosulphate acted only as represented in the equation; when added to hydrogen dioxide it did not reduce it except in presence of HI. When this law became known, Dr. E. J. Mills recalculated Gladstone's experiments, and found that although Gladstone had not observed this relation, yet it existed in the several reactions with which he experimented.

Harcourt and Essen tried several reactions before hitting on this one, but the conditions were not sufficiently simple to show the action clearly. When oxalic acid is added to a solution containing potassic permanganate and hydric sulphate, the permanganate is reduced at first slowly and as the action goes on at an increasing rate, but it was found that the presence of manganese sulphate formed by the change exercised an important influence on the rate.

* Harcourt and Essen, *Phil. Trans.*, 1865, 193; 1866, 117.

These two investigations, considered alone, seem to point to the continuity of all chemical actions. Chemical action is continuous and takes time, the amount of chemical change in a given unit of time is proportional to the acting masses. Mass enters into chemical change. Other experiments, however, seem to lead to a different conclusion. Bunsen* by exploding mixtures of CO and O, and H and O in various proportions, and determining the pressures produced by means of a weighted valve, considers that combustion is not, as was previously supposed, a continuous operation but has definite stages of action. A mixture of hydrogen and oxygen in the proportion necessary for complete combination produces on explosion a pressure equal only to $\frac{1}{3}$ of complete combustion; increase the amount of either hydrogen or oxygen, and, although the temperature falls, yet the amount of combination is increased when the dilution exceeds a fixed amount in an abrupt manner to $\frac{1}{2}$ of total possible. Berthelot has during last year (1877) proved that Bunsen in his calculations made a serious error by not taking into account the contraction produced by combination; that in fact his research proves nothing but the possible limit of temperatures attainable by combustion. He has not proved even that dissociation takes place at all.

Experiments by Debus on the precipitation of baric and calcic salts by sodic phosphate are considered to prove discontinuous action, but almost similar experiments by Chizynski by sodic phosphate show the action of changed mass to be continuous and not abrupt. In fact on this subject the evidence is conflicting in the extreme, and almost the only conclusion we can arrive at is that authorities differ in the most extraordinary manner.

Berthelot's experiments seem to throw considerable light on the subject; he found actions both continuous and discontinuous. He founded his arguments, (1st) on the heat phenomena accompanying the mixture of solutions of salts; (2nd) on a special method founded on the following facts:—When an aqueous solution of an acid such as sulphuric, which dissolves both in ether and water, is shaken up with ether, the acid divides itself between the ether and the water in a constant proportion which is independent of the relative volumes of the water and ether, but is dependent on the strength of the aqueous solution and on the temperature of the experiments. He thus found a coefficient of division which he applied in the following way:

A solution of potassic bisulphate in water behaved to ether in the same manner as a pure sulphuric acid solution of the same acidimetric strength would, but on increasing the amount of sulphuric acid present partial combination seemed to take place between the neutral potassic sulphate and the acid. In a solution of bisulphate of potash on water the acid exists free, but small quantities may combine by increasing the quantity of acid present.

Sodic biacetate and benzoate behaved in the same manner.

His conclusions may be briefly stated.

(1). Acid salts of monobasic acids cannot exist in aqueous solution, but are immediately broken up into neutral salt and free acid.

(2). Acid salts of polybasic acids can exist in solution, but generally in a state of partial decomposition.

Examples: binoxalates, bitartrates and especially bisuccinates of potash and ammonia.

(3). The quantity of salt decomposed increases slowly and continuously with the degree of dilution.

(4). The quantity decomposed changes with the proportion between neutral salts and the excess of acid present, in such a way that with excess of acid the stability of the acid salt is increased, and excess of neutral salt produces the same effect, but at a slower rate.

The heat phenomena prove the same. When nitric or

* *Phil. Mag.*, 1866.

sulphuric acids are added to their respective ferric salts, in aqueous solution the heat evolved shows increased combination.

Other heat reactions show complete double decomposition with equivalent quantities of salts; in fact with stable compounds, salts are formed in the order of their stability.

On the whole it seems to me probable that chemical action is always continuous when the acting substances are in a state of dissociation, or when the compounds formed are under the particular conditions present near their decomposing points. In the preceding experiments we have always found that where the compound acted on and the compound formed are decomposable by the solvent, the action increases with excess of reagent, as in the case of ferric sulphocyanide.

The effect of mass in chemical actions is due to partial decomposition, and not to an inherent continuity in the method of chemical action. Any discontinuous action may be rendered continuous by raising the temperature sufficiently or otherwise changing the conditions; conversely any continuous action may be rendered discontinuous so far as the effect of mass is concerned.

On the motion of the Chairman a hearty vote of thanks was accorded the lecturer, and the meeting brought to a close.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The half-yearly meeting of the members of this Association was held at the rooms, Halford Street, on Thursday, the 31st day of January last. The report, which was unanimously adopted, stated that in reviewing the past session the committee found much to encourage them, although there had been changes, as upon former occasions, which to some extent influenced the general routine of the Association. In addition to the President's inaugural address, Mr. J. E. Weatherhead had delivered a lecture on "Gems of Sea and Land," Mr. W. J. Harrison on "Fermentation," Mr. F. T. Mott on "Ventilation," and Mr. W. B. Clark on "The more important Elements." Each lecture had been well attended, and listened to with appreciation, and the committee desired very heartily to thank the lecturers.

There had also been 43 classes held, conducted by Messrs. Clark, Garrett, Raynor and Hammond, the subjects being Chemistry, Pharmacy, Botany, and Materia Medica. The average number present at each meeting had been eight, and the committee, in order to establish a system of regular attendance, had offered a prize to that gentleman who should be present the greatest number of times. Two further prizes had been competed for at examinations conducted by the class teachers, Messrs. Crane and Lewitt being the successful candidates. The Council of the Pharmaceutical Society had kindly presented a number of materia medica specimens, and also valuable additions to the herbarium, which had greatly conduced to the usefulness of the museum, and the committee desire to express their appreciation and thanks.

The Treasurer's report showed that the receipts during the half year, including a balance in hand of £1 8*s.* 8*d.* from the last balance sheet, had amounted to £21 3*s.* 8*d.* and the expenditure to £11 19*s.* 11*d.* leaving a balance in hand of £9 3*s.* 9*d.*

After the transaction of routine business the members proceeded to elect the committee for the ensuing session, with the following result: J. Garrett, President; C. T. Raynor, Vice-President and Hon. Secretary; W. B. Clark, Treasurer; W. Hammond, J. J. Pratington, C. B. Lomas, C. Hodgson.

On Feb. 7th inst. the nineteenth session of the above Association was opened by a tea meeting, and the usual President's inaugural address.

The President, Mr. J. Garrett, in his address to the members, said he hoped the classes would be better attended than they had been in the last session, and that the students would take part in the classes by asking questions and promoting discussions upon the subjects treated upon by the teachers. By so doing, the teachers would have a better idea of the wants of the student, and the student would find it a good opportunity of clearing up some doubtful point in the lesson.

At the conclusion of the address a vote of thanks was proposed and carried by the members.

Mr. Thirlby, an honorary member, upon being called upon to address the meeting, drew attention to a chart of the metric system hanging in the room. He stated the importance of a sound knowledge of the metric system, and to make the subject more attractive, he offered the sum of 10*s.* to be given in prizes to the successful candidates of an examination held upon the subject at the end of the session.

Mr. W. B. Clark, the Treasurer, then stated the system to be carried out with regard to the Association prizes, to be competed for at the end of the session. The successful candidates must have obtained at least 55 per cent. of the marks in two subjects, and the two subjects having the highest number of marks only to be taken into account. Thus a student being proficient in two or more subjects will stand higher than a student getting a larger total number of marks, though the number in the two best subjects be less. By this method, students not able to take part in all the subjects, will be encouraged to study two or three subjects well.

Mr. Marshall then in a very spirited manner spoke of the past work of the Association, and pictured a bright future to those who mastered their studies with credit.

Readings and songs were given during the evening, being the largest meeting of the members that had taken place for some time.

Upon singing the National Anthem the meeting, which had been thoroughly enjoyed by all, was brought to a conclusion.

LIVERPOOL CHEMISTS' ASSOCIATION.

The eighth general meeting was held at the Royal Institution, Jan. 31, 1878. In the unavoidable absence of the President, Mr. Robert Sumner (Hon. Treasurer) was unanimously voted to the chair.

The minutes of the previous meeting were read and signed. Donations to the library were duly acknowledged.

Mr. J. T. Armstrong, F.C.S., read a paper on "The Perils which attend the use of some of the Burning Oils."

A lengthy and animated discussion on the paper followed, in which the Chairman, Messrs. J. Abraham, A. C. Abraham, T. Farmer, A. Haddock, A. H. Mason, F.C.S., R. Parkinson, and others took part. On the motion of Mr. Parkinson, seconded by Mr. Abraham, a vote of thanks to Mr. Armstrong was carried by acclamation.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

An ordinary meeting of this Association was held on Friday evening, February 1st, at the Memorial Hall, Albert Square. Mr. W. Wilkinson, Vice-President, occupied the chair, and there was a good attendance.

Mr. F. B. Benger exhibited the telephone, and gave a short address on its construction and the scientific principles involved in its successful working. The instruments used for demonstration had been extemporized by inserting 5-inch bar magnets through the bottoms of turned wood tooth-powder boxes, as suggested by Professor Barrett. The bobbins of No. 36 insulated wire had been slipped over the ends of the magnets inside the box, and discs of thin iron (ferrotype plates) were laid on the top of the open boxes, and held firmly in position by the lids, from which they were separated by thin flanges of cardboard; the lids were furnished with holes, half-an-inch in diameter, through which sounds were conveyed to the thin iron plate, and the line wires connected with the ends of the coil inside the boxes by binding screws inserted in the sides.

By means of these simple instruments, which were taken to pieces for demonstration, members were enabled to converse with each other in different parts of the building, etc.

The Chairman then announced that a paper on "Patent Medicines, by whom should they be sold, and under what restrictions," had been sent by Mr. J. B. Payne, who, he regretted to say, had been prevented by illness from being present. The object of the paper, he believed, was to induce discussion on a subject which was of considerable interest to most of them.

Mr. Payne's paper was then read by one of the Secretaries, as follows:—

"What are the advantages of the trade or profession of a chemist and druggist, or pharmaceutical chemist, at the present time? A question frequently asked and simply answered. The exclusive use of the titles Pharmaceutical Chemist and Chemist and Druggist. Practically, that is all. To an outsider, who had for his guidance and information the Pharmacy Act, it would appear that we enjoyed the exclusive right to dispense medicines and physicians' prescriptions, and to retail poisons. With regard to the matter of dispensing, any person connected with the trade has a fairly good idea of its value as a livelihood to the chemist, and with regard to the sale of poisons it is very far indeed from being exclusive. The fact is that the drug trade does not occupy the position that it should, nor does it possess in reality sufficient advantages to compensate for the demands made upon it by the Government, the medical profession or the public. The medical profession has, in return for scarcely any more severe examination, a very exclusive position or monopoly. In the matter of education, the Government protects, in a very marked degree, those schoolmasters who conform to their requirements. In return for a no more severe examination than the Minor a solicitor holds a very distinct monopoly. Until quite recently I believe that it was sufficient for a barrister to 'eat himself in,' and a very agreeable occupation too.

"These remarks are well worn, but we never seem to get beyond them. We complain and complain and end with complaining. I am decidedly of opinion that we should take action, and my more immediate object in reading this short paper is to invite your opinion whether we should request the Council of the Pharmaceutical Society to move in the matter. We shall certainly gain nothing by sitting still, nor must we hope to carry any proposition right before us without hindrance; there is no doubt but that it will require some considerable energy, and a large amount of patience, and when the start is made it must be with a will and determination.

"The two leading features offered by the Pharmacy Act in return for the Government requirements, are dispensing and the sale of poisons.

"I will pass by dispensing, and confine myself principally to the sale of poisons.

"Now, in this matter we do possess an undoubted legal right and monopoly, but that somehow or other has never yet been strictly enforced. The Trade Protection Society has taken the matter up with some spirit, but appears to find many obstacles in the way. What I cannot understand is, that in London and most other large towns poisons are openly advertised and sold retail by unregistered persons.

"To show the importance which is everywhere attached to regulations for the sale of poisons, I have only to point out how frequently and on every possible occasion, magistrates, coroners, and newspaper editors take the opportunity to read the law in very severe terms, and yet the Government actually license any person who chooses to pay 5*s.*, and offer every facility to break the law.

"I refer to the sale of patent medicines containing poisons, and I maintain that it is entirely wrong for the Government to place an Act of Parliament on the statute book containing such restrictions on the sale of poisons and to compel chemists to pass such rigid examinations, even deeming it necessary to require the examinations to be conducted under the very eye of the Privy Council (thus showing how serious they consider the question to be); I say that it is entirely inconsistent for them to license unregistered persons to evade the Act.

"I have selected one or two extracts from the *Pharmaceutical Journal*, which go to show most conclusively how important it is that the public should be thoroughly protected, and what is more that they think they are.

"'Sale of Laudanum.—Censure of a Chemist by a Coroner.*—The jury returned a verdict of 'Accidental Death,' and in so doing expressed their opinion that it was wrong for so young a man as the witness, Cooke, *to be allowed to serve poisons.* The Coroner entirely agreed with the jury." This young man was twenty years of age and had passed the Preliminary examination. Now what an inconsistency for a law officer of the Crown to censure in a case of this kind, when the Crown actually licenses any greengrocer to sell chlorodyne indiscriminately. But principally I would point out this fact, that both the coroner and the jury were evidently of opinion that it was most essential that the sale of poisons should be restricted.

"'Poisoning by Vermin Killer.†—Several members of the jury complained of the readiness given to persons to purchase *deadly poisons* at these chandlers' shops that sold everything. They felt that the sale of poisons should be restricted to the law that affected chemists. Dr. Chapman said that a packet of the vermin killer cost 3*d.*, and would kill five persons. He concurred with the jury on the careless mode of sale.' And so do I.

"In an editorial article‡ on the sale of poisons and its difficulties, the writer says, 'It seems, therefore, desirable not only for the interest of the public but also for mere self-protection that great care should be exercised in the sale of such medicines as are here referred to [paregoric, etc.], and *that the buyers should be warned as to their relatively different potency.* . . . In this way something may be done towards obviating the possible consequences of ignorance and carelessness.'

"In every way, and from every source, we have full proof that the public demand and have a right to expect protection. But under the present Patent Medicine Act any shoe-black, fusee seller, or halfpenny newsman can indiscriminately retail preparations of atropine, strychnine, morphia, prussic acid, and chloroform.

"To wit. It has properly been deemed necessary to place hydrate of chloral on the list of poisons, yet any unregistered person having a patent medicine licence can retail it indiscriminately.

"Or again. *A Chemist* may only sell morphia under certain regulations, yet if morphia be made into pill or solution and covered with a patent medicine stamp, then any unregistered person may sell it without restriction.

"Is that right? Is it safe to the public? and what a ridiculous farce it makes the poisons' register.

"I have been told that this question of traffic in patent medicines has been frequently discussed, and that it is a difficult question to solve. I admit that, but still I maintain that we must begin somewhere and that quickly.

"In the discussion that would be provoked, we should receive many valuable suggestions, and good results must follow.

---

* *Pharm. Journ.*, January 27, 1873.
† *Pharm. Journ.*, April 24, 1875.
‡ *Pharm. Journ.*, April 13, 1872.

I would start with this proposition to which others could be added if thought advisable. "That seeing the largely increasing traffic in medicines of a highly dangerous character, and poisons, under cover of the Patent Medicine Act, by unregistered persons who are totally unacquainted with their character, thus offering and affording a very serious source of accidental and malicious poisoning, and a direct medium for infringing the spirit of the Pharmacy Act, the Council of the Pharmaceutical Society are hereby requested to promote an Act of Parliament for the repeal of that section of the Pharmacy Act which relates to the dealing in patent medicines by unregistered persons whenever such contain any ingredient enumerated in the poison schedule. The proposition desires an Act of Parliament, whereby patent medicines containing poisons can only be sold by registered chemists." This would protect the chemists, and the public. The proposition is given as a basis to commence with, any details could easily be arranged after the general principle was established, and we must be prepared to make some amount of self-sacrifice.

"My object has been to show that we have a distinct right, and that in making out our case we are actually doubly protecting the public.

"It would not interfere with the sale of anybody's goods, as every village has its chemist; it would really add more respectability to them.

"The reason why I advocate quick action is, that if we let the grocers, chandlers, and general dealers get firm hold of the trade, we should then have so much more a large and influential opposition. Even now it would require the united action of the chemists. Every individual member would have to help, as well as every local association."

The following advertisement had been cut from a local paper:—"Special notice—Having enlarged our central premises, we have added patent medicine to our tea and italian trade. All articles will be sold at wholesale price: 1*s.* 1½*d.* bottles at 10½*d.*; 2*s.* 9*d.* at 2*s.* 3*d.* See our price list."

A communication on the same subject had also been received from Messrs. Kay Brothers, and these gentlemen requested that the concluding paragraph which they designated "the remedy" might be read.

"The real remedy we venture to suggest is this—that licences for the sale of patent medicines should only be granted to persons on the register of chemists and druggists or pharmaceutical chemists, or persons approved of by the Council of the Pharmaceutical Society, and that the excise should only grant these licences on production of a certificate from that body, in precisely the same way as now they only grant wine licences on production of a certificate from the magistrates; and to effect this, all that is required is a proper memorial to be brought before the authorities of Somerset House, setting forth in the best manner the reasons why this course is desirable, quite as much in the interest of the public as in that of the chemists, and showing that it could not affect the revenue in any way—also describing the expense and cost of obtaining the necessary qualification to be a chemist and druggist at the present time, and the grievous injury, disrepute and loss they are brought to by the present vendors of tea, grocery, and the like, who sell patent medicines at about cost price in order to catch custom and make better profit out of their tea and other commodities.

"There is little doubt if this could be properly represented to the Board of Inland Revenue by an influential and properly qualified deputation representing the trade and the Council of the Pharmaceutical Society, and also that of the chemists and druggists' and trade associations generally of Manchester, Birmingham, London, etc., etc., with a little pressure (as the Inland Revenue would not by any means suffer from the restriction of licences), it would be a very simple, costless, and effective way of protecting the legitimate trader, the revenue, and the public."

A long discussion ensued, in which a very general opinion was expressed that as patent medicines containing poisons within the meaning of the Act formed such a small proportion of the whole (Messrs. Kay had calculated them to be not more than eight per cent.), it would be useless to attempt to influence legislation in the matter. That small proportion would be scarcely worth the trouble, and was indeed at the present time almost entirely in the hands of chemists.

The following resolution moved by Mr. Hughes, and seconded by Mr. Slack, was carried—

"That this meeting considers it undesirable at present to agitate for any alteration in the law respecting the sale of patent medicines."

The meeting then terminated.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL ASSOCIATION.

At the annual meeting of this Association, the Secretary, Mr. J. Turner, read a brief report. It stated that two general meetings and five council meetings had been held during the year. It had been decided to give up the rooms held in Tudor Place. Some of the articles have been sold, and the specimens, books, cabinet, microscope, and maps have been placed under the care of Mr. H. W. Maleham, 7, West Bar. Copies of the rules of the library, etc., have been forwarded to every member of the trade in Sheffield, and it is hoped that the books will be more used than they have been in the past, as they are now available to every member connected with the Association. Mr. Warner has been appointed collector of subscriptions. Although at the last annual meeting there was only £6 6*s.* 9½*d.* in the hands of the Treasurer, he was glad to say, as would appear from the Treasurer's report, that the balance has been largely increased, notwithstanding that the subscriptions had been reduced from 10*s.* to 5*s.* per annum. Meetings had been held in respect of counter prescribing, when resolutions passed by the Council were forwarded by the Secretary to the Chemists and Druggists' Defence Association. Copies of the resolutions had also been forwarded to the county and borough members and the Pharmaceutical Society. Favourable answers had been received from the members. Resolutions had also been passed approving of the action taken by the Chemists' Defence Association on the lac sulphuris *versus* sulphur præcipitatum question. The President, Mr. W. V. Radley, having removed to Southport, had called them together to a farewell supper before leaving to appoint his successor, when the choice fell upon Mr. W. Ward as president *pro tem.* He felt that all would join in saying how sorry they were to lose the advice and counsel of one who was always ready to forward and help the Association in the fullest manner possible. The number of members at the present time was about 47. The Council wished to impress upon the members the importance of taking united action and interest in the working out of this Association.

The report of the Treasurer was read, which showed the receipts to have been £40 12*s.* 11½*d.*, and the expenditure £5 10*s.*, and that there was a balance in hand of £35 2*s.* 10½*d.*

The adoption of these reports was moved, seconded, and carried uuanimously. The election of officers for the year then took place, with the following result:—Mr. W. Ward, F.C.S., President; Messrs. G. Ellinor and H. E. Ibbitt, Vice-Presidents; Mr. W. Jervis, Treasurer; Mr. J. Turner, re-elected Hon. Sec.; Mr. C. Warner, re-elected Collector; Council: Messrs. G. A. Cubley, H. W. Maleham, J. Watts, Newsholme, J. Otley, G. Carr, J. Clarke, and J. S. Barnell.

The President proposed and Mr. Walls seconded that the best thanks be given to officers for the past year.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, Feb. 7, Dr. Gladstone, President, in the chair. After confirmation of the minutes, etc., the names of the following gentlemen were read for the first time:—Messrs. T. W. Drinkwater, S. A. Goldschmidt, W. J. Macadam, S. S. O. Morris, W. A. H. Naylor, A. N. Pearson, and J. Spencer. The following were duly elected Fellows of the Society: —Messrs. T. C. Cloud, G. F. Dowdeswell, A. Ginders, H. R. Hind, J. Woodland, S. P. Pickering, T. F. Harris, G. H. Spring, W. J. Williams, G. S. Taylor, A. Linnell, J. V. Elsden, A. H. Elliott, C. B. Fox, A. Jamieson, A. H. Hooker, D. A. Louis, W. Watson, W. H. Ellis, J. Hadkinson, W. D. Harland, R. Bodner, H. B. Nason, G. E. Stoddart and G. Kühnemann. Mr. E. C. Gill was elected an Associate.

The first paper was entitled—

The Alkaloids of the Aconites, Part II.; On the Alkaloids contained in Aconitum ferox. By Dr. Wright and Mr. Luff. The alkaloid obtained from *A. ferox* differs from that extracted from *A. Napellus*, in that the latter, aconitine, yields well crystallized salts with facility, whilst the former, pseudaconitine, forms crystallizable salts with difficulty. Aconitine under certain conditions loses the elements of water, forming a crystallized anhydro-derivative. When saponified aconitine breaks up as follows:—

$$C_{33}H_{43}NO_{12} + H_2O = C_7H_6O_2 + C_{26}H_{39}NO_{11},$$

Benzoic acid and a new alkaloid being formed. Pseudaconitine likewise forms an anhydro-derivative, but by the action of saponifying agents it forms dimethylprotocatechuic acid and a new alkaloid quite different to that produced from aconitine. The formula of pseudaconitine is $C_{36}H_{49}NO_{12}$; a formula previously given, having O_{11}, was rendered inaccurate by the presence of some of the anhydro-derivative, apopseudaconitine ($C_{36}H_{47}NO_{11}$). Pseudaconitine was obtained from the roots of *A. ferox* by percolating with alcohol acidulated with 0·05 per cent. (by weight) sulphuric acid. The impure product from this process was dissolved in ether, filtered, mixed with about half its bulk of light petroleum, and crystallized; some resinous matter was removed by alcohol and the purified alkaloid recrystallized several times. By analysis the following numbers were obtained:—C 63·09; H 7·47; N 2·12; theory requires C 62·88; H 7·13; N 2·04. By conversion into the nitrate, recrystallization and reconversion into nitrate, the following numbers were obtained:—C 62·71; H 7·44; N 2·07. Au in the gold salt = 19·24; theory requiring Au 19·10. A determination of nitrogen by combustion with oxide of copper and metallic copper in a Sprengel vacuum, etc., gave 2·06 N. Pseudaconitine is far more soluble in alcohol and ether than aconitine. It forms transparent needles and sandy crystals, but is apt to separate as a varnish if not evaporated extremely slowly. Air-dried the crystals are hydrated; at 100° they lose their water with partial fusion. If the alkaloid be dissolved in just sufficient dilute warm nitric acid to form a nearly neutral salt, a few drops of concentrated nitric acid be added, and the whole stirred vigorously crystallization takes place. The sulphate, hydrochloride, acetate, oxalate, etc., will not crystallize. The gold salt of pseudaconitine is distinctly crystalline. $C_{36}H_{49}\,NO_{12}$, HCl, $AuCl_3$.

Pseudaconitine is sparingly soluble in water; it crystallizes with H_2O and melts 104—105°. Aconitine crystallizes anhydrous and melts at 189°. By heating to 105° a new uncrystallizable base is formed, containing C 65·51; H 7·5. A similar substance is obtained by heating the acetate to 130—140°. When heated to 100° in a sealed tube with alcoholic soda for twelve hours, pseudaconitine splits up into dimethylprotocatechuic acid and a new base, pseudaconine,

$$C_{36}H_{49}NO_{12} + H_2O = C_9H_{10}O_4 + C_{27}H_{41}NO_9.$$

The reaction takes place without a sealed tube in twenty-four hours, but more of a resinous bye-product is formed. The reaction was investigated quantitatively. In melting point and physical and chemical properties, the acid agreed with dimethylprotocatechuic acid. The crude alkaloids obtained from *A. ferox*, on saponification, yielded some benzoic acid, from which circumstance the authors think that they probably contained small quantities of aconitine, either present in *A. ferox*, or from the admixture of a few roots of *A. Napellus*. Pseudaconine does not crystallize; it is soluble in water, forming a strongly alkaline solution having a bitter taste, but not producing the slightest tingling; its analysis and properties are given. Saponifying agents, at temperatures above 100°, form dimethylprotocatechuic acid and apopseudaconine, $C_{27}H_{39}NO_8$, which closely resembles pseudaconine. Dilute or concentrated mineral acids saponify pseudaconitine when heated with that substance. Tartaric acid forms apopseudaconitine. Inorganic acids, with certain precautions, also yield apopseudaconitine. Glacial acetic acid yields acetylapopseudaconitine. Anhydrous acetic acid furnishes the same substance. Benzoic acid yields benzoylapopseudaconitine. The authors then give the constitutional formulæ of the above substances, and point out that pseudaconitine is closely related to the opium alkaloids, narceine, narcotine, and oxynarcotine, which all give rise to derivatives of dimethylprotocatechuic acid; moreover all the natural alkaloids which have been split up by saponification yield acids of the aromatic series. Other bases from the crude aconitine were isolated. In fact about one-fifth of the commercial article consists of substances far less active than pseudaconitine; the authors, therefore, recommend that for medicinal use the alkaloid should be separated by conversion into the nitrate, which is almost insoluble in 10 per cent. nitric acid.

The President said that the Society was deeply indebted to Dr. Wright and Mr. Luff for their elaborate research, which they must have carried out at no small risk, the substances being of such a poisonous nature.

In answer to some critical remarks of Mr. Kingzett, Dr. Wright stated that he wished to withdraw a statement made by him at the Pharmaceutical Conference, viz., "that the alkaloid obtained by Dr. Paul and Mr. Kingzett from Japanese aconite was pseudaconitine."

The next communication was entitled—

"*Notes on the Tannins.*" By Dr. Paul and Mr. Kingzett. The authors, during the examination of various tannins, completely verified the statement of H. R. Proctor, that no two processes for the estimation of tannin give similar or comparable results, although when the same process is used against products of the same nature, the results are tolerably constant, *i.e.*, cutch can be compared with cutch, mimosa with mimosa, etc., but not cutch with tannin, or mimosa with cutch. The term tannin includes, not one common substance, but several astringent principles obtained from different plants. After detailing experiments, the authors conclude (1) that the supposition that natural tannin from gall nuts is a glucoside is rendered doubtful, and (2) that the astringent principle common to cutch and extract of mimosa bark is a glucoside, and yields, on decomposition, unfermentable sugar and a peculiar acid, distinct from gallic acid.

The next paper was read by Mr. E. Riley—

On the Estimation of Phosphorus in Iron and Steel. The author instituted a series of experiments as to the relative values of the two methods of determining phosphorus in iron the molybdate and the magnesia processes. The analyses were carried out by several experimenters working independently, and as a general result the author concludes that the molybdate process gives too low a percentage, and that the magnesia method is the only one to be trusted. Some pure peroxide of iron, almost free from phosphorus, was carefully prepared, the trace present determined, and portions, after mixing with known weights of pure phosphate of magnesia, analysed. The results given by the magnesia method were quite satisfactory and concordant. The process as given by the author is as follows :—The substance is dissolved in strong hydrochloric acid and after dilution reduced with sodium sulphite; the excess of sulphurous acid is expelled from the solution, which is then nearly neutralized with ammonia; acetate of ammonia is added and the liquid boiled; the whole of the phosphoric acid in the solution is thus precipitated. If enough peroxide of iron is not present some dilute solution of perchloride must be added. The precipitate is filtered, and the filter dissolved without washing in strong hydrochloric acid, and thoroughly washed. The solution of phosphoric acid with some iron is then evaporated to a small bulk, about 15 c.c.; to this 13 grms. of citric acid are added, the solution neutralized with ·960 ammonia, and 20-30 drops of magnesia solution added; then a moderate amount of ·880 ammonia, so as to make the liquid strongly alkaline; the total bulk should not exceed 50 c.c. After standing two days and nights with occasional stirring, the precipitate is filtered off, washed with ammonia water, dried, ignited, and weighed. The paper contains many analyses.

Dr. Wright inquired if the molybdate precipitate was weighed directly, or was re-dissolved and re-precipitated.

Mr. Warington thought the low percentage of phosphorus with the molybdate process might be due to the presence of chlorides. They should be decomposed by evaporating to dryness with sulphuric acid. From the paper he should gather that too much citric acid had been used, otherwise the magnesia precipitate would come down completely in three hours.

Mr. Riley replied that if the molybdate precipitate had to be re-dissolved up, etc., he failed to see that it had any advantage either in time or accuracy over the magnesia method; that hydrochloric acid must be used for solution; and that unless 13 grms. of citric acid were used, results would be obtained which were quite fallacious.

The next paper was read by the President, Dr. Russell taking the chair, and was entitled—

An Inquiry into the Action of the Copper-Zinc couple on Alkaline Oxy-salts. By Dr. GLADSTONE and Mr. TRIBE. —In 1873 Professor Thorpe proved that the couple converts all the nitrogen of nitre, in the presence of water, into ammonia. The authors had previously observed that nitrites were at first formed and have now made an exhaustive study of the reaction. This chemical change starts somewhat energetically, then diminishes considerably, again increases, and finally ends more rapidly than it began, ammonia and its equivalent of potash slowly increasing from the commencement until the time when the maximum amount of nitrite is produced, when the latter salt rapidly breaks down and is of course accompanied by an increasing amount of the alkalies. Solutions of ammonia containing 0·026 and ·256 per cent. increase the action of the couple, but stronger solutions diminish it. Solutions of potash from 0·08 to 60 per cent. increase the change. By pouring a 10 per cent. solution of nitre, with enough copper sulphate to colour the liquid distinctly, on to some granulated zinc in a tap funnel and allowing it to remain a few seconds, enough nitrite is formed to give the characteristic green colour of copper nitrite and to give a blue coloration with starch, potassium iodide, and acetic acid. The latter reaction can be used as a delicate test for nitrates; 5 c.c. of solution, 12 drops of copper sulphate, and 4 to 5 pieces of zinc-foil $1 \times \frac{1}{2}$ inch, allow to stand for three minutes then pour into 5 cc. of the starch solution containing potassium iodide and acetic acid. On the whole the authors think that the following is the most probable explanation; that the two metals electrolyze the nitre with the formation of nitrate of zinc, the reduction being effected at the negative pole through the agency of the potassium. Many experiments were made but without absolutely settling the question. By electrolysing potassium nitrate solution in a V-shaped tube zinc nitrate was found in the zinc limb and potassium hydrate with smaller quantities of potassium nitrite and ammonia in the copper limb. The copper-zinc couple converts potassium chlorate readily into potassium chloride; no chlorites or hypochlorites were formed. By electrolysing, the greater part of the hydrogen escapes as gas instead of the potassium chlorate being converted into chloride, the reason being that with the couple the hydrogen is probably wholly occluded the moment it is set free; in electrolysis only a small quantity of the gas is condensed by the negative plate. The authors consider the following statements proved. (1) The action of the copper-zinc couple on these oxysalts is of an electrolytic nature. (2) The negative radical combines with the zinc whilst the positive radical or its equivalent of hydrogen from decomposed water is set free against the copper crystals. (3) The reduction and hydrogenization of the salt take place in the immediate vicinity of the negative metal. Also it is probable that hydrogen is actually set free against the copper, but is condensed by the finely divided metal, and in that condition does its work of reduction and hydrogenization. The action of the couple on ammonium nitrate was found to be substantially the same. If the reaction be attempted at or near the boiling point the nitrite formed is decomposed, nitric oxide being evolved.

The last paper was by Mr. N. C. Jones—

On a New Method for the Determination of Boiling Points.—A piece of glass tube 4 mm. internal diameter and 200 mm. long is bent in a U, so that one end which is open extends at least 15 mm. beyond the other which is closed. The bend is made in the form of a circle about 20 mm. in diameter. The liquid, two or three drops of which will be quite enough for the determination, is introduced into the closed end of the U tube, the open end is placed underneath the surface of some mercury contained in a small porcelain crucible. The whole is then slung by means of copper wire into a water or paraffin bath and the temperature of the latter gradually raised. The liquid will of course boil and the vapour drive before it the air; on cooling the whole tube, which the author calls a tension-tube, is filled with mercury, a bubble of liquid occupying the top of the bend. The tube is then inverted and the liquid transferred to the closed end of the tube. Any water or paraffin is now removed from the tube by means of filter paper and some mercury emptied from the open limb. The method of determining the boiling point is as follows: the tube is immersed in a paraffin bath, care being taken that the open end is freely exposed to the air. The temperature is then gradually raised; as the temperature approaches the boiling point of the substance the mercury falls in the closed limb, the tube being gently tapped. At the moment the mercury levels in the two limbs are equal the temperature of the bath is taken by a delicate thermometer placed close to the liquid in the closed limb. The bath is allowed to cool and the temperature at which the levels pass each other again noted, and so six observations are made, the mean of which gives the uncorrected boiling point. Many determinations are given in the paper which agree well with each other. The advantages of the method are obvious, the small quantity of the substance required being one of the most important. Moreover the tension-tube can be labelled and put away for future verification. By using a spermaceti bath boiling points up to 300° C. can be determined.

The Society then adjourned to February 21, when a lecture on laboratory experiences on board the "Challenger," will be given by J. Y. Buchanan.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held at 17, Bloomsbury Square, on Thursday, Jan. 31, when a paper was read by Mr. Sangster on "Common Salt: its Manufacture and Uses." The author commenced by showing how necessary salt is to the human system, explaining the probable decompositions it underwent by the gastric juice and naming some of the substances resulting from those decompositions. The sources of the salt of commerce were next enumerated, the depth of the mines from which it is obtained, the strata passed through in searching those depths, the condition in which the salt is found, and the methods employed for raising the salt to the surface in the state of solution as brine. Its value to the housekeeper on account of its antiseptic properties, and to the farmer on account of its fertilizing properties was also remarked. The paper concluded with a general survey of the distribution of salt over the surface of our globe.

Mr. Harold Senier then exhibited a pair of electric telephones and described briefly the principle of their construction. The instruments were passed round to each member, and every one present had the satisfaction of hearing and being heard through a length of 300 feet of wire. Both papers were followed by long and interesting discussions, and votes of thanks unanimously awarded to the authors. The meeting then adjourned.

Parliamentary and Law Proceedings.

What is an Adulteration of Milk?

At the Hammersmith Police Court, on January 31, Mr. Bridge gave a decision in two summonses against Robert Edwards, of the Mall, Kensington, and Mrs. Sheen, St. Clement's Road, Notting Hill, for selling milk adulterated with water. Mr. Bridge first proceeded with the case against Edwards. He said the analyst of the vestry made a report that the defendant's milk was adulterated with 8 per cent. of added water, there being no other kind of adulteration in it. The certificate of the Government analyst stated that the fat in the milk was equal to that which was found in milk of good quality, but that the amount of solids, not fat, was low, and from those conclusions he (the analyst) was of opinion that there was not less than 4 per cent. of added water. If there was 4 per cent. of added water that would be an adulteration. Looking at the reasoning of the analysts, not their opinions, and practical works on farming, which stated that milk varied to an extraordinary extent, he was not satisfied that the offence had been committed. Mr. Harding, clerk of the Kensington Vestry, regretted this decision, as it would go forth that dairymen might adulterate their milk to a certain extent. Mr. Bridge said a wrong conviction might drive respectable men out of the trade. Mr. Harding retorted that, practically, a certificate of the vestry's analyst of 8 per cent. would be worthless. Mr. Bridge said it would not be so, as Mr. Harding would find that his analyst stated the amount of fat in the milk was below what it ought to be. Both summonses were dismissed.

Beer Adulteration.

At the Lambeth Police Court, on Thursday, January 31, Owen Haster, beer retailer, late of the George, St. George's Road, Peckham, was summoned by the vestry of Camberwell for selling beer which was not of the nature, substance, and quality of the article demanded. Mr. Marsden, the vestry clerk, said the case was one of considerable public importance. Dr. Bernays, professor of chemistry, had given a certificate that the beer in question was adulterated to the extent of 96 grains of salt per gallon. Mr. Lilley denied that any salt had been put into the porter. The defendant had been obliged to leave the house, and had lost 140*l*. by the place. What he had done was to use liquorice and sugar, in order to satisfy the taste of his customers, who had complained they could not drink the beer. The defendant was willing to plead guilty as to the introduction of liquorice and sugar, but most positively denied using salt. Dr. Bernays, in his evidence, said that there was salt in sugar, which might now account for the statement made by Mr. Lilley, and the more common the sugar the more the salt. The beer in this and other cases promoted instead of quenching thirst. One of the defendant's customers was called, who stated that he had advised him to make his beer palatable, and he used liquorice and sugar only. The practice was common in the trade. Mr. Ellison said the case had been much altered by the evidence of Dr. Bernays, that sugar contained salt, or he should have inflicted the highest penalty. The sooner defendant and others got rid of the notion of adding anything to the beer after it came from the brewers the better for them. He imposed a penalty of 20*s*., and 12*s*. 6*d*. costs.

Alleged Poisoning by Iodine.

On Monday the 4th inst, an inquest was held at Longton, before Mr. J. Booth, Coroner, as to the death of Catharine Marrow. The deceased was stated to be thirty-three years of age, had been ailing for a short time, became worse on January 31, and died rather suddenly on the 1st inst. A bottle produced, and labelled "Poison," was found upon her; but nothing particular was thought about her death till the bottle was found. P. C. Lees spoke to his knowledge of the deceased for the last five years as a drunken, dissipated woman, who had often been in trouble. He visited the house where she had died, and found the bottle produced in her pocket. He ascertained that the bottle was procured by the deceased from Mr. Geant, surgeon; and that it had contained tincture of iodine. It had been given to her for her to paint her back with. There was one drachm supplied, and if swallowed was more than sufficient to cause death. The bottle when discovered upon deceased was empty. Margaret Corcoran, a married woman, spoke to having seen deceased after she was dead, and there was nothing on her back to indicate that it had been painted with anything. It was discoloured, but the colour was of a natural kind. The Coroner put it to the jury whether they would decide upon the statements made or have an adjournment so that a *post mortem* examination of the body could be made. There was clear evidence that the bottle of iodine had been supplied to deceased, that her body showed the iodine had not been used thereon, and that when the bottle was found upon the woman its contents had disappeared. The foreman of the jury said he did not see that any purpose would be served by an adjournment. The Jury returned a verdict to the effect that the deceased woman died from the effects of taking tincture of iodine, but whether wilfully or accidentally was not known.—*Staffordshire Sentinel.*

Poisoning by Chloral Hydrate.

An inquest was held at Folkestone Road, on Monday, February 4, on the body of John Carpon Mallett, Cinque Ports Trinity Pilot, who died on the previous Saturday morning at 3 o'clock. Mr. Sydenham Payn (Deputy Coroner) conducted the inquiry. The widow of the deceased said, he had been suffering from rheumatism, and on Thursday night he took a dose of chloral, one teaspoonful. He got up between 2 and 3 o'clock, and took some more, but she did not see what he took. In the morning he appeared to be in a stupor, so she sent for the doctor. He had been in the habit of taking this stuff for six years. Once before, three years ago, it had a bad effect upon him, he having taken too much. She found a bottle [produced] in his desk, locked up. The other bottle was full when he went to bed, and she believed what was gone he took out of it in the night. It was Hunter's solution of chloral.

Mr. A. G. Osborn, surgeon, said, on Friday morning he found deceased lying on his back in bed quite unconscious, with a very dusky countenance, and breathing only once, twice, or three times in a minute. He was quite incapable of being roused. He employed the usual means for restoring respiration, and a powerful galvanic current from the nape of the neck to the pit of the stomach for nine hours. He remained in attendance till two in the afternoon and the breathing had a little improved. Witness saw him again at 5 o'clock. He was still unconscious, but seemed improving. Witness visited him again at half-past nine and he had quite recently aroused. Rather suddenly he seemed to wake up. He was able to support himself in bed and could answer questions in a rather loud but very shaky voice. Left directions how he was to be watched and fed during the night, but did not see him again alive. When witness inquired what he had taken, his wife said he had taken some chloral. Witness was of opinion that death was caused by some narcotic poison. The death seemed to have arisen from the long exhaustion from the narcotic.

By the Coroner: I do not know whether this is under the Pharmacy Act. It is not in my directory. Chloral is a powder like soda and I cannot say how strong this is, it all depends on the solution. Chloroform and preparations of laudanum are in the directory, but not chloral, though it might have been added since.

The Jury unanimously returned a verdict "That the deceased died from exhaustion resulting from accidentally taking an overdose of Hunter's solution of chloral."

The Jury afterwards resolved to send a memorial to the Home Secretary, requesting him to put this narcotic in the list of drugs sold under the Pharmacy Act, so that it may be distinctly labelled "poison."

Poisoning by Arsenic.

At the Chester Winter Assizes, on the 6th inst., Ellen Johnson was indicted for the wilful murder of her infant. From the evidence it appeared that suspicion having been excited respecting the death of her children, the bodies of two were exhumed as well as that of her mother. In all of them arsenic was found. The Jury found a verdict of guilty, and the prisoner was sentenced to death.

Prosecution under the Pharmacy Act.

During the trial of a charge of coining at the Lincoln Winter Assizes, it transpired that two ounces of cyanide of potassium had been sold to the prisoner by Mr. Shepperley, chemist and druggist, of Nottingham, without the provisions of the Pharmacy Act as to the registration of the sale, etc., being complied with. Mr. Justice Huddleston therefore suggested that proceedings should be taken against Mr. Shepperley. At the hearing of the case the defendant pleaded guilty to having sold the cyanide without making the proper entry in his poison book, but urged, through his solicitor, that as cyanide of potassium is much used by photographers, chemists and druggists are often placed in difficult circumstances.

Dispensing Memoranda.

[54]. Creasote Pills.—In the last monthly summary of the Dispensing Memoranda a method was suggested by which two minims of creasote may be satisfactorily combined with two grains of compound rhubarb pill without the result being a bolus on the one hand or an inconvenient exudation of creasote on the other, and the remarks closed by indicating the value of a little time spent in determining the best proportions of calcined magnesia to each minim of creasote and also the time required for its solidification.

I adopted the hint given, and whilst engaged on the subject my attention was directed to a letter from Mr. Martindale in the Journal (p. 619), expressing a strong objection to the addition of calcined magnesia to creasote for two reasons, one being that the creasote is for the most part combined, and the other that the resulting pills are "as hard and as insoluble as marbles."

Previously to the appearance of Mr. Martindale's letter, I had made my pills, using half a grain of calcined magnesia to each minim of creasote, allowing them to stand a few hours before adding the compound rhubarb pill, and succeeded very satisfactorily. At intervals of one or two days for more than a week I examined the pills thus made, they became firm, but not at all more hard than is usual with pills of varying composition; they broke into pieces with the finger nail and crumbled between the finger and thumb. I did not boil them, for boiling is not represented in any part of the digestive process; but I used water at blood heat and such a gentle motion in the palm of the hand as would best represent the peristaltic action of the intestinal canal in the process of digestion. The pill was disintegrated in a few minutes and the odour of creasote was at the same time developed; the hardness and insolubility referred to, therefore, do not apply to the pills made by myself and with B. P. materials.

Another pill placed in a test tube with warm water to which a little hydrochloric acid had been added gradually yielded up its creasote as the pill fell to pieces. Whatever, therefore, may be the state of combination of the creasote when calcined magnesia is used to make up the pill, it is set free by dilute hydrochloric acid, so that if the creasotic acids do combine with the magnesia they would be liberated by the gastric juices of the stomach.

When creasote is prescribed in the pilular form it may be assumed that the writer has a definite object in view and desires the slower action of the pill as compared with that of an emulsion. If so, his intentions would be fulfilled by a firm pill that gradually, under the influence of the acid secretions of the stomach assisted by warmth and motion, disintegrates, yielding up its creasote in the process of digestion, and this may be just what the prescriber would desire.

In support of "The Month," I ask for the insertion of the result of experiments undertaken at the suggestion it contains in the paragraph referring to these pills.

Pil. Creasoti.

---

[59]. "Pandrodyne."—I had the following presented the other day, and shall be obliged if any reader can furnish me with the composition of Pandrodyne. Several West End houses were tried, but they had no knowledge of the preparation:—

℞	Tinct. Senegæ	℥ss.
	Aq. Lauro-Cerasi	℥ss.
	Pandrodyne (?)	ʒij.
	Acid. Sulph. Dil.	ʒiij.
	Syr. Rhœdas	℥ss.
	Mucilaginis, ad	℥iij.

Misce. ʒj ter die tussi urgente.

J. W. Barnes.

---

[60]. Please inform me, through the Dispensing Memoranda, how to dispense the following:—

℞.	Balsam. Copaibæ	ʒj.
	Pulv. Rhei.	℈ij.
	Magn. Carb.	℈j.

Ft. pil. 24.

Assistant.

---

[61]. Ung. Hyd. Nit. B. P.—Would any correspondent kindly inform me if it is proper to heat the solution of mercury in nitric acid till the reddish brown fumes cease to be given off? Or should the ointment contain free nitric acid?

The nitric acid ordered in B. P. is much in excess of what would dissolve the mercury.

Inquirer.

---

[62]. Plaster Spreading.—In spreading a belladonna plaster on leather, is it usual to make an adhesive margin?

Emplastrum.

The Institute of Chemistry.

Sir,—In your last issue there is a remark reported in a speech by Professor Attfield, at the first general meeting of "The Institute of Chemistry," which is, I think, calculated to do mischief, and which being erroneous, should be corrected with as little delay as possible. In reference to a circumstance which, according to the same report, had been described by Dr. Frankland, the Chairman, as a "temporary opposition of the Pharmaceutical Society to the articles of association as originally drawn," and which after the speech of the Professor the Chairman declared to be "a fair ground of complaint," Professor Attfield is stated to have said "*With respect to the action recently taken by the Pharmaceutical Society, he thought it was pretty well known by this time that that Society was really urged to it by the Privy Council.*"

Having had full cognizance of the whole transaction, I am in a position at once to affirm that that action was in no way urged on the Pharmaceutical Society by the Privy Council.

Professor Attfield puts the saddle on the wrong horse.

The articles of association being submitted to the Board of Trade for approval were in due course handed to the Privy Council, the latter body being, under the Pharmacy Act, the supervising authority over the Pharmaceutical Society.

The Privy Council having this *authority* delegated to them by the Legislature naturally assumed with it the *protection* of the Society, and forwarded the "articles" to the Council of the Pharmaceutical Society for perusal, but certainly without instigating opposition.

To suppose that we could possibly object to a Society formed by such distinguished men, and for such high purposes, seems so unreasonable that I need scarcely say a word on that point.

The real point to which in the interest of our constituents we did take exception was the *title* proposed for the members of the new institute. It was "Professional Chemist." Dr. Frankland remarked that, "he thought the members of the Pharmaceutical Society might with very great propriety term themselves professional chemists," and that it was therefore unwise for the new body to take that title without limitation. "Professional" is a general term, which may be applied to pharmaceutical, analytical, agricultural, and many other chemists, and therefore I think the members of the "Institute of Chemistry" may thank the Pharmaceutical Society for having saved them from so loose a title.

George W. Sandford.

February 13, 1878.

Sir,—Kindly allow me to correct a point in my speech in defence of the Pharmaceutical Society at the meeting of the Institute of Chemistry as described in last week's *Pharmaceutical Journal*. I am reported to have said that the Privy Council urged the Council of the Pharmaceutical Society to take action in the matter. What I did say, following the President, was that the Privy Council, moved by the Board of Trade, initiated, I don't think I said urged, action by laying the matter before the Pharmaceutical Council. My desire was to show that pharmacists were not antagonistic to but in sympathy with the objects of the Institute. A contrary opinion was to my knowledge previously held by many members of the Institute.

John Attfield.

The Dental Practitioners' Bill.

Sir,—The thanks of a number of chemists are due to you for calling attention in your article of last Saturday, "On the Proposed Dental Practitioners' Bill," to the ambiguous wording of part of the clause referring to the qualification for registration. In order to make the point referred to by you quite clear, it behoves those members of the Council who form the Parliamentary Business Committee, to at once move in the matter, or a number of chemists, principally in the country, who have for many years practised dentistry in connection with their business, will be liable to serious interference in this branch of their calling.

Henry Long.

Croydon, Feb. 12, 1878.

Sir,—I think all chemists who are practising dentists as well, and who would suffer considerably if the term "separately" in the proposed Act should be construed in the way that it would exclude any persons other than mentioned from the right of being registered, will be much indebted to you for pointing out such a flagrant injustice to vested interests.

Would it not be all we need, to secure us against such, to modify the clause thus, "separately or in conjunction with the practice of medicine, surgery or pharmacy." Would it be too much to ask you to make such a suggestion in a short editorial note next week? If not I think you will do those interested a great favour. A simple clause similar to the 21st section of the Apothecaries Act 1815, reserving the rights of chemists under this new Act would be advisable. I have written to Sir John Lubbock to-day, drawing his attention to it, and asking as well our member to look to it.

G. J. Gostling.

Stowmarket,
February, 11, 1878.

Sir,—Day by day I have been going to write to you, to ask you what action the Council intend taking with regard to the "Dental Bill" now before the Houses, but each day something or another has occurred to prevent. I am very pleased however to find that it has been made the subject of an article in this week's Journal, and that precisely the same view which I have taken of it is there expressed. Whether it is intended as an insidious attack upon those chemists who practise dentistry or not, I must leave, but certain it is that the Odontological Society and the framer of the Bill have no friendly feelings towards us, which is fully evinced by their literature.

Are we to be sacrificed, whilst any ignoramus who practises dentistry *per se*, is to be registered? to wit, an ex-policeman who actually practises as a dentist in a neighbouring town near here, while another not far off can scarcely write his own name.

I think that not a moment is to be lost in opposing the Bill as it stands, for the words clearly convey that a man must practise dentistry alone or in connection with medicine or surgery to get registered. The way to meet the difficulty of course would be to add the word "pharmacy" after surgery, but how is this to be done?

I am not well informed, indeed informed at all, in parliamentary matters, but I sincerely trust that the Council will instruct their solicitor to take immediate action in the matter.

F. C. Maggs.

Yeovil.
February, 7 1878.

The Preliminary.

Sir,—One might certainly imagine that the questions set at this examination would be easily answerable by the majority of aspirants, but the results prove the reverse. The average intellectual height of candidates falling short of the standard fixed, perhaps it is only natural that some should desire to have the standard depressed, so as to be more in accord with the height of the pharmaceutic recruits. Whether the cries for retrogression are unreasonable is open to criticism. If the tide of education in this country were on the ebb, it might be undesirable or useless for pharmacy to struggle against the stream, but since on every hand there are evidences of progressive educational activity, it might happen that a body attempting to move in a direction opposite to the general current would be in danger of being wrecked upon the banks. So far as personal experience goes, I can testify to the fatal accuracy of the deregatory comments upon middle class education made by certain members of the Council. If the education of middle class schools generally approximates to that received by the writer, then it is high time all private educational enterprises were suppressed or placed under Government inspection. When I quitted the school of idleness where my "education" had been accomplished, I should most certainly have been completely floored by half the questions set at the Preliminary, as then conducted; and yet the dearly bought smattering of scholastic knowledge I possessed was dignified by the appellation of a good education, being like most other articles valued for the price paid for it. But could the cause of so many failures be traced to a rotten system of education, it would be for the system to improve or be improved away altogether, and replaced by methods more after the spirit of the age. To lower the standard of the examination in order to meet the exigencies of a worthless educational machine, would be for a modern ironclad to strike its flag to a rotten wooden hulk of a past generation. It is to be hoped, for the sake especially of the future prestige and position of pharmacy, that there will be no yielding to the party of retrogression.

JUVENIS.

THE PATENT MEDICINE STAMP AND LICENCE.

Sir,—Now that the war panic is over, and the Chancellor of the Exchequer is thinking of his Budget, and is likely to have a surplus to deal with, I think it would be to the interest of pharmacists to ask him to consider the policy of abolishing the Patent Medicine Stamp. We all know how unequally and inefficiently the law works with regard to this tax, which permits a single Steedman's Soothing Powder to be sold without a stamp, but fines a chemist who sells a tooth powder recommended for the prevention of toothache. But it is not on this ground so much as that of the necessity there is of bringing the sales of all preparations containing poisons that are sold with a patent medicine stamp, under the same regulations with regard to the Pharmacy Act as other poisons, vermin killers, etc., are; that is, being labelled with the word poison, registering the sale where necessary, and being sold only by persons registered under the Pharmacy Act. The process of poisoning the public by means of quack nostrums sold as bargains (?) at the numerous stores at prices 30 per cent. below those marked on them, is one which in the interests of the public should be taken cognizance of pharmaceutically, medically, and legislatively. Perhaps the Council of the Pharmaceutical Society might be induced to broach the matter to the Chancellor of the Exchequer, whose chief once said "*Omnia Sanitas.*"

With the abolition of the Patent Medicine Stamp, the Patent Medicine Licence would have to be repealed also. If it be argued the Revenue will not bear the reduction, a general licence on all retailers of poisons might be substituted for it, that is on all pharmaceutical chemists, chemists and druggists and medical practitioners keeping open shop, —say 5 per cent. on their rent. This may be thought to be a retrograde movement, but in the interests of the public (and the Revenue) other professions and trades are regulated by licence, and as the Income Tax is found to be inoperative as regards taxing co-operative stores, by licences they would have to share some of the burdens of traders. By licence also the growth of mushroom stores and pharmacies would be somewhat limited. Perhaps my brother pharmacists will ventilate the subject.

WM. MARTINDALE.

10, *New Cavendish Street,*
January 24, 1878.

LOW PRICES.

Sir,—When we speak to a brother chemist of the absurd prices charged for patent medicines and other articles in many druggists' establishments, and of the desirability of the Society doing something to check, if possible, the rapid growth of this system, we are reminded that the Pharmaceutical Society is not a trade, but an educational Society, and therefore has not, and does not take, cognizance of its members' behaviour towards each other in the matter of underselling. Now this remark may be all very well in a general way, but surely education and a proper mode of conducting business are not incompatible. The butcher and the baker keep up their prices; they seem to work on a sensible principle, and surely if these men can do so there can be no excuse for the suicidal policy of many of the chemists of the present day.

It was but yesterday, I heard of a chemist near Finsbury Square, who had in his window Wright's soap ticketed at 4*d.* per tablet! and not only is this system proving ruinous to those who carry it out, and injurious to their neighbours, but it renders our transactions with our customers no longer pleasant, but most disagreeable; for we are constantly being told, "I only pay 10½*d.* for Cockle's pills at your neighbour's, and he charges me 4*d.* for feeding bottles," etc.

For some time there were very few who descended to these low prices, but now a kind of self-defence has sprung up, and at the eastern part of London full prices will be found the exception.

It is high time some steps were taken with the view of stopping this cutting wave; it is flowing in all directions, its influence will soon be painfully felt throughout the country, and unless its progress is speedily stayed, one of two results must inevitably occur: either the pharmacist will have to make such additions to his stock, to enable him to live, as will so disfigure his business as to render it no longer recognizable as an establishment in which chemical knowledge is exercised, or quietly submit to utter ruin!

J. R. SUMMERS.

Curtain Road, London, E.C.
January 29, 1878.

Erratum.—On p. 638, col. i., l. 40 from top, *for* "matura" *read* "mahwa."

J. Laurie.—Perkins' Cantor Lectures on the Aniline or Coal Tar Colours, published in the *Journal of the Society of Arts*, vol. xvii. Reimann's 'Aniline Colours,' translated by Crookes.

F. B. L.—(1) The Secretary of the Royal College of Veterinary Surgeons is Mr. William Henry Coates, 10, Red Lion Square, W.C. (2) We do not know.

T. Brown.—Probably the result obtained by you was due to the quality of the pyroxylin used.

C. G.—An abstract of the law relating to the registration of trade marks will be found in the Society's Calendar, which is just ready, and in vol. vi., pp. 547 and 553 of this Journal.

"*Vandyke.*"—We are not aware that any such a formula has been published, but in India Goa powder is rubbed up into a paste with vinegar, lime juice, etc.

"*Calcium.*"—Recipes for Coffin's Composition Powder will be found on p. 498 of the current volume of this Journal.

R. C. B.—We are obliged to you for your communication, but you appear to have mistaken the purport of the question, which was not as to the nature of stinking hellebore root, but where a supply of it might be obtained.

W. W. Talbot.—Apply to the Secretary for a copy of the pamphlet entitled 'Hints to Apprentices and Students.'

X. Y. Z.—Metallic copper at a bright red heat decomposes water vapour.

"*Veritas.*"—You will find full information upon the subject in vol. v. of this Journal, pp. 421 and 865, and in many other subsequent pages.

W. R. O. C.—(1) We are not aware that the supply is limited. (2) We are not aware that any restrictions are laid upon the candidates as to the order in which they shall deal with the questions. (3) The answer to this question is included in the answer to the first. (4) Probably the best plan would be to forward to the College of Preceptors a schedule of questions of the nature which you think would be preferable to those at present adopted by the examiners.

C. E. Palmer.—(1) Slightly acidify, distil off the acetic acid, and then test. (2) Water or alcohol would dissolve other substances as well. (3) See the paper on Oxalate of Cereum, by Mr. H. Greenish, vol. vii. of this Journal, p. 909; or Watts' 'Dictionary of Chemistry.'

NOTICE.—Correspondents are particularly requested to comply with the terms of the notice that advertisements should be sent to Messrs. J. and A. Churchill, 11, New Burlington Street. Neglect of this rule frequently involves delay and disappointment.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Talbot, Mr. Watson, Mr. Robson, Mr. Sumner, W. D., R. C. B., "Apothecary," "Misch Masch."

"THE MONTH."

Notwithstanding the mild weather in the earlier part of this month flowers are very backward. Although we hear from the Isle of Wight that the celandine, barren strawberry, dandelion, mouse ear, dog's mercury, and other early flowering plants, as well as the primrose, daffodil, hazel, and willow are coming into blossom there, yet we have not as yet seen many of the flowers which were in blossom at this time last year The buds of the elm are only beginning to be visible, the almond and cornelian cherry show no signs of blossoming, the *Forsythia suspensa* has not even shown flower buds, while the mezereon and spurge laurel are very late in opening their blossoms.

The dog's mercury (*Mercurialis perennis*), although one of our commonest plants in shady woods and thickets, is perhaps better known by sight to many of our readers than by name. Among the British plants of the Euphorbiaceæ it is remarkable for not having milky juice, and for the capsular fruit, consisting of only two cells, all the other British plants having a three-celled ovary. The plant is diœcious, the male flowers being arranged in axillary spikes, each flower having three green sepals and from nine to twelve stamens. The female flowers are arranged in a similar way, but the spikes are usually furnished with not more than two or three distant flowers, sometimes only one blossom being present at the top of the spike. In the female flower there will be found two slender threads between the calyx and ovary ; these are considered to be abortive stamens. At the base of the leaves minute stipules may be found. If carelessly dried, so that the leaves remain damp for several days, a deep bluish tint pervades the leaves. This is owing to a blue colouring matter which is said to be given out when the plant is steeped in water, and is turned red by acids, but destroyed by alkalies. Both this species and *M. annua*, which flowers in July, yield, on distillation with quicklime, a volatile, very poisonous liquid alkaloid, which by the action of the air forms a soft resinous substance.

The gardens are, however, showing signs that spring is at hand. The bright yellow and purple blossoms of the early crocus and the delicate drooping pendants of the snowdrop are springing up here and there, and the favourite Lent lily is preparing to decorate the cottage gardens with its blossoms. Primroses and violets, too, are not wanting in the sheltered spots.

The little winter aconite, *Eranthis hyemalis*, is a flower often to be met with in gardens at this time of year. Its involucre of green bracts might be easily mistaken for the calyx by a careless observer, and the yellow petaloid sepals for the corolla. The true corolla consists, however, of a ring of small tubular petals, something like those of the Christmas rose, almost hidden between the stamens and the yellow calyx. The apparent root of this plant is a corm, as in *Ranunculus bulbosus*.

'Medicinal Plants' for this month contains figures of the following plants :—*Pistacia Lentiscus*, *P. Terebinthus*, *Lens esculenta*, *Ferula Narthex*, *Erigeron heterophyllum*, *Styrax Benzoin*, and *Tylophora asthmatica*. *Lens esculenta*, the lentil plant, and *Ferula Narthex* are perhaps better known under their old names, *Ervum Lens* and *Narthex Asafœtida*. The lentil plant has but slender claims to be considered as a medicinal plant, since they rest only on its use in foods for invalids.

Those who have not been able to obtain a copy of the excellent figure of the asafœtida plant in the Transactions of the Royal Society of Edinburgh will be glad to see the very good representation of the plant given in this number. The branching habit of the flowering stem, so different from the almost bare one of the *Scorodosma fœtidum* and the large leaf sheaths are well rendered. The authors consider that the absence of calyx teeth and involucre and the irregular vittæ in the commissure of the fruit are not sufficient characters to separate the genus *Narthex* from *Ferula*. *Erigeron heterophyllum* is an American remedy for gravel and various kidney diseases. It is called sweet scabious in America, but must not be confounded with the sweet scabious of English gardens, which is a true scabious (*S. atropurpurea*, L.). The application of English names to American plants often leads to curious mistakes. *Tylophora asthmatica* is an Indian plant, official in the pharmacopœia of that country as a substitute for ipecacuanha.

The article upon assafœtida contains the most recent information upon the subject, including Dr. Dymock's recent remarks in this Journal. The materia medica portion of benzoin, however, is not treated upon so fully, no mention being made of the Palembang benzoin which is so frequently to be seen in the drug sales, and from which a large proportion of the benzoic acid of commerce is obtained, nor is Sumatra benzoin in tears alluded to.

The arguments against the habit of smoking have recently received an addition, in the shape of a paper from an eminent Parisian oculist, who finds a form of blindness, resulting from the use of tobacco, to be very common. The blindness referred to seems to differ from that resulting from the excessive use of alcohol, in the fact that the pupil of the eye is contracted.

A very interesting paper by "Mucor," in the *Medical Times and Gazette* of February 2, points out how greatly botanists, and especially mycologists, might assist the study of disease, by observing the various stages of growth of microscopical fungi and their modifications under different conditions. The author puts forward the very reasonable view that many of the bacteria are only parts of a plant which has other forms and other modes of growth and propagation when not confined to the living organism or to fluids, and regards the bacterium as a transitional or provisional, and not as a permanent form, but an abnormal phase of life thrust upon the plant by accident. There can be but little doubt that if investigations of this subject be carefully carried out, and the bacteria traced to their source, that it will be possible to control the spread of zymotic diseases to an extent at present little dreamt of.

From the *Lancet* we learn of the use of nitrite of amyl in ague, the inhalation of the vapour at the commencement of the cold stage causing a glow over the whole body and causing the shivering fit to come to an abrupt end. This remedy has also been recommended in whooping cough. A surgeon, writing to the same journal, recommends the trial of stramonium in hydrophobia, as he believes it to be used successfully in Southern China and Ceylon. It may be hoped that out of the number of remedies suggested during the past year for this terrible dis-case, one may ultimately be found to prove of some service.

In the *British Medical Journal*, Dr. Nairne of Glasgow finds tincture of belladonna, as an external application, very useful to restrain the sweating in phthisis, a result which might have been expected from the success which attends its use in the distressingly profuse perspiration which is sometimes localized in the feet.

Mr. Wills of Chester recommends capsicum, in thirty grain doses every hour, in delirium tremens, and states that he has used it with unvarying success for twelve years; this agrees well with the known effect of a powerful American stimulant, prickly ash bark (*Xanthoxylon fraxineum*) which has a similar action and allays the thirst for drink.

Dr. Wyndham Cottle recommends the use of iodoform as a parasiticide, and for indolent and syphilitic ulcers and wounds, in the form of ointment of the strength of twenty grains to an ounce of lard. Dr. Lennox Browne recommends a solution in the proportion of one part of iodoform to ten or twelve of ether for local application in post nasal catarrh.

Thymol still continues to attract attention, Dr. Radcliffe Crocker using it with success in psoriasis and other skin diseases. He gives the following formulæ for galenical preparations of this substance —For ointment, one to thirty grains of thymol to an ounce of vaseline; for a lotion, five grains of thymol, rectified spirit and glycerine, of each an ounce, water sufficient for eight ounces; also a solution of from five to eighty grains of thymolate of potassium to eight ounces of water. It may be interesting to dispensers to know that when the ointment is carelessly made, so that minute crystals are present in the ointment, these crystals will act as a caustic, and produce minute holes in the skin. On this account it is necessary to dissolve the thymol by rubbing it down with a little alcohol before mixing it with the vaseline.

Iodide of ethyl has recently been employed by Professor Sée as an inhalation in asthma, and is reported to relieve the paroxysms of difficulty of breathing very rapidly.

From *Nature* we learn that Dr. E. Lewy has proved, before a large audience at Vienna, that the human skin is completely impenetrable to the chemical contents of mineral waters, and that therefore the advantage of bathing in these waters must be due to their physical and not their chemical effects. It would be interesting to know whether these experiments relate only to cold water, or to warm as well, since the latter would open the pores of the skin and presumably render absorption possible.

New Remedies is, as usual, full of interesting matter, culled from all possible sources. A paper detailing the popular materia medica of Eastern Tennessee seems to take one back two or three hundred years in the domain of medicine, and gives a ludicrous view of the slow progress of education in that part of the United States. One of the most remarkable of the remedies is the treatment for whooping cough, which is "Nearly drown the child by suddenly pushing him into the water." A barbarous remedy, although doubtless the shock to the nervous system would be beneficial to a certain extent. "Flint" broth and "moleskin tea" are, however, scarcely likely to be serviceable, expect through the medium of faith.

As hydrobromic acid is now coming into use in medicine, the following method of preparing it, recommended by Hager, may be found useful to some of our readers: One hundred parts of sodium hyposulphite, 50 parts of bromine, and 10 parts of water are placed in flask, and the gas which is generated is conducted into the upper portion of 140 parts of water contained in another vessel. When the gas comes over slowly, a gentle heat is applied. The product is from 185 to 190 parts of liquid acid, containing 25 per cent. of absolute hydrobromic acid, and having a sp. gr. of 1·204. It should be kept in a cool place and protected from the light.

A paper in the *Pharmaceutische Centralblatt*, on neurine, a base which has recently been used for diphtheria, gives two processes for its preparation, one from bile and the other from yolk of egg, as well as tests for its purity.

Phosphide of zinc in a granule of from one to two-fifteenths of a grain thrice daily seems to have proved an effectual remedy for hysteria, in the hands of Dr. Gros.

Mesquite gum, which was noticed in this Journal some time ago, has now become an article of export, some 24,000 pounds having been recently gathered in Texas.

The Americans are certainly in advance of the English in one point respecting drugs, they do not allow bad samples to enter the market. The assistant appraiser's report of those which have been rejected at the port of New York during the last year, includes 42 boxes, 29 cases and 1 barrel of guaiacum; and 25 drums, 7 barrels of copaiba, 11 bales of jalap, and smaller quantities of rhubarb, squills, assafœtida, Iceland moss and hellebore roots. It would save much trouble to wholesale purchasers in this country if a similar supervision were exercised by Government at the large ports in this country.

A new application for carnauba wax is reported from France, where a patent has been taken out by M. Thellot, in which it is used in making petroleum soap.

Dr. M. C. Mohr, writing upon the revision of the United States Pharmacopœia, recommends the admission of the following old remedies, *Chelidonium majus*, *Malva rotundifolia*, *Symphytum officinale*, and *Verbascum thapsus*, on account of their being still much valued by the people; and in addition to other new remedies, such as *Coca*, *Grindelia*, *Jaborandi*, etc., he proposes the introduction of *Pycnanthemum linifolium*, as a valuable remedy in atonic dyspepsia. *Cactus grandiflora*, also finds a place among the list of new remedies; while thymol, amyl nitrite, trimethylamine, apiol, and some others have, he considers, but doubtful claims for adoption. The plea that various herbs should be admitted into the national pharmacopœia because they are valued by the people, although seldom used in legitimate practice, is one which, if applied thoroughly, would make the pharmacopœia almost a dictionary of materia medica.

In the *American Journal of Pharmacy*, a paper is contributed by Professor Maisch, on the Useful Species of Viburnum. The only one possessing any medicinal interest is the *Viburnum prunifolium*, recently introduced into notice by Dr. Phares of Newtonia, Miss., as a tonic and preventive of miscarriage. The fruit is stated to be a small edible blue-black drupe, and is known as the *black haw*, and the leaves are said to be used occasionally as a substitute for tea. This shrub occurs in the United States from Connecticut to Florida, and westward to Mississippi. In the paper the fruit of the wild guelder rose (*Viburnum opulus*) is said to be sometimes used instead of the cranberry. The odour of valerianic acid is, however, so strong in these berries, which are not uncommon in this country, that the taste for them must surely be an acquired one. Another paper by the same author, describes the root *Pterocaulon pycnostachyum*, Ell., the *black root* of Georgia, where it is used as an alterative. The other two drugs, *Ledum latifolium* Ait, and *Dioscorea villosa*, L., are not new, an account of the former being given in 'Redwood's Supplement to the Pharmacopœia' and of the latter in 'Wood and Bache's Dispensatory.' The inconvenience of the same name being used for distinct drugs in different States is well illustrated in the black root, this name being applied to *Actæa racemosa*, and to *Leptandra Virginica*.

Some samples of dialysed iron examined by Mr. H. Trimble, and purchased in Philadelphia as five per cent solution of ferric oxychloride, showed a variation from 2·514 to 4·831 per cent., not one out of six samples containing the guaranteed percentage. Doubtless it is not an easy matter to obtain a solution of dialysed iron of definite strength, but it evidently behoves pharmacists to examine the strength of this preparation which is so rapidly coming into favour.

Mr. G. W. Kennedy recommends the substitution of alcohol for proof spirit in the formula for the preparation of tincture of cantharides, on the ground that the marc after making the tincture contains cantharidin, and that in consequence the tincture is not so useful for hair washes as it would otherwise be. The author, however, apparently forgets that the tincture is frequently used internally, and that a greater strength, unless the dose be considerably diminished, might be fraught with serious results in making up old prescriptions in which the present preparation is ordered.

In respect to coto bark, which appears to be exciting some interest, a pertinent remark appeared in a recent number of the *Pharmaceutische Zeitung*. According to our contemporary, the "coto bark" originally examined by Jobst, and from which he isolated cotoin, is not met with in commerce, and the bark which came into the market last year under that name was exclusively "Paracoto bark." If this be correct, it follows that the "cotoin" of some price lists must be represented by para-cotoin, which, as stated by Jobst (*Pharm. Journ.* [3], vii., 495), even when freed as much as possible from leucotin and other bodies accompanying it in the bark, is inferior in its anti-diarrhœic action to the true cotoin.

A short time since a recruit to the now much-diminished army of the animal materia medica was announced in the person of the common cockroach (*Blatta orientalis*), which was reported by Russian physicians to possess diuretic properties, and to yield a crystalline body in which these properties were intensified. On the other hand, two other members, also having an ancient reputation as diuretics, but which, in fact, have not done much service in recent years, have just received their *coup de mort* from Dr. Méhu. The well-known crustaceæ, the wood-louse, (*Oniscus asellus*, L.), and the armadillo (*Oniscus armadilla*, L.), which were official in the older London Pharmacopœias and were sometimes divided into "wild" and "domestic," are still included in the list of *substances naturelles* of the French Codex, which also gives instructions for the preparation of a powder from them. They are but seldom met with now in French pharmacy, however, and the limited demand for them is supplied from Italy. The ancient medical reputation of these little crustaceæ was based upon the supposition that they contained a large proportion of nitrates obtained from the detritus in which they find their food. To test the truth of this Dr. Méhu has been making some experiments. He finds that the *Oniscus armadilla*, after drying at 100° C., by which it loses 2 to 6 per cent. of water, contains about half its weight of mineral matters, and the *O. asellus* one-third. The tegument is especially constituted of calcium carbonate. The ash includes about 8 per cent. of ferruginous silica and 6 per cent. of alumina. There were also obtained 1 per cent. of sodium chloride, $\frac{1}{10}$ per cent. of potassium chloride, a very small quantity of calcium phosphate, but no nitrates. The ash was slightly alkaline. Treatment of the armadillo with ether removed about 1 per cent. of oil containing chlorophyll. Dr. Méhu concludes that the employment of these animals is a remnant of the superstition of a past age, a justification for which is not found in modern therapeutics, and that the wood-louse and its congener should therefore be erased from the next French pharmacopœia.

In a paper communicated to the Faraday Club, Mr. G. E. Davis gives * a number of determinations of the nitrogen compounds present or liable to be present in commercial oil of vitriol. The method employed is a modification of Walter Crum's mode of estimating nitrates in potable water, and consists in agitating 1 c.c. of the acid to be tested with an excess of pure strong vitriol in a measured tube suitably provided and contained over mercury. By this proceeding the mercury reduces the teroxide and tetroxide of nitrogen to the form of nitric oxide, and the whole of the nitrogen compounds being thus obtained in a common gaseous form, nothing remains but to read off the volume and apply the usual corrections.

By the way, it may be added that the Faraday Club is a semi-social, semi-scientific association of the principal chemists in the Lancashire alkali district, and has its head quarters at St. Helen's.

C. A. Burghardt, Ph.D., in a communication made to the Manchester Literary and Philosophical Society, shows that when finely powdered iron pyrites is heated with pure water in sealed tubes to 120° C. for some hours, ferric and ferrous sulphates are formed, also free sulphuric acid and ferric oxide, along with sulphuretted hydrogen. From this experiment he concludes that sulphuretted hydrogen can be produced in the interior of the earth without the intervention of organic substances, inasmuch as all rocks contain more or less iron pyrites disseminated throughout them, and are also saturated with water.

Jörgensen describes † a proto-sesquioxide of platinum obtained by heating anhydrous sodium platinochloride, with dry sodium carbonate in a platinum crucible, at the temperature of incipient fusion. It is a bluish-black powder, not attackable by any of the acids or even by aqua regia. When heated to the melting point of silver it loses oxygen, and is entirely broken up. It is reduced by hydrogen at normal temperatures, with the evolution of light and

* *Chem. News*, vol. xxxvii., p. 45.

† *Journ. prakt. Chem.*, xvi., 342.

heat and the formation of water. It yields platinum black when gently heated with formic acid, carbonic anhydride being simultaneously evolved.

Imitating some experiments made by Schone, in Moscow, during 1874, Sergius Kern,* of St. Petersburg, has determined the amount of peroxide of hydrogen present in rain water. From a table setting forth the results, it is seen that equatorial winds bring rain much richer in peroxide of hydrogen than polar winds. This is interesting, because it bears out the expectation that in districts where vegetation luxuriates the amount of peroxide of hydrogen in the atmosphere would naturally exceed that to be detected in regions where vegetation does not flourish to the same extent. The author, however, seems to have taken no precaution to eliminate certain sources of error in his determinations, such as, for instance, the accompanying presence of nitrous acid, etc.

Berthelot† has investigated the reducing action of hydriodic acid upon benzene; he finds that the final product consists of hexane C_6H_{14}, while the hydrocarbons, C_6H_8, C_6H_{10}, and C_6H_{12}, are also formed intermediately. From these facts he is led to regard benzene as constituted of three groups of molecules of acetylene, or C_2H_2 (C_2H_2) C_2H_2, the side molecules of which have the power of uniting separately with hydrogen.

In other words, on this view benzene is to acetylene what ozone is to oxygen in a general way, and it is interesting to remember, that when the vapour of acetylene is passed through red hot tubes a cer- amount of benzene is produced, just as a certain amount of oxygen becomes transformed into ozone under the influence of induced electricity.

The aconite alkaloids have again come to the fore in the paper read by Dr. Wright, at the Chemical Society, on the 7th inst. It will be remembered that at the Pharmaceutical Conference in 1875, Dr. Wright gave the name of pseudaconitine to the alkaloid extracted by Mr. Groves from *Aconitum ferox*. To this alkaloid, Wright then assigned the formula $C_{36}H_{49}NO_{11}$, and at the Pharmaceutical Conference in 1877, he stated that this alkaloid readily split up under the influence of hydrating agents into pseudaconine and dimethyl-protocatechuic acid, as follows: $C_{36}H_{49}NO_{11}+H_2O=C_{27}H_{41}NO_8+C_9H_{10}O_4$. In his more recent paper, he alters the formula of pseudaconitine to $C_{36}H_{49}NO_{12}$, and the extra atom of oxygen is allotted to pseudaconine. Dr. Wright also retracts the statement made by him at the Pharmaceutical Conference in 1877, that the alkaloid extracted by Dr. Paul and Mr. Kingzett from Japanese roots was "a mixture of pseudaconitine and the decomposition products thereof." He now finds that the Japanese alkaloid does not yield dimethyl-protocatechuic acid, and hence it is not pseudaconitine.

G. Goldschmidt and H. Weidel‡ have examined the bark and wood of *Quassia amara*, L., and find that on extraction with water, it yields a yellow resinous body from which they failed to obtain a crystalline substance described respectively by Winkle and Wiggers. When fused with potash, the substance in question yields acetic and protocatechuic acids. Latour and Magnier de la Source§ have isolated a yellow crystalline principle from the flowers of the *Tagetes patula*. It has the composition $C_{27}H_{22}O_{13}$, $4H_2O$, and loses the water of crystallization at 100° C. They call the substance Quercetagetin, and rejecting Hlasiwetz's formula for Quercetin, viz:—$C_{27}H_{18}O_{12}$, substitute for it, $C_{27}H_{20}O_{12}$.

C. Tanret* states that the alkaloid ergotinine occurs in ergot of rye in the proportion of about one gram per kilogram. In its pure crystalline form it is insoluble in water, but dissolves in alcohol, ether, and chloroform. Both in the solid state and in alcohol solution it absorbs atmospheric oxygen and turns brown. The alcoholic solution exhibits a green fluoresence.

The salts of ergotinine are said to be decomposable by water, although the sulphate has been obtained in a crystalline state. The author finds that the alkaloid is accompanied in ergot of rye by another substance exhibiting properties like those possessed by camphor.

It was shown in a recent "Month," that the researches of Schiff upon the human spleen had rendered it probable that this organ has nothing to do either with the construction or destruction of the corpuscles of the blood, but that its probable function consists in the elaboration of certain ferment-matters rendered available in the processes of digestion. M. G. Pouchet has also just made a communication about the genesis of red corpuscles to the Société de Biologie. He shows that in certain Selachian fishes the elements of the splenic parenchyma are undistinguishable from certain corpuscular elements contained in the blood, and hence he conjectures in opposition to the above view, that the spleen is concerned in the genesis of the blood corpuscles. That the corpuscular elements in the blood of the fishes alluded to ultimately become transformed into red corpuscles appears beyond doubt, but M. G. Pouchet does not seem to have established this to be true of the splenic elements resembling them.

Prof. Binz, of Bonn, and some of his assistants, have recently re-examined† the question of excretion of alcohol by the kidneys and lungs, using Geissler's vaporimeter for the detection of traces of alcohol. This instrument will allow of the detection of as little as 0·05 per cent. alcohol. The authors found that patients suffering from various febrile disorders, excreted by the kidneys during the eight or nine hours after doses of alcohol had been given, not more than 3·1 per cent. of the total quantity, and in some cases no alcohol could be found. It also appears from these experiments, that practically no alcohol escapes by the breath even when large quantities are taken, and hence it is concluded that by far the larger part of the alcohol is burnt up in the body in the processes of metamorphosis of the tissues. This is of course a well-known fact, but its confirmation at this time is not inopportune.

Baumann‡ has published a few more facts about the formation of indican and phenol in the system. Originally, Schunck stated that the body which is present in urine, and from which indigo blue may be obtained, was identical with the indican which he had extracted from certain species of indigoferæ. Thudichum, many years ago, controverted this opinion by showing that the "indigogen" or indigo-blue forming substance in the urine was not a glucoside. Baumann, some time since, confirmed this view, and now he adds a further confirmation to it

* *Chem. News*, vol. xxxvii., p. 35.
† *Compt. Rend.*, lxxxv., 831.
‡ *Wien. Akad. Ber.*, lxxiv., 389—390.
§ *Bull. Soc. Chim.* (2), xxviii., 337—342.

* *J. Pharm. Chim.*, xxvi., 320—324.
† *Archiv. f. Exper. Pathologie*, vi., 287.
‡ *Zeitsch. fur Physiol. Chem.*, i., 60.

on the basis of experiments which lead him to the conclusion that the substance in the urine is a conjugated sulpho-acid.

Baumann also finds phenol to be an oft occurring ingredient of the urine of dogs fed exclusively on flesh meat, and inasmuch as he finds phenol is invariably produced when fresh fibrine is exposed to prolonged digestion with pancreatic tissue, he concludes that that found in the urine comes from the disintegration of albumen in the system.

Notwithstanding the light thrown upon the history of racemic acid by the brilliant researches of Pasteur, the conditions under which it occasionally makes its appearance during the manufacture of tartaric acid have never been satisfactorily elucidated. It is generally accepted that the racemic acid is present in the crude tartar coming from particular districts. But this explanation is not always sufficient; as, for instance, when tartar, taken from the same lot, and worked in different manufactories, yields in one place racemic acid, and in the other none. Dessaignes and Jungfleisch found by experiment that under the influence of heat ordinary tartaric acid is readily transformed into inactive tartaric acid and racemic acid, and the latter chemist thought to find in this fact an explanation of the production of racemic acid. But observations continued through many years upon mother liquors from various tartaric acid factories showed that, although more or less inactive tartaric acid was present in all of them, racemic acid was not, even where they had been subjected to prolonged treatment, and its occurrence in appreciable quantity was confined to a small number of specimens. In fact, some samples of mother liquor from factories where evaporation was carried on in a partial vacuum contained more racemic acid than others from factories where evaporation was carried on over a bare fire. Recently, Jungfleisch noticed that the liquors richest in inactive tartaric acid were also rich in alumina, and the suspicion that alumina favoured the conversion was confirmed by direct experiment; also that the neutral aluminum sulphate has but little action. Jungfleisch has come to the conclusion that when there is an accumulation of alumina in the mother liquor, the conditions are favourable for the production of a large proportion of inactive tartaric acid, and a small proportion of racemic acid, although when the latter is present in considerable quantity it becomes the most manifest through its comparative insolubility. Examination of liquors from which racemic acid has been deposited has always shown them to contain much inactive tartaric acid. This theory does not exclude the probability that certain vines under particular conditions produce racemic acid.

F. Frachoel, writing to the *Chemical News*,* points out the interesting fact that in Switzerland there is a custom of filtering milk, as soon as it is drawn, through a bundle of washed fir-tips. In this way a film of deposit consisting of hairs, skins, clots, &c., is formed on the spicular leaves and thus the milk is not only freed from these, but it appears to acquire the property of resisting the lactic acid fermentation for a considerable time longer than milk not so treated. In fact the milk becomes faintly aromatised—that is to say, enough of the resinous matter of the fir-tips is dissolved into the milk as is required to preserve it from change to a certain extent.

Now that the power of compressing gases is a subject attracting so much attention, *London Society* tells a very funny incident also bearing on the subject and on bottled beer. Fuller, who relates the story cited by *London Society*, says that in the reign of Queen Mary, Alexander Nowell, while master of Westminster school, went fishing one day, and took some beer in a bottle, which, owing to a combination of circumstances, he left near the bank of the river. Upon the accession of Elizabeth he returned to this spot and found "no bottle, but a gun, such was the sound at the opening thereof."

According to some statistics recently published, the production of wine in Italy during 1877 amounted to no less than 28,880,300 hectolitres, or at the rate of 1·03 hectolitre per head of the population. Wine-growing in Italy is not, however, of the importance that it might assume under better management and more scientific treatment. Moreover, while as a matter of fact many of the wines there grown will not keep, scarcely any of them are wines of a definite character. The government seems disposed to give some attention to this industry, in which case better things may come about in relation to its importance.

The *Lancet* adds another item to its list of good services by calling attention in a special report to the contamination of uniforms provided by the army clothing depot in the fever-dens, in which many of the workpeople live and make the clothes worn by our soldiers. Many of the facts elicited by the commission are repellant enough, and it is a marvel that while all the world is talking itself to death with sanitary science some more definite steps are not taken to remove the evils which exist in the very heart of London.

Before dealing with the "Dispensing Memoranda" that have appeared during the past month it will not be inappropriate to quote a passage from the paper read before the Glasgow University Medical Chirurgical Society on the Relations of Pharmacy to Medical Students, by Mr. John Edmund Fairlie, which was published in a recent number of this Journal. The author says, "I am convinced from what I have seen, that a pleasant looking and elegant preparation will go a long way in helping its efficacy, and the apathy and disgust often evinced at the taking of ugly medicines must have a great counteracting effect upon their curative properties. Among these I might mention nauseous oils and resinous juices not made into a proper emulsion; too large powders, pills, etc.; resinous tinctures mixed with water, etc."

These observations, emanating from a member of the medical profession, deserve our careful attention; although intended mainly for the prescriber, they apply equally to the dispenser of medicines, who, taking the Pharmacopœia as his standard for the preparation of the several remedial agents contained in it, has also to carry out faithfully the intentions of the prescriber in the compounding and dispensing of prescriptions.

An experienced dispenser should in most cases be able to state that with certain combinations a departure from the normal condition will eventually take place; it may be a change of colour or a separation. He should be in a position to anticipate the changes which must sooner or later occur, and to explain the reason when it is called in question. This is the result of experience acquired by long practice, but the extent of practice usually necessary may be much limited by the dispenser's

* Vol. 37, p. 50.

intelligent and careful attention to details, assisted by suggestions freely placed at his disposal.

Taking the Memoranda as usual in their numerical order, in No. 59 the composition of an article called "Pandrodyne" is required. Without seeing the original prescription it must be assumed that this name is correctly given; the article has not before been met with, therefore its composition cannot be supplied; it may be the obscure ingredient of one of those prescriptions which are intended to be as dead letters to all but the fortunate men who are in the secret. Referring to mythical practices and mythical prescriptions, Mr. Fairlie again says, "I have been told that arrangements exist between some physicians and chemists whereby a percentage is allowed the doctor for every prescription sent. The physician presents the prescription to the patient in an envelope with the chemist's name and address, remarking that it is the only shop where it can be properly made up, and even resorts to the writing of mythical prescriptions in terms which the chemist alone knows," and adds, "such practices I would stamp as downright conspiracies against the public, and both doctor and chemist ought to be punished by law." Many pharmacists are on this subject quite of his opinion.

No. 60. This prescription contains a rather large quantity of copaiba for a pill mass, with rhubarb and carbonate of magnesia; when made up the mass is too soft for retaining its shape after being rolled into pills. The copaiba may be partly solidified by the addition of magnes. calc., as in the creasote pill, but a better result will in this particular case be obtained by the addition to the copaiba of about half its weight, or less, of slaked lime, allowing a little time for solidification.

There may be a difference of opinion as to the propriety of adding calcined magnesia or slaked lime to solidify copaiba, but with our present knowledge there seems no equally satisfactory alternative. It would be a very proper course for the dispenser to submit to the writer of the prescription a sample of the mass made as prescribed, with another solidified by the best known means. It would need little argument to convince him that the former cannot be dispensed in a pilular form, and perhaps not much more to induce him to sanction the suggested addition. Very few of the medical profession who write prescriptions have had an opportunity of acquiring a practical knowledge of dispensing, and it must be a matter of astonishment to a careful observer that the errors in this respect, though met with occasionally, are comparatively rare.

No. 61 refers to some points in the manufacture of Ung. Hyd. Nit., B.P. The inquiry is "if it is proper to heat the *solution* of mercury in nitric acid until the reddish-brown fumes cease to be given off?" This mode of procedure would be incompatible with the B.P. directions. "Dissolve the mercury in the nitric acid with the aid of a *gentle* heat," and further, while the mixture of fat and oil is hot "add the solution of mercury."

According to Dr. Pereira, the theory of the process is as follows:—"By the mutual action of mercury and strong nitric acid, a nitrate of the binoxide as well as of the protoxide of mercury is formed, whilst binoxide of nitrogen is generated. Part of the latter escapes, and combining with atmospheric oxygen forms nitrous acid; the remainder acts on the free nitric acid, and forms with it hyponitrous acid, or nitrous acid." Whatever the theory of the process may be, practically, it is no easy matter to make this ointment of uniform colour and consistence. The ointment, whilst of good colour, usually contains free nitric acid, and many pharmacists are of opinion that the value of this preparation, as an application to the eyes, has in some measure been sacrificed to its appearance.

No. 61. Should a Belladonna Plaster have an adhesive margin? It is not usual, neither is it deemed necessary to make an adhesive margin to the belladonna plaster prepared in accordance with the B.P. directions. This view can only be adopted when no instructions are given in the prescription, but it frequently happens that the writer indicates his wish that there should be an adhesive margin. In that case the dispenser has no option; he must follow his instructions. But when no special intimation to this effect is given, a dispenser would be justified in sending out a belladonna plaster spread on leather and without an adhesive margin.

The duties of a pharmacist are two-fold. In the first place he has to satisfy himself that every preparation is properly made and also properly preserved for use. In the second place that those preparations be accurately dispensed in accordance with the prescriptions of the several branches of the medical profession. If the former be neglected no amount of accuracy in dispensing will secure uniform results, and if the latter be carelessly attended to, or conducted without a fair amount of intelligence, all the advantages of scientific training which may have been reasonably expected to result in success, will be neutralized.

The current number of the *American Journal of Pharmacy* contains a report of an incident that is worth mentioning in connection with the subject of explosive mixtures, which has more than once been referred to in the "Dispensing Memoranda." A druggist having dispensed a prescription for nitromuriatic acid and tincture of cardamons, handed the mixture to the messenger, who was in the act of putting it into his pocket when he was startled by the bursting of the bottle and the scattering of the contents over his clothes. Like Bruce's spider, the druggist tried again, and handed his second product to the messenger with the caution that he was not to shake it. This injunction, intensified by the bearer's own experience, postponed the *dénouement* until the bottle reached the patient's hands, when the cork was violently expelled, and acid and fumes spirted up into her face, nearly destroying her eyesight and causing several days' suffering. The editorial conjecture is that the acids were mixed and put into the bottle without waiting for the consequent reaction to take place!

A subject that has often attracted the serious attention of the pharmacists on this side of the Atlantic, as to the propriety of educated pharmacists using coated pills, fluid extracts, and other preparations obtained from wholesale manufacturers, was warmly discussed at a recent meeting of the Alumni Association of the Massachussetts College of Pharmacy. The general feeling was that the use of all articles of which the quality cannot readily be tested by the pharmacist should be discouraged. On the other hand, it was contended that the advantage resulting from manufacturing on a large scale might be retained by paying to respectable manufacturers a fair price for their goods.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 23, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

COUNTER PRACTICE.

THE letters which have passed between the Solicitor of the Apothecaries' Company and the Solicitor to the Pharmaceutical Society will doubtless have been read with much interest by the great majority of the chemists and druggists in this country, and we venture to believe that they will very generally be regarded as furnishing a satisfactory solution of a difficulty which has naturally caused considerable uneasiness. We have so often given expression to the opinion that the exercise of mutual forbearance and friendly consideration, is the only mode of dealing satisfactorily with the vexatious questions relating to the demarcation between medical practice and pharmacy, that we can consistently congratulate our readers upon the result that has been arrived at. We believe moreover that with the exception of a small section of the medical profession, comprising by no means the most influential or important members of that body, the substitution of a conciliatory policy by the Apothecaries' Company and the Pharmaceutical Society, for the ill-advised contest provoked by the Medical Defence Association, will be very generally regarded as consistent with the existing relations of medical men, pharmacists, and the public. Indeed, we believe that all reasonable men, whether medical or pharmaceutical, would agree in the opinion that, in regard to those relations, no strict rule can be laid down as to what is proper or improper; but that, under the guidance of mutual respect and consideration between medical men and pharmacists, the individual judgment of those concerned is the best means of preventing interference with the functions of either class.

Considering the importance of the subject, not only as the interests of a great number of chemists and druggists are at present concerned, but also in regard to the maintenance of cordial relations between the trade and the medical profession, we think it desirable to call the attention of our readers to the main points which have been so far settled in accordance with the general principle expressed in the brief statement published in the report of the Council Meeting held last January.

In the first place the Solicitor of the Apothecaries' Company states that he considers it unlikely that the Court will accept the suggestion of Mr. FLUX on behalf of the Pharmaceutical Society to have a test case of simple counter practice tried with the view of settling any question as to its legality. This alone might be regarded as a practical concession of the point at issue. But in addition to this the Act of Parliament Committee of the Apothecaries' Company, after considering the subject, distinctly disclaims having given authority for any attack upon counter practice as well as the intention of doing so, and the correspondence published on page 634 makes it clear that while the Medical Defence Association, in making its attack upon counter practice, has obtained from the Apothecaries' Company authority to use its name by means of a statement of allegations outside counter-practice, it has not in using that authority, relied upon the allegations which were of the gist of the statement on which the authority was obtained. On the contrary, the Association has given evidence merely of counter practice, and finding the County Court judges disposed to regard the attack upon counter practice as being deliberately made by the Apothecaries' Company—the nominal plaintiff in the action—it has been contented to leave the case to stand upon the evidence of counter practice and to take the judgment upon that.

We are not in a position to say how this has been managed, but that it was the case is the only possible interpretation that can be put upon the very specific statements made by Mr. UPTON that the Act of Parliament Committee of the Apothecaries' Company is "unable to discover any case wherein the sanction of the Society has been given to a prosecution on a pure and simple case of counter practice," and again that he has "not authorized any prosecution in a case of pure and simple counter practice." It is perhaps unfortunate that this complication of the matter has arisen, and it shows the necessity of caution in delegating to another body such powers as the Apothecaries' Company possess. In the absence of any statement of the allegations outside counter practice, it is impossible even to conjecture whether there was sufficient foundation for them, but whatever may have been the nature of the representations made by the Medical Defence Association to the Apothecaries' Company, the result has been to make the Company appear in a position at variance with its expressed intentions.

As regards the future it may fairly be inferred that the unlimited leave given by the Apothecaries' Company concerning the use of the letters written on its behalf by Mr. UPTON, would extend to their production in any action in which counter practice might be called in question. This is, we think, a very important result of the communication between the Solicitors of the Society and of the Apothecaries' Company, for it virtually stands admitted that the Company practically does not and will not question that counter practice is within the exemption of the clause in the Act of 1815. In face of this positive declaration it seems to be comparatively of little moment that the Act of Parliament Committee refrains from expressing any opinion as to whether cases of counter practice come within the Act of 1815 or not.

While, therefore, any grounds for apprehension that counter practice will be interfered with may be regarded as practically removed, there is another aspect of the matter which appears to render the amicable settlement of the question far preferable to the appeal to a legal tribunal. It must not be forgotten that the decisions given in cases which have been tried are in favour of the view that counter practice is within the Act of 1815, and this circumstance is referred to by the Act of Parliament Committee of the Apothecaries' Company. Again, in view of the restrictions imposed upon all kinds of professional practice, which it is the tendency of the present time to enforce and extend, it may be questioned whether any legal tribunal would give a decision at variance with this tendency, at any rate without qualifying it with onerous conditions.

Whether in any further trial of Shepperley's case the plaintiffs will seriously raise the question as to counter practice remains to be seen. But it is a matter of clear inference from the letters that there was laid before the Apothecaries' Company a statement of alleged infringement of the Apothecaries' Act outside of counter practice, and it would be contrary to all ordinary experience if at any future trial, evidence as to those other facts were not given and relied upon, in which case it might appear that a conviction would result without counter practice being seriously in question upon that verdict.

As regards the question what constitutes counter practice, we do not think that chemists and druggists generally are called upon seriously to consider this question in the strictest sense. The law cannot extinguish human nature, and it is not in human nature for any man to refuse words of counsel and recommendation on the sale of an article in the way of his business, or on a sudden emergency. The force of this truth was not long since very humorously illustrated in one of the comic journals in a manner which exposed the absurdity of the demands made by a small section of the medical profession, who would restrict the action of the chemists and druggists to the mere mechanical details of vending drugs and dispensing medicine.

What chemists and druggists as a body would take a stand for and what, in fact, they really mean is expressed with fair accuracy in the solicitor's letter in the following words:—"I also mentioned having stated to you that my clients, whilst regarding counter practice as a public and trade necessity, protected by the twenty-first section of the Apothecaries' Act of 1815, did not encourage it and had no intention at variance with discouraging its exercise further than unavoidable." It will be observed, however, that the solicitor's letter did not attempt to defend any holding forth, by advertisements, handbills, sign or otherwise, that the chemist and druggist gives advice or practices medicine, or engages in any practice outside of counter practice.

SCHOOL OF PHARMACY.

The courses of lectures on "Chemistry and Pharmacy," and "Materia Medica and Botany," in connection with the Pharmaceutical Society's School of Pharmacy, 17, Bloomsbury Square, will recommence on Friday, March 1, when Professor Bentley will give his first lecture on Botany. Students who have but a limited time at their disposal will find the ensuing five months to be a favourable period for studying at the School, for between the 1st of March and the end of July they will have the opportunity of attending not only in the Laboratory and at the usual courses on Chemistry and Pharmacy and Materia Medica and Botany, but also the summer course on Systematic and Practical Botany which is delivered at the Royal Botanic Society's Gardens, in Regent's Park, where every opportunity will be afforded to them of obtaining a practical acquaintance with plants.

THE DENTAL PRACTITIONERS' BILL.

The second reading of this Bill was moved in the House of Commons on Tuesday last by Sir John Lubbock, who said its object was to protect the public by limiting the use of titles which would imply that the persons using them had special dental qualifications. The motion was opposed by Dr. Cameron and other members, and eventually, after two divisions, Sir John Lubbock consented to the postponement of the second reading until the 5th of March.

With respect to the ambiguous words that have attracted so much attention as being likely to affect the interests of persons practising dentistry in conjunction with the business of a chemist and druggist, we have reason to believe that the difficulty will be removed by their withdrawal.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association will be held at 17, Bloomsbury Square, on Thursday evening, February 18, at 8 o'clock, when a "Note on Some Substances Employed in Perfumery" will be read by Mr. C. J. Mead; and a note on "Blatta Orientalis, its Use and Preparations," by Mr. J. Hart.

THE CHEMISTS' ASSISTANTS' ASSOCIATION.

It will be seen by a reference to our advertising pages that on Wednesday next a Soirée in connection with the Chemists' Assistants' Association is to be held at the Quebec Institute, Baker Street, W.

LEGACY TO THE BENEVOLENT FUND.

In connection with the Benevolent Fund, we are informed that the Secretary has received, through Messrs. Kay, of Stockport, acting as executors, the sum of £100, less legacy duty, in accordance with the terms of the will of the late Mr. Stephen Carr Sagar, chemist and druggist, of Swinton.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

February 13, 1878.

Present—Mr. Williams, President; Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, Taylor and Umney.

MAJOR EXAMINATION.

Eleven candidates were examined. *Five* failed. The following *six* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Atkins, William Ralph ....Salisbury.
Branson, Frederick Woodward..Northampton.
Cullingford, Louis James ......Bletchingley.
Curtis, Frederic George ....Dorchester.
Miller, Cecil Bradley ....Wellingborough.
Redford, George Alfred .. ..Liverpool.

MINOR EXAMINATION.

Ten candidates were examined. *Three* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Ascott, Tom ....Exeter.
Ashweek, John Sydney ....Torquay.
Budden, George Alfred ....Wareham.
Hawken, Alexander...............St. Austell.
March, Richard ....Stamford.
Need, John ... .Great Malvern.
Thomas, John Edward ....Swansea.

MODIFIED EXAMINATION.

Three candidates were examined. *Two* failed. The following passed, and was declared qualified to be registered as a Chemist and Druggist:—

Hadley, James William ....London.

February 14, 1878.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, Taylor and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-three candidates were examined. *Fourteen* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Albright, Alfred ....Bootle.
Attree, William ....Southampton.
Brumwell, Herbert ....Fleetwood.
Challinor, Cedric ....Bolton.
Hall, Richard Arthur ....Leigh, Lancashire.
Jones, Henry Stevens, jun. ....Fulham Road.
Lockyer, William Walter ......Deptford.
Skelton, John Hardy ....Gainsborough.
Stobbs, Robert ....North Shields.

February 15, 1878.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, Taylor and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-one candidates were examined. *Nine* failed. The following *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bambridge, Arthur John ......Lancaster.
Boor, Jonathan.....................Manchester.
Brothwood, Harry Skarratt ...Shrewsbury.
Chapman, Leonard Parker ......Rochdale.
Corlett, Edwin ....Ramsey.
Crook, Arthur Williams ....Preston.
Davies, Thomas .... Newcastle Emlyn.
Hoare, William Parker ....Cirencester.
Hobson, Charles, jun. ....Windsor.
Jones, George ....Bedford.
Moody, Thomas Sullivan.........Lowestoft.
Murison, John ....Fyvie.

PRELIMINARY EXAMINATION.

The undermentioned Certificates were received in lieu of the Society's Examination:—

Certificates of the College of Preceptors.

Acton, Frederick George.........Worcester.
Lewis, Frederick William ......Hereford.

Certificates of the University of Cambridge.

Cosford, Frederick Robert ......Brighton.
King, Arthur......... ....Norwich.
Sharpe, William Cecil ....Madeley.

Certificate of the University of Oxford.

Joint, Francis ....Barnstaple.

PHARMACEUTICAL MEETING.

Wednesday, February 20, 1878.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

A special Evening Meeting was held on Wednesday last, when Professor Redwood delivered a lecture on "Spectrum Analysis." The lecture, which will be published in the next number of this Journal, was illustrated by spectra thrown on a screen by the electric light and by numerous experiments, in the manipulation of which the Professor had the assistance of Mr. T. Boverton Redwood and Mr. T. Horne Redwood. At the close of the lecture, upon the proposal of the Chairman, a hearty vote of thanks was given to the Lecturer.

The following is a list of the Donations to the Museum during the past three months:—

Pot in which Curari is imported, from Messrs. Hopkin and Williams; Native Cinnabar, from New Almaden Mine, California, from Mons. C. Chantre; Ndilo Oil obtained by expression from the seeds of *Calophyllum inophyllum; Grindelia robusta*, from Messrs. Corbyn, Stacey and Co.; *Grindelia robusta*, from Mr. W. Martindale; specimens of Podophyllin, from Dr. A. Senier and Mr. A. J. G. Lowe; specimens of Salicylic Acid and Salicylate of Soda from Oil of Wintergreen, from Messrs. Hopkin and Williams; specimens of Amyrin, Bryoidin and Elemic Acid, from Professor Flückiger; specimen of *Cinchona calisaya* and the var. *Anglica* in blossom, from Mr. J. E. Howard, F.R.S.; a large and perfect octahedron of common Alum crystallized with Chrome Alum; a large prismatic crystal of Sulphate of Magnesium, having reversed dihedral summits, and a very perfect prism of Ferricyanide of Potassium, from Mr. W. Copney; specimen of Mogador Colocynth, from Messrs. Hearon, Squire and Francis; specimen of Absolute Phenol, from Messrs. Bowdler and Bickerdike; specimen of the Monochloride and Trichloride of Iodine, from Mr. W. R. Dunstan; specimen of Dragonwood, from Mr. Curling; specimens of Oil of Rose Geranium, as described by Professor Dragendorff, of Ammoniated Glycyrrhizin and of Nigella seed, from Mr. H. W. Langbeck; specimen of Poppy-head and of Opium, from China; specimen of Mahwah Flowers, from Mr. T. Christy; specimen of Iron Slag tinted with Manganese, from Mr. W. Y. Brevitt; specimen of Brazilian Copal, from Mons. C. Chantre; specimen of Senna Leaves (*Cassia obovata*) from India, from Dr. Forbes Watson, India Office; specimen of the root of *Scorodosma fœtidum*, from the Curator.

NORTH BRITISH BRANCH.

The fourth meeting of the present session was held in the Society's rooms, 119A, George Street, on the evening of Tuesday, 12th February.

Mr. J. B. Stephenson, President of the Branch, in the chair.

A paper was read, entitled—

Quinine, a Physiological Antidote to the Malarial Poison.

BY FRANCIS MOINET, M.D., F.R.C.P.E.,
Lecturer on Materia Medica and Therapeutics.

The most important and ancient of the uses of quinine depend undoubtedly on the power it has over malarial diseases, both as a prophylactic and curative agent, a power which has not as yet been explained by our knowledge of its physiological action, but which is so evident, that by many it is considered a specific for these diseases. That it is not a specific we need hardly say, unless the term may be applied to a remedy whose powers we know, but of whose mode of action we are ignorant, because it does not always act as a prophylactic when taken as a preventive, nor is it always curative, which would not be the case were it a true specific. But so interesting a problem as the action of quinine in these diseases has naturally brought forward several theories to explain its action. The theory of its specific action hardly deserves the name of such, on account of its improbability ; other theories however, have been adduced of a much more plausible and rational character. Thus, Piorry, Mosler, and others, explain the influence of quinine by an action on the enlarged spleen, viz., that the effect it produces upon the fever is in proportion to the reduction of the spleen, that the disease is cured simultaneously with the subsidence of the splenic enlargement, and that the fever is apt to recur as long as the spleen exceeds its normal size. This enlargement or engorgement of the spleen and other organs is, however, only a secondary phenomenon, and is a result, and not the *origo mali*, as Piorry and his followers aver, who declare the spleen to be the primary seat of the disease. Thus, according to Jacquot, Saurier, and others, people are said to die of malarial fever in Africa without the slightest swelling of the spleen. A singular case is also related, in which a man received an extensive wound of the wall of the abdomen on the left side, through which the spleen escaped ; as it could not be returned it had to be removed. The patient recovered from the operation and had malarial fever afterwards, just the same as before, although eventually a *post mortem* examination showed nothing but the shrivelled rudiment of the spleen left.

Besides, M. Piorry's assertion as to the diminution of the size of the spleen after a dose of quinine has been disproved by many careful cliniciens, and other investigators have failed in their attempts to reduce the size of the spleen in dogs by giving quinine as Kuchenmeister and Mosler declare they did; so that even granting the enlarged spleen to be the cause of the disease, the action of quinine in diminishing its size remains yet to be proved, or rather has been disproved. Besides, in some cases of these diseases, the spleen is not enlarged and yet they are cured by quinine, and in others the fever disappears before the enlarged spleen is reduced in size. Hence, at the present day, M. Piorry's theory is generally held to be untenable, as it is founded on false premises.

Then Professor Binz advanced his theory, taking first for granted the germ theory of malarial poisoning, and arguing from the effects of quinine on the white blood corpuscles, that in malarial fever it acts as an irritant to those germ cells, and so renders them incapable of further development and thus arrests and cures the disease, and by its action on the white corpuscles, destroying them, it diminishes their number, diminishes the functional activity of the spleen, and as a result the organ diminishes in size.

But this theory is based, as it appears to us, upon rather an unstable basis. First, because Binz takes for granted that quinine acts on the white corpuscles in the body as it does out of the body, his experiments not being received as at all conclusive on this point. Besides, the action of quinine in checking the movements of the white corpuscles is much more probably the result of an action on the walls of the capillary vessels, causing them to contract and so preventing the escape of the white corpuscles than on the corpuscles themselves. As no doubt in relaxation of the capillaries approaching stasis the white corpuscles pass readily through the walls of the vessels, and by increasing arterial tension this can be prevented without implying a direct action on the corpuscles.

For this reason Harley is strongly of opinion that the beneficial influence of quinine in ague, and the removal of the splenic swelling, must be attributed to this effect on the blood vessels, by which the congestion is relieved, rather than to a restraining influence on the white corpuscles or leucocytes, as they have been termed. Harley's theory is certainly more probable than that of Professor Binz, because, as he says, if the white corpuscles were a species of entozoa, capable of an independent existence like the infusoria, then a direct action of quinine might be possible. But as we have already said, however desirable it may be to reduce the splenic enlargement, it is not the cause of the disease, and hence treatment directed with this view does not relieve the symptoms of the fever, although it may benefit the local complication. Nor is it apparent that arterial relaxation is more marked in malarial than in other fevers, by modifying which relief from the symptoms may be expected.

Secondly, he takes for granted, what is still unsettled, the germ theory of malarial poisoning.

Thirdly, that on this hypothetical poison, quinine must act as it does on some other germs or on the white blood corpuscles. That in fact quinine is a chemical antidote to the malarial poison. But its effects in these diseases do not support this idea, as we shall immediately see. As to its action on the spleen, that is of little consequence, as of course if the theory fails in the first part, its mode of action in regard to the enlarged spleen must also fall to the ground. All the more so as we have already seen that the beneficial effects of quinine in these diseases are not the results of an action on the spleen. Hence, neither the theory of M. Piorry, of Professor Binz, nor of Dr. Harley, is sufficient to account for the good results which follow the administration of quinine in malarial poisoning.

But by noting the symptoms of malarial fever, and the clinical experience of its treatment with quinine and other remedies, and by examining the action of quinine and other remedies on the nervous system, we might, we think, get some further light on its action, rather than by confining our attention merely to the more common manifestations of its physiological action.

For, by noting the results of treatment, we are often able to explain the action of remedies, in the same way as a knowledge of the action of some remedies in disease has assisted us to a better understanding of the nature of these diseases. So, on the other hand, there is no reason to doubt but that a knowledge of disease and the effects of remedies will often throw light on their physiological action, and explain the *modus operandi* of their curative powers, which is not always apparent from their action in health.

When quinine is administered in malarial fever the beneficial effects which follow cannot be due to it having the power of eliminating the poison from the system, as it has no evacuant action by the bowels, kidneys, or skin. Nor is there any evidence that the symptoms of malarial fever are due to structural changes of any organ, as the spleen, by acting on which quinine might prove curative.

It must, therefore, act in the system, either on the paludal poison itself, by destroying it or paralysing its power, or by an antagonistic action on the nervous system, protect it from the shock of the poison, and so prevent or modify those symptoms which are the usual manifestations of the disease. That is to say, quinine must be either a chemical or physiological antidote : in the one case the poison itself is attacked by the remedy ; in the other the nervous system, at least that part of it which is the seat of selection by the poison, is braced up, so as to resist its power in whole or in part, according to circumstances.

That malaria is a poison cannot be doubted, although of its precise nature we are ignorant, and which by entering the blood gives rise to certain defined and well marked symptoms.

The first of these two theories, viz., that of its being a chemical antidote, is almost analogous to that of Professor Binz, and of which we have already seen there is not sufficient proof. Still, the fact of quinine being a chemical antidote might remain, although Professor Binz's theory be untenable, as it is more properly speaking simply an explanation of its action as a chemical antidote. Hence additional proof is required to refute the idea of its being a chemical antidote in any way.

This idea of its antidotal power appears to be in considerable favour with Stillé, who says, "Admitting that a morbid element in the blood is the immediate cause of the paroxysms of periodical fever, some such cure appears to be most consistent with probability." That it is not most consistent with probability we will endeavour to show, and also that the theory of its being a physiological antidote is the most consistent with probability, as we, like Stillé, believe that the effect of quinine can only be explained by the supposition that quinine elimininates, destroys, or renders inert or inoperative some noxious principle contained in the blood. A strong argument against its power as a chemical antidote is that it and other antiseptics which have been given to cut short or to protect the system from diseases resulting from a poison in the blood have failed.

Thus carbolic acid, sulphurous acid, and corrosive sublimate, which are powerful antiseptics when outside the body, when administered in such diseases as scarlet fever, small pox, typhus, typhoid, or relapsing fever, in which diseases a poison undoubtedly is present in the system, do not possess any antidotal power. Thus the carbolate and hyposulphite of soda, which are readily decomposed in the system into their respective acids and bases and so allow the acids to exert their peculiar power, have not, in my experience at least,—and which can be corroborated by many practitioners,—shown themselves to possess any power of either acting as prophylactics, or cutting short the duration of the disease or diminishing the mortality. That a poison is present in the blood in these diseases has been demonstrated at least in small pox and relapsing fever. Besides, in the recently published results of Dr. J. V. Laborde's experiments on the preventive and curative action of reputed antiseptics, he found—in contradiction of the statement of Professor Binz—that quinine when injected in septicæmia, even in the highest doses compatible with life, neither acted as a preventive to the development of the disease nor averted it when it was produced. There is no reason to believe that quinine has any more affinity for the malarial poison than it has for the poison of these other diseases, and clinical experience supports the opinion.

Besides, the theory of a chemical antidote in such diseases must be received with extreme caution, as it is open to many fallacies: such as, judging from their action outside the body, as to their action in a complex fluid like the blood, and on poisons of whose nature and chemical composition we are ignorant. Also, by the time a fever has developed itself it is very questionable if a chemical antidote would be of much service, as probably the mischief is done by the time the disease manifests itself, viz., that during the period of incubation those changes in the blood and nervous system are brought about and which culminate when this period is brought to a close. Hence to be really serviceable it is probable that a chemical antidote would require to be given at the period of infection, and which by an action then might prevent the development of the disease or modify its future course, while later on it would be useless. But unfortunately, even supposing that we knew of chemical antidotes, it would be almost impossible to make good use of them, as in most cases the patients are naturally ignorant of the time when they received the poison into their system.

And, as I have said, clinical experience does not support the theory of its being a chemical antidote. Thus in malarial fever, although quinine arrests the attacks in some, in others it only diminishes their intensity and sometimes even fails entirely, and always requires to be repeated. This is decidedly against its antiseptic or chemical action, because it is not possible to believe in the power of a chemical antidote which requires to be so frequently repeated as quinine so often has to be, and which sometimes fails, or in a poison which proves itself so speedily active after its apparent destruction, so as to be able to reproduce all its former effects on the economy in so short a time, even after complete removal from the infected district and when no new source of infection is possible. Indeed, the frequency with which quinine requires to be given, and the duration of the disease, notwithstanding its repeated administration, are all insurmountable difficulties in the way of accepting the theory of the chemical action of quinine on the malarial poison, more especially as the secondary lesions are not the cause of the periodical attacks. These paroxysms are perhaps the result of a somewhat similar process to what Heydenreich has shown to be the cause of the relapses in relapsing fever, viz. fresh crops of the germs (*spirillæ*) being cotemporaneous with the fever paroxysms.

That the poison of malaria must have the power of continuing or reproducing itself in the blood is highly probable, both from the duration of the disease and the periodicity of the paroxysms. And if we suppose that quinine arrests a paroxysm by its chemical action on the poison, how is it possible to reconcile this with their continued recurrence after its repeated administration, and it is so far antagonistic to the germ theory of malarial infection, *i.e.*, if quinine is capable of, as Binz asserts, paralysing the irritant miasm by virtue of its antiseptic power or rendering the germs incapable of further development? And certainly there is much more evidence to support the opinion of malarial fever being due to the presence of a poison in the blood than there is in support of the theory of Professor Binz as to the action of quinine. This word paralysing is, however, rather vague and perhaps is meant as an apology for the recurrence of the fever paroxysms and to signify that quinine does not always destroy, but only paralyses for a time, the obnoxious germs.

Surely this expresses a want of confidence in the theory, because after asserting the antiseptic and fatal influence of quinine on such like germs outside the body, Binz argues from that a similar action within the body; and yet if this be true, why does quinine modify what is a fatal action in the one case to a paralysing one in the other, and if it does where is the proof of it? Hence the theory of quinine being a chemical antidote or counter-poison to the malarial poison appears simply untenable, and in the same category we may place the theory of Professor Binz.

The second theory, that of quinine being a physiological antidote, remains to be examined, viz., that by an action on certain parts of the nervous system it diminishes the shock or effect of the poison and thus either prevents or modifies the symptoms which are the manifestations of the action of the malarial poison on these parts. That the nervous system is, in the first place, the principal seat of selection of the poison is generally allowed, both from many of the symptoms of the disease pointing strongly to a direct influence of the malarial poison on the nervous system, and also from the result of treatment, viz., that treatment directed upon this belief is the most powerful and certain in ameliorating the symptoms or curing the disease.

Perhaps, as some believe, an excito-caloric centre is disturbed, whereby intermissions and remissions are produced.

This idea of an action of quinine on the nervous system is compatible with the need of repeating the remedy—which as we have seen Binz's theory is not—as the stimulus of quinine and of all other stimuli to the nervous system can only last a certain and limited time, depending on the dose and the condition of the patient's health, and whether, as in the case of intermittent fever, there is any antagonistic or depressing influence at work. It is not only compatible with repeating the doses, but demands their repetition until the poison is exhausted or dies a natural death, as there is no indication of its being eliminated from the system. From this follows the approved method of administering the remedy before the paroxysm comes on. It also explains what by any other theory is inexplicable, why quinine is sometimes successful, and not always equally beneficial. These results being no doubt due to several causes : to the dose being too small, the use of bad preparations, the varying susceptibilities of patients to the action of the remedy, as is the case with the action of most powerful remedies, and also to the difference in the action and power of the poison in different constitutions and temperaments, the amount of the poison received into the system, the presence or absence of complications or secondary morbid conditions, or to the disease not being correctly diagnosed and being wrongly attributed to malarial poisoning.

Another plea in favour of this theory is that our knowledge of its general physiological action does not explain its effect in malarial fever, unless, according to M. Sée, who ascribes its effects in ague "to its action on the heart, diminishing its force and frequency ; to its action on the peripheral arteries, lowering their tension and producing dilatation ; to its action on the spinal cord and vaso-motor centres, acting as a sedative and diminishing their excitability, and diminishing the temperature of the body." Yet, as he says, it cannot be regarded as a specific or counter poison in the various forms of malarial fever, as it does not prevent malarial poisoning. When taken as a prophylactic, it does not prevent recurrence after a variable period, and it is useless in some of the most fatal forms, especially when the fever tends to assume a continued type. And although this statement of M. Sée's is neither quite accurate in regard to the physiological action of quinine, nor to its power as a prophylactic, it explains what we mean when we say that its action in these diseases cannot be fairly deduced from any of its known or apparent physiological effects, as none of these appear in the smallest degree likely to counteract the action of the malarial poison on the system, if we compare the symptoms of the disease and the known physiological actions of quinine. Besides we have other remedies which act more powerfully in these respects than quinine, and yet which have no curative action like quinine in malarial diseases, as they would undoubtedly have did quinine control the disease by these actions. Hence M. Sée evidently thinks that what, perhaps, no one action is capable of effecting, when they are combined the result is successful. No doubt the beneficial effects of quinine are due to its physiological action, but certainly not to any one or all of those enumerated above.

But although, as we have said, the known physiological actions of quinine do not apparently throw any light on the connection between its action and the beneficial results which follow its administration in ague, do we know all its actions ? Certainly not. If we do not know its action in intermittent fever, then how are we to discover it. As every one knows, there are certain actions of remedies, especially on nerve structures, which it is impossible directly to demonstrate, but an action of which indirectly very strong and even conclusive proof can be obtained by noting their effects ; although this is much more difficult when we have to examine these actions in disease, and of which in health there may be little or no evidence.

Thus Binz says: "We are ignorant of any direct relation between quinine and the nervous system which might be utilised for therapeutic purposes ; although we cannot deny that such may exist, any such influence exerted by quinine upon the nervous system is at present purely hypothetical and unsupported by a single experiment." This is, in fact, just what we might expect. You cannot prove by direct experiment what does not exist, viz., the action of quinine in ague on a healthy man or frog. The proof must be from the effects of its action in disease, *i.e.*, clinical experience ; and in this way it is possible to get, we believe, as conclusive evidence as by direct experiment.

That quinine is a nervine tonic even Binz allows is probable. That it is we think there is sufficient proof over and above its tonic action to the general nutrition by stimulating the digestive functions and retarding tissue metamorphosis. Because in certain nervous derangements it proves curative, we believe, in virtue of this action, as it can be by no other, long before it could have time to improve the general nutrition of the body ; as in periodic neuralgia, asthma, laryngismus stridulus, rigors, etc., etc. In these affections a full dose of quinine will often speedily arrest them if given an hour or even half an hour before the attack is expected, showing that the action must be a direct one, and that through the nervous system. Its beneficial influence in those diseases which we know are due to a disturbance of ennervation must be due, we believe, to an action on the nervous system. This is borne out by clinical experience, for quinine is beneficial in neuralgia just in proportion as the case is of purely nervous origin and occurring in those in whom there is want of tone.

Stillé thus explains its action in periodic neuralgia : "by regulating and moderating the disorder of the nervous system ;" and then explains its action in malarial fever : "by directly neutralizing a material poison, or causing elimination from the system." That it does not do the latter we have already seen, as no eliminative action occurs after the employment of quinine ; as to its being a chemical antidote clinical experience is against it ; then why not apply the explanation of its power in periodic neuralgia to its influence over malarial fever ? It is the most probable of the explanations, and the only one which clinical experience supports. In all these nervous diseases we have mentioned there is good reason to believe that not only is some part of the nervous system either primarily at fault or the point of attack, but also that in some the whole nervous system is in an atonic condition, or unstrung, as they occur most frequently in those of weak constitutions, whether this condition is hereditary or acquired In others the disease or symptoms are the result of a sudden shock which suddenly, and for a time only, reduces the nervous tension and brings it below par.

Take, for instance, the rigor which follows catheterization. This is undoubtedly due to an impression or shock to the nervous system, and which can be prevented or checked by a dose of quinine. The action of quinine on the nervous system is therefore here as evident and undoubted as that the rigor is the result of functional disturbance of the nervous system, the one mutually proving the other.

Quinine can therefore arrest other rigors and fever paroxysms than those which occur in intermittent fever, and that without there being any suspicion of the presence of a poison in the blood, so that its power of arresting certain fever paroxysms is quite independent of an action on a morbid element in the blood. But no doubt poisons in the blood, by acting directly on the nervous system, can disturb it even more readily and directly than the presence of a foreign body in the urethra. Still there is no reason to prevent quinine acting in the one case as in the other, only in the case of a poison in the blood, like the malarial, the quinine must be repeated if these shocks or periodical attacks are to be prevented until the poison has exhausted itself. The greater power of quinine in malarial fever than in other fevers can readily be accounted for, not only by the blood poison being of a different nature, but also by the different seat of selection of these poisons; just as the typhoid poison has a special affinity for the intestinal glands and small pox for the skin and mucous membrane, so the malarial fevers attack chiefly the nervous system, at least in the first instance. Whenever in disease, however, the symptoms approach the type of malarial fever, with a cold, then a hot stage, followed by an intermission, then quinine is beneficial; that is to say, when that portion of the nervous system is involved which is always implicated in malarial poisoning. So that we have proof that quinine exerts the same action in other diseases than those of a malarial origin, which is against the chemical action of the drug, and from the nature of the cases in which it proves useful is strongly corroborative of a tonic action on the certain parts of the nervous system, and therefore of it being antagonistic to the action of the malarial poison, *i.e.*, a physiological antidote.

In health this action of quinine is however not very manifest, but the symptoms of cinchonism, headache, buzzing in the ears, confusion of sight, etc., point undoubtedly to an action on the brain, and that not only does it act on the brain, we may readily infer just as alcohol acts as a stimulant and sedative to other parts of the nervous system in addition to the brain. The cerebral effects are however the most prominent, as they are most clearly and quickly evident from its delicate functions being so readily disturbed, and although the beneficial action of quinine is not usually apparent until some time after the symptoms of cinchonism have disappeared, that is until it has prevented or diminished the next paroxysm of the disease, it does not by any means follow as some have argued that therefore the curative power of quinine cannot be due to a stimulating or sedative action, because those sensible effects have ceased, unless it were held, which it is not, that the malarial poison acted principally on the brain, or that with the disappearance of these most prominent effects, all the other actions of the drug ceased. It simply shows that certain of its cerebral effects have diminished, just as with alcohol which first excites, then acts as a sedative. When the excitant effects pass off or are merged into other symptoms, we cannot say that therefore alcohol has ceased to act, and even when all cerebral symptoms disappear its stimulant action lingers in other parts until it is entirely eliminated from the system. It is even possible to understand that the beneficial result of the stimulant action may be shown after elimination of the stimulant. For instance, if by a dose of quinine the next attack of fever which would naturally occur twenty-four or forty-eight hours afterwards is prevented, it does not follow that quinine waits on the paroxysm and then attack it. Its beneficial action commences as soon as it is absorbed and by its action on the nervous system the paroxysm is prevented, not by an action twenty-four hours after its elemination, but by its immediate action preventing that disturbance, which in time develops into a fever paroxysm. So that we must not always take for granted that the more obvious effects of nervous actions are the only ones produced by remedies, as an action that in health may not be manifest, may in cases of functional derangements be actively remedial. This is the reason why certain curative actions of remedies are only witnessed in disease. Nor is this action peculiar to quinine. Compare for instance the effect of arsenic in St. Vitus's dance with what are ordinarily known as its physiological actions; and in regard to it the same may be said as is said by some of quinine and its action in malarial disease, viz., that its effect in chorea cannot be explained by its known or evident physiological action, yet no one can doubt that arsenic acts in chorea purely as a nervine tonic.

Another link in this chain of reasoning is that other nervous stimulants, as arsenic, caffein, alcohol, gentian, piperine, capsicum, beberia, strychnia, etc., although differing considerably both in kind and degree of action, have some power over intermittent fever and other diseases of a nervous pathology. In fact as adjuvants and occasionally as substitutes they are invaluable, as clinical experience has abundantly shown.

In virtue, however, of certain peculiar properties one is more useful than another in different nervous diseases, due partly to their somewhat different actions, the part of the nervous system affected and the cause of the disturbance. Thus quinine appears to exert an influence on that part of the nervous system for which the malarial poison has a special affinity, and in virtue of this is more curative than the other remedies, just as arsenic has a special tonic influence on the motor nerves, in virtue of which it is more powerful in St. Vitus's dance. Thus arsenic does not act in chorea, or St. Vitus's dance, as a tonic to nutrition is shown by the fact that other tonics to nutrition do not cure the disease; and caffein acts on the pulmonary nerves, which renders it more useful in asthma. Hence we believe quinine to act in malarial diseases as a stimulant or sedative to the nervous system, especially to that part most implicated in these diseases; and that it is principally in virtue of this action that it proves curative by rendering the malarial poison inoperative by an antagonistic action on the nervous system, and that it proves beneficial in proportion as the nervous disturbance is predominant and to the absence of complications. Although we arrive at this conclusion by argument and not direct experience, the evidence in its favour appears to us so strong as to give it the place of a more than probable theory and to be a much more reasonable explanation of its action than any other as yet brought forward; and that by this method of reasoning it is possible to arrive at correct conclusions in absence of direct experiment the literature of therapeutics amply shows.

Messrs. Stephenson, Mackay and Baildon made a few remarks on some of the points touched on by Dr. Moinet, and on the motion of Mr. Stephenson, seconded by Mr. Baildon, a hearty vote of thanks was awarded to the doctor for his interesting communication.

The attention of the meeting was then called to a very interesting collection of specimens presented to the museum by Mr. Robert Jamie, of Singapore. The presentation was made through Mr. H. C. Baildon, who gave a short account of each specimen on the table. Mr. Stephenson proposed a special vote of thanks to Mr. Jamie for the valuable addition to the museum, which was very cordially responded to. The specimens are, Borneo camphor as obtained from the tree; Borneo camphor prepared for the market; a very fine specimen of the edible bird's-nest; resin obtained from the mangosteen tree; salep; fruit and seed of *Uvaria rosea*; bark, root, fruit, and oil of sangsarit; fingered orange; camel bezoar stone; tiger's fat; fine specimen of Japanese oil of peppermint; fruit of *Trapa bicornis*.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The fifth meeting of the session of this society was held in the Manager's Library of Anderson's College, 204, George Street, on the 13th inst., at 9 p.m. Mr. Daniel Frazer, President, in the chair. The Secretary being absent through indisposition, Mr. J. M. Fairlie, Vice-President, acted *pro tem.*, and read the minutes of the last meeting, which, being approved, Mr. W. L. Howie, F.C.S. (Edinburgh), was called upon by the Chairman to deliver his lecture on the telephone. Mr. Howie entered into a history of the origin and progress of telephonic discoveries, described the principle adopted by Professor Graham Bell in his invention, with much clearness, and afterwards referred to the more recent discovery, the phonograph; and concluded a most interesting lecture with practical illustrations both of the speaking and singing telephone. The lecture was listened to with great attention, and evidently much appreciated, while the experiments were most interesting and sometimes highly amusing.

After a few remarks by Messrs. Frazer, Fairlie, Kinninmont, Paul and others, the meeting was brought to a close by a hearty vote of thanks being awarded Mr. Howie.

LEEDS CHEMISTS' ASSOCIATION.

The fifth general meeting of this Association for the present session was held on Wednesday evening, February 13th.

The chair was occupied by the President, Mr. Jefferson, and after the minutes of the previous meeting had been read and confirmed, a lecture on "The History of a Loaf of Bread" was delivered by Mr. E. O. Brown.

The lecturer having explained that his lecture was originally intended for a mixed audience, and, therefore, partook more of a popular than of a scientific character, proceeded to trace the early history of bread, stating that the first mention of it is in the third chapter of the Book of Genesis, and it was then most likely made from maize. Bread was generally understood to be baked dough, and as such he should treat it; but it was formerly simply boiled. Many kinds of corn were used in its preparation, indeed, down to the last century, hardly any wheat was used in the North of England, but, no doubt, wheat was the grain from which bread might now be considered to be prepared. The largest quantity was grown in America, and heavy soils suited it the best. Having stated that the wheat plant belonged to the order Graminaceæ, and was monocotyledonous, the lecturer described its mode of growth, and the composition, organic and mineral, of a grain of wheat; and then proceeded to treat of wheat ash, which, although only 1·7 per cent., yet contained many chemical substances, aluminum being occasionally one of them; hence one liability to err in testing bread for adulteration with alum. The amount of carbon contained in the wheat plant was over one-third of its total weight, so that if the gross product of an acre of ground were 4800 lbs., that would be equivalent to 1734 lbs. of carbon per acre taken from the ground or some other source for each crop. Different theories as to whence this large quantity of carbon was obtained had been advanced, but when the fact was considered that the atmosphere contained over ten times as much as that required, there could be no doubt of its affording the chief supply. The process of cultivating the wheat plant, and of grinding the grain into flour, were then described, and the custom of rejecting the bran, which contained the most nutritious elements, censured. The average composition of bread was stated to be 44 per cent. of moisture, about 2 per cent. of ash, and the remainder combustible matter. The amount of gas given off by the dry distillation of bread crumbs, and its effect in rendering lime water turbid, were shown by actual experiment; and the fermentation, aeration, and the process of baking bread described.

A cordial vote of thanks was awarded the lecturer on the motion of Mr. Highmore, seconded by Mr. Hellowell.

ABERDEEN SOCIETY OF CHEMISTS AND DRUGGISTS.

The second annual conversazione of this Society was held in the Music Hall Buildings, on the evening of Tuesday, 12th of February. The attendance was close on 300, the "Square Room," where the conversazione was held, being quite packed.

Mr. M. Sinclair, senior, wholesale druggist, occupied the chair, and opened the proceedings at 8.30 p.m., with a short and humorous speech. He contrasted the present state of trade in Aberdeen with what it was fifty years ago, mentioning that at that time the ordinary shop hours were from 7 a.m. to 10 p.m., on six days of the week, and not much less on the seventh. The first work in the morning was to light the fire, sweep the shop, clean the oil glasses (there being no gas in those days), and take water from the public well. At that time the Broadgate was the principal place of business, there being five drug shops betwixt the top of Queen Street and the bottom of the Gallowgate, the distance not being over 200 yards. The Chairman then proceeded to make some humorous allusions to the different kinds and price of castor oil then in use; and went on to speak of the vast progress that had in recent years been made in the science of chemistry. He concluded by giving the young pharmacists present an advice to devote their attention to chemistry, in which there was yet a large field open for them to work.

An interesting musical programme was then gone through, the solos and duets being given by the members of the trade and their friends. A hearty vote of thanks was on the motion of Mr. J. Mackenzie, Edinburgh, awarded to the ladies and gentlemen who had contributed to the evening's entertainment. A vote of thanks to the chairman finished the conversazione; after which the company adjourned to the ball room, where they engaged in dancing for the rest of the evening. Supper was served during the evening. There was a telephone set up betwixt the round and west front rooms; but owing to the noise, it could not be taken advantage of.

The third of the course of lectures under the auspices of the above Society was delivered in the Room, St. Nicholas Lane, on Thursday, February 14, at 9 p.m.

Mr. David Ritchie, V.P. of the Society (in the unavoidable absence of the President), occupied the chair, and in a few remarks introduced the lecturer, Mr. George Edward, who, amidst great applause and insuppressible laughter, delivered a lecture on "Daftness." The lecture assumed the character of sketches of various characters who had come under the lecturer's personal observation. All of them seemed to have enjoyed distinguished notoriety in the circle of his acquaintance, and every character sketched manifestly had a *big want*, yet every one of them seemed to leave a record behind worthy of consideration. Such a night's genuine mirth and laughter is rarely to be met with even at the shrine of caterers for public amusement.

Votes of thanks to the lecturer and chairman brought the evening's proceedings to a close.

MEETING OF CHEMISTS AND DRUGGISTS AT ABERDEEN.

A district meeting of the Chemists and Druggists' Association was held in Aberdeen, on the 12th February, at which was present a deputation from the Scotch committee, consisting of Messrs. Mackenzie, Edinburgh (V.P. of the Scotch committee), Kerr and Russel (Dundee), as well as a fair proportion of the town and country members belonging to the Aberdeen division.

Mr. James Paterson, of Messrs. W. Paterson and Sons, presided, and introduced Mr. Mackenzie, who (in the unavoidable absence of the Hon. Sec., Mr. J. M. Fairlie) described the origin and progress of the Association.

Mr. Burnett, Fraserburgh, then moved:—"That this meeting of pharmaceutical chemists, and chemists and druggists, representing the trade in the North of Scotland, rejoices in the formation of the Trade Association, heartily approves of its objects, and commends it to the liberal support of the trade generally," which was seconded by Mr. John Gordon (of Messrs. J. and J. Urquhart), Aberdeen; and supported by Mr. Russel, Dundee.

Mr. D. Ritchie (V.P. of the Aberdeen Society of Chemists and Druggists), then moved:—"That this meeting approves generally of the past action of the Executive, for the spirited manner in which they have defended the unjust attacks of the Medical Defence

Association, and those uncalled for proceedings under the Adulteration Act," which was seconded by Mr. J. Sutherland (Aberdeen); and supported by Mr. Charles Kerr (Dundee).

Mr. G. P. Cruickshank (President of the Aberdeen Society of Chemists and Druggists), then moved :—That while deprecating to the fullest extent indiscriminate prescribing of druggists, this meeting maintains that it is the privilege and duty of the pharmacist to give advice over his counter for simple ailments, and in cases of extreme emergency," which was seconded by Mr. W. O. Ogilvie (Arboath). All of which were passed, *nem. con.*

A hearty vote of thanks to the deputation and the chairman brought the proceedings to a close, which lasted upwards of an hour and a half.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

At the fourth pharmaceutical meeting of the present session, held on January 15th, Professor Maisch called the attention of the meeting to the black root of Georgia (*Pterocaulon pycnostachyum*, Ell.), James' tea (*Ledum latifolium*, Lin.), the rheumatism root of Virginia (*Dioscorea villosa*, Lin.), the black haw of Florida (*Viburnum obovatum*, Walt.), specimens of which plants and drugs were exhibited to illustrate two papers read by him, entitled "Notes on a Few American Drugs" and "The Useful Species of Viburnum."

Mr. E. M. Boring exhibited a plant used by an empiric in the cure of cancer; it was recognized by Professor Maisch as *Ceanothus Americanus*, Lin., and is called American tea, New Jersey tea, or red root, because that is the colour of the root. It was made use of largely during the American Revolution in place of the true tea. Some time during the years 1863 or 1864 an enterprising individual, who had become familiar with the manner of preparing and drying tea in China, commenced the trade of packing the leaves of this plant in a similar manner, at the same time circulating through the newspapers that the *tea* plant grew largely in certain sections of the United States; for a time the trader prospered, but the article soon fell into disuse.

Chloral Hydrate.

The subject of the *impurities in chloral hydrate* was discussed.

Mr. Boring said that his attention had been directed to the subject by a paper of Professor Liebreich, which stated that only such chloral should be used as was in crystals and perfectly dry. He said that all the crystal chloral in the United States market adhered to the side of the bottle. One sample gave no evidence of uncombined chlorine, while in another the evidence was decided; both samples reddened moistened litmus paper suspended in the bottles. He had no trouble with it practically, and had had no complaints, but wanted to be sure that he was dispensing an article that came up to the standard of the authorities on the subject. If they give a false standard, from improper motives, they should be exposed.

Prof. Maisch remarked that of late years he had not had much practical experience with chloral; but from earlier experiments he was convinced that the shape of the crystals was no criterion of its purity, that pure chloral hydrate had a slight acid reaction, and that the density of the white vapours produced with a glass rod moistened with ammonia was largely influenced by the temperature. The practice of giving a little information about physical properties for the purpose of influencing trade was carried on in Europe as well as in the United States; he did not believe that absolutely pure chloral hydrate had as yet been put into the market, and he was strengthened in this belief by the transactions of the Berlin Apothecaries' Society, where this question was incidently ventilated. Of late chloral chloroform, that is, chloroform made by the decomposition of chloral, had been bruited in Germany as the only article worthy of confidence for its purity, but the researches instituted by Schacht and Bilz upon this claimed superiority of chloral chloroform had shown it to be entirely erroneous, as the chloral chloroform when treated with sulphuric acid became discoloured very speedily, like the chloral from which it had been prepared, which was not the case with absolutely pure chloral, or with the chloroformum purificatum of the Pharmacopœia.

Dr. A. W. Miller exhibited some authentic herbarium specimens of plants gathered by Dr. J. F. Rothrock, Professor of Botany in the University of Pennsylvania, during an extended tour through the Western portion of our country. True damiana, that from which the original description of *Turnera aphrodiciaca* was taken, and two specimens of Aplopappus, yielding also so-called damiana, were shown. Three specimens of Eriodictyon were shown, all of them indiscriminately called Yerba santa.

Prof. Maisch stated that the specimens heretofore described as *E. Californicum* had the leaves somewhat different from those shown and a characteristic appearance of being varnished upon the upper surface.

Prof. Maisch stated that he had been examining different samples sold as *Grindelia robusta*, and concluded that probably three species are sold as such, and that much of it is *G. squarrosa;* he hoped that he would soon be able to report more fully upon the matter.

Prof. Maisch presented specimens of *Florida oranges*, having upon their rind what is called "rust," of a greenish brown appearance, and occasioned, as it seems, by a fungoid growth; it is reported that the same tree, in different years, will produce fruit sometimes thus affected and at others free from this defect. It was stated that already in the extreme Southern States the juice of the sour orange has been utilized as a source of citric acid, and oil of petit grain, superior to almost any ever offered in the American market, has been brought into commerce from this source. There would seem to be no good reason why the volatile oils of lemon, orange and neroli, and orange-flower water of excellent quality should not be produced there also.

The preparation of bay rum was discussed. The following formula was said to produce an excellent article: Four pints of alcohol, three pints of water, one pint of Jamaica rum, one drachm of oil of bay and twenty drops of oil of pimento; a few drops of aqua ammoniæ gives the requisite colour to a whole gallon.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held on Thursday, February 14, when a paper was read by Mr. Mason on "Cyanogen." After reference to the origin of the name cyanogen, and the researches of Gay Lussac upon prussic acid, the hypotheses of its constitution were considered, the conditions under which it is formed, and the manufacture of chemical compounds containing cyanogen, such as cyanide and ferrocyanide of potassium. The decomposition to which the acid of the Pharmacopœia is subject, and the preservative agents used, were next noticed. The estimation of hydrocyanic acid was then discussed, the process of the Pharmacopœia, if strictly followed, was shown to be incorrect by the experiments of Mr. Siebold, made in 1874. The gravimetric method was next given, followed by the most delicate and characteristic tests for cyanogen as cyanide, and the use of hydrocyanic acid in testing for picric acid in beer. The toxicology of the subject was fully treated, the methods of detecting hydrocyanic acid in organic mixtures; the length of time after which it could be detected, were discussed, and the author concluded by showing the value of ferrocyanide and ferridcyanide of potassium as a test for several metallic bases.

The paper was followed by an animated discussion, and a "Note on a Test for Bismuth," which will be printed in a future number, was then read by Mr. Savory. After the discussion on this paper the meeting was adjourned till February 28.

Parliamentary and Law Proceedings.

Poisoning by Morphia.

On Monday, Mr. Humphreys held an inquest at Hackney, on the body of Lionel Thomson, aged 27 years, a chemist, whose body was discovered by some workmen in a house in the course of erection in Graham Road, Dalston. The deceased had entered the buildings at night and made himself a resting place on a sack of lime and had a bundle of laths for his pillow. On being searched, several letters were found in his pockets in reply to applications made for employment, and also two bottles containing chloroform and morphia. The body was was removed to the mortuary. It was stated that the deceased had been in the habit of taking opium for some time past. The jury returned a verdict to the effect that the deceased died from an overdose of morphia, but whether taken accidentally or for the purpose of destroying life there was no evidence to prove.

Poisoning by Chloral.

On Tuesday, Dr. Hardwicke held an inquiry at the Argyll Hotel, King's Cross, as to the death of Mary Tyler, 58, wife of Mr. William Tyler, of Argyll Square. Mrs. Tyler had suffered for many years from spinal complaint and paralysis. She took chloral night and day. Mr. Tyler administered it, and there were always two bottles by the bedside, one containing syrup of chloral and the other a solution of one part of the syrup and five parts of water. Both bottles were identical in size and shape, and neither had a label. He gave his wife a dose of the solution on Friday evening, and at midnight she awoke in pain and asked for a strong dose. He gave her the dose, but, the lamp being out, he believed he gave a dose out of the wrong bottle. In the morning he found that his wife was dead. Dr. Dingley said that the cause of death was a fainting of the heart, caused by an overdose of syrup of chloral. An ordinary dose of chloral was from 10 to 20 grains, but Mrs. Tyler had probably taken 80 grains. Mr Tyler was censured for administering chloral year after year without medical sanction, for having two bottles alike in size and without labels, and for carelessness in giving the chloral. A verdict of "Death from misadventure" was returned.—*Times*.

Poisoning by a Narcotic.

An inquest has been held at Harbertonford, near Totnes, by Mr. Henry Michelmore, county coroner, respecting the death of Ann Eden, the wife of a dairyman. It was stated that the woman had been slightly unwell for about a week, and on Thursday she was seen by Mr. Hains, surgeon, of Totnes, who found her suffering from a cold and bilious attack. She complained of not being able to sleep. He prescribed for her, and told her that when she had taken the medicine she would probably get sleep. On Sunday she felt better, and asked the nurse who was attending her to try and get her a smelling bottle, or something to cause her to sleep. Deceased's son was sent to Mr. Prestcott, the manager of the quarry where Eden works, to borrow a smelling bottle. Mr. Prestcott, however, had none, and sent her a draught. The deceased took it, and soon afterwards fell asleep. After some hours, as it was impossible to rouse her, Mr. Hains was sent for, and attended immediately. He informed the jury that he found her in a comatose state. He administered the usual remedies, but they were of no avail. He closely questioned the nurse, who ultimately admitted that deceased had taken a sleeping draught. From the colour of the fluid left in the bottle, and the smell, he concluded that it was a preparation of opium. He had since made a *post mortem* examination of the body. The lungs were congested, the left ventricle contained fluid blood with white clots, the right ventricle contained fluid blood and no clots. The heart was healthy. The liver contained a great quantity of bile pigment, but was otherwise healthy. The membranes of the brain were greatly congested, but the structure of the brain itself was healthy. The contents of the stomach smelt of laudanum.

In reply to the Coroner, witness said in the case of death by narcotic poisoning the vessels of the brain would be found congested.

The Coroner: Would the patient have lived had she not taken the sleeping draught?

Witness: Yes, certainly.

In reply to further questions, witness said the cause of death was directly due to the draught, which was either a preparation of laudanum or Battley's solution.

The Coroner and jury then adjourned to the residence of Mr. Prestcott to take his evidence, as he was suffering from a dislocated shoulder, and was unable to leave his bed.

Mr. Prestcott said the draught he sent was about half the quantity which he had been in the habit of taking himself to procure sleep, and which had been given to him by his medical man. He was ignorant of what it contained.

The Coroner, in summiug up, said he thought the evidence before them would enable the jury to arrive at the conclusion that death was due to misadventure.

The jury returned a verdict of homicide through misadventure.

The Coroner, addressing Mr. Prestcott, said he hoped it would be a warning to him for the future.

Mr. Prestcott replied that it certainly would be.—*Western Weekly News*.

Dispensing Memoranda.

[54]. Creasote Pills.—If "Pil. Creasoti"* would read carefully he would find that I had† "made creasote pills both with light magnesia and with slaked lime, but in either case the creasote is almost entirely combined, and pills made with either excipient are as insoluble as marbles; I have boiled them for some time with water without altering their shape." These are facts, and I have since repeated them in regard to magnesia, but they have reference to pills made of creasote and light magnesia or slaked lime only, *i.e.*, without any compound rhubarb pill in combination. Not that the addition of this would make much difference, as each particle of the powder which Mr. Wilkinson‡ recommends (made by mixing two minims of creasote with one grain of light magnesia) would be almost as inert as a pill made of the same, notwithstanding its being mixed with compound rhubarb pill.

Professor Redwood§ lays down three fundamental rules in the choice of excipients for pills. They must "not be incompatible with any of the ingredients of the pills;" must "modify as little as possible their action either by causing them to become hard or in any other way;" and must "not unnecessarily or inconveniently increase their size."

The use of light magnesia with creasote is inconsistent with the first and second of these; it is incompatible

* *Pharm. Journ.*, Feb. 16, 1878, p. 662.
† *Pharm. Journ.*, Feb. 2, 1878, p. 619.
‡ *Pharm. Journ.*, Jan 19, 1878, p. 579.
§ 'Practical Pharmacy,' p. 350.

with creasote as it makes an inert compound with it and the pills become hard and insoluble.

Hyperbolically, as well might a pharmacist, when a physician orders diluted sulphuric acid for diarrhœa, add light magnesia to neutralize it, because the patient complained that the acid acted on his teeth. There is quite as great a difference between the action of creasote and creasote and its combination with magnesia as there is between diluted sulphuric acid and Epsom salt, and if "Pil. Creasoti" will try a pill made of creasote and light magnesia—say equal parts of each, which make a good pill—I think he will find that nature's vitalized chemical process of digestion has no action upon it. "Pil. Creasoti" has, in fact, emasculated himself; he may be a pill, but not of creasote.

I wrote hurriedly when I sent my last memorandum. Tabulated, this will represent my formula for creasote pills more accurately:—

℞ Creasote . . . . fl. ʒij.
Powdered Animal Soap . . grs. 120.

Put the creasote in a one-ounce wide-mouthed stoppered bottle, add the soap, and mix well. Then digest in a water-bath till they combine. Each two grains of the mass will contain, as nearly as possible, one minim of creasote.

It is not a new subject to me. I have tried many experiments, at different times, how best to administer creasote. At last finding that powdered soap was soluble in creasote when the two are heated together, I conceived the idea that in suitable proportions they would make a good pill. I used the powdered animal soap, as it contains the least free alkali, and this alkali in the drying and powdering will no longer be in the caustic state. Caustic alkalies decompose creasote. To enable the soap to be powdered also it must previously have been freed from most of its water, and, lastly, being principally a stearin soap, it gives more solidity to the pill mass than an olive oil soap would.

WM. MARTINDALE.

---

[59]. "PANDRODYNE" (?).—Mr. J. W. Barnes, under "Dispensing Memoranda," wishes to be furnished with the composition of "*Pandrodyne*" (?). I am sorry I cannot help him in regard to its real nature, because it strikes me the prescription is one of that class designed to puzzle, or which can only be guessed at, or compounded, according to the writer's views, at some one particular house with which there is an understanding—alike undignified and manifestly unfair—not only on the part of the physician but the apothecary or chemist who enters into such an arrangement. I know there are many such—not only in London, but elsewhere. Honest pharmaceutical chemists have no chance of pursuing their trade under such ignoble circumstances without a few heartburnings, and I am sorry the greatest offenders are to be found among the ranks of my own profession. It is akin to disgrace, to say nothing of the unfairness towards an honourable body, for a physician or surgeon to request his patients to go to any particular house. There could be no harm in recommending two or three respectable men; but it is different when the prescription is handed to the patient, with an express order, that Mr. So and So alone understands how to "fill it up." That this is done, day after day, cannot be gainsaid. The quantity of the "pandrodyne" is very small, as the mixture ordered is five ounces, and one drachm for a dose gives three drops at each taking. I have thought over many things in order to find out what "pandrodyne" possibly could mean, and I am inclined to think it is either chlorodyne, or that remedy so much extolled in Australia and some parts of America, called "painkiller."

The derivation of the word also is evidently from the Greek, *pas*, *pasa*, *pan*, and *odune*, which would give it the appellation of a reliever or curer of "all pain"; or its origin may be traced to *pandoura*, a musical instrument of three strings, just as we get the name carminative from *carmen*, a song or charm. But it matters not from what fanciful source it is derived, the physician ordering such medicaments as can only be known to some one in coalition with him should be discouraged in every possible form and manner, for he is no better than any dishonest quack.

Northallerton. HY. BROWN, L.R.C.P., etc.

P.S.—Will you permit me to suggest to many of your correspondents and inquirers that far more attention would be paid to their communications if they gave their names and addresses. If a communication is worth reading, we should know the writer at least by name.

H. B.

---

[61]. UNG. HYDRARG. NIT., B. P.—In answer to "Inquirer" let me say it is not necessary to heat the mecuric solution until all the fumes are given off, because there is no use in applying heat immediately the action of solution commences.

There is nothing to be gained by too hasty solution, and the mercury and acid should at first be placed in a warm place, say at the side of a fire, so as to allow the fumes to escape up the chimney, and when all the mercury is dissolved the temperature of the solution, if necessary, must be raised to 180° or 190° F.

The object of having nitric acid in excess, is to prevent the formation of suboxide of mercury, which is subsequently converted into metallic mercury. The whole subject is well worth close study; and I would recommend "Inquirer" to carefully peruse the article in Christison's 'Dispensatory,' as giving by far the best account with which I am acquainted, Pereira not excepted. As it may not be close to the hand of "Inquirer," I may state that the probable composition of citrine ointment is that of a mixture of nitrate of binoxide of mercury with oleic and stearic acids, and the fatty acid called elaidic. Nitric acid attacks oleic acid with great violence, and a whole series of volatile acids are formed, and any work on chemistry will supply "Inquirer" with all desirable information on this point. It is the nitrous acid which converts oleic into oleidic acid, which is an allotropic form of oleic acid. The Dublin formula was prepared without the aid of heat in dissolving the mercury, and is supposed to have also contained some nitrate of the protoxide of mercury.

I have prepared the ointment upon many occasions, and found the best temperature for combining the mercuric solution with the oily matters to be 180° or 185° F. I had seldom any difficulty; but from first to last the undivided attention of the pharmacist should be devoted to the subject in hand, and the ointment should be stirred with a bone, or ivory, or glass stirring rod until almost cold, and only one way. It should be of the consistence of freshly made butter.

Northallerton. HENRY BROWN.

---

[63]. Can you give me an idea as to the mixing of the following prescription, in order that when dispensed it shall not present a turbid appearance?

℞. Tinct. Ferri Perchlor. . . . . . ʒj.
Liq. Arsenicalis . . . . ʒiss.
Acid. Hydrochlor. Dil. . . . . . ʒss.
Sp. Chloroform. . . . . ʒj.
Syr. Ferri Phosph. . . . . . . ʒj.

The party who brought it said that it was dispensed before, and that it was sent out quite clear without sediment.

I found the above mixture turned black as ink in dispensing.

APOTHECARY.

---

[64]. BLUE PILL.—Where "Blue Pill" is prescribed with soft extracts, should I be justified in using

hydrarg. c. cretâ instead of pilula hydrarg., seeing that they are chemically alike, and identical in strength?

Leicester.

ALFRED CHAPMAN.

---

[64]. The symbol (℥) controversy has been settled and uniformity I hope will be the result.

May I suggest the discussion and settlement of another dispensing matter? I allude to the value of the term gutta.

The following prescription, received a few days ago, will place the question before your readers—

℞. Aq. Laurocerasi . . . . ʒij
Vini Ipecac. . . . . ʒj
Chlorodyne . . . . ʒij
Acid. Hydrocyanic. Dil. . . . . gtt. xx
Aq. ad. . . . . ℥viij
Ft. Mist. Capt. cochl. ampl. j urgente tussi.

In the above are drops or minims of the prussic acid to be dispensed?

Certain published statements say that 20 drops of this acid are equal to about 27 minims.

It would also be desirable to know what chlorodyne is to be used. The author of 'The Companion to the B.P.' gives a formula—Liq. chloroformi comp. (page 93, ninth edition), which has been represented to him as the composition of the popular medicine called chlorodyne. Might this be used?

UNIFORMITY.

---

[65]. Is there any valid objection to the use of Tartaric Acid in the manufacture of Quinine Pills and of Carbonate of Potash in the manufacture of Aloetic Physic Balls for Horses?

S.

---

[66]. A mixture dispensed from the following prescription was brought from the patient's house, by the medical man who wrote it, stating that the separation which had taken place was not necessary to the combination, but due to some error in its preparation. Will you be good enough to place it in the dispensing memoranda?

℞ Quinæ Sulph. . . . . gr. iv.
Ac. Nit. Mur. dil. . . . . . . ʒij.
Tr. Nuc. Vom. . . . . ʒij.
Sp. Æth. Chlor. . . . . ʒj.
Syr. Limon. . . . . ʒiv.
Aquæ . . . . ad ℥viij.
M. ℥j. ter die.

E. A. T.

---

[67]. I should like to hear the opinions of some of your readers as to the best mode of procedure to adopt in dispensing the following prescription which I had handed to me a few days ago, and what should be the appearance of the product:—

℞ Tr. Quiniæ Ammon. . . . . . ℥j.
Potass. Iodid. . . . . gr. xvi.
Syrup. Aurant. . . . . ʒij.
Aq. Piment. . . . . ℥iv.
Aquæ . . . . ad ℥viij.
M. Sumat coch. ij mag. ter die.

MISCH MASCH.

---

[68]. Could any reader inform me what is the best method of making the following:—

℞ Ferri Iodid. . . . . gr. iij.
Excip. q.s.
M. ft. Pil. j. Mitte xij.

A. H.

---

[69]. Would any reader of the Journal oblige by information as to the mode of dispensing the following prescription?—

Pot. Iodid. . . . . gr. 80.
Mucilage . . . . ℥ss.
Sp. Æther. Nit. . . . . ℥ss.
Aq. . . . . ad ℥ij.

A JUNIOR DISPENSER.

---

[70]. Having recently to dispense the following prescription and noticing, after it had been allowed to stand a few minutes, a peculiar separation, I would ask the cause, and if it could be dispensed so that no separation would take place.

℞ Pot. Bromid. . . . . ʒiij.
Tinct. Quiniæ . . . . ℥iss.
Tinct. Hyoscy. . . . . ʒiij.
Tinct. Lupuli . . . . ℥ss.
Aq. . . . . ad ℥vj.
M. ft. Mist.

Cambridge.

G. S.

---

[71]. What is the proper mode of preparing the following ointment:—

Hyd. Ammon. Chlor. . . . . gr. xxv.
Ung. Cetacei . . . . ʒvij.
Glycerinum . . . . ʒj.
Ft. Ung.

I have been told that the slab should be heated; but I should mix them in a cold mortar; first well pulverize the Hyd. Ammon. Chlor. and gradually add the ointment, and I do not see that that method should not yield a very good ointment.

IGNORAMUS.

Notes and Queries.

[576]. BRAHEE SUGAR POWDERS.—Will any reader kindly give me the formula of the article sold under the name of Brahee Sugar Powders?

STUDENT.

---

[577]. A WATER QUERY.—A customer of mine thinking of changing a leaden pump for fear of its contaminating the water, has been recommended to replace it by a cast iron one with a copper sheath, he wishes to know, however, before doing so, whether the constant exposure, first to water and then to the atmosphere would not render it equally as unfit for drinking. If you or any of your readers have any experience of this kind, I would be glad of information.

---

[578]. WRITING INK.—I shall feel very much obliged if some disinterested friend will give me a form for "Blue Black," or "Green Black Ink."

MAJOR.

Obituary.

Notice has been received of the deaths of the following:—

Mr. Stephen Carr Sagar, Chemist and Druggist, Swinton, in Lancashire, died April 6, 1877, and was born in Craven, Yorkshire.

In the early part of this century Mr. Sagar served his apprenticeship in Preston, and about 1835 opened a business in Heywood, from which he retired in 1852 with a competency—choosing for his place of residence the Isle of Man.

Certain failures in his investments made it judicious for him to recommence business at Swinton, where he successfully opened and conducted a respectable business up to the time of his death. He was a good naturalist with great pharmaceutical knowledge, and was remarkable for his conscientious accuracy and careful research into everything occupying his attention. He died respected by all, and his loss is much felt in the neighbourhood.

On the 9th of January, 1878, Mr. John Fergusson, Pharmaceutical Chemist, Strand Street, Liverpool. Aged 63 years. Mr. Fergusson had been a Member of the Pharmaceutical Society since 1842.

On the 20th of January, 1878, Mr. Richard Lewis Jones, Chemist and Druggist, Newport, Mon. Aged 38 years.

On the 21st of January, 1878, Mr. William Mitchell, Chemist and Druggist, Newcastle Street, Strand. Aged 60 years.

On the 22nd of January, 1878, Mr. Joseph Nixon Chemist and Druggist, Bowdon, Cheshire. Aged 31 years. Mr. Nixon had been an Associate of the Society since 1869.

On the 23rd of January, 1878, Mr. Joseph Procter, Pharmaceutical Chemist, Taunton. Aged 54 years. Mr. Proctor had been a Member of the Pharmaceutical Society since 1853.

On the 2nd of February, 1878, Mr. John Wellspring, Chemist and Druggist, Chandos Street, Strand. Aged 74 years. Mr. Wellspring had been a Member of the Pharmaceutical Society since 1869.

On the 1st of February, 1878, Mr. James Ainsworth Marshall, Pharmaceutical Chemist, Waltham Abbey. Aged 66 years. Mr. Marshall had been a Member of the Pharmaceutical Society since 1842.

On the 5th of February, 1878, Mr. Samuel Cormell Price, Chemist and Druggist, West Bromwich. Aged 74 years.

On the 9th of February, 1878, Mr. John Robert Dalton, Chemist and Druggist, Stamford, Lincolnshire. Aged 38 years.

On the 9th of February, 1878, Mr. John Embley, Chemist and Druggist, Brierfield, Lancashire. Aged 33 years. Mr. Embley had been an Associate of the Pharmaceutical Society since 1873.

On the 10th of February, 1878, Mr. George Haldane, Chemist and Druggist, Wakefield. Aged 52 years.

On the 14th of February, 1878, Mr. James Sim, Pharmaceutical Chemist, King Street, Aberdeen. Aged 75 years. The deceased gentleman was a member of the Town Council and a Magistrate of the city upwards of twenty years ago, he was also a Justice of the Peace. Mr. Sim commenced business early in life as a druggist, and by his own personal exertions succeeded in establishing an extensive wholesale connection throughout the North of Scotland, where he gained the personal regard of a large range of acquaintances, who valued him alike for his integrity of character and geniality of disposition. Mr. Sim became a Member of the Pharmaceutical Society in 1853.

On the 15th of February, 1878, Mr. William Henry Ryde, Chemist and Druggist, Penge. Aged 37 years.

On the 17th of February, 1878, Mr. Robert Spear, Pharmaceutical Chemist, Cheetham, Manchester. Aged 32 years. Mr. Spear had been a Member of the Pharmaceutical Society since 1870.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Preliminary Examination.

Sir,—At the last meeting of the Council, in the conversation respecting the recent Preliminary examination, one or two speakers expressed opinions that the elder boys in most national schools would be able to pass that examination, at least the English and arithmetic of it.

Acting upon that idea, I have placed the questions before the first class in one of the national schools here, and in half an hour about 75 per cent. of them were able to answer sufficient of the arithmetic to have passed, and in three quarters of an hour, more than enough of the English. The master assured me that had the boys had a full hour to each subject, several of the remaining 25 per cent. could also have passed.

J. Stainer.

Folkestone, February 20, 1878.

The Dental Practitioners' Bill.

Sir,—My object in writing to you just now is to take the opportunity of saying how heartily I indorse the remarks of your correspondents in last week's Journal, relative to the Dental Practitioners' Bill now before Parliament.

It would be manifestly a "flagrant injustice" to those registered chemists and druggists who have been practising surgical dentistry for a good many years, and in whom the public have the greatest confidence, to have this privilege taken from them at a moment's notice. I certainly think the Parliamentary Committee of the Society would be doing good service if it were to make an effort to secure the exemption from any penalty under the proposed Bill, of the many chemists and druggists throughout the country who now "extract teeth." Trusting that by united and vigorous action our undoubted rights may be preserved.

W. T. Martin.

Cliffe, Lewes.

Sir,—Allow me to thank you for the interest you have taken in calling the attention of that portion of the trade who are practising dentistry, to Sir John Lubbock's Bill; had it not been for you it might have passed unnoticed.

I fully agree with Mr. Long of Croydon, that if the Members of the Parliamentary Business Committee were to take the matter up, they would confer a great boon upon a large portion of the trade. I think if they will consider the matter carefully, they will come to the conclusion that it is a great injustice.

I am acquainted with a barber, an ex-publican, also iron-workers, who are practising as dentists, and doubtless these men will be deemed eligible for registration.

I have written to several members of Parliament calling their attention to the Bill.

Perhaps some of the previous correspondents can suggest a plan of action; we must remember the old *unitate fortis.* Is it possible to have a meeting, and so discuss the best mode of action; something must be done, or the Odontological Society will have their desire granted?

W. Baker.

Stourbridge.

Sir,—I find from Kelly's Directory that there are 201 chemists in the country who are dental practitioners, beside 40 in London. Most, if not all, I have no doubt are skilful in both departments of dentistry, and in the administration of nitrous oxide gas, and it appears to me to be very unjust that simply because we know something of medicine and pharmacy, we should be refused registration. In September, 1874, I applied to the Royal College of Surgeons for admission to examination for the Dental Diploma, and was refused by the Board of Examiners in Dental Surgery for no other reason than that I was the proprietor of a chemist's business. Could not we "chemists and dentists" combine and act at once for our defence? I shall be glad to correspond and to receive communications from others respecting this.

B. W. WESTLAKE.

58, *Peascod Street, Windsor,*
February 19, 1878.

PATENT MEDICINES.

Sir,—As a contribution to the above subject, opened by Mr. Martindale in last week's Journal, I would suggest that the Medical Department of the Privy Council should have the power accorded to it by Parliament of compelling the owners of proprietary medicines which are recommended for the relief or cure of any bodily ailment to deposit with the said department a statement in writing of the exact composition of all such medicines, that a record be kept of the same, and power given to the said department to prohibit the sale of any proprietary medicines should they contain anything which in its opinion might be injurious to health. (I believe there is in France some such regulation in force.)

It might be said if the Poison Regulation Act be complied with danger would be avoided. My answer is, are there not a number of poisons other than those the sale of which is regulated by legislative enactment? Again, it would be said the sanction of the Privy Council having been obtained for the sale of those preparations the use of such medicines would be encouraged; undoubtedly that would be so, but no great harm could result to the public health thereby, and the owners of those compounds would have no objection to paying a handsome registration fee.

J. B. BARNES.

Knightsbridge, February 18, 1878.

REDUCED PRICES FOR PROPRIETARY ARTICLES.

Sir,—This is is a subject very difficult to deal with, and perhaps more suitable for discussion by the Trade Defence Association than the Council of the Pharmaceutical Society; but neither the one nor the other will be able to assist us much while we persist in such suicidal practices. The practice is becoming widespread, and a great many chemists are compelled to yield in self-defence; but it is, as pointed out last week, a very ruinous one, and must lead to very disastrous consequences.

We may take it for granted that reducing the price of medicines, proprietary or otherwise, does not increase the general demand, so that it is to the injury of the trade collectively to lower the price. Instead of trying to compete with the stores (miscalled co-operative) chemists would do well to combine together to buy large quantities for cash, and, selling at the proper marked price, leave a wider margin for profit.

When my customers ask what is the price of so-and-so, or do you sell it at the store price, I reply, "No, certainly not," and add that I do not profess to compete with them, and that I expect a fair and legitimate profit on everything I sell. I do not offer bargains, or sell things at cost price, and have no intention to do so.

There are at the present time several cogent reasons against reducing the prices of our goods. The cost of living has advanced considerably during the last twelve or fourteen years, house rents are going up and assistants' board and salaries have also increased, and as the stores have cut into everybody's business so we find grocers and others interfering with our trade.

Mr. Holloway has recently been sending circulars to all sorts of trades offering his medicines, so that we have not much to expect from some makers of patents, and his example is sure to be followed by others.

I must confess that I have not any remedy to offer, and think we must rely on the support of proprietors and wholesale dealers in asking the marked price for their goods.

My suggestion is, that the Trade Defence Association take the matter in hand and send round circulars to proprietors and wholesale dealers asking them to use their best endeavours and active co-operation in supporting the retail trade, supplying their goods as marked, and marking every package distinctly with the retail price. Proprietary articles may be divided into three classes:—

1st. Medicines proper, whether stamped or otherwise, to be sold by chemists only.

To these might appropriately be added foreign mineral waters.

2nd. Soaps and toilet articles, appropriate to chemists and perfumers.

3rd. Extract of meat and prepared foods, etc., may legitimately be sold by grocers and Italian warehousemen, as well as chemists.

Our trade is registered now, and any wholesale dealer may, on reference to Kelly's Post Office Directory of Chemists and Druggists, confine his circulars to the trade only if he wishes to do so.

Let us each one do what we can individually to bring about a better understanding on the part of the public in this matter, and show them the unfairness of the stores' method of doing business: and let us give our orders to the wholesale dealers who confine their attentions to our own trade and seek to do business through us.

FRATER.

LOW PRICES.

Sir,—I most willingly concur in the opinions expressed by your correspondent, Mr. J. R. Summers, in his letter, under the above heading in last week's Journal. What is to be done to stop "this cutting wave?" I hardly know, while chemists and druggists do not dwell together in brotherly unity in their respective towns, to the extent one could desire. That the practice of selling goods at such reduced prices is as ruinous in many ways as it is foolish, does not require much argument to demonstrate. That members of our profession (?), who have passed their examinations, should set so bad an example in this respect, is indeed deplorable.

I can testify to the "disagreeable" nature of transactions with customers who have purchased their "patents," etc., elsewhere, at these low prices.

Surely the chemists and druggists throughout the country, who have got into this wretched state of slavery, will be amenable to an appeal from their brethren who have not yet come to this sort of thing.

Let this important subject be well ventilated, and let us as dignified, honourable, and educated men, set our faces against this practice.

W. T. MARTIN.

Cliffe, Lewes,

X. Y. Z.—According to an answer received from the Inland Revenue Office (vol. iii. p. 327), quinine wine, if made according to the British Pharmacopœia, does not require a licence for its sale. This seems to imply that the other articles would, unless they were sold as "patent medicines."

"*Another Tom.*"—The receipe referred to was in accordance with the requirements of the correspondent. Other recipes for Brilliantine have been given in this Journal.

J. Sumner.—Your question will be best answered by a careful consideration of the Regulations of the Board of Examiners.

"*Occidens.*"—(1) *Hypnum populeum*; (2) *H. prælongum*; (3) *H. confertum*; (4) *H. rutabulum.*

"*Inquirer.*"—A good depilatory is a strong solution of sulphuret of barium made into a paste with starch. It should only be left in contact with the skin two or three minutes and then scraped off. A watery paste of 1 part of powdered crystallized sulphydrate of sodium, and 3 parts of prepared chalk has also been recommended.

Mr. Bates appears to have misunderstood the drift of the President's remarks, and not to have read a paragraph ina subsequent part of the report respecting a case of copying between two candidates.

E. Kemp.—In the one case thorium is treated as a monatomic and in the other as a diatomic element.

SPECTRUM ANALYSIS.*

BY PROFESSOR REDWOOD.

On a previous occasion† I endeavoured to explain some of the phenomena relating to spectrum analysis. But the subject is a large one, and many interesting illustrations were then omitted which I purpose bringing under notice this evening.

By spectrum analysis we are enabled to obtain evidence of the presence of substances through the effects they produce on light. When light is dispersed by means of a prism we obtain the well known phenomenon of the spectrum, of which the rainbow is a brilliant example. We shall have to work again this evening with dispersed light, and to exhibit several different kinds of spectra.

The light we shall employ will be produced by means of a Grove's battery of forty cells, the disruptive electrical discharge of which from charcoal terminals supplies the best representative we have of the light of the sun. If we produce this light in our lantern, and allow a small beam of it, escaping at a circular hole in the lantern, to pass through a prism, the beam or bundle of rays, which was travelling in a straight line from its source, will be bent or turned into a new direction in passing through the prism, and if it be now received on to a screen it will present the kind of spectrum originally produced by Sir Isaac Newton. The light, which before it entered the prism would have formed a round white illuminated spot on a screen, is now drawn out into an oblong spot of coloured light in which we discern the seven colours of Newton's spectrum. These colours, however, are not all homogeneous or monochromatic, but are some of them produced by the admixture or overlapping of two or more simple colours.

If, instead of allowing the light to escape from the lantern through a round hole, we cause it to pass through a narrow slit with parallel edges, and then through the prism, we get a spectrum of a different form, in which we have a smaller number of more elementary colours. This is the method which was adopted by Dr. Wollaston, and is now usually adopted, for producing the spectrum.

But a spectrum produced in either of those ways by the employment of artificial light, such as the electric or the Drummond light, differs in one respect from a similarly produced spectrum of the sun's light, the latter, when closely and carefully examined, being found to be intersected with numerous dark lines, called Fraunhöfer's dark lines, which are not present in any spectrum of artificial light such as we are using.

I must refer you to the drawing for a representation of these dark lines, but I may also throw an enlarged image on to the screen of a photograph of the spectrum of sun light in which Fraunhöfer's lines are shown, and I wish to draw especial attention to these dark lines, for these are the evidences we obtain by spectrum analysis of the composition of the sun and some of the stars, and it will be one of my objects this evening to explain the way in which we are enabled to infer from these lines in the spectra of the sun and stars the presence of certain chemical elements in those sources of light.

With the exception of the absence of these dark lines from the spectra produced by artificial light, there is a close resemblance in other respects between the spectrum of the sun's light and that produced by the incandescence of solid or liquid substances, provided the light so produced be of sufficient intensity and purity.

The electric light which we are using fulfils the required conditions,—that is to say, it is a light of great intensity and purity. In the production of this light chemical affinity in the galvanic battery develops potential electrical energy in the conducting wires which communicate with our lamp, and this when the charcoal terminals to the wires are brought into contact with each other becomes kinetic energy. If the contact were complete and the conducting power of the wire and terminals sufficient, electrical and magnetic forces would be developed in and around the conducting wire and the battery, but we should have no sensible evidence in the wire or terminals of the production of heat or light. It is when incomplete contact and insufficient conducting power exist between the terminals that heat and light become developed there, and for the production of these in the high degree necessary for our purpose we gradually separate the charcoal terminals in the lamp after they have been brought together, and thus cause the charcoal points to become intensely hot and luminous, the space between the separated points being occupied by a stream of intensely heated particles of incandescent charcoal.

These solid particles of charcoal are the real source of our light, and it is found that the light thus emitted by incandescent solid or liquid substances, and probably also by dense vapours if in sufficient quantity, when dispersed by passing through a prism, yields a spectrum which is continuous within its extreme limits. Such is the character of the spectrum of sunlight, with the exception of the dark lines I have alluded to, and such also, but without that exception, is the character of the spectrum produced with the electric light.

On the other hand, it is found that incandescent gases, when treated in the same way, yield spectra, the light of which is not continuous but is concentrated in bright bands with dark spaces between them. The light thus produced is also much less intense than that produced by incandescent solid or liquid substances, and I shall presently have to direct your attention more specifically to this point, and to show that a weak light may be rendered invisible by a strong light shining in its immediate vicinity, so that an object otherwise luminous or illuminated, if it be so to a slight extent only, may be rendered dark and invisible by a strong light.

Now it appears that each elementary gas, when heated to a sufficiently high temperature to render it luminous, yields a spectrum peculiar to itself, consisting usually of a small number of bright coloured bands, which are distinguished not only by their colours but also by the positions they occupy with reference to fixed points in the spectrum.

We will illustrate this by igniting two or three metals in the lamp and throwing their spectra on to the screen.

First we heat a piece of copper between the charcoal electrodes, the heat of which is sufficient to melt, boil, and vapourize the metal, and its luminous vapour is now throwing off rays of light, which by the dispersive power of the prism are being separated, sorted, and displayed on the screen, as red,

* Lecture delivered before the Pharmaceutical Society, February 20th, 1878.

† *Pharm. Journ.*, May 5, 1877.

green, and blue bands, with dark spaces between them.

We will next treat a piece of zinc in the same way, and you see we get a red band and three very beautiful blue bands, differing in position from those we had before.

And now we will replace the zinc by brass, which, being a compound metal, containing copper and zinc, gives a spectrum in which its elementary composition is represented by the peculiar bands of both metals.

This is the basis of spectrum analysis, namely, that substances capable of being converted into the state of gas or vapour and rendered luminous by heat, yield discontinuous spectra by which they can be distinguished.

These luminous gases are often to a certain extent distinguishable by the colour of the light they emit when viewed without the use of a prism. Thus, for instance, salts of lithium and strontium impart a red colour to flame, while sodium salts impart a yellow colour, thallium salts and boron salts a green colour, indium salts a blue colour, and potassium salts a violet colour. It has long been the practice for chemists to get or to seek evidence of the presence of some of these substances by observing the colour imparted by a compound to the flame of a candle or some other source of light in which there was previously no very decided colour. The indications afforded in this way, however, are not very distinctive or conclusive, for not only will two or more substances impart the same colour to flame, but the colour imparted by one substance will often completely mask the effect of another substance which may be present with it. Thus a mere trace of soda is sufficient to disguise the presence of a considerable quantity of potash, and a larger quantity of soda will also disguise the presence of lithia and strontia, while these in like manner will disguise potash.

Many years ago, in 1858, Mr. Cartmell suggested a method of separating the colours imparted to flame by the alkalies and alkaline earths, which consisted in the use of coloured media through which the light was allowed to pass. These media by selective absorption cut off the rays of some colours and allowed others to pass. Thus it was found that a solution of indigo completely absorbs the yellow colour imparted to flame by soda, while it allows the red of lithia and the violet of potash to pass; and glass coloured blue with cobalt absorbs the red of lithia as well as the yellow of soda, while it freely transmits the violet of potash.

This, which Mr. Cartmell called a photo-chemical method of analysis, was a step in advance of what had previously been done in that direction, but it was still an incomplete process, and it has now been superseded by the more perfect method of spectrum analysis.

The results obtained in spectrum analysis are due to the heterogeneous nature of ordinary white light, every ray of which consists of several rays of light of various colours, differing from each other in wave length and in the frequency of vibrations in the ethereal medium, in consequence of which these elementary coloured rays undergo different amounts of refraction or bending in passing through a prism, and they are thus separated from each other and occupy places in the spectrum which represent their several refrangibilities.

The method of spectrum analysis is used with advantage for revealing the presence of certain elements, especially when these are associated with other substances in quantities so small as to render their detection in any other way difficult if not impossible; but it is not commonly resorted to by chemists in cases in which other processes of analysis are applicable. Its importance and interest have been principally centred in the means it affords us for investigating the composition of bodies which are so distant from us that we cannot otherwise form any reasonable conception, founded on observation, of what they may consist of or contain. It is by this means only that we are enabled to obtain evidence of the existence in the sun and stars of certain chemical elements which form part of the globe we inhabit.

There is perhaps hardly a discovery that has been made or a theory propounded within the present century that has excited a greater amount of interest than this has among those who desire to investigate the phenomena of nature; but there are many, no doubt, who, although, in deference to authority, they have accepted the doctrine which is accredited among scientific men, are still anxious to obtain further insight of the grounds upon which this doctrine is based. Difficulties will inevitably present themselves and questions arise in the minds of such inquirers, and to the solution of some of these it will be my object to contribute this evening.

Now what is spectrum analysis supposed to tell us with reference to the sun and stars? It tells us that the sun is composed of incandescent matter,—that it consists of a nucleus which is either solid or liquid or a dense vapour like smoke, around which there is an atmosphere consisting of matter in the state of a luminous gas. Then it tells us that while the nucleus of the sun is intensely hot and luminous, some of the light which emanates from it is absorbed or obliterated in passing through the sun's atmosphere, and that this absorption of light by the atmosphere surrounding the sun is due to the presence in that atmosphere of certain chemical elements, which, if they were separately heated while in the state of gas to a sufficient extent to be luminous, would produce discontinuous spectra of various colours. It further tells us that the dark lines in the spectrum of the sun's light coincide in regard to the positions they occupy in the spectrum with the positions occupied by the bright and coloured lines in the discontinuous spectra of the vapours of numerous well known chemical elements, from which it is inferred that those elements are present there.

I may here show you, by throwing on to the screen, a representation of the telescopic appearance of the sun during the total eclipse of 1869. The body of the sun being obscured by the moon's shadow, we are enabled to see the bright atmosphere, called the corona, to which I have already alluded, and also the red prominences which are supposed to be principally incandescent hydrogen extending to a distance of five or six thousand miles from the body of the sun.

Such are facts and inferences arrived at by the prismatic analysis of the sun's light, aided to some extent by the use of the telescope.

But beyond what is absolutely revealed to us by the telescope and the prism, it is required for science to account, under conditions that may be reasonably supposed to exist, for the conversion of light into darkness—of bright and coloured lines into dark lines—and still more, for the production of these dark lines, which were so long an enigma, by the action upon pure and brilliant sunlight of matter, itself luminous or illuminated, existing in the atmosphere of the sun, which matter, if it were the sole source of the sun's light, would produce corresponding bright and coloured lines.

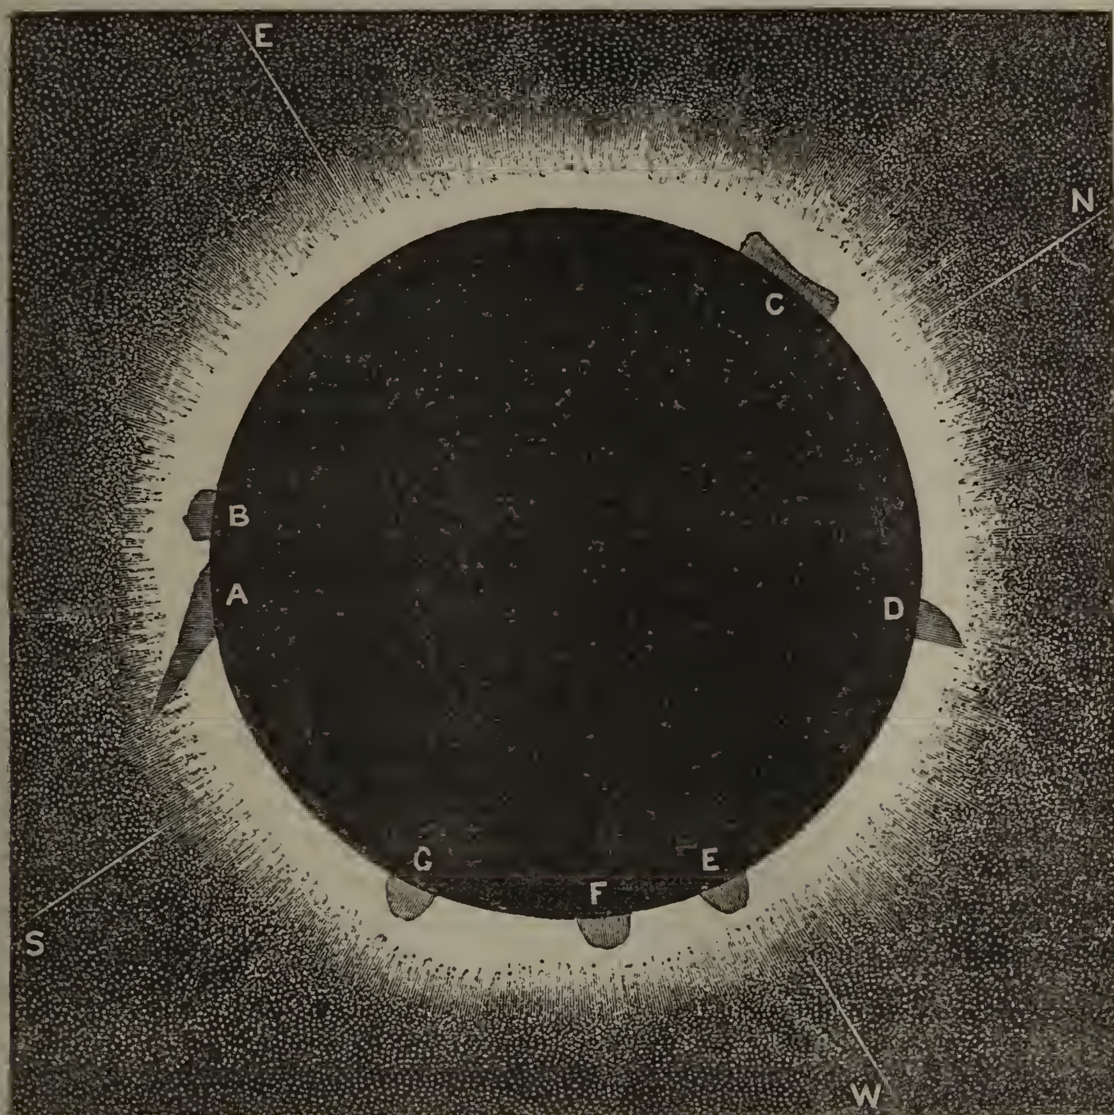

Fig. 1. Telescopic Appearance of the Sun during the Eclipse of 1869.

It is easy to say that the vapours of some fifteen or more well known chemical elements, forming an atmosphere around the sun, absorb just that kind of light which those same elements would emit if they were themselves the principal sources of the sun's light. Many persons accept such statements on the authority of those who make them, but with reference to a subject of such intense interest as this, we may be excused for wishing to see some practical demonstration of the evidences by which the proposed theory is supported. Let us then see what the evidences are which tend to show that the dark lines in the spectrum of the sun's light are due to the presence in the sun's atmosphere of gaseous bodies such as I have alluded to.

In bringing some of these evidences under your notice, I must in the first place refer to and partly recapitulate what I have on a previous occasion stated respecting the supposed nature of light.

It is assumed that light is caused by a vibratory motion, originating in the particles of matter, when these are acted upon by heat at a high temperature, and we use the term matter here to represent that which is affected by gravitation, and is capable of recognition by chemical means. But besides this matter, all space is supposed to be filled with an ethereal medium, sometimes called the luminiferous ether, which, as far as we know, is not affected by gravitation, and cannot be recognized by chemical means. This ether is the medium through which light as well as heat is conveyed through space. Like the more palpable forms of matter, the ether is supposed to consist of particles or atoms, which are infinitely smaller than the atoms of ponderable matter, infinitely small as those also must be.

We may, therefore, say that there are four physical states which we have reason to believe matter exists in; namely, the solid, the liquid, the gaseous, and the ethereal; the first three being those in which ponderable matter exists, and the last being that by means of which heat and light are communicated by radiation.

When the particles of matter, in any of its ponderable forms, are thrown into a state of vibratory motion by heat of some intensity, they become luminous as well as hot, and they are then capable of imparting a vibratory condition to the ethereal medium in contact with them, by which light and heat are conveyed with great velocity in straight lines, to distances which are only limited by the interposition of particles of ponderable matter which may lie in the path through which these lines, or rays, as they are called, are travelling. Heat and light in this state are said to be radiant, and radiation consists in the taking up by the ethereal medium of a certain kind of energy of motion, previously existing in the luminous body from which the radiant heat and light emanate.

When a body, whether it be solid, or liquid, or gaseous, lies in the path of a ray of heat or light, it will affect the ray in one or more of the following ways:—It may *absorb* the ray either wholly or partially, or it may *reflect* the ray either wholly or partially, or it may *transmit* the ray either wholly or partially. To the extent to which *absorption* takes place, the ray, as such, will be destroyed or obliterated—that is to say, the energy of vibration of the ethereal medium will be either taken up by the particles of matter, or they may be transmuted into some new form of energy in the absorbing body. To the extent to which *reflection* takes place, the ray, being rejected or thrown back, may be turned into some new direction, in which it will continue to pursue its course. To the extent to which *transmission* takes place, the ray will pass through the interposed body, and either continue to pursue an unaltered course, or it may be refracted or bent to a greater or less extent.

With regard to light, partial absorption, together with partial reflection or transmission of the rays of white light, produces colour. Thus, an object which appears coloured, when viewed by reflection, has absorbed part of the light, and reflects the other part. If, for instance, it appears red, it has absorbed all the other coloured light found in the spectrum, which with the red would constitute white light. And the same thing holds good with reference to the colour of a transparent object viewed by transmitted light. Heat and light are thus similarly affected, although the results do not produce in us similar sensations. In fact, there is reason to believe that heat and light, which we all know to be intimately associated, are the results of merely modified developments of the same physical cause. But heat vibrations are more easily excited than those of light. A body must have its particles considerably agitated and excited before it becomes luminous; and long before this it will have become sensibly hot. We might even go further and say, for it is an accepted doctrine, according to the theory of exchanges, that heat is radiated from bodies at all temperatures; and it is universally admitted that in this state of radiant heat, it is affected in every respect in the same way as light is. I shall therefore avail myself of means of illustration afforded by radiant heat, for the purpose of explaining some of the phenomena relating to light.

Now, the two influences exerted on light, and also on radiant heat by the particles of ponderable matter, which we shall principally have to consider, are those affecting radiation and absorption. Differences in the nature and condition of bodies, materially affect their power of radiating and also of absorbing both heat and light.

Let us first see how the rays of heat are thus affected. I have here two cylindrical tin vessels of equal dimensions, one of which is coated with lampblack, while the other retains its bright metallic surface. They have been simultaneously filled with boiling water, and each is furnished with a thermometer, affording easily discerned indications of changes of temperature. Exposed to the comparatively cold surrounding air, these vessels with the contained water undergo a process of cooling by radiation of heat into the atmosphere; and the thermometers will show the rates at which the cooling, or in other words the radiation or emission of heat from the surfaces of the vessels, will take place. You will observe that the thermometer in the vessel coated with lampblack indicates more rapid cooling than that indicated in the vessel with a bright metallic surface; and this tells us that a surface of lampblack radiates heat, that is, transfers the heat vibrations of its particles to the ethereal medium in contact with those particles, more freely and rapidly than a bright metallic surface does.

And now I want in the next place to show that lampblack and the bright metal possess the same relative powers of absorbing heat that we have seen they possess of radiating heat. I have two metallic vessels here, precisely similar in form and size, and so constructed that they give very marked indications, by the positions of the coloured liquids in the glass tubes attached to them, of the temperature of the air which each vessel contains. They are, in fact, air thermometers the air chambers of which are metallic. They are placed on opposite sides of a red hot copper ball, and at equal distances from it; but while one vessel presents a bright metallic surface, the other presents a blackened surface, to the ball. An equal number of heat rays from the hot ball falls on each; but those heat rays produce a more sensible heating effect upon the blackened surface than upon the bright metallic surface, as indicated by the rise of the coloured liquids.

This experiment is the reverse of the other, for while the other shows the respective facilities with which the heat vibrations are transferred from the particles of matter on two different but equally heated surfaces, to the ethereal medium, this shows the respective facilities with which the ethereal medium can transfer its heat vibrations back again to particles of ponderable matter; and we see from the results of the experiments that the power of absorbing corresponds with the power of radiating. The blackened surface, which is the best radiator, is also the best absorber.

Let us now see how the case stands with regard to light. We say that those bodies which are the best absorbers of light are also the best radiators of light. Here is a piece of platinum, one-half of which has been blackened by coating it with oxide of copper. The blackened part absorbs the light. It appears black because all the light that falls upon it is absorbed. The other part appears bright and metallic, because the light that falls upon it is not absorbed but is thrown off by reflection. If I heat this strongly by putting it into the furnace at a certain temperature it will begin to radiate light, and when it does so we shall find that the blackened part, which was the best absorber of light is also the best radiator of light. You perceive that the part that was black, now that it is made hot enough to radiate light, appears much more luminous than the other part, although both are equally hot.

Again, here I have a piece of white earthenware with a black pattern upon it. The black is absorbing, while the white is throwing off, reflecting and dispersing or scattering the light which falls upon it in different directions. If I cause this to radiate light by making it very hot, the pattern will be practically reversed—the black part will become intensely luminous and comparatively white, while the white part will be comparatively dark.

A clay tobacco-pipe, one-half of which has been painted over with a concentrated solution of nitrate of copper, and then heated to redness so as to leave the painted part covered with black oxide of copper, affords a good means of illustrating this effect.

Bearing in mind that we assume that radiant heat and light have a similar origin, and consist of a vibratory condition of the ethereal medium, we may obtain further evidence of the relation existing between radiation and absorption by observing the manner in which heat-rays are affected by substances that are capable of transmitting them to a greater or less extent.

Experiments on the transmission of heat show, that while some bodies allow heat-rays to pass through them, as light passes through transparent substances, others are, so to speak, opaque to the heat-rays, and others again allow some of the rays to pass, but absorb or suppress part of the heat, and this they do to variable extents, dependent upon the intensity or quality of the heat. Thus rock salt transmits nearly all the heat-rays that fall on it, and equally whatever the intensity or source of the heat may be; while alum, which is quite opaque, or to use the correct term, athermanous to heat of low intensity, is almost equally so to heat of any intensity; and glass, which allows the greater part of the sun's heat to pass through it, stops most of the heat from a common fire, and all the heat from a body if it be no hotter than boiling water.

But more than this, it appears from the results of experiments on the transmission of heat, that when a certain amount of heat has been absorbed in the attempt to transmit it through a substance—a plate of glass for example—the heat that has not been absorbed but has passed through the glass will pass through another plate of the same substance, with very little loss from absorption, thus showing that it is a particular sort or quality of heat that the glass absorbs, and that this being sifted out by the first transmission, what remains will pass through glass without further absorption.

These results, and others tending in the same direction, seem pretty clearly to show that radiant heat as well as light consists of compound rays, in which the wave-lengths and vibrations vary; and that the difference in the power which different substances possess, of radiating and absorbing heat-rays, depends upon the nature of the vibrations which those substances are susceptible of.

Upon such results have been founded the views entertained with reference to what is called selective radiation and absorption of heat and light rays, in accordance with which it is assumed that vibrating particles of matter can only impart to the ethereal medium vibrations or oscillations which agree in frequency, that is which synchronize, with their own vibrations, and similarly, that the particles of matter can only take up or absorb from the ethereal medium such vibrations as they are themselves susceptible of.

It is necessary here to observe the distinction between frequency of vibrations and amplitude of vibrations. Colour in light, and, as we believe, a corresponding property in heat, depend on frequency of vibration and consequent wave-length in the ether, just as a musical note depends on similar conditions in air; but intensity of light, like loudness of sound, depends, not on frequency of vibration, but on amplitude of excursion of the vibrating particles.

I may best explain this difference by referring to the case of a pendulum. The oscillations in the ethereal medium are comparable to the movements of a pendulum. They are movements to and fro across the line in which the ray of light travels. In a pendulum the frequency of the oscillations bears a fixed relation to the length of the pendulum, and is not at all influenced by the amplitude of the excursions of the oscillating body. So also in light, the colour of a ray of monochromatic light bears a fixed relation to the frequency of the oscillations in its source and medium of transmission, and is not affected by the amplitude or length of the excursions in the vibrating body or medium.

But while this is so with regard to colour, which wholly depends on wave-length and rapidity of vibration, it is otherwise with regard to intensity or amount of light, which depends entirely upon the amplitude of the excursions of the vibrating particles. Whatever the colour of the light may be, it may be either a strong light or a weak light, and it may be so weak as to be scarcely visible. We may even imagine the vibrations to be of the required frequency, but the excursions to be so small as to produce no sensible effect on our organs of vision.

Let me here also direct attention to the great difference that must exist between the particles or atoms of ponderable matter and those of the ethereal medium. It is true that we cannot form any definite idea of size in connection with these infinitely minute particles, but whatever may be the sizes of the atoms or smallest particles of ponderable matter, we cannot fail to conclude that the corresponding particles of the imponderable ether must be very much smaller.

This view of the subject is important in considering the transference of the vibrations of heat or light from the ethereal medium to the particles of ponderable matter, and especially in connection with the absorption of light-rays of greater intensity by radiating particles of matter which are throwing off similar rays of much less intensity.

Notwithstanding the evidences adduced which tend to prove that a substance which is capable of radiating any particular sort or quality of light, is equally capable of absorbing the same light, it may by some persons be found difficult to understand how the stronger light of the sun should be obliterated by the weaker light of the sun's atmosphere, and this not by interference but by absorption.

We know that two waves of light, just like two waves on the surface of water, may neutralize or destroy each other, but this which is called interference is perfectly distinct and different from the destruction of light by absorption; and what we have to account for is the destruction wholly or in part of certain rays of the strong light which emanates from the body of the sun, by the presence in the sun's atmosphere or chromosphere of vibrating particles of matter which, because their vibrations synchronize with such rays, are capable of absorbing, and practically do absorb them.

In accounting for this result it must be recollected that the light that emanates from the nucleus of the sun consists of vibrations in the ethereal medium which are of considerable amplitude, if we can say so of motion so infinitely small as these vibrations are; and that the light which originates in the sun's atmosphere is radiated from particles of ponderable matter the light of which being weak consists of vibrations of comparatively small amplitude.

It must also be recollected that it is not the radiated light of the sun's atmosphere, or in other words, it is not the vibrations of the ethereal medium there, but the vibrating and radiating particles of matter which it contains, that effect the absorption we have to account for.

Now when we consider the vast difference in size which we assume to exist between the particles of the ether and those of the ponderable matter in the sun's atmosphere, it will be evident that the smaller particles of the ether in their impact with the larger synchronizing particles of matter may transfer their energy to, without sensibly augmenting the amplitude of the vibrations of, the latter.

We do not usually find that the light vibrations of the luminiferous ether, when they are absorbed by ponderable matter, are capable of rendering these luminous, and we need not therefore be surprised that such an effect is not sensibly produced in the particles of matter contained in the sun's atmosphere.

On the other hand it is not necessary to suppose that the sun's atmosphere is rendered less luminous than it would otherwise have been, in consequence of the absorption by it of part of the sun's light, for the appearance of the dark lines in the spectrum may be sufficiently accounted for by the effect of the strong light of the other parts of the spectrum.

I may illustrate this by showing two lights side by side. I have here two jars containing combustible gases. One is light carburetted hydrogen or marsh gas, and the other is heavy carburetted hydrogen or olefiant gas. I light the former, and you see that it burns with a luminous, although not a very luminous flame; but now while that is burning I light the other which gives a far more luminous flame, and you see that the intensity of the light of the latter renders the former all but invisible.

Again, here is a metallic ball which has been heated until it is luminous. If the heat be only just sufficient to render it distinctly luminous in a dark place, it will be found that on putting it into the strong light of a lamp, the light it previously emitted will appear to be extinguished and it will become almost black.

The dark lines of the spectrum of the sun's light may therefore be considered to be dark principally by comparison with the much stronger light by which they are surrounded, and but for this effect we might find them to be coloured lines of light of comparatively low intensity.

Having thus brought under notice the sort of evidence on which the opinion is founded, and by which the theory is explained, that represents the dark lines in the spectra of the sun and stars to be caused by the presence of certain well known chemical elements in the atmosphere surrounding those luminaries, I purpose in concluding to show you on the screen the representation of some of the spectra that have been obtained and carefully mapped out, and to explain what the elements are that those spectra are considered to prove the presence of.

Let me once more call your attention to the appearance presented by the sun during a total eclipse. Here the body of the sun is obscured by the shadow of the moon, beyond which we observe red prominences that have been described as flames, and which are the most projecting portions of what appears to form a complete envelope five or six thousand miles in thickness, covering the nucleus or body of the sun. Mr. Lockyer calls this envelope the chromosphere. It appears to consist principally of incandescent hydrogen, with portions of magnesium and sodium, and some unknown element. Then beyond this chromosphere is the so-called corona, the principal atmosphere of the sun, which is probably illuminated more than luminous, and here we discover evidence of the presence of about fifteen different elements of which the following is a list:—

1. Sodium.	6. Iron.	11. Copper.
2. Calcium.	7. Chromium.	12. Zinc.
3. Barium.	8. Nickel.	13. Cadmium.
4. Magnesium.	9. Cobalt.	14. Titanium.
6. Aluminum.	10. Manganese.	15. Hydrogen.

M. Janssen, a French astronomer, was enabled during the eclipse of 1869, to obtain and figure the spectrum of the red prominences, which taken exclusively from that source of light gave, not dark lines, but bright lines corresponding in position with those of hydrogen, magnesium, and sodium, as shown in the representation I now throw on the screen.

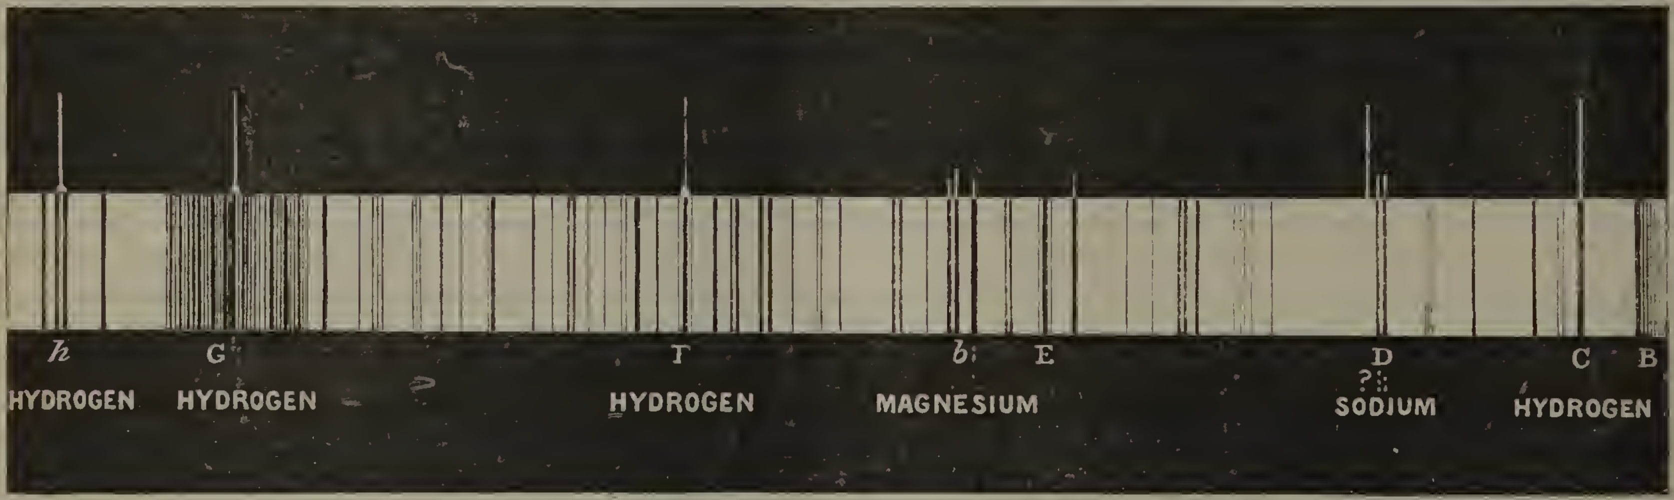

Fig. 2. Spectrum of the Red Prominences in the Sun's Chromosphere.

In this representation you will observe the spectrum of the chromosphere, or rather the part of it forming the red prominences, is given above in bright lines on a dark ground, and the ordinary spectrum of the sun's light is given below in dark lines on a bright ground. You will see that with one exception all the bright lines correspond with some of the dark lines, and they are the lines representing hydrogen, magnesium, and sodium. There is, however, one bright line which has no dark line corresponding to it, and in fact this appears at present to be produced by an unknown element. It is precisely thus that since the introduction of spectrum analysis our new elements have been discovered. It was thus that Mr. Crookes, having observed a beautiful green band in the spectrum produced from the combustion of a variety of pyrites, said "This answers to no known element, there must be a new element here, let us search for it," and he found his thallium. In the same way Bunsen and Kirchhoff, by the discovery of cæsium and rubidium, had previously laid the foundation for the revelations of spectrum analysis, and it now remains for scientific men to discover the element that produces this bright line in the spectrum of the sun's chromosphere.

Spectra have been taken of the light of the moon and planets, but they differ not essentially from those of the sun, thus confirming what we previously knew, that those bodies have no light of their own, but shine with the borrowed or reflected light of the sun.

Turning to the fixed stars, however, we have evidence that they, like the sun, are not merely illuminated but are luminous bodies, and that they consist of, or contain, many elements that are known to us. They yield spectra with dark lines similar to, but not identical with that of the sun's light. Here are the spectra of two stars, Aldebaran and Orionis, the latter of which presents this peculiarity, that hydrogen which is so prominently found in the spectra of the sun and some of the stars is entirely absent from this.

The nebulæ and comets also yield spectra, but in these the lines are mostly bright, which seems to indicate that those bodies consist wholly or principally of gaseous matter. In the nebulæ there appears to be little else than hydrogen and nitrogen, and in comets chiefly carbon.

And now having soared into the sky, explored the heavens, and analysed the sun and stars, we must return again to this lower world, which is but a speck in the universe, and we may contemplate with devout admiration the omnipotence of the creator and author of all things, by whom life and the conservation of energy are maintained, and will be extended, as we believe, to the end of time.

NOTE ON VON KOBELL'S TEST FOR BISMUTH.*

BY J. F. SAVORY AND H. G. GREENISH.

In the *Chemical News* of December 7, 1877, p. 249, under the heading "Detection of Bismuth," Mr. W. M. Hutchings draws attention to this test, and to an improvement he claims to have made in it. The test itself depends upon the formation of red iodide of bismuth, and is performed by mixing a solid bismuth compound, or the substance suspected to contain bismuth, with equal parts of iodide of potassium and sulphur, and heating on charcoal before the blow-pipe. A red sublimate indicates bismuth. Mr. Hutchings finds the mixture of iodide of potassium and sulphur to be very deliquescent, and finds it advantageous to replace them by iodide of copper. He ranks the test as one of the best, in some cases *the* best, for bismuth. It is especially applicable to the rapid detection of small quantities of bismuth in ores.

Professor F. Field, in the same journal, December 14, 1877, p. 267, calls attention to the delicacy of a test for bismuth, devised by himself and Professor Abel, which also depends upon the production of an iodide of bismuth, or perhaps, rather, of an iodide of bismuth and lead.

"It is based," says Professor Field, "upon a curious reaction exhibited by iodide of potassium in the joint presence of lead and bismuth. When iodide of potassium is added to a lead solution, iodide of lead is precipitated yellow, which re-dissolves on heating, and crystallizes again on cooling in brilliant golden yellow scales. If the least trace of bismuth is present, the precipitated scales are no longer yellow, but assume a dark orange or crimson tint, varying with the amount of bismuth present. The test is of such delicacy that ·00025 gr. of bismuth can be easily distinguished; the oxide of lead becoming dark orange; ·001 gr. gives a reddish brown tint, or a bright crimson, resembling in appearance chromate of silver."

A test liquid may be conveniently prepared by adding to a boiling solution of acetate of lead, containing about $\frac{1}{2}$ gr. to the ounce, solution of iodide of potassium in considerable excess. The re-solution of the iodide of lead at first precipitated is materially assisted by the addition of acetic acid. On cooling, iodide of lead is deposited in the characteristic brilliant scales.

A small quantity of this test liquid, including both supernatant liquid and precipitated scales, is transferred to a test tube, and gradually heated till solution takes place. The liquid to be tested is then added, and the whole allowed to cool. The separated scales will show a distinct change in colour if the smallest quantity of bismuth is present.

To test the delicacy of the reaction, one grain of oxynitrate of bismuth was dissolved in a litre of water, with the addition of nitric acid. Each cubic centimetre would contain one milligram of oxynitrate. A second, more dilute solution, was prepared, each cubic centimetre of which would contain one tenth of a milligram of oxynitrate.

5 c.c. of the test liquid were heated in a test tube till clear. 1 c.c. of the strong solution (1 milligram of oxynitrate) was added. The precipitated scales were dark in colour.

5 c.c. of the test liquid with $\frac{1}{10}$ c.c. of the strong solution ($\frac{1}{10}$ milligram of oxynitrate) gave a very decided change in colour.

A blank experiment gave the iodide of lead in the usual characteristic yellow.

As the quantity of iodide of lead present would evidently affect the delicacy of the reaction, a smaller quantity of the test liquid was next used, and the dilute solution of oxynitrate employed.

$\frac{1}{2}$ c.c. of test liquid, with 1 c.c. of the dilute solution ($\frac{1}{10}$ milligram of oxynitrate), gave a very decided reaction.

$\frac{1}{2}$ c.c. of test liquid, with $\frac{1}{10}$ c.c. of dilute solution ($\frac{1}{100}$ of a milligram of oxynitrate), gave a distinct change in colour. Much hydrochloric or nitric acid must be avoided; but boiling the precipitated scales with acetic acid appeared to heighten the delicacy. 5 c.c. of test liquid ($\frac{1}{50}$ milligram oxynitrate), boiled with strong acetic acid and cooled, gave a distinct change in colour; $\frac{1}{100}$ milligram was also evident.

To students of analytical chemistry this test will, we think, prove of assistance. By its means small quantities of bismuth may be detected with ease in the presence of lead; and most are familiar with the difficulties encountered in separating these two metals. We find that if the precipitated hydrates of lead and bismuth obtained in the chart (Attfield's Manual) usually employed in our laboratories, be dissolved in acetic acid, and a portion of the solution be added to the test liquid in the usual manner, an indication of the presence or absence of bismuth will be speedily obtained. The lead may then be detected in the remainder in the usual manner.

* Paper read at a meeting of the School of Pharmacy Students' Association.

CASTOR OIL SOAPS.

About seven years since Mr. Rimmington called attention in this Journal* to the value of castor oil in the preparation of a pure medicinal soap. The subject has since been carried further by M. Giffard, who contributes a paper to the *Bulletin des Travaux de la Sociétéde Pharmacie de Maine-et-Loire* for 1876–77, on the saponification of castor oil and its therapeutic applications.

Castor oil, by saponification, yields three fat acids, namely, margaric, ricinic, and ricinolic acids. Margaric and ricinic acids are present in only small proportions, but ricinolic acid is much more abundant, so that the compounds with bases may be considered to be practically true ricinolates. As a general character they are unctuous to the touch, and the author considers that this property might be frequently utilized in perfumery and soap making.

The ricinolates of potash and soda are obtained very readily, being produced by simple contact of the oil with strong ley. The potash soap is soft, and resembles glycerole of starch. The soda soap is opaque white, and possesses the characteristic unctuosity in a marked degree. It could be substituted for ordinary soap as an excipient in purgative pills, especially those of aloes. When triturated in a mortar it softens and can be readily incorporated with powders, forming a mass of good consistence.

To prepare this soda soap M. Giffard mixes 250 parts of castor oil with 100 parts of soapmakers' ley. After a few days, before the soap becomes too hard, it is kneaded with the hands in a saturated solution of chloride of sodium, and is then allowed to dry.

The ricinolate of magnesia is not obtained directly, but is prepared by double decomposition, by pouring a neutral solution of an alkaline ricinolate into a solution of sulphate of magnesia. The white curdy precipitate that forms is washed several times on a filter or a cloth. This ricinolate melts at 50° C.; it is insoluble in water, but soluble in alcohol, ether and chloroform. From the alcoholic and ethereal solutions, when allowed to evaporate slowly, it is deposited in silky crystalline needles. M. Giffard has experimented upon the internal administration of the ricinolate of magnesia, and found that it preserves the properties of its two components. It acts as a

* *Pharmaceutical Journal* [3], vol. i., p. 682.

gentle laxative which might be useful in constipation. As its soft consistence does not allow of its being made into pills without some addition, M. Giffard uses powdered rhubarb or magnesia. It then forms a moderate purgative, which does not produce colic or the least intestinal irritation.

The ricinolate of lime presents no points of interest.

The ricinolate of iron, obtained by double decomposition, is soluble in ether. M. Giffard suggests that if employed in the same proportions as other iron preparations the constipation which ordinarily attends their use might be avoided.

The lead soap is obtained by direct combination, like ordinary lead plaster. It hardens much less quickly and might therefore be used in the preparation of adhesive plasters.

The ricinolate of mercury is formed as a white precipitate, of rather firm consistence, upon mixing a solution of a mercuric salt with a solution of an alkaline ricinolate.

M. Giffard also prepared a number of other ricinolates, but none of them present points of pharmaceutical interest.

NOTE ON SALICYLATE OF ZINC.*

BY F. VIGIER.

The author prepares this salt, for use in hypodermic injection, by dissolving salicylic acid with heat in distilled water, and as the solution progresses adding successive small quantities of oxide of zinc suspended in a little water. Combination commences at once, and the addition of zinc is stopped when, after boiling the liquor, there is a slight deposit of the oxide. The liquid is then filtered, and upon cooling the salicylate of zinc crystallizes out in long needles. The mother liquor is decanted off and the crystals are dried in the open air, or in a stove between folds of filter paper. The product thus obtained is extremely white. The mother liquor upon evaporation yields a further quantity of salicylate of zinc. During the operation a porcelain capsule should be used and all metallic contact avoided, especially with iron, which would colour the liquid violet. If the solution should be slightly coloured it may be decolorized by boiling it with a little animal charcoal.

When concentrating the solution it is necessary to stop the boiling as soon as the water is insufficient to dissolve the salt, as under the prolonged action of heat the normal neutral salicylate of zinc is split up into salicylic acid, which remains dissolved, and a basic salicylate of zinc, which is deposited as a very light white powder.

The neutral crystalline salicylate of zinc contains three molecules of water of crystallization. None of this is lost upon exposure over sulphuric acid, but two molecules are given off after heating at 100° C. and the other at 150° C. The salt is very soluble in boiling water, from which it crystallizes on cooling in long, very brilliant silky white needles, having a satiny lustre. At first its taste is sweet, then styptic and bitter; 100 parts of water at 20° dissolve 5 parts of the salicylate. It is very soluble in alcohol, ether, and methylic alcohol, and upon evaporation of these solutions it is deposited in short silky needles usually grouped round a common centre. Carbon bisulphide does not dissolve it in the cold, but when boiling it takes up a small proportion, which again crystallizes upon the evaporation of the liquid. In oil of turpentine it is insoluble. Sulphuric acid dissolves it without coloration if the salt is pure. Nitric acid attacks it with difficulty in the cold; when heated it dissolves it with evolution of nitrous vapours. Hydrochloric acid also acts upon it with difficulty in the cold, but dissolves it when heated, and upon cooling the solution forms a crystalline mass. Like salicylic acid an aqueous solution of salicylate of zinc is coloured violet by ferric chloride. Ammonia produces in the aqueous solution a precipitate soluble in an excess of the precipitant. Hydrosulphate of ammonia gives a white precipitate of sulphide of zinc.

The basic salicylate of zinc contains no water of crystallization and is nearly insoluble in water, alcohol, and ether. Upon heating it with salicylic acid and a sufficient quantity of water the neutral salicylate is reformed.

Salicylate of zinc is reported to have been employed by Drs. Poignet and Desmarres successfully as an astringent antiseptic in blenorrhagia, cancerous sores in the tongue, purulent ophthalmia, etc. The proportion used for blenorrhagia is 0·5 to 1 gram in 100 grams of distilled water, and for cancerous sores a 4 per cent. solution.

* Journal de Pharmacie et de Chimie [4], vol. xvii., p. 41.

SOME ANALYSES OF DIALYSED IRON.*

BY HENRY TRIMBLE.

No pharmaceutical preparation of recent times has met with such universal favour as dialysed iron. The physician employs it with marked success, and the pharmacist refers to it as a type of the so called elegant remedies to which he has of late years directed a great part of his energy. So far it has chiefly been prepared by a few wholesale manufacturers, who are constantly calling attention to its strength, purity and general superiority over the other iron compounds. Fearing that the strength of the solution might be sacrificed somewhat in attaining the much-desired elegance, I procured of the leading manufacturers of Philadelphia six samples, and estimated the iron and chlorine by the following process.

About five grams of the solution were taken, diluted with water, treated with ammonic hydrate and heated gently until all the iron was precipitated. This was then filtered off, washed thoroughly, ignited, and weighed as Fe_2O_3. The filtrate and washings were heated to expel excess of ammonia, and treated with hydric and argentic nitrates. The mixture was heated and agitated until the resulting argentic chloride cohered, then filtered and the collected precipitate washed, ignited and weighed as AgCl, from which the percentage of chlorine was calculated.

The following table, containing a summary of the analyses, explains itself:—

	Per cent. Fe_2O_3.	Per cent. Cl.	Per cent. of the salt.	Formula.
I.	3·143	·140	3·192	$29Fe_2O_3.Fe_2Cl_6$.
II.	3·442	·154	3·497	$29Fe_2O_3.Fe_2Cl_6$.
III.	2·394	·156	2·514	$19Fe_2O_3.Fe_2Cl_6$.
IV.	2·583	·286	2·804	$11Fe_2O_3.Fe_2Cl_6$.
V.	4·677	·198	4·831	$31Fe_2O_3.Fe_2Cl_6$.
VI.	2·874	·235	3·058	$16Fe_2O_3.Fe_2Cl_6$.

There would be no criticism to offer on these results, were it not for the fact that the circulars of these manufacturers state that the solutions contain five per cent. of ferric oxychloride, or, as one asserts, of ferric oxide free from hydric chloride, both of which statements are incorrect, and as yet the latter has proved impossible.

Finally, we see that only the manufacturers are at fault, and that a solution of dialysed iron can be and is prepared, which, compared with the iron, contains a much smaller proportion of chlorine than has heretofore been supposed, three of the samples showing this, the only objection to them being that they contain too large a percentage of water.

* From the American Journal of Pharmacy, February, 1878.

The Pharmaceutical Journal.

SATURDAY, MARCH 2, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE DENTAL PRACTITIONERS' BILL.

THE opinion we expressed some weeks since, in reference to the possible interpretation of the fifth section of this Bill, defining the persons who are to be entitled to registration, as being prejudicial to chemists and druggists who practise dentistry has been very generally acquiesced in, as will be seen from the letters that have been published on the subject, and it is satisfactory to find that Sir JOHN LUBBOCK, as one of the promoters of the Bill, recognizes the propriety of striking out the words which might give rise to ambiguity and admit of being interpreted as excluding from registration chemists and druggists who are at present engaged in dental practice.

As regards the general object of the Bill, to restrict the use of the title "dentist" to those who possess competent knowledge and skill for the proper performance of the duties they undertake, we cordially agree with the preamble of the Bill, which states that it is expedient that provision be made for the registration of persons officially qualified to practise as dentists in the United Kingdom. The only point to which we took exception was the provision that those entitled to be registered under the proposed Act must have been engaged in the practice of dentistry, either separately or in conjunction with the practice of medicine or surgery.

It very often happens that in the decision of questions relating to Acts of Parliament, difficulty is experienced in giving proper effect to the meaning intended originally to be expressed by the phraseology of particular clauses, and the definition of persons entitled to registration appeared to admit of an interpretation opposed to what may reasonably be supposed to have been the intention of the promoters of the Bill. As very fairly put by Mr. MAGGS in his letter to Sir JOHN LUBBOCK, that definition may be interpreted as indicating only two classes of persons, viz.;—

1. Those who have practised dentistry exclusively, and,

2. Those surgeons who have included dentistry in their practice.

If such a view were taken after the passing of the Bill, it is possible that a good case might still be made for those chemists and druggists who have been in the habit of combining dentistry with their business as pharmacists; but in any case there would be incurred the undesirable trouble and expense of urging their claim to continue practice as before the passing of the Bill. Moreover, if the clause were allowed to pass as it now stands it might be taken advantage of to the detriment of chemists and druggists, for in the unregulated condition in which the practice of dentistry has so long been, it is not to be wondered at that heartburnings and jealousy should be frequent. Under such conditions it would not be surprising if qualified practitioners, smarting under the injury inflicted upon them by quacks and pretenders, should take a narrow view of the restrictions imposed by the Act and endeavour to give them a wider application than they were intended to have.

As regards this latter point, we do not at all question that the intention of the promoters of this measure is simply that of preventing ignorant and inexperienced persons from imposing upon the public by styling themselves dentists, and in this respect chemists and druggists who practise dentistry may regard it as a protective measure. But however desirable such an object may be, existing rights acquired by usage must be regarded, and it would certainly be inconsistent to admit to registration a number of ignorant persons who have never done anything but draw teeth, while at the same time those chemists and druggists who have combined dentistry with pharmacy, were excluded and summarily compelled to give up this part of their business.

We are glad to be able to state that the propriety of regarding such existing rights is admitted by those who are striving to bring about reform in the the practice of dentistry, and we have been favoured by Mr. JOHN WADE with a letter from the Honorary Secretary of the Dental Reform Committee in which he fully admits this in reference to chemists and druggists. In consequence of the representations of the case made by the Pharmaceutical Society and by various individuals, SIR JOHN LUBBOCK has expressed himself as being quite disposed to adopt such an amendment of the Bill as will secure to chemists and druggists practising dentistry the same consideration that is accorded to other practitioners.

We may therefore regard this matter of amendment of the Bill as having been already provided for satisfactorily, and that there is now probably no further occasion to take action in reference to it. We may, however, mention that a form of petition is being circulated for signature by Mr. WESTLAKE of Windsor, in which it is proposed that the word "pharmacy" should be inserted after the word "surgery" in the sentence we have quoted above from the fifth section of the Bill.

The letters published in the present and previous numbers of this Journal likewise show that several individual communications have been addressed to Sir John Lubbock, and the Chemists and Druggists' Trade Association brings up the rear with a deputation from Birmingham.

The only remaining question now appears to be as to the nature of the amendment. Mr. Gostling and Mr. Westlake suggest the insertion of the word "pharmacy," so that the passage objected to would then read thus, "separately or in conjunction with medicine, surgery, or pharmacy." Mr. Maggs suggests that the amendment should be of such a nature as to indicate the intention "that all who have practised dentistry hitherto, whether in conjunction with surgery or not, should be admissible to registration. The latter appears to us the more simple course, and probably the amendment would best take the form of omitting the words "either separately or in conjunction with medicine or surgery." Though we are not at present in a position to speak positively on this point we can state that it is most probable this will be done.

While dealing with this subject we think it desirable to point out an error into which our contemporary, the *British Medical Journal*, has fallen in speaking of the opposition offered to the Bill by chemists and druggists. After expressing the opinion that they are right in taking that course, it goes on to state that "this Bill proposes to put every existing chemist who has ever pulled a tooth in the position of (dental) surgeon and they think it reasonable that their successors in business should all have the same privilege." These few words contain two flagrant mis-statements: the Bill does not propose to put any chemists and druggists in the position of dental surgeons, neither do chemists and druggists seek to claim that position for themselves or for their successors. All they demand is that those among them who have hitherto been practising *bonâ fide* as dentists shall be allowed to continue doing so and to be admitted to registration in common with others who have been practising *bonâ fide* as dentists. As regards future chemists and druggists who may desire to practise dentistry, not a suggestion has yet been offered in opposition to their being subordinated to the provisions of the Bill intended to secure the competence of dental practitioners in general. That many future chemists and druggists will satisfactorily and efficiently perform the functions of dentists we do not doubt any more than we doubt the fact that many of them have likewise done this hitherto.

THE CHEMISTS' BALL.

A Meeting of the Committee of the Chemists' Ball was held on Monday evening the February 18, when a most favourable report was presented by the Honorary Secretary. The Stewards, and those who were present at the Ball, will learn with satisfaction that the Committee was enabled to hand over the sum of thirty guineas to the Benevolent Fund of the Pharmaceutical Society—this being the largest amount the Committee has yet given. It is only fair to add that the great success attending the Ball this year is largely due to the exertions of Mr. Walter Hills, the Honorary Secretary.

A WRONG MEDICINE.

The last number of the *Bulletin Commercial* reports the prosecution of a *pharmacien* for the supply of a wrong medicine, resulting in a fatal accident. The medicine ordered for the patient was an enema of sulphate of soda and syrup of buckthorn; but that administered was a preparation containing chloroform. Shortly after the patient fell asleep and died the same night without waking. The responsibility for the substitution was disputed; on the one hand the *pharmacien* alleged that the messenger had laid the bottle down after it had been given to him and taken up a wrong one from the counter; on the other, the messenger swore that he had not. The medical evidence was also conflicting as to whether the death was really caused by the chloroform. The *pharmacien* was, however, condemned to pay a penalty of 200 francs, and a further sum of 1500 francs as damages to the mother of the patient.

It is rather curious that a contemporary whose censorship over things in general has this month been extended to the manner in which translations from the English are made for a celebrated French journal, has itself, when referring to this case on another page, through a misreading of the word *lavement*, been betrayed into a ludicrous expression of doubt as to syrup of buckthorn being used as a lotion.

THE EVENING MEETING.

An Evening Meeting of the Pharmaceutical Society will be held on Wednesday next. The chair will be taken at half-past eight o'clock precisely.

THE SOCIETY'S CALENDAR.

The Calendar of the Pharmaceutical Society for 1878 is now ready, and copies may be had upon application to the Secretary, 17, Bloomsbury Square. Full details as to its contents, price, etc., will be found in an announcement in the Advertising sheet.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of this Association will be held on Wednesday next, March 6, when Mr. Wallis will read a paper on "Sponge."

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

The fifth meeting of the present session was held in the Society's rooms, 119a, George Street, Edinburgh, on Friday evening, 22nd February. Mr. J. B. Stephenson, President of the Branch, in the chair.

Mr. H. B. Baildon, B.A., read a continuation of his paper on "Botany," which will be printed in a future number of this Journal.

At the conclusion of the paper, the President moved a hearty vote of thanks to Mr. Baildon; this was seconded by the Rev. Dr. Kerr, who complimented Mr. Baildon for the beauty of the language in which his paper was written. The motion was very cordially acknowledged.

Mr. W. Ivison Macadam, Lecturer on Chemistry, Edinburgh, then read the following paper on Californian Wines:—

THE CHEMICAL COMPOSITION OF CALIFORNIAN WINES.

BY W. IVISON MACADAM,

Lecturer on Chemistry, Edinburgh.

Until lately the principal part of the wines obtainable were those grown on the continent of Europe. Within the last few years, however, several new countries have forwarded small consignments to the British market.

For the proper growth of the wine vine, it is necessary that the climate should not be liable to rapid changes of temperature, for although a hard frost in the winter, when the sap is not ascending, does no damage but rather good to the plant, yet during the spring months the vine must not be exposed to sudden frosts, else the tender fruit branches will be liable to be frosted and their proper growth damaged or permanently destroyed. It is also necessary that the vines should not be exposed to heavy rains during the autumn months, as these deteriorate the fruit crop.

On the continent of America the State of California is particularly adapted to the growth of the vine, for although the temperature is somewhat low during winter, yet the spring, summer and autumn months may be depended on. For the last few years much attention has been devoted in the State to the growth of the better class of wine vine, and great improvement has been made in the vineyards by the introduction from Europe of plants and graftings of the Riessling, Malvoisie, Zinfandel, Orleans, Berger and other high class varieties. The wines manufactured are large in number and include white and red varieties, ports, champagne, etc.

Samples of port, malaga, sherry and a special variety called "Mount Vineyard" were obtained direct from the American vineyards, and submitted to analysis, when they gave the following results:—

PORT.

Specific Gravity of Wine	1022·96
,, ,, ,, *minus* Alcohol	1035·03
Specific Gravity of Distillate	977·01
Percentage of Alcohol *by Weight.*	15·99
,, ,, ,, *Volume.*	19·00

In One Imperial Gallon.

Total Dry Residue	8439·90 grains.
,, ,, *minus* Ash	8194·90 ,,
,, Ash	245·00 ,,
Grape Sugar	5833·00 ,,
Fixed Acid calculated as Tartaric Acid	249·90 ,,
Volatile Acid calculated as Acetic Acid	42·00 ,,

In 100 parts.

Dry Residue	11·786 grains.
,, ,, *minus* Ash	11·444 ,,
Ash	0·342 ,,
Grape Sugar	8·146 ,,
Fixed Acid calculated as Tartaric Acid	0·357 ,,
Volatile Acid calculated as Acetic Acid	0·060 ,,

Taste, sweet.
Colour, rich.

The specific gravity of this Wine is higher than is usual in the case of Portuguese Ports. This is due to the large amount of grape sugar, which also greatly increases the dry residue, which is fully 2 per cent. above the average amount to be obtained in "Natural" Ports.

MALAGA.

Specific Gravity of Wine	1053·56
,, ,, ,, *minus* Ash	1073·27
,, ,, of Distillate	978·66
Percentage of Alcohol *by Weight.*	14·25
,, ,, *by Volume*	17·33

In One Imperial Gallon.

Total Dry Residue	14249·90 grains.
,, ,, *minus* Ash	13974·10 ,,
Total Ash	275·80 ,,
Grape Sugar	10769·23 ,,
Fixed Acid, calculated as Tartaric Acid	254·80 ,,
Volatile Acid, calculated as Acetic Acid	47·60 ,,

In 100 parts.

Dry Residue	19·321 grains.
,, ,, *minus* Ash	18·948 ,,
Ash	0·373 ,,
Grape Sugar	14·602 ,,
Fixed Acid, calculated as Tartaric Acid	0·364 ,,
Volatile Acid, calculated as Acetic Acid	0·063 ,,

Taste, sweet.
Colour, good.

The amount of grape sugar is very large, which increases the weight of the dry residue and specific gravity of the wine.

SHERRY.

Specific Gravity of Wine	993·22
,, ,, ,, *minus* Alcohol	1114·86
Specific Gravity of Distillate	978·83
Percentage of Alcohol *by Weight.*	14·60
,, ,, ,, *Volume.*	17·70

In One Imperial Gallon.

Total Dry Residue	2701·30 grains.
,, ,, ,, *minus* Ash	2536·80 ,,
,, Ash	164·50 ,,
Grape Sugar	1129·03 ,,
Fixed Acid, calculated as Tartaric Acid	292·85 ,,
Volatile Acid, calculated as Acetic Acid	26·60 ,,

In 100 parts.

Dry Residue	3·884 grains.
,, ,, *minus* Ash	3·648 ,,
Ash	0·236 ,,
Grape Sugar	1·623 ,,
Fixed Acid, calculated as Tartaric Acid	0·381 ,,
Volatile Acid, calculated as Acetic Acid	0·038 ,,

Taste, dry.
Colour, pale.

This analysis agrees closely with Spanish "Natural" Sherries.

"Mount Vineyard."

Specific Gravity of Wine	1016·29
" " " *minus* Alcohol	1035·89
Specific Gravity of Distillate	978·98
Percentage of Alcohol *by Weight*	14·00
" " " " *Volume*	17·00

In One Imperial Gallon.

Total Dry Residue	6679·40	grains.
" " " *minus* Ash	6517·00	"
" Ash	162·40	"
Grape Sugar	5185·18	"
Fixed Acid, calculated as Tartaric Acid	235·20	"
Volatile Acid, calculated as Acetic Acid	32·20	"

In 100 *parts.*

Dry Residue	9·389	grains.
" " *minus* Ash	9·161	"
Ash	0·228	"
Grape Sugar	7·288	"
Fixed Acid, calculated as Tartaric Acid	0·336	"
Volatile Acid, calculated as Acetic Acid	0·046	"

Taste, sweet.
Colour, pale.

A large amount of grape sugar present.

These results show that the percentage of alcohol in all of the wines closely resembles the amount generally found in "natural" European varieties, and that the acid, both *fixed* and *volatile*, is below the average; that the high specific gravities of the port, malaga, and Mount Vineyard are due to the presence of considerable quantities of grape sugar, which has doubtless been added to the wine so as to suit the taste of consumers. From the same cause the dry residues obtained from those three wines is considerable. In the sherry the whole of the results point to a wine very closely allied to the Spanish varieties of "natural" sherry. The ash in all the wines is small in amount.

In taste the sherry resembles the dry class of wines, whilst the port, malaga and "Mount Vineyard" are sweet to taste. The port has a rich colour, whilst the sherry and "Mount Vineyard" are pale and bright. On account of the wines being somewhat new, they lack in a degree the bouquet of older wines, but doubtless when aged the ethers will be formed in larger quantities and supply what is at present wanting. They are good sound wines, and somewhat agreeable to taste.

The home consumption of these wines in the State of Californian is considerably above 2,500,000 gallons per year. The export in 1873 was 490,568 gallons, whilst for the first six months of 1877 the total amount sent out of the State was 452,392 gallons, thus showing a considerable increase. The most of the exported material is used on the American continent, whilst smaller amounts find their way to more distant markets. In 1876 Great Britain received 1033½ gallons, being the first consignment, whilst Germany obtained 1525 gallons.

A discussion followed Mr. Macadam's paper, in which Mr. Mackay and the Rev. Dr. Kerr took part. On the motion of Mr. Stephenson, seconded by Mr. Mackay, a very hearty vote of thanks was accorded to Mr. Macadam for his interesting paper.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The ninth general meeting was held at the Royal Institution, February 14th, 1878. The President, Mr. T. Fell Abraham, in the chair.

The minutes of the previous meeting were read and confirmed.

The donations to the Library were announced, and to the Museum a specimen of Ball fruit from Rangoon, and a specimen of Honey from Chili, from Messrs. Bathgate and Son. Votes of thanks were accorded the donors.

Mr. John Williams was duly elected a member.

Mr. Arthur G. Haddock read a paper on "The Theory of Flame." This paper will be printed in a future number of the Journal.

A lengthy discussion on the paper followed, in which the President, Messrs. A. C. Abraham, Davies, Evans, Hargreaves, Mason, Symes, Tanner, and others took part.

On the motion of Dr. Symes, seconded by Mr. A. H. Mason, F.C.S., a cordial vote of thanks was given to Mr. Haddock for his interesting paper.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

A meeting of the Executive Committee was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on Friday the 22nd ult., at 1·30 p.m. Mr. S. U. Jones (Leamington), President.

After a discussion of the Dental Practitioners' Bill by the solicitor and several members of the Committee, it was resolved that the President, together with the London members of the Executive Committee and the solicitor of the Association, should wait upon the promoters of the Dental Practitioners' Bill to urge such modifications in the Bill as shall give to chemists and druggists the right to be registered under it, and such other alterations as they may deem desirable.

The solicitor said he had perused Dr. Lush's Medical Act (1858) Amendment Bill, and no part of the Bill appeared to affect the interests of chemists and druggists.

The President said he was of the same opinion, and he should be glad if the solicitor would report upon pending cases under the Apothecaries Act.

[*** The remainder of the report, relating to the subject of Counter Practice, being merely an expression of opinion involving a personal attack upon an official of the Pharmaceutical Society, and for which there is no reasonable justification, its publication in these pages would be inappropriate.—Ed. Pharm. Journ.]

LEEDS CHEMISTS' ASSISTANTS' ASSOCIATION.

On February 14 the inaugural meeting of this Association took place (preceded by a dinner), at the Griffin Hotel, when a large gathering of masters and assistants was present, supported by prominent members of the medical and scientific societies. The Association is intended, by means of annual subscriptions of the members and with assistance from employers in the trade as honorary members, to promote and diffuse scientific and commercial knowledge amongst the assistants, by providing for them a room where they can meet for social intercourse and interchange of opinions. Weekly papers will be read on some given subject connected with the business to be followed by discussion. It is intended also to invite professors of standing to give lectures, and it is hoped that the employers will freely give their support, as an institution with these views must necessarily raise the status of the assistants, and thus advance the interest of their employers, and help the capital of the West Riding to maintain its proud position.

Mr. Councillor Stead occupied the chair, supported by Mr. Place as vice, and many influential friends. After the usual loyal toasts,

Mr. Highmoor proposed "The Medical Profession." He said the company present augured well for the progress of pharmacy. The medical profession had high claims on all classes of society, especially the chemists, and he esteemed it a high privilege to be associated with them in their endeavours to alleviate the sufferings of mankind, and in meetings of this kind to have their support, and as chemists to render them as much assistance as lay within our province. Speaking of the relations which ought to exist between the physician and the pharmacist, he said the Pharmaceutical Society is an examining body, but the students have to find their education where they can. In his opinion the medical profession stood in their own light and in the way of pharmaceutical progress, in not having chairs of pharmacy established in their own colleges, and making the attendance of students compulsory. By such a course this very important subject might be studied with an advantage that few medical pupils have any idea of. The pharmaceutical examinations would be greatly assisted, their value raised by good example, and a glorious future opened out for the field of pharmacy. The relationship between the two bodies would be enhanced, and they would mutually support each other's interest. The relation of pharmacy at present with the medical profession was very unsatisfactory and extremely delicate. Whilst the chemist and druggist could never be restricted from using the knowledge he had acquired, in respect to the action of simple medicines, or even their application in simple cases (which the profession would not look at), yet he is subject to a great temptation of falling into a custom of counter-prescribing, simply to accommodate his family customers. All this might be obviated were chairs of pharmacy established in connection with the profession, in which constant intercourse would lead to mutual respect and esteem for each other's calling.

The Chairman, in giving "Success to our Annual Gathering," expressed his regret that more of the chemists of the town were not present to show that their relations with their assistants could be something other than a mere business transaction; but no doubt when they found the great importance of the movement they would heartily support it. He reminded the assistants that they had shorter hours than formerly, and consequently increased opportunities for self-improvement. In looking at the results of the examination which they had now to pass, he found the percentage of failures to be 46 per cent., this should not be so, with such advanced facilities of education at the present time. He could not account for it, but he thought the rejections in the Preliminary examinations were to be traced to the fact that young men delayed going to them so long that they forgot much they had learned at school. When once they had passed the Minor he strongly urged them to go manfully forward and study for the Major. These examinations had tended to elevate the trade, and there could be little doubt that the improvement would continue until at length the chemists and druggists would be regarded as members of a learned profession.

The Rev. James H. McCheane, President of the Leeds Philosophical Society, proposed "The Yorkshire College of Science." He reminded them that he was one of the governors of that college, and it might be imputed to him that in commending such a toast he was pleading for "our noble selves." Well, he was ready to maintain that the Yorkshire College was a very noble feature indeed in the recent history of Leeds. It was increasing in usefulness and influence every day, and very soon its new buildings would begin to rise under good auspices. It was obvious what great service such an institution was capable of rendering to chemists' assistants in connection with their daily business, as well as in regard to general and scientific culture. The list of Gilchrist lectures for the present season was very significant of the advance the town had been making. Thanks to the college, all the lecturers and scientific teachers were Leeds men, whereas two years ago the names were those of strangers. He presumed that the invitation he had received was chiefly owing to his being the President of the Leeds Philosophical Society. In that capacity he was clearly under an obligation to evince his interest in any association that was linked as this was with the actual practice, as well as with the principles of science, and in these days, when there was so much to separate people into sects and parties, any movement was to be welcomed by the philosophical mind that brought young men together on the common ground, not of party, or of prejudice, but of their membership in one common calling, which was as honourable and useful as any business or profession that he knew of. As a clergyman he was bound to act upon the old saying: "Homo sum, nihil humani a me alienum puto." "I am a man, and in everything that concerns the needs or the nature of man it behoves me to take an interest,"—a somewhat free, but not erroneous, translation, and if there was one calling in life that was concerned with human needs, surely it was theirs. The days were past when in the celebrated Pickwick trial a chemist, in agony of mind, asked the judge to be excused attending court as he wanted to get back to his only assistant, whose mind was dark as to the difference between Epsom salts and oxalic acid. These things were of the dangers of the times that were past and of those times only. By the contact of mind with mind, as in such social and intellectual meetings as that, a most valuable help was secured to the education of both mind and character. He wished God speed to them all and their undertaking.

Other toasts followed, and the proceedings terminated with thanks to the chair, etc., etc.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.—ASSISTANTS' SECTION.

The first annual supper of the Assistants' Section of the Glasgow Chemists and Druggists' Association was held in the Regent Hotel, 221 Sauchiehall Street, on Wednesday evening, Feb. 6, at 8.30 p.m. Mr. W. Simpson, President, occupied the chair, supported by Dr. Nairne, Messrs. Pettigrew and Walker, and Messrs. Young, McLaren and Welsh, a deputation from the Edinburgh Chemists' Assistants' Association, Messrs. McMillan and Taylor acting as croupiers. About fifty sat down to an excellent supper, after which the chairman gave the usual loyal and patriotic toasts, which were heartilly responded to.

In proposing "Success to our Annual Gathering" he (the chairman) expressed his regret at seeing such a small number of assistants present, and said he thought the Association deserved better support from them seeing the good they derived from it. He alluded to the attempt to get a reduction of the Sunday hours last session, and thought the assistants had themselves entirely to blame for the failure. He commented in severe terms upon a number of druggists and doctors who, rivalling hucksters' shops, kept their shops open all day, more for the sale of "sweeties" and cigars than medicines.

Mr. Walker, in proposing the medical profession, said he thought pharmacy was greatly indebted to scientific medical men, as the majority of new pharmaceutical preparations were introduced by them. Alluding to the relations between doctors and druggists he thought doctors had as good a right to keep open shop as druggists had to keep branch ones without a qualified assistant in charge; in fact keeping open shop was the only way in which a young medical man could bring himself prominently before the public and into a practice in a town such as Glasgow.

Dr. Nairne in reply congratulated the Chemists and Druggists' Association on the advance they were making towards a reasonable separation between their own business and the profession of medicine. In Glasgow young medical men who were determined to get a city practice felt themselves compelled to keep an open shop, where they gave advice gratis and charged, ostensibly, for the medicine supplied in order to make a livelihood: that is to say they practically became druggists, till patients were sufficiently numerous to satisfy their wants. There were various reasons for this state of matters, all of which he hoped soon to see amended, and while medical men might yet be taught, even more extensively than they were at present, the practice of pharmacy, they would find it greatly to their advantage and to the interests of their patients to leave this kind of work in the future wholly in the hands of the true pharmacists.

Mr. McMillan in proposing "The Pharmaceutical Society," said that in every gathering of pharmacists throughout the civilized world the mention of the British Pharmaceutical Society could not fail to meet with a hearty and respectful reception. In spite of opposition and lukewarmness the Society slowly but steadily carried out the aims and aspirations of its illustrious founders. The Council of the Pharmaceutical Society had a great deal to contend with in the carrying out of the Pharmacy Act; and it appeared to him that, at the present moment, quite as much depended upon themselves as local societies, and as individuals, as upon the Council in the working of it. Scientific training could do a great deal, but it required to be supplemented by other kinds of knowledge, by other branches of learning, before the chemist and druggist could take that position in the public estimation to which the importance of his business justly entitled him.

Mr. J. Bardsley replied.

Mr. Taylor, in proposing "The Edinburgh Chemists' Assistants' Association," said that from the fact of its being newly formed, he could not say much about it; but from the energy and spirit which was characteristic of all the Edinburgh assistants, he was sure the success to which it was so justly entitled was not far distant. The only thing in which they were behind Glasgow now, was the hours of business. He believed it was the boast of the assistants of Glasgow that they had far shorter hours than their Edinburgh brethren. He failed, however, to see it, as a paragraph appeared in one of the daily papers advertising "an always open pharmacy," and it was quite a common thing to see shops open at 9.30, ay, even 10 p.m.

Mr. Young, in reply, expressed the pleasure he felt in being present as one of the representatives of their newly-formed Association. He spoke of the letter which appeared in the *Pharmaceutical Journal* (February 2nd), suggesting the formation of an assistants' section of the Pharmaceutical Society. He thought it deserved the consideration of assistants generally, not in the light of a trades' union society, but as a benefit society, whereby a young man out of a situation (through circumstances over which he had no control) might receive assistance if he required it. He could say very little regarding the Edinburgh Assistants' Association, only that it was formed, and by next session it was hoped to have it in full working order.

The other toasts were "The Strangers," by Mr. Paris. "The Committee," by Mr. Fenwick, "The Chairman," by Mr. Welsh, and "The Croupiers," by Mr. Pettigrew.

During the evening the company were greatly enlivened by songs and recitations, in which Messrs. Law, Macfarlane, Bruce, Taylor, Blain, and other gentlemen took part.

Proceedings of Scientific Societies.

UNIVERSITY OF EDINBURGH CHEMICAL SOCIETY.

The fifth meeting of the Edinburgh University Chemical Society was held on 20th February, John Gibson, Ph.D., F.R.S.E., presiding.

Mr. W. L. Goodwin read a paper on "A Method of Removal of Iron from Cupric Sulphate for Analytical Purposes," in which he stated that this could be performed by the replacement of the iron by cupric hydrate.

Mr. Alexander Macfarlane, M.A., B.Sc., read a paper on "The Disruptive Discharge of Electricity" in which he gave the difference of potential energy necessary to produce sparks at different distances, and also with different pressures, and gases as dielectrics.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, February 21st; Dr. Gladstone, President, in the chair.

After the announcement of visitors, reading of minutes, etc., the following certificates were read for the first time:—T. H. Norton and J. Tchermiac. The following gentlemen were elected Fellows:—L. T. Wright, W. Hudson, T. Lichtenstein, G. S. Johnson, and W. B. Lowe.

It was then announced from the chair that the following would retire:—From the office of Vice-President, Dr. Gilbert and Dr. Stenhouse; from the Council, Dr. Attfield and Messrs. Phillips, Tuson, and Thomas Hyde Hills. The names proposed to fill the above vacancies were, as Vice-Presidents, Professor N. S. Maskelyne and Dr. Angus Smith; as members of the Council, Dr. Tilden and Messrs. Riley, Warington and Carteighe.

The President then called upon Mr. J. Y. Buchanan to deliver his lecture—

Laboratory Experiences on board the "Challenger." Mr. Buchanan commenced by describing to the Society his laboratory. It was ten feet long, five feet eight inches broad, and six feet high, and although the dimensions seemed small there was practically quite room enough for one worker. The laboratory was situated in the middle of the ship, on the main deck, on the starboard; *i. e.*, the right hand side looking forward. A locker, two feet six inches high, and two feet broad, ran across the whole of the front side of the laboratory. Supposing that the visitor takes his seat on this locker looking aft the following description will convey a rough idea of the interior:—Immediately on his left is a gun port, which, in the absence of the gun, provides light and ventilation for the room; some light is also obtained from windows in the deck. The locker contains the stores of glass and porcelain, a balance, microscopes, etc. On the right is the blowpipe table, a spirit lamp formed of a wide-mouth stoppered bottle and having a large wick, was found to yield the most convenient flame. A tallow lamp was abandoned on account of the trouble of melting the tallow. On the left hand side further aft, is seen the principal working bench, three feet ten inches high, furnished with drawers containing the reagents, each bottle in a separate compartment. On the top of the bench battens are nailed, so that the bench presents the appearance of the frame of an ordinary door without the panels. Into the places where the panels should be the drawers of reagents can be fitted while in use, and so are prevented from shaking down. Ordinary retort stands were found to be useless, and the following stands were used: a half-inch metal rod was taken, and a long eye cut out at one end (like a needle: into this eye was fitted a staple driven into the joists forming the roof of the laboratory. By this arrangement the retort rod had a certain play up and down. The retort rings having been slipped on from the bottom, the rod was lifted, and then pushed down into a hole made for the purpose in the teak bench. This plan was found very convenient; when not in use the rods were turned up, the eyes forming the pivot, and hooked along the roof. For evaporating, drying, etc., a cast-iron frame set in gimbals and fixed to the side of the laboratory, was found quite sufficient even during the most violent movements of the ship. In the further left-hand corner are the sink and the distilled water vessel. Along the further end are wooden shelves with holes for various pieces of glass apparatus. Many vessels, etc., were slung from and between the beams supporting the deck. On the right-hand side are seen the bottles of standard solutions with burettes; the latter were made like pipettes, and filled by sucking up the solutions from below; in this way barium hydrate solution was found to keep its titre for two to three months, though used every day. On the same side the specific gravity apparatus, hydrometers and piezometers were stowed away. The lecturer stated that in all ordinary weathers, and in fact as long as the port, which lighted and ventilated his laboratory, could be kept open he found no difficulty in working on board ship.

Mr. Buchanan then proceeded to explain the various investigations he had carried out as to the compressibility of distilled and sea water, mercury, glass, etc. Before starting it seemed to him very desirable to have some means of checking the depths as indicated by the sounding line, and it was clear that some sort of barometric method must be used. Air had already been tried without success, and so water was finally adopted. The piezometer used consisted of a thermometer, the bulb having a capacity of about 9 c.c., the stem being thirteen inches long, and 1 mm. in diameter. The thermometer was inverted, after filling with water, in a little flask filled with mercury, the neck of the flask is connected to the stem by a short piece of india-rubber tubing, between which and the stem a piece of glass rod is inserted, so as to admit the external pressure to the surface of the mercury. By warming the bulb enough water is forced out to allow the mercury, on cooling the apparatus, to rise to a convenient height in the stem. In the stem is a little index similar to those used in Six's thermometer. The stem is divided into millimetres, and was carefully calibrated. If such an instrument be sunk with a sounding line it is clear that the water will be compressed, and that the mercury with the index will rise, such rise being the sum of the decrease in temperature and the increase of pressure. If a thermometer properly protected be sunk at the same time the temperature will be registered, and thus the increase of pressure can be found. Before starting it was thought that a gauge similar to those used with hydraulic pumps might be employed to determine the pressure, but on examination the gauge furnished was found unreliable, and after all, the length of the sounding line furnished the best gauge of the pressure, provided that care was taken that no currents, bad weather, etc., interfered with the result. If there is a current its existence is always rendered evident by the behaviour of the sounding line, as it goes up and down, so that practically there is no difficulty in saying when a sounding is good. The lecturer experienced some difficulty with the springs of the indices, and it was only on his way home, between Tahiti and Valparaiso, in a depth of 2000–2500 fathoms that he was able to get satisfactory results as to the compressibility of water. As a mean the compressibility of distilled water per 100 fathoms was found to be 0·0009, or per atmosphere, 0·000049; Regnault finding 0·0000486. The results at various depths agreed well; thus at 1000 fathoms 0·0008 at 2000, 0·0009; at 3000, 0·0008. The compressibility of sea water was determined in precisely the same instrument, and was found to be at 800 fathoms, 0·00077; at 1000, 0·00078; at 1500, 0·00073 per 100 fathoms. These experiments were all made by attaching the piezometer to the sounding line, the temperature being from 1° to 3° C. In order to determine the compressibility at higher temperatures recourse was had to a hydraulic instrument; but as no reliable gauge was at hand the only results possible were comparative; between sea-water and distilled water, at 26·5° C., distilled water = 100, 93·6, 25·8°: 92·0: 22·1°, 92·8: 22·5°, 92·0: 13·7, 92·6. A solution containing 4 per cent. sodium chloride, gave results, (distilled water = 100): 26·5°, 90·51 : 25·8°, 88·13 : 22·1°, 86·61: 13·7°, 86·84. The compressibility of mercury was next determined, and found to be, per 100 fathoms, 0·0000271, and per atmosphere, 0·0000015. The apparent compresibilities of water and mercury having been thus determined, the next task was the practical one of applying the results to control the soundings as obtained by the line, and the temperatures as indicated by the thermometer. Two piezometers, one charged with water, the other with mercury, were sent down on the sounding line. Now water is very sensitive to changes of pressure, but not to changes of temperature. Mercury, on the other hand, is less affected by changes of pressure, but considerably more by variations in temperature. The true temperature and true depth were obtained from the readings of the two instruments, thus: the rough depth as given by the sounding line is applied to correct the temperature as indicated by the mercury piezometer; by this temperature the reading of the water instrument is corrected, and thus the correct depth is obtained to within twenty-five fathoms. This is again applied to the mercurial instrument, and so by correcting backwards and forwards both the correct depth and the correct temperature are found. For great depths the piezometer above described is useless, a pressure above 3000 fathoms forcing the mercury into the bulb. To obviate this difficulty a bulb was blown in the middle of the stem, and its size was so arranged that the contraction up to 1500 fathoms was covered by this bulb, and so the stem was left to indicate greater pressures. The lecturer had endeavoured to measure the compressibility of glass, but for want of accurate measuring apparatus good results have not yet been obtained. The apparatus consists of a glass tube in which is a glass rod, slightly shorter than the tube, an index is brought down on to the rod; when exposed to pressure the glass tube contracts, the rod, however, maintains its length, and as a consequence the index is pushed up, and thus the amount of contraction is determined.

The lecturer then described the apparatus by means of which the amounts of oxygen and nitrogen in sea-water were estimated. About 900–1000 c.c. were used. The sample was collected in a brass cylinder furnished with stopcocks having a three-quarter-inch bore and was transferred to the flask in which it was to be boiled with as little disturbance as possible. To the flask is fitted an india-rubber cork, through which a glass tube, having a large bulb attached to it, passes; the tube and bulb are filled with distilled water, the end of the tube in the flask being closed by a simple device. The bulb is now boiled for ten minutes and the upper end of the tube closed. The lower end is now connected with the water in the flask and the latter boiled for one and a half to two hours. The gases evolved are collected in the bulb and analysed. The carbonic acid was determined by distilling about one quarter of a litre of water to dryness after the addition of 15 c.c. of barium chloride solution to prevent bumping. The steam was passed through a still and the distillate with evolved gases collected in flasks and tubes containing standard baryta water. This by titration with hydrochloric acid, rosolic acid being used as an indicator, gave the amount of carbonic acid. The following are the results of the analyses of about one-third of the gas samples obtained:—Oxygen + nitrogen = 100. In surface water, O = 33·67 at 25 fathoms 33·4 50 f. 32·3 100 f. 30·2 200 f. 23·4 300 f. 11·4 400 f. 15·5 800 f. 22·6 below 800 f. 23·5. So that from the surface downwards the oxygen decreases to 300 fathoms; below this depth it increases in amount. This increase is in all probability due to the decreasing amount of animal life at depths greater than 300 fathoms. Experiments with the tow net at various depths confirmed this view. As regards superficial distribution, the cold water at the Antarctic regions, both at the surface and below, is thoroughly aerated, the gases diminishing in quantity as we approach the equator, increasing again as we proceed northwards. From many experiments it was found that the absorption of nitrogen by sea-water varies considerably from that by distilled water, especially at high temperatures. The lecturer then pointed out the distribution of sea water as regards density in depth and superficially with the aid of several diagrams. Two regions of maximum density exist north and south of the equator, the north maximum being 25° north of the equator, the south about 15° south; towards the equator the density at the surface falls off, whilst towards the Arctic and Antarctic regions the density decreases rapidly. These regions of maxima correspond to the regions frequented by the trade winds. It is known that the south trade blows much nearer the equator than the north, and so the maximum of density is nearer the equator on the south. As to vertical distribution, the maximum penetrates some depth, but at 350 fathoms a great tract of water of low density is found. At the equator we find, first an increase as we go down, then a decrease, and last of all again an increase of density near the bottom. The densest water is found in the Atlantic. In the Pacific a certain imitation of the areas of dense water just described is found. Near ice very light water is found; again, near Hong Kong, just after the monsoons, the superficial water is very light, but during the dry season the water becomes more dense. The maxima of density lie in the north hemisphere to the S.W., in the south to the N.W. of the maxima of barometric pressure. It is at these latter spots that the cold dry winds descend from great altitudes and flow outwards, taking up moisture from the sea in their course and not becoming saturated until they are near the equator.

The President said that the very best thanks of the Society were due to Mr. Buchanan for the very careful lecture just delivered. He had invited them first into his small but compact laboratory, and explained the ingenious methods for determining various physical questions. He had then detailed the more distinctly chemical results, of great interest, as to the distribution of gases and especially as to the diminution of oxygen above and below 300 fathoms, with respect to which he would like to ask whether this always held good for 300 fathoms, whatever the total depth might be.

Mr. W. L. Carpenter had listened with great interest to the lecture, especially as he had performed the same sort of work on board H.M.S. Porcupine. His laboratory was much smaller, the naturalist and himself having a table only four feet square between them. He was glad to hear that Mr. Buchanan's extended experience confirmed in several respects the results which he had arrived at. He would like to ask why the carbonic acid had been separately determined? whether an increase in the quantity of oxygen had been observed during rough weather in the surface water? whether any effervescence had been seen in water brought up from great depths? and whether any chlorine estimations had been made in relation with the specific gravity determinations?

Mr. Warington asked if any determinations of ammonia and nitric acid had been carried out with reference to the theory that the trade winds came to our shores rich in ammonia while our soils lost nitric acid to the rivers, etc.

Mr. Buchanan replied that the depth of 300 fathoms was irrespective of the total depth; that the carbonic acid was determined separately because it had been shown that it could not be driven out of sea water by boiling *in vacuo* satisfactorily. In one case of cold water brought up near the river La Plata he had seen effervescence resembling that of natural seltzer water, but from want of time he had not made any number of chlorine, nitric acid, or ammonia determinations.

A hearty and unanimous vote of thanks was then given to Mr. Buchanan for his interesting lecture, and the Society adjourned to March 7, when the following papers will be read:—"On the Action of Ammonia on Anthrapurpurin," and "On Some New Derivatives of Anisoïl," by Mr. W. H. Perkin.

Parliamentary and Law Proceedings.

Methylated Finish.—Excise Prosecution.

At the Worship Street Police Court, Mr. Thomas Sanders, chemist and druggist, of Abney Park Terrace, Stoke Newington, appeared to a summons charging him with having sold methylated spirits without being licensed. —An inspector proved that on the 8th of November he purchased at the defendant's shop half a pint of spirits, which purported to be "methylated finish," but which on analysis at the laboratory, Somerset House, was found to contain less than the required amount of gum. A gallon of methylated spirit to be sold as finish, for which no licence was necessary, was required to contain 3oz. of gum, and the contention for the defendant was that if in the portion analysed there was less than the proper amount of gum, it was the result of accident.—The defendant, who conducted his own case, submitted that the analysis should have been conducted by troy weight and not avoirdupois, as had been the case, as then the proportion would have been correct. The admixture, he said, was made not merely for the trade of polishers and cabinet makers, but to prevent methylated spirit being drunk, as was at one time customary in the North of England. The defendant complained of the time the authorities had allowed to elapse before taking proceedings, and added that he had purchased methylated finish of the manufacturers, and sold it as it was supplied to him.—Mr. Bushby decided against the defendant, and ordered him to pay the minimum fine of £12 10*s.*—*Standard.*

Dispensing Memoranda.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be considered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.

[54]. Creasote Pills. The discussion with reference to creasote pills has arisen from a request in the dispensing memoranda for information how best to dispense pills containing each two minims of creasote and two minims of compound rhubarb pill. Referring to these pills in the month's summary the writer suggested that half a grain of calcined magnesia should be added to each minim of creasote prior to its being mixed with the compound rhubarb pill.

Mr. Martindale objected to the addition of calcined magnesia stating as a reason that it renders creasote pills "hard and insoluble as marbles." I replied to this by quoting the results of some experiments tending to prove that his extreme views on this subject must be in great part erroneous. In his reply he states that the remarks in his former letter refer to pills made of creasote with calcined magnesia alone. It would have been better if he had definitely stated this at the time, as, from the first, one formula only for the "creasote pills" has been under consideration; however, he adds that the pills would be about as inert as regards the creasote even with the addition of compound rhubarb pill.

The experiments on the solubility of these pills, detailed in my former letter, go far to disprove the statements in the first and third paragraphs of Mr. Martindale's last letter. Professor Redwood's three fundamental rules governing the choice of excipients may be accepted as safe truisms, but they throw no additional light on the subject in dispute.

The fourth paragraph commences "hyperbolically." Referring to this word in the dictionary, I find that hyperbola is "a figure of speech which expresses much more or less than the truth." It might be considered fortunate for its readers that the *Pharmaceutical Journal* does not deal much in hyperbole. If the paragraph were not hyperbolic, I would ask for some authority for the statement, or some facts to prove that there is just as great a difference between the action of creasote and creasote in its combination with magnesia as there is between sulphuric acid and epsom salts.

In the last paragraph Mr. Martindale states that "caustic alkalies decompose creasote." The combination which takes place does not imply decomposition in the ordinary acceptation of the term. Pereira, in giving the details of the process for the preparation of creasote, states, "it is mixed with strong solution of potash, which combines with the creasote, the alkaline solution is then neutralized by sulphuric acid and the oil separates;" "this treatment with potash followed by neutralization and distillation requires to be frequently repeated." Miller says "the heavier oil is then treated with solution of caustic potash; by this means the creasote is dissolved, when cold dilute sulphuric acid in slight excess is added to the liquid and the creasote set at liberty." "Creasote combines with potash, and forms with it a crystalline compound."

From my experiments already detailed it will be seen that the creasote pill made as suggested readily disintegrates when placed in lukewarm water, with the development of a strong creasotic odour,—the creasote therefore as a medicinal agent cannot be inert in these pills; also that the acid existing in the stomach is capable of combining with the magnesia and liberating the creasote previously combined with it may, I think, be fairly accepted from the results obtained in the said experiments and under conditions somewhat analogous to those which exist in the stomach.

My remarks throughout apply to the original combination the subject of the inquiry, two minums of creasote with two grains of compound rhubarb pill in each pill.

I send you by this day's post a specimen of the pills.

PIL. CREASOTI.

---

[64]. In reply to the query as to whether drops or minims should be used in the following mixture, I answer minims, as drops are of very uncertain size, in a great measure depending upon the shape of the lip of the bottle in which the acid. hydrocyan. dil. is kept, etc.:—

℞	Aq. Laurocerasi	℥ij.
	Vini Ipecac.	℥j.
	Chlorodyne	℥ij.
	Acid. Hydrocyan. dil. . . .	gtt. xx.
	Aquæ	ad ℥viij.

In fact, I think that whenever guttæ are prescribed minims should be, and invariably are used.

Collis Browne's chlorodyne I think should be used, as it is the best known, and sanctioned by medical men of the greatest repute.

C. E. P.

[64]. In answer to query No. 64 in the "Dispensing Memoranda" of last week's Journal, I certainly think that when "blue pill" is prescribed, "blue pill" should be used, and that it would be an unpardonable substitution to use hydrarg. c. creta, seeing that they are not chemically alike, hyd. c. creta containing two-thirds its weight of prepared chalk, and blue pill none.

When blue pill is prescribed with a soft extract I usually use the extract in the form of powder.

C. E. P.

---

[66]. Necessarily there is no separation in this mixture. I made it last Saturday, and it has stood until to-day (Tuesday) without the slightest signs of any separation.

I dispensed it as written, with the exception of adding the spt. æther. chlor. last. I should suggest that the separation which occurred in the mixture, as made by E. A. T., was due to one or more of the preparations used not having been prepared strictly according to the B. P. formula.

C. E. P.

---

[69]. In dispensing the following—

Pot. Iodid.		80 gr.
Mucilag.		℥ss.
Spt. Æther. Nit.		ʒss.
Aquæ	ad	℥ij.

When pot. iodid. is prescribed with spt. æther. nit., the spt. æther. nit., which is generally acid, should be first neutralized with carbonate of potassium, otherwise a portion of the iodine will be liberated from the iodide of potassium, and give the mixture a brown colour, more or less deep, according as the spt. æther. nit. was more or less acid. This liberation of iodine is completely prevented if the spt. æther. nit. be neutralized before using. I dispensed the prescription as follows:—

Put a quantity of powdered acaciæ equivalent to the ℥ss of mucilage ordered into a mortar, add ℥j of aqua and stir until a mucilage is formed; in this dissolve the potassium iodide, then add gradually the neutralized spt. æther. nit. with constant stirring, pour into the bottle and fill up with aqua. The mixture thus prepared has a whitish opaque appearance.

C. E. P.

Scarborough.

---

[69]. This can be made a perfectly clear mixture by dissolving the pot. iodid. in the water, then the mucilage, and shaking, then gradually adding the sp. æth. nit., shaking the bottle after each addition, letting it stand a short time until effervescence ceases.

E. J. EATON.

Lowestoft.

---

[71]. Last week I had to dispense the following prescription, which is a similar one to that referred to by "Ignoramus:"—

℞	Zinci Oxyd.		℥j.
	Ung. Cetac.		℥vij.
	Aq. Rosæ		
	Glycerin.	āā	℥j.

Ft. ung.

The following is the mode of procedure I adopted. First, melt the ung. cetac. to a creamy consistence, next add the aq. rosæ and glycerine (previously mixed), and stir well together. Lastly, add the zinci oxyd. well pulverized, and stir until cold.

The above method yields a very good ointment, and upon experiment I find that "Ignoramus" would be able to dispense his prescription in a similar manner to the above.

E. A. HANSON.

Leeds.

[72]. How should pills, as per prescription, be made? I put ♏v ol. carui, and used gly. tragac. as excipient. The pills were soft, and my customers complained of their being larger than those obtained from the first maker.

℞ Calomelas . . . . gr. iv
Pulv. Doveri . . . . ℈ij

Notes and Queries.

[578]. WRITING INK.—The *Bunzlauer Pharm. Zeitung* gives the following prescription:—

Take 7lbs. of logwood and 2lbs. of galls in coarse powder, and boil them with 60 pints of water for two hours. In the strained and cooled decoction dissolve 4 lbs. sulphate of iron, add 6 ounces, by weight, of strong solution of perchloride of iron and after having exposed the liquor to the air in an open vessel for ten hours, add finally 2 ounces, by weight, of acetic acid and gum acacia quantum satis.

HUGO W. LANGBECK.

Obituary.

Notice has been received of the deaths of the following:—

On the 1st of February, 1878, Mr. John Harvey, Chemist and Druggist, Newark. Aged 57 years.

On the 18th of February, 1878, Mr. Thomas Cook, Chemist and Druggist, Northgate Street, Gloucester, Aged 65 years.

On the 23rd of February, 1878, Mr. Thomas Colton, Pharmaceutical Chemist, Ousegate, Selby, Yorks. Aged 72 years. Mr. Coulton had been a Member of the Pharmaceutical Society since 1852.

On the 24th of February, 1878, Mr. Samuel Lacey, Chemist and Druggist, Vassall Road, Brixton. Aged 35 years. Mr. Lacey had been a Member of the Pharmaceutical Society since 1875.

Review.

PROCEEDINGS OF THE AMERICAN PHARMACEUTICAL ASSOCIATION AT THE TWENTY-FIFTH ANNUAL MEETING Philadelphia: Sherman and Co. 1878.

The Proceedings of the American Pharmaceutical Association for 1877 follows closely upon the heels of its English brother. The volume, as usual, commences with a number of reports, including that on the progress of pharmacy, which corresponds to the English Year-Book. Then follow the papers read during the meeting of the Association at Toronto, and after these the discussions respecting them.

Some of the reports contain very interesting information; for instance, that on the Drug Market includes an account of the collecting of Canada balsam, well worth reading. It will be remembered that the last meeting of the Association was held at Toronto, consequently many of the statements have a special bearing on Canadian circumstances. It appears that a portion of the trade in crude drugs that were formerly imported entirely from Europe has recently been diverted to New York. But the great bulk of Canada's supply of chemicals still comes from Great Britain, and it is admitted that the "prejudice" among physicians and druggists is strongly in favour of British goods. In fact, the reporter states, that it is doubtful if an ounce of quinine of United States' manufacture is to be found in half a dozen stores in the province. Under these circumstances it is not surprising to notice that a member has proposed to extend the influence of the Association—so far as this can be done by pen and ink—by declaring one of its objects to be "to unite the educated and reputable pharmaceutists of *America*," instead of the "United States" as heretofore.

The volume is only about two-thirds of the size of that for the previous year, but it constitutes a valuable addition to pharmaceutical literature.

A TREATISE ON THE MANUFACTURE OF PERFUMES AND KINDRED TOILET ARTICLES. By JOHN H. SNIVELEY, Ph.D., Nashville: C. W. Smith; London: Trübner and Co. 1877.

Until within the last few years, works on perfumery were scarce, and those which have hitherto appeared in this country, although affording very interesting reading, and giving processes mostly adapted for business on the large scale, were comparatively useless to the retail chemist and perfumer. The art of mixing perfumes satisfactorily is one which is only attained after considerable personal experience, and by long and continued training of the olfactory organ; hence good formulæ are of enhanced value to those who have no means of acquiring experience in the art, and for the same reason are generally kept as secret as possible.

Professor Snively's work is one, however, which bears the impress of the author's familiar acquaintance with the subject of which he treats, and will, we think, meet the wants of the retail chemist better than any book of the kind which has yet appeared in this country. How far this is owing to the work being published by an apothecary, it is impossible to say; but it is very certain that many of the formulæ are exceedingly good.

The first thirteen pages of the book are devoted to introductory matter; the various processes used on a large scale, such as enfleurage, distillation, etc., being briefly glanced at.

Then follow about eighty pages devoted to the crude materials used in perfumery, and the remainder of the book (more than one hundred pages) is taken up with formulæ for perfumes, sachets, pastiles, cosmetics, hair washes, hair dyes, dentifrices, etc.

In the portion in which the crude materials are described, a figure of the plant, etc., from which it is derived, the amount of essential oil it yields, and the uses to which it is put are fully entered into, and useful practical hints are often given; thus with regard to quillai bark:—

"It is crushed without much difficulty, but the powder arising in the operation is exceedingly annoying to the operator, causing violent sneezing and much irritation of the throat and even affecting the eyes; hence it should be moistened and simply bruised when prepared for maceration."

Remarks of this description abound, and show that the author must have acquired practical experience of the need of them. No one who has attempted to powder quillai bark, preparatory to making hair-wash from it, will forget the unpleasantness of the task if he has not adopted the precaution recommended in the above note. The index reveals the American origin of the work, for while we find formulæ for Florida water, bay rum, and other essentially American productions, recipes for milk of elder flowers, areca nut, and cherry tooth paste, tincture of myrrh and borax, and a few other favourite compounds in daily request in this country, are conspicuous by their absence. In a few instances too, better methods of manipulation might have been mentioned, as under rose lip salve, liquid rouge, and pearl powder. No work, however, has ever yet been published in which there was no room for improvement, and trifling omissions of this kind are easily remedied in a second edition. Taken as a whole, the book is well and carefully written, and the retail chemist and perfumer in this country will probably find not only much in it that will be new to him, but many recipes which he will be able to turn to a good account.

Correspondence.

Dental Practitioners' Bill.

Sir,—On the 13th inst, I wrote to Sir J. Lubbock, calling his attention to the fifth clause in the "Dental Practitioners' Bill." On the 21st inst. I received a reply from him. I enclose you copies of the correspondence which you are at liberty to publish, and which I think will be read with interest by those chemists practising dentistry.

There can be no doubt as regards our rights being protected by Sir J. Lubbock, and I think we may leave the matter in his hands with perfect confidence.

Thos. C. Maggs.

Yeovil, February, 23, 1878.

Copy.

"*Yeovil, February* 13, 1878.

"To Sir John Lubbock, M.P., D.C.L., F.G.S., etc.,
"35, Albemarle Street, London.

"Sir,—In the fifth clause of the Bill introduced by you to amend the law relating to dental practitioners, the words "either separately or in conjunction with the practice of medicine or surgery" have been supposed by some persons to imply a meaning so foreign from what I feel to be your intention, that I venture to address you on the subject.

"It is considered this might be interpreted as naming one of two classes of persons.

"1. Those who have practised dentistry and nothing else

"2. Those surgeons who have practised dentistry.

"This would leave out all others who added dentistry to a cognate art or profession, such for example as that of a legally qualified pharmaceutical chemist, while it would admit as qualified practitioners a mass, however ignorant, who had done nothing but draw teeth.

"The construction that I have heard put upon the clause, and which I think most agreeable to common sense and justice, is that all who have practised dentistry hitherto, whether in connection with surgery or not, are eligible.

"It would be a great satisfaction to pharmaceutical chemists practising dentistry to hear from you that the last interpretation expressed your views and intentions, and if you could honour me with a line to that effect I shall feel deeply obliged, and

"I have the honour to be
"Your obedient servant,
"Thos. C. Maggs."

Copy.

"*High Elms, February* 21, 1878.

"Sir,—I beg to acknowledge the receipt of your letter. My attention has been already directed to the point, and I am quite disposed to support such an amendment as you suggest.

"I am your obedient servant,
"John Lubbock.

"Thos. C. Maggs, Esq."

Sir,—Annexed I give you a copy of the reply by Sir John Lubbock, in answer to my letter to him of the 11th inst., suggesting that the words standing in the Bill "separately or in conjunction with the practice of medicine or surgery" should be amended thus, by adding the word pharmacy, "separately or in conjunction with the practice of medicine, surgery, or pharmacy."

His reply, I think, is highly satisfactory and will, I hope, lead to practical results.

Geo. Jas. Gostling.

Stowmarket, February 27, 1878.

Copy.

"*High Elms, February* 21, 1878.

"Sir,—I have duly received your letter in which there is much force. My attention has been already directed to the point, and I am quite disposed to support such an amendment as you suggest.

"I am your obedient servant,
"John Lubbock.

"Geo. Jas. Gostling, Esq."

Sir,—It is evidently intended by the expressed words of the "Dental Practitioners' Bill," that chemists who are now at this moment carrying on the practice of dentistry in connection with their own business or profession, should be entirely ignored, notwithstanding their right in common with others (who follow it separately) to the title dentist.

I would ask why the so-called dentist (without any diploma or qualifications) should be registered as a properly qualified dentist, according to the proposed Act, and the chemist who does possess in general some legal qualification, and who is equally efficient as a practical dentist, be excluded and not even allowed to register.

It would be very unjust if such a Bill were allowed to become law.

I sincerely trust this will not come to pass, and that may be safely predicted should the Pharmaceutical Society timely interfere in the matter by acting at once upon the suggestions which have been thrown out in your Journal.

W.

Burnley, February 21, 1878.

The Discrepancy of Examination Results.

Sir,—In reading over the report of the proceedings at the last meeting of Council, I feel considerably interested in the projected scheme of sending a deputation of Examiners from London to Edinburgh, and making a corresponding appointment of members of the Scottish Board to attend the examinations held in the metropolis.

While unwilling to trespass upon your space, I cannot refrain from expressing my firm convictions with regard to the cause of such a conspicuous want of uniformity in the results of the Minor and Major tests at the two places where they are conducted, a difference which seems to suggest to some minds the idea of unfairness on the part of the adjudicators.

I have often had to "assume the defensive" on behalf of the North British Branch, and assure the complainer of the strict impartiality, yet thorough sifting, manifested at both centres. The great outcry in England is to the effect that in Edinburgh the examiners are much more lenient than their southern brethren. Now the absurdity of such a rumour could only be paralleled by the assertion that when in one town, on a certain day, sixty per cent. of the candidates pass, while only half that number give satisfactory answers on the next, it may be inferred that either the questions put on the second day of meeting were twice as difficult, or else the examiners were in a crotchety mood.

I will venture to tender an explanation on the subject, though it may not allay the groundless suspicions of captious critics. In the first place I think Mr. Bottle is quite right in his surmise that the out-door situations (so general in Scotland), and consequent shorter hours of business, are more conducive to the maintenance of studious habits, than the long confinement to badly ventilated shops, followed up by restriction in the evenings which unfortunately is so customary in so many parts of England.

But I go further and say that the success of the "Canny Scot" is in great measure due to the indomitable perseverance and extreme caution, inherent in his nature, whereas the higher average of failures south of the border may be attributed to the lack of such a spirit, *i.e.*, the want of persistent application, the love of liberty, and a rather high estimate of ability, leading to premature attempts "to qualify."

However wise the adoption of Mr. Schacht's proposal may be, I consider it a one-sided investigation so long as the national traits of character are disregarded. While upholding the efficiency of either board and comparable degree of stringency, I do not doubt the possibility of attaining a still greater similarity, in fact a stereotyped system of dragging candidates through the ordeal, yet I fear the relative percentage of failures will vary but slightly from former results.

I do not say that the intellectual capacity of the Highlander is of a higher type than that marking the South Briton, although contrast of the form of cranial structure would indicate the prevalence of *Brachycephalæ* (short heads) north of the Tweed, while the long heads, *Doliocephalæ*, appear to predominate amongst the English people; and physiologists tell us that the former possess greater cerebral development than the latter. But "the race is not always to the swift nor the battle to the strong," so there is no reason why competitors from any part of this island should not equally distinguish themselves.

To remedy the evil, let masters be more considerate to their apprentices, allowing them opportunity for advancing in the pursuit of knowledge, so that with the motto "Slow but sure" (remembering the fable of the tortoise and the hare), they may push on with unflinching energy not only to pass through the "wicket gate," but steadily progress in the path they have chosen, culling flowers by the wayside, and reaping the harvest in the end.

In conclusion I may add that absolute uniformity can only be arrived at by abolishing the present system of oral examination and introducing printed papers and written answers (which may be checked by a second party), then all candidates would receive a fair test, and nervous individuals would stand the same chance as their less easily agitated fellows.

Newcastle-on-Tyne, Feb. 14, 1878. JAMES B. L. MACKAY.

THE PRELIMINARY EXAMINATION.

Sir,—Now that the question of the Preliminary examination has forced itself on the attention of the Council, I do trust that the matter in all its bearings will be carefully considered.

The large proportion of failures ever recurring in this department is becoming a serious affair, painful to the candidates themselves, to their parents and guardians, and last, not least, to their employers.

The question seems to resolve itself into two issues, either that the quality of the article examined is deteriorating, or, that the qualifying test is too stringent. Now, from all I can learn I do not think there is any falling off of the quality of the article, at least north of the Tweed. What the antecedents of the candidates are further south I leave for Mr. Schacht to determine. After some inquiry I find that for the last ten years at least, the chemists in Scotland are as careful as they can be to obtain proper, well-educated lads for apprentices. The metrical system I have no doubt is to blame for a great many of the failures, and this is a point where some latitude ought to be allowed in judging of the candidates, seeing that they have never, in a great number of instances, learned it at school, and on the day of trial they get bewildered with it. But why, it will be asked, were there so many failures at the last examination, when there were no metrical questions at all? I can only answer this on the supposition that the candidates had exhausted their powers preparing for the dreaded metrical, to the exclusion of the other questions. One point brought out at the discussion in the Council was that the middle-class education was defective, another was the nervousness of candidates, and a third was the remissness of superintendents. To give the question a practical turn, might I with all respect suggest the following?—

1. That four hours instead of three be the time for the examination.
2. That half a guinea only be exacted for each failure.
3. That in the event of the candidate's failing the first time, he should be informed what his weak point was.

These I consider modest demands on behalf of our young men, coming forward. Of course I throw them out like a ball set rolling, expecting a knock or two in the process. Something such as the foregoing, or a diminution in the number of points insisted on by the examining body would, I submit, be a boon to the candidates, while the "safety of the public" would not be interfered with.

I trust, Sir, that something will be done to allay the irritation, now almost getting chronic, in reference to this question, and that the result will be the framing of a new and equitable code of regulations for future guidance, which will satisfy the great body of the trade whether pharmaceutical chemists or chemists and druggists.

Stirling, February 13, 1878. WM. DUNCANSON.

[*** Our correspondent is under a misapprehension in supposing that the subject of the Preliminary examination has only now forced itself on the attention of the Council, or that it has not long since received careful consideration.

As regards the quality of what our correspondent designates "the article," there is another alternative which appears to have escaped him, viz., that its quality has been, and in many instances, still is, far below the requisite standard. Herein lies what we believe to be the true explanation of the many lamentable failures in an examination so simple as the Preliminary.—ED. PHARM. JOURN.]

V. A. W.—See Ure's Dictionary under "Acetic Acid."

Cera Alb.—Both the methods of carrying on business described would, in our opinion, be illegal. Should such proceedings be within your cognizance you are recommended to communicate full particulars to the Registrar.

A. P. S.—We believe there is no restriction on the practice of pharmacy in the colony at present.

"*Examination in Arts.*"—Apply to the Secretary, 17, Bloomsbury Square.

G. A. Watkins.—See an article on the Phosphate Syrups in the *Pharmaceutical Journal* for December 22 last, p. 481.

E. J. Wall.—Yes.

R. W.—Practically there is no difference.

J. W. J. T.—(1) Pepsine wine may be prepared by macerating pepsine in any wine suitable for the purpose. (2) No formula for the preparation has been published.

E. Kemp.—The specific gravity of bismuth is given as 9·83; that of thorium as 7·65.

W.—Not at present.

C. Collins.—The subject referred to in your letter shall have our attention.

W. S. Turnbull.—We know of no reason why the lotion described should produce a black stain upon linen.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Kay Bros., Mr. Campbell, Mr. Cox, Dr. Morel, Mr. Wade, Mr. Jackson, Mr. Stoakes, Mr. Haddock, Mr. Cleland, Mr. Wigner, Nil Desperandum, One who loves Justice.

CROTON OIL.*

BY HAROLD SENIER, F.C.S.

The late Mr. Warington in a paper published in the *Pharmaceutical Journal* (vol. vi., p. 382) gives a series of experiments from which he concludes that the solubility of croton oil in alcohol increases with the age of the oil or of the seeds prior to expression. Dr. Pereira had previously expressed a similar opinion, founded on experiments made by himself and also by Professor Redwood, as detailed in a paper published in the first series of the *Pharmaceutical Journal*, vol. ix., p. 499. I have recently been engaged in an investigation into the causes of these variations in solubility, and have a few observations to report which seem to be of interest.

In the first place, I examined the solubility of two samples of commercial oil, kindly furnished me by Mr. E. M. Holmes, one being about three months, and the other about three years old. These I afterwards supplemented by three other samples, one of which was expressed by myself. The mode of determining the solubility of the different samples was as follows:—10 cubic centimetres of oil were measured into a finely graduated hundred cubic centimetre measure, and 50 cubic centimetres of solvent added. The measure was then closed with a rubber stopper, the whole well agitated and allowed to stand until both the oil and the supernatant liquid became perfectly clear, and the line of demarcation well defined. This generally required from 12 to 24 hours, and then the reading was taken. This operation was repeated with fresh spirit until only an unappreciable amount of oil was dissolved on a fresh addition of the solvent.

My first experiments were made both with absolute alcohol and rectified spirit (specific gravity 0·838), the results of which showed that although absolute alcohol dissolved the soluble portion of the oil more readily than the rectified spirit, the final results were apparently the same. In all the succeeding experiments, therefore, rectified spirit was used, and it was found that to entirely separate the soluble portion from 3 to 5 agitations were necessary. The results of the examination of the five samples of oil before alluded to are given below in a tabular form.

No.	Age.	Percentage dissolved.
1.	Freshly expressed	20
2.	3 months	40
3.	3 years	55
4.	More than 3 years	60
5.	?	35

The above oils were all of British manufacture, and the experiments were made at a temperature of from 50° to 60° Fahr. These results tend to show that the solubility of croton oil in alcohol increases with increase of age, but none of the samples tried by me were found to be wholly and permanently soluble. In the experiments recorded by Dr. Pereira, it was found that all those samples of oil operated upon which had been expressed in this country dissolved in alcohol without subsequent separation at common temperature, and Mr. Warington describes one sample having that degree of solubility.

It is not, however, to these experiments that I wish to allude chiefly in this paper, but rather to some others to which they led. As a matter of curiosity I applied to my arm a small portion of the residual oil left after well washing with alcohol in one of the above experiments, and was surprised to find that it produced no effect whatever. I applied it in larger quantities with like result. I then evaporated, over a water-bath, the alcoholic solution of the oil and obtained a residue, which when applied to the skin was exceedingly active, giving evident signs of irritation in a few minutes, and in a few hours a distinct eruption. This experiment was repeated with each of the five samples above mentioned, and in every case the part soluble in spirit was found to be active, while that part insoluble in spirit was devoid of activity, that is, of the power of producing the characteristic eruption upon the skin.

By subjecting a larger portion of oil, No. 5, which is a commercial oil of guaranteed purity, to the solvent action of spirit, repeated until no more was dissolved, evaporating the supernatant alcoholic solution at 212° Fahr., and drying the residual oil at the same temperature, I obtained the part soluble in rectified spirit. This is a viscid oil at ordinary temperatures, of a reddish-brown colour with a slight fluorescence and the strong characteristic odour of croton oil. It is turbid owing to the suspension of a quantity of acicular crystals which are soluble on slightly warming the oil. At a temperature of 50° Fahr. the oil is too viscid to flow, and at 32° Fahr. it becomes of the consistence of butter. At 60° Fahr. it has a specific gravity of ·987. The oil insoluble in rectified spirit is at ordinary temperatures of a light yellowish colour, not fluorescent, having a very slight odour, quite clear, and begins to thicken only at a temperature of 16° above zero, Fahr. It has a specific gravity of ·924 at 60° Fahr. The oil soluble in alcohol when heated to 460° Fahr. by itself, and to 360° Fahr. with hydrochloric acid, and to the same temperature with a strong solution of potassium hydrate, does not appear to lose any of its activity; therefore the active principle is probably not volatile.

From the above experiments it may reasonably be concluded that for medicinal and pharmaceutical purposes an oil extracted by alcohol would be a more satisfactory preparation than the crude oil.

Whether the factor of age increases the gross activity of the oil, as it increases the soluble portion, I have as yet been unable to determine, but investigations upon this and other points are still in progress.

[*The discussion on this paper is printed at p.* 718.]

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, March 6, 1878.

DUBOISIA MYOPOROIDES, *R. Br.**

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

Some specimens of this plant having recently been presented to the herbarium by Dr. J. Bancroft, of Brisbane, an opportunity occurs of laying before the Society such particulars concerning the plant as can be readily obtained.

The duboisia is a small tree or tall shrub, about twenty feet in height, with long slender erect branches, arising from the stem at an acute angle, the leaves generally covering only the tops of the branches, so

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, March 6, 1878.

that except at the summit the woody portion of the tree is rather bare.

The leaves are alternate, shortly stalked, quite smooth, and entire, lanceolate in shape, from three to four inches long, and about one inch broad in the middle. The flowers, which are pale lilac or white, and very small, are arranged in terminal panicled cymes. The corolla is regular, bell-shaped, erect, and only two lines long. The stamens are didynamous, with the rudiment of a fifth one, and the fruit is small, succulent, and berry-like. From the above description it will be seen that the plant appears to be nearly allied to the *Scrophulariaceæ*, on account of its didynamous stamens, while in the regular corolla it approaches to the *Solanaceæ*. Accordingly, botanists have been somewhat puzzled as to which family it naturally belongs. Together with *Anthocercis*, *Petunia*, and several other genera forming the natural group *Salpiglossidæ*, it was, by several botanists, formerly placed in the *Scrophulariaceæ*, but has now found a resting place among the *Solanaceæ*. This view of its natural position receives confirmation from the fact that the properties of several of the plants of the group, such as *Anthocercis viscosa* and *Duboisia myoporoides*, have recently been found to possess properties similar to those of belladonna. The reniform seeds, with a wrinkled and pitted testa, also resemble those of many of the *Solanaceæ*.

Of the genus *Duboisia* the plant now under consideration is the only one known with certainty, although Baron von Mueller considers that two other plants, which he has provisionally named *D. Hopwoodii* and *D. Leichardtii*, should be placed in the same genus. Until the fruit of these plants is discovered, it is not certain whether they should be referred to *Anthocercis* or *Duboisia*, the former genus having capsular and the latter a baccate fruit.

Duboisia myoporoides is a native of Australia, occurring in various localities from near Sydney to near Cape York. It has been found also in New Caledonia, and more recently, by Baron von Mueller, in New Guinea also.

About Brisbane it grows plentifully on the borders of vine scrubs, and springs up after the forest of timber has been burnt off.

The history of the discovery of the properties of duboisia is somewhat interesting. Dr. J. Bancroft had been investigating the botanical source of pituri, and sent some leaves to Baron Mueller, who identified them with his *Duboisia Hopwoodii* and suggested that Dr. Bancroft should try the properties of *Duboisia myoporoides*, stating that in his opinion the leaves of that plant would be found to possess properties similar to those of stramonium. Dr. Bancroft followed out the suggestion, and tried an extract of the leaves upon some of his domestic animals. He found that the pupil of the eye became widely dilated, and that cats and dogs when under its influence walked about as if blind and helpless, falling over the least irregularity of surface, but that if let alone they would go to sleep. He then tried it on human beings in ophthalmic cases, and found its action both powerful and rapid in dilating the pupil of the eye. The extract appears to be almost equal to atropine in strength and is now used instead of that alkaloid both at Brisbane and Sydney. The aqueous extract is the preparation which has hitherto been used, the active principle not having been isolated. There is, however, every probability that it will be found to be an alkaloid similar to, if not identical with, atropine The properties of the extract have lately been examined by Dr. Ringer and Mr. Tweedy, and an account of their experiments appeared in the *Lancet* for March 2.

Dr. Ringer finds that besides dilating the pupil of the eye, it dries the mouth, arrests the secretions of the skin, and produces headache and drowsiness; it also increases the action of the pulse, antagonizes the action of muscarine, and after some days excites tetanus in frogs. Mr. Tweedy arrives at the conclusion that if there be any difference between them, the extract of duboisia is more prompt and energetic than atropine and certainly very much more so than the strongest extract of belladonna. When diluted with twenty parts of distilled water the solution does not cause smarting and but little watering of the eyes, while the pupils become more rapidly and completely dilated than when the undiluted extract is used. In every case in which the duboisia has been used by Mr. Tweedy its action has been beneficial, and he is tempted to believe superior to that of atropine.

For the above notes I am largely indebted to Dr. Bancroft's paper on Duboisia and Pituri, read before the Queensland Philosophical Society at Brisbane.

My object in bringing these notes before the Society is to point out that there exists a plant in tolerable abundance from which an active principle may probably be obtained more economically than from belladonna, and which possesses the same properties as atropine. As an external application duboisia might also prove a valuable remedy.

[*The discussion on this paper is printed at p.* 720.]

NOTE ON THYMOL.

BY W. WILLMOTT.

The substance most frequently in use at the present time as an antiseptic is undoubtedly carbolic acid, and this is so unexceptionable in all respects save one, that it will presumably be difficult to find any compound of a similar character that will permanently take its place. Carbolic acid, however, is an irritant poison, and even when used surgically in the form of spray, or interspersed through the now familiar gauze, is liable to become absorbed into the circulation. For this reason any available substance of a non-poisonous or non-irritant character, which may be shown to possess equivalent antiseptic power, would be gladly welcomed as supplemental to it. Considerable attention has of late been directed to thymol, and, unquestionably, thymol is a very powerful antiseptic.* I have recently tested its effects in varying proportions on some of the more putrescible infusions, commencing with the two-thirds of a grain to the ounce, or 1 in 720, and gradually decreasing the quantity down to the forty-eighth of a grain to the ounce, or 1 in over 20,000.† In the case of infusion of hay there was not a single breakdown in the whole series, though the specimen prepared without the antiseptic gave way within

* I am not prepared to endorse the conclusion of Bucholtz that thymol possesses ten times the strength of carbolic acid. In my hands it has proved only as four to one.

† The thymol used was obtained from Messrs. Morson and Son, of Southampton Row, and this I found to be fairly soluble in 720 parts of distilled water (gr. j in ℥iss) at or above 120° Fahr. There was slight opalescence when cold, but no crystalline or other deposit.

the usual three days. Here, then, was a distinct effect produced in the wide proportion of 1 to 20,000, or, strictly speaking, 1 to 23,040. Calumba broke down at the one-sixteenth of a grain, the one-twelfth of a grain remaining intact. Gentian, which is not so putrescible, held its ground up to the one-twenty-fourth of a grain, but old hay, which is extremely liable to ferment, succumbed in every instance above the one-eighth of a grain, at which point it remained without change. It was an exceedingly interesting experiment now to innoculate the pure infusions with living bacteria and note the result. So far as it has yet gone (and time may modify the conclusion), the inference to be drawn from this experiment is, that, well within the range of its solubility, thymol not only prevents the quickening of germs, if germs they are, but arrests the growth of developed organisms. This, of course, is a very important element in the case.*

But though thymol may be an effective preservative as regards putrescible infusions, it does not necessarily follow that it will be found efficient or even available for the antiseptic treatment of wounds, because the conditions are different. Very good results, however, appear to have been obtained from its use in this way by some professors in Germany.

With regard to its internal administration as an antiseptic febrifuge, we must not, I think, be too sanguine of its success. Many substances of a similar kind have already been tried, such as sulphurous acid, peroxide of hydrogen, chloroform, salicylic acid, and so forth. All these are powerful non-poisonous antiseptics, and yet they fail to apply themselves to the doctrine of *contagium vivum*. It is quite possible, however, that thymol may be an exception to this rule.

Referring for a moment to the solvents of this substance (a point which has already been ably dealt with by Mr. A. W. Gerrard), we should rather expect that chloral hydrate, itself a good antiseptic, would have some solvent action upon it, and so, in fact, it has. If thymol be dissolved in a small quantity of absolute alcohol, the mixture is not soluble in distilled water, but it is freely soluble in a strong solution of chloral hydrate when the proportion reaches 1 of thymol to 12 of the solid hydrate. The thymol in this combination (about 20 grs. in the ounce) is again soluble in distilled water to the extent of about 1 in 600. The gain is not much, but I mention the fact for what it may be worth.

Though promising to take an important position amongst antiseptics, the progress of thymol in this direction is not, perhaps, of so marked or rapid a character as might be desired.† On the other hand, the essentials of ready solubility, convenience of application, and certainty of result, seem more than likely to secure indefinitely for carbolic acid—with which comparisons have been made—a prominent share of the high favour it now so justly commands.

* The results here given are entirely independent of conclusions arrived at by MM. Bucholtz and Lewin in their experiments with this and other substances of a like nature.

It may be worth remarking that the antiseptic power of commercial oil of thyme is not altogether lost by the absence or withdrawal of the thymol it is supposed to contain. This oil is sufficiently soluble in water, with or without extraneous aid, to render it an antiferment of considerable potency. Hence, probably, its good effect in preventing or retarding the rancidity of oils and fats.

Thymol, in solution, exposed to the air, passes quickly away. A fully protected specimen left in an open vessel a few days since is now being rapidly attacked by the mould fungus.

† It may be mentioned, as a circumstance favourable to its increasing use, that it is now undergoing an extended trial in the practised hands of Professor Lister, who, for the present, gives the preference to the formulæ successfully adopted by Volkmann.

HYDROBROMIC ETHER.*

BY JOSEPH P. REMINGTON.

Hydrobromic or bromhydric ether, C_2H_5Br, although discovered so long ago as 1827, has remained in comparative obscurity until lately.

Attention has been drawn to it through its asserted superiority as an anæsthetic to the agents usually employed, and reasoning from its chemical composition and the therapeutical effects of its component parts, it is really surprising that it has not been brought to notice before, and used extensively. Under the head of a "New Anæsthetic Agent,"† a notice, as follows, appears of it: "Rabuteau, in a memoir read before the Académie des Sciences, states that he has investigated the physiological properties and mode of elimination of hydrobromic ether. He has satisfied himself that this anæsthetic agent, which possesses properties intermediate to those of chloroform, bromoform, and ether, might be advantageously employed to produce surgical anæsthesia. The hydrobromic ether is neither a caustic nor an irritant. It can be ingested without difficulty, and applied without danger, not only to the skin but to the external auditory meatus and to the mucous membrane. It is eliminated completely or almost completely by the respiratory passages in whatever way it may have been introduced into the system." ‡

Dr. Lawrence Turnbull, of Philadelphia, is at present engaged in investigating its physiological properties, and measurably confirms Rabuteau in his views, although his labours are as yet not complete. At the request of Dr. Turnbull, the writer undertook the preparation of the compound, and found that several methods had been suggested. Almost all of them were tried with a view of developing the most practical formula, and the processes will be considered in the order of their publication, and all, it will be seen, depend upon the action, in some way or other, of bromine on alcohol. Serullas, who is entitled to the credit of discovering the liquid, prepared it as follows: One part of phosphorus and forty parts of alcohol of 38° Bm. are introduced into a tubulated retort, and seven or eight parts of bromine gradually added, whereupon the mixture becomes heated and hydrobromic and phosphorous acids are produced. The tubulus is then closed, the mixture distilled at a gentle heat, the distillate collected in a cooled receiver, and the hydrobromic ether separated from it by water, to which, if the distillate contains acid, a small quantity of potash is added.

Löwig prepares it as follows: "Absolute alcohol gradually mixed in a distillatory apparatus with a treble quantity of bromine, and heated from without, towards the end of the process yields a distillate consisting of two layers. The lower reddish stratum, which consists of bromide of ethyl, a small quantity of bromide of carbon, C_2Br_4, and free bromine, is freed from the latter by agitation with dilute potash till it loses its colour, and then from bromide of carbon by distillation."

De Vrij states that it may be prepared by distilling four parts pulverized bromide of potassium with five parts of a mixture of two parts strong sulphuric acid and one part of alcohol of 96 per cent.

Personne (*Compt. Rend.*, lii., 468) recommends for its

‡ *Med. and Surg. Rep.*, February 24th.

preparation the use of amorphous instead of common phosphorus. Forty grams amorphous phosphorus are mixed in a retort with 160 grams absolute alcohol, and 100 grams of bromine are slowly poured in through a narrow tube passing through a cork fitted into the neck, the retort being kept cool. The mixture is then distilled into a cooler receiver, the distillate treated with water, and then dried over chloride of calcium and rectified.

Hofmann, whose valuable researches on the anilins have rendered his name famous, in the course of his indefatigable pursuit after colours hit upon a method of making ethyl bromide pure enough for his purposes by simply heating amyl bromide with ethyl alcohol.

Amyl bromide, $C_5H_{11}Br$, is prepared by saturating amyl alcohol with gaseous hydrobromic acid, mixing the saturated solution with an equal volume of the aqueous acid, sp. gr., 1·5, and digesting slowly at the heat of a water-bath in a suitable vessel, finally washing the product with water.

The reaction which takes place when amyl bromide and ethyl alcohol are mixed is represented by the following formula:

$$B_5H_{11}Br+C_2H_5OH=C_5H_{11}OH+C_2H_5Br.$$

De Vrij's process, whilst promising good results with a minimum amount of labour, was found to produce some common ether through the action of the sulphuric acid on the alcohol, which thus contaminated the product. The process of Serullas was not desirable on account of the necessity for great care in avoiding explosion on bringing such active agents as phosphorus, bromine, and absolute alcohol together.

Bromoform, $CHBr_3$, might be a contamination also here, as its method of production by action of bromine and potash on alcohol would indicate.

The following formula in the writer's hands was found to possess less objections, and to produce a purer hydrobromic ether than any of the others that were tried:

Thirty-three troy ounces of absolute alcohol are introduced into a retort or flask, and the whole placed in an ice or cold water-bath, and allowed to become thoroughly cooled. Six troy ounces of amorphous phosphorus are then added to the cooled alcohol and the whole shaken. A glass-stoppered bottle of the proper size to hold twenty-six troy ounces of bromine is now selected; this quantity is then weighed into it, and having inserted a small fragment of broken glass between the stopper and the lip of the bottle the stopper is secured in this position, so that the bromine may be readily dropped on inverting it without the escape of any more fumes than is necessary.

The bromine is now to be slowly dropped into the mixture, care being taken to avoid too great elevation of temperature. When all of the bromine is added the whole mixture is allowed to stand twenty-four hours, when the flask is connected with a good distillatory apparatus and placed in a water-bath, and the distillation is continued as long as any liquid comes over. The distillate is then washed with water, and if acid to litmus-paper a small quantity of potash or soda solution is added to the water, and after separating the hydrobromic ether from the water it is redistilled after adding some fragments of chloride of calcium to the flask, to free from remaining traces of water.

Hydrobromic ether is a transparent colourless liquid, having an agreeable ethereal odour; heavier than water; specific gravity, 1·40 (Löwig); vapour density, 3·754 (R. Marchand); very volatile; boiling point, 40·7 C., when the barometer stands at 757 mm. (Pierre). Löwig considers its taste as strongly and disagreeably sweetish with a somewhat burning after-taste. The vapour when inhaled exerts an anæsthetic effect like chloroform. It is sparingly soluble in water, but mixes in all proportions with alcohol and ether.

It burns with difficulty, but with a beautiful green flame, which does not smoke, a strong odour of hydrobromic acid being at the same time evolved (Löwig). It is not decomposed by nitric acid, sulphuric acid, or potassium. With ammonia it yields hydrobromate of ethylamin.

DIALYSED IRON.*

BY W. H. PILE.

The attention of the medical fraternity has recently been directed to the subject of dialysed iron, or, as termed in Europe, ferrum oxydatum dialysatum. Although not entirely unknown in the United States, having been employed in France and Germany for some time, and its therapeutic virtues highly extolled in various European journals, it appears to have suddenly sprung up into notice, and the demand for it could hardly be met at first. However, accommodating manufacturers, ever alive to the wants of their co-labourers, soon undertook to supply the new demand, and learning that the only genuine article, so called, from Paris, would cost about \$5 per pound, our friends generously offered their equally reliable solution at only \$3 per pound. In a couple of weeks the price was still lower, falling to \$2·50, \$2, \$1·50, and we have now before us a card in which the writer, frankly admitting the enormous and unreasonable charges of his predecessors, offers a solution at \$1 per pound. It has certainly not reached bottom yet.

Having our thoughts directed to this subject, and learning from Graham's investigations on dialysis that chloride of sodium would pass through a parchment septum with greater rapidity than any other crystalloid substance, we concluded to use a solution of carbonate of soda in place of aq. ammonia, which was proposed by others. From a few random notes taken at the time, August 1st, 1877, we read: That to a pint of sol. sesquichlor. iron, U. S. P., add slowly, and with constant stirring, a cold saturated solution of carb. soda until a small quantity of the precipitate carb. iron remained undissolved. Poured the whole on the floating dialyser, which consisted of a sheet of genuine parchment-paper firmly bound to a broad hoop and immersed in a tub of pure water. Here I may remark that the gravity of this solution was 1·175. In twenty-four hours, the water in the tub, which had become strongly saline, was replaced with fresh water. The gravity of the iron solution was now only 1·055. This was found to depend not alone on the removal of the chloride of sodium which had passed through the parchment, but upon the passage upwards of a large quantity of water. By continuing this daily change of water for five days, the gravity of the iron solution becoming daily less and the quantity at the same time increasing, I found the quantity in the dialyser to be nearly five pints, and it was then nearly tasteless. Replacing the solution in the dialyser again, with the addition of a slight excess of sol. carb. soda, continued the process for three days more. The finished product was then found to have a gravity of 1·0295, tasteless, clear, and bright. By evaporating 100 grs. of this to complete dryness 5 grs. were left. Samples of this solution are here shown. From an experiment with a solution obtained from another house, the gravity of which was only 1·022, I obtained a dry residue of not quite 3 grs., while from still another, of gravity of 1·029, a residue of 5 grs. was left. The taste of all these samples was about similar. They all show the presence of hydrochloric acid by precipitating with ammonia, filtering, and saturating with pure nitric acid, and testing with nitrate of silver. The amount of acid in these, however, I did not determine from want of time. The gravity I suggest would give a reliable test of the strength of the preparation, 1·029 = 5 per cent.

THE WEIGHTS AND MEASURES BILL.

THE correspondence between the Board of Trade and the President of the Pharmaceutical Society, which came under the consideration of the Council at its meeting in February, will have made known to our readers the intention of the Government to bring in a Bill to consolidate the law relating to weights and measures. This Bill has now been printed, and on Tuesday last it was read a second time in the House of Commons and referred to a Select Committee. Although professedly only a consolidation of the existing law, as contained in various statutes dating from Magna Charta onwards, it is necessarily more than this, for whilst it was not primarily intended to ask Parliament to do more than to say whether the present law is or is not correctly re-enacted in the Bill, yet the bringing into one Bill of the contents of several Acts passed at different and, in some cases, distant dates has necessarily involved certain amendments of detail. These amendments may be divided into three classes: (1) those necessary from the consolidation of laws varying for different parts of the kingdom; (2) those necessary through changes of circumstances and practice that have grown up and become partially sanctioned since the passing of certain Acts; and (3) those desirable for removing doubts as to the construction of the law and for the correction of mistakes. In the third class of amendments specially, and in the Act generally, there are several points worthy the attention of pharmacists.

The principal clause of the Bill, the 19th, enacts that every contract, bargain, sale, or dealing in the United Kingdom, for work, goods, wares or merchandise, or other thing done, sold, delivered, carried, or agreed for by weight or measure, shall be deemed to be made according to one of the imperial weights or measures "ascertained by this Act," or some multiple or aliquot part thereof, or if not so made, with the exception to be presently mentioned, shall be void. Such dealings are for the purposes of the Bill defined as "trade," and any person trading by any denomination of weight or measure other than one of the imperial weights or measures, or some aliquot part thereof, is to be liable to a fine of forty shillings for every such sale.

The "imperial measures of weight and capacity" are those with which we as pharmacists are most concerned. The latter may be briefly dismissed with the statement that the gallon is to be the unit or standard of capacity from which all other measures of capacity, as well for liquids as for dry goods, shall be derived, and the gallon is, as at present, to contain ten avoirdupois pounds of distilled water weighed in air at a temperature of 62° Fahrenheit, and with the barometer at 30 inches.

The measures of weight are to have for their unit the imperial standard pound, which is identical with the present avoirdupois pound, and the relations of this to the dram, ounce, stone, hundredweight and ton, are defined in accordance with and are to be known as the avoirdupois system. But there is to be one notable addition, and that is the avoirdupois grain, or the one-seven-thousandth part of the imperial standard pound, the Bill thus practically endorsing the action of the Medical Council in introducing an avoirdupois grain for the purposes of the British Pharmacopœia. In the clause applying the Bill to Ireland, however, the grain is omitted, and the "quarter" is introduced. There is one exception to the avoirdupois system, the ounce troy, which is defined as 480 grains, but the troy pound and the troy pennyweight are omitted.

By clause 20, all articles sold by weight are to be sold by avoirdupois weight, except that gold and silver, and articles made from them, also platinum, diamonds, and other precious stones, may be sold by the ounce troy, or by any decimal parts of such ounce, and drugs, when sold by retail, may be sold by apothecaries' weight. Every person who acts in contravention of this clause is to be liable to a fine not exceeding five pounds. We may suppose that the permission to use apothecaries' weight in the retail sale of drugs is a concession to the opinion expressed by the Council of the Pharmaceutical Society, but it is worthy of note that whilst it has been considered necessary to define the troy ounce, no definition is given of any of the weights of the apothecaries' system. Further, although clause 24 enacts that any person who has in his possession for use for "trade" a weight or measure which is not of the denomination of some Board of Trade standard is liable to a fine of five pounds for a first offence, and ten pounds for a second, neither the scruple nor the drachm apothecaries' appears as such in the list of Board of Trade standards given in the second schedule to the Bill.

We are sorry to notice, moreover, that in making what are termed in the memorandum accompanying the Bill "inevitable amendments" for the purpose of clearing up doubtful points, a decidedly retrograde step has been taken with respect to the metric system. It will be recollected that in 1864 an Act was passed, the preamble of which recognized the expediency of legalizing the use in this country of the metric system of weight and measures. The three sections of the

Act, however, whilst establishing the validity of contracts or dealings in which the weights or measures expressed or referred to are weights and measures of the metric system, hardly went so far as might have been anticipated from the phraseology of the preamble, and the Scotch and English legal authorities are at issue as to whether, this Act notwithstanding, the use of a weight or measure that is not an imperial weight or measure is or is not illegal, even when not used for commercial purposes. The present Bill cuts the knot by proposing to repeal the Act in question. In its place it enacts, as previously quoted, that none but imperial weights and measures shall be kept or used for "trade" purposes. On the other hand this limitation of the prohibition to weights used for "trade" purposes allows of their being kept for scientific purposes. Neither is a contract or dealing to be invalid because the weights or measures expressed or referred to therein are those of the metric system; but the third schedule of the Bill contains a table giving in terms of imperial weights and measures the equivalents of the weights and measures of the metric system, and this table may be lawfully used in computing and expressing the weights and measures of the metric system. So that it would appear that if a pharmacist had a foreign prescription, expressed according to the metric system, brought to him to dispense, he would not be at liberty to use metric weights and measures, although they might be in his possession for other than "trade" purposes, and he would have to render the quantities into their equivalents of the imperial system.

But although the Bill contains some features which, in our opinion, might be advantageously altered, it would be a decided gain to get the law relating to weights and measures thus concentrated into one Act. The consideration of the subject would be thus much simplified, and a clear perception of the future modifications that may be necessary much facilitated.

THE BOTANICAL SOURCE OF TOBACCO.

In the recently published Catalogue of the Museum of the Pharmaceutical Society, *Nicotiana rustica* is said to yield "Latakia, Turkish and Manilla" tobacco and *N. repanda* "the Cuban and Havana." These statements, which are made in several materia medica treatises, including 'Pharmacographia,' whence they have been copied into 'Medicinal Plants,' are incorrect. With regard to Latakia tobacco, it has been recently conclusively shown to be manufactured from *N. Tabacum* and not from *N. rustica*. As to Cuba and Manilla tobaccos, we are not aware of the original source of the above statements or of the data upon which they are founded. *N. repanda*, Willd., is a Mexican plant with small foliage; the authority for its occurrence in Cuba is Dunal, who referred to it the *N. lyrata*, H. B. & K., which was found near Havana in that island. During a visit to London last year Senor Vidal of Manilla examined the species of *Nicotiana* in our great herbaria, and he stated that, so far as he knew, no such plant as *N. repanda* is now found in Cuba either wild or cultivated, and that the whole of the tobacco crop now grown there is the ordinary large-leaved form of *N. Tabacum*, var. *macrophyllum*, Dun. He also stated that the Manilla tobacco is absolutely identical with that of Cuba, having indeed been imported there from the latter colony. It thus appears that the old well-known species *N. Tabacum* affords the bulk of the best tobaccos of the world.

QUOS DEUS VULT PERDERE DEMENTAT PRIUS.

The House-Surgeon at the West London Hospital (Mr. E. Wilson), in a communication to a recent number of the *Lancet*, supplies a fresh illustration of the fact that human stupidity may sometimes triumph over poison cupboards, poison bottles, poison labels and all their allies. A woman and her daughter were recently admitted to the above hospital suffering from having swallowed between them an ounce and a half of lotion, containing about three grains of sulphate of atropia. A bottle having been required, and none other being handy, the poison label was scratched off that in which the lotion had been supplied, and the lotion poured out into a tea cup. Subsequently the patients, forgetful of what had been done, and not noticing the lotion, had filled the tea-cup with tea and drunk the mixture between them. Under suitable treatment both patients recovered.

A continental patient, however, according to the *Belgian Medical Press*, recently outdid even this, and succeeded in making his medical attendant *particeps criminis* in what might have otherwise been designated a suicide. The man was suffering from lead paralysis, and had been ordered to take two strychnine pills. These producing no effect, the quantity was increased, but still with no result. At last the medical professor under whose charge he was, increased the dose to five, with the difference, however, that he saw them taken himself. Two hours afterwards the patient was dead, and the previous doses of pills were found under his pillow.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A Meeting of the above Association will be held on Thursday evening, March 14, at 8 o'clock, when a paper will be read by Mr. W. R. Dunstan on "The Chlorides of Iodine."

DEATH OF AN ANNUITANT.

We regret to have to announce the death of another Annuitant on the Benevolent Fund in the person of Mrs. Sophia Wick, who died on Sunday last, March 3rd. Mrs. Wick was elected an Annuitant in 1874, after the death in the same year of her husband who had also been an Annuitant.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, March 6, 1878.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atkins, Betty, Bottle, Churchill, Cracknell, Gostling, Greenish, Hampson, Hanbury, Hills, Mackay, Robbins, Sandford, Schacht and Shaw.

The minutes of the previous meeting were read and confirmed.

The Deputation to Scotland.

The President said he felt it only right to say a few words in reference to the deputation which was appointed at the last meeting to visit the North British Branch on the occasion of the last examination. It was decided by the Council that two members of the Board of Examiners should be requested to form part of the deputation, but upon the matter being brought before the body, three gentlemen were nominated, Messrs. Corder, Moss, and Taylor, from whom he felt it difficult to make a selection. He therefore took upon himself the responsibility of asking all three to go to Edinburgh, feeling that in their persons were represented the three main departments of the examination, viz., Chemistry, Botany, and Pharmacy. It was not his place to say anything in regard to the nature of the examinations, on which no doubt those gentlemen would make a report to their Board. He could only speak as to the general system of examination as carried on in the North, and he must say at once that he was exceedingly gratified in all he saw of the arrangements as far as he could understand them. In the first place the accommodation was much better than it was when he visited Edinburgh a few years ago; there were three rooms, the largest of which was a light, pleasant room, well adapted for the purpose; the middle room was devoted to dispensing, and another room at the back was well adapted for the chemical part of the examination. The dispensing department he thought reflected great credit on the examinations in the North, and probably the deputation would be able to indicate to the London Board certain points in which they might introduce improvements, though of course he did not wish to prejudge any decision the examiners might come to. There were some little matters, perhaps, as with regard to the reading of prescriptions, in which they were not quite on all fours with the practice in London. The larger room contained the museum, which was by no means to be despised. He was exceedingly pleased to find it was so good; some of the specimens, if not unique, being such as were not to be found in the museum at Bloomsbury Square. He hoped, therefore, that when a supplement to the catalogue was published, such specimens in the Edinburgh museum as were worthy of special notice would be included in it. With regard to the examinations generally, they appeared to him to be conducted very much in the same way as in London. A few differences in the merest detail were all that occurred to him. He noticed, however, that the examiners were, as a rule more advanced in years than the English Board, and he did not know that they were any the worse for that. He had been much pleased with the earnest and kind way in which they conducted the examinations. He believed it would be very useful if such an interchange of visits were made more frequently, as thus any misunderstanding as to the mode of conducting the examination which might be supposed to exist would be removed. He hoped, therefore, that the visit would soon be returned by a deputation from the Scottish Board; and in conclusion, he expressed his warmest thanks to Mr. Mackay for his unremitting efforts to make the visit of the deputation pleasant.

Mr. Sandford, after heartily confirming the remarks of the President, said he went to Edinburgh, feeling it well that there should be an occasional interchange of communications between the bodies North and South of the Tweed, and he returned more fully convinced on that point. With regard to the examinations no doubt the examiners who had attended would make a report, but speaking generally, he could not see anything to find fault with. The examiners seemed to be quite as strict as in London, but were perhaps more kind in leading on their candidates; as he looked upon it to be as much the object of the examiners to pass candidates as to reject them, he thought they were quite right in doing so. They did not put the answers into the young men's mouths in any way, but seemed disposed to lead them on; being older men, not quite so fresh from the school, might be the reason of it. He was sorry to see a great many failures on the day the members of the deputation were there, and this might perhaps be partly accounted for by their presence, which might somewhat embarrass the young men. He very much admired the dispensing counter, and could not help thinking that the more a young man was made to feel at home when he was being examined the better. As for the hospitality of their friends in the North, and their loyalty to the Pharmaceutical Society, he could not say too much, and hoped there would be a return visit paid in April next.

Mr. Hills asked if the rooms were all that could be desired.

The President said they were very good as far as they went, and he was much pleased with them, but at the same time another room was much wanted. There was no waiting room for the candidates waiting to be examined, who had to sit on forms in a portion of the dispensing room parted off by a screen. It also necessitated their all breaking off for refreshments at 1 o'clock, even if in the middle of an examination.

Mr. Mackay said it was very gratifying to him to find, both from the President and Mr. Sandford, how much pleased they had been with their visit. Although not a member of the Board of Examiners, he might be allowed as Secretary to say that few things had gratified him more than the deputation of last week. He might add, however, that the deputation came down under somewhat peculiar circumstances. A short time ago, certain discrepancies in the returns were noticed, and many members felt it was very remarkable that during 1877 the rejections should be about 25 per cent. in Edinburgh, whilst they were about 48 per cent. in England. The North British Branch therefore went into the matter somewhat carefully, and an examination of the books showed there were the most curious divergences of results in different days; for instance, on one day only three or four out of fourteen would pass, and the next day, the proportion would be reversed. They therefore went further back, three, five and six years, and when they came to add up the rejections in Edinburgh for a series of years and contrast them with the rejections in the same time in London, it was astonishing to find how nearly the results approximated. The average percentage of rejections for five years was 38 or 40 in Edinburgh, and from 46 to 50 in London; so that there was a discrepancy, but not much. He had no doubt the members of the Examining Board would say something in their report on this point, and there was nothing the Edinburgh Board desired more than that there should be perfect uniformity in the examinations in all respects. Mr. Sandford had alluded to the style of examination being a little different from that in London; he had never been present at an examination in London, but he knew that in Edinburgh the examiners did lead the candidates a little. He had known examiners who put certain substances before a candidate, or asked him certain questions, but never told him whether he was right or wrong, and he had known candidates who failed to be utterly surprised, fancying they were going on all right. It seemed to him perfectly right to tell a candidate whether he was right or wrong; if he were right it encouraged him, and if he were wrong, it made him more careful.

Mr. GREENISH was very glad to hear from the President that the dispensing arrangements in Edinburgh were so satisfactory. He had more than once brought the arrangements of the dispensing counter before the Council; the octagon room had been rearranged under the superintendence of the President, and he hoped the same thing would be done for the dispensing. When so many candidates were rejected in dispensing it was important that every facility should be afforded to them.

Mr. BOTTLE thought it would be well that a deputation from the Scottish Board should be invited to attend the examination in London in April next. Without anticipating any report the examiners who had attended would make, he thought the Council was in a fair way of equalizing the examinations. Probably the President was right in saying that any differences were owing to the greater age, as a rule, of the Scottish examiners. Probably they showed more judgment in drawing candidates along, and therefore succeeded in passing more. He would move, therefore, that a deputation from the Scotch Board be invited to come to London at the next examination.

Mr. ROBBINS seconded the motion.

Mr. SCHACHT asked if it would be legal for a member of the Scotch Board to take part in the examinations in England, and *vice versâ*.

The PRESIDENT said not as examiners, only as visitors.

Mr. SCHACHT regretted to find that this was so, because he thought the best way of making the examinations identical would be a positive part to be taken by members of the one Board in the examinations conducted by the other. If this could not be done, and the difference as it appeared was slight, he thought, perhaps, one return visit would be sufficient, and they need not have them continually as was suggested.

Mr. SANDFORD said he had mentioned to the examiners in Scotland Mr. Schacht's suggestion as to the interchange of examiners, proposing a slight development of it to this extent, that one or two men should be appointed on both Boards, so that there might be two Englishmen who should attend the Scotch examination as well as the English, and two Scotchmen who should attend the English as well as the Scotch. He was quite sure that their friends in Edinburgh were of the same opinion as to the desirability of uniformity, but when he mentioned it to them the other day there seemed to be a doubt whether they could find a couple of examiners who could spare the time, because it would consume a great deal of time to go backwards and forwards so often. There was no doubt the suggestion was an excellent one if it could be carried out.

Mr. SCHACHT said Mr. Sandford's elaboration of his suggestion struck him as being very good indeed.

The PRESIDENT thought by appointing occasional deputations, not always consisting of the same men, they would hear and see more of what went on, and any discrepancies could be corrected.

Mr. HAMPSON expressed his gratification at the development given to Mr. Schacht's proposal by Mr. Sandford. It struck him that it would be much better to have an interchange of examiners actually working on the different Boards than to have these visits of deputations, who were witnesses rather then examiners. They must consider not only that it would be more beneficial in introducing equality in examinations, but it would be also fairer to the candidates, and, after all, their feelings ought to be considered. A Scotchman examining at the English Board would have an opportunity of ascertaining the character of the examinations in England, and *vice versâ*; but when there was a deputation present and a Government visitor besides, it must work disadvantageously to the candidates; in fact, he should say it would amount almost to serious embarrassment. On these grounds he hoped there would be another opportunity of considering this matter, and that the Council would not decide anything off-hand.

Mr. MACKAY said such a change could not be effected during the present year, and therefore there would be ample time to consider it. He would suggest, however, whether it would not be better to invite the deputation from the Scotch Board to attend in June rather than in April, because in that month they had no examination of their own, and would be, therefore, more at liberty.

The VICE-PRESIDENT thought Mr. Mackay's proposition an admirable one, and also Mr. Schacht's; but in the latter he saw practical difficulty, because the gentlemen appointed examiners in England could only act legally for their respective appointments, and he thought they would require an alteration of the Bye Laws to meet the suggestion.

Mr. BETTY said that this was a most important proposition, and he was glad to see the few words Mr. Schacht had thrown out at the last meeting had been so thoroughly agreed to. They might, by an occasional interchange of visits, produce uniformity; but what they wanted was to produce identity, and unless they did that they only went half way. If they agreed that this was a desirable object, it was not for them to be deterred by small matters of detail, such as had been mentioned. It appeared to him a most simple matter when they elected a new Board of Examiners to elect them indiscriminately for England and Scotland. He did not doubt there would be every facility given if the Council wished to so constitute the next Board that the members might attend either one centre or the other; at any rate, that would be a point of detail which could be discussed in committee. The principle involved was of such serious importance that he hoped before the next meeting Mr. Schacht would move that a committee be appointed to consider how such a Board could be appointed, and to report before the next election of the Board of Examiners, so that practical effect might be given to the very valuable suggestions which had come out of this discussion.

Mr. BOTTLE thought the mixed Board of Examiners was not practicable without amending the Bye Laws, because section 2 of Bye Law 10 said that the Council shall at the first meeting in December appoint fit and proper persons *in* Scotland. He read that to mean persons residing in Scotland. He did not think there was any restriction with regard to the members of the English Board, but he did not see how Englishmen could go to Scotland.

The PRESIDENT said this matter was talked over before the North British Board, and he gathered the opinion that gentlemen in North Britain would not feel themselves justified in accepting the post of examiners in London as they could not spare the time. They were mostly gentlemen of eminence who would not be tempted by any fee the Society could afford to pay to sacrifice so much valuable time as would be required.

Mr. HANBURY entirely agreed with the suggestion that, if it were possible, arrangements should be made to elect one general board, the members of which should thus be qualified, *ex officio*, to attend at either centre indiscriminately, and he could not believe that the difficulties were insurmountable.

Mr. ATKINS also agreed in the desirability of getting the examinations identical, but after all they had heard that day he could not help thinking they were making a much more serious matter of this than was necessary.

The PRESIDENT said he was much struck with the way in which the examinations were conducted, and it appeared on taking a larger series of years that there was not so much difference between the results as had been supposed. He thought it would be wiser to go on with an occasional interchange of visits such as they had had, and effect what was desired without altering the Bye Laws.

It was then resolved unanimously—

"That two of the Examiners of the North British

Branch and Mr. Mackay be invited to attend the meeting of the Board of Examiners in London, in June, and that they be severally paid their travelling expenses and two guineas for each day on which they attend the meeting of the Board."

It was also resolved—

"That the Parliamentary Committee consider upon the desirability and practicability of such an alteration or alterations in the mode of appointing examiners by the Council under the Pharmacy Acts as may conduce to a joint system of examination being introduced in England and Scotland, and report thereon."

The following being duly registered as Pharmaceutical Chemists were respectively granted a Diploma stamped with the Seal of the Society:—

Atkins, William Ralph.
Branson, Frederick Woodward.
Cullingford, Louis James.
Curtis, Frederick George.
Miller, Cecil Bradley.
Redford, George Alfred.

Elections.

MEMBERS.

Pharmaceutical Chemists.

Atkins, William Ralph ....Salisbury.
Branson, Frederick Woodward..London.
Cullingford, Louis James ......Bletchingley.
Curtis, Frederick George.........London.
Miller, Cecil Bradley ....London.
Phillips, Evan ....London.
Redford, George Alfred ....Liverpool.

Chemists and Druggists.

James, John ....Weston-super-Mare.

ASSOCIATES IN BUSINESS.

The following having passed their respective examinations, being in business on their own account and having tendered their subscriptions for the current year were elected "Associates in Business" of the Society:—

Minor.

Agger, Joseph Edward .. ..London.
Biddiscombe, Charles ....London.
Collitt, William.....................Gainsborough.
Edwards, Frederick William ...Keighley.
Finney, Arthur Cook .. ..Brigg.
George, John ....Wolverhampton.
Halhead, John Armistead ......Carlisle.
Holgate, Sam Verity ....York.
McAlley, Robert ....Edinburgh.
Newitt, Herbert Henry ....Long Buckley.
Purrell, John Rushton............Liverpool.

Modified.

Blissett, William ....Romsey.
Cole, George ....Jersey.
Harrop, William Hutchinson ...Crewe.
Knight, William ....Hinckley.
Mount, James ....Addiscombe.
Shirtliff, William ....Shepherd's Bush.
Weaver, Theophilus.. ....Birmingham.

ASSOCIATES.

The following having passed their respective examinations and tendered (or paid as Apprentices or Students) their subscriptions for the current year were elected "Associates" of the Society:—

Minor.

Ascott, Tom ....Exeter.
Ashweek, John Sydney ....Torquay.
Brumwell, Herbert ....Fleetwood.
Budden, George Alfred ....Wareham.
Chapman, Leonard Parker..... Rochdale.
Crook, Arthur William ....Preston.
Gourd, William.....................Stoke, Devonport.
Hall, Richard Arthur ....Leigh, Lancashire.
Hawken, Alexander...............St. Austell.
Hoare, William Parker ....Cirencester.
Jones, Evan Jones ....Lampeter.
Jones, George ....Bedford.
Lockyer, William Walter ......Deptford.
Martin, William Lee ....Derby.
Need, John ....Great Malvern.
Russell, William ....Aberdeen
Skelton, John Hardy ....Gainsborough.
Stobbs, Robert ....North Shields.
Thomas, John Edward ....Swansea.

Modified.

Hadley, James William ....London.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary Examination and tendered their subscriptions for the current year were elected "Apprentices or Students" of the Society:—

Benson, Henry Thomas ....Aberystwith.
Buckham, William Thomas ...New Shildon.
Carr, John Walter ....Barnsley.
Carveth, William Uglow.........Plymouth.
Francis, Frederick Tanton ......Tavistock.
Glaisyer, Edmund .. ..Brighton.
King, Arthur.........................Norwich.
Littlewood, Harry ....Hempstead.
Lockwood, Thomas ....York.
Milner, Thomas ....Thirsk.
Orange, Edward Henry ....London.
Pars, Charles Frederick R........Lincoln.
Platt, Joseph.........................Stalybridge.
Richardson, Chas. Bloomfield ...Chesterfield.
Robinson, Alfred Edward ......Birmingham.
Scammell, Luther Robert ......Adelaide.
Scammell, William Joseph ......Adelaide.
Sharpe, William Cecil ....Madeley.
Watts, Robert ....Sheffield.
Way, John Francis ....Lower Tottenham.
Whitrod, Henry Frederic ......Diss.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Reports of Committees.

FINANCE.

The report of this Committee was received and adopted, and various accounts ordered to be paid.

The Auditors' report was also laid on the table.

The PRESIDENT remarked that the receipts were much the same as usual, but there had not been so much expended.

The VICE-PRESIDENT said it was satisfactory to find that the expenditure on the Journal had been £158 less, and there was also a less expenditure on fixtures and fittings.

Mr. SHAW said the item for carriage of books was smaller than last year. He supposed that showed a less circulation.

The PRESIDENT replied that was the case. He had pointed out when in the North that the library was equally available for Scotland as for England, and he might add there was a proposition before the Library Committee that the carriage one way of books borrowed by associates and apprentices should be paid by the Society.

Mr. ATKINS asked if the amount paid to the College of Preceptors for conducting the Preliminary examinations was an addition to their expense, or did it replace a similar item which had been paid before.

Mr. Cracknell said it was according to the number of papers sent up, and was on the same scale as formerly.

The report of the Auditors was then received and adopted.

It was also resolved that the preparation of the annual report be referred to the Library, Museum and Laboratory Committee.

Annual Meeting and Conversazione.

It was resolved that the Annual Meeting of the Society be held on Wednesday, the 15th of May, and that a Conversazione be held on the same evening; that the Secretary be instructed to apply to the Lords Committee of Council for the use of the South Kensington Museum, and that Messrs. Betty, Greenish, Robbins and Sandford be appointed a Committee to carry out the arrangements, with an instruction that no refreshments be provided by the Society.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to a registered chemist and druggist, aged 72, who has had two previous grants.

£5 to the widow of a registered chemist and druggist, aged 48.

£10 to a registered chemist and druggist suffering from acute illness. Applicant had a similar grant in November last, but has not yet quite recovered.

£10 to a registered chemist and druggist, aged 60, who has been unfortunate in business, and was now without resources.

£10 to a female registered chemist and druggist who had a similar grant last year.

£10 to the widow of a recent annuitant.

The consideration of another case was deferred. The Committee also recommended that the Treasurer be requested to purchase £200 Consols, to the account of the Benevolent Fund, which amount included donations received since the commencement of the year, and the legacy of £100 bequeathed by the late Mr. Sagar, of Swinton, Lancashire, making the total sum invested £18,000.

The Secretary reported the death of Mrs. Sophia Wick, an annuitant, aged 78, who was elected in 1874.

Mr. Atkins asked if there was any method of registering permanently the legacies paid to the Fund, and suggested that they should be inscribed on a board, and suspended in the Society's premises.

Mr. Hanbury said they had a very good precedent in St. Bartholomew's Hospital, where one of the points of interest in the large hall was the list of the bequests and the names of the donors.

Mr. Hampson suggested that the matter should be referred to the Committee to consider; and this was agreed to.

The report of the Committee was then received and adopted.

Mr. Mackay said he did not know whether it was known to the Council, but it was known to him, that it had been the practice for a long time to make special efforts to get interesting and valuable papers for the monthly meetings of the Society held in Edinburgh, and he thought the members would agree with him that many valuable papers had been contributed. They had never paid any one who had come forward to read these papers, but those gentleman had always been informed that in the event of the paper being printed *in extenso* in the Journal that twenty or twenty-five copies of it should be supplied to them free of charge. That had been the entire expense thrown on the Society for the contributions which had from time to time appeared in the Journal, but he had just been surprised to hear from the Editor that in future he must decline to make such a concession. He replied he was always under the impression that the Society was only too glad to get the papers on these terms, but the Editor said that if he did it to one local association he must do it to every one, and therefore he must decline to do so on his own responsibility, but if he would bring the matter before the Council, and the Council thought fit to treat the North British Branch in the same way as the London evening meetings, the authors would then get the copies gratuitously. If it were determined that these papers were not to be paid for he would willingly pay for them out of his own pocket; but he did think it was splitting hairs to say that a large Society like that should determine not to give to those gentleman who read papers a few copies. He wished to know whether he was still to promise gentlemen that they should receive twenty or twenty-five copies of the Journal free.

The President was very much astonished to hear Mr. Mackay's communication, and thought it was quite a misapprehension on the part of the Editor. He was sorry the question should have been raised, and his own opinion was strong that all papers read before the North British Branch should be considered the same as those read at the London evening meetings. He was also of opinion that the authors should receive printed copies of those papers.

Mr. Shaw understood the President to mean that when a paper was read at a provincial society, and was inserted in the Journal, it should be paid for the same as if it had not been read beforehand, and that the author should also have copies at the expense of the Journal department. He hoped that arrangement would be carried out, because there was often a little difficulty in getting good papers for local associations, when they were not recognized in any shape or form. Gentlemen spent a great deal of time in preparing them, and they should not be debarred from receiving the honorarium given to persons contributing to the Journal.

Mr. Mackay said Mr. Shaw was widening the subject which he had raised, and he hoped the Council would limit the discussion to the point before it.

Mr. Hampson understood that all Mr. Mackay required was that readers of papers in Scotland, in connection with the North British Branch, should receive copies of their productions. As to the reception and payment for papers read at local associations, that was another question.

Mr. Greenish asked if twenty-five copies was the number which had generally been applied for.

Mr. Mackay said on one occasion he was asked to supply fifty. He was told at the office that the number was excessive, but that twenty-five would be allowed.

Mr. Bottle then moved—

> "That scientific papers read (and printed in the Journal) at the North British Branch should be entitled to the same privilege that they have hitherto enjoyed, and that it be an instruction to the Editor to continue the same."

He was surprised that any attempt should be made to stop the distribution of twenty-five copies of papers to gentlemen who had contributed such admirable papers as had been contributed by the North British Branch.

The Vice-President seconded the motion.

Mr. Greenish said he thought it probable that the difficulty had arisen from the large number of copies asked for in some instances.

Mr. Mackay said after that intimation he would only ask for twenty-five copies in future.

The President hoped Mr. Mackay would ask for as many copies as he thought could be usefully distributed.

The resolution was unanimously carried.

LIBRARY, MUSEUM, AND LABORATORY.

The report of this Committee included the Librarian's report, showing the average attendance during the preceding month to have been, day, 25; evening 11. Circulation of books, town 197; country, to 27 places, 41; carriage paid 13*s.* 10½*d.* The following donations to the Library were reported:—

'St. Bartholomew's Hospital Reports, 1877.' From the Hospital.

'Calendar of the Pharmaceutical Society of Ireland, 1878.' From the Society.

'Journal of Eastern Asia.' Vol. 1. No. 1. From Mr. James Collins.

'Werthbestimmung des Wismuths und des käuflichen Magisterium Bismuthi,' by J. Löwy; 'Beiträge zur Chemie der wichtigeren Gummiharze, Harze und Balsame,' by E. Hirschsohn. From Professor Dragendorff.

'An Easter Holiday in Liguria, with an account of the Garden of the Palazzo Orengo at Mortola.' From Professor Flückiger (the Author).

'The Pharmacy and Poisons Act, with Regulations.' From the Pharmacy Board of Victoria.

The Librarian reported that an apprentice at Boston, who had borrowed a book from the library, declined to pay the carriage. A discussion ensued thereupon, and it was finally resolved by the Committee to recommend that in future the carriage, one way, of books borrowed by associates and apprentices in the country, be paid by the Society, and that all associates and apprentices be allowed to retain books for the same time as members and associates in business.

The Curator had reported that the average attendance in the Museum had been, day, 11; evening 3. Also that he had received a letter from Dr. Lorentz of Uruguay, saying that he had forwarded a specimen of *Aspidospermum Quebrachs*, for the Museum; he had also received offers of specimens from Sierra Leone and Monte Video. Professor Attfield had offered to supply any chemical specimens which were badly represented in the Museum, if the crude materials were supplied to him, in cases of articles not included in the usual course of laboratory study.

The following donations to the museum had been reported:—

An Octahedron of Common Alum and Chromic Alum crystallized together, a large Crystal of Sulphate of Magnesia, a fine Crystal of Sulphate of Copper, a very perfect Crystal of Copper, and a very perfect Crystal of Red Prussiate of Potash, from Mr. W. Copney; Fine Specimens of Mogador Colocynth, from Messrs. Hearon, Squire and Francis; Specimens of Amyrin, Bryoidin, and Elemic Acid, from Professor Flückiger; Specimen of Absolute Phenol, from Messrs. Bowdler and Bickerdike; Specimens of the Monochloride and Trichloride of Iodine, from Mr. Dunstan; Specimen of Dragonwood, from Mr. G. Curling, jun.; Specimens of Artificial Oil of Rose Geranium, of Glycyrrhizin combined with Ammonia, and of Nigella Seed, from Mr. Langbeck; Specimen of Poppyhead from China, from Mr. W. A. Thirlby; Specimen of Mahwah Flowers, from Mr. T. Christy; Specimen of Iron Slag, tinted with Manganese, from Mr. W. Y. Brevitt; Specimen of Salicylic Acid and of Salicylate of Soda from Oil of Wintergreen, from Messrs. Hopkin and Williams; Specimen of Brazilian Copal, from Mons. C. Chantre; Specimen of Senna Leaves from India, from Dr. Forbes Watson; Specimen of the Stem of *Scorodosma fœtidium*, from the Curator; Specimens, in blossom, of *Cinchona calisaya*, and the hybrid *C. Anglica*, from Mr. J. E. Howard, F.R.S.

It had been resolved to recommend the purchase of two copies of 'Diccionario de voces de Historia Natural Americanas par E. Uriocœchea' now in course of publication, one for the library, and the other for the use of the Curator.

The Secretary had reported that he had received 2000 copies of the Museum Catalogue, and had forwarded copies to members of the Council, of the Board of Examiners, Government Visitors, and the Professors. He had been also instructed to send copies to honorary members, scientific societies to whom the Journal is sent; towns where the Conference had met and which possessed libraries, and to such other scientific men in England or abroad as might be suggested by Mr. Greenish, in conjunction with the Curator. It was recommended that the price fixed for the sale of the Catalogue, to those not entitled to a copy gratis, should be 2*s.*

The Professors had reported favourably of their respective classes.

The report was received and adopted.

In reply to Mr. Schacht,

The Secretary said there had been numerous applications for copies of the Museum Catalogue.

Dr. Redwood's Lecture on Spectrum Analysis.

The President thought the Council ought to pass a vote of thanks to Professor Redwood for his very able lecture on Spectrum Analysis, which, he was glad to say, was very well attended.

Mr. Greenish seconded the motion. He hoped there would occasionally be a course of lectures delivered in the Society's lecture theatre, such as he recollected some years ago.

The resolution passed unanimously.

HOUSE.

The report of this Committee was received and adopted.

SCHOOL OF PHARMACY.

A return respecting the School of Pharmacy was laid on the table.

LAW AND PARLIAMENTARY.

The report stated that at a meeting of this Committee, held on Feb. 20, a further communication had been received from the Secretary of the Board of Trade, with regard to the Weights and Measures Bill, and Professor Redwood had been invited to attend the Committee. The matter being considered, an answer had been directed to be sent, substantially adhering to the opinion already expressed.

A correspondence had been laid before the Committee respecting the Dental Practitioners' Bill, including the Solicitor's opinion on certain words in clause 5, which, it was feared, in some quarters, might be held to interfere with the interests of chemists practising dentistry.

A communication had been also read from the Home Secretary to the President, enclosing a letter from the coroner for Dover, calling attention to a case of death from "Hunter's Solution of Chloral," and suggesting that this substance should be treated as a poison. In reply, a letter had been sent pointing out that in accordance with a resolution of the Council, approved by the Privy Council, chloral hydrate and its preparations had become poisons, within the meaning of the Act, and also that the preparation referred to in this special case was a patent medicine and as such entitled to the exemptions granted to patent medicines by the 16th section of the Pharmacy Act, 1868.

At a subsequent meeting of the Committee, held on March 5, several cases of alleged infringments of the Pharmacy Act had been considered.

It being reported that the Weights and Measures Bill was referred by Parliament to a Select Committee, it had been recommended that application be made for permission to give evidence thereon before that Committee.

With regard to the Dental Practitioners' Bill, a letter sent by the President, on February 22, to Sir John Lubbock, calling attention to the objectionable words in clause 5, and asking for their omission, had been read to the Committee. The following reply had been received:—

"15, Lombard Street, E.C.,
"26th Feb., 1878.

"Sir,—I have duly received your favour of the 22nd. The point you urge seems to me to have much force in it, and I shall be happy to omit the words in question. "I am,
"Your obedient servant,
"JOHN LUBBOCK.

"J. Williams, Esq."

The Committee recommended that the Pharmaceutical Society's certificates for chemistry, materia medica, and such other subjects as it is proposed should be required in obtaining qualifications under the Bill, be accepted as part of the suggested curriculum for future examination in dentistry.

The Solicitor's Report as to certain cases placed in his hands had been also read.

The Secretary had reported that he had written to the local secretary and the informant in all cases of infringement of the Act which had been brought under his notice during the latter half of 1877. Some of the replies received had been read to the Committee.

Mr. SANDFORD said he was one of a deputation which on the 21st of February waited on Mr. Tomes, the principal promoter of the Dental Practitioners' Bill, who was quite prepared to entertain the objections laid before him, but referred the deputation to Sir John Lubbock. The correspondence with the honourable baronet had been read, and he could only say that the answer appeared perfectly satisfactory, as Sir John, in his letter of the 26th of February, had undertaken to remove those words which might be held to interfere with chemists and druggists practising dentistry.

The PRESIDENT asked if anything was said about examinations in future.

Mr. SANDFORD said the Council could not ask Sir John Lubbock to recognize rights which did not exist. If it were necessary to have examinations for dentists the Council could not ask that chemists and druggists should be exempted therefrom if they wished to practise dentistry. Referring to the paragraph in the Committee's report suggesting that the certificates of the Society should be accepted as part of the suggested curriculum for future examinations, he did not see how the Council could interfere with that. The Bill only proposed that such examinations should be held as should be determined hereafter by certain recognized bodies. This was not the right stage to deal with that question. To attempt to introduce such a thing in an Act of Parliament would be altogether out of place.

Mr. ATKINS asked who it was suggested the curriculum.

Mr. SANDFORD said it seemed to him the Committee was doing it.

Mr. ATKINS thought there would be plenty of time to see about that.

Mr. CHURCHILL said the present examination of the Royal College of Surgeons for a licentiate in dentistry would require a man who had passed the Major examination to go through a fresh examination in chemistry. That was the point the Committee wished to meet.

Mr. HAMPSON saw no objection to the report as it stood. It only showed a desire to utilize the Society's own examination so that any one who had passed an examination in materia medica and chemistry should have his attainments recognized. There was no doubt those two subjects would form part of the curriculum.

Mr. SHAW said the regulations of the Dental College required, amongst other things, that the person seeking admission must have attended chemistry and materia medica lectures. What was wanted was to ask the college which was to be formed, to receive the Society's certificates in those two departments.

The PRESIDENT thought one mistake was being made in this matter, that it was not the examiners' certificate which would be required by the future dental body, but the certificate of the professsors that the pupil had attended so many lectures.

Mr. CHURCHILL said that was the grievance. There were very few of their members who attended the lectures in the Society's school, but it was contended that those who had attained a certain amount of knowledge and had passed an examination were entitled to the benefit of it.

After some further discussion it was decided to refer back this part of the report to the Committee for further consideration.

The Weights and Measures Bill was then discussed, and some difference of opinion appeared to prevail with regard to it.

Mr. ROBBINS said that the dram avoirdupois was well known in Cornwall, but it was only known for one purpose, namely, selling saffron.

Mr. SCHACHT said there were at present three terms in common use, the drachm, the ounce, and the pound, which did not always represent the same weight. The question was, whether it would not be an advantage to have a definite idea attached to the meaning of these words.

The VICE-PRESIDENT said the question really was whether they could dispense with the drachm and the scruple, and that had been conceded by the Government.

Mr. SCHACHT said it was for vending purposes only that one set of weights should be recognized. It had been lately said that two large wholesale houses in the trade gave two distinct weights when a drachm was asked for. A pound should be so many grains, but there were avoirdupois and apothecaries' pounds, and the vendor had as much right to sell an apothecaries' pound as an apothecaries' drachm.

Mr. CHURCHILL said he knew of one or two wholesale houses which would send one-eighth of an ounce and call it one-eighth of an ounce if a drachm were asked for.

Mr. ATKINS said he himself had never seen an avoirdupois dram. He kept on his scale two weights, avoirdupois and apothecaries'. The former only was used for retail purposes, but he could quite understand that even with a drachm a technical question might arise. If a man were to ask for a drachm of nitrate of silver he would get more than half what he would if he asked for a quarter of an ounce.

Mr. CRACKNELL said it having been stated that the dram avoirdupois was used in Cornwall and simply for the sale of saffron, he had made some inquiry, and was told by a gentleman in business there for many years that he did not think the avoirdupois dram was to be found in any shop in the county. There were a few people who had a dram avoirdupois, but practically it was never used. The manner in which saffron was sold was, if a customer asked for a dram that a quarter of an ounce was weighed and divided by the eye into two parts.

Mr. SHAW produced an avoirdupois dram which he had procured in Liverpool. He said it appeared to him that the Government wanted chemists to give up the exemption they had a right to, and when he received a communication from the President on the subject he thought there would be no difficulty in complying with the wishes of the Government in respect to the use of the weights, not only in the larger denomination but the smaller also.

Mr. SANDFORD saw no reason why the Council should put itself forward to give evidence on the Bill before the House of Commons. What the Committee had asked had been conceded, and he thought it might be very well satisfied without going on a roving commission, which perhaps would undo what had been done.

Mr. HAMPSON said that in the Committee he was in favour of seeking an opportunity of giving evidence, but on reconsideration he had come to the conclusion that it would be wiser not to do so.

This part of the report it was also resolved to refer back to the Committee; and with these exceptions the report was received and adopted.

Mr. BOTTLE drew the attention of the President to the communication with regard to the chloral hydrate question, and took exception to the terms of the letter in reply, in which it spoke of the drug which had been used as coming under the exemption of a patent medicine. They had lately been interfering with cattle medicine because it contained a small proportion of opium, and if a preparation which was nothing but a solution of chloral in water could be sold by anybody who took out a patent medicine licence nothing would be easier than to evade the Pharmacy Act.

The PRESIDENT thought the wording of the letter did not bear the interpretation Mr. Bottle had put upon it. It did not commit the Council to a statement of what the exemptions were, but only said that the solution being a patent medicine was entitled to such exemptions as were contained in the Pharmacy Act.

Mr. SANDFORD said he believed this particular preparation was sold before chloral was introduced into the Pharmacopœia.

Mr. BETTY then moved—

"That the report of the Sub-Committee appointed to consider and report upon any amendments that may be expedient in the Pharmacy Act be received, adopted, and acted upon at a suitable opportunity, with such additions or modifications as may at that time be resolved upon."

He said his object was simply that the Council should receive formally, as it did every other report, the report of this Sub-Committee, which had taken much pains in the matter. It did not wish to bind the Council in any way, as would be seen by the terms of the motion, but simply that the work of the Committee should not be lost.

Mr. SANDFORD suggested that it was too late to discuss this motion, but drew especial attention to the words "acted upon." The report in question was a most crude report, and was unfit to be the subject of such a resolution.

The PRESIDENT suggested that the report of the Sub-Committee should be received and entered on the minutes.

Mr. HAMPSON said it was desirable to discuss the matter before coming to any resolution. There was not time then, but he hoped the Council would not let this matter pass in an informal way. If a time were appointed for its discussion at the next meeting some useful information might be got out of it, and he therefore suggested that the President should fix a time when it should be taken.

The PRESIDENT said it was no use passing any resolution except to receive the report and enter it on the minutes.

Mr. HAMPSON thought it was not fair to those who had taken the trouble to go into the matter that the report should be shelved.

Mr. ATKINS could not but join in the expression of opinion that when a sub-committee had been appointed, and had made a report, that report should be discussed. If it was worth nothing, and contained no practical suggestions, then dismiss it, but this could not be done until it had been considered *seriatim.*

Mr. BETTY also urged that the report should be considered and discussed.

After some further conversation it was decided to defer the discussion till the next meeting, Mr. Betty saying he would give notice of motion regarding it.

REPORT OF THE BOARD OF EXAMINERS.

February, 1878.

PRELIMINARY EXAMINATION.

Seven certificates received in lieu of this examination:—

2 College of Preceptors.
3 University of Cambridge.
1 University of Durham.
1 University of Oxford.

A letter was read from the Chairman of the Committee of the Chemists' Ball, thanking the Council for the use of the Society's rooms for the meetings of the Committee.

A letter was also read from the Honorary Secretary to the Chemists' Assistants' Association, thanking the Council for the loan of materia medica specimens for exhibition at the *soirée* lately held by the Association.

PHARMACEUTICAL MEETING.

Wednesday, March 6, 1878.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting having been read and confirmed,

The PRESIDENT said it was his pleasing duty to inform Professor Redwood that the very cordial thanks of the Council were given to him for the brilliant, beautiful, and instructive lecture which he delivered a fortnight ago.

A number of specimens, of which the following is a list, were exhibited:—

Herbarium specimens of *Duboisia myoporoides*, and various gums, from Dr. J. Bancroft; Specimens of Yellow Turtle Oil, from Jamaica, and of a root used for boils from Accra, from Mr. Ernest Samson; Specimens of Coto bark, false Cinchona, and false Ipecacuanha root, from Messrs. Curling and Co.; Specimens of Tartrate and Acid Tartrate of Strychnia, from Mr. J. F. Savory; Specimen of Sumbul root, from Mr. J. B. Allen; Specimens of Diphenylamine, Oxyacanthin, and Belladonine, of the artificial oil of Meadowsweet, Peony root and seeds, fruits of *Carduus marianus*, flowers of *Matricaria Chamomilla*, *Lamium album*, and *Primula veris*, and the dried herbs of *Melilotus officinalis*, *Fumaria officinalis*, *Galeopsis grandiflora*, and *Agrimonia Eupatoria*, from Mr. H. W. Langbeck; Analysed specimens of Java Cinchona Barks; crystals of the Bromhydrates of Quinidine and Cinchonidine, both acid and basic, and of Nitrate of Pilocarpine, from Mons. Petit, Paris; Specimen of the root of *Atractylis gummifera*, and of the seeds of *Andira anthelmintica*, from Dr. Méhu, Paris; Specimens of the bark of *Drimys Granatensis*, and of the bark of *Hura crepitans*, and false Jalap, from Professor Planchon, Paris; Specimen of false Ipecacuanha root, from Messrs. Hearon, Squire and Francis; Specimen of Ashantee Copal, from Mr. F. C. Heron.

Mr. E. M. Holmes called attention to a series of barks which had been presented to the museum by a French pharmacist, M. Petit, of Paris. Each bark had been analysed, and its ingredients were stated on the labels of the specimens, and they were therefore much more valuable than ordinary specimens. The specimen of Ledger bark contained 6 per cent of quinine. Among the articles given by the same French pharmacist was an excellent specimen of nitrate of pilocarpine and of the hydrobromates of cinchonidine and quinine. Hydrobromate of quinine was attracting general attention at the present time. There was also a specimen of copal, which though not a very pretty one, had some interest in its having been brought over by the son of the King of Ashantee. *Drimys Granatensis* sometimes came into commerce under the name of pepper bark, and was very similar to true Winter's bark, which was not an article of commerce. The coto bark he believed to be the one which contained cotoin, and not the one from Bolivia which contained paracotoin. The specimens of false yellow cinchona bark had very much the appearance of hard Carthagena bark; but Dr. Paul, who had examined it, had informed him that it contained an alkaloid similar to, if not identical with, paricine. The turtle oil was said to be used in Jamaica for consumption. It had no taste and but little odour, and although now semi-solid was liquid in Jamaica. As an animal oil it might perhaps be useful for making pomade. Several things on the table had been presented by a German chemist, who noticed that they were absent from the catalogue which had just been published. Some of them were of interest as curious chemicals. One specimen, oxyacanthin, was a neutral bitter principle obtained from the white hawthorn, and not the alkaloid oxyacanthine from the root bark of *Berberis vulgaris*. The specimen of belladonine he believed was not perfectly pure; but still it was a nice sample. He would also call attention to a specimen of false ipecacuanha which had recently appeared in the market. It was very easily distinguished from the genuine kind by its much paler colour and larger medi-tullium. Whether it contained emetine or not he did not know; but he had a sufficient quantity to supply any gentleman who would like to examine it.

Dr. Paul asked Mr. Holmes whether he had made out anything with regard to the origin or character of the false cinchona bark. A sample of one of the parcels of bark came into his (Dr. Paul's) hand, and was marked "Cinchona Bark," but it contained no quinine, and not even cinchonine, but a considerable quantity of an alkaloid which very much resembled paricine, an alkaloid which had been found in some kinds of red bark. It was amorphous, and was stated to be identical with beberine from the green-heart tree, and also with an alkaloid obtained from pareira root, and from one or two other sources. It formed amorphous salts and the peculiarity of it was that the neutral sulphate was precipitated in the form of a resinous mass on the addition of a strong solution of sulphate of soda, or almost any strong saline solution. The quantity of alkaloid in this bark was considerable. The bark was very bitter, and he believed that it was bought for the purpose of supplying it to the druggists for the making officinal cinchona preparations. With reference to the coto bark which was coming to be an article of commerce, he did not gather from Mr. Holmes what source the sample came from.

Mr. Holmes said that he did not know whence it was obtained, but he received it from Messrs. Curling and Company.

Dr. Paul said that he had examined six or eight samples of coto bark, one of which was brought into the market some two years ago, and he had not obtained results agreeing with the statements that were published some time ago by Mr. Jobst with regard to the crystallizable substance cotoin which he said was obtainable from this bark; but they all agreed in yielding a considerable amount of soft resin in which, after exposure to the air, there was a formation of acicular crystals. The character of that substance corresponded more exactly with what had been described by Mr. Jobst as paracotoin, obtained from a bark which was said to be not identical with that which he originally examined, but from another source, although presumably from the same tree. That he (Dr. Paul) believed to be the article which was chiefly to be met with now under the name of coto bark in commerce.

Mr. Umney said that he had noticed in the drug market the original packages of false ipecacuanha and also of coto bark to which Mr. Holmes had alluded. One bale of the former was in the market and four or five of the latter was a few weeks since offered for sale. He took a specimen of it, and he thought that it was *Ionidium*, and he sent it to Mr. Holmes, who confirmed his opinion in the matter. He believed that the coto bark was bought by a continental firm.

A paper was then read on—

Croton Oil.

BY HAROLD SENIER, F.C.S.

The paper is printed on p. 705, and gave rise to the following discussion:—

The President said that the paper was certainly an interesting one, because it appeared to point out a fact the reverse of what had been hitherto recognized; that was, that this drug seemed to improve in quality through being kept rather than to deteriorate. The general experience with drugs was in the opposite direction. It was a curious point that the oils which had been kept the longest yielded a larger proportion soluble in alcohol than recent oils, and it appeared that the portion soluble in alcohol was far more active than the insoluble. In fact, it would almost appear that the activity depended upon the proportion of the croton oil which was soluble in alcohol.

Professor Attfield asked Mr. Senier whether he had made, or intended to make, any experiments on the composition of the portion which was soluble in alcohol, as compared with the portion which was insoluble in alcohol. It would be interesting to know whether the more active part of the oil was the more highly elaborated, and whether the alteration that went on was due to chemical agency, such as oxidation, or whether it was a physical change.

The President observed that, as a general rule, oxidation meant degradation. In this instance it appeared that the oxidation had the reverse effect, and made the oil more active as a vesicant.

Mr. Postans said that Mr. Senier had stated that his experiments were all conducted with oils of British manufacture. He found that in two books of some standing it was stated that croton oil prepared by expression in this country was soluble in alcohol. Passing to the reference which Professor Attfield had made to the composition of the soluble and the insoluble portions, he (Mr. Postans) believed that Professor Tuson years ago experimented to some extent on croton oil, and his investigations led him to surmise that the isolated principle was somewhat analogous to cascarilline. Professor Tuson did not appear to have given any name to this substance, but he prepared it by treating the crushed seeds with continued portions of boiling water, and then evaporating the solution to an extract, and again treating the extract with boiling alcohol, evaporating it, and decolorizing with animal charcoal. Another gentleman who had investigated the subject spoke of crotonic acid, which was found on further investigation to be inert.

Mr. Cleaver said that it struck him that if croton oil was of the ordinary composition of an oil, namely, a compound of acid with glyceryl, rancidity might take place which would increase with age, and the acidity thereby produced might set free the natural acid of the oil, which would be more soluble than the oil itself.

Mr. Gerrard said that it frequently happened in hospitals that croton oil was prescribed in the usual minim doses, and it might be supposed that if the activity increased with age the variation would attract notice, but he had found no complaint, either of the increase or decrease of activity, though the specimen which was in use now at University College Hospital had been there to his knowledge five years. From the fact that physicians continued to prescribe the minim dose, he thought it might be inferred that age did not increase the activity of croton oil.

Professor REDWOOD said that he thought that it had long been considered that croton oil consisted principally of an oil of ordinary constitution, which was comparatively inert, if not entirely so, and that there was some principle contained dissolved in the oil to which the activity of it was to be ascribed. What the nature of that active constituent was was unknown. It was originally thought that the activity depended upon the presence of a certain body which was termed crotonic acid. He had had more than a little experience of croton oil for more than a quarter of a century. It must be about thirty years ago that croton oil was a subject which was very largely worked upon in that institution, and his friend Dr. Paul was then engaged with him in making experiments upon that substance From these experiments they first obtained their knowledge of the fact that croton oil, when pressed from seeds in this country, was perfectly soluble in alcohol. In these experiments it was indicated for the first time that the oil did not owe its efficacy in the slightest degree to the crotonic acid, this substance being found to be entirely medicinally inert. The experiments which had been made by Mr. Senier were certainly interesting in two or three points. Mr. Senier stated that croton oil at the present time, which was obtained by expression in this country, was not permanently soluble in alcohol. That result was entirely at variance with the results that were obtained by him (Professor Redwood) from a vast number of experiments which were made, and which were detailed by Dr. Pereira in a paper published in the *Pharmaceutical Journal*, and alluded to also in his work on Materia Medica. The experiments were made upon oil pressed on those premises within a few yards of the spot where the President was then sitting, and Dr. Paul was engaged in the expression of the oil. He should like to hear from Dr. Paul himself what was his idea as to the real source of the activity of croton oil, because in the process of grinding the seeds, in which Dr. Paul was engaged, an effect which was certainly a very unusual one, was produced upon Dr. Paul. The action was not in the usual direction. It was entirely different. Dr. Paul was suddenly found at the further end of the laboratory stretched upon his back upon the floor, in a perfectly insensible condition, and he remained in that condition for an hour or two. They thought that his case was a serious and a dangerous one, and probably it was, but after a time he recovered. Dr. Pereira, in his work upon Materia Medica, relates a very similar case which occurred in one of the docks to a man who was engaged in operating upon the seeds. This man suddenly fell down and remained insensible for several hours. He was sent to an hospital, and did not entirely recover until several days had elapsed. It was quite obvious, therefore, that, whilst on the one hand they might entirely eliminate crotonic acid from among the substances which gave activity to croton oil or croton seeds, they had yet to find out what the active principle was. As far as could be made out, the oil appeared to be merely the solvent of the active principle, and he thought that Mr. Harold Senier would have to carry his investigation further to show that what he had extracted by means of spirit consisted entirely of the active principle. He (Professor Redwood) should have liked to find that Mr. Senier had a little more strictly followed the course of proceeding which had been previously adopted of treating the oil with spirit. In all previous experiments in which it was treated with spirit or alcohol—for it was treated with both—an equal volume of alcohol was added to the oil, and all English pressed oils of which he (Professor Redwood) could get samples from any source during his experiments proved to be entirely and permanently soluble in an equal volume of alcohol, taking absolute alcohol and not rectified spirit. It remained soluble as long as the temperature of the air was about sixty degrees, but if it were put into a freezing mixture or the temperature was reduced to something approaching 32° Fahr., a separation took place. Mr. Warington in his last communication specified that he met with one sample of oil which reacted in the same manner. Mr. Senier appeared to have used a larger portion of spirit, having had five volumes of alcohol or spirit to one of oil. That might affect the result, for he (Professor Redwood) knew from experience in the case of vegetable extractive matter that such matter might be perfectly soluble in a small quantity of water and yet insoluble in a large. That fact must be familiar to those who had had any experience in the preparation of concentrated extracts, therefore he felt that it was quite possible that in the case of croton oil a smaller amount of spirit might exert a more powerful and more complete solvent action upon the oil than a larger quantity. However, as he had said before, the first point of interest in the paper was that whereas previously all the oil pressed in this country had proved to be perfectly soluble in alcohol, the English pressed oils which Mr. Senier had operated upon had not proved to be. The question arose, "What can be the reason of this?" At the time his (Professor Redwood's) experiments were made he found that all foreign pressed oil reacted just as Mr. Senier had found the English pressed oil to react. A separation took place. The oil might be miscible or soluble upon the application of a little heat, but when it was cooled down to about 60° or 65° F., a separation took place. Dr. Pereira originally suggested that in all probability the difference was due either to some alteration which the oil itself underwent, or to some change which the seeds underwent. In his (Professor Redwood's) opinion, it was not due to an alteration which the oil underwent, for he had found, as Mr. Gerrard had found, that he could keep a sample of foreign oil—East Indian croton oil—for years without its degree of solubility increasing. At the time of his experiment thirty years ago there was in the market a large quantity of seeds, some which had been in stock for some time and therefore might have undergone that kind of change which caused an oil to be extracted from them to contain a large quantity of the active principle which rendered the oil soluble in spirit, whereas all the oil pressed in India would be much more likely to be pressed from fresh seeds which had not undergone the change. That seemed to be the most rational explanation. It appeared to him that the most important and interesting part of Mr. Senier's communication was the latter part, where he alluded to the mode of getting in a more concentrated condition the active matter of the seed.

Professor BENTLEY said that he should like to ask Mr. Senier whether he was familiar with the experiments made by Schlippe upon the composition of croton oil. Schlippe showed that croton oil was composed of fixed oil, crotonic acid, tiglinic acid, and a dark brown oil which he termed crotonol. This latter substance might be the principle which Mr. Senier had described that evening. At all events it was one which was worth Mr. Senier's attention. This brown oil, so far as he (Professor Bentley) knew, had never been isolated by any other chemist. Schlippe further described this principle as the vesicating principle of croton oil. Mr. Senier in his paper said, "From the above experiments it may reasonably be concluded that for medicinal and pharmaceutical purposes, an oil extracted by alcohol would be a more satisfactory preparation than the crude oil." He (Professor Bentley) did not think that this necessarily followed from Mr. Senier's experiments. The experiments were perfectly clear so far as the vesicating principle was concerned, but it did not naturally follow that the purgative principle was the same as the vesicating principle. Schlippe laid no claim to crotonol being the purgative principle. He (Professor Bentley) could entirely corroborate what had been said by his colleague, Professor Redwood, about the purgative principle, which had not as yet been isolated. It would seem probable that there would be found to be both a vesicating principle and a purgative principle in croton oil. Mr. Senier's paper raised many interesting points. For instance it would be interesting to pursue a similar investigation with regard to castor oil, which was in some degree connected with this subject. What was the purgative principle of castor oil? It was said to be an acrid resinous substance, but it had never been isolated. It was well known that castor oil which was extracted from the seeds by alcohol was much more active than that expressed from the seeds, and that fact bore somewhat upon the experiments of Mr. Senier. The whole subject with regard to the therapeutic effects of croton oil and castor oil and their active principles was one which he ventured to commend to Mr. Senier for further investigation.

Mr. UMNEY said that some thirty years ago, the time to which Dr. Redwood had alluded, croton oil was pressed in certainly more than one laboratory in London, but at the present time all the croton oil of Great Britain was pressed by one firm only. All the croton oil of the country might be traced to that one source. No other firm would press the seeds. He made this remark so that persons should not suppose that croton oil at the present day varied in quality through coming from different sources.

Dr. PAUL said that he had a very lively recollection of the fact to which Professor Redwood had alluded. He did not remember much in connection with these experiments, as he was but a student at the time, but he had a very distinct recollection that the effects produced upon him by the seeds were more like the effects of a narcotic than of anything else, and were not accompanied with any of the purgative or irritating effects which were common to croton oil.

Mr. E. M. HOLMES said that in Hanbury's 'Pharmacographia' he had observed a remark which might throw a little light upon the subject, It was, "The solubility of the oil in alcohol, sp. gr. 0·974, appears to depend in great measure upon the age of the oil, and the greater or less freshness of the seeds from which it was expressed, oxidized or resinified oil dissolving the most readily." If this were the case, the oil might become resinified or oxidized in old seeds or in oil which had been kept for some time, and thus a larger amount would be found to be soluble in older specimens of the oil. The remark which he had quoted from 'Pharmacographia' would also bear out Mr. Gerrard's suggestion. Mr. Gerrard seemed inclined to think that although the portion soluble in alcohol might increase in quantity by age, the oil did not increase in strength by keeping. If the increase of the soluble portion was due to the production of resinified oil, it would not necessarily follow that the oil would be more purgative. With regard to the case of the man at the docks to which Professor Redwood had referred, he (Mr. Holmes) imagined that the seeds at the dock were entire, not crushed seeds, and that the effect produced upon the man was probably due to the irritating principle contained in the coat of the seed. In handling croton seeds he had frequently noticed that the powder which arose from the seeds being rubbed together was exceedingly irritating to the nostrils. He would suggest that there should be a separate investigation of the coats of the seed, and of the kernels. He should be glad to learn whether in Professor Redwood's experiments absolute alcohol was used.

Professor REDWOOD: Absolute alcohol.

Mr. SENIER in reply said that he used absolute alcohol of a specific gravity of about ·794. In reply to Professor Attfield he had to say that experiments on the point which he mentioned were still in progress, and he proposed to include the result in another paper. Mr. Cleaver had suggested the possibility of the change of the solubility being due to the oil having become rancid, and the fact that an acid was liberated. He might say that the oils which he examined were perfectly neutral to test paper. In reply to Mr. Gerrard he might remind them that in the paper he did not say that the activity of the oil was increased by age. He merely said that the quantity dissolved in alcohol increased by age. He should like to ask Professor Redwood whether, in the experiments he mentioned, heat was not used when the oil was mixed with the alcohol.

Professor REDWOOD said that no heat was used in the experiments with English pressed oil. It dissolved instantly upon mixing the two together in equal volumes. He could not recollect whether the experiments were made in the summer or in the winter, but he knew, although oil dissolved readily in alcohol without the application of heat, separation took place when the oil was cooled down to between 30° and 40°. The mixture was kept for some months at an ordinary temperature without any separation occurring.

Mr. SENIER said that all his experiments wer conducted at a temperature of between 50 and 60 degrees. In reply to Professor Bentley he might say that he had seen the experiments that he alluded to with regard to croton oil. He had also seen the statement in Watts's Dictionary that nobody but the first discoverer had ever succeeded in isolating the active principle. He had tried the experiment, however, with one of the samples, but obtained no crotonol. He thanked him for his kind suggestions as to future investigations, and he would endeavour to follow out some of them.

A paper was then read upon—

DUBOISIA MYOPOROIDES, *R. Br.*

BY THE CURATOR.

The paper is printed on p. 705, and gave rise to the following discussion.

The PRESIDENT said that the communication was a most interesting one. He supposed that they might gather that the alkaloid had not been isolated. If it was true that the plant could be obtained in abundance, and that it yielded an alkaloid of the nature of atropine, but more abundantly, then the fact was a very important one. As far as the results obtained by the medical men had gone the product seemed to be very satisfactory; but they must not be too sanguine about it, for they knew that every remedy was very much praised when it first appeared.

Mr. HOLMES, in reply to a question put by the President, stated that he believed that the plant was plentiful in Australia. In this country there were at present a few pounds of the extract which Dr. Bancroft had brought over with him.

Mr. GERRARD said that the extract of Duboisia which had been used at the University College Hospital did not appear to him to be a first class pharmaceutical preparation, and that with a really good preparation probably better results might be obtained. He might say that it had the appearance of a partly resinous and a partly watery extract. It was very acid, so that it was likely to be irritating. The extract which he had used he had received from Mr. Tweedie.

The PRESIDENT said that his own experience was that extracts made in this country from imported plants were generally better than extracts made in hot climates by the natives, and particularly those made in India.

Professor BENTLEY said that the subject was one of very considerable interest, for the plant appeared to be one which could be got in any quantity. They were waiting to hear the results of Dr. Ringer's experiments, and the matter could not be in better hands.

The PRESIDENT announced that the next meeting—the last for the session—would take place on Wednesday, 3rd April.

EXAMINATIONS IN EDINBURGH.

Present—Mr. Williams, President; Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson and Young.

Messrs. Sandford, Corder, Moss, Taylor and Richard Bremridge were present as a deputation from London.

Professor Maclagan was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

One candidate was examined, but failed to pass.

MINOR EXAMINATION.

Twelve candidates were examined. *Seven* failed. The following *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Billing, Charles ....Edinburgh.
Murdoch, James William Aitkin Dumfries.
Richards, John Wesley ....Saltburn-by-the-Sea.
Russell, William ....Aberdeen.
Watt, George William............Huntly.

MODIFIED EXAMINATION.

One candidate was examined, but failed to pass.

PRELIMINARY EXAMINATION.

The undermentioned certificate was received in lieu of the Society's Examination:—

Certificate of the University of Durham.

Lovegrove, Charles ....Liverpool.

Provincial Transactions.

HULL CHEMISTS' ASSOCIATION.

The fifth meeting of the session of this society was held at the Cross Keys Hotel, Market Place, on Thursday evening the 21st ult., the President, Mr. C. B. Bell, occupying the chair. The minutes of the previous meeting having been read and approved, the president drew the attention of the members to the Dental Practitioners' Bill, now before parliament. After some discussion had taken place upon this Bill, votes of thanks were unanimously accorded to the Pharmaceutical Conference for the 'Year-Book of Pharmacy' for 1877; and to the "Sanitas" Company for samples and specimens of their manufactures. The President then called upon Mr. Baynes, F.C.S., F.R.M.S., etc., borough analyst, to deliver his lecture on Disinfectants.

Mr. Baynes commenced by observing that most ridiculous statements had been made and believed concerning the chemistry of disinfectants, and then proceeded to describe the composition of organic matter, and the several conditions requisite for the putrefactive process, enumerating the noxious gases emanating from decomposing matter. He next explained the meaning of the words disinfectant and antiseptic, and noticed the following natural and artificial disinfectants, soil, air, heat, cold, the manganates and permanganates, nitric acid, chlorine, sulphur, lime, carbolic acid, etc., stating that the great value of the air as a disinfectant was apparently due to ozone.

After alluding to infection, Mr. Baynes drew the attention of the members to samples of the new disinfectant "Sanitas," and stated his belief that it was the most perfect disinfectant, antiseptic and deodorizer, and concluded by describing the origin and process of its manufacture.

On the motion of Mr. J. F. Smith, seconded by Mr. Oldham and supported by the president, a cordial vote of thanks was awarded to Mr. Baynes for his very valuable and interesting paper.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The usual monthly meeting of this Association was held at Britannia Chambers, Pelham Street, on Wednesday evening, February 20, 1878. The chair was occupied by the Treasurer, Mr. J. Rayner, and there was a large attendance of members and associates.

The minutes of the last meeting were read and confirmed and a new member elected, after which the Honorary Secretary announced that he had received the *Pharmaceutical Journal* regularly since the last meeting, that he had received the 'Year-Book of Pharmacy," from Professor Attfield, and a donation of five guineas from Messrs. Langton, Harker and Stagg, of London. On the motion of the chairman a hearty vote of thanks was awarded to the respective donors.

The chairman then introduced Mr. H. Major, B.A., B.Sc., F.R.G.S., who delivered a most interesting lecture on Germs, which was listened to with great attention and loudly applauded at the close.

Mr. R. Jackson proposed a vote of thanks to Mr. Major for the very eloquent and instructive lecture he had delivered, which was seconded by Mr. Parker and carried unanimously.

Proceedings of Scientific Societies.

PARIS SOCIÉTÉ DE PHARMACIE.

New Medicines and Preparations.—At a meeting of this Society held on the 9th of January, under the presidence of M. Méhu, the subject of new remedies was discussed on the receipt of a letter from a provincial society expressing its thanks for the report recently issued (which has appeared in this Journal), and suggesting other preparations for which formulæ might with advantage be authorized. On the proposition of M. Baudrimont it was decided to appoint a permanent commission whose duty it should be to receive and examine all propositions relating to new medicines and new formulæ, and to report upon them to the Society. The members of this commission are Messrs. Schaeuffèle, Lefort, Desnoix Marais, Duquesnel and Petit, and the first business referred to it was a proposal to substitute *eau sucrée* for dilute alcohol in the Codex formula for cinchona wine, macerating with heat before adding the wine, and a proposal for a modification of the formula of syrup of bitter orange peel.

Cremocarpus setigerus.—M. Martin presented a specimen collected in California of this Euphorbiaceous plant, which resembles the crotons. It yields a hydrolate, having an odour recalling that of a goat. To carbon bisulphide it gives up a brown fatty matter, having the same odour, and to alcohol a very hygroscopic extractive which is very bitter and acrid to the taste.

Salts of Cinchona Alkaloids.—M. Petit presented to the Society specimens of acid hydrobromate of quinine and acid hydrobromate of quinidine which he had prepared. The composition of these salts, which M. Petit proposes to study more closely, appears to be one equivalent of base, two of acid, and four of water. M. Petit also referred to the neutral sulphate of quinidine, at present occurring rather abundantly in the market. He had examined two samples, one from London, the other from Val-de-Grace. They were exactly similar in respect to their rotatory power, and upon heating them in a stove to 100°, the loss of weight in neither case exceeded 0·5 per cent. He therefore concludes that neutral sulphate of quinidine does not contain water of crystallization.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

A meeting of the members of the deputation appointed by the Executive Committee to wait upon one or more of the promoters of the Dental Practitioners' Bill, with a view to amend the same, was held at the Inns of Court Hotel, High Holborn, London, W.C., on February 28, 1878, at 2.30 p.m. Mr. S. U. Jones, President, in the chair.

Present—Messrs. Andrews, Greenish, and the Solicitor of the Association.

A letter was read from Mr. Hampson regretting his inability to attend the meeting or accompany the deputation.

The Secretary reported having corresponded with Sir John Lubbock, M.P., the principal promoter of the Dental Practitioners' Bill, and that he had consented to receive the deputation at the House of Commons on that day at 4 p.m.

Considerable discussion took place on those parts of the Bill affecting the interests of the trade and on the alterations to be suggested to the promoters of the same.

The deputation then proceeded to the House of Commons. The Secretary having introduced the members of the deputation to Sir John Lubbock,

Mr. S. U. Jones said there appeared to be several clauses in the Dental Practitioners' Bill, of which the honourable gentleman was the principal promoter, that were hostile to the interests of chemists and druggists, and that the deputation of which he had the honour of being a member was appointed by the Executive Committee of the Chemists and Druggists' Trade Association of Great Britain to wait on the gentlemen who had charge of the Bill, with a view to suggest some important modifications in the objectionable clauses. It would appear from a careful perusal of the Bill that, if passed into law, it would prevent all those chemists and druggists who were at that time practising dentistry from continuing to do so, or at all events from recovering "any fee or charge in any court, for the performance of any dental operation," unless they obtained their registration under the Act, for which there seemed to be no provision in the Bill ; on the contrary they were by the fifth clause debarred from registration, not being "licentiates in dental surgery or dentistry of any Royal College of Surgeons in the United Kingdom, or of the Faculty of Physicians and Surgeons of Glasgow ; or at the passing of that Act *bonâ fide* engaged in the practice of dentistry, either separately or in conjunction with the practice of medicine or surgery." This prohibition would be very severely felt by many of Her Majesty's poorer subjects throughout the kingdom, and it would be a source of great inconvenience to all classes of the public residing in country districts where no professional dentist was to be found. He would suggest to the honourable gentleman the desirability of amending the fifth clause, by the addition of the following words to subsection (*a*), "any duly registered pharmaceutical chemist or chemist and druggist practising dentistry at the time of the passing of this Act," or, if this was a concession that could not be granted, the addition to subsection (*b*) of the words, "or the business of a chemist and druggist;" in either case placing these words at the termination of the sentences. He would next direct the attention of the honourable gentleman to the seventh clause, which provided that "No name shall be entered in a register under this Act except of persons authorized by this Act to be registered, nor unless a registrar be satisfied by sufficient evidence that the person claiming is entitled to be registered." It appeared to be a very open question what would be deemed by the registrar "sufficient evidence" for this purpose. He thought too much power was being placed in the hands of the registrar; of course by a further provision in the same clause any person whom the registrar refused to register could appeal against this decision to the General Council, but it would be an exceedingly inconvenient and expensive recourse for gentlemen residing at some distance from London, and he would suggest that this power to veto registration should not be placed in the hands of a registrar, but that a clear definition of the meaning of the words being "*bonâ fide* engaged in the practice of dentistry" should be appended to the declaration contained in the schedule to the Bill, and that an attested declaration from persons claiming registration should be deemed sufficient evidence that they were "practising dentistry at the date of the passing of the Act," and entitle them to be registered under the Act.

The Solicitor said he thought it a very important matter that the term "practising dentistry" should be clearly defined in the Bill, and pointed out that in the absence of explanation litigation would probably ensue. He also, alluding to the 13th section, said as there were powers given in the Bill for the appointment of examining boards it should not be compulsory for persons seeking registration by passing the examinations to walk hospitals, or attend several courses of lectures in London, as was necessary for obtaining the degree of licentiate in dental surgery; the proper test, he urged, would be the candidate's fitness to perform dental operations, no matter where or by what means he gained such knowledge.

Mr. Andrews referred to the vested rights of chemists and druggists in the practice of dentistry, and said there were very many members of the trade, particularly in country districts, who practised somewhat extensively. It appeared to him, and he hoped it would appear to the honourable gentleman also, that such interests should be respected and protected; it was usual he thought in Bills of the kind they were discussing to preserve the rights of persons practising at the time.

Sir John Lubbock said he was much obliged to the members of the deputation for their kindness in coming there. He would very carefully consider the points referred to, and talk them over with Sir Philip Egerton, Mr. Tomes, and the medical gentlemen under whose direction the Bill was prepared. He should like to say it was not the intention of that Bill to interfere with such simple operations as extracting or stopping teeth, which did not require any extended period of study, being performed by chemists ; certain things were allowed and no penalties were attached, yet they were to be discouraged. The object of the Bill was not to prevent such simple operations as he had referred to being performed upon any one who liked to submit himself to the same, but to prevent a person holding himself out to the public as being especially qualified as a dentist when he was not so qualified; although, by the provision of the Bill, no unregistered person would be entitled to recover any fee or charge by legal action, the same did not prevent an unregistered person asking a fee or obtaining it. If they were to amend the schedule containing the blank form of declaration, as suggested by Mr. Jones, they might modify clause 7, but it had not occurred to him that any difficulty would arise on that point, a registrar refusing to register qualified persons would be liable to legal proceedings ; but he saw a little difficulty about a person being in a position to satisfy the registrar that he was entitled to be registered, and they would consider that question and see if the promoters of the Bill could in any way remove the difficulty. With reference to the question of vested interests he was quite disposed to go with the deputation. It was a very reasonable point and he thought subsection 6, clause 3, should be modified.

The Secretary said he was pleased to hear from the honourable gentleman that he was prepared to recognize and protect the vested interests of the trade in amending the Bill before them, and that it was not the intention of the promoters of the Bill to prevent chemists and druggists extracting or stopping teeth, but he should like to direct the honourable gentleman's attention to a portion of the third clause which if passed into law would preclude a chemist from publicly informing his customers—the public—that he did perform such operations. This clause provided that a person may not use the name or title of dentist either alone or in combination with any other word or words "or any name, title, addition, or description implying that he is especially qualified to practise dentistry unless he is registered under this Act," under penalty of a sum not exceeding £20, so that any chemist and druggist exposing the words "Teeth Extracted" or "Teeth Stopped" on labels, placards, brass plates, etc., would be liable to this penalty, as he would thereby clearly use a "description" implying that he was especially qualified to extract and stop teeth. It seemed an anomaly for a person to be permitted to do certain things, while if he explained to the public that he did them he rendered himself liable to a heavy penalty, and he would submit to the honourable gentleman the advisability of modifying that clause.

Sir John Lubbock said he would make a memorandum on the subject and he should be disposed to erase the words "addition or description" from the third clause, which would remove the objection.

The Secretary inquired if the members of the deputation may be assured that the honourable gentleman would so modify the Bill as to carefully protect the vested interests of chemists and druggists in the practice of dentistry.

Sir John Lubbock assented.

Mr. S. U. Jones then thanked the honourable gentleman for his kindness in receiving the deputation and for the concessions promised.

UNIVERSITY OF EDINBURGH CHEMICAL SOCIETY.

The sixth meeting of the Edinburgh University Chemical Society for session 1877–1878, was held on February 27, Mr. Inglis Clark, B.Sc., in the chair.

A paper on "Electrolysis" was read by R. M. Morrison, D.Sc., Chemical Demonstrator of the University, in which he traced the history of electrolysis down to the present time, showing that as recently as 1840 the art was practically in its infancy; and that at the present day it was in numberless ways made use of. The chief points of theoretical and practical interest were dwelt on, both with regard to the various metals which could practically be used, and to the solvents from which the best results were attainable.

THE LONDON CHEMISTS' ASSISTANTS' ASSOCIATION.

On the evening of Wednesday the 27th February, a most successful *soirée* was held in connection with the above Association, at 28, Baker Street, W., in rooms kindly lent for the occasion by the Council of the Quebec Institute.

Notwithstanding the unfavourable weather upwards of 300 ladies and gentlemen were present.

There was an exhibition of microscopes by Mr. Crouch of Barbican; graphoscopes and revolving stereoscopes by the London Stereoscopic Company, Regent Street; raw chemicals lent by Messrs. Hopkin and Williams, and Mr. S. Lloyd Bullock; Materia Medica specimens lent by the Council of the Pharmaceutical Society; telephones (connecting two rooms), and a fine collection of drawings, photographs, and water-colours, lent by Mr. Stuart; model of the ear, lent by Dr. J. S. Stocker; a case of terebene preparations, lent by Messrs. F. S. Cleaver and Sons; several powerful galvanic batteries, lent by Messrs. S. Maw, Son, and Thompson. Views were shown at intervals by a dissolving view apparatus from the Royal Polytechnic Institution.

After tea the guests were entertained by several members of the Association and others, with pianoforte and violin solos, spirited recitations and songs.

The entertainment throughout the evening was of an interesting character, and the friends of the Association appeared unanimously to wish that the *soirée*, which proved so successful, might become an annual event.

At the close of the meeting the President, Mr. P. Princep, made a few appropriate remarks, and proposed a vote of thanks to the Council of the Quebec Institute for the use of the rooms, and to all friends who, by exhibits or personal exertions, had assisted to render the evening so successful. The singing of the National Anthem then closed the evening's entertainment.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held at 17, Bloomsbury Square, on Thursday, Feb. 28, when a note on "Some of the Substances employed in Perfumery," was read by Mr. C. J. Mead. The paper gave an interesting account of some of the principal substances used in the manufacture of perfumery.

The reading of this paper was followed by a note on "Blatta orientalis, its use and preparation" by Mr. J. Hart. The author first announced that the "new drug" was a very old acquaintance, the common "black beetle," and followed this statement by a description of the insect. The therapeutic action was diuretic and it was supposed to be of special value in Bright's disease. The usual method of administration was in the form of a tincture prepared by macerating half-a-pound of beetles in a pint of rectified spirit and filtering. The resulting clear liquid was of a yellowish colour, and became opalescent by the addition of water. Its taste was not in any way disagreable, as could be proved from the sample Mr. Hart exhibited.

Both papers were followed by discussions, and votes of thanks awarded to the authors, after which the meeting was adjourned till March 14.

Dispensing Memoranda.

[72]. May I suggest to Mr. R. Turner that I always find ♏iij., of the oil sufficient, rubbed up with the dry powders, and then add as an excipient a little Ext. Gent., firm pills are thus made, having the advantage of being small.—J. C. Culfe, *Ipswich.*

[72]. A few drops of mucilage of acacia will make a very convenient mass for rolling, and not cause any increase in size.—J. De Carle.

[73]. Suggests its own mode of mixing, as I conceive there is little dispensing acumen required in its composition, the ingredients can only be temporarily suspended in the liquid by shaking and as quickly swallowed.
J. De Carle.

[74]. In answer to this query, I should, if practicable, communicate with the writer prior to dispensing the prescription; if that was not feasible, I should have dispensed it as follows:—

℞	Tinct. Nucis Vomicæ.	℥iss.
	Pepsinæ Porci	ʒiv.
	Acid. Nitromur. dil.	ʒiij.
	Acid. Hydrocyanic. P.B.	ʒiss.
	Liquor. Bismuthi	℥ij.
	Aquæ	ad ℥xl.

℥j. ter die statim post cibos sd.

I think it is quite evident there is an omission of the aqua.—Dyspepsia.

[75]. A few drops of alcohol should bring this mass into subjection, only that the Bals. Peruv. is given in excess.—J. De Carle.

[76]. Will you kindly favour me with your opinion as to the correct method of dispensing the following prescription?

Copy.

℞	Sodæ Bibor.	℥ss.
	Glycerini	q.s.
	Aq. Destill.	Oss.

Ft. Lotio.

The method I employed was to add sufficient glycerine to the borax to dissolve it, and then to fill up to ℥x. with aq. dest., but as the lotion develops a fungoid growth after keeping a week, the patient concludes it is not prepared correctly.—Alex. Courtenay.

Notes and Queries.

[577]. A WATER QUERY.—I think there is no reason to change a leaden pump for a cast iron one with a copper sheath, as the copper by its combination with the ingredients of well water is still more objectionable.

M. Fordos was unable to find the slightest traces of lead in 10 litres of river water taken from the reservoir in the Pharmacie de la Charité à Paris.

The bicarbonate of lime, carbonic acid, and sulphate of lime contained in the water will cover the walls of the leaden pump with carbonate and sulphate of lead, and both being insoluble in water a contamination cannot happen.*

According to Raland, carbonate of lead produced through the bicarbonate of lime contained in nearly every spring water can, if in fine powder, be suspended in such a way that it will even pass through an ordinary filter. Treated with sulphuretted hydrogen it certainly blackens but being so finely divided is nearly invisible. If to the water are added a few drops of a solution of tartrate of ammonia, the insoluble hydrate, sulphate, carbonate, phosphate, etc., of lead will be dissolved and the reaction of sulphuretted hydrogen easily perceived, as I found out in repeating the test in my laboratory.

H. W. LANGBECK.

* A contamination of water with lead can only happen in presence of nitric or nitrous acid combined with ammonia which acts in the same way as tartrate of ammonia.

Obituary.

Notice has been received of the death of the following:—

On the 24th of February, 1878, Mr. Peter Carter Yarrington, Chemist and Druggist, East Dereham, Norfolk. Aged 34 years.

On the 26th of February, 1878, Mr. Charles Service, Chemist and Druggist, South Lambeth Road. Aged 76 years.

Correspondence.

THE PRELIMINARY EXAMINATION.

Sir,—In your last issue I noticed a letter from a correspondent, residing at Stirling, complaining of the great percentage of failures in the above examination, and attributing it either to the deterioration of the candidates or the stringency of the qualifying test, particularly as regards the metric system; but having recently passed the examination I should like a short space in your valuable Journal to express my opinion on the subject.

Firstly, as regards deterioration. The percentage of failures has no doubt greatly increased since so many chemists have taken as apprentices mechanics' sons and errand boys (knowing several instances myself), who have received a very limited education, and in some cases scarcely any at all, and after being a few months in the trade they are persuaded to present themselves for examination, and the result is that 90 per cent. fail to obtain the number of marks required to pass.

Secondly, "As to its stringency." The subjects of the qualifying test (the metric system excluded) are simple enough for any respectable youth leaving school to pass, and the questions given on the metric system being only elementary, could be easily learnt by the candidate with a fortnight's extra study before presenting himself. The Act was passed to get a better qualified class of men to bear the great responsibilities connected with the trade, and I do not think it would be just to the public at large, or to those who have already passed their examinations, to lower the standard in any way whatever, as by so doing greater facilities would be offered to the lower classes to enter the trade, and since so many grocers and co-operative stores are selling drugs and patents at such cutting prices, I do think the best motto for those now in business is "The fewer the better."

A PRELIMINARY STUDENT.

March 2, 1878.

THE DISCREPANCY IN EXAMINATION RESULTS.

Sir,—I must beg of you to spare me a small space in your Journal wherein to criticize the letter which appeared in this week's issue, from Mr. Mackay.

Whilst congratulating the North British Branch of the Pharmaceutical Society of Great Britain in general, and the Examining Board of the aforesaid North British Branch of the Pharmaceutical Society of Great Britain in particular, on the fact of having Mr. J. B. L. Mackay to "assume the defensive" on their behalf, I scarcely think he is justified by recent events in assuming the superiority of the "Brachychephalæ" over the "Dolichocephalæ." Taking the last Preliminary examination pass list as a criterion of the respective capabilities of the North and South Britons (and to this Mr. Mackay cannot surely take exception, as it is a "written," and undoubtedly "fair" examination), I find that whilst 40·6 per cent. of those who presented themselves at the English centres passed only 26·2 per cent. of the candidates presenting themselves at the Scotch centres (presumably Brachycephalæ) came unscathed from the ordeal.

These figures certainly do not bear out the insinuations of Mr. Mackay, and I believe that were it possible to analyse the pass lists of the North British Branch in reference to the Minor examination (first deducting the despised Dolichocephalæ, who prefer to try their fortune at what is generally supposed to be the more lenient Board, and who help to swell the North British percentage of successful candidates), we should find little, if any, difference in the results.

That the Edinburgh Board has the credit of more easily passing candidates there can be no doubt; at any rate such was the case seven or eight years ago when I was myself a student, and that the same idea still exists seems borne out by the fact that such large numbers of candidates go from England to that Board. Thus at the December examination (Minor) no less than half the successful candidates hailed from this side the Tweed. I fancy Mr. Mackay will have to examine the London pass lists some time ere he will find many of his northern friends figuring therein. They either prefer facing the Edinburgh Board, or if they do present themselves in London—well the less said about the greater cerebral development of the Brachycephalæ the better.

In reference to the abolition of oral examinations, I do not see how the capabilities of candidates in such subjects as dispensing, pharmacy, and reading prescriptions can be properly gauged by any other means, though I quite agree with Mr. Mackay that, where possible, a written examination places candidates on more equal terms.

E. H. S.

London.

T. C. Thompson.—*Pulmonaria officinalis.*

W. M.—The following is from Wilson's 'Skin Diseases,' and is probably what you require :—

℞	Olei Amygdalæ Dulcis	℥j.
	Liq. Ammoniæ Fort.	℥j.
	Sp. Rosmarini	℥iv.
	Aquæ Mellis	℥ij.

Misce. Fiat lotio.

Cymro.—If your property is illegally detained we should advise you to consult a solicitor.

J. P. H. is recommended to consult a work on dentistry.

E. Lloyd.—The objectionable tint is probably due to ultramarine, added to conceal the bad colour of the sugar.

W. D.—See a paper on the Preparation of Glycerine Jelly in vol. v., p. 401, of the present series of this Journal.

"*Cera Alb.*" who is requested in future communications to send his name and address, is referred to the advice given in our answer to him on p. 704.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Symons, Mr. Pittendrift, Mr. Williams, Mr. Footit, Mr. Elton, Mr. Fitch, Mr. Powler, Plymo, Student, Caledonian.

NOTE ON A CRYSTALLIZABLE INDIFFERENT RESIN OF GURJUN BALSAM, AN ADDITION TO THE 'PHARMACOGRAPHIA.'*

BY PROFESSOR FLÜCKIGER.

In the 'Pharmacographia,' p. 204, it is stated that copaivic acid is by no means an abundant and common constituent of copaiba. The only kind of that balsam I have ever met with, which readily yields crystallized acid is that mentioned in the said book. The drug alluded to was contributed from Trinidad to the London Exhibition of 1851. The crystals before me are of decidedly acid reaction on litmus paper. I have recently again examined several varieties of copaiba, but have not been successful in obtaining copaivic acid from them. At the same time I prepared the essential oils from them and was astonished to find them all levogyre, although I had submitted to distillation not only levogyre varieties of the balsam, but also strongly dextrogyre ones. I must say in fact (see 'Pharmacographia,' 204), that I have as yet not met with an *oil* of copaiba deviating to the right.

Some time ago I noticed in the price list of Gehe's and Co., Dresden, "crystallized copaivic acid." On applying for it, and at the same time for the very balsam from which it had been extracted, I was at once informed that the material by which the acid had been afforded was "East Indian copaiba." The balsam sent, together with the crystals, proved indeed to be Balsamum Dipterocarpi, as described by Hanbury and myself in 'Pharmacographia,' 81. I therefore supposed the crystals sent by Gehe and Co. to agree with gurjunic acid, but found them to be devoid of acid character. They were slightly yellowish and undoubtedly crystalline, and soluble, although not precisely in abundance, in the usual solvents for resins. Among them I found petroleum spirit, boiling at about 80° C., the most suitable for purifying the crystals. If they are dissolved in about twelve parts of that liquid, tolerably well-formed crystals, thin prisms—sometimes as long as two-fifths of an inch—are obtained by exposing the solution to cold. I have not been able to get finer crystals, either by evaporation of the petroleum spirit solution, or by using alcohol.

The purest, perfectly transparent, and colourless crystals of the best crops, begin to melt at 126° C. without diminishing their weight; they are in fact anhydrous; somewhat more considerable quantities cannot be perfectly liquefied before reaching 130°. Gurjunic acid,† according to Werner (*Zeitschrift für Chemie*, 1862, 588), melts at 220°. The resin under notice, as purified by me, after it has been melted, forms an amorphous mass, reassuming immediately the crystalline form as soon as it is slightly touched with alcohol. By heating the crystallized resin in a platinum capsule it is partly volatilized, and evolves the same odour as is given off by heated colophony—partly it is charred, the small amount of charcoal being easily burnt away.

The crystallized resin is not dissolved even by boiling caustic lye, nor does it possess an acid reaction on litmus paper; it is in no way capable of yielding any compound with basic substances. Its saturated solution in petroleum spirit displays no rotatory power on polarized light.

It forms an orange solution with concentrated sulphuric acid, becoming decolorized and turbid on addition of water. If submitted to destructive distillation an acid oily liquid of a rather agreeable odour is produced. By using potash the resin under notice is not much altered, nor by heating it with anhydride of acetic acid.

Submitted to ultimate analysis by Dr. Buri, in my laboratory, the resin in burning yielded:—

	I.	II.	III.
	0,2476	0,2354	0,2492
CO_2 . . .	0,7369	0,6996	0,7419
OH_2 . . .	0,2535	0,2410	0,2557

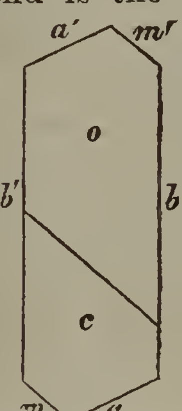
Answering in percentages—

C	81,16	81,05	81,16
H	11,38	11,37	11,40
O	7,46	7,58	7,40

The formula $C_{28}H_{46}O_2$ would require:—

28 C	336	81,16
46 H	46	11,11
2 O	32	7,73
		100,00

The crystallographic character of the resin has been examined and carefully described by Dr. Bücking, in Professor Groth's 'Zeitschrift für Krystallographie,' Liepzig, 1877, 389. The crystals belong to the asymmetric system. They are long prisms (the horizontal section of which is represented in the accompanying figure), formed by the reflecting surfaces *a b m*, and truncated towards *b*. At the end is the sharply inclined face *o*, also reflecting, and a nearly horizontal face *c*, which is always so uneven that not even an approximate measurement can be made. Consequently the relation of the axes could not be calculated. The angles observed were as follows:—



$a : b = 66° 58'$.
$a : m = 65° 54'$.
$b : m = 47° 8'$.
$o : a = 57° 6'$.
$o : b = 79° 20'$.
$o : m = 46° 51'$.

---

* Translated from the *Archiv der Pharmacie*, February, 1878.

† It is called "gurgunic acid" in the German books, owing no doubt, to a misprint, for I am not aware that in India they ever write "gurgun balsam" but alway "gurjun," although I am unable to say what this word signifies.

THE TURPENTINES AND RESINOUS PRODUCTS OF THE CONIFERÆ.

BY DR. JULIUS MOREL,

Professor of Chemistry in the Industrial School, Ghent.

(*Continued from page* 545.)

Distinguishing Characters of Commercial Oils of Turpentine.—The volatile oil extracted from turpentine not only varies with different species, but the oil yielded by the different parts of the same plant is variable, the boiling point varies between 152° and 172° C., and the specific gravity at the ordinary temperature between 0·856 and 0·870. This difference is especially manifest in the optical properties, the oil rotating the plane of polarized to the right or to the left and also in varying degree. The odour also differs according to the species that has yielded the oil.

The properties of oil of turpentine described above apply to the common variety (from *Pinus maritima*, etc.), and I shall now proceed to pass in review the principal characters of the other oils extracted from the different turpentines that have been described.

Oil of Venice Turpentine (from *Larix Europœa*) boils at 157° C., and rotates the plane of polarized light 6·4° to the left. Venice turpentine contains 15 per cent. of this oil.

Oil of Canada Turpentine (*Abies balsamea*) obtained, according to Flückiger and Hanbury, by the distillation of that turpentine with water, is colourless and presents rather the odour of common turpentine than the pleasant smell of Canada balsam. Besides the body of the composition $C_{10}H_{16}$ it contains a very small quantity of an oxygenated compound, the presence of which can be demonstrated by the evolution of hydrogen, when a fragment of metallic sodium is added to it, care being taken previously to remove any water that might be present by distillation of the oil over fused calcium chloride.

The distillation of the oil commences at 100° C., but the greater part does not distil until about 170° C., or even a higher temperature is reached. The oil collected at 167° C. has a specific gravity of 0·863 and deviates the plane of polarized light 5·6° to the left; that collected at 160° C. presents the same properties; but that collected at 170° C. and beyond deviates the plane of polarized light 7·2° to the left.

Glacial acetic acid dissolves this oil of turpentine freely; at a temperature of about 54° C. equal parts of the acid and the oil can be perfectly mixed, but upon cooling a certain part of the acid separates.

Oil of Canadian turpentine treated with gaseous hydrochloric acid gas does not give a crystalline combination, but one is easily obtained by adding fuming nitric acid and then heating the mixture gently; the interior of the retort becomes coated with crystals having the formula $C_{10}H_{16}+HCl$.

This oil of turpentine approaches that yielded by the cones of *Pinus Pinea*, L., or by the leaves of *P. Pumilio*,* Haenke, and the greater part of the oils of turpentine of French origin, whilst oil of turpentine of American origin rotates the plane of polarized light to the right, and combines immediately with hydrochloric acid gas to form the crystallizable compound.

Canadian turpentine yields about 20 per cent. of oil when the extraction is effected by the water-bath, and 18 per cent. when extracted with water.

Alsatian oil of turpentine (*Abies pectinata*), purified after treatment with sodium, rotates the plane of polarized light 8° to the left, and boils at 163° C. After being kept two or three years in a well-closed bottle it becomes thick and dextrogyre. When saturated with hydrochloric acid gas it does not give a solid compound. This oil has the pleasant aromatic citron-like odour of the turpentine from which it is extracted. The oil extracted from the cones of the same tree is more odoriferous and rotates the plane of polarized light much more strongly (51 to the left); nevertheless no difference has been recognized in its chemical composition. Strassburg turpentine contains about 24 per cent. of oil.

Burgundy oil of turpentine rotates the plane of polarized light 8·5° to the left. It contains a small quantity of oxygenated oil, from which it can be freed by treatment with sodium. In the pure state it does not yield a crystallizable compound with gaseous hydrochloric acid.

Uses.—Turpentine oil is employed in medicine and in the veterinary art, both for internal and external administration. It has been recommended as an antidote in cases of poisoning by phosphorus, where it would act in opposition to the tendency of the phosphorus to deprive the hæmatose of the blood of oxygen. According to Köhler and Schimpff it forms under these circumstances terebintho-phosphorous acid, which is innocuous in its action and is easily eliminated by the urinary organs.

The property turpentine oil possesses of dissolving resinous substances leads to its employment in the manufacture of varnish. It readily dissolves fats, and formerly it was employed nearly exclusively in removing grease from cloth, etc. It dissolves linseed oil that has been rendered siccative by treatment with lead and manganese oxides, and the solution is used for varnishing leather and making oil-cloth. Its power of dissolving crude linseed and poppy oil leads to a considerable consumption of it by painters; it is also used in the preparation of body colours, its oxidizing action probably contributing to the quick drying of the picture. Finally, heated, it is used as a solvent of caoutchouc.

Adulterations.—Notwithstanding the comparatively low price of turpentine oil it is the subject of numerous sophistications, of which the following are the best known. It is believed, however, that an adulterated sample will not answer to the characters described in a previous paragraph.

(1) Fixed oils. These, if present, may be easily detected by placing a drop of the suspected turpentine oil on paper and heating moderately. If the sample be pure the spot disappears completely, but if it be mixed with a fixed oil a greasy stain remains. Further, oil of turpentine dissolves completely in 90° alcohol, whilst fixed oils only yield a small portion (the fat acids) to that solvent.

(2) Water. Leuchs points out that the clear appearance of essential oils is no proof of their absolute freedom from water. Small quantities of water may, however, be detected by shaking the oil with two or three volumes of petroleum, when the mixture becomes turbid owing to the separation of the water.

(3) "Swedish oil of turpentine," a name applied to a product of the distillation of wood. This adulteration is practised in Sweden, and the turpentine oil then has a disagreeable smell. Sandström has found that its presence can be clearly distinguished by pouring the oil carefully into a test tube containing commercial nitric acid, so as to float on the top of the acid. If "Swedish turpentine oil" be present it is immediately coloured brownish, even when mixed with four times its volume of pure oil. Genuine turpentine, whatever its origin, is not coloured at once, and only acquires a yellowish tint after some time. If "Swedish turpentine oil" be shaken with twice its volume of commercial nitric

* The *oil of pine leaves* is a greenish yellow liquid, with an aromatic odour recalling that of oil of lavender; it is soluble in alcohol and ether and has the composition of the oils of turpentine.

Oil of Pine branches (Oleum templinum) is the product of the distillation of the young twigs and buds of *P. Pumilio*; it is of a greenish yellow colour, and has an aromatic odour and the composition of oil of turpentine. It is prepared in Germany and is supplied especially from the Carpathian mountains.

acid, a brownish colour is quickly produced that becomes darker, and finally black in proportion as the mixture is thoroughly effected. Pure turpentine oil, treated in the same manner, is at first only coloured by the acid yellow, becoming at the end of two hours yellowish red. In this experiment the turpentine oil does not mix thoroughly with the acid, a portion, having a pale yellow colour, floating on the top. If the "Swedish turpentine oil" is not completely colourless it does not mix intimately with the acid, and the formation of a brownish black resinous layer can then be observed.

(4) "Oil of Pine" (German, *Kienöl*). To detect this sophistication Lintmans recommends to take 2 grams of the suspected oil, add to it 4 grams of ammonia, sp. gr. 0·96, filter, and treat the filtrate with a few drops of a 10 per cent. solution of potassium nitrate; then add carefully 10 drops of nitric acid, sp. gr. 1·3, so that it descends to the bottom of the aqueous layer. If "oil of pine" be present a yellow or yellowish brown colour is produced. A mixture of 1 part of "oil of pine" with 19 parts of turpentine oil gives a perceptible colour.

(*To be continued.*)

NOTE ON HYDROBROMIC ACID.*

BY EDWARD R. SQUIBB, M.D.

Among the recent additions to the materia medica hydrobromic acid seems likely to take a permanent place if some method of preparation and some standard of strength can be adopted whereby a moderate degree of precision in its use might be attained.

Various modes of preparation have supplied the market up to the present time with acid of various, and commonly unknown strengths; and generally not pure enough for medical uses. And the various arbitrary doses published with the various acids as sold seem to bear no proper relation to its strength or to its therapeutic power as compared with the bromides for which it is used as a substitute.

Hence, as might reasonably be expected, the experience and testimony, in regard to its utility, are confused and often conflicting, and this apparently without any suspicion that the confusion and failures might depend on the quality and strength of the acid used.

Physicians prescribe such articles, and pharmacists buy and dispense them, too often as if there could be but one thing supplied. For example, the physician prescribes hydrobromic acid in half drachm doses. The pharmacist goes to the manufacturer, or to the importing house, and buys it to dispense, and too often neither of them know that it may be of any strength from one to fifty per cent. And, when the percentage strength is known, few will calculate what should be the dose equivalent to the bromide for which it is to be substituted, or appropriate to the bromine effect that is desired.

It is true that the dose cannot be determined by the quantity of bromine present in the acid as compared with that present in the bromides, no more than the dose of chlorine could be determined by the quantity present in the chlorides, or of cyanogen by the quantity present in the cyanides; yet there is doubtless some relation, and this relation when studied is the best basis for the accumulation of facts and experience.

The acid is a sedative neurotic, and its principal uses as developed up to this time are as an occasional substitute or alternate for the bromides of potassium, sodium and ammonium. It is well established that the bromine is the active medicinal agent, whose influence is sought in the use of these salts. And it is also well known that the alkaline bases,—and especially potassium,—when given for a long time, are liable to enfeeble the muscular tissues; and produce other changes not desirable, through undue alkalinity of the blood and the secretions; and, through the secretions to enfeeble the digestive and assimilative processes. It is true that the proportion of cases in which such effects come into undue prominence is small, but to correct them where they do occur, and to forestall them when likely to occur, without suspending the bromine, whose continuous sedative action is often very important,—this acid now comes into use.

It is, however, certainly not well adapted to very prolonged use, for like other so-called mineral acids, it would be very liable to interfere more with the normal processes of the economy than the bromine salts with alkaline bases. Therefore, for the present at least, it must be regarded simply as an alternate for the bromides, for occasional and exceptional, rather than for general use. Such uses are, however, very important in the treatment of chronic affections of the nervous system, even when neither functional nor organic mischief is observed or apprehended, for several reasons, among which the disgust which patients often acquire for salines when long continued is not the least. In hospitals for the insane, especially in the epileptic wards, it should be very useful both in effect and in facility of administration, because it can be given in the form of lemonade, if moderate or small doses should prove effective.

It has been highly spoken of as a corrective and preventive remedy for the headache, ringing of the ears, and general cerebral distress which often follows upon the use of salts of quinia,—which should be called quinism and not cinchonism. When given with or after the salts of quinia the disagreeable head symptoms are said to be prevented. It should be remembered, however, that as a general rule some degree of this quinism is necessary to indicate the full power of quinia salts, and that irrespective of the quantity given the full influence as an antiperiodic is never assured without some degree of the head symptoms; and, that the dose required to produce the full antiperiodic effect varies very much in different individuals, and even in the same individual at different times. In those cases where small quantities of any of the salts of quinia produce head symptoms of disproportionate severity, so that the desired benefit of the antiperiodic cannot be attained because the sufficient dose cannot be borne,—this acid is said to be very useful, either given with the quinia salt, or later, when the head symptoms begin. It is also said to be useful in nervous headaches and tinnitus from other causes than the administration of quinia salts, and to be effective when given at any stage of the affection.

Other uses to which the acid has been applied with alleged advantage are not yet confirmed.

The first necessity in the application of a new remedy is to know its relations of quantity and effect upon the economy, and this starting point being generally difficult to obtain, many valuable agents are lost, while others blunder into use through confusion and difficulty, or become a prey to empiricism. Thus the beneficent effects of potassium bromide as a sedative neurotic, failed of full recognization for more than twenty years, through the inadequate quantities directed as doses by standard authorities; and it was only where the so-called toxic doses were exceeded that its utility in a large class of cases was realized.

It being now generally established that it is the bromine element which is effective in all the bromides, the base merely giving direction to the sedative action, and to the rate of elimination, the doses required for a given effect are approximately proportionate to the quantity of bromine present in the different bromides. Potassium bromide contains 67·22 per cent. of bromine; sodium bromide, 71·4 per cent.;* and ammonium bromide 81·6 per cent., and

* From the 'Transactions of the Medical Society of the State of New York, 1878.

* The sodium bromide of the United States market seems to be neither the anhydrous salt, containing 7·77 per cent. of

therefore their doses, to be equivalent in bromine, are nearly in the ratio of 9, 8, and 7½. That is, 20 grains of potassium bromide is equal to a dose of 18·8 grains of the sodium salt, or 16·5 grains of the ammonium salt, the quantity of bromine being constant in all three at about 13·44 grains. But such a quantity as 13·44 grains of uncombined bromine put into the stomach would probably be a fatal poison.

Hydrobromic acid,—which is really hydrogen bromide, or bromide of hydrogen,—is a gaseous substance containing 98·76 per cent. of bromine. But the solution of the gas in water which constitutes the liquid commonly known as hydrobromic acid, may contain the gas in any proportion, or be of any strength, and when stronger than about 40 per cent. it is corrosive and inconvenient for any ordinary uses.

The potassium salt is, of all the bromides, the most commonly used, and its doses to obtain given effects are best established. Hence if this salt be used as a standard for hydrobromic acid, as it is for other bromides, and the acid be adjusted in strength so as to bear some easily remembered relation of its bromine constituent to the potassium salt, a base or starting point would be established for its general and accurate use, whether the bromine when combined with hydrogen should prove more active than when combined with potassium or not. Then as the potassium salt contains, in round numbers, say 68 per cent. of bromine, a solution of hydrobromic acid containing also 68 per cent. of bromine would have the same bromine value, though not necessarily the same bromine effect in medicine. But an acid of this strength would be unnecessarily difficult to make and to dispense. The next most simple relation is to have an acid of half the bromine strength of the salt, or 34 per cent. Such a strength can be made, kept and dispensed without unusual difficulty, and represents the bromine of the potassium bromide in the proportion of about 2 to 1, a relation easily remembered, and convenient in use. Therefore this strength has been adopted as a proper and convenient one, and the quantity of such an acid equal to the bromine of 20 grains of potassium bromide would be 40 grains, though the equivalent dose might be smaller to produce a given effect, should bromine when combined with hydrogen prove more active than when combined with potassium.

The formula and process for making an acid of this strength are as follows :

Take of Potassium Bromide	Six parts.
Sulphuric Acid, s. g. at 15·6°C.=60°F. 1·838, at 25°C.=77°F. 1·828.	Seven parts.
Water	Nine parts.

Add to the sulphuric acid one part of the water and cool the mixture. Then dissolve the potassium bromide in six parts of the water by means of heat, supplying the loss of water by evaporation during the heating. Pour the diluted sulphuric acid slowly into the hot solution with constant stirring, and set the mixture aside for 24 hours that the sulphate of potassium may crystallize. Pour off the liquid into a retort, break up the crystalline mass, transfer it to a funnel, and having drained the crystals, drop slowly upon them two parts of the water so as to displace and wash out the acid liquid. Add the liquid thus drained off and washed out to that in the retort, and distil the whole nearly to dryness, or until nothing further distils off by moderate heating. The distillate will weigh about ten parts and should contain about 37 per cent. of hydrobromic acid. Assay this by means of normal volumetric solution of sodium, and add distilled water until it shall have the strength of 34 per cent. of hydrobromic acid. The product will weigh about eleven parts, and the loss of hydrobromic acid as calculated from the potassium bromide will be about 1·2 per cent.

---

bromine, nor that with four equivalents of water containing 57·55 per cent., but a mixture of the two containing about 9 per cent. of water, and therefore containing about 71·4 per cent. of bromine as above stated.

Solution of hydrobromic acid thus prepared is a limpid, colourless, odourless liquid, having a strongly acid taste. At 15·6°C.=60°F. it has a s. g. of 1·274. At 25°C.=77°F. the s. g. is 1·257 both compared with water at 15·6°C.=60°F. It is free from sulphuric acid, or gives but an unimportant trace when tested with solution of baric chloride; and is free from sulphurous acid when tested by its action on pure zinc, yielding a gas which does not blacken paper moistened with solution of plumbic acetate. It leaves on evaporation no residue, or but an accidental trace.

It consists of about 33·4 per cent. of bromine, about 0·6 per cent. of hydrogen, and 66 per cent. of water ; or, of 34 per cent. of hydrobromic acid, HBr=81 and 66 per cent. of water. Its formula is (H=1+Br=80=) HBr=81+Aq.

In making this acid on a scale suited to the physician or pharmacist each part in the formula may be represented by 2·835 grams = 1 ounce avoirdupois, and the process answers very well upon this scale, yielding about 366 grams=12·47 ounces.

Tared beakers, a retort about double the capacity of the liquid, with a strip of wire cloth around it where the heating flame is applied, and a small Liebig's condenser, are necessary for this process, and in the distillation here, as indeed everywhere, the lamp flame should be applied to the side of the retort.

If the mixture of sulphuric acid and water be not cooled it causes spattering and loss when poured into the hot solution of the bromide. In dissolving the bromide in an equal weight of water by heating, there is loss of water by evaporation, and unless this loss be made up it will not be practicable to get a perfect solution. But an entirely perfect solution is not essential, provided the undissolved portion be in a finely divided state, for when the diluted sulphuric acid is poured slowly in with stirring any small proportion of the bromide will be dissolved by the additional amount of liquid, and by the stirring. After standing 24 hours the lower part of the vessel will be occupied by a mass of crystals of large size, easily broken up to drain and wash. The quantity of sulphuric acid taken for the process appears disproportionate, being in excess of the quantity necessary to form acid potassium sulphate ; but unless such excess be taken the salt will not crystallize out as completely, and then the distillation will be defeated when only about half finished, by bumping in the retort. Smaller proportions of acid were successively tried, and when bumping occurred the process was stopped, and the contents of the retort were turned out, cooled and the crystals separated, drained and washed, but this is troublesome and entirely unnecessary if the larger proportion of acid be used, for then almost the whole of the salt crystallizes out, rendering the process easy when it would be otherwise either troublesome or entirely impracticable. Near the close of the distillation the heat must be kept moderate, because if increased much, sulphuric and sulphurous acids are liable to be distilled over in considerable quantities. The minute quantities of both which do go over, even in a well managed distillation, are probably thrown over mechanically by the bursting of bubbles on the surface of the boiling liquid. The quantity of either in the distillate of a well managed distillation is but a trace, and so small as to be unimportant. But should it be desired to have the distillate entirely free from these acids, a very small quantity of barium hydrate must be added and the whole be re-distilled. In the distillation the hydrobromic acid comes over comparatively weak at first, the strength gradually increasing to about 47 per cent., hence the distillate should be well stirred before being tested or assayed.

In testing for sulphurous acid it is only necessary to put a small piece of pure zinc into a test tube, pour upon it a few drops of the acid, push into the upper part a loose wad of cotton wool, and lay the paper moistened with solution of plumbic acetate on to the cotton wool.

The assays and adjustment of strength are conveniently and easily made as follows: The atomic weight of HBr being 81, a half of the tenth part of this number, namely 4·05 grams, is weighed off, and normal sodium solution is dropped into it from a burette to the point of saturation, as ascertained by means of a small piece of litmus paper kept floating in the acid as it is stirred during the dropping in of the volumetric sodium solution. Usually 18 to 19 c.c. of the volumetric solution is required for saturation.

Then, as only half of 8·1 grams was taken for the assay, this reading from the burette must be doubled, and therefore indicates 36 to 38 per cent. as the strength. Then weigh the distillate again, and add to it 5 per cent. of its weight of distilled water and again assay it as before. By calculation from the quantity of water used to reduce it to this new strength, the additional quantity of water necessary to reduce it to the 34 per cent. required is easily found. When this shall have been added, and the whole well stirred, a final assay should be made to verify the result.

This acid, in common with all the others, should be dispensed by weight. A troy ounce of it contains almost exactly 400 minims (401·48 +) and the fluidounce, of 480 minims, weighs almost exactly 574 grains (573·86 +). A drachm of it, therefore, would contain 50 minims, and would be the bromine equivalent of 30 grains of potassium bromide. A gram of the acid is equal to 12·86 minims, and therefore 4 grams would be 51·44 minims, equal to 30·86 grains of the potassium bromide, a very large sedative dose.

The acid is not very easily administered in full doses in consequence of the large dilution necessary, and the disagreeable effect of "setting the teeth on edge." A dose of 50 grains, equal to 41·66 minims, and to 25 grains of potassium bromide, requires not less than 8 fluidounces of dilution. And the dilution must contain not less than an ounce of sugar or two ounces of syrup to make it easily drinkable. This will be found to be the principal drawback to the use of the acid unless it shall be proved to be effective in smaller quantities than its equivalence to the bromides indicates. And this effectiveness in much smaller doses is not only probable, but almost certain if the experience of Fothergill and others may be trusted, since they give it in doses of one-eighth to one-fourth of those here indicated as being the bromine equivalent of potassium bromide. That is to say, the doses advised by those who appear to have used it with the best effects are equivalent to about 6 to 8 grains of potassium bromide.

This published experience would make the average dose of the acid here described, say about 12 to 16 grains, or the bromine equivalent of only 6 to 8 grains of potassium bromide. In the very limited experience of physicians around the writer these doses are too small, and 20 to 30 grains, equal to 10 to 15 grains of potassium bromide are needed for a prompt sedative effect, while 40 to 50 grain doses are not uncommon. And such doses have to be repeated at times in controlling the headache, etc., of quinism. Even such doses require a dilution of two to four fluidounces of water for easy administration.

If 60 grains=50 minims of the acid here described be added to 1140 grains of syrup, the mixture will measure two fluidounces and weigh (60+1140=) 1200 grains. Each 75 grains of this, 1 fluidrachm, will contain 4 grains nearly, or a little more than 3 minins of the acid. And 4 fluidrachms of this, equal to 15 grains of the acid when diluted with ice water to 2 to 4 fluidounces makes a dose which is easily administered and probably effective. Such a dose is equal to 12·5 grains of potassium bromide.

Beside the administration of single doses for temporary sedative effect, it will, however, doubtless come into occasional use for a more prolonged and permanent effect, as a partial substitute or alternate for the bromides, to correct or prevent alkaline saturation. The doses for such continuous uses do not seem to have been ascertained, for no instance of bromism from its use has been published so far as this writer has seen. Therefore as bromism must be the test of effective quantity, the doses must be considered as unsettled. If the bromine as present in this acid should prove capable of producing bromism in much smaller quantity than that present in the bromides, as seems to be foreshadowed in its use up to this time, then an important advantage will have been gained, and the doses of the acid will be correspondingly smaller.

At present it appears that for continuous use as a substitute for the bromides, to be continued through several weeks, or until the bromides can be resumed doses of 20 to 30 grains might be sufficient. It may also be found that by adding smaller quantities of the acid to reduced doses of the bromides the alkaline saturation might be postponed or avoided. For example, where an epileptic may be taking 25 grains of potassium bromide three or four times a day, it may, and probably will be found that the dose of bromide can be reduced to 20 grains or less by adding one, two or three grains of this acid to the smaller dose. Such uses as this for the acid are well worth careful trial, and in such quantities it can be easily administered.

The acid will also undoubtedly prove very useful for making solutions of various bromides extemporaneously. For example, lithium bromide should by its composition be very useful in medicine, as the salt contains nearly 90 per cent. of bromine,—or more bromine and less base than any other neutral salt possible. This is easily made, simply by saturating the acid with lithium carbonate, and adjusting the volume of the solution to the dose required.

Many formulas have been published for making this acid for medicinal uses, but all so faulty and inaccurate, or so difficult as to be impracticable for ordinary use where any moderate degree of precision in medication is required.

That of Fothergill was among the earliest, and has been by far the most used. It is given in his 'Handbook of Treatment,' American edition of 1877, p. 569. The formula is loose and inaccurate, containing a considerable excess (161 grains) of potassium bromide. Its quantitative defects are easily remedied, but it yields a complex solution containing much tartaric acid and potassium, and is otherwise objectionable, having all the faults of the process upon which it is modelled, namely, the process for hydriodic acid by Buchanan, of Glasgow. Made by Fothergill's formula it will commonly contain between 8 and 9 per cent. of the hydrobromic acid, and as the dose is stated at "ʒss. to ʒi," if this be by weight as it is written, it will be equivalent to 4 to 8 grains of potassium bromide only.

Fothergill's process was very much improved by Mr. Charles Rice; see *New Remedies* for April 16, 1877, p. 107. But this preparation, though much more definite, is still liable to the objection of containing much tartaric acid and potassium, and therefore of being difficult to identify or verify, or to discriminate by tests or by assay.

Much better results are obtained by the original process of Balard, particularly as modified by Professor J. M. Maisch. See 'Proceedings of The American Pharmaceutical Association for 1860,' p. 220, or as still farther modified by Professor G. F. H. Markoe, see 'Proceedings of The American Pharmaceutical Association for 1875,' p. 686. But these and many other published processes are less simple and easy than that here proposed.

That here given is not original with the writer, but is alluded to in all standard works on chemistry: but, without the variation in quantity of sulphuric acid used, and without crystallizing out the potassium sulphate before the distillation, the process is impracticable,—or at least has always proved to be so in the writer's hands, and in the hands of all whom he has known to have tried it.

Brooklyn.

THE UNIVERSAL INTERNATIONAL EXPOSITION OF 1878.

Mr. Editor,—Having recently returned from a visit to Paris on business connected with pharmacy, it has occurred to me that some of your readers might be desirous of knowing what progress has been made with the International Exhibition there. Although there is now little to report of pharmaceutical interest, yet there promises to be a very great deal to see in two or three months' time.

The exhibition proper occupies the whole of the Champ de Mars from the Seine to the Military School, and is in the form of an immense parallelogram about half a mile long and nearly a quarter of a mile broad. On the opposite side of the Seine and crowning the hill of the Trocadero stands the large Concert Hall, extending in the form of a crescent the whole width of the Champ de Mars, while in front of it and covering the slope of the hill down to the river are ornamental grounds, which are connected with those of the Exhibition proper by a newly erected bridge. The Exhibition itself is not a very conspicuous object until seen from the hill opposite, and then it is too large to be seen at a glance, but the appearance of the Concert Hall is commanding in the extreme. Although little more than the outside of this handsome building was completed at the time of my visit, yet, it was evident that when the ornamental grounds with the cascades in the centre and the flower beds and fresh water aquarium are finished, together with the picturesque buildings representing Japanese, Chinese, Persian, Algerian, Swiss, and Norwegian dwellings, it will form an exceedingly attractive picture, and the best view of the Exhibition will undoubtedly be obtainable from the gallery which runs along the whole length of its frontage.

The Exhibition proper is progressing much more rapidly in some parts than in others. As might be expected, the French departments were most advanced, whilst the Canadian and English showed signs of rapid development. The English department occupies a considerable space on the right of the main entrance, and the spaces for exhibition were allotted, numbered and named, and the tramway for facilitating the movement of heavy packages was already at work.

In the United States' department, which occupies the next position on the right, scarcely anything had been done.

In the French departments the progress made was very unequal: in a few places some cases and fittings were already in position, as in the colonial portion, and in the part where leathern articles and jewellery, travelling accompaniments, etc., are to be exhibited; while elsewhere nothing but bare wooden partitions were to be seen. This unfortunately was the case with the portion devoted to chemical and pharmaceutical products. In the Chinese department some natives of that country were leisurely unpacking the fittings preparatory to putting them together. Although the French do not cease working on Sundays, there is evidently an immense deal to be done in the fifty days that still remain for the purpose. The railway is being brought close to the entrance, and a station is being erected near the right hand corner of the front of the Exhibition, while tramways are being laid down from all parts of the city. The latter terminate on the opposite side of the Seine, just where it is crossed by the new bridge before mentioned.

As might be expected some of the best restaurants will be represented, and, with the usual taste displayed by the Parisians, they will either occupy spots affording excellent opportunities for seeing all that is passing along the Seine, etc., or will be perched where the prettiest views in the ornamental grounds may be obtained.

But although there was little to see in the International Exhibition, the Palais d'Industrie, where an Agricultural Exhibition was being held, was well worth visiting. Around the building were all kinds of novelties in agricultural implements, one of which particularly attracted my notice for its simplicity and ingenuity; it was the application of the principle of the "fox and geese" game to gates, so that by simply pushing the gate it closed up, and occupied barely a quarter of the space it filled when at rest.

The beautifully neat stalls for the animals, and the exceeding cleanliness of the animals themselves were remarkable, while the arrangements for the locomotion of visitors left nothing to desire. In one corner, however, might be seen the disgusting operation of feeding fowls by machinery, each dose of food being forced down their throats, and its quantity regulated and pointed out on a dial. But it was not this portion which presented anything of interest to the pharmacist. In the upper storey of the building, in the rooms where the vegetables were being exhibited, many curious fruits were to be seen.

Specimens from Algeria included the curious form of citron, known in China as Buddha's claw, in which some of the carpels become almost distinct, so as to give the appearance of a hand compressed laterally, or of the claw of an animal. Other objects of interest were the café nègre, consisting of the small seeds of *Cassia occidentalis*, used in various parts of Africa as a substitute for coffee; Gobbo, the sliced unripe fruits of *Hibiscus esculentus*, used for thickening soups, and ambrette or musk seed from *Hibiscus abelmoschus*. Another curious object noticeable here consisted of some rolls of yellowish looking bread made from large gourds, beside which they were placed. The delicate perfume of the vanilla from the Isles of Bourbon, Martinique, and Gaudeloupe attracted many customers on the last day of the show. The cherrymoyers, a most luscious fruit, although furnished with a rough looking exterior, were also shown.

From Martinique several edible roots were exhibited, among which were noticed those of *Colocasia esculenta*, one of the roots which are cultivated also in the Sandwich Islands under the name of Taro; the leaves also are used as a vegetable. The curious fruit of *Sechium edule*, about the size of a large quince and covered with small prickles like the prickly pear, which is used in slices for salad, being first washed in salt water, was likewise represented. This is the chocho of the West Indies, but the fruits were labelled chayotes, a name under which they sometimes appear in Covent Garden market. The large fleshy root of the same plant, which is cooked like a yam, was also to be seen.

Other singular objects, but exhibited merely as curiosities, were the long pods of the poincillade royale (*Poinciana regia?*), and some smaller ones from one of the copal trees (*Hymenæa Courbaril*).

Some excellent specimens of honey and beeswax were also exhibited in this department. The specimens of beeswax of Mons. J. Lediard, which won the first prize, were remarkably fine, and in point of colour, odour, and consistency left nothing to be desired.—"EXPOSITION."

The Pharmaceutical Journal.

EFFLUVIUM NUISANCES.

ABOUT three years since, at the suggestion of Mr. SIMON, the President of the Local Government Board charged Dr. BALLARD with a general inquiry into the "effluvium nuisances" which arise in connection with various manufacturing and other branches of industry, especially with regard to the effect of each nuisance upon the public health and the degree to which it might be preventible. The first report of Dr. BALLARD upon the work accomplished by him in this direction has just appeared in the form of an Appendix to the Annual Report of the Medical Officer to the Board, and it gives every indication that this important investigation will be carried out in a most thorough and impartial manner. The Report contains a vast amount of information concerning the manner in which some of the industries that are the subject of the inquiry are carried on, so that it would be impossible here to enter into the details; but a brief space may be profitably devoted to recapitulating the principal results and inferences which Dr. BALLARD has drawn from his experience so far as it has gone, not only because the question is one of primary importance to the public health, but because many of the problems that it presents will probably have to be solved by the chemist.

While inquiring into the extent and degree of the inconvenience to the community occasioned by industrial nuisances Dr. BALLARD found that the frequency of complaints is not a trustworthy criterion of the extent or intensity of a nuisance. This is due to various causes, such as the desire not to be thought unneighbourly, the fear of displeasing an influential offender, the greater or less dependence of those most inconvenienced upon the industry as a means of sustenance, the difficulty where several establishments stand close together of distinguishing from which the nuisance proceeds, and especially the fact that habitual exposure to trade effluvia tends to render people less sensitive to their influence, so that sometimes a nuisance is less complained of in the immediate neighbourhood of a manufactory than at a distance where the effluvia is only occasionally wafted by the wind. It is evident, however, that the immunity of the immediate neighbourhood may sometimes be more real than would appear at first sight, and the distance at which the nuisance becomes most manifest may be dependent upon the height of the chimney from which the effluvia are discharged, the density of the vapours, and other conditions.

The classification of the businesses which give off effluvia creating nuisance is very difficult, and that adopted in the report is rather arbitrary than scientific. But Dr. BALLARD has no difficulty in awarding the palm for pre-eminence in giving off offensive effluvia to the trade processes in which the materials used consist mainly of animal matters, the most disgusting of all being gut scraping and the preparation of sausage skins and catgut, the preparation of artificial manures from "scutch" (or refuse from the glue manufacture), and the melting of some kinds of fat. Manufactures dealing with vegetable materials are often very offensive, but rarely give rise to disgusting effluvia; among the most offensive being the effluvia given off during the heating of vegetable oils, as during the boiling of linseed oil and the manufacture of palmitic acid from cotton oil or palm oil, and the manipulation of some varnishes. Of industries dealing with inorganic materials, those yielding the most offensive effluvia are the manufacture of ammonium sulphide and chloride, and some other processes in which there is a copious evolution of sulphuretted hydrogen, gas making, and the distilling of tar. The principal complaints in reference to the acid and irritating fumes given off in the alkali and bleaching-powder manufacture appear to have relation rather to the injury they cause to vegetation than to their effect upon the public health.

As to what extent trade effluvia are to be considered injurious to the public the determination is still more difficult, so much depending upon the definition of "injurious." It may be held to mean a temporary discomfort or other functional disturbance occurring as a result upon exposure to a certain effluvium, but tending by repetition, if not to a clearly defined form of disease, to an appreciable impairment of health and strength. On the other hand, it may be limited to the cases where persons exposed are definitely injured in health and have their lives shortened, or are rendered more susceptible to attacks from, and less able to cope with, various forms of disease. Again, cases occur where individuals, either through idiosyncrasy or an already impaired state of health, suffer severely from exposure to an effluvium that is at the most disagreeable to others. This part of the subject is so complicated, and the dearth of data that would assist in forming a judgment is at present so great, that the reporter is able only to touch the fringe of it.

In dealing, however, with the argument so frequently put forward by persons interested in this class of manufactures, as to the innocuousness of offensive effluvia, based upon the health of the workmen engaged in the works and continually exposed to them, Dr. BALLARD points out that this is probably due to a great extent to a kind of selection and survival of the fittest. Moreover, there appears to be no doubt that in well managed and ventilated works, men employed within the building may be less exposed to noxious gases evolved during the operation than people outside. It has also been urged that some of the effluvia escaping from chemical works, such as chlorine, sulphurous acid, or tar vapour, are actually beneficial by virtue of their known disinfecting properties; but as Dr. BALLARD points out, such disinfecting agents to be effectually operative against any contagion need to be applied to it in a state of concentration far greater than that of the diluted effluvia met with outside chemical works.

There are four conclusions to which Dr. BALLARD has come in respect to the influence effluvium nuisances may have upon the public health. First, that trade effluvia decidedly contributes towards the atmospheric impurity, to which the comparative insalubrity of towns is due. Secondly, that in distinguishing between different kinds of effluvia, those which have their origin in the decomposition of organic matter, and especially animal matter, under the influence of a septic ferment, stand out as unquestionably dangerous and the source of much fatal disease. Thirdly, that there are some businesses in which the refuse matters dealt with are liable to be infected with the specific contagia of infectious diseases, and that when the effluvium produced is consequently charged with infectious matter it cannot fail to be dangerous to persons exposed to its influence. Fourthly, that in some cases the effluvia consists of definite chemical compounds which are poisonous or irritant in a concentrated form, and that even when diluted with atmospheric air they are more or less injurious.

LATAKIA TOBACCO.

THE statement made in our editorial columns last week that the error as to *Nicotiana rustica* being the botanical source of various kinds of tobacco having been copied into 'Medicinal Plants,' is incorrect as regards Latakia tobacco, as may be seen from the following extract from Part 8 of that work:—"Professor THISELTON DYER has just proved that Latakia Tobacco, which has hitherto been always supposed to be derived from *N. rustica*, L., is prepared from the flowering panicles and even the capsules of *N. tabacum*." This Part was published on 1st May, 1876, and the above was the first printed notice of Mr. DYER's observations which were only communicated to the Linnean Society at their meeting ten days before (on April 20th), and were not published in the Journal of the Society till the July following.

ARTIFICIAL GEMS.

NOW-A-DAYS the "philosophical stone," contact with which would convert the baser metals into gold, is looked upon as a chimera, although it is admitted that the search for it had a very beneficial influence upon the development of chemistry. But the attempts of chemists to produce other precious stones promises to be more successful, and not only to advance the interests of science, but also to become an indirect source of the noble metal to the workers. Following in the footsteps of Sainte-Claire Deville and others, MM. E. Frémy and Feil have obtained some very interesting results in attempting to produce the corundum, ruby, and topaz artificially. The method found to give the best results is to maintain a fusible aluminate, such as aluminate of lead, for a considerable time at a red heat in the presence of a silicious substance. The silica gradually displaces the alumina in a condition favourable to its crystallization. Thus, upon heating equal weights of alumina and minium in a crucible made of a refractory silicious material, the oxide of lead attacks the silica of the crucible to an extent sufficient to produce the conditions just described, and when these have been kept up long enough, upon cooling, two layers are formed, one consisting of silicate of lead, the other frequently full of fine crystals of alumina or corundum. To produce the ruby colour it is only necessary to add 2 or 3 per cent. of bichromate of potash to the mixture, whilst the sapphire blue is produced by a small quantity of oxide of cobalt and a trace of bichromate of potash. The ruby crystals are usually covered with a film of lead silicate that has to be removed; but sometimes crystals are nearly pure, and possess the composition, lustre, hardness, and crystalline form of the natural stones. Like the natural ruby, the artificial one loses its rose colour upon being heated, and recovers it upon cooling. As a rule, however, the artificial crystals yet obtained do not possess the lustre required by the jeweller, or present to the lapidary conditions favourable for cleavage or cutting, though quite fitted for horological purposes. The fusing operations were carried out in the furnace of a glass-works.

THE LIVERPOOL CHEMISTS' PRICE LIST.

UNDER this title the Liverpool Registered Chemists' Association, some time since, issued a price list for the use of the Chemists and Druggists of the Liverpool district. So well has this little work been appreciated that a second edition has become necessary, in which the improvement has been introduced of arranging all the articles in alphabetical order. Further particulars will be found in the advertising sheet of the present number.

PROSECUTION UNDER THE PHARMACY ACT.

ON another page will be found a report of the proceedings before a magistrate in a prosecution initiated by the Pharmaceutical Society, under the 17th section of the Pharmacy Act, 1868. The case promises to be a very important one, but as it is at present undecided we refrain from comment, further than to express the hope that a case may be granted in order that the points in dispute may be decided in a superior court.

NORTH BRITISH BRANCH.

Thoughts on Botany*—*continued.*

BY H. B. BAILDON, B.A. CANTAB.

Mr. President and Gentlemen,—When I had last the honour of addressing you, I submitted to you some reflections which had occurred to me when contemplating those facts which the science of botany makes known to us. The reflections I had made and the arguments deduced from them tended to combat and refute the views of certain eminent scientific men, whose philosophy may best be denominated automatism. Broadly stated the thesis of this school is that the universe, especially the physical universe, is self-acting, self-evolving; that no external control, no guiding intelligence, no creative energy beyond the necessary and inherent properties of matter are required or have been engaged in producing the present state of things. That this automatism is characteristic of their whole scheme is shown by the facts that they push it forward even into the very highest ranks of being, and invite their followers to consider not only plants and animals, but man himself as automatic. To the uninitiated common sense of mankind this seems arrant folly, yet to those who would be our teachers it appears to be the supreme wisdom. The error, as I deem it, into which these philosophers have fallen has arisen in a manner sufficiently simple for a youth, if not a child, to understand. The proposition that man is an automaton is precisely as true and yet as incomplete, as a description of man, as a hundred other assertions that could be made. Man is a heavy body, man is a locomotive being, man is a biped, man is a mammal, etc., etc. Each of these propositions embodies a truth, but not the whole truth; and it is the same with regard to the statement that man is an automaton. Man regarded as a mechanism is an automaton, the most wonderful ever yet produced; he *goes by himself* more completely than any other machine can be said to do, is more thoroughly automatic than any other automaton. But regarded from other points of view, the term automaton ceases to be applicable. Thus to say that a man thinks or loves automatically is either a contradiction in terms, or is merely equivalent to saying he thinks or loves. For an automaton is, by our very notion of the thing, a machine capable of accomplishing through some physical impetus an action or movement which in the first instance it required conscious intelligence to perform. That instrument is not automatic which is, like a spade or hammer, directed immediately by intelligence; but that which, like a reaping machine, dispenses with this intelligent direction in part, is, so far, automatic. Thus by its very notion and nature an automaton opposes itself in meaning to any conscious being; if conscious, it is not automatic, if automatic not conscious; and yet we are presented with the phrase *conscious automata*, which are phenomena just as likely to exist as solid liquids or hot ices. So the theorem which those of this school are committed to maintain is that animals, *i.e.*, conscious beings, are also automata, *i.e.*, unconscious machines, for other meaning than this for automata the usage of the language disallows.

This, so far, is by the way and introductory, intended to elucidate my own position by means of defining that to which it confronts. For the difference between our views is exactly analogous to the difference between an automaton and a living being. Nature from their point of view is a huge automaton, started somehow at some time, and threatening eventually to run down and stop, hanging thereafter through eternity, idle and impotent as a rusted and disused water-wheel over a channel deserted of its once forceful waters. To me nature seems vital throughout, instinct to the minutest particle with immortal energies, not in the same sense and degree vital in all parts, any more than the human frame is equally vital in its parts, yet nevertheless a living whole, not devoted to dissolution, but destined to eternal existence and everlasting growth. In thus regarding nature, it is hardly necessary to say I do not confine my regard to nature in its narrower sense. The nature I refer to includes man in all his faculties, and will include higher beings that may succeed us, or which may already exist; and this, I do not hesitate to assert, is the truly philosophical notion of nature, that which by virtue of its very breadth escapes the errors into which less extended conceptions of nature are constantly leading men. Nature in this sense is identical with fact, reality, whereas in its narrower senses it corresponds only to certain classes or groups of facts, or to facts viewed in some special relation. As for example *natural* philosophy is a purely physical science, and natural history a zoologic one; with one poet nature means external non-human nature, with another the original forces, impulses and desires seated in man. These and many other uses of the word are legitimate and even necessary, but we must be careful to mark in which sense we are using it. For now we are about to continue an appeal to nature, and, directly, only to a certain class of natural facts; but we intend to bear in mind that the nature to which our appeal is embraces many departments of which that to which our attention is directed is but one. Thus will we guard against becoming materialists, because we happen to be considering a physical subject, as in the converse case we would fortify ourselves against falling into mysticism or spiritualism, because the subject under our notice chanced to be of a metaphysical character. And this warning which we take to ourselves suggests or perhaps is suggested by the indictment, to which it seems certain high scientific authorities lay themselves open, viz., that they allow the results of their special studies too largely to dominate, too completely to determine, their conceptions of the universe at large, which universe is too mysterious and complex to render trustworthy answers to those who interrogate it in only one manner.

In my previous paper on this subject, I had commenced to trace, in a summary manner no doubt, some of the progressive stages in the history of vegetable life, to mark certain epochs in the creative epic. We had begun to consider what we called the second stage which embraced the *Musci*, *Filices*, *Lycopodia* and *Equisetaceæ*, but had only reached the first of these orders, so that it is now the *Filices* or Fern-family to which we naturally direct our attention.

The fern may be regarded as the heir or successor to the moss, seeing that in the history of soil formation, it appears requisite that the one be preceded and prepared for by the other. The one, like a prudent sire, has accumulated the capital upon which the other may subsist. The fern, though requiring as a rule but a slender portion of soil and evidently nourishing itself mainly by means of the moisture that reaches it, still does require the said capital with which to start. It demands, it implies a predecessor.

Had nature been the blind, mechanical, mindless, soulless automaton which some seem to regard her as, it must be thought highly creditable to such a mechanism, a matter remarkable in such a cosmic musical-box, that it should have produced in the humble orders already present on the earth, forms so exquisite and variety so exhaustless, but now, when it would have seemed quite sufficient that the soil should be covered with giant mosses or lichens of monster growth, this versatile machine plays, as it were, a fresh melody, a harmony of larger compass, a movement of grander volume and more stately progress. From the lowly film-fern, content to consort with the mosses of the ground, to the graceful fern-tree surmounting its slow-built stem with crowning lace-like fount of leafage fairer, if less proud, than any palm's, the fern-

* Read at an Evening Meeting of the North British Branch of the Pharmaceutical Society, Feb. 22, 1878.

world is the home of ever fresh and finished beauty of form, of ever-assiduous originality and delicacy of design. Not, be it at once admitted, that all forms are of equal beauty, or that some are not by comparison even homely, but that, contemplating the order as a whole, it is characterized by a clearness and cleanliness of surface and of shaping, a mastery, simplicity and subtility of curvage, a thorough and elaborate symmetry, which seem to represent nature's final self-defying effort in the direction of leaf-beauty, where that beauty is to depend mainly upon form. For nature, like a wise human artist, in the midst of her boundless resources appoints herself laws and limits. Thus colour in the fern would seem to be held subordinate to form and used rather to define and illustrate form than put itself forward as a distinct beauty. Yet a worthy and helpful servitor it proves itself, throwing as it were into relief the grace and perfection of nature's draughtmanship. This is well seen in the brownness of the wire-drawn frond stems characteristic of the adiantum. Thus coloured, the stem gives to the light pinnæ an unobtrusive and almost invisible support and attachment, thus greatly enhancing the aerial, weightless elegance of the plant. To this the maiden-hair owes much of its matchless grace. Matchless, I say advisedly, for this fern appears to me a very miracle of ethereal elegance, the very embodiment, as it were, of a sensitive maiden soul, tremblingly alive to the lightest influence, and yet strong and safe in its very delicacy and refinement. To me this seems one of those creations that touches the zenith of its possible excellence and defies the energy that produced it to produce its peer again. No doubt it may be argued that the lightness and strength displayed by this plant may be the very cause of its survival. But, apart from the fact that this is a mode of argument which can obviously be adopted in any case wherever anything appears well adapted to its environment, and which is merely equivalent to saying that a thing exists because it is adapted to exist—we need not stint our wonder and admiration that utility and beauty should thus blend in one perfection, nor need we abate our incredulity that a blind, aimless, unconscious automaton should exhibit at once adaptation so perfect, and design so delightful.

As you will have already perceived, the main argument upon which I am depending, both in this paper and in those that preceded it, is what may be called the argument from beauty. It contains a challenge flung to the Darwinist to account, on his hypothesis, for the existence of so much that charms the senses of man, to explain away, if may be, the apparent control which a subtle and exquisite sense of beauty seems to exercise over natural objects. It may be described as a flank attack on the utilitarian, automatic and atheistic position, from the æsthetic or artistic stand-point. We shall first require to establish, and this in reference to the vegetable kingdom we shall be abundantly able to do, that at least beauty of some kind is arrived at as a rule by the plant, and that, great as may be the disparity in grace and charm between different individuals, still in the existence of each there is observable an effort usually, if not always, successful to contribute to the earth's adornment and the delectation of man. If this be true, the burden of explanation, a burden, so far as my reading has gone, never yet undertaken, still less removed, lies upon those of the automatist school. A single analogy may render the position more clear. If I were to find a piece of paper upon which were a series of ink-marks, I might go through the following stages of inquiry and deduction as to the origin or originator of these markings. If I could find in them no method or law, I might say they were produced accidentally or mechanically. But supposing I at length concluded they were not mere marks but written characters, I should infer the author of them to be at the least a child of sufficient age and intelligence to form letters. If then, further, these characters were found to form words, and these words to form a rational sentence, one would, naturally, attribute their production to some person at least capable of understanding language, and of thinking. But, finally, if the communication were wise, or learned, or beautiful, or elevating, it would be only logical to ascribe the qualities wisdom, erudition, poetry or nobility to the author (it being of course assumed for the sake of simplicity that *one* person is the author both of the actual writing, and the idea expressed). From which illustration we are, I think, entitled to infer, that as it would have been foolish to suppose that the wisdom, beauty, etc., of the communication was the result of a hap-hazard arrangement of letters, so it will be irrational to conclude that the wisdom and beauty nature exhibits are accidental, automatic, and authorless. And as it would appear not only irrelevant but irrational to put forward the physical properties of pen, ink, and paper as affording the efficient causes of the writing, so is it equally irrational, as well as irrelevant, to attribute to causes purely mechanical and chemical the phenomena of life, sensitivity and consciousness.

We may here, however, frankly admit, that while we have never yet been able to discover *matter* in a condition in which it is free from the impress of mind, so likewise, so far as our present experience goes, mind has never yet been found capable of existing, disassociated from matter. Hence the obvious, it would seem, impossibility of settling the dispute as to priority of existence on anything like scientific grounds. For although, doubtless, mind, as existing in the finite beings, man and other animals, is a phenomenon which is, in the history of the physical universe, subsequent to the phenomenon of unconscious matter, nevertheless the most primitive conceivable form of matter seems to involve a pre-existent idea or scheme. Thus, if matter can in any sense be said to afford the promise and the potency of all terrestrial existence, it is only as thus endowed initially by a pre-existent intelligence.

But now let us recur, before passing onward to other instances, to our contemplation of the Fern genus. Ferns appear to me to stand in the same relation to other orders of plants as the ancient Greeks do towards the various races of men. They are the classics of nature, owing their charm to symmetry, balance, refinement, restraint. As the Greek statue or poem seems to be conceived and executed with such an exact prudence, such an accurate estimate of the limits and possibilities of art, so seems the fern, as though instinct with a power of exquisitely true precalculation, as though aware with precision of its own resources and capacity, to succeed in realizing its own dream of perfection. Its aim is rather to be, than to produce. Neither fruit nor flower, in the ordinary sense, is for it, content as it is to be beautiful and no more. And in compensation for this restraint, in reward for this—in its place—beautiful self-sufficiency, there is for it no blight and withering of flower-bell, no fall and decay of fruit. Even the very fronds refuse to fall away, but dwindle with a gradual decline and, restoring their elements to the spot whence they sprung, bequeath their bodies as true patriots to the soil of their nativity. Nor in its historic function is the fern tribe dissimilar to the Hellenic race, for as the latter has accumulated and bequeathed the fundus that underlies and renders possible all modern culture, so the former, through slow conquest and gradual accretion, has collected and compiled the rich soil, the fertile compost in which plants of greater growth and higher aspiration may dwell and flourish. And it is this function which assures us of the fact that, broadly speaking, the fern must have been the immediate successor to the moss, although there is no necessity to rely exclusively on such an argument, seeing that the main facts of palæontology tend strongly to support this conclusion. It is also instructive to note in this reference that ferns are but little adapted to contribute to the necessities of man or even of animal life as at present existing, the inference being that they belong originally to a natural economy in which such animals had no place.

Before finally parting from this portion of our subject, I should like to draw your attention to what may be termed aspiration and ingenuity in nature. As originally organized and constructed the fern is adapted for covering and adorning the surface of the ground to a height limited to that of the individual frond. But, uncontented with that, the ardour of the race, as we may call it, carried it on to an attempt to exalt itself further above the earth's surface, to form for its frondage a pedestal or column whereon it might be born aloft in honour and beauty. Having no power of producing in this instance a true stem, it would puzzle human ingenuity to predict how nature would surmount the difficulty. The expedient used is one which at once by its felicity, simplicity, and success cannot but compel our admiration. The strong leaf bases of the old fronds are, so to speak, economized as a platform within and upon which the succeeding generation of fronds is reared, to leave in their turn a higher platform for its heirs. And thus, with the infinite patience characteristic of natural processes, the column is slowly raised, season after season and tier on tier, till the feathery frondage uncurls on high from the summit of a taper shaft.

At the risk of appearing to press the analogy too persistently, I would remark that, as Greek sculpture remains unrivalled in point of pure grace, so the leafage or frondage of ferns remains peerless in nature in respect of gracefulness, variety, and refinement of form. Nature, it would seem, being for this genus shut out from the possibility of those effects that may be produced by a combination of leaves with twigs, branches, and stem, and also for the embellishment of blossom or flower, has thrown all her fictive genius into the designing of the leaf pattern and the contrivance of charmful modes of frond arrangement and curvage. By how exquisite an adjustment of relative strength and weight, for instance, must the parabolic curves of some fronds be attained: some having the aerial spring of a rocket as it rises and spreads towards the zenith of its flight; others the energetic shoot of a stream over rocks; one the idle curl of an ostrich plume; another the strong poise of a gull's wings stretched over sea. Not, with however wild a grace she may carry it off, does nature disregard method in the order and manner in which the fronds are given off from the root. There are some collected in a nest or crown, some flinging themselves up, as if on tiptoe, each higher than the last, and yet others waywardly following each other through the woodland, as though they played at some fairy follow-me-leader.

This is not mere sentiment, sentiment at least that may be used as a reproach. It is statement of facts, facts of human experience. For the proposition that these ferns are delight giving and beautiful depends for its validity on experience, just as directly and purely on experience as the most commonplace and universally accepted proposition, such as that honey is sweet. The appeal lies, as in all scientific matters, to the tribunal or test of human perception, and that appeal is for us the ultimate one; and the process of establishing the one proposition would be closely analogous, if not identical, with that which must be employed in the establishment of the other. Honey has been put to the test of taste by innumerable human beings, and has by an overwhelming majority been pronounced sweet. Certain other things, such as pearls and diamonds, have been pronounced beautiful. The one verdict is no more open to be stigmatized as mere sentiment than the other. Still, let us at once admit that there is a difference. It is quite conceivable and highly probable that if they could communicate their opinion many animals besides men would vote with the majority in the matter of honey; but it is difficult to perceive and highly improbable that any animal except man has the faculty of discerning between what is beautiful and what is the reverse.* It is even extremely likely, if it has not been already proved, that this faculty exists to a very slight extent in the lower races of mankind, and there can be no doubt of its having developed along with the progress of the race. Still it is remarkable that one of the earliest instincts of the savage and the child is towards the acquiring of objects of bright and, even to our taste, pleasing colours. This faculty, then, appears to be distinctively human and to be dependent on a higher cerebral development than any infrahuman; from which conclusion we may draw two inferences, first, that the faculty itself may safely be classed as a higher and more intellectual one than that which discriminates between what is sweet to the palate and what is not so; secondly, we may with equal safety conclude that it will improve and develop with the progress of the race and become more refined and subtle in its discernment. It may be as well to remark in passing that this development could not go on had the world been filled with objects of equal beauty or even of objects all beautiful. We are now in a position to discern more clearly what the difference is which was acknowledged to exist between the two cases which were instanced as analogous. In the first place, it is, I think, clear that the special faculty to which appeal is made on the matter of beauty is higher, more intellectual and truly human than that of mere taste, and secondly, we may conclude that the testimony of the more highly developed races and of the most cultured individuals in those races will be entitled to greater weight than that of inferior races and less cultured individuals. If, then, it should be for a moment disputed that such beauties and charms as I have claimed for the fern tribe do really pertain to them, decision would not be made on a mere show of hands. It would be necessary to appraise the votes according to the advancement and culture of the voters. Thus to the verdict of civilized and intellectual nations would be accorded a value many times greater than that allowed to races barbarous and unenlightened. And, among individuals, there would be decreed a vote value to the artist and the poet outweighing that of many less sensitive souls. Proceeding in this manner there is no doubt the proposition would be carried by an overwhelming majority. That is to say, it would be established as a fact upon the same basis upon which alone science admits facts to be at all established, viz., upon that of human perception and experience. Of course it is not for a moment supposed that the process just roughly indicated could be carried out in detail. I have merely endeavoured in some sort to define the kind of testimony upon which facts of this order implicitly found themselves and by which they are continually buttressed into additional security of acceptance.

(*To be continued.*)

* This is certainly an obscure point, since, although Mr. Darwin has pointed out an apparent relation between sexual attraction and beauty among birds, there is still lacking any proof that the category of beauty exists in the mind of any being lower than man.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

Assistants' Section.

The fourth meeting of the present session was held in the Andersonian College, on Wednesday evening, 27th February; Mr. William Simpson, President, in the chair The minutes of last meeting were read and approved of, after which Mr. W. P. Blain read a paper "On the Sea." The author treated the subject more in a literary than a scientific manner, and at the close referred to the many chemicals that are contained in sea water.

After a few remarks by some of the members, a hearty vote of thanks was awarded to Mr. Blain for his paper.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Thursday evening, March 7th, a lecture was delivered at the rooms of the above Association, Halford Street, by Mr. J. Young; subject, "The Telephone," Mr. J. E. Weatherhead occupying the chair.

The lecturer in explaining the meaning of the word "telephone," stated that though it is new to the public the name was old, the 'Imperial Lexicon,' which was printed many years ago, giving the word telephonic. The history of the telephone up to the present time was narrated, the lecturer giving Professor A. Graham Bell credit for having introduced the metal diaphragm, by which the vibrations of any sound can be reproduced. The difference between the working of Bell's telephone and the "pill box" telephone was described. In the latter, the actual vibrations were transmitted through the cord from one box to the other; but in the former, the sound or vibrations did not pass through the wires, but the magnetic influence formed by the vibrating diaphragm at one end affected the diaphragm at the other end, thus giving out the same number of vibrations as received. The construction of the telephone was made very clear by the lecturer putting the parts together in the sight of the audience, and by drawing on the black board. The difference between hard and soft steel, and the bar magnet being permanently magnetized was fully explained and illustrated. The talking phonograph was also alluded to, as being an instrument invented by an American, by which sounds can be preserved or registered, and let out of the machine as required. Thus a person speaking into the box can have his speech reproduced in his exact voice, even after his death, so that it was not only possible to have the image or photograph of a departed friend preserved, but his exact words and voice. The telephone was then put into practical use, a wire having been put in connection with a room some distance off.

The usual votes of thanks were given to the lecturer and chairman, and suitably responded to, the audience then dispersed, it having been one of the most successful meetings that the Association has had for some time.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, March 7th; Dr. Gilbert, Vice-President in the chair.

After the confirmation of the minutes of the preceding meeting, the following certificates were read for the first time:—G. H. Rutter, R. H. Jude, A. K. Huntington, K. H. C. Nevile. The name of Mr. M. Zingler, whose certificate was read for the first time on February 7th, was accidentally omitted in the report of that date.

The list of the officers proposed for election on March 30th was read from the chair. The names of those who will retire, etc., were given in the report of the last meeting, with one exception, that Mr. C. E. Groves retires from the Council instead of Professor R. V. Tuson. It was also announced that Mr. Hall was prepared to receive subscriptions (of 10*s*) from Fellows for the next volume of the 'Proceedings of the Royal Society.

The Chairman then called on Mr. PERKIN to read his paper—

On some New Derivatives of Anisoïl. Dry precipitated methylorthoxyphenylacrylic acid is placed in contact with hydriodic acid, sp. gr. 1·94 for two or three days, the mixture being frequently agitated; the resulting product drained by a filter pump, and then added in small quantities to a cold saturated solution of sodium carbonate, great care being taken to prevent any rise in temperature. The milky fluid thus obtained is distilled, orthovinylanisoïl separates from the distillate as an oily layer. It polymerizes so quickly as to prevent the correct determination of its boiling point, which is about 195°–200° C. Heated for an hour to 150° it solidifies to a transparent glass-like substance. The odour of orthovinylanisoïl differs from that of its isomer paravinylanisoïl, and resembles coal tar naphtha. Sp. gr., at 15°, 1·0005 at 30°, 1·000.

By a similar process, substituting, however, hydrobromic acid, ortho-allylanisoïl was obtained, boiling without polymerizing, at 222°–223° C. It is a highly refracting liquid, with sp. gr. at 15°, ·9972. Similarly with hydriodic acid orthobutenylanisoïl was obtained, boiling at 232°-234°, sp. gr. at 15°, ·9817.

In a previous paper the author described how he had endeavoured, without success, to prepare paravinylanisoïl from methylparoxyphenylacrylic acid by treating with hydrobromic acid, etc. By substituting hydriodic acid he has obtained this substance, resembling in its properties the body prepared by distilling methylparoxyphenylacrylic acid; its fuming point was, however, + 3° instead of —1°; sp. gr. at 15°, 1·002. In conclusion, the author compares the ortho and para compounds as regard their physical properties.

1. *Boiling Point.*

6 Paravinylanisoïl	204°-205°.
Ortho	Uncertain.
Paraallylanisoïl	232°.
Ortho	222°-223°.
Parabutenylanisoïl	242°-245°.
Ortho	232°-234°.

2. *Specific Gravity.*	At 15°	At 30°
Paravinylanisoïl	1·0029	·9956
Ortho	1·0095	1·000
Paraallylanisoïl	———	.9852
Ortho	·9972	·9884
Parabutenylanisoïl	———	·9773
Ortho	———	·0740

The ortho compounds refuse to crystallize even when placed in a freezing mixture; the para bodies crystallize freely.

α methylorthoxyphenylacrylic acid from coumarin, treated with hydriodic acid and then with an alkaline carbonate, yields an oil which is apparently identical with the orthovinylanisoïl prepared from the β acid. The author is engaged in the investigation of this acid.

The next paper was also by Mr. PERKIN, and was entitled

Note on the Action of Amonnia on Anthrapurpurin.—In a previous paper the author mentioned that an ammoniacal solution of anthrapurpurin changes to an indigo blue colour when heated in a sealed tube to 100° C. Hydrochloric acid throws down from this solution a dark purple precipitate, redissolving in ammonia to a blue solution. This substance dyes alumina mordants a purple, and weak iron mordants an indigo blue colour. On examining this substance it proves to be unstable, easily resolvable into anthrapurpurin. If the solution above mentioned be heated in a sealed tube to 160°-180° instead of 100° a purple solution results. On acidifying with hydrochloric acid a chocolate-coloured precipitate forms. This, when boiled with barium hydrate (after washing), dissolves to a purple solution; on acidifying a precipitate is formed. This, after washing and drying, is dissolved in alcohol, on concentration, the dark red solution yields dark greenish or black crusts. This substance the author proposes to call anthrapurpuramide or amidoalizarin; it has the formula $C_{14}H_9NO_4$. It does not dye mordants. By the action of nitrous acid isoanthraflavic acid was obtained.

After some remarks by Dr. Witt and Dr. Armstrong, the thanks of the Society were given to Mr. Perkin for his communications. The Chairman then called on Mr. G. S. Johnson to read a paper

On Certain Polyiodides.—In December, 1876, the author described the compound KI_3. As the mercury compound $Hg I_6$ is well known, it seemed probable that the true formula might be K_2I_6, and, if so, that substitution compounds might be obtained by displacing one atom of potassium by one atom of some other monatomic element. Silver was the element first tried; $AgK_3I_{12}KI+5H_2O$ was however the only salt the author succeeded in isolating. It is efflorescent over strong sulphuric acid but deliquesces in air. It can be recrystallized by dissolving in a small quantity of water and evaporation over sulphuric acid. The crystals present a stepped arrangement, are almost black, with a peculiar lustre; an excess of water decomposes the salt. The author next endeavoured to prepare the compound, $K_2Tl_2I_{12}$, but without success, the only compound obtained being that discovered by Willm, TlI_3KI+2H_2O. Before the isolation of potassium triiodide, Biffard supposed that the solution of iodine in aqueous potassium iodide contained a definite periodide, because it gave a dark coloured precipitate with a solution of acetate of lead. By using alcohol as a solvent instead of water, the author obtained a crystallized compound, a specimen of which was exhibited, not deliquescent, crystallizing in square prisms. By gradual evaporation, fairly large crystals were obtained with six faces, two having a dark purple, and four a greenish golden reflection. The compound can be recrystallized from hot alcohol. Sp. gr. 3·084. Analyses of the constituents led to the complicated formula, $Pb_8C_{36}H_{54}O_{28}K_6I_{17}$. The author has not yet been able to suggest a rational formula.

The next paper was—

On an Improved Form of Wash Bottle. By T. Bayley. To prevent the reflux of steam or other gases, such as ammonia, etc., into the mouth of the operator, the author suggests the following modification of the ordinary wash bottle. The mouth piece is provided inside the bottle with a Bunsen valve, *i.e.*, a piece of indiarubber tube with a slit, a third tube is inserted in the cork, having two T tubes outside the bottle, the ends of these Ts are connected by a piece of caoutchouc tube which can be closed by pressure. The orifice of this third tube between the two Ts is closed by a small cork. The only connection therefore, passing outwards, between the inside of the bottle and the atmosphere, except by the washing jet, is through the indiarubber tube connecting the two Ts. The operator blows in through the Bunsen's valve, closing the said indiarubber tube by pressure; as soon as he ceases blowing, the valve shuts and prevents any reflux, whilst he can by taking off his finger from the indiarubber tube, stop the action of the washing jet, or by keeping the pressure on continue the action for nearly a minute. This third tube also serves to pour out water when the bottle is reversed. A sketch of the arrangement accompanies the paper.

The last paper was—

On the Preparation of Glycollic Acid. By R. T. Plimpton. The author made two attempts to prepare calcium glycollate by following the directions of Professor Church, *Journal of the Chemical Society*, series 2, vol. I. 2 lbs. of granulated zinc, and 2 oz. of oxalic acid were used in each operation. Some needles resembling calcium glycollate were obtained, but the quantity was too small for analysis.

The Society then adjourned to March 21, when papers on Aromatic Nitrosamines, by Dr. Otto Witt; on a New Process for the Volumetric Estimation of Cyanides, by J. B. Hannay; and on Certain Bismuth Compounds, by M. M. P. Mulr, will be read.

Parliamentary and Law Proceedings.

Prosecution under the Pharmacy Act.

At the Marlborough Street Police Court, before Mr. Newton, in the cases of Pharmaceutical Society of Great Britain *v.* Mackness, and the same Society *v.* the London and Provincial Supply Association, Limited, Mr. Flux, Solicitor of the Society, appeared on Tuesday, the 12th inst., in support of three summonses, which he said could be taken together or separately.

Mr. Sanders, who appeared as counsel for the defendants, said he preferred taking them separately.

Mr. Flux suggested that the evidence given in one should be applicable to the others, so as to avoid repetition, to which Mr. Sanders assented.

Mr. Flux then said that the first summons was taken out under the Pharmacy Act of 1868, the 31 and 32 Vic., cap. 121, sec. 17. There were other sections which Mr. Sanders might desire to call attention to, but he thought they were hardly material. He then read the section which is the one requiring that all poisons sold shall bear the name and address of the seller.

Mr. Sanders said he would save Mr. Flux any trouble in this matter by admitting that his client had involuntarily committed a breach of this section, but there were certain facts he wished to bring to the attention of his worship which he thought would influence his judgment. His client had been for some time carrying on a very large business at 113, Tottenham Court Road, where although he designated the business the London and Provincial Supply Association, he himself, down to February was the sole proprietor; and it was whilst he was sole proprietor this breach of the Act took place. It was quite involuntary on his part, for he engaged a properly qualified pharmaceutical chemist as his assistant, but of course he was responsible for anything he did. The penalty for such a breach of the Act as had been committed was £5, or any lesser sum the magistrate might think fit to impose, but there were circumstances in this case which he believed would induce his worship to inflict only a nominal penalty.

Mr. Newton said he understood the summons was for selling oxalic acid without distinctly labelling the cover or wrapper within which the poison was contained with the name and address of the seller of the poison.

Mr. Sanders said, yes; that was an offence under section 17, but he wished to draw attention to something which came under section 15, which was, in point of fact, the same act of negligence for which Mr. Mackness had already paid the penalty, and then he would leave his worship to judge. His client was the subject of an application from Mr. Flux with reference to a breach of the 15th section for acting as a chemist and druggist without being a member of the Pharmaceutical Society; he was not convicted, but steps were taken with reference to an information leading of course to conviction. It was the same transaction, although under two different sections. On the 14th of January the letter which he was about to read was written, and this information was laid on the 5th of March, with reference to a breach of the Act committed on the 28th of December. Between those times, viz., on the 14th of January, Mr. Mackness received from Mr. Flux a letter saying that by having on the 28th of December, 1877, sold oxalic acid, a poison, and acted as a chemist and druggist without being on the Register of Chemists and Druggists he had incurred a penalty of £5 (that was the penalty under section 15), payable to the Pharmaceutical Society of Great Britain, under the provisions of the Pharmacy Act, 1868, and by having sold the same poison without having caused it to be labelled with the name and address of the seller (which would be an offence under section 17), he had also rendered himself liable to other penalties, and that as solicitor for the said Society he applied to him for the above-mentioned penalty, and unless the same with 5*s.* costs were paid forthwith he should sue for the amount. He also mentioned that the fact of trading as a chemist and druggist was a continued infringement of the law respecting the sale of poisons, and that if he continued to do so that would be pressed against him, and so on.

Mr. Flux: So far as may be necessary to secure obedience to the law.

Mr. Newton: Let me understand, did you write that letter with the intention of Mr. Mackness paying the £5 without a hearing?

Mr. Flux said the penalty was to be sued for in a civil action in the county court.

Mr. Newton: Did you write that letter intending the £5 should be paid on the receipt of that letter?

Mr. Flux replied in the affirmative.

Mr. Newton: Then I think you acted wrongly.

Mr. Sanders said he believed it was an act for which Mr. Flux could be indicted.

Mr. Newton said he considered Mr. Flux had acted very wrongly.

Mr. Flux said perhaps his worship would hear him on that point.

Mr. Newton said Mr. Flux had no right to put a pistol to a man's head, which it was, and say unless you give me £5 I shall fire the pistol off.

Mr. Flux trusted his worship would hear him on that point more in detail. These penalties were to be recovered in the county court.

Mr. Sanders said that any penalties recovered under this Act were to be paid to the Commissioners of Her Majesty's Treasury, when they were recovered in the county court, but when they got them in this way they put them into their own pockets.

Mr. Flux said they dealt with them as the Commissioners of the Treasury directed.

Mr. Sanders said it was really an act of extortion on the part of Mr. Flux, though he did not suppose he intended it to be so. Of course Mr. Mackness, feeling he was in the wrong, consulted his solicitor, who told him he had no doubt violated the Act of Parliament, and that he had better pay the £5, and the 5*s.* for the application. That in point of fact was the same transaction as the one for which he was now summoned, and it had been advertised as being the recovery of a penalty. Now there had been no recovery of a penalty, but it was voluntarily paid without contesting the matter. Under these circumstances he hoped his worship would be of opinion that his client had substantially paid for his neglect, and that he would not visit him with any further penalty.

Mr. Newton said he did not see how Mr. Flux could very well go on, having taken the step he had.

Mr. Flux said the considerations which had now been urged upon his worship had in other cases—before other magistrates—

Mr. Newton said he must request Mr. Flux not to refer to other cases or other magistrates before him. Each case which came before him was dealt with on its own merits.

Mr. Flux asked leave to draw his worship's attention to the fact that the penalty of £5 to which his letter referred was a penalty recoverable only in a civil action, and not in a police-court, and that as to the mode which he, as solicitor for the Society, took to recover penalties in civil actions he was exposed of course to the remarks of judges of the county court, and in his conduct with regard to these civil proceedings he had had distinct regard to the emphatic utterances of the learned judges who had impressed upon him that in such suits in which both sides were exposed to the costs of the action, the proper, ordinary, and courteous course to be adopted by a solicitor was to send a letter before action, and upon the letter asking for payment the penalties then recovered were distinctly accounted for and dealt with under the Act of Parliament.

Mr. Newton: Surely not a letter with a threat.

Mr. Flux replied it was the common letter before action.

Mr. Newton said he had only heard the letter read casually.

Mr. Flux said he would hand up to his worship a copy; it was the ordinary form of solicitor's letter before action.

Mr. Newton said he set his face against that kind of thing and always should do so.

Mr. Sanders remarked that Mr. Flux had no right to the amount unless it was recovered.

Mr. Newton again repeated that he did not see how Mr. Flux could come for a penalty for selling this on the 28th of December having already recovered £5 for it.

Mr. Flux said the penalty of £5 already paid was for carrying on the business of a chemist and druggist in infringement of certain clauses in the Act of Parliament, whilst the penalty for which the accused was now pressed was a penalty for the protection of the public in regard to the manner, not to the person, but the manner in which the sale was conducted. The law said that certain persons and only certain persons could lawfully sell poisons, but if persons not selling lawfully do sell they should be liable to a penalty of £5 to be sued for in the county court.

Mr. Newton said the letter distinctly said unless you pay me £5 and 5*s.* costs, I shall immediately recover that money from you. If that was not a condonation of anything that had occurred up to that date he never heard one.

Mr. Flux said that was for the above mentioned penalty of £5.

Mr. Newton considered it was for everything done up to the 14th January. If he had intended to sue under this section he should not have written this letter.

Mr. Flux said there were two separate penalties under two separate clauses. In the one case it was to be sued for by the institution designated—a corporate body; in the other it was a matter of criminal penalty, to be pressed for at the instance of a prosecutor.

Mr. Newton said he should not have written that letter if he had intended to take further proceedings for what occurred on the 28th of December.

Mr. Flux said if this gentleman had not further offended against the Act of Parliament they would not have further pressed him.

Mr. Newton said the case would have stood very much better if they had not taken out the summons for what occurred on the 28th of December.

Mr. Flux said he had submitted all the considerations which arose on the case, but he would ask his worship to reserve his decision for the present until he had heard the other summonses.

Mr. Newton said he would hear the second summons, which was for having sold poison on the 4th February without distinctly labelling the wrapper in which such poison was contained, namely, red oxide of mercury, with the name and address of the seller.

Mr. Flux said the red oxide of mercury was not in the schedule to the Act itself; but the Act contained power for the Privy Council and the Pharmaceutical Society by concurrence and notice in the *London Gazette* to add to that schedule of poisons, and this red precipitate had been so added, as he could prove by the original *London Gazette.*

Mr. Sanders said he would admit that the red precipitate was a poison within the meaning of the Act, but he should like to know the date of the *Gazette.*

Mr. Flux said it was December 2nd, 1869. He had witnesses who could prove it if necessary.

Mr. Joseph Brooker Ward was then sworn and examined by Mr. Flux. He resided at 24, Avenue Road, Clapton, and was clerk to Messrs. Flux and Co. On the 4th February, 1878 he attended at 113, Tottenham Court Road, the same address at which he had purchased the poison mentioned in the earlier summons. He went to the counter, which had the appearance of being an ordinary chemist's counter, being fitted up with bottles and so on, like a chemist's shop. He did not notice any writing or inscription that he remembered; he thought he read the word "dispensing," or something of that kind. He saw a person who he afterwards found to be Mr. Longmore, and asked him for a small quantity of red precipitate. He supplied him with a small packet (produced). Witness asked how much it was, and he stated 2*d*. That was labelled "Red Precipitate. Poison. London and Provincial Supply Association, 113, Tottenham Court Road, London, W. H. E. Longmore, Chemist and Druggist." That label corresponded with the label on his earlier purchase, with the exception of the difference in the name of the article.

Mr. Newton thought he said he had only purchased red oxide of mercury on the 4th of February. Then he could not go into the oxalic acid question.

The Witness continued: He kept the article in his possession until he handed it to Professor Attfield for analysis.

Mr. Sanders said he would admit that the article was a poison, but he did not exactly comprehend the nature of the complaint made. What was the objection to the label?

Mr. Flux: That Mr. Mackness did not label it with his name and address.

Mr. Sanders: He did not buy it of Mr. Mackness, he bought it of Mr. Longmore.

Mr. Flux said Mr. Mackness admitted it was his business.

Mr. Sanders said Mr. Mackness admitted nothing.

Mr. Flux to the Witness: Had you previously ascertained that Mr. Mackness was the proprietor?

Mr. Sanders objected to the question.

Mr. Flux: Had you previously purchased poison at the same premises?—I had.

Had Mr. Mackness admitted that he was the seller of the poison?

Mr. Newton: Stop, that will not do, you must shape your question in another way.

Mr. Flux: Had you any means of knowledge as to who was the proprietor of the shop?—I had from the solicitor of Mr. Mackness. His clerk called on me and told me.

Mr. Sanders objected.

Mr. Newton: That is merely hearsay.

Witness: Since then Mr. Mackness himself has admitted he was the proprietor.

Mr. Newton: Admitted will not do, you cannot say he admitted. What did he say?

Witness: He had a long conversation with me and told me how this institution of his had grown up from a small business, and that his father had found him the money to go into the business and to carry it on, and that Mr. Longmore was a servant of his.

Mr. Sanders said this summons appeared to be addressed to Mr. William Mackness and the London and Provincial Supply Association by their secretary Polley; whom did he go against?

Mr. Flux said against both. Mr. Mackness had by his counsel to day admitted that he was the seller.

Mr. Sanders said the remarks he made previously had reference only to the 28th of December.

Mr. Newton said here was a poison sold admittedly by Mr. Longmore, a chemist and druggist, 113, Tottenham Court Road.

Mr. Sanders: Every requisite of the Act being complied with.

Mr. Flux said that sale was a sale by Mr. Mackness according to the admission of his own counsel.

Mr. Newton: That was the sale in December.

Mr. Flux: Which was the very foundation of the proceedings against him.

Mr. Newton: Then I think I see my way pretty clearly; if you have nothing else but that, because you have obtained £5 from Mackness by means of writing that letter, you propose to prove that Mr. Longmore is not a chemist and druggist, that is what your case must be.

Mr. Flux: Not the seller.

Mr. Newton said Mr. Flux had proved that Mr. Longmore was the seller.

Mr. Flux replied that Mr. Longmore was simply the paid servant of Mr. Mackness, as was admitted.

Mr. Newton: That is just what it is not. You are so fond of that word "admitted." There is no such thing as admitted, particularly in a criminal court. The witness has said that Mackness told him he had that shop and that Longmore was his servant. This poison was sold by Longmore who was within the words of the Act.

Mr. Flux said he had a letter from Mr. Mackness's solicitor of the 30th of January admitting that he was the proprietor of the business, because he said he had sold, and a man could not sell a thing of which he was not proprietor.

Mr. Newton asked Mr. Flux if he had looked at the 15 and 16 Victoria, the 12th and 14th sections.

Mr. Flux said he did not know that that had any bearing on the matter. He did not dispute that Mr. Longmore was on the Register.

Mr. Newton said he was the seller.

Mr. Flux submitted the Act of Parliament said, "That the person on whose behalf any sale is made by any apprentice or servant shall be deemed to be the seller." That was clause 17.

Mr. Newton said Mr. Longmore did sell.

Mr. Flux: He sold as a servant.

Mr. Newton: He is a servant, therefore he comes within the two; he is the servant and the seller.

Mr. Flux: If a servant sells, the person on whose behalf he sells is liable.

Mr. Newton: It says the servant shall be called the seller, or the apprentice shall be called the seller.

Mr. Flux submitted that a reperusal of those words would show that was not the meaning.

Mr. Newton: It strikes me as being beyond all dispute.

Mr. Flux: That the servant shall be deemed to be the seller?

Mr. Newton: Yes, read it again. It is sold by Longmore, as the seller.

Mr. Flux submitted that Longmore was the servant of Mackness, selling in Mackness's premises and nothing else, and admittedly so.

Mr. Newton: No.

Mr. Flux said that being the case and Mr. Longmore being present be would put him in the box.

Mr. Sanders said the meaning of it was that a person should not shelter himself under these penalties by saying he does it by a mere servant or apprentice, but here there was a qualified person.

Mr. Flux said if a grocer employed a duly admitted solicitor that did not justify a grocer in carrying on the practice of a solicitor.

Mr. Newton: No, but according to what Mr. Flux had admitted Mr. Longmore was a member of the Society.

Mr. Flux: Not a member of the Society but a chemist and druggist; he was on the Register, in the same way as any solicitor would be on the Rolls of Solicitors, but that would not authorize any person not on the Rolls to carry on practice.

Mr. Newton said this man, being on the Register, he would be qualified to become a member of the body.

Mr. Flux said he was qualified to carry on business for himself, but not to carry on business for a person who was unqualified. He submitted the theory of the Act of Parliament was that the public should be protected in regard to the matter of sales, and that on every article sold they should have the name and address of the person against whom, in case of injury, an action would lie, or who, in case of neglect, would be liable to a prosecution for manslaughter.

Mr. Newton said the person who was put at the head of this department of the store was a person admittedly capable of doing that which he was asked to do, namely, sell poisons.

Mr. Flux said if he were conducting the business on his own account he would be qualified to sell poison.

Mr. Newton said the Act was passed to prevent unqualified persons selling poisons. It so happened this man was a qualified person.

Mr. Flux: But the Act of Parliament requires the name and address.

Mr. Newton did not think the Act of Parliament ever intended this case. It seemed to him rather a case of oppression.

Mr. Flux said if his worship would follow out the third case, he would see what gross negligence occurred, and the third case took place before any proceedings were taken. When he found that oxalic acid was sold in a screw of paper as if it were so many lollipops, then his clients, being charged in some degree with the carrying out of this Act of Parliament, felt they would be guilty of gross neglect of duty to the public if they allowed it to pass.

Mr. Newton: Do you not think the real object of this prosecution is to stop the sale of drugs at this particular place?

Mr. Flux said it might have that effect.

Mr. Newton: That is your object in bringing these proceedings here?

Mr. Flux said when his worship saw the third case he thought he would see the other was the motive, and that there had been a very flagrant case indeed.

(Mr. Henry Edward Longmore was sworn).

In answer to Mr. Flux he said: I live at 10, Storey's Gate, St. James Park. I lived there on the 4th February last. That was my address on that day; I had no other.

What were you on that day, a master-man or a servant? —I was a master-man. I was a partner in the firm of the London and Provincial Supply Association.

What do you mean by a partner?—A shareholder. I was a shareholder on that day. I cannot tell you the date when I became a shareholder; if you look at the minute books you will see.

Mr. Flux: Are the minute books produced?

Mr. Newton: No, you have not given them notice to produce; you must carry out these things if you are going for a criminal prosecution, which this is, according to law. I cannot permit you to go one bit out of the line. I never do permit anybody if I can stop him.

Witness continued: I will pledge my oath I was a shareholder on that day. I hold five £10 shares. I was drawing a salary. I was a paid servant at that time of the company. The business at 113, Tottenham Court Road belonged on that day to the London and Provincial Supply Association. It was a registered company, as far as my knowledge goes, and I believe was incorporated. It was a Limited Company.

Then the word "Limited" was part of its name?—Certainly it was.

Is that the company (handing a document to the witness)?—I do not know. I know the signature of Mr. William Mackness. I think it is his signature.

Will you swear you were a shareholder prior to the 20th of February?—If you refer to the minute books of the Society you can see; it is a question I could not swear to, but to the best of my knowledge I was.

Do you know when any change of ownership took place?—When we received notice from you that we were doing wrong, and that fine was paid.

Were you engaged by Mr. Mackness originally?—I was engaged by Mr. William Mackness originally. There was a change in the arrangement when I was made a shareholder and when I took shares.

You said you were a salaried servant at that date, being a shareholder did not alter that?—One's salary need not be altered because he takes shares in an association.

Then you mean there was no new agreement, but you went on?—There was a consideration that need not be mentioned, as it does not relate to the present case.

There was a consideration for which you became a shareholder?—Quite so.

But was there any change made in your hiring?—No.

Or in the conduct of the business?—The conduct of the business was this, everything of course was bought by the manager, Mr. Wm. Mackness, the acting manager, I may say, of the Association.

Look at those two packets; do you recognize that label?—I do.

Look at the other one.

Mr. Newton: I thought you were upon the third summons.

Mr. Flux: Upon the second summons.

Mr. Newton: Does that relate to the second summons?—This is the original summons.

Mr. Flux: You recognize that label?—I do.

Do you recognise the other?—I cannot recognize that because it is partly torn off. I wrote the "red" written underneath the "white," and the white being scratched out is my writing.

In fact on the 4th February you used labels which had previously been in use?—Yes.

And the London and Provincial Supply Association, Limited, was your employer on the 4th February?—You asked me that before, and I have answered it.

How?—I said I could not tell you at the time but to the best of my belief it was.

If any company it was that?—I think so. I referred you to the minute books I think.

If you will produce the minute books?—You should have asked for them; your clerk has seen them already.

I should like to see them.

Mr. Sanders: Have you given us notice to produce them.

Mr. Flux: No. I do not want to see your minute books, but if the witness says "Refer to the minute books and I will tell you," he may refer, and then I shall see them.

Mr. Sanders said he had nothing to ask Mr. Longmore.

Mr. Flux submitted that against either one or other of these parties, Mr. Mackness or the company, there must be a conviction. He had shown that Mackness was the proprietor of the business in December, that certain labels were used and a continuation of the same labels on the 4th of February, the date of this summons. If it could be said that this chemist was the seller there was an absence of his address from the label. He submitted that the Act of Parliament was clear; that although this chemist had conducted a business it was not for himself; he was, according to his own admission, a paid servant, and then he was within the 17th clause.

Mr. Newton said he was a shareholder, a part proprietor.

Mr. Flux said there were plenty of decisions that shareholders were not part proprietors; that the ethereal thing called the company was the proprietor, and that the share was an ethereal thing and the holder of it was not part proprietor. But then if he as a shareholder put his name, he represented the company, and he as a shareholder should have put his own address as well as name on the label. But if it were the company—which came to a certain extent as a matter of surprise, seeing the continued use of the label—then there was this fact that although it continued the name the London and Provincial Supply Association, the word "Limited" as part of the name, so as to give the public a knowledge that the company was registered as a limited company and was the institution against which he could proceed, was not there.

Mr. Newton: How would you have them label their poisons?

Mr. Flux: London and Provincial Supply Association, Limited, 113, Tottenham Court Road.

Mr. Newton: Then because they omitted the word "limited" and put in "Longmore, Chemist and Druggist," you say this is insufficiently labelled. I want to understand your position.

Mr. Flux: Technically that is so.

Mr. Newton: I think that is a mere splitting hairs, if you admit the fact, pardon my saying so, that they have a right simply to call themselves London and Provincial Supply Association, Limited, and you would not object to that.

Mr. Flux: If the sale had been conducted for that company.

Mr. Newton: But it was conducted for the company.

Mr. Flux: If your worship so thinks, then my point stands upon that only, that they have not got their name there, that they have only got a part.

Mr. Newton: Is that all you submit to me?

Mr. Flux said he had nothing to add on that case, but the third was a most serious one.

Mr. Newton: Very well, let me hear the third case.

Mr. J. B. Ward, recalled said: On the 20th February, 1878, I went to 113, Tottenham Court Road; the external and internal appearance of the place was the same as before. I went to the same counter and asked for a small quantity of oxalic acid. The person asked how much, twopenny-worth? I said, yes, that would do, and he took some from the drawer and handed it to me. It was done up in one paper with no label whatever. He took a pen and wrote on it "Oxalic Acid, Poison." I put it in my pocket and then went to see the Secretary.

Mr. Newton: He knew who you were?—He did not.

Who was the man who served you?—I do not know, he was a stranger to me, I had never seen him before, and have never seen him since.

But he might have seen you?—I don't think he had, because I have reason to believe he was a new servant.

Mr. Flux: Do you produce the packet?—I do. Having made that purchase I went to a gentleman who I thought—

Mr. Newton: That will hardly do.

Mr. Flux: It was to the Secretary, who is summoned.

Mr. Sanders: No, he is not summoned, it is the London and Provincial Supply Association, Limited.

Mr. Flux: By their Secretary, Arthur Polley.

Mr. Newton thought Mr. Flux had enough evidence for his purpose.

Cross-examined by Mr. Sanders: It was about the middle of the day I went. I do not think it was dinner time. It was very late for dinner, between two and three. I expected to find Mr. Longmore there; I rather hoped to find him. I went primarily to search the register of shareholders. I purchased it to see if they were still infringing the Pharmacy Act. I had no use for the acid myself.

You bought it to get a case against the parties?—I certainly did it to see if they were still infringing the Act.

You of course were perfectly well aware of the provisions of the Act?—Very well aware.

It never occurred to you to tell the man to put his name upon it, or his master's name?—Certainly not.

Why did you not; did you want the man to commit an offence?—I did not wish him to commit an offence.

Why did you not tell him you ought to put your name upon this or you will be exposed to penalties?—I did not think of it.

You were glad of an opportunity of laying an information?—No, I rather hoped to get something different.

You have no reason to give why you did not tell the man, by way of caution, that he ought to put his name?—I have done such things before, it did not strike me that it was necessary to do so. I afterwards found out he was a registered chemist.

Did you not observe he was not the usual man who served in the shop?—I observed it was not Mr. Longmore.

Did you ask for Mr. Longmore?—No, I asked for Mr. Polley.

Mr. Newton: Would it not be dangerous to leave a mere stranger in the shop.

Mr. Sanders said in point of fact it was nothing but a mistake.

Mr. Newton said there was no mistake here he was afraid.

Mr. Sanders said he believed this man was instructed not to sell poisons, but merely to mix up and compound prescriptions. The word "poison" was written upon the packet, so that it was a technicality rather than a matter of substance; it was not likely to mislead any one. The great thing was that it had the word "poison" on it.

Mr. Newton asked if it was a man who sold it.—The witness; Yes; I believe he was a registered chemist and druggist, because in conversation with Mr. Mackness and Mr. Longmore about it—

I only asked you one question, was it a man or a boy?—It was a man.

Mr. Sanders: Did you notice he was searching for a label and could not find one?—I do not think he was. I will not swear positively. He wrote that himself.

Mr. Newton: What did you pay for it?—2*d*.

At an ordinary chemist's what do they charge for it?—About the same price, I suppose. I do not know.

Mr. Sanders said that was all he had to ask.

Mr. Flux said he would call Dr. Attfield to prove that the contents of the packet were oxalic acid.

Mr. Sanders said he would not dispute that.

Mr. Flux: Then I will not trouble your worship further.

Mr. Newton said he did not see what answer Mr. Sanders could make to this summons.

Mr. Sanders said he would make this answer in the first place, which, if necessary, he would have proved; but it was already admitted, that this was a limited company, and was addressed in that capacity.

Mr. Newton said if there were any technical objection of that sort he would alter it in a minute by a stroke of the pen. He would not advise Mr. Sanders to take that point.

Mr. Sanders said he did not wish to make objection of a technical kind, but he submitted as it was a corporation it was not amenable to these proceedings; that a corporation could not be sued either by indictment or by summary information; that in point of fact a corporation had no identity, no individuality.

Mr. Newton: Do you hold yourself above all law, then?

Mr. Sanders: No. If an Act of Parliament specifically applied, if it said "any person, or any corporate body," it would be different.

Mr. Newton asked if he meant to submit that they could not do anything criminal because they were a body corporate. Suppose they infringed the law by selling adulterated milk, or, as in this case, by selling poisons.

Mr. Sanders said the difficulty amongst other things would arise in the process; for instance, how would his worship carry out any penalty?

Mr. Newton said if they did not pay the penalty he should sent his warrant officer to seize their goods to the amount.

Mr. Sanders: And suppose there were no goods to seize, what would be the ultimate remedy? his worship could not commit anybody to prison.

Mr. Newton said he should see about that. He thought he could find somebody to do it.

Mr. Sanders thought the thing would be impossible.

Mr. Newton said he hoped that eventuality would not occur. He understood the point was that the words in the Act of Parliament were "any person," and the question was whether "person" would include a corporate body.

Mr. Sanders did not think his worship would find in any law-book or any treatises any dictum which would go to that extent. A corporation could not be sued as an individual. A very good description was given of a corporation in Blackstone's Commentaries; it is "an invisible body, existing only in the intentment and consideration of the law."

Mr. Newton: Cannot you indict a railway company?

Mr. Sanders: Yes, under an Act of Parliament. There are provisions there that that shall be done, but here they were under the common law, and the Act of Parliament gave no remedy against a corporation.

Mr. Newton said when the Act of Parliament was passed no one had any idea that corporate bodies were going to sell drugs.

Mr. Sanders said very likely it was a *casus omissus*.

Mr. Newton said he thought he could settle it, and let Mr. Sanders take a case if he was wrong, which would at once put it right. The short point he had to determine was whether under the Pharmacy Act, 1868, a "person" included a corporation, and whether they could be sued for penalties under the 17th section.

Mr. Sanders said that was the point. If his worship had a strong opinion upon it he would not argue it further.

Mr. Newton said he had not a very strong opinion upon it, because he had not thought much about it until now.

Mr. Flux said he had a case under the Truck Act in which a company was convicted, and there the word was "employer."

Mr. Sanders said that was a different thing.

Mr. Newton said if there was anything in the point he should like to have a case taken upon it.

Mr. Sanders said under this Act of Parliament they could not sell poisons unless they were members of the Pharmaceutical Society, but it was impossible that a corporation could be members.

Mr. Newton: Then you have taken into your body a shareholder who is a member of that body.

Mr. Sanders said that would not render the corporation members of the Pharmaceutical Society. Before the passing of this Act anybody might sell poisons under any circumstances without restriction. This Act of Parliament was passed, but the person who drew it did not carry in his mind's eye the whole of the circumstances that would occur.

Mr. Newton: He did not have a prospective view of the Civil Service stores.

Mr. Sanders said the Civil Service stores had been in the habit of selling for years, but this was a joint-stock company. This might very likely be a *casus omissus*, but he did not see how it could be altered as far as these associations were concerned.

Mr. Newton said this was a new point, and he would be much obliged if the two gentlemen would look into any cases that had been decided and come before him again on Saturday next at half-past twelve, because a decision on this case might be of very great importance.

Mr. Sanders said there would be a difficulty in a case being stated under the 20th and 21st Victoria, because he did not see who could enter into the recognizances.

Mr. Flux said upon his side every facility would be given.

Mr. Newton said he could send a case up to the court at once; there would be no difficulty about that.

Mr. Flux said in case anything should turn upon it he should like to have it proved whether Mr. Longmore was a shareholder in the company at the date in question.

Mr. Newton: It is your own witness; you cannot discredit him.

Mr. Flux: But he would not pledge himself as to the date at which he became a shareholder.

Mr. Crouch (defendant's solicitor) said Mr. Flux might take it from him he was a shareholder before that date.

Mr. Flux said he would accept that statement.

Mr. Newton said the doubt had crossed his mind whether Mr. Ward was not perfectly well known to the shopman, and whether the shopman did not know that there was something behind, and sell him that knowing who he was. That was why he asked Mr. Ward the question.

Mr. Flux said there was nothing of the kind.

Mr. Sanders asked his worship to dispose of the two first summonses.

Mr. Newton said he should rather not do so, because if a case had to be drawn up it might be necessary to have all the facts placed fully before the court.

Mr. Flux having given his worship a reference to the case he had mentioned of Weaver *v.* Floyd in the 21 *Law Journal*, page 151, which went up to the Court of Queen's Bench and was decided by Justices Pattison and Whiteman, the case was adjourned until Saturday the 16th, at half-past twelve.

Poisoning by Colocynth.

Mr. Malcolm, the Leeds borough coroner, held an inquiry at the Leeds Town Hall, on March 10, relative to the death of Mary Stead (32), wife of a coal miner, living at 44, Spring Close, Bank. She was taken suddenly ill on Saturday morning, and on her husband calling in Mr. Heald, the police surgeon, she told him that she had taken some bitter apples to procure abortion. She died on Sunday morning after about twelve hours' illness. The deceased bought two pennyworth of bitter apples at the shop of Mr. Thomas Arnold, druggist, Sussex Street. Bitter apples, although a vegetable irritant poison, is not scheduled in the Pharmacy Act. Mr. Heald, on making a *post mortem* examination, found the stomach largely distended, and it and the intestines very much inflamed. He was of opinion that death had resulted from inflammation of the covering of the bowels, caused by some irritant poison, probably bitter apples. Bitter apples was a vegetable poison commonly supposed by women to produce abortion. The woman had had four children, and was two months advanced in pregnancy at the time of her death.

The jury returned a verdict to the effect that the deceased had died from the effects of poison administered by herself, but there was not sufficient evidence to show what was the state of her mind at the time.

Dispensing Memoranda.

[77]. Could any reader inform me of the best mode and excipient for making the following:—

℞ Ferri Sulphatis	gr. xxiv.
Ext. Aloes Aquos.	gr. xij.
Ext. Hyoscyami	gr. xxiv.
Ol. Sabinæ	ℨss.

M. pil. xxiv. Capt. ij. omni alt. nocte.

Thos. F. Elton.

27, *Park Street, Cirencester.*

[78]. The following prescription when dispensed accurately causes a separation of the quinine in a resinous form. I have even seen it collect into one mass, which floats on the surface of the fluid.

℞ Spt. Ammon. Arom.	℥vj.
Potass. Bromidi	ℨij.
Ferri et Quiniæ Cit.	ℨj.
Aquæ	ad ℥vj.

Would it therefore be consistent on the part of the dispenser to send the mixture out in this manner, or to remove the solid by filtration? It, however, must be borne in mind that in neither case would the patient be benefited by the separated quinine, as in the former it would remain in the bottle after the medicine had been taken, therefore the result would be the same as were the dispenser to remove it.

W. A., *Norwich.*

[79]. Would any reader inform me through the columns of the *Pharmaceutical Journal* the reason of a separation in the following mixture, which rises to the top to the extent of half an inch in an eight ounce mixture, and suggest the best means of avoiding it?

℞	Potass. Bicarb.	gr. xv.
	Decoct. Pareiræ	℥j.
Misce ℥viij.		

T. P. B.

[80]. I was handed a prescription a few days ago for a certain quantity of boracic acid ointment, which I prepared according to the receipt published in the Journal some time ago, viz.:—

Boracic Acid Ointment (*Lister's*).

Take of—

Boracic Acid in fine powder . .	1 part.
White Wax	1 „
Paraffin	2 „
Almond Oil	2 „

The ingredients after being mixed by melting the wax and paraffin, are stirred in a mortar till the mass thickens, and then set aside to cool, after which the firm substance is reduced in a cold mortar in successive portions to a uniform soft ointment. This forms an ointment having a very gritty appearance although carefully prepared. I should feel very pleased if any of the numerous readers of the Journal could tell me how to make a smooth ointment of it, or whether they could give a more preferable receipt.

QUERENS.

[81]. Will some one kindly inform me how I can make the following pills hard, what excipient I should use? A firm in Manchester make them quite hard.

℞	Ext. Rhei.	gr. xlviij.
	Ext. Chelidonii	gr. xlviij.
	Quinæ Sulph.	gr. xxiv.
Misce, ft. pil. xxiv.		

J. K. G.

[82]. Will some one kindly tell me the nature of the deposit in the following mixture, and if it is possible to dispense it in such a manner as to avoid it?—

℞	Quiniæ Sulph.	gr. xij.
	Potass. Bromid.	ʒiij.
	*Sol. Acid. Bromohydric.	℥vj.
	Aq. Destill.	ad ℥vj.
M.		

A. H.

Obituary.

Notice has been received of the death of the following:—

On the 21st of February, 1878, Mr. Robert Denoon, Chemist and Druggist, Inverness. Aged 31 years.

On the 12th of March, 1878, Mr. Joseph Hick, Pharmaceutical Chemist, Bradford, Yorks. Aged 56 years. The deceased gentleman had long occupied a prominent position amongst his townsmen, and for nineteen years filled the office of churchwarden. In 1871 he was elected an alderman, and in 1876 was placed on the commission of the peace for the borough, in the discharge of the duties of which office he had had been sitting in the Borough Court on the day of his death, which resulted from apoplexy. Mr. Hick became a Member of the Pharmaceutical Society in 1845.

The Examination Results.

Sir,—Taking, as I do, a deep interest in everything that pertains to our examinations and their results, I have been watching carefully for some time the various reports presented from time to time to the Council, together with the opinions that have been expressed, both by yourself, Mr. Editor, the members of Council, and other members of the Society, through your correspondence columns, on this subject, and I have come to the conclusion that however qualified our friends south of the border may be to judge of the circumstances as it affects themselves, they certainly fail to understand or appreciate the position of affairs on this side of the Tweed. In the first place I have noticed that there is a lurking suspicion, if not openly expressed, on the part of some of our English friends, that the Scotch Examining Board has been more lenient with the candidates then they should be; hence it (is assumed) the larger percentages of passes supplied from Edinburgh than from London. It is, therefore, gratifying to observe that the members of Council, if not the Examining Board at London, have become so far convinced of their error. I say "so far," for if the Council was thoroughly convinced why this proposal to draft our Scotch Examiners up to assist at the London Board and *vice versâ*? I do trust that our Scotch Board will be firm in resenting this proposal, the time has not yet come when the two Boards may be merged into one, and no doubt this will just be the thin end of the wedge for some such purpose. I think the two Boards, so long as they are kept distinct, are necessary; one way in which I think they do good is in giving young men a choice. It is a fact that many young men when they fail at London come forward the second time to the Edinburgh Board, and this is perhaps one reason why the Scotch Board shows a higher percentage of passes than the London Board; those young men from the South being more successful on their second attempt, for they are not all Scotchmen who present themselves at Edinburgh, as seems to be assumed by Mr. Mackay of Newcastle in his letter of the 2nd inst. I do not think it is possible to get absolute uniformity in our examinations, any more than it can be got in teaching, nor do I think it is desirable. Was it not the uniformity that was supposed to exist in the questions that gave the idea of "cram" such prominence a few years ago? Different examiners will adopt different methods of examining, whether they are English or Scotch, if they have any originality at all, and while it is necessary that our Council should inquire in every possible way into what may look like discrepancies, I trust the members will not go out of their way for the present to make the examinations any more strict then they are.

I cannot conclude without saying a word or two respecting the Preliminary examination and the large number of failures that has been reported of late. I sympathize to some extent with Mr. Duncannon's remarks on this subject in a recent issue of the Journal, and I do not think that his suggestions were deserving the offhand critique you were pleased to bestow upon them. You say that the "quality of the candidates has been far below the requisite standard," but who is the judge of the quality and what is the "requisite standard?" This is just where opinion differs. In legislating for a country such as ours, all circumstances have to be taken into consideration. Acts of Parliament are seldom passed to gratify the whim of any particular set of individuals; the requirements of each locality are weighed, and that law is generally agreed to which is calculated to confer the greatest amount of good on the greatest number. Now I grant that in some places, such as Edinburgh, it may be an easy matter for a section or even a majority of the trade to obtain young men as apprentices fresh from school, who will with perfect ease pass the present Preliminary examination, but looking at Scotland as a whole I say it without fear of contradiction that there is not one-tenth of the chemists here that will say that they can get apprentices at all but with the greatest difficulty, and as for passing the Preliminary before they commence their apprenticeship, the thing is absurd and is never thought of or proposed, far less expected here. The best test, Sir, of the position of affairs is the results, and the results have spoken volumes of late, that the examinations have been too stringent for the class of young men that are presenting themselves.* You may wail about the quality as you like, but we who have the engaging of the lads have to take what we can get, and the Council must regulate the examination questions accordingly, because this continual two-guinea fine will not continue long, and the Pharmaceutical Society's exchequer will feel it in due time. We have seen that some good has resulted from the deputation to the examinations recently held at Edinburgh, and we doubt not that the members of the Scotch Board will benefit from their approaching visit to London, and when this question of deputations is under consideration, might it not be advisable to look forward to extending them even beyond London and Edinburgh. The question of provincial education has not been mastered yet, and there are many other questions affecting the trade at large which must sooner or later be considered by the Council, if, indeed, there is not a crying need already for an amendment of the Pharmacy Act. Before entering on these large questions, might it not be advisable for the Council to appoint a roving commission for a month with power to examine witnesses in all the large centres, and in this way arrive at a correct notion regarding the real wants and requirements of the trade? At present all is hap-hazard.

Glasgow. JAMES M. FAIRLIE.

THE PRELIMINARY EXAMINATION.

Sir,—Your correspondent, "A Preliminary Student" writes like some scion of the aristocracy who has condescended to patronize the trade. But perhaps his shuddering dread of base born mechanics is simply the result of elation, induced by his recent success.

"A Preliminary Student" ascribes the numerous failures to the influx of "mechanics' sons and errand boys, who have received a very limited education, and in some cases scarcely any at all." It is difficult to determine the degree of difference between a very limited education and scarcely any at all, and still more difficult to satisfy one's mind as to the accuracy of the statistics on which your correspondent has based his ninety per centum estimate. However, I suppose "A Preliminary Student" could easily furnish every information with that clearness and precision which are among the results of an unlimited education.

Now taking for granted this "lower class" theory, how to bar the door against their ingress would be a problem worthy of the haughty genius of "A Preliminary Student," and its successful solution would confer upon him more lustre than does his advice to students of the metrical system, whom he recommends to best answer the questions set thereon by learning the questions themselves, for thus writes your correspondent, "the questions given on the metric system . . . could be easily learned by the candidate," etc.

May I be allowed to remind "A Preliminary Student," that after all, the mainspring of business is self interest, and he may depend that such members of the trade as are given to the unfortunate practice referred to are doubtlessly guided in their course by consideration for themselves, being content to leave to the operation of the Pharmacy Act those higher interests which have at best but a remote connection with the chief object of business, which must necessarily be the acquisition of money.

If a druggist finds that his errand boy is likely to be of more service to him than a dilettante young gentleman apprentice, it is probable that the druggist will take the boy into the business, and I for one fail to see why an intelligent youth of good character, whatever the social position of his parents may be, should be debarred by absurd notions of caste from becoming of service to himself and others. No doubt "the Act was passed to get a better qualified class of men," but it nowhere dictates the exclusion of members from any social class, provided the qualifications are complied with.

I entirely agree with "A Preliminary Student" in his remarks about the injustice to passed men and the public, which any lowering of the examination standard would involve, and I deplore the practices which he condemns, but I do not admire the scornful spirit of contempt for the so-called lower classes with which your correspondent's letter is imbued.

"The fewer the better" may be "the best motto for those now in business," but he who would have them adopt it should remember that it admits of practical elucidation by himself. Let him therefore act up to his convictions, and by seeking "fresh woods and pastures new," make the pharmacists of the future fewer and perhaps worse by one.

A REGISTERED STUDENT.

THE PINT MEASURE.

Sir,—Your article last week upon the Weights and Measures Bill, coupled with a letter from Mr. Courtenay in which Aq. dest. Oss., was interpreted as f ℥ x, suggests to me the desirability of calling attention to the anomalies existing among us in the use of the term pint.

Although imperial measure was legalized as far back as 1824, and introduced into the Pharmacopœia in 1836, yet there are still numbers among the medical profession who intend by Oj, f℥xvj. and not a few among ourselves who would dispense it as such.

To come to ordinary trading, the sixth of a gallon wine bottle is still called a pint and a half, and while for a pint of linseed oil or of turpentine 20 fl. ozs. would be well nigh universally given, for a pint of cod liver oil, castor oil, or any other medicine most frequently but 16 ozs. Surely these inconsistencies should cease.

JOHN THROSSELL.

PATENT MEDICINES.

Sir,—It is not at all likely that the Legislature or the Privy Council would carry out Messrs. Kay's "remedy" (page 653). May I suggest that a more practicable way of attaining the object aimed at, and which would also tend to the benefit and safety of the public, would be to enlarge the poison schedule by adding a third list of powerful and active medicines which, while not requiring a poison label, should only be sold with a caution label. Then it should be also enacted that with all patent medicines containing any article on either list, it should be distinctly stated on the attached label the proportion of such article or articles in the medicines, and also that such medicines could only be sold by duly registered chemists. In some such way the object aimed at may be probably attained, and such an amendment of the Poison Act may probably be carried through Parliament. Although such an arrangement would not by any means include all patent medicines, it would include such a proportion as practically to leave the trade in the hands of responsible chemists, to whom it rightfully belongs. I doubt also whether Messrs. Kay's 8 per cent. is not far too low, as to the present proportion of patent medicines containing articles in the present poison schedule. In any alteration of the poison schedule surely some modification should be introduced to obviate the necessity for labelling paregoric, paregoric lozenges, etc., poison, as must now be the case if the law be strictly carried out.

Barnstaple. W. SYMONS.

"*Occidens.*"—(1) *Hypnum populeum;* (2) *H. molluscum;* (3) *H. palustre;* (4 and 6) *H. rusciforme;* (5) *Didymodon rubellus.*

G. A. Webb.—The presence of some free hydrochloric acid would probably prevent the precipitation.

The Discrepancy in Examination Results.—*Anglicus* writes to endorse the opinions expressed in the letter of *E. H. S.* (p. 724) on this subject. He remarks that when a man is spoken of as being "long-headed," the meaning is that he is anything but stupid.

"*Aqua.*"—We must refer you to the prospectuses of the different makers.

"*Hydrargyrum*" is recommended to address his question to a medical contemporary.

C. Collins.—The subject of your letter is under consideration and will be dealt with at the earliest opportunity.

COMMUNICATIONS, LETTERS, etc., have been received from Professor Dymock, Mr. Banks, Mr. Bingley, Mr. Holden, Mr. Hessell, Mr. Mackay, Mr. Barrett, Practice, In a Groove, Beta, T. N. F.

* Our correspondent appears to reiterate, in other words, the remarks we made in reference to Mr. Duncannon's letter; but we fail to perceive any logical sequence in his argument that the standard of the Preliminary examination must be lowered because the lads available as apprentices are not equal to passing it as it is.—ED. PHARM. JOURN.

SULPHATE OF QUINIDINE.

BY DR. J. E. DE VRIJ.

In reading on page 721 of the Journal the transactions of the Paris Société de Pharmacie in the meeting on the 9th of January, my attention was struck by the conclusion of M. Petit "that the neutral sulphate of quinidine does not contain water of crystallization." This conclusion, combined with the wish of a Dutch chemist expressed in one of our journals to become acquainted with a cheap reagent to test the purity of the commercial sulphate of quinidine, induces me to communicate some particulars about this compound.

Professor A. C. Oudemans determined the molecular rotation of this salt dissolved in absolute alcohol.

A salt prepared by himself, $2\,(C_{20}H_{24}N_2O_2)\,SO_4H_2 + 2H_2O$, in which he found experimentally 4·5 per cent. of water yielded a molecular rotation of 255° 2′ ♂.

A salt beautifully crystallized in very long needles, presented to me by Messrs. Howard and Sons, in which he found 4·5 per cent. of water, yielded a molecular rotation of 255° 4′ ♂.

A salt presented to me by M. Tallandier, of Argenteuil, in which he found 4·6 per cent. of water, yielded a molecular rotation of 254° 9′.

From these experiments it follows that the crystallized sulphate is scientifically not anhydrous, but contains two molecules of water of crystallization = 4·603 per cent. From a commercial point of view, however, I found that M. Petit is right, for 7·003 grms. of commercial sulphate of quinidine, presented to me a few years ago by Messrs. Howard and Sons, lost only 0·025 grms. = 0·35 per cent. by a long exposure to the heat of a water-bath. It seems therefore that the pure crystallized sulphate loses its water of crystallization very easily.

The test for the purity of this salt is based upon the fact, which I found more than twenty years ago, that the hydriodate of quinidine requires more than twelve hundred parts of cold water to dissolve it.

One gram of sulphate of quinidine, prepared by myself in 1856 chemically pure from a specimen of quinidine kindly presented to me by Mr. J. Eliot Howard, was dissolved in 50 grms. of hot water, and to this solution added 0·5 grm. of potassium iodide. By this addition a heavy sandy crystalline powder of hydriodate of quinidine was precipitated, and on filtering off the liquid on the next day, the clear liquid was not altered by the addition of a few drops of liquor ammoniæ, but remained *perfectly clear.*

Having ascertained by this experiment the behaviour of the chemically pure sulphate of quinidine under the circumstances mentioned, I applied this test to the good commercial sulphate, presented to me a few years ago by Messrs. Howard. I found that the liquid filtered from the precipitated hydriodate of quinidine became *slightly* turbid by the addition of liquor ammoniæ, but without separating an appreciable precipitate.

Therefore, the practical test for the purity of the commercial article is to dissolve one part of the salt in fifty parts of hot water, and to add to this solution a half part of iodide of potassium. If the precipitate is not sandy, but resinous, no further trouble need to be taken, for this resinous aspect proves that the salt contains either cinchonine or cinchonidine, or perhaps both of them. If, however, the precipitate constitutes a heavy sandy crystalline powder, the filtered liquid is after some hours tested by liquor ammoniæ. If this addition makes the liquor only slightly turbid *without formation of an appreciable precipitate*, the conclusion is that the salt is really good sulphate of quinidine, and contains only traces of other cinchona alkaloids, which generally is a slight trace of cinchonine.

The Hague.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 566.)

HELICTERES ISORA, *Linn.*, STERCULIACEÆ. *The fruit. Vernacular*, MAROREE, MARORPHALI (Hind.); MURADSINGH KAWUN (Bomb.); VALUMBIRIKAI (Tam.).

History, Uses, etc.—This is a tall shrub, or small tree, much resembling the common hazel; the flowers, which are bright red and showy, appear in the rains. In Sanskrit it is called "Avartani." The peculiar twisted form of the carpels has probably led to its use as a medicine according to the ancient doctrine of signatures. Ainslie notices its use by the Hindus as a remedy for offensive sores inside the ears. At the present time it enters into most prescriptions for the cure of griping in the bowels and flatulence, especially in the case of children. Its chief virtue seems to be its harmlessness.

Description.—The fruit consists of five slender angular carpels twisted like a corkscrew, and together forming a cone about 1½–2 inches long. The carpels are pubescent, and of a greenish brown colour; they contain a single row of dark brown angular seeds. The internal surface is of a light greenish hue and highly polished; taste mucilaginous. Medicinally we may consider this drug to be simply demulcent.

Commerce.—It is kept in all druggists' shops, and as a domestic remedy is perhaps one of the best known articles in the Hindu materia medica. Value Rs. 3½ per Surat maund of 37½ lbs.

PTEROSPERMUM SUBERIFOLIUM, *Willd.*

The white fragrant flowers of this tree, which appear in May, rubbed into a paste with kángika (rice vinegar), is an ancient and well known Hindu remedy for hemicrania. The Sanskrit name of the plant is "Muchukunda," which is also the current name in Bombay for *P. suberifolium* and *P. acerifolium.*

BALSAMODENDRON OPOBALSAMUM, *Kunth*, TEREBINTHACEÆ. *The balsam and wood. Vernacular.—The balsam*, BALASAN (Arab., Pers., Bomb.). *The wood*, AOOD-I-BALASAN (Pers. and Bomb.).

History, Uses, etc.—Arabic and Persian writers describe the balm of Gilead tree as having hoary leaves like rue, and say that it is affected by heat and cold, drought and moisture, like a human being. They affirm that it sprang from the blood of the slain in Mahomet's conflict with the tribe of Harb, and that the Prophet used the balsam for the resuscitation of the dead. Antakia says that the Christians have a tradition to the effect that when the holy Virgin Mary and our Lord fled to Matriya, in Egypt, our Lord washed his clothes at a well, and from the waste water which ran upon the ground, the balsam tree sprang up; that on this account the tree is held in great veneration by the Christians who value the balsam at its weight in gold. The wood is called Aood-i-balasan; it is heavy and red, with yellowish bark. Genuine balasan when thrown into water sinks; cotton dipped in it can be washed quite clean in water. When rubbed upon a stick and inflamed, it should burn without injuring the wood, like naphtha (*Vide* 'Makhzan-ul-adwiya,' article Balasan). Abd-ul-Latif, who lived from 1161 to 1231, has described the extraction of the balsam at the garden of Matriya, near Cairo. He says that incisions are made with a sharp stone through the bark down to the wood, the juice is scraped from the tree by the fingers, and preserved in bottles which are buried in the earth for a time, and afterwards exposed to the sun until all the balsam has separated from the impurities; it is then subjected to some secret process, after which it is stored in the king's treasury. The annual produce of the garden is about 20 ratls (*Vide* Husn-ul-muhasarin fi Akhbar Mier wa ul Kahirah). The balsam is also extracted by boiling the leaves and wood in water.

Description.—Balsam of Mecca when freshly imported into Bombay is a greenish turbid fluid of syrupy consistence, having a very grateful odour, something like oil of rosemary; when dropped into a vessel containing water it rises and forms a thin film upon the surface of the liquid, which after about a quarter of an hour can be raised entire by touching it with a pencil. When rubbed upon the palm of the hand for a few minutes, it loses its essential oil and becomes very sticky. Dissolved in 6 parts of spirit 60 O.P., it forms a turbid greenish solution with many opaque flakes floating in it; these are soon deposited and adhere to the bottom of the bottle.

The spirituous solution dropped on paper and placed in the sun rapidly evaporates, leaving a slightly sticky varnish upon the surface of the paper. The balsam itself dropped upon common scribbling paper spreads a little, and soon becomes very thick; the paper beneath the drop becomes translucent only. After twelve hours it becomes so hard, that when touched it no longer adheres to the finger.

Treated with 6 parts strong sulphuric acid, B.P., the balsam forms a rich red-brown translucent solution, of the colour and consistence of Stockholm tar, which upon being poured into water throws down a dull brown resinous deposit. Balsam of Mecca which has been kept some time in the shops becomes yellowish and more viscid. The essential oil would appear to be very volatile, as after a short exposure the balsam does not render paper translucent, and has a simply terebinthinate odour. The taste is aromatic, bitter, and somewhat acrid. It would, then, appear that the Bombay balsam is very nearly of the same character as that described by Guibourt and supplied to him by M. Delessert, only that being fresher it differs in colour and contains more essential oil (confer *Hist. Nat.*, 6ème *ed. t. iii. p.* 507).

Chemical Composition.—Trommsdorff found in a sample of this balsam 30 per cent. of volatile oil, 64 per cent. of hard resin, 4 per cent. of soft resin, and 0·4 per cent. of bitter principles. The volatile oil was mobile, colourless, fragrant, and had a rough taste; it dissolved in alcohol and ether, and with a deep red colour in sulphuric acid, whence it was precipitated by water as a resin. It was also resinized by nitric acid. The hard resin was honey yellow, transparent, brittle, of specific gravity 1·333, softened at 44° C., and melted completely at 90° C. It dissolved with difficulty in alcohol and ether at ordinary temperatures, easily with aid of heat; it was likewise soluble in oils, both fixed and volatile. It was altered by hot nitric and sulphuric acids, and appeared to combine with alkalies, forming compounds insoluble in free alkali. The soft resin was brown and very glutinous, inodorous, and tasteless; melted when dry at 112° C. It was insoluble in alcohol and ether, but soluble in oils, both fixed and volatile. It was not attacked by alkalies or by strong sulphuric acid; with nitric acid it swelled up and became friable.

MELIA AZADIRACHTA, *Linn.*, MELIACEÆ. *The root bark and fruit. Vernacular.*—BAKAYAN (Hind.); GOREE NEEM (Bomb.); MALAI-VÉMBU, MALAI-VÉPPAM (Tam.).

History, Uses, etc.—The Persian lilac was probably introduced into the southern parts of India by the Mahometans. It is a native of the sub-Himalayan tracts, and has a Sanskrit name, "Mahanimba." The Hindus do not appear to have paid much attention to it, but it has long been used by the Arabs and Persians, who consider it to be hot and dry, and to have deobstruent, resolvent, and alexipharmic properties. The flowers and leaves are applied as a poultice to relieve nervous headaches. The juice of the leaves administered internally is said to be anthelmintic, antilithic, diuretic, and emmenagogue, and is thought to resolve cold swellings, and expel the humours which give rise to them. The bark and leaves are used internally and externally in leprosy and scrofula. A poultice of the flowers is said to kill lice and cure eruptions of the scalp. The fruit has poisonous properties, but nevertheless is prescribed in leprosy and scrofula. The root bark of *M. azadarachta* is placed in the secondary list of the United States Pharmacopœia as an anthelmintic. It has a bitter nauseous taste, and yields its virtues to boiling water. It is administered in the form of decoction (four ounces of the fresh bark to two pints of water, boiled to one pint), of which the dose for a child is a tablespoonful every third hour until it sensibly affects the bowels or stomach, or a dose may be given morning and evening for several days, and then be followed by a cathartic. In large doses it is said to produce narcotic effects, but these if produced passed off without any perceptible injury to the system.

Description.—The fresh root bark is thick and rather spongy, the external surface is very scabrous and warty, of a dark brown colour, beneath the epidermis it is of a deep pink, internally white; taste acrid, nauseous, astringent and slightly bitter.

Microscopic structure.—No starch is to be seen either in the wood or bark, nor does iodine indicate its presence. The cells containing red colouring matter are mostly grouped in patches immediately beneath the epidermis.

POINCIANA PULCHERRIMA, *Linn.*, LEGUMINOSÆ. *The bark, leaves, flowers, etc. Vernacular.* — GUL-I-TURAH, KRISHNACHOORA (Hind., Beng.); GUL-MOHR (Bomb.); MAIL-KANNAI, KOMRI (Tam.).

History, Uses, etc.—This elegant shrub, named after M. de Poinci, once Governor of the Antilles, has become quite naturalized in India, and is one of the commonest garden shrubs in Bombay. According to

Ainslie it was introduced into the Botanical Gardens in Calcutta in 1792. He gives the following description of it. "The species in question is a most beautiful tree, which commonly rises to about 12-14 feet high, with leaves doubly pinnate, and leaflets oblong-oval, emarginate; they and the calices smooth, corymbs simple, petals fringed, stamens very long. It would appear to be a native of both the Indies. It is the Hoa-phung of the Cochin-Chinese; on the Malabar coast it is called Tsietti-mandaru; in Ceylon its common name is Monora-mal, and from its extreme beauty, Burmann gave it the appellation of 'Crista pavonis flore elegantissimo variegato.' The French in the West Indies call it 'Fleur de paradis.' The flowers come out in loose spikes at the extremity of the branches; the petals, which have an agreeable odour, are beautifully variegated with a deep red or orange colour, yellow, and some spots of green." All parts of the plant are said to be emmenagogue and purgative, but there appears to be no record of any exact observations upon this point. The plant is not used medicinally in Bombay.

Description.—The bark is ash-coloured, smooth, thickly studded with small elliptic corky warts; the whole of the suber readily separates like birch bark, disclosing a streaky mottled green and pink surface, which is marked by numerous small scars corresponding to the warts above mentioned. The substance and internal surface of the bark is of a pinkish tinge. Taste rather nauseous, very astringent. Microscopic structure not in any way peculiar. Parenchyma loaded with starch; many cells contain red colouring matters.

CASSIA SOPHORA, *Linn.*, LEGUMINOSÆ. *The leaves, seeds, and roots. Vernacular.*— SARI-KASONDI, KALI KASONDI (Hind. and Bomb.); PONNA-VIRAI, PÉRA-VIRAI (Tam.); KAL-KASONDA (Beng.).

History, Uses, etc.—The Sanskrit name of this plant is Kasamarda, and signifies "destroyer of cough." It is supposed by the Hindus to have expectorant properties. It is also noticed in Mahometan works as a remedy for snake bites. The root is directed to be given with black pepper. A plaster or poultice of the root with sandal wood is said to cure ringworm.

Description.—Annual, erect, branched, glabrous; leaflets six to twelve pair, lanceolate, or oblong-lanceolate, acute, with a single gland near the base of the petiole; racemes terminal or axillary, few-flowered; upper petal retuse; legumes long, linear, turgid, glabrous, many seeded; suture keeled; seeds horizontal with cellular partitions; flowers middle-sized, yellow. The plant has a heavy disagreeable smell, and a purplish tinge; the root is fibrous and woody. It springs up on waste ground during the rains, and flowers in November.

CASSIA OCCIDENTALIS, *Linn.*, LEGUMINOSÆ. *The leaves, seeds, and roots. Vernacular.*—KASONDI, BARI-KASONDI (Hind.); KIKAL (Bomb.); NATTAN TAKARAI (Tam.).

History, Uses, etc.—This plant is treated as a variety of the last mentioned by the natives of India. It has the same Sanskrit name, and is considered to have much the same medicinal properties. Mahometan writers also treat the two plants as varieties of the same species; they describe Kasondi as alexipharmic, useful in the expulsion of corrupt humours and to relieve cough, especially whooping cough.

Description.—Annual; erect; branches glabrous; leaflets three to five pairs without glands between them, ovate-lanceolate, very acute, glabrous on both sides; petiole with a large sessile gland near its tumid base; flowers longish-pedicelled, yellow, upper ones forming a terminal raceme, lower ones three to five together on a very short axillary peduncle; legumes long, surrounded with a tumid border. The plant appears in the rains upon waste ground and rubbish; it has a sickly offensive smell.

BOA-TAM-PAIJANG (STERCULIA SCAPHIGERA, *Wall.*).

BY JOHN R. JACKSON, A.L.S.,

Curator of Museums, Royal Gardens, Kew.

At page 6, Vol. III., 2nd series of the *Pharmaceutical Journal* for 1861-62. in the well-known "Notes on Chinese Materia Medica," by the late Daniel Hanbury, is a notice of the "Ta-hai-tsze" or "Boa-tam-paijang," the seeds of which were introduced into France many years since as a remedy for diarrhœa and dysentery. Though at the time of their introduction in, 1854, they were quoted in the wholesale price list of a large Parisian druggist at about £3 13*s.* per pound, they were ascertained by careful tests to give no satisfactory results. In the notes above referred to, they are described as the fruits of *Erioglossum* (?) or *Nephelium* (?) but from specimens contained in the Kew museum, which were apparently obtained from the first sample brought to Europe, and which have been named *Erioglossum edule*, Bl., they seem upon comparison with authentic herbarium specimens to belong to *Sterculia scaphigera*, Wall. This plant differs in its fruits from most species of *Sterculia*. They are of a thin papery texture, and follicular or boat shaped in form, with veins or nerves running parallel the whole length. As the fruit ripens, this follicle bursts, leaving the solitary erect seed which is attached to the base exposed to view. This seed is brown and wrinkled, and is accurately described and figured in Mr. Hanbury's notes. It seems that these seeds have been mistaken for entire fruits, the large papery follicle which easily becomes detached not having been present in the samples described. Whether these seeds, which are said to be produced in great abundance, can ever be utilized for any other purpose beside that for which they were first introduced, is, I think, a point worth considering. Their extremely mucilaginous or gelatinous nature would seem to indicate some useful application.

THE THEORY OF FLAME.*

BY ARTHUR G. HADDOCK.

All gases, and all solids and fluids which are converted into gases by the heat necessary for their combustion, can burn only as gases, and it is the light emitted by their combustion in this manner which we call flame, and is, in fact, gaseous matter in a state of incandescence.

If the oxygen, or air, necessary for the combustion of a gas, is uniformly mixed with it beforehand, the burning takes place immediately, with explosive violence, and the mixture appears equally luminous throughout.

The same effect is seen when the combustible is in the

* Read at a Meeting of the Liverpool Chemists' Association, Feb. 14, 1878.

solid state, as in charcoal, and is mixed with some substance containing oxygen which it readily gives up, as potassium chlorate. Immediately the mixture is brought in contact with a hot substance, the ignition commenced at the point of contact spreads itself throughout the whole, a great amount of gas is formed suddenly, and a noise is produced, owing to the violent concussion of the air, caused by the sudden expansion of the gases produced by the combustion.

But if the combustion is made to take place in a more gradual manner, by allowing the gas or vapour to issue from a jet or wick into the air, where the burning can only take place at the point of contact of the combustible gas with the air, we get the production of flame.

Flame-producing substances may be divided into two classes (1), those which give a non-luminous flame, and (2) those which give a luminous flame.

Of the first class are hydrogen, alcohol, sulphur, carbonic oxide; and the flame of any of these may be rendered luminous by the introduction of a solid body, either in a fine state of division or otherwise.

A bright flame is produced by (1) compounds containing carbon, in which a portion of the carbon is separated as soot by the heat of the combustion of the part which is actually ignited, the soot being first made incandescent, and subsequently burning. Examples of this class are olefiant gas, tallow, wax, oil of turpentine, oil of petroleum, colza oil, etc. (2), Substances which when burnt in oxygen, produce a compound, which is solid at the temperature at which the substance burns, as phosphorus, potassium, zinc, etc.

We derive from this that the luminosity of a flame is due to solid particles (or dense vapours) suspended in it, and these particles being raised to a state of incandescence by the heat developed during the combustion. A proof of this general rule is seen in phosphorus, which when burnt in oxygen forms phosphoric pentoxide—a solid substance—and a light of dazzling brightness is emitted. If, however, the phosphorus is burnt in chlorine, it burns with a very slightly luminous flame, owing to the chloride of phosphorus which is formed remaining as a gas.

An alcohol flame may be rendered luminous by burning it in chlorine. The chlorine unites with the hydrogen of the alcohol, and having no affinity for carbon, the latter is separated in the form of soot, which becomes incandescent. Alcohol may also be made luminous by the introduction into the flame of a paper soaked in calcic chloride solution, which when burnt leaves an ash in a fine state of division, and great brilliance is thus given to the flame.

Then again, the hydrogen flame may be rendered luminous by the insertion of a spiral of platinum wire, or a piece of asbestos; and so on with the other bodies.

On the other hand, the luminosity of the flame of carbonaceous substances may be destroyed by mixing the gases or vapours with a sufficient quantity of air or oxygen before they are burnt, and thus preventing the separation of carbon, since it is obvious that we cannot have carbon existing free in the presence of oxygen. This is seen in the Bunsen lamp, which I shall speak of further on, and in the blowpipe flame.

In order to render a gaseous body luminous it is necessary that it should contain some of the heavy hydrocarbons (such as benzol, naphthaline), which, either by separation of carbon, or by themselves becoming white-hot, shall emit light, or that some solid body should be introduced into the flame. Leaving out such substances as hydrogen, with spiral of platinum, magnesium, etc., as impracticable, we find ourselves reduced to the hydrocarbon compounds, for furnishing us with our artificial light. Such compounds we have in coal-gas (or in gas obtained by the destructive distillation of wood, peat, shale, etc.); in tallow, wax, paraffin, palm oil, etc., which we burn in candles; in petroleum oil, colza oil, kerosene, fish oil, solar oil, refined oil of turpentine, etc., which we burn in lamps; or in the water gas, which is sometimes used, and consists of a mixture of equal volumes of hydrogen and carbonic oxide, the carburation of which has been effected by the vapours of fluid hydrocarbons.

It has been a mooted point as to whether the luminosity of burning hydrocarbons is due to the separation of carbon, or to the presence or formation of dense hydrocarbons having a high boiling point, which themselves become incandescent. These vapours are present in illuminating gas. According to Dr. Frankland, who investigated the matter in 1867, it is not free carbon, but rather the dense vapours of these heavy hydrocarbons, which when ignited are the cause of the luminosity of the flame, in the same way that the vapour of arsenic makes the flame of hydrogen luminous.

There is a great deal to be said in favour of this theory. As a proof that it is solid carbon, momentarily eliminated, it is pointed out that if a cold porcelain plate is held in the flame we get a deposit of soot. But then this soot is not pure carbon, but seems rather a conglomerate of the different vapours of dense hydrocarbons, condensed on the cold surface, and we know that to get pure carbon from lamp-black, it requires long ignition at a high temperature in a covered crucible, and we have to pass chlorine gas over it at a white heat before we can get rid of all the hydrogen which it contains. Then again the flame could not be so transparent if its luminosity was caused by opaque particles of solid carbon, and it would make a difference in photometrical operations according as the flame was placed with its narrow or broad edge towards the photometer, if the light were due to opaque particles, whereas we find that such is not the case.

So that, on the whole, I think that Dr. Frankland has pretty conclusively demonstrated that the luminosity is due to the dense hydrocarbons.

It is possible that carbon is separated in a slight degree by the decomposition of the dense hydrocarbons.

The more slowly hydrocarbons are burned, the greater is the quantity of dense vapours separated, but the luminosity of the flame is less because the particles are less strongly heated. If the gases are burnt more quickly there are fewer dense particles separated, but the temperature to which they are raised is much higher, and a brighter light is emitted from them.

Pressure has an influence on the luminosity of flame. On the summit of Mont Blanc candles and gas burn with a very feeble flame. Experiments which have been made in artificially rarefied atmospheres show that the luminosity of the flame increases or decreases in direct proportion to the pressure upon it, down to fourteen inches pressure of mercury. Below that point it diminishes rather more slowly. Between the limits of thirty inches and fourteen inches the luminosity has been found to decrease according to the following law:—Of 100 units of light emitted from a gas flame, burning at a pressure of thirty inches of mercury, in air, 5·1 units are extinguished by each reduction in pressure of one inch of mercury. Under increased pressure the luminosity is found to increase in direct proportion up to two atmospheres' pressure, after which the increase of light is more rapid and attended with smoke.

These variations in the luminosity do not seem to be caused by the alteration of temperature. Davy and Frankland have found that rarefaction and compression do not influence the temperature of the flame, as though in rarefied air the temperature within the flame is lower, the escape of heat from the exterior is less, and the two balance each other. Neither is the variation caused by imperfect combustion, as the gases from a flame burning at a pressure of eight inches are found to have the same composition as those from a flame burning at the ordinary pressure. The cause seems to be that with higher pressures, there is a greater separation of dense hydrocarbons, since a candle evolves more and more of them at increased pressures, and the flame of alcohol at a pressure of four atmospheres becomes luminous. On the other hand, rarefaction, by increasing the mobility of the gaseous particles, brings a greater supply of oxygen into that part of the flame where the dense vapours which produce the luminosity are being formed, and by their being oxidized before they become white hot, the luminosity is diminished.

The rate of combustion of a candle or gas is found not to be sensibly affected by alteration of the pressure upon it, and a candle will burn on Mont Blanc at pretty much the same rate that it would at the level of the sea.

Having now considered the reason of the luminosity of flame, and the various influences which affect the luminosity, we will briefly examine the flame itself, taking as an example, that of a candle or gas.

Firstly, then, as to its shape. As soon as the wax is vaporized by the heat applied, the gaseous particles have a tendency to fly outwards, which they do, producing the broad base, and the surrounding air becoming heated, and consequently specifically lighter, ascends, making a current, and pressing on the flame on all sides, which prevents its further divergence, and it gradually tapers off to a point, as the combustible materials get expended.

The flame of a candle may be said to consist of three distinct parts (1) an inner dark zone, surrounding the wick, in which the unburnt gaseous substances are heated. (2) a central luminous zone, which is white-hot, and where the gases are not completely burnt, and (3) an outer non-luminous zone, where the combustion is perfect.

That no combustion is going on in the inner zone may be shown by placing a piece of phosphorus on the wick of a spirit-lamp, the phosphorus not taking fire when the lamp is lighted, unless the flame is blown over on one side. Or we may conduct the vapours through a bent glass tube by inserting one end of it in this zone, when on applying a light they will burn at the other end of the tube.

In the second (central) zone, the gases are become sufficiently heated to burn, and come in contact with the oxygen of the air, but not enough for their complete combustion. As the gases for the most part are composed of carbon and hydrogen, the oxygen having a greater affinity for the hydrogen, takes away the greater part of it from the carbon, leaving gases containing a much greater proportion of carbon to hydrogen (such as naphthalene, etc.) than the original gases, and having, consequently, a greater density. By the combustion of the hydrogen, these dense vapours become white-hot, and emit light. They pass on to the outer zone, where they meet with a fresh supply of oxygen, and are completely burnt, and converted into carbonic anhydride and water, the products of the combustion.

According to experiments made by Deville, the denser the vapours present in a flame, the greater will be the luminosity of it. From this we should expect that those hydrocarbons which are the richest in carbon would be the most suitable for lighting purposes. This is so ; but if the substance contains more carbon than accords with the formula C_2H_4, or six parts by weight of carbon to one part by weight of hydrogen, it will burn in air, free from draught, with a smoky flame. Thus, oil of turpentine, which contains $7\frac{1}{2}$ parts of carbon to 1 of hydrogen, burns with a sooty flame in air, owing to the separation of a greater amount of dense hydrocarbon vapours than can be oxidized with the supply of air. In order to remedy this a lamp glass is used, which by creating an upward current, brings more oxygen in contact with the flame.

Oil of petroleum, which is a mixture of the higher compound homologous with marsh gas, and contains five parts by weight of carbon to one part of hydrogen, will produce by its ignition more light than an equal weight of coal gas, in which, reckoning the free hydrogen, the proportion of carbon to hydrogen is about 2·3. And as the carbon in these substances is ultimately converted into carbon anhydride, the amount of that gas produced by the burning of a given weight of oil of petroleum will be considerably greater than that produced by the combustion of the same weight of coal gas. But this, by the way.

Having now dealt with the nature of luminous flame, we will proceed to examine that non-luminous coal-gas flame which we so often use in the laboratory, and which we obtain in the Bunsen lamp. And for most of what I shall say on this subject, I am indebted to the valuable paper Professor Thorpe has written upon it.

The Bunsen lamp consists of a brass tube, screwed on an iron foot. At the bottom of the tube is a jet through which the gas issues from a pipe with which it is connected and in the tube are two or more holes, on a level with the jet, through which air passes and is carried up with the gas, and is uniformly mixed with it in the length of the tube, so that when the mixture is lighted at the top of the tube it burns with a non-luminous flame. And it may be seen that it is really the air mixed with the gas, which has rendered it non-luminous, by closing the holes at the bottom of the tube so that no air can enter, when it immediately becomes luminous. It is clear also, that to get perfect non-luminosity there must be a relation between the size of the jet by which the gas enters, and the size of the holes by which the air enters the tube. If the jet is too large the flame is tinged with white and deposits soot on a cold surface held in it; if the holes are too large the flame sinks to the bottom of the tube. There must also be a certain relation between the height and width of the tube.

Let us see how it is that by having two holes at the bottom of the tube, air will enter and mix with the gas in sufficient quantity to make it non-luminous. If a box filled with compressed air is perforated on one side and held with the perforation over a small disc of cardboard, it is found that the disc is forcibly sucked towards the hole against the escaping air and in opposition to gravity, and is held there with considerable force. Instead of this we should, *à priori*, expect the disc to be blown away. Faraday used to show the same thing in a beautifully simple manner, by placing his hand flat over a card at a short distance from it, and then blowing between the knuckles of his first and second fingers. The card was lifted up to his hand and remained suspended there as long as he continued blowing. This seemingly paradoxical effect is due to what Professor Thorpe calls an area of low pressure in the vicinity of the orifice through which the issuing gas escapes. This low pressure seems to be induced by the current of air formed by the blast taking away in its course the circumjacent air, and thus forming a partial vacuum.

Spray-distributors are constructed on this principle. They consist of two tubes at right angles to each other, the end of one just overlapping the end of the other. If now one of these tubes is placed in the liquid which is to be distributed, and we blow down the other tube, the fluid rises and is dispersed with great force in the form of spray. The blast of air passing over the top of the tube inserted in the fluid, takes along with it the air in that tube, and a vacuum is produced. The fluid immediately rushes up the tube to supply the place of the expelled air, and in its turn is carried away with the blast. So it is with the lamp. The gas escaping under pressure from the burner inside takes along with it the surrounding air. More air rushes in through the holes, and so a constant stream is supplied. That there is an upward current of air entering may be seen by stopping up one of the holes with a cork and inserting a glass tube in the other. If now the lamp is lighted and the flame of a candle is held at the end of the glass tube, it will be seen that the flame is bent over and drawn into the tube.

When the gas leaves the jet it rapidly spreads out, and for this reason the air mixes uniformly with it in its passage up the tube.

For the mixture of gas and air to burn at the top of the tube it is necessary that the speed at which the gas flows from the burner should be equal to or greater than the rate of combustion. If the rapidity of inflammation is greater than that of the gas flowing from the tube the flame retreats down the tube and the gas burns at the bottom. If we lower the gas, for instance, and thus lessen the rate of efflux, when we get to the point when it is less than the rapidity of inflammation the flame will retreat unless we put a piece of wire gauze over the tube, which will have a cooling effect on the flame, and will also help to give a uniform speed to the gas, as one cause of the flame retreating is the friction of the sides of the tube retarding the progress of those particles of gas nearest to them. The narrowing of the top of the tube as proposed by Professor Morton prevents the flame from retreating, as it tends to make the motion of the particles more equal by increasing their velocity.

The gas as it issues from the tube of an ordinary lamp is mixed with about two or two and a-half volumes of air. M. Mallard has found that if coal gas is mixed with less than three and a-half or more than eight times its volume of air, it is not combustible. In the flame, therefore, we have a very large area of unburnt gas, as it is only able to burn at the edges, where it can obtain from the air the additional quantity of oxygen necessary for its combustion. The existence of this cone of unburnt gases may be shown by fixing a fusee match so that the head appears above the top of the tube. When the gas is lighted it will be seen that the match does not burn.

We will now see how it is that the admixture of air with the gas makes the flame non-luminous. It was formerly supposed to be entirely due to the oxidation of the carbon into carbonic anhydride simultaneously with the oxidation of the hydrogen, and that therefore it was the oxygen in the air mixed with it that destroyed the luminosity. This idea has, however, been exploded, and it is now shown to be due rather to the nitrogen in the air.

We will stop up one of the holes in a Bunsen lamp and fasten in the other a tube connected with an apparatus for generating carbonic anhydride. Of course, as long as the coal gas comes up the tube alone the flame is luminous. If now, however, we pass carbonic anhydride in through the tube the luminosity rapidly diminishes and is eventually destroyed. The same result would have occurred if nitrogen or steam had been used. In fact any indifferent gas will destroy the luminosity.

The natural inference from this is that the non-luminosity is due to dilution of the gas. This is one, but not the only reason.

Of course the admixture of such a large volume of air or other gas will lower the temperature, as we have a greater quantity to be raised to the heat required, and this reduction of temperature will lower the illuminating power of the flame. If we fit a platinum tube to the brass tube of the lamp and heat this with a Herepath blowpipe the flame becomes luminous, just as if the air was shut off, and as the tube cools the luminosity decreases and we again get the normal Bunsen flame. The heat thus added to the gas is therefore sufficient to make the flame luminous.

The result of this experiment seems rather to clash with Dr. Frankland's theory, since by heating the gases they have become expanded and rendered less dense, but I think we may reconcile the theory with the facts by the supposition that although the gases before combustion are rarefied, more than a proportion of the hydrogen first unites with oxygen, and denser hydrocarbons are formed.

We may say, then, that the non-luminosity of the Bunsen flame is due to several causes, and we cannot say that it is due to any of these separately. They are, the dilution of the gas, the reduction of temperature by the heat abstracted by the products of combustion and the nitrogen, and the rapid oxidation into feebly luminous bodies.

The last point to be noticed is the flame when the gas burns at the bottom of the tube. When this happens, as it often does when the flame is turned low and the room is at all draughty, we have a very disagreeable smell and deposition of soot on a cold surface. This shows imperfect combustion, which we should expect, as the only oxygen it can obtain is what comes in through the holes at the bottom of the tube, and this quantity is insufficient for the complete combustion. Blochmann has analysed the gases in the tube before and after combustion in this manner, with results as below:—

	Gaseous Mixture. Before the Combustion.	After the Combustion.
H	19·91	9·14
CH_4	14·82	13·49
CO	2·26	4·64
C_2H_2	...	·75
C_2H_4	1·57	·63
C_4H_8	1·20	·26
N	46·54	46·54
O	12·25	...
CO_2	·45	3·02
OH_2	1·00	17·33
	100·00	95·80
Contraction		4·20

Nearly half the hydrogen has gone, there is a marked decrease in the ethene compounds and a little decrease in the marsh gas. There is a large increase in the amount of water vapour, due to the oxidation of the hydrogen. It will also be noticed that the carbonic oxide is twice as much after combustion, and that there is formation of acetylene. Both these gases are poisonous. The oxygen has entirely disappeared, and this may be demonstrated by replacing the brass tube of the lamp by a glass tube and lighting the gas at the bottom. If now a sulphur match be held in the tube it will be seen that the composition melts and volatilizes, but will not take fire until withdrawn from the tube into the air, when it immediately blazes up. The matches such as are now generally used will not do for this experiment, as they contain the oxygen necessary for their combustion in themselves in the form of chlorate of potassium.

Without stopping to notice the construction of the Davy lamp and other points of great interest in connection with it, I will conclude by recommending the subject to your consideration, as I am sure great pleasure and benefit may be derived from the study of it, both by the practical chemist and by the lover of science in the abstract.

THE USEFUL SPECIES OF VIBURNUM.*

BY JOHN M. MAISCH.

The genus *Viburnum*, which belongs to the natural order Caprifoliaceæ, tribe Sambuceæ, attracted my attention more closely when, in July last, a correspondent in Georgia sent me some branches of a woody plant, stating that the specimens came from near Orange Springs, Florida, where it was regarded as possessing valuable medicinal properties as a substitute for quinia; the shrub was said to bear a small black berry, and to be called there *black haw*, but it was mentioned that it differed from what is known by the same name in other parts of the country. Although the specimen was not accompanied by flowers or fruit, its characters were such as to lead to the supposition that it might belong to the genus *Viburnum*, and this was verified by comparing it with the plants in the College herbarium, with one of which it entirely agrees.

Viburnum obovatum, Walt.—This species is mentioned in Gray's 'Manual' and in Chapman's 'Flora of the Southern United States,' the latter of which describes it as a shrub or small tree, while the former states it to be

* From the *American Journal of Pharmacy*, Feb., 1878

a shrub 2 to 8 feet high. It occurs on river banks from Virginia to Florida and westward. The branches are opposite and covered with a thin brown or reddish-grey bark, which adheres firmly to the white wood; in the youngest branches the bark is more green, but soon becomes covered with minute brownish, corky warts, which, on becoming confluent, give the older bark a somewhat irregular striate appearance. A distinct ridge runs from the base of each petiole downward to the next internode, and may be observed, also, on somewhat older branches, but gradually becomes indistinct through the development of the surrounding corky tissue. The leaves are small, about ½ to 1 inch long, opposite, thick, varying in shape from broadly obovate to spatulate, obtuse at the apex, wedge-shaped at the base towards the short petiole, and on the somewhat revolute margin either entire or slightly crenate or denticulate, chiefly towards the apex. Both surfaces are smooth, the upper one being dark green and glossy, the lower one more greyish-green and marked with numerous minute brownish dots. The inflorescence consists of small sessile three-rayed cymes, with white perfect flowers, which produce small ovoid-oblong black and one-seeded drupes. The wood is tasteless, the bark has quite a distinct bitter taste; but the bitterness of the leaves is by far more persistent. As far as may be judged from the taste, the leaves would appear to mainly possess whatever medicinal virtue may reside in the plant; how effectual they maybe as an antiperiodic I am unable to say.

Viburnum prunifolium, Lin.—Dr. Phares, of Newtonia, Mississippi, in 1867, called attention to the properties of the bark of this species, ascribing to it nervine, antispasmodic, tonic, astringent and diuretic properties, and recommending it as particularly useful in preventing abortion and miscarriage. The species is a tall shrub or small tree, from 10 to 20 feet high, growing in thickets, and is readily recognized by its oval or obovate, sharply serrulate leaves, which are opposite, glossy above, about two inches long and raised upon short, slightly margined petioles. It occurs in the United States from Connecticut south to Florida and west to Mississippi, and is generally known as *black haw*, the fruit being a small edible blue-black drupe, containing a flat and smooth putamen. The leaves, like those of the allied *V. nudum*, Lin., and its variety cassinoides, have occasionally been used as a substitute for tea.

Viburnum opulus, Lin.—This species is quite extensively distributed. It is indigenous to Canada and found in the northern United States and southward along the Alleghanies to Maryland; likewise throughout a great portion of Europe and of the northern section of Asia. In favourable localities it attains a height of 12 to 15 feet, but is more generally a lower shrub, with a grey or greyish-brown bark, broad, three-lobed, toothed or crenate leaves, and globular, acidulous bright red drupes, having a flat, smooth putamen. From the resemblance of the fruit to the cranberry, this species is known on this continent as *high cranberry* or *cranberry tree*. The shrub preferring moist locations, and the inflorescence resembling that of the elder, its popular German name is *Wasserholder* or *water elder* (*Sambucus aquaticus*), under which name it was formerly officinal. A variety produced by cultivation, has all the flowers sterile and the cymes more or less globular and showy; it is known by the names of *snow-ball* and *Guelder-rose*. The indigenous species was described by Pursh as *V. oxycoccus* and *V. edule*.

The bark and flowers of the water elder were formerly employed for their supposed alterative and antispasmodic properties, the common name *cramp bark* indicating the popular estimation in which it was and is, perhaps, still held in some localities. The fruit has the general properties of acidulous fruits, and where it is frequent is sometimes used in place of the cranberry.

Other North American Species of Viburnum.—Chapman enumerates nine species as being indigenous to the Southern United States east of the Mississippi; of this number only one, *V. scabrellum*, Tor. and Gr., is peculiar to that section, while the remaining eight are likewise found in the Northern States, some extending into Canada; three additional species are found in the northern section, making twelve indigenous to the United States. Aside from *V. prunifolium*, referred to before, the following are met with from the New England States southward to Florida, the last two (perhaps all three) being likewise indigenous to Canada; they are, *V. nudum*, Lin., or *white-rod; V. dentatum*, Lin., know as *arrow-wood*, and *V. acerifolium*, Lin., or *dockmackie*. Their leaves have a bitter taste, while the bark is bitter and astringent. I am not aware that they are medicinally employed in any part of North America.

Exotic Species.—De Candolle's 'Prodromus' enumerates altogether 47 species, besides four doubtful ones from Japan, which are insufficiently known. Deducting those which are at present regarded as mere varieties of other species, the number is reduced to about 40 species, 28 of which are exotic and distributed over Europe, the Canary Islands, Africa, Asia, the East Indian islands, the West Indies and South America. Only a few of these appear to be put to some use.

Viburnum Dahuricum, Pall., produces a sweet fruit, which is eaten in its native country, the eastern section of Siberia.

Viburnum Tinus, Lin., is known as *laurestine* or *bastard laurel*, the *laurier-thym* of Southern France, on account of its evergreen, glossy leaves, which are entire and slightly revolute at the margin, and hairy on the nerves beneath. It is occasionally met with in cultivation, and produces black-blue drupes, which are said to possess cathartic properties, and are, in some localities of the Mediterranean basin, employed as a remedy in dropsy.

Viburnum odoratissimum, Ker., from China, is likewise occasionally met with as an ornamental shrub; it is evergreen, and has the leaves somewhat toothed and dense cymes of white, very fragrant flowers.

Viburnum lantana, Lin., occurs in thickets of central and southern Europe, and is known as *litby tree* and *giddy berry* (Schwindelbeere). The grey-brown, smooth, or, when young, mealy pubescent bark has an acrid taste and produces blisters when applied to the skin in the fresh state. The leaves are oval or ovate, sharply serrate, and mealy pubescent on the lower surface, have an astringent taste, and were formerly used in diarrhœa and similar complaints. The fruit when fully ripe is black, mucilaginous, sweet and astringent, and was employed in various inflammatory diseases. The branches have been used for making pipe stems.

Chemical Investigations.—The species mentioned above comprise all, I believe, which have been more or less employed in medicine, and of those only two have been subjected to chemical investigations.

During his patient and elaborate researches on the constitution of fats, Chevreul observed in the berries of *Viburnum opulus* a volatile acid, which he recognized as identical with the phocenic acid discovered by him in the fat of the dolphin. Afterwards Dumas proved phocenic acid to be identical with valerianic acid. H. Krämer (1834) examined the volatile acid obtained from the bark of the same shrub, compared this *viburnic* with valerianic acid, and found it to differ from the latter in odour and in the characters of several salts; however, the analytical results obtained by L. von Monro (1845) appear to establish the identity of the two.

Valerianic, besides acetic and tartaric acids, was found by Enz (1863) also in the berries of *Viburnum lantana*, which contain likewise a tannin colouring iron salts green. Krämer found in the bark examined by him malic acid and tannin giving a blue reaction with iron salts.

The bitter principle called *viburnin* was isolated by Krämer from the ethereal extract of the bark by treating it with hot water, removing the tannin from the solution by means of hide (parchment), and decolorizing afterwards with animal charcoal; the colourless liquid left on evaporation a light-yellowish mass, which yielded a nearly white powder, of neutral reaction and purely bitter taste; it was slightly soluble in water, more freely in alcohol, and on incineration left a little ash.

Enz found in the fruit of the species mentioned an acrid and a neutral bitter principle, the latter being yellow, hygroscopic, readily soluble in water, and uncrystallizable, even after dialysing it; the fruit was boiled with lime and water, the filtrate neutralized with muriatic acid and treated with animal charcoal; the latter was washed, dried and exhausted with alcohol, the solution evaporated to a syrupy consistence, deprived of the acrid principle by ether, and then evaporated.

Leo's experiments (1834) for determining the nature of the colouring matter of the fruit of *V. opulus* did not yield any important results.

The remaining constituents were those very generally distributed throughout the vegetable kingdom, such as pectin, resin, fat, gum, etc. It would be of interest to ascertain the nature of the bitter principles contained in the two first-named species, both of which are indigenous to this country and called black haw.

ANTISEPTIC DRESSINGS IN GERMANY.*

An article with this title, in a recent number of the *Progrès Médical*, gives an account of the antiseptic materials which seem to have superseded Lister's carbolized gauze, and which claim for themselves greater economy, diminished irritability, and freedom from liability to poisoning.

Thiersch has come to the conclusion that a saturated solution of salicylic acid—that is to say, 1 to 300—prevents putrefaction of the blood and secretions of a wound, while it produces no irritating effect upon recent or granulating wounds, and gives no cause for alarm by the passage of salicylic acid into the circulation. He uses a solution of salicylic acid for washing instruments, and the hands of the operator and his assistants. The spray is of salicylic acid, which proves, however, very irritating to the mucous membranes of the persons engaged in the operation. The dressings are simple enough. Salicylic acid being non-irritant, no protective is required, according to Thiersch; but, at least in healing surfaces, the protective has the additional advantage of protecting the granulations and the delicate new epithelium covering them from the danger of sticking to and being injured by the dressings on their removal. But Thiersch uses no protective. He places immediately upon the wound a layer of wadding containing 3 per cent. of salicylic acid; then another layer containing 10 per cent.

Blaser, pharmacist to the hospital at Leipzig, employs the following formulæ for the preparation of these dressings. For the 3 per cent. wadding: Dissolve 750 grams of salicylic acid in 7500 grams of alcohol of specific gravity 830. Add 150 litres of water at 70 to 80° cent. (158 to 176° Fahr.). Place in the mixture 25 kilogrammes of cleaned wadding. For the 10 per cent. wadding: Dissolve 1 kilogramme of salicylic acid in 10,000 grams of alcohol of specific gravity 830. Add 60 litres of water at 70 to 80° cent. Place in the mixture 10 kilogrammes of cleaned wadding. To saturate the wadding he uses a shallow vat, in which it is laid layer by layer, taking care not to put in more than two or three kilogrammes at one time, and that one layer is well saturated before the next is put on. When all are in, they are to be turned over, so that the bottom one comes to be at the top and left for ten minutes; then removed; and, as they cool, the salicylic acid crystallizes out. Finally, the the wadding must be dried in a warm place. Thiersch has also tried a dressing composed of jute saturated with salicylic acid; but the powder was disengaged in large quantities, and was extremely disagreeable to the surgeon; and it proved, besides, too permeable to the secretions of the wound, being less cohesive and fine than the wadding; so Thiersch himself has abandoned it.

Kohler, Medical Director-General of the Prussian Army, has suggested the use of carbolized jute. The preparation is very simple. The jute is made up into cakes one to two centimetres thick, fifteen centimetres in diameter, and weighing four or five grams. They are left to soak some hours in a five per cent. solution of carbolic acid, and are then left in two per cent. solution until required for use. To apply them, the wound is covered with a slip of gutta-percha intead of the protective; then some cakes of jute; and the whole is kept in place by a gauze bandage. It requires to be renewed every three or four days; earlier, if there be discomfort, or the discharge have come through; later, if the patient remain well. It is calculated that Thiersch's wadding is about a third cheaper than Lister's gauze, while Koehler's dressing only costs about a twentieth of the price of the latter. Cheaper, and at the same time efficient, antiseptic dressings are desiderata, and we think that these may be found as useful here as they are said to be in Germany.

* From the *British Medical Journal*, March 9, 1878.

THE PREPARATION OF PEPTONE.*

In the session of the Pharmaceutical Society of Berlin, of December 18th, 1877, Mr. Hobe read an interesting paper on the above subject, for which we are indebted to the *Pharm. Zeitung* (No. 102).

The best process for preparing the so-called peptone, or pancreatic meat-solution, is due to Dr. Adamkiewicz. Fresh blood is converted into a colourless mass by quirling and protracted kneading, followed by washing with frequently renewed soft water, holding in solution a small quantity of ammonia. The pressed white fibrin thus obtained is comminuted into fine shreds in capacious dishes, and covered with a large quantity of water containing 0·2 per cent. of hydrochloric acid. The fibrin thereby soon swells up, and gradually becomes converted into a pellucid jelly, which is now ready for the addition of the ferment, namely, pepsin. The latter is obtained from the mucous membrane of the hog, and for the present purpose is preferably extracted by means of glycerin. Alcohol is first added to the finely cut membranes, in order to coagulate the albumen, after which they are dried by exposure to air, and then covered with glycerin, which abstracts the pepsin in the course of a few weeks. The clear yellowish-red glycerole of pepsin is poured over the fibrin-jelly, and the whole heated for some time in a water-bath at a temperature of 50—60° C. (122—140° F.) The compact mass soon begins to liquefy, and is coverted finally into a thin fluid of grey opalescent colour. In from two to five hours large masses of fibrin may in this manner, as it were, be digested. The crude liquid is now separated by straining from any undigested shreds, and carefully neutralized with sodium carbonate, which causes the separation of a flocculent grey precipitate, the so-called para-peptone. This is removed by filtration. The filtrate, which has a clear straw-yellow colour, is faintly acidulated, once more filtered and evaporated to the consistence of honey at a temperature not exceeding 70° C. (158° F.).

Peptone is distinguished from ordinary albumen by its proneness to solidify in the cold, and to return to a liquid state when heated, being thus just the reverse of albumen. For internal administration, it has been found best to mix it with extract of beef in the proportion of 5 parts of the latter to 100 parts of peptone. Sixteen grams, or one spoonful, of this peptone are equivalent, in nutritive power, to 20 grams of lean meat. A dry peptone may be prepared by precipitating the original liquid with alcohol, treating the precipitate repeatedly and for some time with alcohol and ether, then dissolving in a little water, and drying at 30° C. (86° F.). In this state it forms a glassy, brittle mass, easily pulverizable and readily soluble in water. Long keeping is said to impair its solubility. It has a neutral reaction, and reduces alkaline copper solution.

The Pharmaceutical Journal.

SATURDAY, MARCH 23, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PROSECUTIONS UNDER THE PHARMACY ACT.

IN order to place clearly before our readers the precise nature of the prosecution of Mr. WILLIAM MACKNESS and the London and Provincial Supply Association by the Pharmaceutical Society, we purpose to recapitulate briefly some of the more prominent points referred to in the report published last week, so that they may be considered in connection with the magistrate's decision, which is reported at p. 759 of the present number of the Journal.

The London and Provincial Supply Association, Limited, appears to be a joint stock company carrying on various descriptions of retail trade in Tottenham Court Road, and among others the business of a chemist and druggist. As appears from the statement of the defendants' counsel, this business was originally carried on under the designation of the London and Provincial Supply Association, and up to February last the sole proprietor of it was Mr. WILLIAM MACKNESS, who, being unregistered according to the requirements of the Pharmacy Act, had thus committed a violation of the fifteenth section of that Act, which rendered him liable to pay a penalty of five pounds. Mr. MACKNESS upon being communicated with on behalf of the Registrar, and consulting his solicitor, found he was in the wrong, and acting under the advice given him, paid the penalty, sending at the same time an intimation that he was taking steps to terminate any violation of the law. These steps, however, did not consist in the simple and effectual expedient of ceasing to keep open shop for the retailing, etc., of poisons, but were devised by having recourse to the provisions of the Limited Liability Acts, and some time after the payment of the penalty Mr. MACKNESS sent a letter to the Society's Solicitor stating that he had sold his business to the London and Provincial Supply Association, Limited.

It does not appear that beyond the addition of the word Limited to the title of the Association, there was any material change in the conduct of the business, for the same labels that had been used prior to the change, continued to be used afterwards. Mr. MACKNESS was still a proprietor, and several other persons of the same name were among the limited number of shareholders. The counter in the shop had the appearance of being an ordinary chemist's counter, and during both periods it appears that Mr. H. E. LONGMORE, a registered chemist and druggist, was engaged by Mr. MACKNESS to conduct the business, and his name appeared upon the labels.

Up to February it was admitted that Mr. MACKNESS was responsible individually for anything done by Mr. LONGMORE, who was then acting as his assistant; but after the transfer of the business to the limited company, Mr. LONGMORE was made a shareholder, and it was contended that Mr. MACKNESS was then no longer responsible for his acts, although it appears to be admitted that Mr. MACKNESS was virtually still the proprietor of the business.

The three summonses brought before Mr. NEWTON last week at the Marlborough Police Court were taken out under the seventeenth section of the Pharmacy Act, which provides that any poison sold retail shall bear the name, the word poison, and the name and address of the seller.

The first summons was against Mr. MACKNESS for having sold poison on the 28th December last, inasmuch as it was contended that in addition to the penalty incurred under the fifteenth section of the Pharmacy Act, he had incurred this further penalty under the seventeenth section of the Act. In regard to this case, Mr. MACKNESS pleaded guilty, but threw himself upon the mercy of the Court upon the ground that he had already paid a penalty of five pounds. His counsel also argued that the penalty here sued for being for the same act of negligence this circumstance should induce the magistrate to inflict only a nominal penalty, and Mr. NEWTON looking upon that as equivalent to his having paid the penalty already, took the most lenient view of the case and only ordered him to pay the costs of this summons.

In regard to this case, however, the fact is not to be lost sight of that there are really two distinct penalties under two separate sections of the Pharmacy Act. That the payment of one penalty does not remove liability to the other, may fairly be inferred from the circumstance that each is to be sued for in a particular manner, the one being incurred by carrying on the business of a Chemist and Druggist without being registered, while the other penalty is for the protection of the public in regard to the manner in which the sale of certain articles is conducted. A person carrying on business in violation of the provisions of the Pharmacy Act may therefore by one and the same act render himself liable to the two penalties.

The second summons was against Mr. MACKNESS and the London and Provincial Supply Association, Limited, for having, on the 4th February sold poison without having labelled it with the name and address of the seller. The poison sold was red precipitate, and it was labelled with the name of the article, the word poison, together with the words, "London and Provincial Supply Association, 113, Tottenham Court Road, London, W. H. E. LONGMORE, Chemist and

Druggist," this label being similar to those used before the conversion of Mr. Mackness's business into a limited liability company. It was contended by the defendant's counsel that in this case every requisite of the Act had been complied with, and a long discussion took place as to who was to be regarded as the seller of the poison, whether Mr. Mackness, the London and Provincial Supply Association, or Mr. Longmore, the result being that notwithstanding the words of the seventeenth section of the Pharmacy Act, "that the person on whose behalf any sale is made by any apprentice or servant shall be deemed to be the seller," and the argument that the object of the Act was to afford protection to the public by having on every article sold the name and address of the person against whom, in case of injury, an action would lie, or who, in case of neglect, would be liable to a prosecution for manslaughter, the magistrate leant to the opinion that Longmore was the seller. In giving his decision on this case he held that the law had been complied with, and he dismissed the summons.

The third summons was against the London and Provincial Supply Association, Limited, for the sale of poison labelled as such, but without any name and address. In this case there was little room for defence, but legal ingenuity was exercised in the attempt to make out that if an offence against the Pharmacy Act had been committed, it was without rendering anyone liable to a penalty since it had been committed by an intangible entity, to wit a corporation, which it was contended was not amenable to proceedings in a police court, and could not be sued either by indictment or by summary information. Mr. Newton, however, was not disposed to entertain this idea of the existence of a corporation that was above all law, and though the defendants' counsel suggested the possibility of a difficulty in getting at the goods of the corporation or in committing anyone to prison, Mr. Newton thought he could find someone to do it.

The point to be determined was whether the word "person" in the seventeenth section of the Pharmacy Act included a corporation, and whether such a corporation—a joint stock company for instance—could be sued for penalties under that section. The case was therefore adjourned to last Saturday to allow of further inquiry on this point and with the view of sending a case up to a superior court if requisite.

As will be seen from the report published at page 759, the course contemplated by the magistrate of sending a case up to a superior court was not carried out by him, although provision had been made for this contingency by securing the appearance of Mr. Lumley Smith as counsel to represent the Pharmaceutical Society.

In the interim the Act 7 and 8 Geo. IV. had been found to apply to such cases as those in question, and consequently Mr. Newton decided the third summons as well as the others, by finding that the London and Provincial Supply Association, Limited, had not complied with the 17th section of the Pharmacy Act, and taking all the facts into consideration he ordered the defendant to pay a penalty of fifty shillings and costs.

Mr. Newton's decision has at least established one thing of no small importance in regard to the attempted evasion of the Pharmacy Act by unregistered persons, even when associated together into a corporation. Such associations cannot escape from liability to penalties under the 17th section of the Act by pleading that they are not comprised within the designation "person," since the Act of Parliament brought forward in the course of the adjourned hearing provides a sufficient remedy for any apparent defect in the wording of the Pharmacy Act itself.

AN UNEXPLAINED EXPLOSION.

A few weeks since an explosion occurred in a candy manufactory in New York, resulting in the loss of twelve lives, and the destruction of the building, the cause of which has not yet been ascertained in any of the more commonly recognized conditions that induce such disasters. It appears, however, that a large quantity of starch was used in the building in preparing the moulds, and it is thought probable that the atmosphere may in this way have become charged with a fine powder which igniting caused all the mischief. Similar explosions are known to occur in flour mills, and a short time before the roof of a linoleum factory in Staten Island had been blown off, through the ignition of cork dust, diffused throughout the atmosphere of the building. It will be remembered that this subject was dealt with two years since in a lecture on accidental explosions, delivered by Professor Abel, at the Royal Institution, the lecture being reported in this Journal (vol. vi., pp. 73 *et seq.*)

DUBOISIA MYOPOROIDES.

Just as we are going to press we are informed by Mr. A. W. Gerrard that he has obtained from the *Duboisia myoporoides*,—the plant which was the subject of a paper read at the last Evening Meeting of the Pharmaceutical Society, by Mr. E. M. Holmes —a powerful alkaloidal substance that he proposes to describe more fully in an early number of this Journal.

DEATH OF M. LAMY.

The death is announced of this celebrated French chemist, who in 1862, and almost simultaneously with Mr. Crookes, succeeded in isolating the metal thallium.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association will be held on Thursday evening, March 28th, at 8 o'clock, when the following papers will be read:—"Note on the Various kinds of Valerian," by Mr. W. R. Atkins; "The Action of Glycerine upon Borax," by Dr. A. Senier and Mr. A. J. G. Lowe; "The Flame Test for Boracic Acid," by Mr. W. B. Mason.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

THOUGHTS ON BOTANY*—*continued.*

BY H. B. BAILDON, B.A. CANTAB.

(*Concluded from p.* 735.)

The remark will not be out of place here, and indeed has in great measure been led up to, that the attack upon theological positions, which has been inaugurated and carried on from the basis of operations furnished by the recent discoveries of physical science, may be impugned on the grounds that the basis so obtained is not broad enough to justify the superstructure of negation and atheism which is sought to be reared thereon; and what is more immediately relevant in the present reference, the kind of testimony upon which the facts they appeal to rests, and is, in a sense, of a low order. What is meant is, that however brilliant the intellect by which scientific generalizations are made, the witness to the facts is that of the physical senses employed in complete independence of the moral and æsthetic faculties, and this necessarily so, because for such faculties to interfere during a scientific research would be to colour and obscure that cold and colourless light in which the man of science desires to view his facts. There exist, therefore, other series of facts, which by their very nature must rest upon testimony involving the use of these higher faculties. These other facts lie beyond the sphere of the student of physical science so long as he appears in that character only. But whenever he intrudes his conclusions into the sphere of theology, or as we may call it, in order to evade the difficulty the term involves, cosmology, the study of the universe in all its phases and relations, he must be prepared to find even his own facts viewed in new relations and taking very different aspects, while he will also be confronted by arrays of facts equal in importance to his own, but which could not be established by the methods he had made use of. But it is too often the case that the votary of a special branch of science fails to perceive and acknowledge the force and validity of deductions drawn from investigations other than his own. Hence it is that we may behold the sorrowful spectacle of a learned professor, launching out into positive invective against a study which in reality offers a necessary complement to his own, or the no less sorrowful one of an eminent scientist assaulting with iconoclast enthusiasm the inmost citadel of faith. Still we may congratulate ourselves that they are not men of the very first scientific rank who so conduct themselves. It is not a Sir William Thomson who emits tirades against metaphysics nor does Darwin in person head the crusade of atheism.

I trust that in diverging into these considerations I have not caused you to lose sight of the point I am endeavouring to establish. My aim was to repel in anticipation the charge of sentimentality which might otherwise have been urged with seeming effect against such views as those here expressed. To this end I attempted to show that the statement that beauty belonged to the genus to which I referred was really as much capable of proof and establishment in the rank of a fact as common place propositions which no one ventures to controvert. Now by sentimentality in its bad sense is meant, or at least ought to be meant, that state or mood or habit of mind, in which facts are disregarded or undervalued, and preconceptions and impulses permitted unrestrained predominance. It is sentimental to bestow charity indiscriminately and therefore mischievously, but it would be a gross profanity to stigmatize as sentimental an act of wise generosity and intelligent, timely benevolence. Sentiment, indeed, depends for its value on its relation to facts. If it disregard or misconceive them it is misleading; if it respect and understand them it is a sacred guide. But withal there is the fact, too frequently neglected or forgotten, that sentiment is itself a fact, a phenomenon as undoubted in its existence as the solidest matter, the best established law. Man is not man apart from sentiment, as an atom is not chemic apart from its affinity; sentiments are the affinities of the soul. We may then, I think, with all respect to the soberest and the sternest facts that science can lay before us, still permit ourselves not only to reap delight but also to reinforce our highest and best hopes from the beauty the fern world presents to us. Undiscouraged may we re-measure in imagination those æons that we are told separate us from the era of the Acrogens, and re-picture to ourselves the splendours of those solitudes primæval, where moss and fern and lycopod seem entwined in silent struggle for empire and supremacy; where in glory unregarded the sunlight smote through tangled and glistering vistas of tropic frondage, while yet the dawn rose unsaluted of any song bird and sundown built its brilliant cloud dreams unbeheld of man. From a spectacle so impressive in its mighty repose, so tranquilising in its mute imperceptible progress, we would gather not chilling inference of human littleness or nature's impassivity. But we would the rather feel a solemn elevation in that so vast and imposing a prelude, an overture of such broad and stately movement should precede the drama of life, feeling thereby assured that preparation so leisurely and ample, an apparatus so elaborate and splendid, are the prophets and precursors of such action and event as shall prove themselves of equal and adequate grandeur. That colossal past we now contemplate is no cumbrous pyramid to fix our hopes for ever in the dust. It is rather the massive immovable piers and foundations, whereon without sound of hammer or any instrument, shall be up reared the temple of the future.

Nor here, although language metaphorical has been used, can the hue and cry of "sentiment" be permitted. To the expert in physical investigations we appeal, it may be, against himself. Have you not, we ask, with elaborate patience and study discovered for us, and pointed out to our delight and edification the extraordinary economies of nature? No extravagance is allowed in her household. The disused organ dwindles, the unnecessary defence is removed. Is nature then only "penny wise and pound foolish?" A miser of the scraps of matter and force, and yet a spendthrift of centuries and of races? To us this is inconsistent, incredible; so, friend, is not our sentiment in harmony with your fact? Is not our faith in the future but the prolongation of the line you yourself have drawn for us?

It would be as undesirable as tedious to review the whole system of plant life with even that degree of detail with which those parts about which we have been hitherto concerned have been scrutinized and commented upon by us. It is our belief, or at least mine, that however great the range and orbit of nature; however multifarious and multitudinous its phases, it remains a seamless web, woven on one loom, a single organism, as it were, with one spine of purpose and character running its whole length. Still it is desirable in an attempt to establish any case that a sufficiency of corroborative evidence be called; and therefore, we shall not hesitate to throw up additional buttresses and supports to a thesis already advocated, wherever we find fit opportunity and material.

But before we finally leave the cryptogams, *i. e.*, those plants in which the leaf or frond represents the highest specialization of function, it may be well to devote some thought to this organ itself. Its importance cannot be exaggerated, it is the great typical and representative organ of plant life. If we could but understand how a leaf grows and why it thus grows, no other problem of botanical science would remain sealed to us. But we do not. To a certain extent we know how it grows, having discovered the materials of which it is built up, and some

* Read at an Evening Meeting of the North British Branch of the Pharmaceutical Society, Feb. 22, 1878.

of the chemical changes which lifeless matter undergoes ere becoming part of the vitalized tissue. The conditions of growth are likewise ascertained. We are thus enabled to kill a plant and encourage its growth; but in other respects nature is equally mysterious and obstinate. No one can, nor indeed ever will, at least upon mechano-chemical grounds, explain the shaping of the simplest leaf, nor could all the *savans* of Christendom induce a daisy to grow a dandelion leaf, or an elm to produce a single acorn. From germs structurally similar, often chemically identical, plants of complete diversity spring, not shaped by the apparently vast surrounding forces, but fashioned by an apparently feeble inner law. This secret, mysterious vital power, this invisible, undescried formative influence, which is to the plant exactly what original character, that human mystery which is all but the whole of human fate is to man, is a force more subtle and no less compelling than the harder, larger, ruder forces of which this planet in its infancy was the playground and arena. Let it not be supposed that this is said in ignorance or disregard of the fact that all vital energy is conditioned by these physical forces. But let us not confuse relation and identity. One individual, say a child, may have his life conditioned by the action of others, and may perish or survive according to the treatment it receives. We do not, however, argue from that the identity of the child and the persons on whom it is dependent. No more can we consent to identify that directive energy by which the form of an organism is determined with those forces by which its existence is conditioned and supported. This is a point not of small, but of the very last and highest importance. It indicates the Thermopylæ which must be held at all risks against materialism, whose thesis is that all sublunary existence can be accounted for by those properties with which matter in its unorganized condition was primarily endowed. If a stand is to be made, it must be made on the threshold of life; because if it once be established that any life is to be accounted for and has been caused by the original qualities of matter alone, there remains no point at which a stand can be made, at least until we come to the region of consciousness. On the other hand, if this position can be secured, materialism is held at bay and prevented for ever from threatening the domain of humanity. For if these supposed omnificent properties do not account for the formation of a frond, still less can we expect to find in them the promise and the potency of the mind and heart of man.

There requires no apology for the assertion that the shapes of leaves have never yet been accounted for, because it is a simple indisputable fact, easily proved so far as proof is required by a citation of an attempt made by the eminent De Candolle to explain leaf-formation. His theory is to the effect that "the shape of the leaf may be viewed as dependent on the distribution of the veins and the quantity of parenchyma scattered through their interstices—the general outline being determined by the divisions and directions of the veins, by the greater or less abundance of parenchyma, through the midst of which the veins are distributed." The least amount of reflection makes it evident that this is no explanation of cause whatsoever; for obviously while the direction of the veins and the proportion of parenchyma constitute the elements of the leaf-form, they are not the cause of it.

What we want to know is what determines the direction of the veins and the quantity of parenchyma. The above explanation, if it can seriously be regarded as such by the author or any one else, is exactly as intelligent and intelligible as an explanation of the form of a statue would be, which consisted in saying that it depended on the bulk of marble left in one part and chiselled off at another. Both statements would be true, but neither explanatory.

Of course it may be argued that although the required explanation is not forthcoming at present, it is sure to come to hand in course of time. To this it may be replied that such a belief implies a faith in the method employed which we do not possess, and we therefore decline in the interests of science to admit a proposition that still awaits proof. If then, a breakdown occurs in this intended triumphal procession of matter so soon after setting out, it seems improbable that the goal will ever be safely reached.

There are two aspects or relations in which it will be convenient and instructive to regard the leaf, viz., its relation to man as an object which must meet his eye, and its economic functional relation to the plant of which it forms part. The latter is that chiefly regarded from the strictly scientific and especially from the Darwinist point of view, but the other clearly demands consideration. Not a little remarkable is it that the æsthetic and the functional importance of the leaf vary to a great extent together, and bear a sort of proportion. In the ferns, for example, the leaf is the all-in-all of the plant, both as regards functions and ornament. While performing the absorptive, assimilative and reproductive offices it never fails to exhibit at least a comely and often an exquisite form. Among flowering plants, however, the leaf, having lost its functional supremacy, seldom if ever asserts a decorative precedence. In the case of those plants popularly called "flowers" the leaf is almost always æsthetically subordinate to the flower, the flower being really the leaf in its highest phase of beauty; the aim of the plant, or its main effort, being apparently to blossom. But in the case of large trees, whose object is rather the upbuilding of trunk and the preservation of the whole, both the individual flowers and leaves as a rule are subordinate in decorative value, the form of the tree, and the effect of flowers and leaves as massed upon it, being the points to which attention seems directed. Thus the flowers of our forest trees are usually green and inconspicuous, at most affording, before the expansion of the leaves, a graceful but scant embellishment; and one can well perceive how much more in accordance with the sober dignity of treehood is such chaste decoration than anything more brilliant and ornate. An oak pranked with white blossom or an elm garlanded with yellow florets would appear as inappropriate as a soldier with butter cups in his hair or a sage with daisies round his hat. (It is quite possible that the soldier or the sage might please us so decorated, but not unless we understand that childish hands had set the flowers there in loving frolic.) But admitting this limitation, that the leaf is often subordinate and therefore shows no ostentatious elaboration of form, it still may confidently be maintained that the great majority of leaves have a tendency to beauty of design, most frequently amply fulfilled. Mr. Ruskin in his beautiful and interesting, if also erratic and immature, work on botany ('Proserpina'), to which both now and heretofore I am largely indebted, proclaims the laurel, or as he calls it, Apolline, leaf to be the noblest of leaf forms. I have no intention to dispute his dictum on this point, but in reference to what has gone before, wish to say that, while as a tree leaf, a citizen of a large commonwealth of leaves, in which it is intended that the individual shall not be missed but secretly replaced, it may be the king of leaves, I would still assert that as a piece of sheer beauty it cannot be compared with any of the more graceful fern-fronds.

There is one principle which I should like to ennunciate clearly and to emphasize, seeing that it may save us much disappointment and gloom in our studies of nature. It is this, that Nature, I use this term in its personal sense as being much more reverent and appropriate to the occasion than a continual reference to the Deity would be, does not aim always at doing many things at a time, or at least usually exhibits one aim as dominant over the rest. Thus in plant life, seeing that plants form the garment of the earth, and must be continually seen of men, the leading aim is often to all appearance beauty; while in the case of animals, which have the power of motion and ability to avoid man when there is hostility between them, the result aimed at is rather strength, activity and self-defence, although often extreme grace or dignity of movement is likewise attained. Nor, on the other hand can we often, if ever, find in nature a one-ideaed action; other ends appear to be kept in view even though one seem largely to predominate. Thus, while, as we have observed, leaves tend to beauty of individual form and also of combined effect, they never fail in fulfilling their debt of utility to the plant to which they belong. They are no otherwise made than in that mode best fitted, so far as we can judge, to the necessities of that plant. And because they are so admirably made in this respect, man must forsooth, raise his heel against nature, and cry, "There is here no wonder and no divine design, plants are perfect in their place because the imperfect have been eliminated in a struggle for existence." It is somewhat hard on Nature to turn her perfection of utility against herself. For it is clear that, whether an organism comes into being by creation or evolution, the fact of its existing at all argues a harmony between it and its environment, involves a quality of utility in its structure; for to say that its structure and faculties are unfitted to its environment, is to pass sentence of death upon it. So that really no argument contrary to a creative hypothesis can be drawn from the often self-regarding economy of an organism, seeing it is a necessity inherent to the circumstances; but, on the other hand, an important inference may be drawn from the observation of the fact that while apparently so completely self-regarding in their economy they nevertheless are linked by relation of utility, and become adapted to perform services to parts of creation which cannot be looked upon as forming part of their immediate environment. Thus, while it might be difficult to prove *seriatim* that all other beings are constructed with reference to man,—for it often happens that by the very ill-adaption, as it seems, of some creature to man and his comforts that creature plays an important part in the development of the higher human faculties,—it remains and will remain an impossibility to prove that Nature is devoid of provisions for the eliciting of, not only lower energies and inferior faculties, but even the highest qualities and loftiest endowments of man. Certain is it that the student of nature, whether he seek truth or pursue beauty, need never weep the tears of an Alexander for new worlds to conquer. If he do, they will be, like those of the Macedonian, tears also of ignorance. The only limits we have yet discovered are the limits of our own faculties. An improved telescope apprises us of a score of unknown systems; a higher power attained in the microscope may multiply by thousands the population of a drop. Nor is the increase in mere quantity and number. Beauty behind beauty, and wonder behind wonder greet us as we advance. Nature is no piece of veneered and varnished elegance. Sawn through the centre, the graining is constant and undegenerate. No scamping is there in the workshop of nature, the smallest pollen-dust is bedight with delicate coatings, the most minute of diatoms has its tiny disc graven with a fair design. To me it is a mystery how any man can come from a contemplation of nature with the weary soul and the dreary creed of an atheist. Man may find, indeed, much that humiliates him, bidding him reflect that he is not the cynosure of the universe, seeing that the existence of the meanest creature seems fenced with like care to his own, causing him to speculate that as there are unfathomed deeps of being beneath him, so there may be heights as immeasurable above, and yet leaving him a conviction of his own possible dignity and worth, a creature for whose production past æons have laboured, the crown of the visible creation, and a confidence that the pervading power that has indued the meanest atom with indestructible existence, quickened dead matter with the wonder of vitality, and exalted it into the very home of feeling and palace of thought, cannot be such as to be careless of the souls of his children, callous to the destiny of man.

Provincial Transactions.

COVENTRY AND WARWICKSHIRE PHARMACEUTICAL ASSOCIATION.

The second general meeting of the above society took place in the Committee Room of the Provident Dispensary, under the presidency of Mr Councillor Wyley, on the evening of the 13th ult.

There was a fair attendance of students, evidently attracted by the title of Mr. Dewson's lecture:—"How to prepare for the Minor." The President having briefly opened the meeting, the Hon. Secretary (Mr. F. J. Barrett, F.C.S.) read the following list of donations to the library and museum:—

The Pharmaceutical Society, current numbers of the *Pharmaceutical Journal*; Messrs. Burgoyne and Company, *Monthly Magazine*; British Pharmaceutical Conference, 'Year-Book of Pharmacy'; P. Squire, F.L.S., 'Supplement to the Pharmacopœia'; Mr. F. Harwood Lescher, 'Elements of Pharmacy,' 'On the Microscope'; Mr. W. L. Scott, F.C.S., 'On the Microscopical Examination of Water'; Dr. Poore, 'Electricity in Medicine and Surgery'; Mr. S. U. Jones, 'United States Pharmacopœia'; Dr. Thorpe, 'Chemical Science,' 'Quantitative Analysis'; Mr. Kay Shuttleworth, 'Modern Chemistry'; Mr. J. B. Smith, 'Pharmaceutical Guide'; Mr. Bambridge, two old Pharmacopœias; Dr. Farquharson, 'Guide to Therapeutics'; Professor Roscoe, 'Elements of Chemistry'; Mr. Stephen Darby, 'Wittestein's Chemistry'; Dr. Nevin, 'Analysis of Pharmacopœia'; Dr. Hassall, 'Food Analysis'; Dr. Campbell Brown, 'Analytical Tables'; Dr. Lauder Brunton, 'Materia Medica'; Mr. Canning, 'Select Notes & Formulæ'; From the Publishers, 'Cooley's Latin Grammar'; Professor Barf, 'Inorganic Chemistry'; Professor Madan, 'Inorganic Chemistry'; Mr. Hodgkinson, a file of old prescriptions for the prescription book.

The Honorary Secretary also announced that he had received a number of valuable medical and surgical works from a distinguished London physician, who did not wish his name to appear in print. Mr. Axford proposed and Mr. Holdcroft seconded, and it was unanimously carried, that the best thanks of the members be forwarded to the various donors to the library of the Association.

Mr. Iliffe (Nuneaton), Mr. Pratt (Warwick), were unanimously elected members of the council.

The President then briefly introduced Mr. Stokes Dewson (Honorary Secretary of the Midland Counties Chemists' Association) as the lecturer of the evening.

The lecturer began by pointing out that the subject was too extensive to be properly dealt with in a short lecture, and he must therefore confine himself to a few of the more important principles to be kept in mind in reading for the "Minor."

In the first place he urged the necessity of cultivating habits of observation, so as to be accustomed to notice changes occurring in course of dispensing and seek for the causes producing them, and the nature of the results. The student should not, however, expect to write a formula for every cloudiness and precipitate which presented itself, as many would appear of uncertain or even unknown composition. Latin was a subject the student should aim at retaining; he would want it at the Minor. The speaker believed it was best for the student who was without a tutor to write out in full Latin the prescriptions from Pereira's 'Selecta,' and next day to correct them from the full unabbreviated form given at the end of the work. The Pharmacopœia, they must remember, was the compass of the pharmacist; this must be well got up, the composition and strength of all the preparations committed to memory, nor must they forget that the examiners required the processes to be explained; not only how a preparation was made but why it was so made.

The nose, he said, was an organ of great delicacy, but it required educating. The student should try to train his nose, for when well trained it was of wonderful service in the recognition and distinction of drugs and preparations. The student should practise the recognition of tinctures and extracts by smell and he would soon find that preparations in which at first he could scarcely find any odour had often very characteristic ones. Nor should it be forgotten that the nose could detect quantities of odorous substances so small as to completely elude chemical analysis. With regard to botany the student must not hope to get it up from books alone, he must go into the field, bring home wild flowers, sit down with Lindley's 'School Botany' or some such book, and examine what he has collected; he should not be disappointed if he cannot find all the medicinal plants he would like to see, but remember that a considerable amount of botanical knowledge could be got by the careful dissection and study of the commonest plants, buttercups, daises, clover, etc. He should collect such and try to write descriptions of them and afterwards compare the descriptions with those of the book, if he have no one who can correct them; this would give him confidence in the examination room at Bloomsbury Square. As to materia medica the student should bear in mind that examiners not only require the candidate to recognize the drugs presented, but also to say how they know them; this could be got up best by comparing the drugs, etc., with the descriptions contained in the Pharmacopœia, and carefully remembering the chief characters. An examiner had recently asked a candidate how he knew a drug (which he, the candidate, said was sassafras) to be so, the candidate replied "By the smell, sir." Then said the examiner, "If I had given you deal shavings which had lain long in the sassafras drawer, you would have declared them to be sassafras." The speaker recommended students never to trust to a single character in deciding the identity of a drug. Then, again, as to chemistry, he need not tell them it was an important subject. This could not be got up from books only; it was essentially an experimental science. The student could have no better book than Attfield's 'Chemistry' in preparing for the "Minor," but he must read a portion carefully and then go through the experiments, make the preparations, or the more important ones, and at the end of each group test for each metal; he could not do better than get a fellow student or assistant to give him pharmaceutical chemicals to examine after he had once been through the testing for the metals, and should on no account neglect to write equations for the changes he observed in the course of testing. After the student has gained some confidence in his results, he should then examine pharmaceutical chemicals as directed under 'Characters and Tests' of the Pharmacopœia. The lecturer warned them against supposing that all this required an expensive set of apparatus; a few shillings spent in test tubes, platinum foil, a Bunsen burner, etc., would provide apparatus with which a very fair acquaintance with elementary chemistry could be acquired. He concluded by explaining some examples of manufacturing processes which could be easily imitated on a small scale by such simple apparatus.

At the close of the lecture, which was well listened to and frequently applauded, Mr. T. Sellers (Vice President) proposed a hearty vote of thanks to Mr. Dewson for his lecture. The proposition was seconded and carried unanimously. The Honorary Secretary announced that the Council had arranged to commence the Minor class forthwith in the room they then occupied. On Tuesday the junior class would be conducted by Mr. Axford and other gentlemen, and the hon. secretary would take the senior class every Wednesday. The council had also appointed, as their teacher for Preliminary subjects, Mr. Gibbs who had kindly consented to instruct associates at reduced fees. He could heartily recommend all students who had not already passed their Preliminary examination to place themselves under Mr. Gibbs. They had also arranged to have a letter-box placed in the room into which questions, suggestions, etc., could be dropped, and at frequent stated times answered and considered. The books from the library would be lent out every Wednesday. He hoped that the classes would be a success, and that in six months time they would be able to send a batch of the more advanced students to Bloomsbury Square, and welcome them back again as registered chemists and druggists.

The Vice-President said it had been resolved to offer the following prizes for competition at the end of the present year, the prizes to consist of books, or chemical apparatus, selected by the successful student. Two prizes for Preliminary subjects, two for Minor subjects and a prize value one guinea for the best original essay on any subject of pharmaceutical or chemical interest, and half a guinea for the second best. He would particularly recommend every student to "go in" for the essay prizes. Select some subject of interest, thoroughly read up all obtainable information and then try to add some original matter or work out some unfinished problem connected with it. He concluded by saying that they had that evening heard from Mr. Dewson "How to prepare for the Minor," the members of the Association had provided them with the *means* of preparation, and it rested entirely with themselves whether they accepted Mr. Dewson's advice and the Association's liberal assistance. The examinations must be passed, unless they cared to remain unqualified druggist's assistants all their lives. The *only* way of passing successfully was by *work*, and the earlier they commenced their work the easier it would appear. They were growing older year by year, and as age increased disinclination for study increased, or business cares and responsibilities interfered. To the pharmaceutical, as well as to all other students, no more emphatic advice could be given than that contained in sacred writ.

"Work while it is called to day,
"The night cometh when no man can work."

A hearty vote of thanks to the President brought a successful evening to a close.

The first of a series of students' meetings of the above Association took place on the 27th ult. in the library. The deputy treasurer (Mr. J. Whiting) occupied the chair and there was a fair muster of associates.

A very interesting paper was read by Mr. J. W. Axford, "On Oleic Acid and its Combinations." After explaining its mode of manufacture and exhibiting various acids (kindly contributed by Price's Patent Candle Company), Mr. Axford glanced at the pharmacopœial oleates of ammonia, soda, potash and lead, and explained their preparation by means of equations. He then spoke of oleates of mercury, morphia, etc., which had been more recently introduced, criticized the use of oleic acids in various other preparations as suggested by Professor Tichbourne, and concluded by giving examples of the use of oleic acid, in forming oleates soluble in oils, such as cod liver oil and quinine, strychnine, etc., etc.

At the close of the paper a vote of thanks was accorded to Mr. Axford.

On the same evening Mr. Barrett gave his first lesson on "Minor Subjects," to be continued weekly.

LIVERPOOL CHEMISTS' ASSOCIATION.

The tenth general meeting was held at the Royal Institution, February 28th, 1878. The President Mr. T. Fell Abraham, in the chair.

The minutes of the previous meeting were read and signed. The donations to the library were duly acknowledged.

Mr. H. S. Jackson was elected a member, and Mr. J. C. Jackson elected an associate. The meeting was entirely devoted to miscellaneous communications.

The eleventh meeting was held March 14th. The President in the chair. The minutes of the previous meeting were read and signed.

The donations to the library were announced and thanks accorded the donors.

Messrs. George Taylor and J. H. Morris were unanimously elected members.

Mr. Symes said he had pleasure in presenting for the museum a sample of a Brazilian drug, "Caroba," the produce of *Jacaranda procera*, N. O. Bignoniaceæ. The genus is composed of elegant trees having much the habit of the fine leaved acacias. This drug consisted of the dry leaves with some twigs; it yielded an extract possessing a bitter and slightly astringent taste, of which he showed a sample. He was rather surprised at the large yield of this, viz., 5 lbs. from 23 lbs. of the leaves, or over 20 per cent. The drug is included in the Brazilian Pharmacopœia, and is also mentioned in Dorvault's 'L'Officine' as a component of the celebrated antisyphilitic confection. Dr. Symes added that Dr. Barnsley has prescribed it with advantage in skin diseases arising from syphilis. It is prescribed as an infusion, decoction, and fomentation; also in the form of extract.

In reply to Dr. Nevins, Dr. Symes said that caroba could scarcely be said to act like sarsaparilla; indeed to associate it with sarsaparilla would be to endanger its trial by a number of medical men, who either as the result of experience or prejudice regard sarsaparilla as valueless. This was really an active drug and one that he felt satisfied merited attention .There was the authority of Dr. Barnsley for its value in the class of complaints mentioned, and these complaints were in hot climates like Brazil somewhat formidable.

Mr. Edward Davies, F.C.S., contributed a highly interesting paper entitled "Notes on some Recent Additions to the Lists of Substances which ignite Spontaneously." The paper was illustrated with experiments, several of which were entirely new to the members present.

On the motion of Dr. Symes, seconded by Dr. Nevins, an unanimous vote of thanks was accorded Mr. Davies with acclamation.

ABERDEEN ASSOCIATION OF CHEMISTS AND DRUGGISTS.

This Association held its monthly meeting on Thursday, 14th inst. Mr. Strachan, secretary, occupied the chair, and introduced Mr. Giles to the audience, who delivered a lucid and instructive lecture upon Heat.

The lecturer set before his hearers a very complete and concise account of the various characters and actions of heat, tracing their discovery and nature, and giving a history of their practical utility and place in the economy of the universe, concluding by giving a critical summary of the various philosophic theories of the ultimate tendencies and results of cosmic heat. Mr. Giles's lecture was loudly applauded, and votes of thanks brought the meeting to a close.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held on Thursday, March 14, when a paper was read by Mr. W. R. Dunstan on the "Chlorides of Iodine." In the course of his paper the author stated that only two definite compounds of chlorine and iodine had been obtained, the monochloride ICl, and the trichloride ICl_3. A tetrachloride is said to have been obtained in the solid state, a pentachloride in the state of aqueous solution.

Monochloride of iodine is prepared by passing dry chlorine gas into dry iodine until the latter is liquefied. A small quantity of trichloride is, however, always formed, and to free it from this the monochloride should be distilled from iodine at a temperature of 100° to 102° C.

The resulting monochloride of iodine may be obtained in crystals fusing at 24° to 25° C. to a brown oily liquid. It is soluble in alcohol, ether, and glycerine. Specimens of this substance and of its solutions were exhibited, and its action upon a number of substances, organic and inorganic, was described.

Trichloride of iodine is prepared by passing excess of chlorine into iodine. It can be obtained in yellow crystals, which will readily sublime; when heated chlorine is given off but is reabsorbed on cooling. One of the most interesting compounds of this body shown by the author was the chloriodide of potassium, a substance formed when chlorine gas is passed in excess into a solution of iodide of potassium. It is obtained in the form of yellow needle-shaped crystals, and quantitative analysis would point to the formula ICl_3KCl.

On the conclusion of Mr. Dunstan's paper a discussion ensued, in which most of the members present took part, and after passing a hearty vote of thanks to the author the meeting adjourned.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the above Association, held on Wednesday last at 28, Baker Street, in a room kindly lent by the Council of the Quebec Institute, Mr. Princep, President, in the chair, a lecture was delivered by Dr. C. E. Saunders on the "Structure and Functions of the Human Body."

The lecturer stated that it was a laudable thing to make men acquainted with that which affected them so nearly as their own bodies—"the proper study of mankind is man"—and he therefore proceeded to bring before his audience in succession the various striking points of interest connected with the human skeleton, with the muscles, nerves, the respiratory, circulating, and digestive organs. He insisted on the proper cultivation of the brain, so as to produce a degree of subjection of the senses and passions to the intellectual faculty.

At the close of the lecture, which was listened to with much interest, Dr. Saunders replied to a few questions from members of his audience. After a hearty vote of thanks had been accorded to Dr. Saunders for his instructive and excellent discourse, and also to the Council of the Quebec Institute for the loan of the room, the meeting dispersed.

Parliamentary and Law Proceedings.

Prosecution under the Pharmacy Act.

The three summonses by the Pharmaceutical Society of Great Britain *v.* Mackness and the London and Provincial Supply Association, Limited, reported last week, were disposed of by Mr. Newton on Saturday the 16th.

Mr. Lumley Smith said he appeared on this occasion on behalf of the prosecution.

Mr. Newton said he understood the case was closed. All he wanted to know was who it was who sold poison on the 20th of February.

Mr. Sanders said a man of the name of Sharman, who was no longer in the employ of the Association. When this occurred of course they thought it right to dismiss him.

Mr. Newton: Was he an authorized person?

Mr. Sanders said, No, he was not. He was only in charge of the premises for a very short time whilst Mr. Longmore went to dinner, and during that unfortunate period Mr. Ward went to procure this oxalic acid.

Mr. Newton: Then you admit that there was an unauthorized person selling poison in your establishment?

Mr. Sanders: Yes.

Mr. Newton: Do you not think that is a clear infringement of the law?

Mr. Sanders: If we are liable as a corporation. That was the point I took last time.

Mr. Newton: Is not that a clear infringement of the law?

Mr. Sanders: By somebody; it may be an infringement by the man.

Mr. Newton: In your establishment; the poison was sold contrary to law.

Mr. Sanders: If the law applies to us it was so.

Mr. Newton: That is what I asked you the other day. Do you hold yourselves above the law?

Mr. Sanders: It was for that reason your worship adjourned the case that we should look at the law upon that point, and I have done so.

Mr. Newton: I want to knew exactly whether you do put yourselves above the law for this particular Act.

Mr. Sanders: If your worship will be kind enough to hear a few words from me I think I shall be able to put the case before you in a very tangible point of view.

Mr. Newton: Very well; what would you like to say upon it?

Mr. Sanders: You of course remember all about the case and that this matter was adjourned that we might have an opportunity of further considering the point. I have done the best I can to consider the point. I have looked up all the authorities I could refer to and I find as regards corporations that no doubt the general rule is that unless they are specially mentioned they are not liable, inasmuch as they are an invisible body, and the Legislature now is very careful to include these corporate bodies under the term "person." In the Judicature Act, for instance, there is an interpretation clause which says that the word "person" shall include corporate bodies. As regards civil proceedings, therefore, there cannot be much doubt, and the only question is about criminal proceedings. We know that as regards corporations they are often indicted for not repairing highways and so on, and they may under some circumstances be amenable to the law of libel, as we know from the case of the telegraph company which was held to be guilty of libel in sending a libellous letter. It would be very unjust on my part to attempt to beguile the Court or to attempt to deceive the Court in any way. I am bound to lay everything before the Court to enable it to give a proper judgment whether it makes for me or against me, and I must say in this case I have come across an Act of Parliament which appears to put me somewhat out of court on this point. In candour and fair practice I hope I should never think of concealing from the Court anything the Court ought to know, although it is against me, and if your clerk will be good enough to refer to 7 and 8 Geo. IV. I shall be able to explain better what I mean.

Mr. Newton: Do not you come under the ordinary Joint Stock Companies' Act without that?

Mr. Sanders: No, I think not.

Mr. Newton: Why not?

Mr. Sanders: We are now considering the Act of Parliament as regards the sale of poisons, and the question is whether "person or persons" includes a corporation.

Mr. Newton: I do not think there is anything turns upon that; you are a corporate body, but surely you are liable to the criminal law.

Mr. Saunders: Not generally. We should only be so under a statute. At common law we should certainly not.

Mr. Newton: To a certain extent.

Mr. Sanders: You cannot pursue a corporation. They have no individuality. You cannot point out any one in particular who has done wrong; you cannot take a corporation into custody.

Mr. Newton: What occurs to me is this: that if I say this summons will not do because it is against the London and Provincial Supply Association, Limited, and therefore I am to dismiss the summons, they will ask me for another summons as against the person who sold it.

Mr. Sanders: I do not wish to keep up the contention any longer.

Mr. Newton: I think you will agree, then, the question is this, What is the best to be done for the future?

Mr. Sanders: We know what to do for the future; our object is to show the Court that we really were conducting the business in a lawful way. I think you were satisfied of that the other day except in regard to this mistake.

Mr. Newton: The third sale I think was wrong.

Mr. Sanders: I want to make that conclusive to your mind because it may come before you again. There is an Act of Parliament, 7 and 8 Geo. IV., chap. 28, sect. 14; it applies very generally to these cases, and perhaps you will forgive me saying it may be useful to you again.

Mr. Newton: What is it called?

Mr. Sanders: It is called an Act for improving the administration of justice. It is the Act which did away with the benefit of clergy and so on. I have copied out the section.

Mr. Newton: Just read it.

Mr. Sanders: I admit, of course, it is against me, but I think it is right you should know how it is: "And be it enacted that wherever this or any other statute relating to any offence, whether punishable upon indictment or summary conviction, in describing or referring to the offence or the subject matter on or with respect to which it shall be committed, or the offender or the party affected or intended to be affected by the offence, hath used or shall use words importing the singular number or the masculine gender only, yet the statute shall be understood to include several matters as well as one matter, and several persons as well as one person, and females as well as males, and bodies corporate as well as individuals." That is whenever any statute makes an offence punishable and individuals are mentioned it shall include corporate bodies as well as individuals, "unless it be otherwise specially provided or there be something in the subject or context repugnant to such construction." I cannot contend there is anything of this sort in this Act, and that seems to me to give you jurisdiction with regard to a corporate body, and therefore they need not be mentioned in this Act inasmuch as they come under the provisions of this 14th section. I think that certainly concludes the legal view of the matter, and therefore with your permission I would say a word or two with reference to the merits.

Mr. Newton: I thought you admitted all that.

Mr. Sanders: I am going to say something in mitigation.

Mr. Newton: I thought you had closed.

Mr. Sanders: I was addressing you with regard to the penalty, and I should call evidence if necessary.

Mr. Newton: Now you are going on the merits. I thought you had closed the case.

Mr. Sanders: I closed the case as regards the facts, but I was going to make some observations with regard to the facts.

Mr. Newton: You admit the fact that this poison was sold in your establishment without being properly labelled.

Mr. Sanders: Yes.

Mr. Newton: You might have expected that proceedings would be taken against you because you had notice by the letter Mr. Flux wrote to you before. You had it clearly brought to your notice that you ought not to sell poison without having complied with the law.

Mr. Sanders: Of course there is every degree of criminality in these matters.

Mr. Newton: It is great carelessness allowing somebody to be in the shop who does not know his business or trade.

Mr. Sanders: He did know his business.

Mr. Newton: But he was away.

Mr. Sanders: He must be away at times.

Mr. Newton: But the public is not to be poisoned.

Mr. Sanders: Your worship will recollect this, that we did not sell this poison without giving all that which was the material matter.

Mr. Newton: Except this, that you did not put the label upon it.

Mr. Sanders: But we say oxalic acid and poison.

Mr. Newton: But you did not comply with the statute.

Mr. Sanders: The statute certainly ought to be complied with, but it is not of that importance as though we had sold this without putting "poison" upon it.

Mr. Newton: If you had not put "poison" on it I should have put on the full penalty.

Mr. Sanders: That is what I am addressing you upon. This is a question in which I think we may fairly ask for a mitigation of the penalty.

Mr. Newton: I have made up my mind before what to do under the circumstances.

Mr. Sanders: There is one observation I think I may make in justice to my client. When we were here before Mr. Flux said we were in the habit of selling poisons.

Mr. Newton: We have done with all that.

Mr. Sanders: I was going to say this. That observation appeared in the papers. It was very unjust and very untrue, and may have the effect of very much prejudicing our business. The fact is it was made up in the regular way but had not got a proper label.

Mr. Newton: I have to deal with these three summonses. On the first summons Mr. Mackness pleaded guilty and threw himself on the mercy of the Court because he said he had paid £5 under a sort of threat which was made to him by Mr. Flux that unless he would pay that money proceedings would be taken against him. I look upon that as equivalent to his having paid the penalty already, and I therefore only order him to pay costs of the summons upon that.

With respect to the second summons, I think that the London and Provincial Supply Association, Limited, have complied with the law, because they put "The London and Provincial Supply Association, 113, Tottenham Court Road," and the name of the seller, Longmore, upon the poison that they sold. I think, therefore, that summons fails, and I dismiss it.

With respect to the third, I think that the company is wrong. They allowed a man to sell poison, having had due notice given two months at least before that there was a suspicion against them for acting wrongly. They were wrong in allowing a man to sell the poison, not complying with the 17th section of the Act, and they should have had the name of the seller upon that packet. Therefore I think, taking all the facts into my consideration, on that summons the defendant must pay the penalty of fifty shillings and two shillings the cost of the summons.

Dispensing Memoranda.

[78]. Dissolve the pot. bromid. in ℥ij of water, add the sp. am. aromat. and ℥ij of mucilage, then dissolve the ferri et quin. cit. in a little water and pour into the first solution through a small funnel, afterwards adding rest of the water. The addition of mucilage appears to me more justifiable than straining out the quinine. W.

[83]. I have received the following prescription to dispense:—

℞ Ext. Ergotinæ . . . . . gr. iij.
Quiniæ Dis. . . . . gr. j.

Ft. pil. ter quaterve die sumenda. Mitte xviij.

Is there a definite preparation known as Ext. Ergotinæ?

INQUIRER.

[84]. Would any reader be kind enough to inform me of the formula for "Nervine Balsam," as I had a receipt to make up a few days ago in which ℥j of that preparation was ordered? SPES.

[85]. Will some one kindly inform me through the medium of the Journal which is the best excipient for a pill containing Aloes, Ipecac., Quinine, and Ext. Nucis Vom.? X. Y.

[86]. Can Ung. Plumbi Co., P. L., be made of a soft consistence? I have tried it several times and find that even with half the quantity of Emp. Plumbi it becomes hard and crumbly. The physician who orders it tells the patient that it can only be made by one firm in London.

Southsea. H.

[87]. How is it possible to produce a pill, containing all the active properties of the two ingredients ordered in the following prescription in one grain and a quarter? Such a pill has been produced to me as prepared from:—

Podophyllin Resin . . . . gr. ij.
Ext. Hyoscyam. . . . . ℈j.

M. fiat. pil. *six* (6).

Allowing that an ext. hyoscyam. durum, or even superlatively hard extract be used, is it possible to make a pill by heat meeting the views of the prescriber, it always being understood in terms of B. P. of consistence to form a pill. PRACTICE.

[88]. GLYCERINE OF BELLADONNA.—Can any reader oblige me with the formula for Glycerine of Belladonna, which was ordered in a prescription that I received this week? ANDREW H. CLELAND.

[89]. A CURIOSITY.—I shall be glad to know if any reader could conscientiously prepare the enclosed receipt, which is the most peculiar one I ever had presented.

Boston. W. R. FOWLER.

"Take conserve of burrage, buglos, red roses, each one ounce; balm, one ounce; saffron, a scruple; citron peel and shreds of myrobalans, candied, each one ounce; extract of wood aloes, each a scruple; pear, half a dram; red coral, ivory, each a dram; precious stones, a scruple; candied nutmegs, two drams; syrup of apples and quinces, one ounce."

[90]. Will you kindly insert the following prescription in the next issue of the Journal under "Dispensing Memoranda?" I should like to know if it could be dispensed so as to leave but little sediment:—

℞ Pulv. Bismuthi . . . . . . ʒiss.
Acid Hydrocyan., dil. . . . . ♏xl.
Sp. Amm. Fœtid. . . . . . ʒss.
Glycerini . . . . ʒss.
Potass. Bromid. . . . . . . ʒiss.
Liq. Calcis. . . . . . ad ℥xij.

M. Sum. ℥j ter die. T. E. T

[91]. I should be glad to know through the "Dispensing Memoranda" if it is possible by any order of mixing to dispense the following prescription without causing turbidity. It was sent out perfectly clear from one of the first houses in London, but I can obtain it so only by filtering, which gives the customer dissatisfaction:—

℞ Liquoris Plumbi Diacet. . . . . ʒiss.
Acidi Carbolici . . . . gr. xv.
Aquæ Rosæ Destill. . . . . ad ℥iij.

Misce, fiat lotio. A few drops to be poured into the ears night and morning.

Would it be right to separate the precipitate by filtration? A. W.

Obituary.

Notice has been received of the death of the following:—

March 14, at Kennet Lodge, Simeon Street, Ryde, Mr. Richard Taylor, Pharmaceutical Chemist, age 55. Thousands of visitors to the Isle of Wight, and amongst them it is to be hoped a fair number of chemists, have been confronted immediately on leaving Ryde pier, by the name of the deceased over the shop where now the name of a worthy successor, Mr. T. S. Flower, appears. Here Mr. Taylor carried on business for twenty-one years. He became a Member of the Society in the year of the great influx, 1853, but he passed the Major examination in November of that year—the well known names of Henry Deane and Charles Cracknell being appended to his certificate, with those of Davenport, Gale and Bird as Examiners. He did not study, however, for the sake of a diploma, but for the acquisition of knowledge, and consequently the acquirements thus obtained were not shelved amongst other obsolete stock, but were brought into daily requisition, and obtained for their possessor a sterling reputation as a pharmaceutical chemist. It was to the science of meteorology that he gave more particular attention; and in this field his observations were most careful and accurate, as his regular contributions to the local press testify. Upon his stores of information both the public and his *confrères* drew almost at pleasure, and speaking of things that he knew, Mr. Taylor was wont to express himself with a confidence that occasionally dispensed with the finer suavities of speech. He retired from business four years ago; and some of his fellow townsmen hoped that his intellect and abilities would have been devoted to the service of the borough, but he chose rest, probably induced by incipient symptoms of the disease which eventually carried him off to the regret of many friends.

Correspondence.

Discrepancy of Examination Results.

Sir,—There is an order of people who are never satisfied with things as they are. It is peculiar at the same time that these same people can never say explicitly how they would wish things to be. It seems to be their particular mission and forte to grumble and keep up a certain amount of a disagreeable sense of dissatisfaction, so that people who take the management of affairs may never have the pleasure of regarding with complacence the work which they have done in their official capacity. To this order seems to belong Mr. Duncanson of Stirling. He grumbles about the Preliminary examination, simply, it appears to me, because he fancies that he ought to, not because he feels certain about the particular element in it with which he is dissatisfied. It is ridiculous and tiresome to have people continually grumbling about an examination like the Preliminary. The Preliminary is a very mild test of a student's scholastic knowledge; the questions are fair, and as they are chiefly elementary, very easy; the time allowed is sufficient to permit the candidate to reply to all the questions, and if he cannot make a pass in three hours, there is little probability that he would make a pass though he were allowed three days; the candidate who fails to pass very thoroughly deserves to be plucked.

That the percentage of failures in the arithmetic is larger than in the other subjects, need surprise no one. The Latin can be crammed by going over the first book of Cæsar two or three times, with a translation, and the rules of grammar —all that are required for this examination—can be easily committed to memory. The merest schoolboy should be able to pass in the English; that any one proposing to enter the trade should not know sufficient English grammar to enable him to pass is disgraceful to himself, and would be a slur upon the trade if it should take him. But the arithmetic cannot be crammed, for the questions can be varied, so that cramming in a particular direction is for little good. The fundamental principles of the subject must be thoroughly understood, and the powers of thought and reason cultivated, so that when the candidate is placed face to face with a numerical problem which he has not previously seen, he can by their legitimate exercise, and without external aid, readily solve it. According to published statistics of the Preliminary, some candidates have presented themselves for examination who failed to obtain a single mark in this subject. This shows very plainly that "the article," as Mr. Duncanson calls it, though it may be better than it was ten years ago, is yet slightly in want of improvement.

The examination would require to be very considerably cut down to bring it within reach of the capacity of these candidates. To blame the examination for the failure of these is more, I daresay, than even Mr. Duncanson would venture to do. Candidates will not take time and patiently master their arithmetic. They get possession of a few examination papers, do the sums therein, go upon chance, and of course get plucked. Would they but face their work honestly there would be fewer failures. The fault is not in the examination but in the candidates themselves. Besides, I do not consider it judicious in Mr. Duncanson to encourage this slipshod preparation, and going upon "spec," and he is most assuredly doing so when he proposes any lowering of the standard of examination and reduction of the "try again" fee; it is neither fair to the trade nor to the candidates. The standard of education of the trade is not as high as it might be, and retrogression in educational matters is not the order of the day. The candidates themselves will be the gainers by the higher attainments necessary to pass the more severe examination, and when once they have passed they will bless the necessity which was the cause of their additional exertions and consequently superior attainments.

With regard to Mr. Duncanson's third proposition, it is harmless and needs no comment. Further on, however, he says, "or a diminution in the number of points insisted on by the examining body, would, I submit, be a boon to the candidates." I fail to comprehend in what way this would be a boon to the candidates, unless that giving them encouragement to remain satisfied with a grossly insufficient elementary education can be so considered. It might, it is true, allow a few more to prepare and go up for the next examination, the passing of which would entitle them, pharmaceutically speaking, to be called "qualified" though certainly not educated men.

It is to a higher education, both of public and pharmacists, that we must look for the rescue of the trade from its present unsatisfactory condition. The education of the public is daily becoming of a higher kind, and the position which pharmacists are to occupy in the future, will be determined by the manner in which they keep pace with and adapt themselves to the higher requirements of the public.

To lower the standard of the examinations would be suicidal, and if any change be made in any of them, I feel sure that the Council of the Pharmaceutical Society will see the propriety of letting that change be in the direction of higher requirements.

Peter Boa.

March 6, 1878.

Sir,—Kindly permit the insertion of a reply to the letter on the above subject in this week's number of the Journal.

Your correspondent might have observed that it was the Minor examination that I wrote about, and which attracted the attention of Mr. Schacht and other members of the Council.

I did not assert the superiority of the "short heads" over the other type, but merely gave it as a physiological opinion, or rather an ethnological fact commonly held by physiologists. Far less do I despise the other class, on the contrary I rather excused them on the ground of want of the same facilities (particularly time), and the absence, or at least possession in a moderate degree of the praiseworthy quality of indomitable perseverance so easily discernible as constituting part and parcel of the national character of the Scot.

Apropos of the Preliminary failures and the objection raised to the theory of their dependence upon the relative magnitude of the "centre of mind," I shall try to give reasons for the apparent anomaly.

1. As a rule, younger apprentices are taken in Scotland than in England, and in consequence thereof the primary education is more limited.

2. They are not old enough to stick so rigidly to the requisite tasks, nor comprehend them so well as in after years.

3. Youths in hilly Scotland do not mature so quickly as the inhabitants of the sunny south, hence the development of the brain of the former is not so proportionately large before they are out of their "teens" as after they have attained majority, as in the case of the latter.

Still, I would not take the last examination as a specimen —indeed it is not a fair sample—let the average be taken from a range of years, and in the event of the English having the advantage, I question whether the knowledge of the unsuccessful northerner be not deeper and more permanent than the superficial "polish" so quickly imparted to residents in English boarding schools.

E. H. S. disputes, somewhat illogically, the actual difference between the success of the Caledonians and Anglo-Saxons. If it be true that the high percentage of passes in Edinburgh depend on English candidates, why don't the latter not only "help to swell" the London list, but altogether prove their pre-eminence in mental culture, so that failure be unknown? To follow out an opposite argument to Mr. Schacht's it may be the case that if Englishmen ceased to present themselves at the Scottish capital the number of rejections there would be sensibly reduced. Many of those who go to Edinburgh from this side of the border do so on account of the less distance (as probably all those cited by Mr. Schacht as trying their fortune there last December), and some, I know, in order to see the beautiful city. But your correspondent is wrong with regard to the fruitless search for my northern friends in the London pass list. I often see their names published, and know not a few who have passed the ordeal there, hailing even from the "far north," and doubtless there are numbers of others go there too because it is near; for as everyone knows, Scotchmen are scattered all over the provinces, and form no inconsiderable portion of the metropolitan population. Again, a good few of my kinsmen qualify at head-quarters after a course of study at one of the adjacent schools of pharmacy. But why should not the northerners appear for examination in their own centre? Are they afraid of being "plucked" in London? No! I am astonished at one speaking so disparagingly of their abilities who did not figure so high himself at the test. I do not wonder at a person failing to notice the record of registration of natives of Alford, Insch, and other places in the "land of cakes," if his acquaintance with geography be rather rusty.

I cannot see how the subject "dispensing" can be oral any more than written, neither could "analysis," but surely, as in Government science and art examinations, questions could be set, practical work done, and the results committed to paper.

Lastly, I would ask, were the respective merits of candidates not properly "guaged" in the written competition in pharmacy for the Council prize of books to "honour's men?" The system worked satisfactorily enough; then why could not the correct rendering of a medical prescription or the best method of compounding a difficult mixture be transcribed on foolscap as well as a translation of a passage from any of the classics?

March 12, 1878. JAMES B. L. MACKAY.

[*$_*$* We do not think that much light will be thrown upon the problem by a continuation of the argument in the craniological direction, and request that any future correspondence on this subject may be confined within more pertinent limits.—ED. PHARM. JOUR.]

THE MINOR EXAMINATION.

Sir,—I have asked myself the following question so many times without getting a satisfactory answer, I deem it worth while to ask it in your pages.

Is the Minor examination a real test of a man's ability to conduct the business of a chemist and druggist?

My experience tells me that the growing race of chemists will not take the place of many who are passing away, who thoroughly grounded in the practical part of the business, availed themselves of the opportunity to become scientifically qualified.

The tendency of the examinations, and also the conditions of the Bell Scholarships, is to draw pupils from interest in the practical drudgery of the business, by which alone it can be mastered, to more tempting scientific studies, and that from the very commencement of their career.

It has long been a pet idea of mine that something analogous to the examinations for candidates desiring to become officers in the mercantile navy could be applied with great advantage at our own Board. If a candidate fails in seamanship he is sent to sea for twelve months, if in the more scientific part for only three months is he referred to his studies.

It has also been a great question with me whether men who are destined to do all the executive work, and also composing the ruling class of the Society, should be compelled to pay all the expenses of the Society which gives its protection, at least in the matter of title to both classes of chemists, for that is what the pharmaceutical chemist in fact will do in the future under our present system.

I therefore propose the following programme of examinations in lieu of that at present in force:—

Before Apprenticeship—the present Preliminary—fee £2 2*s*. After Apprenticeship, or still better, a year later, examination in practical dispensing, pharmaceutical Latin, physiology, and the galenical portion of the pharmacopœia; fee £2 2*s*. That would qualify for the pass examination (chemist and druggist),—fee £6 6*s*. Should the candidate obtain a sufficient number of marks in the various subjects, that would qualify him without further fee to the third day's examination in practical chemistry, and on passing that would give him the title of pharmaceutical chemist, or enable him at any future time to do so by simply passing what I call the third day of the examination.

This programme would assist the cultivation and secure testing of the candidates' counter work, it would give the stimulus to study that "honours" were supposed to incite, it would place the higher title as the reward of merit, and all would pay the same fees. It would secure on the Board of Examiners an adequate force of matured knowledge, and of scientific acumen not necessarily requiring the wisdom of middle age.

I put this scheme forward as a suggestion to my fellow members whose greater experience may negative my idea, perhaps improve on it. I find no fault, but our motto should always be, "Onward."

SALE OF PATENT MEDICINES.

Sir,—I see in the Journal, page 715, the account of a communication received from the Home Secretary, respecting Hunter's Sol. Chloral Hydrat, and the reply thereto.

I believe our Council wish to help us over our business difficulties, instance the "Dental Bill;" but there is a far more serious evil affecting chemists than any dental bill, in a monetary point of view; I refer to the sale of patent medicines by all sorts of little shops. This is being very seriously felt in this and many towns in the north. I saw an account of a meeting the other day where the chairman thought it was not a matter anything could be done in at present. However, I cannot help but differ from him. I think we should agitate and ventilate the subject until something is done to make it compulsory for all patent medicines containing poisons to be sold by registered persons. I have written to several makers of these articles and the general opinion is that the Excise might be induced to grant licences to persons only who have a recommendation from the Registrar of the Pharmaceutical Society; they will not be losers by it in the long run; the spirit licences and others are granted only on like terms. The mischief is, any little shop having a patent medicine licence considers itself justified in selling paregoric sine opio. chlorodyne sine prussic acid, Godfrey's cordial, sp. sweet nitre, 2d. ounce, and all other little articles which make up the chemist's daily returns, and poor people buying these weak preparations get accustomed to giving large doses. The danger is their giving the pure article in the same dose, to the chemist's risk. A case of this kind occurred some time ago: the assistant fortunately cautioned the person about the strength, seeing where the last had been obtained. The woman, either forgetting the caution, or negligently, gave the usual large dose, and the child died. The caution of the assistant probably only saved the chemist from trouble. I hope our Society will try and do something in the matter, and that other more able pens may write upon the subject.

T. KCUB.

March 12, 1878.

Sir,—According to the Journal of the 9th instant, under head "Law and Parliamentary," a communication has been sent direct to the Pharmaceutical Council from the Home Secretary directing attention to the fact that a poison scheduled under the Pharmacy Act had been sold, such poison causing death. The answer of the Pharmaceutical Society —Council or Solicitor not stated—was that, as a patent medicine it was entitled to exemption, and distinctly entitled under the Pharmacy Act, 1868.

How great a space of time longer is such a state of things to last? Up to this date the Pharmaceutical Council have devoted their attention to education, benevolence and æsthetics. Ethics and technics they leave entirely aside as, I presume, being out of their province. The fact published in their Journal, discussed by them prior to an answer being sent on the above published case, has now brought the question of the sale of patent medicines publicly before the attention of the whole body of chemists and druggists, and it will be impossible for the Council to shelve the subject as hitherto done. It must be discussed at their next meeting and made a prominent subject at the yearly meeting.

I do not pretend off hand to find a definite solution of the sale of patent medicines by unqualified persons, but my view of the question is this:—that all chemists in England and Scotland wait upon their local secretaries and request them to forward to the Pharmaceutical Council the expression of their opinion that it is time that immediate steps be taken to compel the proprietors of patent medicines to declare the ingredients of which they are composed and to register the same, and payment of royalty, the said sale being computed by a trade mark, stamped numerically by a legally constituted authority, which would do away with present ad valorem duty. A revision of the scale of duty payable by retailers, say £1 for towns under 20,000, and £2 above that number. The sale of proprietary articles containing poison would be thus vested in the hands of the legally constituted authority, the chemist, whereas at present it is "Tom Tiddler's ground." The highest home governing authority having had the matter so recently before him, immediate legislation may result and the question be definitely settled.

Should the Council be unable to take steps leading to a speedy settlement of the question, I would suggest that chemists should support "the Trades' Protection Society" to the same extent they have previously done the parent society, on the principle that "God helps those who help themselves," leaving to the Square the motto that appears as heading to a short leader of last Journal, "Quos Deus vult perdere, etc."

FRED. B. BINGLEY.

Guildford, March 11, 1878.

Sir,—Licences for the sale of alcoholic beverages are only issued by the excise authorities to those who have previously obtained a certificate from the magistrates that they are of good character, competent, and do not permit of the abuse of the articles in which they deal.

A licence for the sale of patent medicines (5*s.* say) is granted to any one who chooses to ask for it, whether shoemaker, grocer, stationer, or chemist.

This is wrong and is being abused in an unprecedented manner, without saying anything about the temptingly low prices at which they are offered. If the excise authorities could be persuaded only to issue the licences for the sale of patent medicines to chemists qualified by being upon the register of chemists and druggists and pharmaceutical chemists, a wholesome restriction would be placed upon the trade. The chemist would occupy his true position, and he with the public would in consequence be benefited.

This, one would think, could easily be accomplished by a proper representation of the Pharmaceutical Council to the authorities of the Inland Revenue at Somerset House.

K.

February, 1878.

THE WEIGHTS AND MEASURES BILL.

Sir,—In an article on the Weights and Measures Bill, in your Journal of last week, you have, I think, fallen into a slight error. You say, "but there is to be one notable addition, and that is the avoirdupois grain, or the one-seven-thousandth part of the imperial standard pound, the Bill thus practically endorsing the action of the Medical Council in introducing an avoirdupois grain for the purposes of the British Pharmacopœia." Now in Balfour Stewart's 'Elementary Treatise on Heat,' p. 69, we have "and it is enacted 'that the platinum weight deposited in the Exchequer shall be denominated the imperial standard pound, avoirdupois, and that the one-seven-thousandth of it shall be a grain, while 5760 such grains shall denote one pound troy.'"

From this it would seem that the grain is primarily an avoirdupois weight, and that it is so by Act of Parliament and not by any enactment of the Medical Council. I heartily agree with you, however, in the opinion that the proposal to repeal the Act permitting the use of the metric system is a decidedly retrograde movement, and it is one I think which ought to be resisted by those scientific societies which have influence with the Government. Every one, I presume, admits the vast superiority of the French system over ours, and the only objection to its introduction exists in the inconvenience that would result from so radical a change. In this regard we are too apt to forget that other nations have submitted to that very inconvenience, and actually survived it. As a writer on the subject well remarks, "The very idea of a cosmopolitan system carries with it that of national abnegation; and of this the French have set a noble example, they have put aside their ancient toise, their lieu, their pied, and their pouce, to adopt a measure which commends itself to all nations alike by its want of nationality, and the decimal system of measures and weights must, whether we will it or no, prevail against all others."

D. B. DOTT.

24, *Castle Street, Edinburgh,*
March 15, 1878.

CHLORAL, A POISON.

Sir,—Now that chloral and its preparations are included in the Poisons Act schedule, I presume that proprietary articles, avowedly containing chloral, will require to have a "poison" label and vendor's address attached before being sold; also that it will be illegal for unregistered persons to trade in them, for I scarcely think that the Government stamp will protect the patent medicine dealer when the name of the active ingredient is declared.

If such be the case, it would be advisable to caution the "trade," lest anyone unwittingly commit a breach of the law.

Perhaps you will express your idea with regard to this matter.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Hanbury, Mr. Blaikie, Mr. North, Mr. Harvey, "Color," "Oleum."

"THE MONTH."

Notwithstanding the biting winds and the clouds of March dust, flowers are more forward than during the same time last year. In hedges and copses the hazel is almost over and the "palms" or willows, as well as the alder and poplars, are putting forth their catkins, and the delicately tinted blossom of the wood anemone and the handsome yellow flowers of the lent lily are decorating the woods everywhere. The pale primrose, too, is beginning to scatter its nosegays of blossoms beside the clear rivulet and on the shady hedgerow. The dark glossy leaves of the stinking hellebore, surmounted by its racemes of pallid green, purple tipped flowers may now be looked for in thickets, and its near relative the green hellebore is showing its light green flowers here and there in damp orchards and meadows. The marsh marigold, too, with its handsome yellow calyx, often mistaken for a corolla, may now be seen in marshy places. The pretty little moschatel, with its singular head of flowers, may now also be looked for in damp woods. This curious little plant is well worth examination. The flowerhead consists of five flowers, four lateral and one terminal. The four lateral flowers have each a three-parted calyx, a five-parted corolla, and ten stamens in five pairs, each pair being alternate with a corolla lobe, and united into a sort of ring at their base. The terminal flower has a two-parted calyx, a four-parted corolla and eight stamens. The root, or rather rhizome, is white and coralline in appearance, and is furnished with a number of fleshy scales, from the axil of some of which proceed slender underground branches which propagate the plant.

Among medicinal plants in blossom this month may be mentioned the elm, almond, mezereon, spurge laurel, violet, dandelion, coltsfoot, balsam poplar, and lungwort. Those who have the advantage of living near the New Forest or in the Isle of Wight will find the rare narrow-leaved lungwort, *Pulmonaria angustifolia*, in blossom; specimens of this lovely blue flower having recently been received from our local secretary at Ryde. In that favoured island, too, the broom and other plants usually flowering in May, are already in blossom. The common lungwort (*Pulmonaria officinalis*, L.), called also by Gerarde, cowslip of Jerusalem, spotted comfrey, sage of Jerusalem and sage of Bethlehem, possesses demulcent properties, which enabled it to retain for some time a hold upon the popular estimation it is supposed to have obtained in the first place from the resemblance of its spotted leaves to lungs. The scales usually present behind the stamens in so many of the Boraginaceæ are absent in this little plant, and the scorpioid character of the inflorescence is much less evident than in many others of that family. A lichen (*Sticta pulmonacea*) bears also the name of lungwort, and is described and figured in Pereira's 'Materia Medica.'

In the Botanical Gardens at Regent's Park *Styrax officinale* has been in blossom during the past few weeks. The leaves much resemble those of the quince, and are also downy underneath, while the flowers in shape much resemble those of the orange, but the petals are soft and delicate, not thick and succulent as in the orange. The coca (*Erythroxylon Coca*), of which there are two thriving plants in the economic house, are also in full bloom. A variety of *Citrus vulgaris*, with small leaves like those of the myrtle, and a species of pepper from Java, are also in blossom. In the open ground the almond, mezereon, spurge laurel, lungwort, and periwinkle, and the asarabacca (*Asarum europæum*, L.), may be seen in blossom.

On Wednesday last the first flower show of the year was held at these well-known gardens, and the day being remarkably fine an unusually large number of visitors were present. Usually the corridor only is used, but this year the exhibitors occupied the end and side of the large conservatory also. The show of "Spring Flowers" included orchids and other stove and greenhouse plants, deutzias, bouvardias, azaleas, and cyclamens, hyacinths, tulips and lilies of the valley. Some of the roses exhibited were unusually fine plants for this time of the year, one of the pot roses being of good form and about two feet in diameter by nearly three feet high. A new cyclamen attracted especial attention by its magnificent colour, which is easier to remember than to describe. The large conservatory itself is now quite gay with azaleas, rhododendrons, red and white camellias, acacias and the graceful dielytra, besides innumerable hyacinths and tulips, so that the whole effect of the show was excellent. The next show of spring flowers takes place on April 14.

At Kew the *Drimys Winteri* has been sparingly in blossom and one or two varieties of the orange and of tobacco are still in flower, while in the orchid house a species of Sarracenia (*S. flava*) is flowering freely. In the open ground *Jeffersonia diphylla*, Pers., is full of buds. This plant is known in the United States as rheumatism root, or twinleaf, but is not official in the American Pharmacopœia. Its properties, etc., have been fully described in this Journal by Professor Bentley.* Like most of the Berberidaceous plants, the parts of the flower are four in number and the anthers open by valves. The flower much resembles that of *Sanguinaria canadensis* in appearance, but the leaf is very different, consisting of two kidney-shaped leaflets, whence the name of the plant, "twinleaf." *Mandragora vernalis* and *Hyoscyamus orientalis* are also in blossom and afford to botanical students an opportunity of seeing plants of the natural order Atropaceæ at a time of year when it is very difficult to meet with them.

Through the kindness of Professor Balfour we are enabled to state that at Edinburgh Botanical Gardens the orange, twinleaf, and *Coptis trifoliata*, or gold thread, as it is called in North America, are now in flower, also *Daphne Mezereum*, *Kalmia latifolia* and *Mandragora vernalis*.

'Medicinal Plants' for this month contains figures of *Juniperus Sabina*, *Garcinia Hanburii*, *Cinnamomum Camphora*, *Indigofera tinctoria*, *Guaiacum officinale*, *Sassafras officinale*, and *Amomum Melagueta*. The figure of savin is taken apparently from one of the smaller lateral shoots of a branch, so that all the leaves are closely imbricated, and thus the drawing presents a very different appearance from the more elongated twigs which are generally met with in commerce, and in which the leaves are longer and more spreading. It is a pity that a small piece of a twig with spreading leaves was not figured side by side with the other. The figure of the camphor plant is one of the worst that we have seen. The grotesque distorted appearance of the leaves by no means represents the habit of the plant as we have seen it growing in Kew Gardens, where the figure is said to have been made. The peculiar twist which the artist seems to delight in giving to the leaves is

* Series 2, vol. iv, p. 104.

noticeable also in the leaves of the gamboge plant; but with these exceptions the number is quite equal to the average both in plates and matter.

The preparations for war made by this country are not altogether without their effect upon the domain of pharmacy. Such large supplies of quinine, and citrate of iron and quinine have been laid in by Government as temporarily to cause a considerable and sudden rise in the price of those drugs. Singularly enough, however, large quantities of otto of rose have recently been offered, probably with the view of obtaining high prices. Coca leaves, although often appearing in the lists, do not appear to be in much demand, while of jaborandi there is but little offered. Coto bark has, however, figured more frequently of late in the English market, but is believed to be chiefly exported to Germany again.

Thymol seems to increase in favour, and is rapidly rising to the rank of a valuable disinfectant. The *Medical Times and Gazette* and the *Doctor* have each a paper on the subject, and the former gives a formula for a gauze dressing for wounds, as follows:—Bleached gauze, 1000 parts; spermaceti, 500; resin, 50; thymol, 16 parts. The gauze so made is extremely soft and pliant, and can be accurately adapted to a wound, and according to Dr. Ranke sucks up the blood and secretions of the wound like a sponge. When kept in stock it should be enclosed in a tin case or in parchment paper. Dr. Ranke's experiments show that although thymol is twenty times as expensive as carbolic acid, yet the difference in price is more than compensated for by the extremely small amount of secretion induced by thymol, and the consequent reduction in the number of bandages necessary. He further points out that the redness, vesication and eczema produced by carbolic acid dressings have entirely disappeared when thymol has been substituted.

Mr. Squire has hit upon the excellent idea of adding thymol to adhesive plaster in the proportion of one part to one thousand, so as to render it more antiseptic and less irritating. Dr. Stone, of Westminster Hospital, has found thymol of use in chorea in doses of two to five grains thrice daily.

Dr. F. T. Bond, who is interested in terebene, refers the antiseptic properties of that preparation to the presence of cymene, which he considers to be an isomer of thymene, and "the essential basis of thymol."

The telephone has recently been turned to account for medical purposes. Mr. J. Blyth, secretary to the Society of Engineers of Edinburgh and Leith, has adapted it so that by its means the hearing power of one or both ears can be accurately measured.

From a paper that recently appeared in the *Gazette Hebdomadaire* we learn that wood tar creasote, which is sometimes used in phthisis, is difficult to obtain pure in commerce, and that Messrs. Bouchard and Gimbert, who have been investigating it, give the following as the best tests for its purity:—It boils at 219° C., forms crystallizable salts with potash, but not with soda, gives no precipitate with collodion, and a green and then brown colour to an aqueous solution of perchloride of iron. They recommend the neutral creasotate of potassium as the best form for therapeutical purposes. To make this salt the beechwood creasote is dissolved in half its volume of ether, and mixed with a concentrated alcoholic solution of caustic potash.

Dr. Fothergill, writing from London to the *Philadelphia Medical Times*, recommends strychnia in combination with carbonate of ammonia and tincture of squills, in bronchitis, when the stage of free secretion of phlegm is reached, and also in many cases of difficulty of breathing. It must be supposed that the quantity of strychnia used is not sufficient to be precipitated by the alkali, or the mixture would be a dangerous one.

A new crystalline substance, called phyllic acid by its discoverer, has been discovered in several rosaceous plants, as well as in jaborandi, the fig, etc. It is obtained by treating with ether an alcoholic extract of the leaves, from which resinous and waxy matters have previously been removed by deposition.

Caffeine, in the form of hydrobromate or citrate, has recently been brought into notice as a diuretic by M. Gubler, who states that it acts more powerfully and promptly than digitalis.

Another diuretic which savours somewhat of ancient pharmacy, or of Chinese materia medica, has lately come into notice, and is being advertised in some of the American journals. This is the brown cockroach, *Blatta orientalis*. The dose given is from fifteen grains to half a drachm, in powder or infusion, three or four times a day. It is used in dropsy, and is said to increase both the secretion of urine and of perspiration.

Dr. Galezowski recommends the use of neutral sulphate or nitrate of pilocarpine in preference to eserine in the proportion of one-twelfth of a grain to an ounce of laurel water, which he says possesses the following advantages. When applied to the eye it does not cause the acute pain and nausea sometimes caused by the use of eserine, while the laurel water prevents the formation of fungi and the consequent inertness of the solution.

The application of carbonate of soda to burns and scalds is still under discussion in the medical papers. Dr. Macdonald of Glasgow, who uses ordinary washing soda, in the proportion of 1 lb. to a wash-hand basin of water, finds that the application causes intense pain for from a few minutes to half-an-hour, but that after that time there is no pain, and healing takes place rapidly, so much so, that in some cases after undergoing agonizing pain the patients had nothing to show next day and were looked on as impostors.

Many as are the substitutes that have been proposed for quinine, yet another has recently come under notice, namely the root of *Cassia occidentalis*, which is used in Angola for the treatment of fevers. The plant is known under the name of "Fedegozo," and a decoction is made from the roots which are exceedingly bitter. The seeds after being roasted and ground are used either with coffee or as a substitute for that beverage. In Mauritius, the plant has become naturalized, and there the seeds are also used for a similar purpose to that just mentioned, and are moreover said to be useful in cases of asthma. The plant is also found in both the East and West Indies. Other plants used by the natives in Angola in the treatment of fever are *Vernonia senegalensis*, known as the "Matuto," the leaves of which are very bitter, and are used in infusion; *Chenopodium ambrosioides*, or "Herva Santa Maria," and the "Sangue Sangue," apparently a species of *Cymbopogon*. Mr. Monteiro says—"A common method they have of curing fever is to induce strong perspiration by squatting over an earthen pot (just removed from the fire), sunk in a hole in the ground, in which "Herva Santa Maria" and 'Sangue Sangue' have been boiled. The patient is well covered over, and the aromatic vapour-bath soon produces its desired effect. I have seen blacks cured of severe attacks of fever with one or two applications of this simple remedy." The *Chenopodium ambrosioides* is found in many parts of the tropics, and is generally known as Mexican tea. Its tonic and antispasmodic properties are known in most countries where it grows. In Angola it is said that "in almost every complaint the natives first apply this plant as a remedy. For internal pains of every kind it is taken in decoction, or the crushed plant rubbed over the seat of the pain. Poultices of the fresh plant are employed for swellings, bruises, or blows, and when the back aches from carrying heavy loads, fresh leaves are rubbed on the spine and a handful of the crushed plant is placed between the skin and the waistcoat. For headache the crushed plant is rubbed over the head and plugs of the leaves pushed up the nostrils."

Substitutes for quinine appear to be numberless. An American contemporary quotes a statement from the *Anglo-Brazilian Times* to the effect that a large quantity of the bark of *Cinchona ferruginea*, Mart., has been brought down from Minas Geraes to Rio for extracting from it an acid resin which exists in it in combination to the extent of about 5 per cent. This resin is known in Brazil as Vieirina, or Vieirino, and is said to have been successfully employed instead of quinine as a tonic or febrifuge.

Mustard and cantharides also, may according to Dr. Coutivier, in *L'Union Médicale*, find a rival in extract of pimento, which is said to manifest a rapid and satisfactory revulsive action when applied to the skin. It is conveniently prepared for application by working it into a plastic mass and spreading it on squares of paper; these plasters will then adhere to the skin without warming, although it is as well to use a bandage when applying them to parts subject to much movement.

A new source of musk, or a good substitute for it, Dr. Bertherand, of Algiers, believes he has discovered in the droppings of a small antelope (*A. dorcas*, L.), common in the Sahara. The dried excrement is said to yield to rectified spirit 7 per cent. of a mixture of a resinous principle analogous to musk, benzoic acid, and biliary acid and colouring matters. The resinous principle may also be extracted with carbon bisulphide, but this, as might be expected, affects its odour. The portion soluble in water (3·1 per cent.) contains ammonia and a large proportion of sodium chloride, and there is 26·5 per cent. of insoluble mineral substance, principally calcium phosphate.

Among the "new remedies" which have been recommended lately, the following appear to have arrived at the dignity of being quoted in the price lists; though for how long remains yet to be proved. The quotation is from the spring circular of Herr Merck, of Darmstadt. Acidum cressotinicum; Acidum cressylicum; Acidum laricinicum cryst.; Acidum hydrobromicum; Carboneum monochloratum; Calcium chlorhydrophosphoricum sicc. and liq.; Ferrum citric. effervescens; Gelsemin hydrochloratum and sulphuricum; Hydrargyrum peptonicum fluidum; Lithium valerianicum; Lithium salicylicum; Magnesium ergotinicum; Natrium borosalicylicum; Natrium copaivicum; Natrium cressotinicum; Natrium sylvinicum; Neurin; Zincum boracicum; Zincum oleinicum.

On the above mentioned preparations it may be remarked that the chlorhydrophosphate of lime, in which the phosphate of lime is rendered soluble by hydrochloric acid, was included among the new remedies dealt with recently by the Paris Society, and that a formula for its preparation will be found on p. 1041 of the last volume; the hydrochlorate and sulphate of gelseminine are both said to be freely soluble in water, whilst the uncombined alkaloid is only difficultly soluble; the boro-salicylate of sodium would appear to represent the compound formed when borax is added to increase the solubility of salicylic acid in water, and should at least suggest a doubt as to whether such an addition is justifiable; whilst the salicylate of lithium has been suggested as reducing the difficulty to a minimum, in consequence of the small proportion of alkali in combination.

Salicylate of soda has now been for some time a favourite with the profession, it is readily soluble, and as usually prescribed presents no difficulties, but of late there has been introduced a salicylate of iron which is very insoluble, and a mixture with this salt in it cannot claim to be considered as elegant pharmacy.

It is worth mentioning also that Herr Merck calls attention to certain lamelliform so-called salts of eserine,—sulphate, hydrobromate and hydrochlorate,—that are just now to be met with, which he alleges to be simply the aqueous extract prepared in lamellæ, containing only traces of the alkaloid and no acid.

The question of the antagonistic action of morphia and atropine is being gradually cleared up by constant contributions of facts and cases. Dr. Mackay of Brighton shows that atropine probably circulates much more quickly through the system than morphia. While Dr. Harley points out that one grain of sulphate of atropine injected hypodermically will usually prove fatal whether opium has been previously administered or not, Dr. Fothergill records a case of poisoning by an amount of laudanum equal to twelve grains of opium, which was cured by the subcutaneous injection of the supposed fatal quantity of sulphate of atropine. Another correspondent in the *Lancet* shows that one-fiftieth of a grain of atropine may, where there is idiosyncrasy, be an exceedingly dangerous dose. Thus it appears that in calculating upon the antagonistic action of the two drugs several circumstances must be taken into consideration.

Dr. Farquharson's recent remarks on materia medica examinations in the *British Medical Journal*, are not altogether without interest to those engaged in pharmacy. He considers that the present manner of teaching that subject in medical schools perpetuates the vices of "grinding" in their worst form, and goes on to say that the student of medicine should not be expected to know anything about the adulteration of drugs, as it concerns almost entirely our wholesale druggists.

It may be that the student of medicine has too many subjects to learn at the hospitals, and doubtless it would be far better if such subjects as materia medica, botany, and chemistry formed part of a university education, to be learnt before walking the hospitals; but surely so long as medical men prepare and dispense their own medicines, it is just as much incumbent upon them as upon the pharmacist to know whether their scammony and jalap, their quinine, ipecacuanha and opium, etc., are of good or bad quality, and whether they are adulterated or not. Nor does the subject of adulteration of drugs concern almost entirely our wholesale druggists. It is the retail dealer who is more deeply concerned, and who is liable to penalties for adulteration. The remark that after the necessary examinations "the qualified man restores the elasticity of his brain by throwing much of its tightly packed cargo overboard," is undoubtedly true, but this only tends to show that the examinations are to blame which necessitate the study of such useless learning. This defect is to be seen not in medical schools alone, for the non-medical students who are liable to be asked the ingredient of any preparation in the Pharmacopœia feel bound to "cram" the whole of the Pharmacopœia into their brain until the examination is over, and then forget it as speedily as possible, and use the Pharmacopœia itself when necessary. If, however, Dr. Farquharson's remarks lead to the adoption of measures for altering some of the anomalies which exist in medical schools, or to the removal of some subjects now taught in hospitals to the universities, great good will have been done.

Dr. Churston, of Leeds, writing on the same subject, points out that some of the subjects taught in the hospitals ought to form a portion of the matriculation examination, while Mr. Jessop, of Clifton, calls attention to the necessity of endeavouring to make the student more efficient by practical work.

That a deficiency of material for such work in materia medica exists in some of our hospitals will be evident enough to any one who chooses to visit the museum of the Pharmaceutical Society and see in the attendance book the number of names of medical students who avail themselves of the opportunity of studying practically the characters of drugs.

As evidence of the necessity for such practical knowledge, Mr. Jessop alludes to scores of incompatible prescriptions which he has seen from hospital experts, and mentions two which have recently come under his notice, one of a mixture of dilute nitro-muriatic acid and prussic acid, and the other an acid solution of quinine prescribed with Fowler's solution. He adds, with reason, that "if the youngster does not know the druggists' work he certainly will never get credit for his prescriptions, and if he were to stand (invisible) behind the counter he would hear what would make his ears tingle." It might be added that on account of this want of practical knowledge on the part of medical men, and when the address of the prescriber is unknown, or there is not time to communicate with him, a burden of responsibility is frequently thrown upon the dispensing chemist which the dispenser ought not to be required to bear. For instance, when iodide of potassium and nitrous ether are ordered together (as is not unfrequently seen in a prescription) in a small bottle of medicine, either the patient must be warned against taking the mixture when it becomes dark coloured, thus implying incapacity on the part of the prescriber, or must run the risk of having the blame of bad dispensing cast upon himself, as is sometimes ungenerously or ignorantly done by the prescriber in such cases.

Lecoq de Boisbaudran and E. Jungfleisch have published* an exhaustive paper on the extraction of gallium from the ores in which it is found associated with indium. The blende of Bensberg (the richest gallium ore known) is pulverized, and then roasted in a Perret furnace, by which treatment the greater part of the indium is volatilized. The residue is treated with sulphuric acid in quantity sufficient to dissolve almost all the zinc, and there is thus obtained a residue, which is treated with excess of sulphuric acid. The per-salts of iron present are then reduced by means of metallic zinc, and the filtrate fractionally precipitated with carbonate of sodium; the precipitates are re-dissolved in sulphuric acid, and the reduction with zinc and the fractional precipitation repeated, the latter operation being in both cases watched with the spectroscope. The precipitate containing the gallium concentrated in a small bulk is re-dissolved in acid, and the excess of the latter reagent removed by evaporation, after which it is boiled with much water. The filtrate separated from the sediment containing titanic acid, which forms, is treated with sulphuretted hydrogen, then mixed with acetate of ammonium, and again treated with sulphuretted hydrogen, which throws down the galliferous sulphide of zinc free from alumina. Again the precipitate is dissolved in sulphuric acid, and the solution fractionally precipitated with carbonate of sodium, which operation, guided as it is by spectral examination, entirely removes the zinc. By once more dissolving in the exactly necessary amount of sulphuric acid, and treating with sulphuretted hydrogen, cadmium, lead, indium, and zinc are removed, and the filtrate is then largely diluted with water and boiled. The bulky sub-salt of gallium which separates at this temperature is treated with potash, which leaves iron, indium, etc., undissolved, and the alkaline liquor when treated with sulphuretted hydrogen, and subsequently with sulphuric acid to slight acidity, yields a deposit consisting mainly of sulphide of indium. The slightly acid liquid is then boiled with much water, and the deposit of sub-salt of gallium thus obtained is dissolved in potash, and the solution subjected to electrolysis, by which means a metallic deposit of gallium is obtained.

In an interesting paper, by Fr. Mohr,† it is shown that carbonic anhydride has the power of effecting a number of decompositions hitherto but imperfectly known. For instance, when passed through solutions of the acetates of barium, zinc, and lead, these salts are all decomposed to some extent, and simultaneously the carbonates of the above enumerated metals are precipitated. Mohr further shows that solutions of chromate of potassium, borax, sodium phosphate, microcosmic salt, acetate of sodium, and the tartrates of sodium and potassium, have all the power of absorbing carbonic anhydride, in some instances at least, with decomposition.

H. Klinger‡ has obtained trimethylsulphiodide, crystallizing from alcohol in colourless prisms, by heating methyliodide with sulphur in sealed tubes at 160° to 190°. He has also obtained a platinochloride compound of the formula $((CH_3)_3SCl)PtCl_4$, which crystallizes in cubes and octahedra.

Since the last "Month," Claude Bernard the well-known French physiologist has died. Among his

* *Comptes Rendus*, No. 7, February, 1878.
† Liebig's 'Annalen,' clxxxv, 286—295.
‡ *Deut. Chem. Ges. Ber.*, x, 1880—1881.

most famous researches were those on the pancreas and liver, and the production of artificial diabetes by puncture of the fourth ventricle. On more than one occasion his work in these directions has been noticed in the columns of this Journal, and particularly so, his studies upon glycosuria and the presence of sugar in the blood, a subject, it will be remembered, upon which Pavy holds somewhat different opinions. Then again, Bernard made a fame for himself by his continued studies of the action of various poisons, and among them curare. Among his varied contributions to knowledge was one on the prevention of pitting in small-pox. During an epidemic of small-pox in 1870, Bernard had occasion in a number of cases to puncture each somewhat developed pustule with a needle, washing with tepid water being afterwards resorted to, and he found when this treatment was repeated several times, so as to keep the small wounds open and to allow of the ready removal of the variolus matter, that most satisfactory results were attained in preventing what is usually termed "pitting."

In a note communicated by Pasteur to the Academy of Medicine, regarding septicæmia, he points out that the vibrios characteristic of this disease cannot sustain the presence of oxygen, but they can live *in vacuo* and in carbonic anhydride and be under the circumstances transformed into fully developed germs which can then resist the otherwise destructive action of the atmospheric oxygen.

G. F. Dowdeswell in a communication to a recent number of *Nature*, describes experiments in which water from different sources was allowed to stand at perfect rest for a given time ; on then examining the lowest stratum of liquid in the cylinders, he detected the presence of organisms in large numbers. This fact is interesting only as a confirmation of Pasteur's statement to the same effect, and it will be perceived that the method of investigation is parallel to that employed by Tyndall in his experiments upon the motes the vibration of which in the atmosphere gives visibility to a ray of light in its passage through a darkened chamber.

P. Fürbünger, in some observations on urine, concludes that oxalic acid is a normal and perhaps constant constituent of this liquid, the quantity excreted daily being under 20 mgrm. Part of this oxalic acid seems to exist in the forms of oxalate of calcium kept in solution by the solvent agency of phosphate of sodium.

The *Medical Record* has recently called attention to what it terms, "Sensational Therapeutics," and its remarks are indeed well timed. The special matter to which our contemporary refers, is a statement,* according to which, Dr. Liron has successfully treated three cases of acute articular rheumatism by the subcutaneous injection of a few drops of cold water in the vicinity of the affected part. It is more than foolish even to suppose that such a treatment could have any virtue for the relief of a disease which evidently depends more or less upon a morbid chemical condition of the blood; and yet such assertions as that above referred to are by no means uncommon, even in leading scientific journals. The truth is that the entire age is sensational; men pine for premature fame—for mere empty word-praise, and the more extraordinary their methods of investigation, the more illogical and impossible their conclusions and their results, the greater is the public appreciation which is too often awarded them.

It is the fashion now-a-days to inject all sorts of preparations subcutaneously with the mere object of recording the observed results, and journals on therapeutics are filled with the records of such proceedings. But this is not science. To take half a dozen different substances having no characters in common and no particular chemical relationship, and to inject these into the bodies of animals is likely to prove so much mere waste of time. It is a different thing when parallel experiments are made with a series of substances having definite and determined chemical relations. Here there is some little better hope of increasing the sum of knowledge, for from past experiences there seems to be some sort of connection—indefinite as it is—between the chemical constitution and physiological action of certain principles. But even in such case the act of subcutaneous or other mode of injection interferes with the normal state of the body, and to a large extent the mere effect of the operation cannot be distinguished from the effects of the agent employed.

In imitation of other sensations got up by certain analysts and to which the English public are now well inured, certain continental chemists have caused a scare by announcing the detection of arsenic in a number of samples of beer. If present, its amount is matter for interesting speculation, as it must have been derived from that small quantity present in the pyrites used in making sulphuric acid for converting starch into glucose. Its amount must therefore be something considerably less than that of the copper present in preserved peas, but no doubt there are not wanting in the ranks of scientific men those who are prepared to swear that the presence of infinitesimal traces of arsenic is sufficient to promote the death of persons who persist in drinking this beverage. While writing of beer it may be mentioned that the German Society for the Encouragement of Industry has offered a prize of £125 for the best method of detecting glycerine in beer, it being not an uncommon apprehension in Germany that this fluid is sometimes adulterated with the substance in question.

M. C. Tellier has suggested the use of trimethylamine as a frigorific agent possessing many advantages over ammonia, ether, etc. It is obtained from the residues of the beet root employed in the manufacture of sugar, and is particularly adapted for use in ice-making machines, owing to the slight pressure required for its condensation. A disadvantage attending its use, however, is its disagreeable odour, but this should not prove a serious obstacle to its employment if it can really be obtained in sufficient quantity, and further if, what is more important, it possesses the absorption-capacity for heat which is attributed to it.

Writing to the *Chemical News* of the 8th inst., Lieutenent Bertram A. Muirhead states that safety matches, which, according to advertisement, ignite only on the box, will strike freely on common coal, and he suggests that the reason of this is that the combustible carbon of the coal takes the place of and acts like the amorphous phosphorus of the rubber. It is very much to be doubted, however, whether as the writer suggests, this will lead to the manufacture of a safety match without the employment of phosphorus.

The fact that safety matches can be ignited by

* *Gaz. des Hopitaux*, No. 92, 1877.

friction on a surface of coal has been confirmed by another correspondent of the same journal, and he points out that certain wooden surfaces are also equally efficacious. In such cases the ignition is most probably due to the heat generated by mere friction.

A serious outbreak of diphtheria is reported by Dr. Tripe to have occurred at Upper Clapton, and from his inspection it is evident that the cause of the disease was the access of sewer gas into the water supply of the house, thus making it probable that the continued epidemics of this nature are to be attributed to defective drainage.

The medical world is again agitated by another case of a fasting girl residing at Borth, and of course as in all other cases of this kind she is alleged to have outgrown her clothes and increased in body-weight, notwithstanding that for some time she has been confined to her bed and has eaten nothing. The fact that there are many people and even medical men who place credence in such assertions is as surprising as the mania of Don Quixote and as pitiable as the fanatical views of religious zealots.

In an article on the practice of smoking, the *Daily Telegraph* of a recent date pointed out that in tobacco there is a narcotic and sedative more potent than any known to the Pharmacopœia, if this be true and statistics are worth anything, smokers at least are well narcotized, for in 1841 the quantity of tobacco cleared for consumption amounted to about fourteen ounces for each head of the population; in 1851, the quantity increased to seventeen ounces; in 1861 it had reached nineteen and half ounces; in 1871 twenty-one and a half ounces were consumed, while in 1876, the consumption amounted to nearly one pound and a half for each head of the population.

Every object in creation is said to have its mission; that of the couch grass (*Triticum repens*) has hitherto been pretty generally supposed to be one of plaguing the farmer. A French pharmacist, M. Planchud, has, however, recently suggested for it the nobler mission of a food material, and this in more forms than one. This gentleman has obtained from 100 grams of the dried plant, 3 grams of crystallizable sugar, 4 grams of glucose, 13·9 grams of starch, albumenoid matter represented by 1·45 grams of nitrogen, and 3·25 grams of ash, consisting of silica, lime, magnesia, potash, soda, ferric oxide, phosphoric acid (10·90 per cent.), and sulphuric acid. M. Planchud points out that the proportion of nitrogen in couch grass is therefore as large or larger than in rye, potatoes, beets, hay, or clover, and he suggests it as a cheap source of nourishing fodder and as also capable, mixed with wheat flour, of yielding a bread which though not very white has a more pleasant taste than rye bread. This is not quite new, as the roots are used to some extent in Italy as fodder, and have been used for bread-making in times of scarcity; the grass, however, is not generally deemed to be very nutritious. But M. Planchud further suggests that considering the small value of the material the starch (13·9 per cent.) might be profitably extracted industrially, or by suitable treatment converted into sugar, and, with the sugar existing ready formed, fermented, and used as a source of alcohol. Should it be found profitable to carry out this utilization of waste, it might create a future for many sandy tracts at present lying apparently unreclaimable.

To revert to affairs more specially pharmaceutical, considerable progress is being made in the preparation of materials to be available in the revision of the United States' Pharmacopœia, the next edition of which promises to create some stir in the pharmaceutical world. The committees appointed by the American Pharmaceutical Association and the Philadelphia College of Pharmacy, working in conjunction with two medical committees, have already come to decisions upon several points, and are apparently fairly in accord. The Philadelphia committee is of opinion that the present pharmacopœia should be modified so as to include only one alphabetical arrangement, to have the description of the physical properties of drugs and chemicals extended, and the formulæ for the manufacture of chemicals omitted, except where different results are produced by different processes, descriptions of the substances with tests of identity and purity being substituted. This committee further agreed to recommend the abandonment of measures of capacity, and the substitution of parts by weight. It also favours the introduction of powdered extracts, and that the fluid extracts shall represent grain for grain. At a joint meeting of the committees a resolution was passed that weights and measures ought not to be introduced into the formularies except when required for convenience of dose, and that then the weights should be in grains, with the equivalent metric weight appended between brackets.

It has been remarked in a previous note on the "Dispensing Memoranda," how frequently difficulties occur in dispensing prescriptions through contamination of one or more ingredients, imperfect manipulation in the manufacture of the preparations with which the prescriptions are compounded, or deficiency in strength of the product. In no other way can the result obtained by a correspondent in dispensing the mixture No. 63 be accounted for. Carefully dispensed, and with B.P. preparations, it is the colour of pale sherry, perfectly clear and without sediment, but apparently in the writer's hands it has produced in one instance a "turbid mixture," and in the other one that "turned black as ink." The presence of tannin must be looked for to account for this latter appearance. An imperfectly washed measure will sometimes occasion such a result, which may be designated careless manipulation, or it may arise through some error in the manufacture of one of the preparations. The cause of this change of colour should, if possible, be traced out.

It is an axiom in dispensing that there should be no substitution; when the writer of a prescription orders a preparation of the British Pharmacopœia, his instructions should be strictly carried out. In the instance No. 64 there is not the shadow of a reason for deviation from the strict letter of the law. If the pil. hyd. and the extract were each of the proper consistence, there could have been no difficulty with these pills and the unpardonable crime of substitution would never have entered the mind of the inquirer.

Opinions have for many years been much divided as to the value of the term "gtt." in prescriptions. The question 64* is not by any means new; every now and then it crops up in the Journal, and settles down again into its former position of doubt and uncertainty. At the present time opinions vary as much as ever, and as a necessary consequence there is a divergence of practice, the real question at issue is not, Which is the more accurate, dropping, or measuring? but when "gtt." occurs in a prescription should the ingredient to which it refers be dropped from the bottle, or measured by the minim measure?

It will no doubt be urged that drops vary so much, depending on the density of the liquid, the shape of the lip, the quantity of fluid in the bottle, and also whether the stopper be kept partly in the bottle whilst dropping or be entirely removed, that for accuracy and even in some instances safety the minim measure should in every case be used. But this is begging the question, and may be met by the remark that there is no evidence to show that the writer of the prescription is not as well aware of the difference between a drop and a minim as those are who have taken the trouble to publish tables showing these differences, and that he prescribes his drops accordingly.

In 1842 Mr. Allsop introduced a minim meter, and at the same time remarked on the variable character of drops as compared with minims. Mr. Barnard Proctor shortly afterwards followed in an article commencing with the question, "What is meant by 'gtt.'"? and accompanied it by a table giving the results of many experiments to show the difference between drops and minims. He also suggested the more general use of the minim measure, but he left the real point at issue just where he found it.

What is a drop? "A small portion of any fluid in a spherical form, which falls at once from any body." From a very early period "gtt." has occupied a place in prescriptions, but although the minim as a measure of capacity was introduced into the Pharmacopœia in the early part of the present century, as the smallest liquid measure, still the introduction of the minim does not supersede its more ancient rival, the drop. Guttæ cannot be rendered minims any more than minims can be rendered guttæ; at the same time it must be admitted as most desirable that writers of prescriptions should discontinue the use of the term "guttæ," uncertain and unsafe as it is proved to be, and substitute for it the more definite "minim;" but the change, however much to be wished, must be initiated by the writer of the prescription and not by the dispenser.

The observations in an article in the *Pharmacist* of 1874 on this subject are very much to the point. "The remedy for this evil rests not with the pharmacist but with the physician, whose duty it is, and whose interest it will soon be, to protect him from it." So long, therefore, as the medical profession in their prescriptions make use of the term "gtt.," so long should a dispenser drop that fluid, of which it stands as the symbol of quantity, or an equivalent of that ingredient, determined by previous experiment, by measure, and the responsibility must rest on the the writer of the prescription.

In the present advanced state of medical knowledge and the present position of medical science, it is an anomaly to find "nostrums" of unknown composition take the place of those remedial agents of known and definite composition of which the Pharmacopœia is the depository; but whilst such is the case that preparation generally accepted as the original should be used; in no case can a formula, "represented as the composition of the popular medicine," be accepted by the dispenser of the prescription. Report is no authority.

It is sometimes found that a substance, not of a simple character, as an excipient should be, and foreign to the prescription, has the peculiar property of assisting the formation of a pill mass. It is a fact, and may be worth recording, but at the same time not admissible in a prescription. An instance of this kind occurs in No. 65, where quinine is directed to be made into pills; tartaric acid should not be employed, confection of hips will answer the purpose, but as this excipient colours the pills glycerine and tragacanth is to be preferred.

A medicine is occasionally sent out without any appearance of that change which subsequently takes place. This is exemplified in No. 66; the mixture when prepared show a slight opacity, due to the resin of the tr. nuc. vom., but in twelve hours or so a flocculent matter separates, and subsequently rises to the suface of the mixture, the amount of flocculent matter, which is the resinous portion of the nux vomica in a finely divided state, will depend very much on the care taken in making the tincture. From the result of some inquiries on this subject by Dr. Siebold, embodied in a paper read at the Glasgow Conference, it would appear that much of the tincture of nux vomica examined by him was very deficient in strength. It is quite possible that the writer of the prescription, who may have seen such a mixture when just dispensed, would consider when he saw a flocculent separation at the house of the patient that it had not been properly prepared. The separation of this resinous matter is unavoidable, and would rather indicate that the tincture of nux vomica was of B.P. standard. At the same time such a result suggests a habit of observation, in order to furnish, when called upon, a satisfactory explanation.

Quinine mxtures, such as that of No. 67, have been already commented on. As a rule there is a separation of the quinine, and the same treatment as previously recommended, the addition of a little mucilage, will generally obviate it.

Iodide of iron may be made into pills as in No. 68, by a little glycerine and tragacanth, an excipient very suitable in this case, and the pills may be rolled out without difficulty. As iodide of iron is seldom met with in a satisfactory condition, a better result may perhaps be obtained by proceeding as in pil. ferri iodid., B.P., calculating the proper proportion of iodine and iron to yield the required amount of iodide of iron.

Some pharmaceutical preparations are, through the joint action of light and air, constantly undergoing change, and sp. æther. nit. is one of them. Whatever may be its condition when first drawn over, it very soon becomes strongly acid. In dispensing a prescription with such a preparation, care must be taken that no essential ingredient is decomposed by its action. In No. 69 there is pot. iodid., which would be at once decomposed in contact with acid sp. æther. nit. It is necessary therefore to neutralize the acid present by the addition of an alkali, and probably pot. bicarb. may be most suitable for this purpose. Dissolve the pot. iodid. in a little water, add the remainder of the water to the sp. æther nit., neutralize and mix with the mucilage. In preparing this mixture care must be taken to neutralize the sp. æther. nit., or iodine will be liberated by its contact with pot. iod., and water must be added to the sp. æth. nit. before its addition to the mucilage, or the gum will be precipitated.

The method of procedure in No. 70 will be the same is indicated in other quinine mixtures, where there is a separation of the quinine. The hop contains a good deal of tannin, and the separated portion is most probably tannate of quinine.

It is an important point in making ointments to use a good large mortar. In such an instance as No. 71, the hyd. am. chlor. should be rubbed into a very smooth condition with the glycerine, and the ung. cetacei being subsequently added will make an unexceptionable ointment. The result is not so satisfactory when the ointment is made on a slab, and there is an objection to heating the ointment, since it promotes oxidation and is quite unnecessary.

Sometimes a trifling addition to a prescription requires a change in the method of procedure in dispensing it. No. 71 is an illustration of this; the formula differs from that just commented on by the addition of aq. rosæ to the glycerine. In this instance the plan of melting to a creamy consistence may be adopted, but certainly not the addition of the oxide of zinc in powder. The zinc should be rubbed in a mortar with the glycerine and rose water till quite smooth, and the ung. cetacei being added, the whole should be stirred till cold. There is, however, even here no necessity for melting the ointment; the same plan may be adopted as in the preceding case, namely, the use of a good-sized mortar.

Prescriptions are frequently met with where an essential oil is one of the ingredients, with "q. s." attached to it; but the oil sometimes interferes with the formation of a good mass. Five minims of ol. carui would be, in No. 72, a very good proportion. In this instance a small quantity of glycerine and tragacanth excipient will make a firm mass, easily rolled into pills that will not lose their shape by keeping. When glycerine and tragacanth excipient is used, the mass should be well-kneaded, or more of the excipient will be employed than is necessary, and the subsequent mass may be softer than is desired. The addition of ext. gent., as recommended by a correspondent, is not admissible.

Some difficulties in dispensing are purely imaginary, in as No. 73. It seems scarcely possible to point out any method of procedure, which consisted in putting the ingredients together, that would not result in a satisfactory mixture. The ferri carb. and pulv. rhei, should be rubbed together in a mortar with the sp. chlorof. and water previously mixed. Of course a label to shake the bottle should accompany the mixture.

When a prescription is placed before a dispenser, the vehicle of which has evidently been left out, and he is unable to communicate with the writer he should calculate the dose of each ingredient, taking care that he keeps them all within Pharmacopœia limits. Such a case as this occurs in 74. Probably, as one correspondent has suggested, the mixture was intended for forty ounces, and this would keep each ingredient within B.P. maximum doses.

Not the least difficult part of a dispenser's duties is to compensate for the want of practical pharmacy on the part of some members of the medical profession. If the prescription in No. 75 be written in accordance with the ancient view of the order of a prescription, that the first ingredient should be the basis, the second the auxiliary, the third the corrective, the fourth the vehicle, the balsam of Peru must be an important element, but as it does not enter into a single preparation of the British Pharmacopœia, its medicinal value may be doubted. It forms, however, an ingredient in this prescription, and must be dealt with accordingly. If from half to one-third its weight of calcined magnesia be stirred into the balsam Peru and the mixture allowed to stand some hours the mass may be made into pills; careful manipulation, however, is requisite to accomplish this.

The development of a fungoid growth in a lotion, No. 76, must be due to foreign organic matter in one of the ingredients. It should be prepared by dissolving the borax in the water, adding some, perhaps ℥j of glycerine, and making up to ℥x with distilled water. If it develops a fungoid growth in a week, there must be some impurity present, and the conclusion of the patient would not be far wrong.

Frequently a large quantity of essential oil forms part of a pill mass; how to combine it so that a mass of pilular form and consistence may be made is a difficulty, as in No. 77, and in this instance the ol. sabinæ is an essential part of the formula. It may be done by evaporating the ext. hyoscyam. to a tolerably firm extract, adding some glycerine and tragacanth excipient, and finally, a little powdered tragacanth; the whole of the oil may be taken up, and a good firm pill be made.

Quinine with sp. am. arom. will, as soon as the water is added, separate as a resinous substance, and adhere to the sides of the bottle, whether the quinine be alone or in combination, such as ferri et quin. cit. in No. 78. The addition of a little mucilage, as suggested by a correspondent, will to a certain extent obviate it. The separated substance is quinine, and on no account should it be removed; if it cannot be rendered miscible, it must be left in the bottle, but mucilage judiciously applied will suspend it.

A separation will frequently occur on the addition of an alkali to an infusion or decoction, as in No. 79, where pot. bicarb. is mixed with dec. pareiræ. This is not a case where it is desirable to add anything to diffuse the separated matter. A label to shake the bottle would be all that is necessary.

In making boracic acid ointment, No. 80, it is necessary to dissolve the boracic acid in a little water. This may be done in a test tube, and having melted the other ingredients, add the solution, and stir constantly till cold.

A good deal of trouble in dispensing is caused by want of attention to B. P. instructions, and this is very frequently the case with the extracts. The Pharmacopœia directs that they should be of a pilular consistence. If this were attended to, and extracts always found in that condition, there could be no difficulty in making up such a prescription as No. 81. If to the extracts of a pilular consistence the quinine in powder be added, the resulting mass must almost necessarily be firm. If the extracts be soft they should be evaporated at a low temperature, in a current of air or in a drying closet.

Bromohydric acid made after Fothergill's process contains acid tartrate of potash, and with quinine would throw down tartrate of quinine. If it be pure, —the only article admissible in dispensing—there would in a prescription, such as No. 82, be no precipitate, the mixture would be clear when made, and remain so. No matter by what processs the bromohydric acid be made, the resulting product if used in dispensing prescriptions should be pure. In connection with this subject, Dr. Squibb's paper, which appeared in a recent number of this Journal, is of considerable interest.

Ext. ergotinæ is Bonjean's extract of ergot, a soft extract, and is often combined with quinine, as in No. 83. A very good paper on the preparation of ergotine will be found in the 'Proceedings of the American Pharmaceutical Association, 1877.'

Nervine balsam is occasionally met with in family recipes, and in reply to No. 84, one formula for its preparation is appended.

Expressed Oil of Nutmeg	1 oz.
Oil of Rosemary and Cloves of each .	1 drachm.
Oil of Amber	½ „
Bals. Peru	1 „

Triturate together.

As an excipient perhaps glycerine and tragacanth is more generally applicable than any other, and with the ingredients of the prescription in No. 85, one of the best; a small quantity will be sufficient to convert them into a very satisfactory mass that may be rolled into pills which will maintain their shape.

Ung. plumbi. comp. P.L., as referred to in No. 86, is to some extent dependent on the make of the emp. plumbi. It was a favourite ointment with the late Sir Benjamin Brodie, and he recommended that made by one particular house. Probably the deficiency of the P.L. formula being recognized, great attention to the preparation enabled that house to make a more satisfactory ointment.

It is not professed to do impossibilities in the columns of this Journal, or assistance would gladly be offered in a solution of No. 87. The dispenser should make the pills so that together they weigh 22 grains and rest his reputation on accurate dispensing.

There is no official formula for glycerine of belladonna, but in reply to No. 88, it may be made the same strength as ung. bellad., using glycerine instead of lard. When there is no official formula the dispenser must, in the absence of the writer, be guided by some corresponding preparation that has Pharmacopœia sanction.

That curiosity which is given under No. 89 must in the present condition of our materia medica be considered as having outlived its reputation; some, if not all of the articles composing the receipt, will be found in the old Pharmacopœias, but more elegant pharmacy has taken their place.

It is impossible to make No. 90 without the whole of the bismuth as a sediment, and in addition a gradual subsidence from the lime water. The mixture should have a label indicating that the bottle is to be shaken before each dose.

There must necessarily be a precipitate on adding carbolic acid to liq. plumbi diacet. in making the lotion No. 91, and it certainly cannot be sent out clear, neither should the sediment, carbolate of lead, be filtered out.

If a dispenser studies the variety of combinations which come daily under his notice, and the decompositions which occasionally take place, he will be able to combat these minor difficulties, be in a position to state to his customers that he has accurately dispensed the prescription, and with average intelligence, and a little chemical knowledge, to explain why a certain result ensues, and that if correctly dispensed, no matter from what "London House" it emanates, it must have a similar appearance.

THE ORIGIN OF TRAGACANTH.*

BY M. GIRAUD.

The formation of gum in plants seems to depend upon a peculiar morbid condition, the main phases of which were investigated and described by Trécul in 1860. Although he studied the formation of gum only in the rosaceæ, it has been taken for granted that a similar process yields the gum of the acaciæ, which, being an article of commerce, is of much greater importance. The gum-disease is caused by a fulness of sap in the young tissues, whereby the new cells are softened and finally disorganized. Thus cavities are formed filled with liquid containing the fragments of the destroyed tissues. The cavities gradually increase in size in consequence of the disintegration of the neighbouring cells, and whenever they occur near the epidermal layers they may force an opening through them, and thus cause larger or smaller fissures; but if they remain enclosed on all sides they become receptacles of gum. This gum near the walls of the cavity appears in the shape of gelatinous warts, which grow, turn yellow or brown, and finally fill up the hollow space. When near fibres, it appears first to exude from them and gradually to alter them together with their contents. If the cavities occur near the bark, or near soft woody tissue, their contents occur in the well-known shape of transparent tears.

This is the origin of the gums in the rosaceæ and acaciæ, which consist mainly of gummic or metagummic acid. Tragacanth differs from these gums both in its origin and properties. Hugo v. Mohl considers it likewise as a pathological product, having some similarity with the other gums, and to be the result of a more or less complete transformation of the cells of the pith and of the medullary rays into a gelatinous substance, which swells by the imbibition of water to several hundred times the size of the original cells. On examining the anatomical structure of the astragali furnishing this substance we find that the pith and medullary rays have changed more or less and all the intermediate stages in this gradual transformation are observable. The cells, which originally assumed a hard horny consistence without altering their shape, ultimately condense into a homogeneous mass, in which the cell walls are no longer perceptible. This seemed to confirm the opinion of Guibourt, that the soluble portion of tragacanth consists of arabin and the insoluble portion of a mixture of cellulose and starch, both partly altered. But this view is as little exact as the statement generally met with in the books, that the soluble portion differs from arabin in not being thickened by ferric salts, and that after precipitation by alcohol it possesses a peculiar mucilaginous consistence. The portion insoluble in hot water was called bassorin, and stated to have the general constitution of amylaceous substances, to differ greatly from cellulose, and to be characterized by swelling greatly in water.

Guibourt mentions starch as a constituent and others have observed the same, and that vermiform tragacanth contains more than the flakes; the manner in which tragacanth forms, according to Mohl, would easily explain the presence of starch. But, evidently, if the recognition of such an easily recognizable body has been so difficult, it is even more so to recognize the nature of the main constituent which imparts to tragacanth its principal properties. Indeed, much confusion has existed on this point, and we are therefore the more rejoiced at meeting with researches by Giraud, by which an unexpected light is shed on it.

If, says the author, one part of tragacanth is digested in fifty parts of water, containing 1 per cent. of hydrochloric acid, the liquid filtered and then mixed with baryta water in excess, the gradually deposited precipitate will consist of pectate of barium. If this is collected, washed, diffused in water and then treated with muriatic or acetic acid, the base will dissolve, while the residue will consist of pectic acid. In this manner tragacanth will yield 60 per cent. of pectic acid. The process described shows plainly that pectic acid does not pre-exist in tragacanth, but is formed from some other substance. Giraud explains as follows:—

1. A very small percentage of tragacanth only is soluble

* Translated from *Archiv d. Pharm.*, December, 1877. From *The American Journal of Pharmacy*, March, 1878.

in cold water, not 30 to 50 per cent., as is sometimes stated. The soluble portion is not a substance similar to arabin, but a mixture.

2. If tragacanth is digested, in a water-bath, with 50 times its weight of water, the entire gummy constituent is transformed into a soluble gum, which after having been dried will not swell. The new product is not arabin, but pectin.

3. By subjecting this principle, with water containing one per cent. of acid, to the heat of a water-bath for two or three hours, it becomes entirely soluble, but still consists mainly of pectin, and, though precipitated by alcohol, is not gum, as usually stated. Sugar, formed simultaneously, amounts to scarcely one-tenth of the substance employed.

These experiments show that tragacanth is transformed by these processes into pectin, which is soluble in water, precipitated by alcohol, and by alkalies converted into pectates and metapectates. The pectin is generated from an insoluble pectinous principle, which constitutes more than one-half of the tragacanth, and is apparently identical with Frémy's pectose.

It is well known that pectose occurs largely in the tissues of many fruits and roots; it accompanies, nearly always, cellulose, with which, however, it cannot be confounded; for by the action of acids cellulose is transformed first into dextrin and afterwards into sugar, but never into pectin.

Giraud's observations, it will be seen, contradict Mohl's views, according to which the cellulose of the astragali is transformed into tragacanth.

The author has found tragacanth to have the following average composition;—20 water, 60 pectinous principle, 8 to 10 soluble gum, 3 cellulose, 2 to 3 starch, 3 per cent. of mineral constituents and traces of nitrogenated matter.

THE CULTURE OF CINCHONAS IN JAVA.

The following abstract is taken from the report on the Dutch Government Plantations for 1877:—

First Quarter.—The month of January was very stormy, with relatively a small quantity of rain. At Ragrak the plants suffered very much, about one thousand trees being uprooted. In February and March there were continuous rains. 21,128 Ledgeriana, 1290 succirubra and 6092 officinalis plants were planted. The incessant rains prevented the commencement of the collection. The Ledgeriana plants flowered freely and applications for seeds of this kind have been made from all sides. At the end of March the number of plants was:—

	In the Nurseries.	In the Open air.
Calisaya Ledgeriana	214,489	1,163,405
Succirubra and Caloptera	12,945	163,663
Officinalis	81,607	509,906
Lancifolia	500	36,054
Micrantha	—	512
	309,541	1,873,540

Second Quarter.—Rain fell during April, but the months of May and June were dry. This early dry weather was very favourable for the harvest, which was commenced in the middle of May.

A royal decree of the 28th of May authorized the Director to increase the number of cinchona plants in the plantations by one million.

The collected barks, examined by Oudemans and Stellingwerff, were found to be all that could be desired. The waste from the barks, which was formerly exported after previous pulverization, is now sent away just as it is, with the result that it is more sought for.

In consequence of the favourable season it was possible by the end of June to send to Yicao 25,568 pounds of cinchona bark, whilst a nearly equal quantity was quite ready for a fresh consignment. It is estimated that the general harvest amounted to upwards of 100,000 pounds (Dutch).

Lately the cinchonas have suffered from the ravages of a hemipterous insect, the *Heliopeltis theiovora*, which also attacks the tea plant. These insects, when winged or in the young unwinged state, feed upon the juices contained in the younger portions of the bark. The parts invaded by the insects cease to grow, the leaves as well as the young branches droop, shrivel, and become black, and when all the young branches are attacked, which is generally the case, the plant ceases to grow until the new buds form. For some time past precautions have been taken against the multiplication of this pest, and the destruction of birds in the neighbourhood of the cinchona plantations has been forbidden. It has also been recommended to cut off and burn the young branches that have turned brown, as containing the eggs of the insects. One point worthy of notice is that the low lying plantations suffer most from the attacks of this insect; in those above 3000 feet attacks are rare; whilst above 6000 feet the insect does no harm.

Third Quarter.—These three months were characterized by remarkably dry weather. Rain was rare, and in some stations only one or two rainy days were reckoned. During the whole of this period the temperature frequently descended to 6·6, and twice there was a slight frost during the night. This extraordinary dryness did not injure the larger plants, but many of the smaller plants succumbed. The frosts were very injurious at some of the plantations. The great drought also gave rise to several fires, which in some places spread to the plants. Towards the end of August, when the insects had become rare, the branches that had suffered from them were cut off and burnt.

The harvest now terminated. During the three months there were sent to Yicao, for shipment to Holland, 63,220 pounds of bark, and 3130 pounds for the medical service in Java. About 7000 pounds more were ready for consignment. In September an enormous quantity of seeds was sent out. At this time the numbers of the plants in the plantations were as follows:—

	In the Nurseries.	In the Open air.
Calisaya Ledgeriana and Hasskarliana	201,969	1,118,717
Succirubra and Caloptera	32,437	153,785
Officinalis	83,207	503,268
Lancifolia	500	36,017
Micrantha	—	512
	318,113	1,812,299

WARREN'S STYPTIC BALSAM.

The original formula appears to have been published by Dr. James Warren, of Boston, in the New York *Journal of Medicine* in 1854, and read as follows:—

℞. Acid. Sulphurici .... ℨ v. (by weight)
Spt. Terebinthinæ
Spt. Vini rectif ....āā f. ℨ ij.

Place the acid in a Wedgwood mortar, and add the turpentine slowly, stirring it constantly with the pestle; then add the alcohol in the same manner, and continue stirring it until no more fumes arise, when it may be bottled, and should be stopped with a ground-glass stopper. None but the purest materials must be used, and when done, it should exhibit a dark but clear red colour, like dark blood; but if it be a pale dirty red it will be unfit for use. The dose is 40 drops, and the method of using is as follows: Put a teaspoonful of brown sugar in a tea-cup, and rub in 40 drops of the balsam until thoroughly incorporated, and then slowly stir in the water until the cup is nearly full; when it should be immediately swallowed. This dose may be repeated at intervals of an hour, until three or four doses have been taken, if necessary; and its use should be discontinued when fresh blood ceases to flow. After standing a few days, a pellicle forms upon the surface of the balsam, which should be broken and the liquid below it used. It does not deteriorate by age, if tightly stopped.

The "balsam" is recommended to be used in hemoptysis, hematemesis, epistaxis, and menorrhagia, and some of our correspondents say that it has proved very serviceable in their hands.

The Pharmaceutical Journal.

SATURDAY, MARCH 30, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE MEDICAL ACTS AMENDMENT BILL.

SOME months ago, when Dr. LUSH's Medical Acts Amendment Bill was under the consideration of the Medical Council, it was the opinion of the Committee which reported on the Bill, that the Legislature would never accept a provision of such stringency as that by which any unregistered person practising medicine or surgery for gain would have been rendered liable to prosecution and penalties. The same Committee suggested that attempts to repress medical imposture should be deferred until such time as the Medical Acts had received all requisite amendments in the provisions relative to the medical profession itself; for, as Mr. SIMON tersely pointed out, the Council could not conveniently consider how to deal with trespassers until it was known what were the limits of the medical profession as fixed by law.

A step in the direction of providing that internal regulation of the medical profession has just been made by the introduction into the House of Lords of another Bill to amend the Medical Acts.

The Duke of RICHMOND and GORDON, in presenting the Bill, said it was intended to remedy some of the defects of the Medical Acts now in force, and especially to meet the difficulty existing in Scotland owing to which it has not yet been feasible to establish a conjoint Board and have one uniform qualifying examination for medical practitioners.

To judge from the comments of the several medical papers, this Bill does not appear to be regarded with much favour by the medical profession, and the *Times* characterizes its various provisions as forming a sort of ornamental frame, the weak point of which is that it contains no picture.

The sections of the Bill which have, as they now stand, most interest for the trade are those relating to unregistered persons and to the practice of dentistry.

The section relating to this latter subject provides, like Sir JOHN LUBBOCK's Bill, for the registration of all persons, *bonâ fide* engaged in the practice of dentistry, either separately or in conjunction with the practice of other branches of medicine or surgery. It also provides that any unregistered person who practises dentistry for gain, and uses the designation of dentist or its equivalent, is to be subject to a penalty of twenty pounds.

As regards the general practice of medicine or surgery the Bill recognizes but two classes of persons, viz., those who are registered and those who are not registered, and it provides that if any one of the latter class takes or uses the designation of any qualification or medical diploma which entitles a person to be registered or call himself physician, surgeon, apothecary, or doctor, or by any other designation used to distinguish registered practitioners of medicine or surgery, or to indicate the possession of a qualifying certificate or qualification to practise medicine or surgery, he renders himself liable on summary conviction to a fine of twenty pounds.

It is important, however, to note in reference to this section of the proposed Bill that all it does with the object of enabling the public to distinguish between competent and incompetent practitioners is to restrict the use of titles to such persons as have been placed upon the medical register and have thus become duly qualified. There is not only no approach towards a prohibition of practice by unregistered persons, but there is a direct assumption that such persons do practise; and in the very wording of the section this is evident, since it speaks of persons who, not being registered in medicine or surgery, practise for gain or are engaged in the cure or treatment of diseases or injuries, and it is these persons who are to be liable to penalties not for practising but for assuming titles indicating qualification, or in other words that they are registered.

There is also in the Duke of RICHMOND's speech a like recognition of the fact that medical men properly so-called who possess the due legal qualification have not thereby any special monopoly of the practice of medicine, for after pointing out that the Bill does not attempt to prohibit any unregistered person from practising he remarked parenthetically—"that is impossible." The *Times* likewise expresses the same view in commenting upon the Bill as one which deserves to be considered by all actual or possible patients almost as closely as by practitioners themselves, and while insisting that unqualified persons ought not to be able to represent themselves as being other than they are, admits that no one would wish in the present state of civilization and enlightenment to render so-called medical practice by unqualified persons impossible.

These expressions of opinion are of no small importance in reference to the pretensions of a certain section of the medical profession, and they have such a cogent bearing upon the attempts which have recently been made to stir up strife between medical men and chemists and druggists that we think it worth while to call the attention of our readers to them as endorsing what we have always maintained to be a proper view of the subject.

We thoroughly agree with those who think that there should not be any question with regard to the propriety of granting special privileges to those who take the pains to acquire the skill and knowledge requisite for rendering efficient medical or surgical services to the community, inasmuch as these special privileges constitute a means of fostering and encouraging such skill and knowledge. But while doing this it is by no means necessary to admit that other persons, who have not applied themselves in the same manner, are not to be at liberty to recommend the use of simple remedies without trenching upon the legitimate province of the medical man. To do this would be to debar every housewife from administering the wholesome dose of brimstone and treacle, whose virtue she has learnt from her grandmother, without dreaming of the medical register, and if unregistered persons generally have the right to recommend and administer medicines to each other in this way it is simply ridiculous to contend, that those among them who from their training and daily avocations are necessarily most conversant with the properties and uses of drugs and medicines should be in a legal point of view less competent to do what it is open to anybody else to do without limitation.

We do not attempt to contend that in what is termed counter practice, no chemists and druggists exceed the limits within which such practice should be restricted, and at the same time we know that a large number refuse altogether to prescribe, upon the principle that it is undesirable for the pharmacist to do so. But neither circumstance can be reasonably urged as furnishing an argument against the propriety of a chemist and druggist giving his customers the benefit of his knowledge of drugs and their uses to suit the requirements of the moment, and if it can be maintained that this is practising medicine that does not in any degree lessen our belief in the soundness of the opinion that it is impossible to prevent it.

THE EVENING MEETING.

An Evening Meeting of the Pharmaceutical Society will be held at 17, Bloomsbury Square, on Wednesday next, the 3rd of April, when the following papers will be read:—"Salicylic Acid," by Mr. J. Williams; "Note on Grindelia robusta," by Mr. E. M. Holmes; and "Note on the Alkaloid of Duboisia myoporoides," by Mr. A. W. Gerrard. The chair will be taken at half-past eight o'clock precisely.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the above Association will be held on Wednesday next, April 3rd, at its room, 29, Brewer Street, Regent Street, when a paper on "Pill Coating" will be read by Mr. Bull.

We are glad to know that Mr. James George Frazer, who has taken the second honours in the Cambridge University Classical Tripos, is the son of Mr. Daniel Frazer, Pharmaceutical Chemist, of Glasgow. It appears to us to be a subject for congratulation that although some persons think the Preliminary examination too severe a test of the education required by a young man aspiring to become a chemist and druggist, there are instances which show that pharmaceutical associations are not always deemed incompatible with a much higher standard.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on March 22, Dr. Gladstone, F.R.S., President, in the chair. After the announcement of visitors, etc., the following certificates were read for the first time:—Messrs. G. A. George, W. Jago, H. W. Jones, and J. W. Knights. The President then announced that Mr. E. Neison having proposed Mr. C. T. Kingzett as a member of the Council, the name of the latter gentleman would be suspended along with the list of names recommended by the Council.

The first paper was read by Dr. Otto N. Witt—

On Aromatic Nitrosamines. In 1874 the author made some experiments on the action of nitrous acid and especially its ethers on secondary and tertiary amines; the facts observed were communicated to the chemical societies of Zurich and Berlin. In his inaugural dissertation (1875) the author gave a detailed account of the formation and properties of diphenylnitrosamine. Since that time a more careful study of some complicated reactions of diphenylnitrosamine has been made, and the results of these investigations the author gives in the following paper:—Whenever a secondary amine is acted upon by nitrous acid water is given off and a nitrosamine (*i.e.*, a substituted ammonia which contains, instead of at least one hydrogen, the monovalent group NO in immediate connection with the ammoniacal nitrogen) is formed. Thus—

$$\underset{\text{Diethylamine.}}{\begin{matrix} C_2H_5 \\ | \\ NH \\ | \\ C_2H_5 \end{matrix}} + HONO = H_2O + \underset{\text{Diethylnitrosamine.}}{\left\{\begin{matrix} C_2H_5 \\ | \\ N{-}NO \\ | \\ C_2H_5 \end{matrix}\right.}$$

Similarly by the action of ethylic nitrite, amylic nitrite, or nitrous vapours on diphenylamine, diphenylnitrosamine is formed. This latter substance crystallizes readily in large honey-coloured monoclinic crystals, melting at 66·5°, soluble in alcohol, benzol, etc. It dissolves rapidly in concentrated sulphuric acid with a beautiful blue colour, large quantities of nitric oxide being evolved. Powerful reducing agents split off ammonia and reproduce diphenylamine. The action of aniline and other primary monamines on diphenylnitrosamine is violent, diphenylamine being regenerated with the formation of diazobenzol, the latter forming successively diazoamidobenzol and amidoazobenzol. Under certain circumstances a secondary reaction takes place, a substance, $C_{36}H_{29}N_5$, being formed, which when heated with sulphuric acid gives a blue colouring matter with a crimson fluorescence and a spectrum with three dark bands. If ordinary ethylic nitrite, obtained by passing nitrous vapours into alcohol, be used, a mixture of products is formed, in the investigation of which the author encountered much difficulty. When burnt in a combustion-tube these bodies gave off rapidly large quantities of nitrous vapours, whilst a very dense charcoal was left behind which was difficult to burn completely.

On investigation, the author found that the substance commonly called anhydric nitrous acid (prepared by the action of nitric acid on starch, etc.) is really N_2O_4, and splits up by contact with alcohol or water into nitric and nitrous acids. Thus ordinary ethylic nitrite always contains nitric acid. The author therefore used mixtures of pure amylic nitrite and nitric acid; acting with these on known weights of diphenylamine, and moderating or accelerating the reactions by the use of various solvents, he has obtained mononitrodiphenylnitrosamine, and two bodies, which on the removal of their nitroso groups, yielded dinitrodiphenylamine and an isomer,—mononitrodiphenylnitrosamine. To 20 grams of diphenylamine finely powdered, a mixture of 15 c.c. nitric acid, 35 grams pure amylic nitrite and 100 c.c. of methylated alcohol is added; on shaking, and if necessary heating, crystals separate; the liquid is now cooled by ice, when a crystalline deposit is obtained which is filtered off, washed with spirit, dried and recrystallized from chloroform. This substance forms light yellow plates, melting at 133·5° C., soluble in benzol, hot alcohol and glacial acetic acid; when treated with strong sulphuric acid it gives off nitric oxide, the liquid becoming purple. By the action of aniline or alcoholic potash, mononitrodiphenylamine was obtained in pale yellow glistening scales melting at 132° C.; it does not colour sulphuric acid, but dissolves in alcoholic potash with a fine red colour. By the action of bromine on mononitrodiphenylnitrosamine dissolved in glacial acetic acid, two products were obtained: one in canary-yellow coloured silky needles, fusing at 208·5°-209°, the second in heavy well-shaped small prisms, melting at 214·5° to 215°. If instead of the quantities given above, the following be used: 17 grams diphenylamine, 50 c.c. glacial acetic acid, 40 c.c. nitric acid, 50 c.c. methylated spirit, and 48 grams nitrite of amyl, a light yellow sandy powder is obtained which dissolves in sulphuric acid with a dirty violet colour, nitric oxide being given off. The analyses seemed to indicate a formula intermediate between di- and trinitrodiphenylnitrosamine. The author therefore acted on the substance with aniline and alcoholic potash, and precipitated the resulting liquid with dilute hydrochloric acid. By treating this precipitate with alcohol, a solution was obtained, which furnished long thick pointed dark yellow needles, fusing at 214°, dissolving in alcoholic potash with a bright purple colour. Analysis proved this substance to be dinitrodiphenylamine. The residue insoluble in alcohol was recrystallized from xylene and obtained in granular vermilion crystals, fusing at 211·5° which dissolve in alcoholic potash with a scarlet colour. Analysis proved this substance to be isomeric with the last. All the above substances, when treated with strong nitric acid, yield hexanitrodiphenylamine. The author points out that the method of nitration above described will probably be found applicable in many cases where nitration has hitherto offered unusual difficulties, and also lends some support to the theory that the formation of nitroso compounds always precedes the introduction of the nitro-group into the molecule of aromatic substances. The author mentions in conclusion that Mr. Meldola communicated to the *Chemical News* (February 8th, 1878) a note on a new colouring matter; on examination this new dyestuff "citronin" turned out to be a mixture of mono- and dinitrodiphenylamines. Mr. Meldola, on learning that the author had been engaged with these bodies for some years, relinquished the investigation. For this act of courtesy the author thanks Mr. Meldola, but wishes to state that the merit of the practical application of this substance as a dyestuff belongs solely and entirely to that chemist. The author promised a second paper in continuation of the research, and stated that but for the incident just referred to he should not have published his researches at so early a date.

Mr. Meldola said that Dr. Witt had given a perfectly correct statement of the case as far as he was concerned; at the time he first obtained citronin, he was aware that Dr. Witt had been working at the subject, and therefore thought that he was the proper person to communicate with; his communication, he ventured to think, considering the interesting paper they had just heard, had been attended with the happiest results as regards the Society and himself.

Mr. Groves remarked that when phenol is acted upon by dilute nitric acid a small quantity of nitroso compounds seems to be first formed; also in the formation of trinitroorcin, nitroso compounds seemed to be at first produced, thus confirming the statement of Dr. Witt.

Dr. Armstrong thought that although in many cases we had evidence of the preformation of nitroso compounds, yet it probably was not always the case. Thus some of the sulpho acids of phenol nitrate with very great readiness, without any indication of nitroso compounds being formed.

After a short discussion between Drs. Armstrong and Witt as to the constitution of the bodies mentioned in the above paper, the President gave the best thanks of the Society to Dr. Witt for his interesting paper, which was illustrated by experiments and the exhibition of specimens of the above beautifully crystallized substances.

The next paper was read by Dr. Armstrong, and was entitled—

On a New Process for the Volumetric Estimation of Cyanides. By J. B. Hannay. The cyanide is dissolved in water and the solution is rendered alkaline by ammonia. A half strength decinormal solution of mercuric chloride is run in with constant stirring. At first the reaction $2KCN + HgCl_2 = Hg(CN)_2 + 2KCl$ takes place, but as soon as all the cyanide has been thus decomposed, the slightest trace of mercuric chloride renders the liquid distinctly opalescent. The end of the reaction is sharply marked and very delicate. Many experiments were performed as to the action of alkaline sulphites, chlorides and nitrates; the results were similar to those already obtained by Tuson and Neison (*Chemical Society's Journal*, 1877, ii., 679). Very large quantities of ammonium salts prevent the appearance of the opalescence; cyanates and sulphocyanides do not interfere; the presence of silver salts does not hinder the reaction. The author, therefore, recommends the process as one of great facility.

The next paper was read by Mr. M. M. P. Muir—

On Certain Bismuth Compounds. Part VII. In the first portion of this paper the author details reactions illustrating some points of contrast between bismuthous and phosphorous chlorides. The latter substance is oxidized with comparative ease, and therefore acts as a reducing agent in certain reactions; the former undergoes only incomplete oxidation, and therefore exerts no action in such cases. The two oxalates of bismuth, $Bi_2 3 C_2 O_4 . 6 H_2O$ and $Bi_2C_4O_8$ are then studied. Experiments on the production of some so-called bismuthates are next detailed. The author inclines to the hypothesis that the higher oxides of bismuth exhibit exceedingly feeble acid characters. The paper concludes with the description of some experiments on bismuthous iodide. The oxidation of this compound by air when in a fused state is compared with the behaviour of the corresponding chloride and bromide under similar conditions; the iodide oxidizes much more slowly than either the chloride or bromide. Bismuthous iodide prepared in the wet way is more readily decomposed by water than the same salt prepared in the dry way.

The thanks of the Society were given to the author, who exhibited an interesting series of bismuth compounds.

Mr. Williams then exhibited a splendid sample of a salicylic acid, about twenty-four ounces, prepared from the oil of wintergreen, the natural product crystallizing apparently better than the artificially prepared acid; also about one gallon of pure methylic alcohol.

Dr. Witt, in answer to Mr. Maxwell Lyte, said that the "vinasses," formerly a waste product of the beetroot sugar manufacturer, had lately been utilized under a patent for the production of methylic chloride, which was largely used by the aniline colour manufacturers. The gas was prepared, washed, and pumped into metal reservoirs each containing twenty-five kilogrammes. The patentee, Brigonnet, making as much as one thousand kilos a day.

The Society then adjourned to April 4 (Anniversary Meeting, Saturday, March 30), when a lecture "On the Application of the Microscope to some Special Branches of Chemistry," will be delivered by H. C. Sorby, F.R.S.

UNIVERSITY OF EDINBURGH CHEMICAL SOCIETY.

The seventh meeting of the session was held on March 13; Mr. W. Inglis Clark, B.Sc., in the chair.

A paper was read by Mr. Adrian Blaikie on the "Salts of Trimethylsulphine," containing the results of an investigation carried on by Professor Crum Brown and the author.

The hydrate of trimethylsulphine obtained by acting on the iodide of trimethylsulphine with moist oxide of silver in concentrated solution rapidly absorbs sulphuretted hydrogen, forming a sulphydrate of trimethylsulphine.

$$(CH_3)_3\,S.OH + H_2S = (CH_3)_3S.SH + H_2O$$

The strong solution of this hydrate has all the reactions of an alkaline sulphydrate, and when evaporated oxidizes slowly to the hyposulphite of trimethylsulphine.

The sulphide of trimethylsulphine is obtained by mixing equal quantities of solutions of oxyhydrate and sulphydrate of trimethylsulphine.

$$(CH_3)_3\,S.OH + (CH_3)_3SSH = \left\{(CH_3)_3S\right\}_2 S + H_2O$$

The aqueous solution when evaporated over phosphoric anhydride in an atmosphere of coal gas, does not crystallize out, but after a certain strength of solution has been reached begins to decompose into sulphide of methyl,

$$\left\{(CH_3)_3S\right\}_2 S = 3\,(CH_3)_2S$$

which, when the solution is contained in a sealed tube, separates out, forming a layer of sulphide of methyl above the aqueous solution. This solution has, however, all the characteristics of an alkaline sulphide. It dissolves sulphide of antimony, gives the reaction with sodic nitroprusside, and with hydrochloric acid gives off sulphuretted hydrogen, leaving the chloride of trimethylsulphine, easily recognized by mercuric chloride, when the double salt crystallizes out. When exposed to the air the sulphide of trimethylsulphine is rapidly oxidized to the hyposulphite.

The hyposulphite of trimethylsulphine is best obtained by oxidation of the polysulphide obtained by dissolving sulphur in the sulphide.

$$\left\{(CH_3)_3S\right\}_2 S + 4S = \left\{(CH_3)_3S\right\}_2 S_5$$

By exposing the polysulphide to the air for a few days the sulphur crystallizes out, and the hyposulphite is left in solution, and by careful evaporation is obtained in clear four-sided prisms with one molecule of water of crystallization.

$$\left\{(CH_3)_3S\right\}_2 S_5 + 3O = \left\{(CH_3)_3S\right\}_2 S_2O_3 + 3S$$

The following are results of analysis:—

I. 0·1192 gr. substance gave 0·0745 gr. H_2O 0·1086 gr. CO_2

II. 0·2299 gr. substance gave 0·1402 gr. H_2O 0·2056 gr. CO_2

III. 0·2600 gr. substance gave 0·8459 $BaSO_4$ = 0·1161 gr. S.

	Found I.	II.	III.	calculated for $\left\{(CH_3)_3S\right\}_2 S_2O_3 + H_2O$
C	24·85	24·64	——	25·35
H	6·94	7·06	——	7·04
S	——	——	44·65	45·07

The salt is very hydroscopic, sparingly soluble in alcohol and gives all the reactions of an alkaline hyposulphite. Over phosphoric anhydride the water of crystallization is given off. 7·261 grams of the salt lost 6·37 per cent of water, which is present in the crystallized salt to the extent of 6·33 per cent.

This compound if interesting from a theoretical point of view, since the constitutional formula may be represented with dyad, tetrad, and hexad sulphur atoms in one molecule.

$$\begin{matrix}(CH_3)_3\equiv S^{iv} - S^{ii} \\ (CH_3)_3\equiv S^{v} - O\end{matrix}\Big\rangle S^{vi} \begin{matrix} = O \\ = O\end{matrix}$$

For the same reason, on the assumption that the polysulphide is a sulphate in which all the oxygen atoms are replaced by sulphur, and also because in it, on this assumption, we may have seven atoms of sulphur directly grouped together, is the polysulphide of trimethylsulphine from which the hyposulphite is obtained.

$$\begin{matrix}(CH_3)_3\equiv S^{iv} - S^{ii} \\ (CH_3)_3\equiv S^{iv} - S^{ii}\end{matrix}\Big\rangle S^{vi} \begin{matrix} = S^{ii} \\ = S^{ii}\end{matrix}$$

The anhydrous hyposulphite when carefully heated to 135° C. gives off sulphide of methyl. 5·545 grams gave off when heated 23·58 per cent. sulphide of methyl, leaving on cooling a white crystalline mass soluble in water, alcohol, and ether, and very hydroscopic. The quantity of sulphide of methyl given off points to a methyl-hyposulphite of trimethylsulphine, since if the hyposulphite gave off 23·30 per cent. sulphide of methyl we should expect a substance having that composition.

$$\left\{(CH_3)_3S\right\}_2 S_2O_3 - S\,(CH_3)_2 = \begin{matrix}CH_3 \\ (CH_3)_3S\end{matrix}\Big\rangle S_2O_3$$

This product of decomposition is at present under investigation; by further heating at 140° sulphurous acid gas is evolved.

The oxalate of trimethylsulphine is obtained by acting on the iodide with oxalate of silver, and can be obtained in clear very hydroscopic plates with one molecule water of crystallization. The following are the results of analysis:—

I. 0·1526 gr. substance gave 0·1082 gr. H_2O 0·2068 gr. CO_2

II. 0·1823 gr. substance gave 0·1296 gr. H_2O 02489 gr. CO_2

	Found I.	II.	Calculated for $\begin{matrix}COO—S(CH_3)_3 \\ COO—S(CH_3)_3\end{matrix} + H_2O$
C	36·95	36·78	36·92
H	7·87	7·89	7·69

On carefully heating the salt at 110° C. the water of crystallization is given off, and at 140° C. sulphide of methyl, leaving pure oxalate of methyl, which crystallized out, and was recognized by its melting point 51° C. and its boiling points 157° C.

$$\left\{(CH_3)_3S\right\}_2 (OOC)_2 + H_2O = (CH_3)_2(OOC)_2 + 2S(CH_3)_2 + H_2O$$

The chromate and iodate of trimethylsulphine can both be prepared by means of the silver salts from the iodide. Both these salts on heating to about 140° C. melt, but immediately afterwards explode, the former leaving green oxide of chromium. The further decomposition of the hyposulphide of trimethylsulphine and of various other salts is under investigation.

A paper was also read by Mr. John Treharne, M.B., C.M., "On the Cooling of Fats."

If equal bulks of the fats of mutton, beef, pork, and butter, and palm oil be heated to 100° C. in small flasks fitted with a thermometer through the cork, and then allowed to cool by radiation under the same conditions for each, the temperature is found to fall regularly to a certain point (which is different for each of the fats above named), and then to rise to a certain turning point. These turning points are approximately as follows:—

For Mutton	fat	40° C.
,, Beef	,,	28·5°
,, Pork	,,	26·5°
,, Butter	,,	23·5°
,, Palm oil	,,	21°

The extent of the rise in temperature is different in each fat, being greatest in that of mutton, and least in that of butter and palm oil. The extent of the rise is also greater within certain limits the greater the quantity of fat employed; but, as a rule, the turning point is pretty constant for the same fat. There is also a little difference in the turning points and the extent of rise according to the part of the carcase from which the fat has been taken.

If temperature and time be taken as co-ordinates, and the rate of cooling be represented by curves these latter will be characteristic of the respective fats.

A mixture of equal parts of mutton and butter fats does not give a curve intermediate between those of its two components; but is such as to indicate that less heat is given out in cooling (to 20° C. say) than in the case of butter, which, compared with mutton fat, gives off very little heat.

LONDON INSTITUTION.

On Monday, March 11th, a most interesting lecture was delivered at the London Institution by Mr. Francis Darwin. We take the following report of it from *Nature.*

The Analogies of Plant and Animal Life.*

BY FRANCIS DARWIN, M.B.

Let us begin our inquiry into the analogies of plant and animal life by comparing the egg of an animal with the seed of a plant. Let it be the ripe seed of a common plant, and the egg of a bird. Both seed and egg may be said to consist of the young creature and a supply of food which is stored up for its use, and is gradually exhausted as the young creature develops. Every one who has tried when a boy to blow a late bird's egg must have been painfully alive to the fact of its containing a young animal, and the egg we eat for breakfast may serve to remind us of the store of food which we diverted from its proper course of nourishing a young chicken.

Here is a diagram representing a section through the seed of a poppy, in which the young plant may be seen lying in its store of food containing a supply of carbohydrates and nitrogenous matter, which is consumed as the yolk of the egg is consumed by the young chicken. Other seeds, such as a bean, an acorn, or an almond, seem at first sight to consist of nothing but the young plant, and to have no store of food. The two halves into which a pea split are the two first leaves or cotyledons of the young plant, the embryo stem and root being represented by the little projecting mass lying between the two halves at one end of the seed. Here the store of food is laid up in the body of the young plant just as many young animals carry with them a store of food in the shape of the masses of fat with which they are cushioned; the two leaves which seem so gigantic compared with the rest of the plant are filled with nutriment, and perform the same function of supplying food for the growth of the seedling which is performed by the mass of nutrient material in which the embryo of the poppy seed is embedded. Recent researches have shown that embryo plants are possessed of powers which even in the present day it seems almost ludicrous to ascribe to them. I mean powers of digestion. Gorup-Besanez,† a distinguished German chemist, found that in the germinating seed of a vetch a ferment exists similar to the ferment in the pancreatic secretion of animals—a secretion having the power of reducing both nitrogenous bodies and starch to a condition in which they can be utilized and absorbed by the tissues, so that the embryo plant behaves exactly as if it were a minute animal digesting and absorbing the store of food with which it is supplied. The power of digesting starch possessed by the embryo plant has been brilliantly demonstrated by van Tieghem,* who found that the embryo removed from the seed of the marvel of Peru (*Mirabilis jalapa*) was distinctly nourished if placed in an artificial seed made of starch paste. He found that the starch paste was actually corroded by the young plant, proving that a digestive ferment had been at work.

This wonderful experiment is of special interest as proving that the digestive ferment is a product of the young plant itself, just as the digestive juice of an animal is a secretion from its stomach. It is indeed a striking thought that whether we grind up a grain of wheat to flour and eat it ourselves as bread, or whether we let the seed germinate, in which case the young plant eats it, the process is identically the same.

The power of storing up food in a fixed condition and utilizing it when required is a most important function both in animal and plant physiology. And just as this utilization is seen in the seed to be brought about by a ferment—by a digestive process—so probably wherever the transference or utilization of food stores occurs it is effected by ferments. If this be so it would seem that the processes of digestion proper, as they occur in the stomach and intestines of animals and on the leaves of carnivorous plants, I say it is probable that these processes are only a specialization† of a widely spread power, which may exist in the simplest protoplasmic ancestor of animals and plants. In this case we shall have no right to consider the existence of carnivorous plants anything strange or bizarre; we should not consider it, as seems sometimes to be done, an eccentric and unaccountable assumption of animal properties by plants; but rather the appearance of a function which we have quite as much right to expect in plants as in animals. Not that this view makes the fact of vegetable digestion any less wonderful, but rather more interesting as probably binding together by community of descent a wide class of physiological functions. Let us now pass on to consider the analogies of plants and animals in a more advanced stage of life.

Great differences exist among animals as to the degree of development attained before the young ones enter the world. A young kangaroo is born in a comparatively early stage of development, and is merely capable of passive existence in its mother's pouch, while a young calf or lamb soon leads an active existence. Or compare a human child, which passes through so prolonged a condition of helplessness, with a young chicken which runs about and picks up grain directly it is out of its shell. As analogous cases among plants, we may take the mangrove and the tobacco plant. The ripe seed of the mangrove is not scattered abroad, but remains attached to the capsule still hanging on the mother plant. In this state the seeds germinate and the roots grow out and down to the sea-level, and the plant is not deserted by its mother until it has got well established in the mud. It is due to the young mangrove to say that the conditions of life against which it has to make a start are very hard on it. The most intrepid seedling might well cling to its parent on finding that it was expected to germinate on soft mud daily flooded by the tide. Perhaps the same excuse may be be offered for the helplessness of babies—the more complicated the conditions of life, the greater dependence must there be of offspring on parent.

Now compare a young tobacco plant with the mangrove. All the help the seedling tobacco receives from its parent is a very small supply of food; this it uses up in forming its first pair of leaves; it has then nothing left by way of reserve, but must depend on its own exer-

tions for subsistence. By its own exertions I mean its power of manufacturing starch (which is the great article of food required by plants) from the carbonic acid in the air. In this respect it is like a caterpillar which is formed from the contents of the egg, but has to get its own living as soon as it is born.

In many cases there is a certain degree of independence in young creatures, which are nevertheless largely dependent on their parents' help. Thus, young chickens, though able to feed themselves, depend on their mother for warmth and guidance. A somewhat parallel case may be found among plants. It has been shown that the large store of reserve material in a bean is not all needed for the development of the seedling. It has been proved that well formed and flourishing seedlings are produced, even when a large part of the cotyledons has been removed. In fact, the store of food in the bean has been said to play a double part in the plant* first, as giving absolutely necessary formative material, and secondly, as protecting the young plant in the struggle with other plants, by supplying it with food till it is well established and able to make its own food. This view was fully established by my father,† who sowed various kinds of seed among grass in order to observe the struggle; he found that peas and beans were able to make a vigorous start in growth, while many other young plants were killed off as soon as they germinated.

The young bean is thus indirectly protected by its mother from death, which the severe competition entails on less fortunate seedlings. This kind of protection can only in a certain general sense be compared with the protection given by parent to offspring. Nevertheless, a more strictly parallel case may be found among animals. Certain fishes retain the yolk bag, still containing a supply of food, and swim about leading an independent life, carrying this store with them. Among plants, a good case of a retention of a store of food occurs‡ in the oak. Young trees possessing woody stems and several leaves may still have an acorn underground with an unexhausted store of food.

In comparing the lives of plants and animals, one is struck with the different relation which the welfare of the race bears to the welfare of the individual. In plants it is far more obvious that the aim and object of existence is the perpetuation of the species. The striking and varied development of the reproductive organs in plants is one factor in this difference. Roughly speaking, plants strike us most by their flowers and seed—that is by organs serving the interest of the race. Animals are most striking on account of their movements, which are chiefly connected with the wants of the individual. If a child wants to know whether a stick *is* a stick or a caterpillar, he touches it, and if it walks off classes it in the animal kingdom. Of course, I do no not mean that the power of movement is a mark of distinction between animals and plants, but it certainly is a power which is well developed in most animals, and badly developed in most plants. It is the absence of locomotive powers (as opposed to the absence of simple movements) that especially characterizes most plants. One sees the meaning of this if one inquires into mode of life of stationary and of locomotive animals. Stationary animals either inhabit the water, or else are parasitic in habits, and live on tissues of plants or animals. In either case the absence of locomotion has the same meaning. Many aquatic animals derive their food from the minute organic particles floating in the water, so that even though they lead a stationary life, food will be brought to them by the currents in the water. Parasitic animals obtain their food directly from the juices or sap of their host, so that they do not need to move about as other animals do in search of food. In the same way plants live like parasites on the earth, penetrating it with their roots and sucking out its juices; and their food—carbonic acid—is brought to them by the currents of the air, so that like both an aquatic and a parasitic animal, they have no need of locomotion as far as concerns the obtaining of food.

In the case of many young animals their powers of locomotion would be useless unless the eggs were deposited by the mother in a proper place; one cannot imagine anything more forlorn than a caterpillar reared from an egg laid anywhere by chance, and expected to find its proper plant. The necessity of finding proper places to lay her eggs implies the necessity of locomotion on the part of the mother. This need of locomotion is, of course, equally a need to the plant, but it is supplied in a distributed way. The seeds themselves becomes locomotive; they either acquire plumes to fly on the wind like the seeds of dandelions or they become burrs and cling to passing animals, or are distributed in other ways. Various and strange are the means of transport adopted by seeds; for instance, the acorn seems to distribute itself by deliberately trading on the carelessness of creatures which are usually considered its superiors in intelligence. Good evidence exists that young oaks which grow scattered in large number over a wide extent of wild healthy land have sprung from the acorns accidentally dropped by passing rooks. In all these cases the young plant has to trust to chance as to what kind of soil it will be deposited in, and this of course accounts for the enormous number of seeds produced by plants. Some seeds are more fortunate in possessing a kind of mechanical choice or power of selecting suitable places to grow in. Many years ago my father described a plumed seed which, when damped, poured out a sticky substance capable of gluing the seed firmly to whatever touched it. Imagine such a plant blown by the wind over some sandy waste; nothing tends to stay its course till it happens to pass by a region where the soil is damper; then it sends out its sticky anchors, and thus comes to rest just where it has a chance of germinating favourably. Again, some seeds have a certain amount of locomotive power independent of such external agencies as wind or passing animals. I mean a power of burying themselves in the ground; the seeds of grasses are the best known of these self-burying seeds; and among them the feather-grass, or *Stipa pennata*, is the most conspicuous. These seeds possess a strong, sharp point, armed with a plume or tuft of recurved hairs, which act like the barbs of an arrow and prevent the seed from coming out again when it has once penetrated the soil. This arrow-like point is fixed at the lower end of a strong awn, which has the remarkable property of twisting when dried and untwisting when wetted. Thus the mere alternations of damp nights and dry days cause the arrow-like point to rotate, and by another contrivance, which it would take too long to go into, the point is pressed against the surface of the ground and actually bores its way into it. Fritz Müller described in a letter to me how these twisting grass seeds bury themselves in the extremely hard and dry soil of Brazil, and are thus no doubt enabled to germinate. Unfortunately these boring grass-seeds do not always confine themselves to penetrating the soil, but exercise their powers on both men and animals. I have received accounts from India and from Italy of the way in which the sharp-pointed seeds work their way through thick trousers into the legs of unfortunate sportsmen. But the most extraordinary case is that of certain grass-seeds which work their way into sheep. They often penetrate the skin deeply and in large numbers, inflicting great tortures and often causing death by emaciation. Mr. Hinde, of Toronto, has given me the details of this plague to sheep farmers as it occurs in Buenos Ayres. Another observer described it in Australia.* He states that not unfrequently

* Haberlandt, 'Schutzeinrichtungen in der Entwickelungen der Keimpflanzen,' 1877, p. 29. The idea is quoted as originally given by Sachs, *Vienna Acad.*, xxxvii., 1859.

† See 'Origin of Species,' 5th edition, p. 60.

‡ 'Haberlandt,' p. 12.

* C. Prentice, *Journal of Botany*, 1872, p. 22.

the seeds are found actually piercing the heart, liver, and kidneys of sheep which have died from the effects. I believe that the northern part of Queensland has been actually given up as a sheep country because of the presence of this grass.

Another use to which locomotion is applied by animals is that of finding a mate at the proper season. The curious imitation of the courtship of animals which is found in vallisneria is well known. The stalk grows with extreme rapidity up through the water till the female flower reaches the surface, and there awaits the approach of the male flower, which breaks loose and floats down the stream to meet her. But most plants have not even this amount of locomotive power, and are therefore compelled to employ either the wind or insects as go-betweens. Fortunately for the beauty and sweetness of our woods and fields, insect fertilization is the commonest means adopted; and all the bright flowers and sweet smells of flowers are nothing but allurements held out to insects to entice them to carry the fertilizing pollen from one flower to another. It is curious to find a plant adopting a new mode of conveying its pollen when the old one fails. Thus, a wild cabbage-like plant which grows in Kerguelen's Land is now fertilized by the wind; that is, it produces dry dust-like pollen, which is easily carried by the wind. Now this cabbage is the only species in the enormous order of the Cruciferæ which is not fertilized by insects; so that we may be certain that a change has taken place for which some sufficient reason must exist. And the reason of the change is no doubt that the insects in Kerguelen's Land are wingless, and are therefore bad distributors of pollen. And to go one step further back, the reason why the insects are wingless is to be found in the prevalent high winds. Those insects which attempt to fly get blown out to sea, and only those are preserved which are gradually giving up the habit of flying. Thus the pollen of the cabbage has to learn to fly, because the insects will not fly for it.

In considering the analogies between plants and animals, one cannot merely compare those functions which are strictly and physiologically similar in the two kingdoms. One rather sets to work and studies the needs which arise in either a plant or an animal, and then discovers in what way the same need is supplied in the other kingdom. There is no connection between a plant having bright flowers and an animal's power of walking about, yet they may, as we have seen, play the same part in the economy of the two lives.

In the life of animals the first needs that arise are supplied by certain instinctive movements. The young chicken only escapes from its egg by some such movements. Mr. W. Marshall has also shown that the chrysalides of certain moths possess instinctive movements by which they escape from the cocoon or outer case. In one case a sharp spike is developed, sticking out from the side of the chrysalis, and as the latter rotates the spike saws the cocoon all round, so that the top lifts off like a lid. Again, in young chickens Spalding has shown the existence of an instinctive power of obtaining food, and instinctive recognition of the hen by sound only. This was proved by a newly-hatched chicken, which had never heard or seen its mother, running towards a cask under which a clucking hen was hidden. The powers of growth which exist in young seedlings would certainly be called instinctive if they existed in animals, and they are quite as indispensable as those just mentioned in supplying the wants which first arise.

These two instincts are the power of directing the growth in relation to the force of gravity, and in relation to light; the first being called geotropism, the second heliotropism. As soon as the young root emerges from the seed-coats, it turns abruptly downwards, perceiving like the chick in what direction the earth, its mother, lies. Thus the young plant fixes itself firmly in the ground as quickly as possible, and is enabled to begin to make arrangements for its water supply. At the same time the young stem grows upwards, and thus raises itself as much as possible over its neighbours. The power of directing itself vertically upwards is also a necessity to the plant, because without it no massive growth like that of a tree would be possible. It would be like a child trying to build a wooden house with bricks that did not stand straight. Thus, both the young stem and the young root have an instinctive knowledge as to where the centre of the earth is—one growing towards the point, the other directly away from it. This fact is so familar to us, that we fail to think of it as wonderful; it seems a matter of course, like a stone falling or a cork floating on water. Yet we cannot even generalize the fact so far as to say it is the nature of all stems to grow up, and all roots to grow down, for some stems, such as the runner of a strawberry, have a strong wish to grow down instead of up, and side roots that spring from the main ones, though their method of growth is identical with that of the main roots, have no wish to grow downwards. We can find no structural reason at all why a root should grow down and a stem up. But we can see that if a plant took to burying its leaves and rearing its roots into the air, it would have a bad chance in the struggle for life. It is, in fact, the needs of existence which have impressed these modes of growth on the different organs of the plant in accordance with their various requirements. On the other hand, the plant is not absolutely tied down by geotropism, it is not bound to grow *always* in a vertical line, but is ready to be turned from its course if some other direction can be shown to be more advantageous. Thus Sachs* planted peas in a little sieve, and as the roots emerged underneath, they were enticed from the vertical by an oblique damp surface. This power of giving up the line of growth for the sake of a more advantageous position, must be of great service to roots, by enabling them to choose out damp places in the earth which a blind adherence to rule would have caused them to pass by.

(To be continued.)

Reviews.

EPITOME OF SKIN DISEASES. By TILBURY FOX, M.D., F.R.C.P., and T. C. FOX, B.A., M.B. Second edition. Renshaw. 1877.

Although not written to supersede "larger works" on the same subject, this little book has been correctly named an epitome, as it contains in a small compass a large amount of information on the causes, diagnosis, and treatment of skin diseases, rules for diet, and a very comprehensive "Cutaneous Pharmacopœia."

The formulæ are so important that they merit more careful revision and the adoption of more uniform nomenclature. To justify our criticism and recommendation we will take preparations of *lead* for example In formula 14 "lead water" occurs; elsewhere we find "solution of lead," "solution of subacetate of lead," and in 77 "lead." Again, in formula 48B oil of almonds is ordered: is essential or fixed oil intended? As it stands a dispenser would use fixed oil and be justified in doing so; a fault not very important possibly, yet recognizable. Formula 92 puzzles us as to the quantity of yolk of egg, as does 75 with regard to the quantity of sulphate of zinc intended. These may probably be (we conclude ʒi of vaschine is in 134) typographical errors, yet they may leave prescribers in doubt, which is not desirable. In making "iodide of starch," is it advisable "to boil together" the starch, glycerine, and water?

The "Diet for Skin diseases" with which the book concludes will doubtless prove of service and be read with interest as the expression of opinion on such a subject by such eminent dermatologists as the authors of this valuable "epitome."

* 'Text Book of Botany,' Eng. Tr., p. 764.

A GUIDE TO THERAPEUTICS. By ROBERT FARQUHARSON, M.D. ED., etc. London: Smith, Elder and Co. 1877.

The comparatively small size of this work and the absence of anything absolutely new in it might naturally lead to the inquiry, for what class of readers is it intended? An examination of the title page and a dip into its pages will soon unravel the mystery. The way in which the whole subject is condensed into as small space as possible, and, with few exceptions, rendered in simple and lucid wording, exhibits such practical knowledge as would only be attained by considerable experience as a lecturer in a medical school. The work is evidently intended as a text book for medical students and by no means as a classical work of reference. The author is well aware how necessary it is to impress upon the student the most important facts and principles. That this is the case is further proved by the arrangement of the drugs in the same order as that in which they are found in the works in materia medica, so that the two subjects can, as it were, be studied in parallel lines. The preliminary chapter on therapeutics is exceedingly valuable and should be read and re-read until thoroughly appropriated, by every student of medicine who aspires to succeed in his practice. In one point in this chapter it is, nevertheless, difficult to agree with the author. He states that in these enlightened times, "the cases are very rare in which it is necessary to conceal from patients the presence of any particular drug in their mixture." If this be so, the practice of physicians at hospitals and elsewhere is at variance with the statement. The strong common sense, however, which runs through the preliminary chapter may well be illustrated by the following quotation.

"Tablespoons, teaspoons, and all domestic measures, are absurdly variable in size, and we shall do well to steadily discountenance their use in all cases, and to insist that our patient shall carefully regulate his dose by means of those graduated glasses which are within the reach of all but the very poorest."

The way in which prescriptions are scattered irregularly throughout the work, nearly always without directions as to the special circumstances in which they should be used, appears inexplicable. Of these an example will best illustrate their apparent uselessness, at least in the way in which they are presented to the student in this work.

"℞ Tincturæ hyoscyami ♏xxx; potassæ carbonatis gr.x; syrupi papaveris ʒij; aquæ camphoræ ad ℥jss. Misce fiat haustus horâ somni sumendus. Narcotic."

This prescription follows a paragraph in which hyoscyamus has been recommended in lunacy practice, in affections of the bladder, and for cough mixture, and not long after another paragraph in which a remark has been made as to the peculiar property of fixed alkalies of acting as antidotes to the narcotic properties of belladonna, which are known to apply equally to stramonium and hyoscyamus. It must be confessed too that the heading for veratria is exceedingly puzzling, as it stands "SABADILLA, VERATRIA (THE ALKALOID OF CEVADILLA)." This, as well as the substitution of the name of Professor Attwood for Professor Attfield on p. 282, and the fact that coca, on almost the last page of the volume, is included among the substances yielding caffeine, seem to point to the author becoming a little careless as the work approached completion. The book is, however, closed with an excellent series of questions, which are not only carefully framed so as to be eminently practical and adapted to bring out as much knowledge as possible in the answers to them, but are highly suggestive of the directions in which the student should prosecute his reseaches. The medical student who has but limited time at his command and who wishes to acquire a practical knowledge of therapeutics will do well to peruse carefully this work before entering upon such classical treatises as Ringer's or Bartholow's, or Wood's.

Dispensing Memoranda.

[80]. I should have ventured to have answered this last week, but was in hopes of some one kindly suggesting a better way, at least one that would do away with the large amount of trituration that this ointment undoubtedly requires to ensure success. I have made large quantities of this ointment, from the fact that Professor Lister's antiseptic treatment is practised at this hospital, and seemingly with great success. I make it thus: First dissolve the wax and block paraffin in the almond oil; then transfer to a mortar "previously warmed;" then add the boracic acid finely powdered and rub well together for some time until it presents somewhat the appearance of whipped cream; then transfer to a cold mortar in pieces of about an ounce at a time and continue the trituration until a smooth ointment is formed, which I generally succeed in producing in appearance like the zinc ointment of the B. P. This ointment will keep good any length of time.

J. A. CULFE.

Ipswich.

[80]. If "Quærens" will rub the Boracic Acid with a few drops of Spt. Vini Rect. to reduce the acid to a fine powder he will have no difficulty in preparing a smooth ointment with his recipe.

I also send the following formula, which is easily and quickly prepared, and answers its purpose:—

℞ Acid. Boracic. . . . . . 1 part.
Spt. Vini Rect. . . . . . q.s.
Adipis Præpar. . . . . . 5 parts.

T. WALTON.

[84]. NERVINE BALSAM.—In answer to "Spes'" inquiry, I beg to enclose him formula for "Nervine Balsam":—

℞ Oil of Mace . . . . ℥iv.
Beef Marrow . . . . ℥iv.
Melt and add—
Oil of Rosemary . . . . . . ʒij.
Oil of Cloves . . . . ʒj.
Balsam of Tolu . . . . ʒij.
Camphor . . . . ʒj.
Dissolved in—
Spt. Rectif. . . . . ʒiv.

"AN ASSOCIATE."

[84]. NERVINE BALSAM.—

Beef Marrow . . . . ℥4 } melt.
Oil of Mace . . . . ℥4 }
Balsam of Tolu . . . . . . ʒij.
Oil of Cloves . . . . ʒj.
Camphor . . . . ʒj } dissolve.
Spt. of Wine . . . . ℥ss }

M. S. A.

[84]. NERVINE BALSAM.—In answer to "Spes" I beg to hand the following recipe for Nervine Balsam—

℞ Beef Marrow, Expressed Oil of Mace each ℥iv.
Balsam of Tolu . . . . ℥ij.
Oil of Cloves, Camphor . . . . each ʒj.
Rectified Spirit . . . . ℥ss.
Mix.

Nottingham. W. W. TALBOT.

[85]. Extract of Gentian, if of soft consistence, will be suitable. It would have been better if a copy of the prescription had been given, the size of the pills being intimately connected with the excipient required.

WM. DUNCANSON.

[85]. Glycerine Mucilage to soft consistence.

J. B. L. M.

[87]. I should imagine the first dispenser read the number as xvi. instead of vi.; at least this would account for the size.

J. B. L. M.

---

[88]. GLYCERINE OF BELLADONNA.—

℞ Glycerini . . . . ℥ss.
Ext. Belladonnæ. . . . . ʒj.

Misce.

It should form a thin paste. ℥iss of the belladonna is sometimes used. Triturating the extract with a very few drops of water before adding the glycerine will facilitate the combination.

WM. DUNCANSON.

---

[88]. GLYCERINE OF BELLADONNA.—In reply to Mr. Cleland's inquiry two formulas are given in Squire's 'Pharmacopœia of the Hospitals,' either of which I presume may be termed "Glycerinum Belladonnæ."

The formulas are

1st. Extract. Belladonnæ . . . . . . ʒj.
Glycerini . . . . ʒiv.

This is the London Ophthalmic Hospital formula.

2nd. Extract. Belladonnæ,
Glycerini, āā partes æquales.

This is the Middlesex Hospital formula.

AN ASSOCIATE.

---

[88]. GLYCERINE OF BELLADONNA.

℞ Ext. Belladon.,
Glycerini, partes æquales.

Misce bene.

JOHN W. TINDALL.

---

[88]. GLYCER. BELLADONNÆ is made of different strengths, the most useful being one part of Ext. Bellad. rubbed smooth with three parts of glycerine.

THOMAS WALTON.

---

[88]. GLYCERINE OF BELLADONNA.—In reference to this query in the Journal of 23rd inst., I shall be glad if you will insert the following answer.—At University College Hospital we use a preparation of glycerine and belladonna which is made as follows—Extract of Belladonna 4 parts, to which is added 1 part of water. This being rubbed into a smooth paste an equal quantity of glycerine is added. The water is added to satisfy the hygroscopic action of the glycerine, as if no water be added it is rather troublesome to get the preparation of a smooth consistence.

H. J. PAVEY, *University College Hospital.*

---

[91]. The rosewater has absorbed carbonic acid, which is the cause of the turbidity of the mixture. In making distilled water I reject all that does not stand the test of liquor plumbi diacet.

GEORGE THOMPSON.

Alston.

---

[91]. If freshly distilled rosewater free from carbonic acid be used, and the lead solution likewise be clear, the resulting lotion would be free from opacity or precipitate.

J. B. L. MACKAY.

---

[92]. Will you kindly insert the following prescription in the next issue of the Journal under "Dispensing Memoranda"?—

℞ Magnesiæ . . . . ʒj.
Aquæ Anisi . . . . ad ℥vj.
Spirit. Ammon. Aromat. . . . ʒij.
Tinct. Card. Co. . . . . . . ʒij.
Chlorodynii . . . . gtt. xx.

M. Capiat cochl. ampl. ij. bis. in die.

In dispensing the above, which B. P. preparation of magnesia would be the correct one to use?

T. F. E.

---

[93]. How can I dispense the following prescription which may be called "A Puzzle"?

℞ Potassii Iodidi . . . . ʒij.
Ext. Cinch. Flav. Liq. B. P.
Aquæ . . . . āā ℥iss.

M. Capiat coch. min. j. bis die c. aqua.

I have tried several methods, but find in every case I fail, for directly the pot. iodid. is added the bark separates and sticks to the side of the bottle, and violent shaking has no effect upon it; in fact I gave it up as a bad job, besides spoiling three ounces of ext. cinch. flav. liq. Perhaps some of your readers can enlighten me. I used aq. destill.

30, *Highbury Park.* FREDK. HEATH.

Notes and Queries.

[578]. HOPGOOD'S SEDATIVE OINTMENT.—Can any one inform me what the formula for this is?

WM. DUNCANSON.

---

[579]. Can any of your readers kindly give me the formula for making Mist. Ferri Comp. Conc. so that one drachm of solution with two and a half grains of Ferri Sulph. shall be equivalent to one ounce of Mist. Ferri Comp., B.P. I have obtained preparations from two different wholesale houses; one sends me a thick solution to make it with, the other a clear one—which is correct?

BETA.

---

[580]. SAFFRON PASTE.—Will some reader kindly give information concerning Saffron Paste, its nature, its value, and its uses?

HARVEY, *Margate.*

---

[581]. IRISH SLATE.—Will any of your English correspondents say what is supplied when "Irish Slate" is asked for?

W. L.

---

[582]. ESSENCE OF GINGER.—Will you kindly inform me through the medium of the Journal the best method of making Gingerade with Essence of Ginger without rendering it turbid?

F. W. ANDREW.

---

[583]. CELLAR LABELS.—Can any reader suggest a reliable Label Varnish for ordinary written labels for cellar stock, to prevent damping and falling off?

Stony Stratford. H. J. W. COX.

Obituary.

Notice has been received of the death of the following:—

On the 9th of March, 1878, Mr. Charles George McCarthy, Chemist and Druggist, Cardiff. Age 43 years.

On the 21st of March, 1878, Mr. George Hick, Pharmaceutical Chemist, Bradford, Yorkshire. Age 26 years. Mr. Hick had been a Member of the Pharmaceutical Society since 1872.

Correspondence.

**** No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

Patent Medicines.

Sir,—I was glad to see three letters in the last week's issue having reference to the sale of patent medicines. I think it is high time the vast body of chemists and druggists were bestirring themselves in the matter, and getting the sale of patent medicines confined only to persons who are on the register. That a licence costing only 5*s.* can be obtained by any person who chooses to apply for it, thus enabling him to sell medicines containing poisons, ought not any longer to be allowed, as it not only robs us of what is the legitimate right of a qualified and registered chemist, but also materially interferes with our returns.

As to the scandalously low prices which grocers and drapers charge for patent medicines, the practice is too well known to need any remarks from me.

In these days of competition and great depression in trade it behoves us to look very sharply after our interests, for what with Adulteration Acts, etc., we are harassed more than our position (since the passing of the Pharmacy Act) justifies. In conclusion, let us bear in mind that "Unity is strength," and try our utmost to get the excise authorities to refuse to grant patent medicine licences to unqualified persons

"Tento."

Discrepancy of Examination Results.

Sir,—Will you allow me, through the medium of your columns, to promulgate a few remarks upon the above subject.

I thoroughly indorse and concur with the letter by Mr. Boa which appeared in your last issue.

The Preliminary is essentially an elementary examination; the questions asked are evidently selected with this object in view, and nothing is required but what should and ought to be forthcoming from every would-be student of the Society. Apropos of the subjects for examination, I think these were fully and sufficiently explained and treated upon by Mr. Boa, and therefore need no additional remarks of my own.

I have it upon most reliable authority that a youth who has passed his respective standards at a national school, or at any other school under the new Educational Code, would pass readily and most satisfactorily both in the English and the arithmetic required for the Preliminary. The Latin, as previously shown by Mr. Boa, is a minor consideration, and would not involve the expenditure of very much time in preparing for it.

The following came under my cognizance a year or two ago. A youth educated at a middle-class school, who had a moderate general knowledge, together with a slight groundwork of Latin, but had never read an author, after having left school two years, during which time all studies were neglected, prepared for one month only, presented himself for examination, and passed creditably.

Obviously, the standard is not so high that the requirements are not within the reach of any ordinary student, consequently there are no grounds to warrant the lowering of it.

"Examination" is universally acknowledged to be a very inefficient and insufficient test of knowledge and education, notwithstanding there are those who not only do not scruple to avail themselves of the advantages afforded by its deficiencies, but also wish to dishonourably augment the general defects by proposing that the standard be lowered (no personal allusion is here made to any previous letter writer). Such a procedure would be irrational and *mal à propos*, egregiously incompatible to all sound sense, and an irreparable wrong to the pharmaceutical community at large.

If persons desirous of becoming chemists fail to see the necessity for adopting some fair and sensible standard, or find themselves incompetent to pass the necessary examinations, let them quietly withdraw from the "chemical world" and not disturb the general peace by superfluously complaining about such trivialities.

Sutton-in-Ashfield. George Daubeny.

The Election of Council.

Sir,—It has been my privilege to vote at recent elections of the Council of the Pharmaceutical Society. Under the existing plan I think it more than probable that I have each time voted for some candidates who entertain different views from myself on various subjects of interest to myself and chemists generally, to obviate which I propose that each candidate should issue a short address stating the principles he intended advocating if elected. The addresses might be issued on one sheet as a supplement to the *Pharmaceutical Journal*.

A Provincial C. and D.

Note on Boa-tam-paijang.

Sir,—In a note in the last issue, Mr. J. R. Jackson points out that this drug is the seed of *Sterculia scaphigera*, Wallich., and implies that this fact was not known to the late Daniel Hanbury, apparently having overlooked Mr. Hanbury's paper in the *Pharmaceutical Journal* (2nd series), vol. iv., p. 106, which is also copied into 'Science Papers,' pp. 289, 290. In the 'Hist. des Drogues,' 6ième ed., vol. iii., p. 646, published in 1869, it was also referred to *Sterculia scaphigera*, Wall.

The identification of the drug appears to be due in the first place to M. Decaisne, who requested, in May, 1862, the late Daniel Hanbury to compare it with the above-named plant. In the Hanbury herbarium, now in the possession of the Pharmaceutical Society, is a specimen of the leaves of the seedling plant raised at Bangkok by Sir R. H. Schomburgk in 1859, and a seed with the large leafy follicle attached, accompanied by a letter from the late Dr. A. O. Black, bearing date Royal Gardens, Kew, May 19, 1862, and stating that the seed, with follicle attached, was one of Mr. Griffith's specimens from Malacca. It would thus appear that on receipt of M. Decaisne's letter Mr. Hanbury at once compared the drug with the herbarium specimens at Kew, and, being convinced of their identity, published the note above alluded to in the *Pharmaceutica Journal* in August, 1862. E. M. Holmes.

A Correction.

Sir,—Will you allow me to correct an error made by the compositor in setting the type for my letter bearing on the examinations in last issue? I refer to p. 763, col. i., lines 35 and 40 from top, where what I penned as "Mr. S——" has been inserted as "Mr. Schacht."

James B. L. Mackay.

D. A.—See an answer to a similar question in vol. iv., p. 1011 of the present series of this Journal.

"*Neglected.*"—You are recommended to consult the Secretary, 17, Bloomsbury Square.

W. Blain.—You are mistaken in supposing that the regulations concerning the examinations are kept "'neath a mystic covering," since they are printed in the published Calendar of the Society, besides which we believe a copy of the Regulations is supplied to any person making a proper application for one to the Secretary.

J. B. L. M.—We believe the publication is only partial. You could obtain the information from the Librarian of the Institution.

"*Dispenser*" is thanked for his communication.

"*Exposition.*"—The office of the *Moniteur de la Pharmacie* is at 6, rue Git-le-Cœur, Paris.

A. P. S.—Apply to the Secretary, 17, Bloomsbury Sq.

"*Aberdonia.*"—Strictly speaking there is a difference, but the two terms are frequently used to designate the same substance, as in the case of the ordinary chloral hydrate.

T. H. North.—The formula of the preparation has not come under our notice; perhaps the maker might give you the information you ask for.

"*Oleum.*"—We cannot find in the Petroleum Act any such provision as that described by you.

"*Member of the Pharmaceutical Society.*"—The fi meeting was held at the Crown and Anchor on the 15th February, 1841.

A. Billington.—A letter addressed to the Company at Newcastle-on-Tyne would reach them.

Communications, Letters, etc., have been received from Mr. Hardwick, Mr. Hick, Messrs. Hogarth, Mr. Hudson, Professor Landerer, Mr. Troughton, Mr. Andrews, An Assistant.

NOTE ON SALICYLIC ACID.*

BY JOHN WILLIAMS, F.C.S.

Having had occasion during the past few months to prepare some quantity of salicylic acid from the natural source, namely, the oil of wintergreen (*Gaultheria procumbens*), an oil of American origin, and much used as a scent in the United States, I have been led to make some practical observations on this acid, which, although still very incomplete, I will venture to lay before the Society.

Salicylic acid is now so extensively made by the artificial process discovered by Professor Kolbe, and has proved of so much importance both in medicine and the arts, that the comparison of the natural acid with the artificial, tending as it must to throw light upon the real nature and purity of the artificial article, is a matter of great interest, not only to members of the Pharmaceutical Society, but to the medical profession and scientific chemists generally.

It is not my intention to give any account of the chemical constitution or properties of the acid; that has been done so well and so fully by others, and reported in our Journal, that I shall not take up the time of the meeting by entering into any details of that nature.

The oil of wintergreen is, as is well known to chemists, mainly composed of salicylate of methyl, a natural combination of salicylic acid and methyl alcohol (or wood naphtha); it is accompanied in the oil by a small quantity of another essential oil, not acted on by caustic alkalies, and possessing a very pronounced and characteristic odour, not at all like the wintergreen oil from whence it is derived.

When the wintergreen oil is treated with a solution of caustic potash and distilled the compound salicylate of methyl is decomposed, the salicylic acid uniting with the potash, while the methyl alcohol, together with other volatile matters, distil over. The salicylate of potash thus produced is decomposed by hydrochloric acid, which precipitates the very insoluble salicylic acid; this is subsequently recrystallized several times from boiling water, treated with pure animal charcoal, and finally recrystallized from weak spirit (one part of alcohol to four or five of water); in this way the acid is produced in fine crystals, large, white, and distinct. The methyl alcohol which has been distilled over in the first part of the process can be recovered and purified; it must be largely diluted with water to separate the neutral oil, then filtered several times through charcoal to remove the last traces of that oil and afterwards rectified, and finally distilled from dried carbonate of potash, and, if required absolutely anhydrous, from fresh quicklime. In this way methyl alcohol is obtained quite free from the empyreumatic flavour which is generally associated with the idea of naphtha! Samples of the salicylic acid, the methyl alcohol, and the undecomposable essential oil are on the table.

The artificial salicylic acid is made from carbolic acid; and in very few words, for the benefit of the younger portion of those present, I will give an outline of the process, which is one, I may add, of very great interest to chemists from a purely scientific point of view, as well as important in a commercial sense.

Simply stated, the process consists in uniting carbolic acid with soda to form a neutral salt. This is subjected to a temperature of about 200° C. when a current of dry carbonic acid is passed through it. Half the carbolic acid united to the soda combines with the carbonic acid to form salicylic acid, which remains united with the soda, the remainder of the carbolic acid distils off. The resulting rough salicylate of soda is decomposed by hydrochloric acid, and the salicylic acid thus separated purified by suitable recrystallizations.

It is a remarkable fact that if potash be substituted in the above process for soda, no salicylic acid is produced, but another closely allied body, named paraoxybenzoic acid, is the result; this acid is described as being very different in its chemical properties to salicylic acid and is stated to be quite inert as an antiseptic.

When we consider the nature of this process we readily see that there are many practical reasons why the resulting product should not prove uniform, and that it is very necessary to check the result by comparing it with what we know ought to be obtained.

In the first place, the carbolic acid employed is a body of very varying constitution. We know it is offered commercially of very different melting points, due to the proportion of cresylic acid contained in the sample and also at very different prices, according to the quality. Being a product of coal tar it cannot, without great difficulty, be obtained absolutely pure, and if it could the price would be too high for its use for the purpose of making salicylic acid artificially. The ordinary carbolic acid being thus a mixture of that acid and cresylic acid, and probably other bodies, it is quite natural that the salicylic acid produced from such a mixture should vary much in quality. There is another source of impurity in the difficulty of perfectly purifying the salicylic acid from the last traces of what I may call carbolic residue. It is true the acid may have no perceptible smell of carbolic acid, but I have been given to understand that when given internally frequently great pain and irritation in the stomach are produced, which is not the case when a perfectly pure acid is administered.

Now, again, when we compare the physical and chemical properties of the artificial acid with the natural, made from wintergreen oil, we are much struck with a great difference in appearance, and when we proceed further to subject the two to comparative chemical tests we discover still stronger indications that the two substances are not in every respect identical. Different samples of the artificial acid, as imported from abroad (mainly Germany), differ considerably in colour and appearance; some samples are brownish powders, still clearly possessing the characteristic carbolic acid smell; others are white and without smell. The best samples I have seen are fairly white, free from smell, and crystalline, but the crystals when compared with the crystals of the natural acid are very different, being quite small and indistinct.

I intend in the present note to limit my remarks mainly to better qualities of the artificial acid; the lower qualities need hardly occupy our time, as they are obviously not suited for any medicinal purpose, and should, I should say, hardly be employed in the arts.

If we attempt to recrystallize this crystalline artificial acid we fail in getting it to crystallize like the natural acid, even when the conditions are apparently

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, April 3, 1878.

exactly alike, the artificial still giving small and confused masses of crystals, and if the beaker in which the crystallization is proceeding be watched, it will be observed that the crystallization assumes different appearances as the liquid cools, the first crystals appearing much more needle-like than those deposited when the liquid becomes cooler. Crystallization from chloroform also fails to give the two acids an identical appearance.

It is a very instructive experiment, and I think teaches us a great deal as to the comparative purity of the samples of acid we are examining, if we take a known quantity, say one drachm, and observe what is the smallest quantity of boiling water capable of dissolving it. A drachm of the pure natural acid will be found to require just about three ounces of boiling water, the best quality of artificial (crystalline) acid about two ounces, very low qualities will frequently only require one-and-a-half. Now if to these hot saturated solutions about one-fifth of alcohol is added, and the liquids allowed to cool in beakers, we shall find that the pure natural acid will crystallize in separate distinct crystals, not cohering together; the best artificial in a fine network of needle-shaped, but very small, crystals, from which the mother liquor can be drained by simply inverting the beaker. The lower grades of artificial acid form a woolly looking mass of very small and indistinct crystals, which refuse to allow the mother liquor to drain from them, but hold it like a sponge. The mother liquor can, however, be absorbed from the mass by blotting paper and thus a dry white woolly like mass eventually obtained. I place samples of these results on the table; it will be observed how different in appearance are the various products.

I have also investigated the action of sulphuric acid upon these various qualities of salicylic acid; very different results were, as might be expected, obtained from the various samples. It is not, however, my intention to call further attention to this part of the subject at present.

The general result of my experiments to this point was to cause me to have considerable doubt as to the actual identity of the artificial with the natural salicylic acid, but further experiments now in progress are sufficiently advanced to allow me to clear up the difficulty and to prove that the artificial acid as supplied in commerce is really made up of two bodies having very different properties, and that when these two substances are separated all difficulties vanish.

To break up the artificial salicylic acid of commerce into its constituent parts, I have had recourse to the following process. The acid is dissolved in boiling water, and carbonate of lime added to neutralization. As the solution cools, the sparingly soluble salicylate of calcium is deposited; if the acid employed was of fair quality the crystals formed are pretty distinct and of light colour; if of low quality the crystals are very brown and indistinctly formed. The crystals of salicylate of calcium thus produced must be recrystallized several times from boiling water until they are white or nearly so and in hard well defined crystals, the salt decomposed with hydrochloric acid, and the salicylic acid thus produced purified by recrystallization and final crystallization from weak alcohol as described in the process for making the natural acid. Thus purified the artificial acid is obtained in large white well formed crystals absolutely identical in appearance with the natural acid, and as far as I can at present ascertain agreeing in every respect with it. For instance the salicylate of soda produced from the natural acid crystallizes in large pearly plates, very different in appearance to the salicylate of soda made from artificial acid usually employed in medicine. The soda salt of this purified artificial acid is also in white platy crystals, exactly like the salt produced by the natural acid both in appearance and taste.

By further concentration the mother-liquor from which the salicylate of calcium is obtained yields further quantities of crystals, consisting of salicylate of calcium in a very impure state; the final brown nearly uncrystallizable mother-liquor when decomposed with hydrochloric acid yields a large quantity of an acid quite distinct from salicylic. In appearance and in many of its properties it differs very much, and at one time I thought it must be paraoxybenzoic acid; but upon closer examination it proved to differ from the description of that acid. I am, at present in doubt as to its real nature, and am still investigating the matter and hope to be able to give a more perfect account of it in a short time. In the meantime I may state that when purified and crystallized in the same way as salicylic acid it crystallizes in silvery plates. It is much more soluble both in hot and cold water than the salicylic acid, but much less soluble than paraoxybenzoic acid is stated to be. Its solution with perchloride of iron does not give a yellow precipitate, characteristic of paraoxybenzoic acid, but still gives the so-called characteristic reaction of salicylic acid, but this may be due to my not yet having obtained the acid quite free from salicylic, and owing to the short time I have had this acid in my possession I cannot at present enter more fully into its characters. I place a specimen of it on the table, and would suggest that, as it is probably derived from cresylic acid, we might name it cresyl-salicylic acid, at any rate until a better name is found for it.

The quantity of this second acid contained in the various samples of commercial salicylic acid made by the artificial process, appears to vary considerably, but it is present in somewhat large quantities. I have not been able as yet to obtain anything like accurate results as the waste of working is very considerable, but I think from 15 to 25 per cent. may probably be taken as the proportion. Respecting the medicinal properties of this acid, I can say nothing as yet; it may be like paroxybenzoic acid inert, and would then be simply a diluent of the salicylic acid, or it may be active as an antiseptic, or it may be mischievous; whatever it be there can, I think, be no doubt that the artificial salicylic acid at present used for medicinal purposes is not as pure or as uniform as is desirable, and that it should be more highly purified and freed from this second acid I have described before it or its salts are used in medicine.

Before concluding, I may mention that if instead of carbonate of lime being used, and the liquid thus kept neutral, milk of lime is employed in excess, so as to render the liquor highly alkaline, nearly insoluble calcium salts are deposited, and the two acids cannot be separated by the fractional crystallization of their basic salts; the neutral salt of the cresyl-salicylic acid on the contrary is extremely soluble as described.

I cannot conclude this note without expressing my thanks to my friend Mr. Myles Smith, to whose suggestions and assistance I have been much indebted in carrying out the experiments detailed in this note.

[*The discussion on this paper is printed at p.* 796.]

NOTE ON GRINDELIA ROBUSTA.*

BY E. M. HOLMES, F.L.S.

Curator of the Museum of the Pharmaceutical Society.

In the report of the Pharmaceutical Meeting, at Philadelphia, on January 15th, Professor Maisch states that he had been examining commercial specimens of *Grindelia robusta*, and that he concluded that three species were sold under that name, much of it being *G. squarrosa.*

It therefore occurred to me that the specimens imported into this country would probably be found similar in character to the American drug and might be worth examination. I have, therefore, compared the specimens which have been presented to the Museum with the specimens in the Herbaria at the British Museum and at Kew, and with such descriptions of the species as have been published recently, and find that the drug as imported into this country is not *Grindelia robusta*, Nutt., but *G. squarrosa*, Dunal.

The genus *Grindelia*, according to Asa Gray, is one which is characteristic of the plains west of the Mississippi, extending to the Pacific coast and to Mexico, with two or three species in similar regions in South America. They are, however, most abundant in Mexico and Texas. The chief distinguishing character of the genus lies in the pappus, which consists of from two to eight rigid awns that a touch is almost sufficient to break off, and which in fact fall off early.

The species are very intricate, and run so much one into the other through a variety of forms that it is difficult to say how many of them have a right to that distinction. Consequently it is a difficult matter to define any good character by which the species may be distinguished. Those which have been chiefly relied on in describing these plants have been the shape and serration of the leaves, the character of the scales of the involucre, and the number of the awns of the pappus. The latter character is, however, of little practical value, since the number is variable in the same species, and the flowerheads are usually so resinous that it is difficult to examine a dried specimen without the pappus falling off.

The species which seem to possess this resinous matter, upon which it may be presumed the active properties of the plant depend, and which are most likely to be met with in commerce, are *G. squarrosa*, Dunal., *G. rubricaulis*, Dec., *G. robusta*, Nutt., *G. integrifolia*, Dec., *G. inuloides*, Willd., and *G. glutinosa*, Dunal. For pharmaceutical purposes these may be roughly distinguished as follows: *G. squarrosa* has leaves which are narrowly lanceolate, tapering downwards to a small cordate base, so that the upper portion of the leaf is the broadest, and the scales of the involucre are subulate, and strongly curled backwards. In *G. robusta* the leaves are oblong, broadest at the base, nearly twice the width of *G. squarrosa*, and obtuse at the apex; the scales of the involucre are similar to those of *G. squarrosa*, but are less squarrose. *G. integrifolia* has the leaves entire or very sparingly serrated, with the leaves longer and more tapering at the apex than those of *G. robusta*, which it otherwise resembles. *G. inuloides* is a very well marked species, the flowerheads being almost immersed in large leafy bracts so that they have a sessile appearance; the leaves are nearly as broad as those of *G. robusta*, oblong, and much wider near the base, and are furnished with short closely set teeth, which are more obtuse than in the other species. *G. glutinosa* has lanceolate leaves, broader than those of *G. squarrosa*, also tapering to the base, but the scales of the involucre are linear, with a short point, and are not bent backwards but erect. *G. rubricaulis* is easily distinguished by the hairiness of the involucre and purplish stem, and by the uppermost leaves being larger at the base, while the lower leaves taper towards the stem. It is this last species which, under the name of *G. hirsutula*, is mentioned in Wood and Bache's 'Dispensatory' as a remedy for the irritation caused by the poison of *Rhus Toxicodendron.*

The amount of resin developed in the plants appears to vary according to the situation in which the plant grows, those which are found in hot dry places being apparently most resinous.

Although it is probable that the resin does not differ in properties in the various species, it is at least satisfactory to know that although the one to be met with in commerce in this country is not *G. robusta*, it is quite equal to that species in the amount of resin it contains, and indeed appears to be one of the richest in medicinal properties of the whole genus.

THE ALKALOID AND ACTIVE PRINCIPLE OF DUBOISIA MYOPOROIDES.*

BY A. W. GERRARD, F.C.S.,

Teacher of Pharmacy, University College Hospital.

The natural order in which the above named plant has been placed (Solanacæ), and its powerful physiological action, especially in dilating the pupil of the eye and causing dryness of the mouth and thirst, are facts which when considered together lead at once to the inference that its activity must be due to an alkaloid having properties in common if not identical with atropine. The drug having come somewhat prominently under my observation through my having made the preparations referred to in Drs. Ringer and Tweedie's paper on duboisia in the *Lancet* of March 2, and having heard Mr. E. M. Holmes's paper read before the Pharmaceutical Society, on March 6, I felt desirous to investigate it closely but the material at my command was insufficient to carry on a research for its active constituent, until through information conveyed me by Mr. Holmes I was able to obtain supplies of the extract.

The extract I received proved upon examination to be an aqueous one, and was submitted to the following treatment: one thousand grains when thinned by the addition of an equal volume of water were treated with alcohol till no further precipitation occurred; the alcoholic solution was filtered and the insoluble matter washed with alcohol; the alcohol was now distilled off and the residual extract diluted with a small portion of water, treated with ammonia in slight excess, and shaken with chloroform; the chloroform separated and distilled yielded a varnish-like residue having a powerful alkaline reaction. By re-solution in dilute sulphuric acid and addition of ammonia a dull grey precipitate was produced, imme-

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, April 3, 1878.

diately aggregating into oil-like drops heavier than the mother-liquor. The alkaloid was finally abstracted with ether, which yielded after evaporation 21 grains. The alkaloid appeared as a yellow viscous mass freely soluble in alcohol, chloroform, ether, benzol, and carbon bisulphide, fairly soluble in water, and imparting to it a decided alkaline reaction; solutions of the alkaloid in the preceding solvents upon spontaneous evaporation yielded no crystals. A portion of the new alkaloid converted into sulphate and treated with various reagents was found to give reactions so similar to atropine that I determined to test it side by side with that alkaloid, the better to observe their relations and differences.

Both duboisia alkaloid and atropine gave white precipitates with tannic acid and iodohydrargrate of potassium, those with tannic acid being soluble in hydrochloric acid. Hydrates of potash, soda, and ammonia gave white precipitates with both, soluble in excess; chloride of gold and perchloride of platinum yielded lemon-yellow precipitates; a common characteristic of the preceding precipitates was that they rapidly formed conglomerate masses. Neither sulphocyanide of potassium nor perchloride of mercury gave precipitates, unless with the latter reagent when the alkaloidal solutions were concentrated. Strong nitric acid causes no visible change with atropine, but with duboisia alkaloid a very slight brown colour is produced. With strong sulphuric in the cold, atropine remains unaffected, but on heating the mixture it darkens, evolving a pleasant aromatic odour which the addition of bichromate of potash intensifies, and at the same time yields a green precipitate of oxide of chromium and vapours of an acid reaction. Duboisia akaloid in contact with sulphuric acid behaves differently to atropine. In the cold it gives a reddish-brown colour, and when heated an odour unpleasant and suggestive of butyric acid; upon the addition of bichromate of potash no reduction of the chromium to its oxide was apparent, but the evolved vapour was of acid reaction.

Both duboisia alkaloid and atropine, when heated between watch glasses, partly volatilize, condensing as transparent varnishes; both their salts dissolve easily in alcohol and water, but with difficulty in ether.

I prepared small quantities of neutral solutions of sulphate, chloride, nitrate, phosphate, acetate, hydrobromide, and tartrate of duboisia alkaloid upon watch glasses, and left them to evaporate spontaneously; only in the case of the sulphate and hydrobromide were a few tufts of needle-like crystals observable. The material at my disposal did not admit of further attempts to obtain it crystalline. The neutralizing power of dilute sulphuric acid upon the new alkaloid was tested side by side with atropine, and found to be thus: two grains of new alkaloid required four drops of the acid, whilst the same quantity of atropine required three drops.

As no individual reaction which specially distinguishes atropine from other alkaloids had been applied to the duboisia alkaloid one was sought for with that object. I found in Gmelin's 'Chemistry,' vol. xvi., it is stated by Hinterberger that an alcoholic solution of atropine assumes a blood-red colour when cyanogen gas is passed through it. I have twice repeated the experiment, passing the gas ten minutes through the atropine solution, but no colour change whatever was observable; it was therefore useless to apply this test, and I conclude that the statement of Hinterberger must be an error.

Again, Selmi, in the *Gazetta Chimica Italiana*, vi., 155,* mentions that atropine boiled with barium hydrate in contact with air gives a pleasant odour of hawthorn flowers. Portions of atropine and duboisia alkaloids were treated with barium hydrate and boiled; the odour evolved by atropine was pleasant but rather more suggestive of oil of gualtheria than hawthorn, whilst the odour evolved by duboisia alkaloid was unpleasant and altogether different to the atropine odour. After a search through many chemical works I failed to find any other reactions of atropine worthy of a trial, and it is a matter for regret that chemistry should be at a loss for a reaction to indicate with certainty this powerful poison.

It being desirable to obtain physiological properties of the new alkaloids, Dr. Sydney Ringer and W. Murrell undertook the work, and to them I am indebted for the following notes:—

Physiological Action of the Alkaloid of Duboisia.

BY SYDNEY RINGER AND WILLIAM MURRELL.

Action on the Eye.—We find that it quickly and widely dilates the pupil. Mr. Blake dropped a small quantity of a solution, 1 in 120, into an eye. In ten minutes the pupil was widely dilated.

Action on the Skin.—Mr. Blake injected one-sixtieth of a grain under the skin of a patient troubled with night sweating. The sweating was much prevented.

Effect on the Mouth.—Mr. Blake injected one-sixtieth of a grain hypodermically into two patients. The injection caused great dryness of the mouth.

Antagonism to Muscarine.—We find also that like atropia it antagonizes the action of muscaria on the heart of a frog. We exposed the heart of a brainless frog, and applied a minute quantity of extract of aminita muscaria. The heart-beats had nearly stopped in five minutes, there occurring only an occasional pulsation. We then applied a small quantity of solution of the duboisia alkaloid, one in twenty, and in half a minute the heart beat strong and naturally thirty-four per minute.

Tetanizing Property.—Like atropia also this alkaloid produces tetanus after the lapse of some hours or days. We injected one-seventh grain, one-fifth grain, and one-seventh grain respectively, under the skin of three frogs. Slight but distinct tetanus occurred in two in twenty-four hours.

The preceding experiments show that in its physiological action duboisia alkaloid entirely agrees with atropine, but this agreement by no means proves that alkaloid to be atropine, for most alkaloids of the order Solanaceæ have common physiological actions, and at one time were considered to be chemically identical, but now they are generally understood to be different bodies, and although it has been shown that in the majority of its properties this duboisia alkaloid is like atropine, I am inclined, for the following four reasons, to the conclusion that it is not atropine:—

1st. Its solubility in water is twice or more than twice that of atropine.

2nd. It has more power in neutralizing acids than atropine.

3rd. Its behaviour to sulphuric acid in the cold,

* An abstract of Selmi's paper is contained in the 'Year-Book of Pharmacy,' 1877, page 114.

and also when heated with bichromate of potash, differs from the behaviour of atropine.

4th. When boiled with baryta the odour it evolves is entirely different to that given off by atropine under the same conditions.

I have submitted to Dr. Paul a quantity of this new alkaloid, and he has been good enough to undertake its examination; when this is accomplished perhaps a definite conclusion can be arrived at as to the name it shall bear. If it does not prove to be atropine, following the usual rule, it should be called duboisine; meantime it must remain an alkaloid without a name.

In conclusion, I think medical men and pharmacists in Australia may congratulate themselves that they have at their disposal, provided the supplies of the plant are abundant, a source from whence to obtain by the simple process I have here given a therapeutic agent of great value.

[*The discussion on this paper is printed at p.* 797.]

LIQUOR FERRI, PEROXYCHLORIDE OF IRON, DIALYSED IRON, CATALYTIC IRON.*

BY EMIL SCHEFFER.

The different views regarding the composition of dialysed iron, of whose preparation a great deal has been written in our periodicals for the last twelve months, induced the writer to make a series of experiments which will no doubt throw some light on the subject and also show the relation of peroxychloride of iron, dialysed iron and catalytic iron.

By precipitating a solution of ferric chloride with ammonia, the precipitate differs according to the quantity of ammonia used as precipitant. Ammonia added as long as a precipitate is formed yields an oxychloride, and the liquid above the precipitate has *acid* reaction. Ammonia added carefully until the supernatant liquid has become perfectly *neutral* produces a more basic oxychloride. Ammonia added *to excess* yields a precipitate free from chlorine, but containing ammonia. Of these three precipitates the first two are soluble in water, the third is insoluble.

In the following experiments 300 c.c. of the officinal ferric chloride solution were diluted with water to 1500 c.c., and 150 c.c. of this dilute solution were taken for each experiment. The ammonia was also diluted with water, but spec. grav. was not taken, as it was not deemed necessary.

a. To 150 c.c. of the dilute ferric chloride solution dilute ammonia was added, in small quantities at a time, to saturation, that is, to the point at which a further addition of ammonia produced a permanent precipitate. To effect this, 81·3 c.c. of ammonia were required; the smallest quantity of ammonia added now produces a copious precipitate, and on an addition of 1·7 c.c. more, or about two per cent. of the quantity needed for saturation, all iron was precipitated, while the clear, colourless liquid above the precipitate showed acid reaction.

The same experiment was repeated, but to the mixture obtained after the addition of respectively 81·3 and 1·7 c.c. of ammonia, ammonia was added to perfect neutralization of the supernatant liquid, 6 c.c. being required, making the total of ammonia 89 c.c. Although the liquid is perfectly neutral, the precipitate is not pure ferric oxide, but contains still a considerable quantity of chlorine.†

The precipitate of *a*, washed several times by decantation, until on addition of fresh water it settles slowly and remains suspended for a long time, is then collected on a filter and after thorough draining washed carefully with small quantities of water at a time. The liquid passes through very slow, and assumes, after a time, a yellowish colour, which becomes deeper yellow by continued washing; the precipitate on the filter changes thereby its appearance, shrinks considerably, and obtains at last a darker brown, almost black, colour, and has the consistence of a jelly. When all the precipitate is converted into a black jelly, which in thin layers is transparent and of a deep garnet-red colour, the wash water no longer passes through the filter unless a very large quantity is above the precipitate, when it may happen that it dissolves at once, forming a black-red liquid. If the jelly is taken from the filter, a small quantity of water added to it is sufficient to dissolve it entirely after some time. The solution has, in reflected light, a pure black colour, dissolves in more water to a transparent deep red solution, is neutral, but still contains ammonium chloride, as the jelly forms before it is all washed out.

A second precipitate, obtained in the same way, was, after draining off the supernatant acid liquid, subjected to dialysis. In the same degree as the acid and ammonium chloride is removed, the precipitate in the dialyser changes at first into a jelly-like black mass, and afterwards into a turbid thick liquid of the consistence of cream. Taken then (after three weeks) from the dialyser, it dissolves on the addition of a little water, after a few days, to a perfectly clear thin liquid, of a brownish-black colour.

By using more ammonia than is necessary to precipitate the iron, precipitates are obtained, which are also soluble in water, provided that ammonia was not added in excess. The more ammonia is used the more basic the precipitates will be; these have the advantage that the ammonium chloride can be more perfectly removed by washing before the precipitates begin to dissolve, which is evidenced by the yellow colour of the filtrate, so that they may be washed until the filtrate becomes merely opalescent on addition of silver nitrate, or keeps perfectly clear. It is of the greatest importance that these more basic precipitates be as free as possible from ammonium chloride, since a small quantity prevents their solution. (It is the presence of ammonium chloride, also, that causes the gelatinization of solutions of the less basic oxychlorides.)

These more basic precipitates do not form a jelly after being thoroughly washed, but finally form a thick blackish syrupy liquid, which when taken from the filter gives, on addition of a little water, a very turbid mixture, and, on standing several days, a thin clear liquid, of a brownish-black colour, or they only change their colour by washing to a somewhat darker but not black hue, without losing much of their bulkiness. This is the case with the precipitates that were removed from a neutral supernatant liquid. After they are washed until the filtrate remains clear on addition of silver nitrate, the precipitates are taken from the filter and transferred with a little water into bottles, so that they can be shaken from time to time. The colour of the mixture is then reddish-yellow or reddish-brown, but darkens from day to day as the precipitate enters solution. In the course of several weeks a clear thin liquid, of brown colour, is obtained. A temperature of 80° to 85° F. accelerates the solution of the precipitates, while a much higher temperature prevents it.

A few experiments were made by adding to the precipitates, in perfectly neutral liquids, respectively one-half and one per cent. of the ferric solution. Under frequent stirring the mixture was allowed to stand for two days, after which the washing was commenced, and concluded finally on a filter, as above mentioned.

The writer gives below the results of the analyses

---

* Read at the February Pharmaceutical Meeting of the Louisville College of Pharmacy. From *The American Journal of Pharmacy*, March, 1878.

† By calculation it was found that 92·6 c.c. of the ammonia were necessary to bind all the hydrochloric acid in 150 c.c. of this dilute ferric chloride solution.

of different preparations obtained by the above explained methods, the analyses being made as follows:—

The solutions were thoroughly mixed with an excess of pure sodium carbonate and evaporated to dryness. After dissolving the excess of sodium carbonate and the sodium chloride in water, the filtrate was acidulated with nitric acid, and the amount of chlorine determined with a tenth normal solution of nitrate of silver; the ferric oxide was calcined and weighed.

a. Solution of precipitate obtained with 81·3+1·7 c.c. ammonia—·490 Fe_2O_3 + ·061 Cl = ·441 Fe_2O_3 + ·0953 Fe_2Cl_3=82·6 per cent. Fe_2O_3+17·4 per cent. Fe_2Cl_3.

b. Solution of precipitate obtained with 81·3+three times 1·7 c.c. ammonia—·365 Fe_2O_3 + ·0248 Cl = ·346 Fe_2O_3+·0385 Fe_2Cl_3=90 per cent. Fe_2O_3+10 per cent. Fe_2Cl_3.

c. Solution of precipitate obtained with 81·3+four times 1·7 c.c. ammonia—·614 Fe_2O_3 + ·0382 Cl = ·5853 Fe_2O_3+·0583 Fe_2Cl_3=91 per cent. Fe_2O_3+9 per cent. Fe_2Cl_3.

d. Solution of precipitate obtained with 81·3+4·5 times 1·7 c.c. ammonia—·411 Fe_2O_3+·0223 Cl=·3942 Fe_2O_3+·034 Fe_2Cl_3=92 per cent. Fe_2O_3+8 per cent. Fe_2Cl_3.

e. Solution of precipitate obtained by adding 1 per cent. of ferric chloride solution to the precipitate caused by 89 c.c. ammonia—·455 Fe_2O_3+·0308 Cl=·4318 Fe_2O_3 +·047 Fe_2Cl_3=90·2 per cent. Fe_2O_3+9·8 per cent. Fe_2Cl_3.

f. A precipitate formed by adding to 150 c.c. of the ferric chloride solution 91·5 c.c. of ammonia, and washed until the filtrate remained perfectly clear on addition of silver nitrate, gave on analysis—·416 Fe_2O_3+·00602 Cl =·4115 Fe_2O_3+·00917 Fe_2Cl_3=97·83 per cent. Fe_2O_3+2·17 per cent. Fe_2Cl_3.

This precipitate was transferred to a bottle, with a little water, and shaken occasionally. At the date of this paper it has stood a little over seven weeks, during which time over three-fourths of the original precipitate has dissolved. The writer is fully convinced, to judge from its appearance, that it will ultimately dissolve entirely.

g. Another precipitate, obtained with a little more ammonia than *f* gave—·424 Fe_2O_3 and ·00318 Cl.

This precipitate has, at the date of this paper, not shewn the least sign of ever dissolving, although it has stood as long and been shaken as often as *f*.

For comparison, the writer has examined several *commercial* preparations of *dialysed iron*:—

I. ·604 Fe_2O_3+·0371 Cl=·576 Fe_2O_3+·057 Fe_2Cl_3= 91 per cent. Fe_2O_3+9 per cent. Fe_2Cl_3.

II. ·255 Fe_2O_3+·01275 Cl=·2454 Fe_2O_3+·01947 Fe_2Cl_3=92·6 per cent. Fe_2O_3+7·4 per cent. Fe_2Cl_3.

III. ·534 Fe_2O_3+·0203 Cl=·5187 Fe_2O_3+·031 Fe_2Cl_3 =94·47 per cent. Fe_2O_3+5·53 per cent. Fe_2Cl_3.

IV. ·274 Fe_2O_3+·0125 Cl=·2646 Fe_2O_3+·0191 Fe_2Cl_3 =93·3 per cent. Fe_2O_3+6·7 per cent. Fe_2Cl_3.

Dr. Hager's *Liquor ferri peroxychlorati*, which he prepares by dissolving the ferric hydrate obtained from 115 parts of ferric chloride solution in ten parts of the same ferric chloride solution, contains, when all the ferric hydrate is dissolved, 85 per cent. Fe_2O_3 and 15 per cent. Fe_2Cl_3. No doubt a more basic preparation could be realized by Dr. Hager's method, that is, by dissolving ferric hydrate in ferric chloride solution, if the ferric hydrate were perfectly pure. But, as his ferric hydrate always contains ammonia, which cannot be removed by washing, this ammonia forms, when the precipitate is added to the ferric chloride solution, ammonium chloride, which sets a limit to the solution of ferric oxide. The basicity of this preparation stands in inverse ratio to the quantity of ammonium chloride in it.

Dr. Wagner, the originator of dialysed iron, does not communicate the method for making his later preparation, the *catalytic iron*, but asserts that it is not made by dialysis, and that it takes three months to make it. To judge by this, the supposition might not be far from wrong, that it is a solution of a basic oxychloride precipitate, obtained as above explained. The writer could not obtain any of Dr. Wagner's catalytic iron, and therefore cannot say how much chlorine it contains in proportion to the ferric oxide; that it does contain chlorine Dr. Hager has fully proven.

The above experiments teach us that the preparation of a perfectly pure ferric hydrate is very difficult, almost impossible, as in one case it is apt to contain chlorine, in the other ammonia. They prove that the precipitate of oxychloride of iron is soluble in pure water, and that in its more basic combinations it is only soluble when free of saline compounds.

They likewise prove that a solution of very basic oxychloride can be prepared without dialysis, and that the product may be made to contain a less per cent. of chlorine than that found in the best commercial sample of dialysed iron examined by the writer.

By referring to the precipitate of experiment *g*, it becomes evident that the solvent power of ferric chloride on ferric hydrate has a limit. This indicates at the same time that a pure ferric hydrate will not dissolve, and that in all the different iron solutions, whether they be called peroxychloride, dialytic or catalytic, the ferric oxide is kept in solution by ferric chloride. As the proportion of these two ferric compounds can be changed at will, a chemical combination of them cannot be well thought of.

TEST FOR ELATERIN.*

BY DAVID LINDO.

The active principle in elaterium affords a very beautiful reaction with carbolic acid, and concentrated sulphuric acid. The test may be applied as follows:—

Place a few crystals of elaterin in a small porcelain capsule, and add one or two drops of liquefied crystals of carbolic acid (Calvert's No. 1 liquefied by moisture).

The elaterin dissolves in the carbolic without production of colour; but if two or three drops of concentrated sulphuric acid are allowed to flow into the mixture, an intense and beautiful carmine colour is developed, changing at first to orange, and after some time to scarlet. Alkalies discharge the colour. I have not been able to obtain a reaction resembling this with any of the alkaloids and carbolic acid, nor with any other substance tried.†

If liquefied crystals of carbolic acid are not at hand the solid crystals can be used. After adding them to the elaterin, add a drop of chloroform or alcohol before applying the sulphuric acid. The addition of sulphuric acid alone to elaterin gives rise to no characteristic colour. The elaterin cakes together, dissolves slowly, and imparts a yellow colour to the acid. If the carbolic acid is now added the reaction is obtained very imperfectly. The reagents should therefore be added in the order stated above.

The test can be applied direct to some samples of the elaterium of commerce (dried sediment of the juice) if they are reduced to fine powder.

Other samples may require the powder to be agitated with chloroform and the solution filtered. A few drops of the filtrate evaporated to dryness by blowing on the surface will afford a residue for testing.

---

* From the *Chemical News*, January 25, 1878.

† If a nitrate in the dry state is treated in the same way with carbolic and sulphuric acids, a deep green colour is developed, which changes to red on the addition of a little water.

THE DENTAL PRACTITIONERS BILL.

THE close similarity between the section of the Duke of RICHMOND'S Medical Bill which relates to the examination, licensing and registration of dentists, and the Bill brought in by Sir JOHN LUBBOCK admits of the conjecture that the latter may eventually be abandoned if the Medical Acts Amendment Bill be proceeded with; but it is nevertheless deserving of mention that up to the present time it does not appear that any notice of amendment has been given with the object of carrying out the intention expressed by Sir JOHN LUBBOCK in his letter to the President of the Pharmaceutical Society.

The point urged by the President in his communication to Sir JOHN LUBBOCK was that the terms of the fifth section of his Bill might possibly be interpreted in such a manner as to preclude chemists and druggists who have been engaged in the practice of dentistry from continuing this branch of their business, inasmuch as it might be held that they had not been engaged in the practice of dentistry "either separately or in conjunction with the practice of medicine or surgery." Such an interpretation would certainly be a great injustice to those who have been in the habit of carrying on the practice of dentistry and in many cases it would be attended with considerable inconvenience to the public.

Sir JOHN LUBBOCK appears to have fully appreciated this view of the matter, and in his letter to the President of the Pharmaceutical Society he admits that the point urged against the section referred to seemed to him to have so much force in it that he should be happy to omit the words in question. It appears, therefore, somewhat remarkable that among the amendments to the Bill, of which notice has been given, there is no amendment which proposes to deal with the objections raised by chemists and druggists engaged in practising dentistry. It is true that the time fixed for the Bill to be taken in Committee is still sufficiently distant to afford ample opportunity for notice of the amendment desired by chemists and druggists being given, either by Sir JOHN LUBBOCK himself, or by Mr. RICHARDSON GARDNER, the member for Windsor, who has also expressed his intention of proposing an amendment calculated to meet the views of those chemists and druggists who are apprehensive that the fifth section of the Bill, as it stands, might operate to their prejudice.

On a previous occasion we mentioned that Mr. WESTLAKE, of Windsor, suggested the presentation of petitions by the chemists and druggists practising dentistry in every borough, town, or county throughout the kingdom, and he has undertaken the preparation of such a petition, which was signed by one hundred and twenty-nine chemists and druggists and presented by Mr. RICHARDSON GARDNER.

But whatever may be the ultimate fate of Sir JOHN LUBBOCK'S Bill, and whatever amendments may be proposed in regard to it, the danger apprehended in regard to the practice of dentistry by chemists and druggists still threatens them from another quarter, for, as we mentioned last week, the objectionable words of the Dental Practitioners' Bill are almost exactly reproduced in the twenty-third section of the Medical Acts Amendment Bill introduced into the House of Lords by the Duke of RICHMOND and GORDON. It will therefore be necessary to renew in the House of Lords the representations that have already been made in the interests of chemists and druggists engaged in the practice of dentistry, and to lay them before the Duke of RICHMOND in the same manner that they have already been urged upon the consideration of Sir JOHN LUBBOCK and other members of the House of Commons.

It will be noticed in the report of the Council proceedings that this course was recommended by the Law and Parliamentary Committee in the report submitted to the Council. The second reading of the Duke of RICHMOND'S bill is fixed for the 15th of April, and as the report of the Law and Parliamentary Committee of the Council was adopted the requisite steps will doubtless be taken in the interim to provide for the protection of chemists and druggists in respect to the practice of dentistry.

PHARMACY IN URUGUAY.

THE Republic of the Banda Orienta del Uruguay does not appear to present many attractions for pharmacists; but as it may be that the ubiquitous longings natural to the inhabitants of these islands occasionally turn the thoughts of some of the readers of the Journal in that direction, it will not only be interesting but useful to put on record some information received from a correspondent as to the position of pharmacy in that country.

In the first place, as the examinations of the Pharmaceutical Society of Great Britain are not recognized in Uruguay, a registered British pharmacist who wished to carry on business in Monte Video would have to pass an examination carried out under the authority of the Republic. The examination is conducted in the Spanish language, and the examinee if successful, is privileged to bear the title of "Apothecary of the Republica Banda Oriental," and also to pay for it the enormous fee of one hundred and eighty dollars, equal to £37 10s. In paying this large sum, moreover, he has not the consolation of hoping that any portion of it goes towards the promotion of pharmacy. Still as these fees are payable to the State, and the rulers who for a longer or shorter—but generally shorter—time direct the destinies of the republic, are generally quite able to appreciate the adage, to "make hay while the sun shines," they probably help to develop in high quarters an appreciation of the profits to be derived from the cultivation of science.

The examination being passed and the fee paid, the pharmacist must be prepared for hard work, for long hours appear to be prevalent in Monte Video. The pharmacies, our correspondent says, are as a rule opened at half-past six in the morning, and closed at eleven at night, while there, as here, there are nevertheless some which are earlier and later than others.

There is one respect, however, in which the Uruguayan pharmacist enjoys an advantage. He lives in the midst of a region specially rich in medicinal plants, many of which are already in use among the people, although unknown in the science of therapeutics, and their systematic examination would probably richly reward the chemical investigator.

PROFESSOR SCHWANN.

We learn from *Nature* that in the course of a few weeks a festival will be held in the city of Liége the object of which will have an especial interest for botanists and students of vegetable physiology. Theodore Schwann, the founder of modern histology and the originator of the cell theory, occupies the position of Professor of Physiology in the University of Liége and it is to celebrate the fortieth year of his professorship that it is proposed to hold the festival and to invite scientific societies and individuals to join in the expression of sympathy with the object of doing homage to the genius of Schwann. It appears that a committee has been formed in order to make the requisite arrangements, and to communicate with foreign societies, Professor Edouard van Beneden of Liége acting as the Secretary, and letters to be read at the celebration are to be forwarded to him or to Mr. Ray Lankester, Exeter College, Oxford. It is requested that those who have been occupied in the same field of research as that opened up by Professor Schwann should communicate with one or other of the above-named gentlemen and forward their photographs for insertion in an album which is to be presented to him on the occasion.

AMERICAN EDITION OF 'PHARMACOGRAPHIA.'

We learn from *New Remedies* that arrangements are being made by Professor Fluckiger with Messrs. Wood and Co., of New York, for the publication of an edition of the 'Pharmacographia' specially adapted to the materia medica of the United States, Canada, and the West Indies.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, April 3, 1878.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atkins, Betty, Bottle, Churchill, Cracknell, Gostling, Greenish, Hampson, Hanbury, Hills, Owen, Rimmington, Sandford, Schacht, and Shaw.

The minutes of the preceding meeting were read and confirmed.

Nominations for Council and Auditors.

The Secretary reported that there had been *thirty* nominations to fill the fourteen vacant seats on the Council, and the following *twenty-one* nominees had signified their willingness to accept office if elected :—

Andrews, Frederick, 34, Leinster Terrace, Hyde Park, W
Atkins, Samuel Ralph, Market Place, Salisbury.
Betty, Samuel Chapman, 6, Park St., Camden Town, N.W.
Butt, Edward Northway, 13, Curzon Street, Mayfair, W.
Fairlie, James Mitchell, Charing Cross Corner, Glasgow.
Frazer, Daniel, 113, Buchanan Street, Glasgow.
Gostling, Thomas Preston, Market Hill, Diss.
Greenish, Thomas, 20, New Street, Dorset Square, N.W.
Hampson, Robert, 205, St. John Street Road, E.C.
Hills, Thomas Hyde, 338, Oxford Street, W.
Mackay, John, 119, George Street, Edinburgh.
Owen, John, 51, Holloway Road, N.
Richardson, J. G. F., Houghton House, Stoneygate, Leicester.
Sandford, George Webb, 47, Piccadilly, W.
Savage, William Dawson, 4, Park Road East, Brighton.
Schacht, George Frederick, 7, Regent St., Clifton, Bristol.
Slipper, James, 86, Leather Lane, E.C.
Symes, Charles, 14, Hardman Street, Liverpool.
Williams, John, 16, Cross Street, Hatton Garden, E.C.
Wills, George Sampson Valentine, 62, Lambeth Rd., S.E.
Woolley, George Stephen, 69, Market St., Manchester.

The following *nine* nominees declined to accept office, if elected :—

Atherton, John Henry, Nottingham.
Brown, William Scott, 113, Market Street, Manchester.
Hills, Walter, 338, Oxford Street, W.
Hodgkinson, William, 127, Aldersgate Street, E.C.
Jones, Samuel Urwick, Chirton House, Leamington.
Mackenzie, James, 45, Forrest Road, Edinburgh.
Morson, Thomas, 124, Southampton Row, W.C.
Vizer, Edwin Bennett, Church Rd., Cliftonville, Brighton.
Whitfield, John, 113, Westborough, Scarborough.

Nine nominations for Auditors had been received, and the following *five* had signified their willingness to accept office if elected:—

Harvey, Edward, 6, Giltspur Street, E.C.
Hodgkinson, William, 127, Aldersgate Street, E.C.
Squire, William, 5, Coleman Street, E.C.
Stacey, Samuel Lloyd, 300, High Holborn, W.C.
Thompson, H. Ayscough, 22, Worship St., Finsbury, E.C.

The following had declined to accept office:—

Barron, Frederick, 2, Bush Lane, Cannon Street, E.C.
Horner, Edward, 20, Bucklersbury, E.C.
Watts, Wm. Manning, 32, Lower Whitecross St., E.C.

It was proposed by the President, seconded by the Vice-President, and resolved unanimously—

"That Mr. Frederick Barron having expressed a wish to withdraw his name on the present occasion from the list of proposed auditors, the Council cannot allow the circumstance to pass without recording its thanks to him for the valuable services he has rendered to the Society for so many years."

Elections.

Members.

Pharmaceutical Chemists.

Bouttell, Harold ....Edinburgh.
Maggs, Frederick Richard ......Yeovil.

Chemists and Druggists.

Drinkwater, Peter Bramwell ...Manchester.
Laird, George Hardie ....Edinburgh.
Polglase, Francis J. W. ....Newcastle-on-Tyne.

Associates in Business.

The following having passed their respective examinations, being in business on their own account and having tendered their subscriptions for the current year were elected "Associates in Business" of the Society:—

Minor.

Cooley, Walter Bromley.........Wolverhampton.
Hill, William ....King's Lynn.
Moon, Murray James ....London.
Moore, Joshua ....Preston.
Moses, Joseph ....Bishop Auckland.
New, Thomas Cheney ....Stratford-on-Avon.
Plumer, William Cork............London.
Richards, John Wesley ....Alnwick.
Shenstone, James Chapman ...Colchester.
Shepley, Frederick Thomas ...London.
Thomas, John Rush...............London.
Thornton, Edward ....Leamington.
Woodhouse, George...............Ludlow.

Modified.

Baker, John Thomas ....St. Helier's.
Bambridge, James Williams ...East Dereham.
Breton, Harvey Wolstenholme Leicester.
Lloyd, Thomas Edwin............Garston.
Lynn, Sam..........................London.
Wallace, William..................Glasgow.

Associates.

The following having passed their respective examinations and tendered their subscriptions for the current year were elected "Associates" of the Society:—

Minor.

Brown, Francis Arthur ....Liverpool.
Dingle, James Hender ....Penzance.
Hendy, Albert......................Bristol.
Hobson, Charles, jun. ....Windsor.
March, Richard ....Stamford.
Murdoch, James Wm. Aitken Dumfries.
Watt, George William ....Huntly.
Williams, William ....St. Clears.
Wood, Frederic Percy ....Bolton.

Modified.

Wrighton, Alfred..................Birmingham.

Apprentices or Students.

The following having passed the Preliminary Examination were elected "Apprentices or Students" of the Society:—

Bartlett, Geo. Fredk. Handel...New Wandsworth.
Charlesworth, Moorhouse ......Saltaire.
Cook, Wm. Richard...............Bath.
Dutton, Hugh Odard ....Rock Ferry.
Freeman, John Henry............Ipswich.
Gulliver, William Inchle ......London.
Harries, David ....St. Clears.
Hubbard, A. E. L. F. W. A....Downham Market.
McNay, David ....Thornhill.
Norfolk, John William ....Beverley.
Phillips, Albert William.........Notting Hill.
Remfry, Samuel Alfred ....London.
Shannon, Robert James ....Birmingham.
Wright, Robert.......................Buxton.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The name of the following person was restored to the Register of Chemists and Druggists:—

James John Young, 8, Major's Corner, St. Hellen's, Ipswich.

Honorary Members.

The Council proceeded to select the names of persons for election as Honorary Members at the next meeting, and the names selected were ordered to be exhibited until that time in the library, in accordance with the Bye-law.

The President observed that there were at present forty-three honorary members, leaving seven vacancies to make up the number of fifty. He suggested that it was not desirable to fill up all the vacancies.

Reports of Committees.

Finance.

The report of this Committee was received and adopted and sundry accounts ordered to be paid.

Benevolent Fund.

The report of this Committee included a recommendation of the following grants:—

£10 to a registered chemist and druggist, formerly in business, now out of employment and suffering from paralysis.

£10 to a registered chemist and druggist, formerly in business, now out of employment.

£10 to an applicant, aged 62, who has received four previous grants of like amount.

£15 to a pharmaceutical chemist and former member, now suffering from paralysis, and entirely dependent on his friends.

£5 to a female registered chemist and druggist, now out of business and in distressed circumstances. The case to be further considered.

The Secretary reported the death of Mrs. Goldfinch, one of the annuitants, and of Mrs. Knight, who was an unsuccessful candidate at the last election.

The report was received and adopted.

The President thought the question would have to be considered by the Committee, whether a small grant should be made to assist in meeting the expenses incurred in respect of the last illness and funeral of annuitants. The time was often one of great pressure, and he thought the suggestion he had thrown out would be worth consideration.

Mr. Hampson said the difficulty would be to place the money in the right hands.

The President said that could be left to the judgment of the Committee. When the person applying was a near relative of an annuitant the Council might make a small grant.

Mr. Greenish said there were many applications of this sort, and the subject was well worth consideration.

It was unanimously agreed that the Committee should take the matter into consideration.

Sub-Committee to consider proposed Amendments to the Pharmacy Act, 1868.

Mr. Betty, in accordance with the notice he gave at the last meeting, moved—

"That the report of the Sub-Committee appointed to consider and report on any amendments which may be expedient in the Pharmacy Act be received, adopted, and acted on at a suitable opportunity with such additions or modifications as may at that time be resolved upon."

Mr. Hills moved that the discussion should take place in committee.

Mr. Betty said his remarks would be so general that he thought it would be rather beneficial to the Pharmaceutical Society that they should be published.

Mr. Sandford said the resolution was clearly that the amendments proposed should be adopted and acted upon, and therefore would require such detailed discussion as could only properly take place in committee.

Mr. HAMPSON said the question Mr. Betty was about to introduce arose out of a report from the Sub-Committee appointed by the Council to consider any proposed amendment of the Pharmacy Act. The advisability of appointing this Committee and entertaining the question of any amendments at all was considered openly by the Council and freely discussed, and he could not see why when the report of the Committee was brought forward in the form now adopted the discussion should be held with closed doors. It looked as if the Council was afraid to discuss the Pharmacy Act at all. He maintained that there was nothing at all to conceal, and any action that might be taken in connection with the amendment of the Act of 1868 was a fit subject to discuss openly. Nothing was wanted from the Legislature but what was for the public benefit as well as for that of the trade.

Mr. BETTY assured the Council he would not say one word which might not with advantage be published, and he was sure that the same judgment which would guide him would operate with other gentlemen round the table. Therefore he thought the Council might safely discuss the question openly.

Mr. ATKINS asked if anything on this matter had already been published, or was it then starting *de novo.*

The PRESIDENT said none of the proposed amendments had been published.

Mr. BETTY said the matter was referred to in the proceedings of last month.

Mr. CHURCHILL saw no reason for going into committee.

Mr. HILLS said his only ground for proposing to go into committee was that he did not think the time was ripe for taking any action.

Mr. SANDFORD said the manner in which this question arose was as follows:—There were certain measures expected to come before Parliament in which Mr. Hampson thought the Council might get certain clauses inserted for the benefit of pharmacy, and he proposed that a committee should be appointed to consider the question when an opportunity arose. That led to a long discussion, and Mr. Atkins proposed as an amendment that a committee should be formed to consider what alterations were necessary in the Pharmacy Act, without confining it to any opportunity which might arise. The Committee was appointed and that was all that was published at the time. Then the Committee came to certain resolutions which Mr. Betty now proposed to consider, and therefore he said that if the discussion were published it would go forth entirely as a new publication. He thought there were some things which it might be wise to try for and some which it would not, and therefore he thought it would be unwise to discuss them publicly.

Mr. HAMPSON said Mr. Sandford was entirely mistaken in saying that the view he took in introducing the question was that there was some probability of a Bill being introduced. His efforts were not entirely directed to making use of that opportunity.

A vote was then taken on the motion that the Council resolve itself into committee to consider Mr. Betty's motion, with the following result;—

For—Messrs. Bottle, Cracknell, Gostling, Greenish, Hills, Rimmington, Sandford, Savage.

Against—Atkins, Betty, Churchill, Hampson, Owen, Schacht, and Shaw.

The motion was therefore carried, and the discussion was taken in committee.

On resuming, the following resolution was carried unanimously.

"That the report of the Sub-Committee of the Parliamentary Committee appointed to consider and report upon any amendment that may be considered expedient in the Pharmacy Act, be received, approved, and recorded, as a basis to be acted upon at a suitable opportunity, with such additions and modifications as may at that time be resolved upon."

LIBRARY, MUSEUM AND LABORATORY.

This report included the report from the Librarian, stating that the average attendance in the library during the preceding month had been, day, 27; evening, 12. Circulation of books, town, 155; country (21 places), 37; carriage paid 12*s.* 10½*d.* The following donations had been made to the library:—

'Pharmacopœa generalis.' By J. R. Spielmann. Venice, 1785-6. From an Associate, per Mr. R. Reynolds.

'Cataract and other Eye Affections.' From Jabez Hogg, Esq. (Author).

Cooley's 'Cyclopædia of Practical Receipts.' 6th Ed. Part 1. From the Publishers.

'Des Quinquinas,' and ten other pamphlets. From Professor Planchon (Author).

'Remarks on the Ipecacuan Plant.' From Professor Balfour (Author).

'Chemische Beiträge zur Pomologie,' and three other pamphlets. From Professor Dragendorff.

The Committee recommended that the sum offered to Professor Redwood for editing the 'Historical Sketch of the Progress of Pharmacy' be increased in order that he might employ assistance and get the work completed in the shortest practicable time. Also that a general index to the Journal for the last ten years be prepared by the Sub-Editor. The Committee had had an interview with the Editor of the Journal with regard to the resolution passed at the last Council meeting that authors of papers read at the North British Branch should be supplied with reprints of such papers when published in the Journal, and it was recommended that the number of such reprints should be limited to twenty-five.

The Curator had reported the average attendance in the museum to have been, day, 16; evening, 4. That he had received a letter from Dr. Keik enclosing a list of 1237 herbarium specimens, besides eight special collections for disposal, and that he had selected about 200 specimens which he thought it would be desirable to obtain for the museum.

The Committee recommended that these be purchased.

The Curator had also reported the donation to the museum of the specimens reported in the proceedings of the last evening meeting; also that Professor Planchon, of the School of Pharmacy in Paris, had made arrangements with him to exchange duplicate specimens of drugs; that Professor Bommer, of Brussels, had forwarded a list of duplicate specimens of drugs and desiderata; that he had received a list of desiderata from Herr Oberdorffer, of Hamburgh, and that he had prepared a list of duplicate specimens in the museum for disposal.

The Committee recommended that the list be forwarded to Edinburgh for selection of specimens, and that a list of the remainder be published in the Journal.

The Curator had also laid before the Committee numerous letters from eminent men acknowledging the receipt and approving of the Catalogue.

The Professors had reported favourably of their respective classes.

An application from the Honorary Secretary of the Chemists' Assistants' Association for the use of a room in the Society's house for a lecture had been considered, but the Committee did not recommend compliance with the request.

The Committee had also prepared the draft annual report.

The report and recommendations of the Committee were received and adopted.

Reprints of Papers.

Mr. BOTTLE said last month Mr. Mackay reported that the Editor had refused copies of papers read by gentlemen at evening meetings of the North British Branch, such copies having formerly been given. He then moved that such gentlemen should be entitled to the privilege they had hitherto enjoyed, but it appeared from inquiries made of the Editor that it was not twenty-five copies which he refused to supply, but requests for a much larger number. Such requests seemed to him to be unreasonable, and with a view to limit it, he would move—

"That twenty-five copies of each paper read at evening meetings of the Society in London or Edinburgh and published in the Journal be sent to the authors of them, and that no further copies be supplied."

Mr. GREENISH asked if this would prevent the author of a paper from obtaining twenty-five more copies if he were prepared to pay for them.

Mr. BOTTLE thought it well to preclude gentlemen from getting more copies from the Journal printing office, which should not be made a convenience for trade purposes. On some occasions papers were read with a view to being subsequently advertised. Twenty-five copies was as many as a man could want for distribution amongst his friends, and those who required them for trade purposes should publish them themselves.

Mr. HANBURY suggested the addition of the word "gratuitously" at the end of the motion.

The PRESIDENT said that involved the principle whether further copies could be had on payment.

Mr. GREENISH said there were very few papers which could be considered as being read for trade purposes.

Mr. BETTY said the Committee had gone carefully into the matter, and the rule was proposed to prevent abuses.

Mr. SHAW thought this resolution would limit the privilege to papers read at London and Edinburgh; but he thought papers which were read at other provincial societies if inserted in the Journal should be entitled to the same privilege.

The PRESIDENT said he believed this privilege had never been extended to provincial societies.

Mr. SHAW said he had himself some years ago received copies of a paper he had read at Liverpool.

The PRESIDENT explained the different considerations which applied to papers read in London and at provincial societies.

Mr. SCHACHT said he had hitherto received on application copies of any papers he had read, and as he understood the present resolution it would preclude him ever asking for them and offering payment. As to the objection to advertising, the mere insertion of a paper in the Journal was a grand advertisement and a few more copies more or less afterwards could be of no material consequence.

Mr. HAMPSON supported the motion as it stood. He did not wish to undervalue any papers read at provincial associations, but he must admit that the papers read in London and Edinburgh in connection with the Society stood on somewhat different footing. When the large number of copies of which the circulation of the Journal consisted had been distributed he thought all had been done that could be expected. It would be better to have a definite rule to follow.

Mr. SANDFORD did not think the motion would in any way prevent the supply of papers such as had been referred to by Mr. Shaw and Mr. Schacht. The question of provincial societies was raised last month, when Mr. Mackay disclaimed any intention of touching it at all, and confined his attention to the papers read at the North British Branch. It seemed to him the motion only followed that.

Mr. SHAW said the motion mentioned two places only, and by inference all others would be excluded.

The PRESIDENT said copies were hitherto only sent to those who applied for them. No doubt that would be continued.

Mr. SHAW said it would be satisfactory if that expression of opinion were recorded.

After some further conversation, it was decided to refer the matter back to the Library Museum and Laboratory Committee for further consideration and report.

The Annual Report.

The Council then went into Committee to discuss the draft report, which with certain verbal alterations was agreed to in order to be presented to the Council at its next meeting.

HOUSE.

The report of this Committee referring to certain matters of detail affecting the repairs and furniture of the house, and recommended certain painting, cleaning, etc., to be done in the autumn recess, was received and adopted.

The PRESIDENT remarked that next year the International Pharmaceutical Congress would meet in London, and therefore it would be desirable that the house and premises should be put in good condition so as to exhibit a good appearance. It would be a question for the Committee to determine whether specifications and estimates should be obtained or not.

LAW AND PARLIAMENTARY.

The report of this Committee referred to some alleged cases of breaches of the Pharmacy Act, and to the usual report from the Solicitor. It also suggested that a letter should be sent to the Duke of Richmond with reference to the Medical Act Amendment Bill, in similar terms to that sent to Sir John Lubbock with regard to the Dental Practitioners' Bill.

The report was received and adopted.

GENERAL PURPOSES.

At a meeting of this Committee reports from the Professors had been laid before it as to the Prize Examinations.

Professor Redwood had reported very favourably of the regularity and attention of his class. The weekly *vivâ voce* examinations had been attended by all the pupils, and to this he attributed the more than usually satisfactory results of the examination. The number of competitors was fifteen, and fourteen completed papers were produced. Six papers had an aggregate of values attached to the answers of more than 75 per cent., the highest being 90 per cent. of the full value.

The Committee having opened the six motto envelopes containing the names of the successful competitors recommended the following awards:—

Chemistry and Pharmacy.

Bronze Medal ....William Brandwood Mason.
Certificate of Merit ...John Graham Sangster.
" " Henry Allen.
" " John Goodwin Cox.
" " Fredk. Wm. Collinson.
" " John Sydney Ashweek.

Professor Bentley had reported that eighteen candidates had competed for the bronze medal and certificates, and the results were most satisfactory, especially in the case of the first four. From some experiences in other educational institutions he had no hesitation in saying that such a high average of marks was but rarely obtained. The number of pupils had been about the same as at the same period of last year, and the proverbial good character of the school had been thoroughly maintained. He had still further developed the system of examination by testing the progress of the pupils after each lecture, and examining them in rotation on the subjects treated in the preceding lecture, so that practically each lecture now occupied from one and a half to two hours.

The Committee having opened the motto envelopes containing the names of the candidates who obtained the highest number of marks recommended that the following awards be made:—

Botany and Materia Medica.

Bronze Medal ....Henry Allen.
Certificate of Merit ...John Goodwin Cox.
" " Wm. Brandwood Mason.
" " John Sydney Ashweek.
" " John Graham Sangster.
" " Fredk. Walmsley Warrick.

The report and recommendations were received and adopted.

THE CONVERSAZIONE.

A meeting of the Conversazione Committee had been held and arrangements made similar to those on the last occasison. The report was adopted.

PHARMACEUTICAL MEETING.

Wednesday, April 3, 1878.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

A number of specimens, of which the following is a list, were exhibited :—

Indifferent Resin of Gurjun Balsam ($C_{28}H_{46}O_2$) crystallized (see before, p. 725), from Professor Fluckiger; Herbarium specimens of *Urechites suberecta*, Muell. Arg., from Jamaica, Urechitin, amorphous and crystalline Urechitoxin, Distilled Essential Oil of Orange Rind, of Orange Leaves, and of Red Cedar, and Expressed Oils of the seeds of *Hura crepitans*, and of *Calophyllum Calaba* from Mr. J. J. Bowrey, the Government Chemist in Jamaica; Specimens of the Double Chloride of Iodine and Potassium (KCl,ICl_3), from Mr. W. R. Dunstan; Specimen of Mercuric Chloride in crystals, from Mr. J. F. Savory; Specimen of Ozokerine, and of Angica Gum, from Brazil, from Messrs. Hearon, Squire, and Francis; Specimen of Resin called "Copal," from the Fiji Islands, from Mons. C. Chantre.

The minutes of the previous meeting having been read and confirmed—

The CURATOR called attention to the specimens from Jamaica. The oils of cedar and of orange peel appeared to him to be of excellent quality; the latter although it was distilled two years ago was still as sweet and as fragrant as if it had been made recently by the cold process; it was very rare in commerce to find oil of orange peel keep fragrant so long. The oil of the sandbox tree (*Hura crepitans*), was a drastic purgative in doses of 4 or 5 drops; perhaps it might be turned to account in the form of pills. The glucosides urechitin and urechitoxin were probably the most powerful poisons known, since he had been informed by Mr. Bowrey that $\frac{1}{500}$th of a grain sufficed to kill a pigeon. A specimen of the plant from which it was procured (*Urechites suberecta*, Muell. Arg.), was also upon the table. He believed that a paper on its physiological action had been forwarded to the Royal Society, and another on its chemistry to the Chemical Society, by Mr. Bowrey, and it would therefore be premature to say anything more about the poison at present. The specimens had been presented on this occasion as the donor was shortly about to return to Jamaica. The pretty specimen of corrosive sublimate in crystals and the double chloride of iodine and potassium were prepared by gentlemen who were studying in the laboratory of the Society, and were very creditable specimens. The ozokerine was, he believed, intended to compete with vaseline and was offered at a cheaper price, but whether equal to the latter he was unable to say. It appeared to be free from odour and of a convenient consistence. The copal from the Fiji Islands appeared to him to be very similar to Kauri gum, but he had not as yet examined it carefully. He thought it was very important that the products of foreign countries should be sent home for trial, and this appeared to be now done to a much greater extent than formerly.

Mr. BOWREY said the oil exhibited was prepared from ripe Seville oranges, just as they were turning yellow. They were brought down to his laboratory from the hills, peeled as quickly as possible, cut up in a sausage machine, and then distilled by means of superheated steam, at 120° to 130°C. These specimens had now been made for two years and three months, and had been a year in England. The oil of cedar was from a large log, which was cut up with a hatchet, and twenty pounds yielded one pound of the oil.

The PRESIDENT asked if Mr. Bowrey had formed any theory why these oils kept so much better than those generally used.

Mr. BOWREY said the subject was quite new to him and he knew very little about it.

The PRESIDENT said that oil of orange peel, especially, soon underwent a change, and then had a turpentiny odour.

Mr. BOWREY said he had carefully dried these specimens with plaster of paris, and besides possibly the freshness of the fruit had something to do with it. One sample of peel which was kept for about a day gave an oil which soon underwent a change. When he returned he intended to experiment with the green fruit which he expected would yield a larger quantity of oil, and probably a more fragrant product.

Mr. HILLS having taken the chair, a paper was read on—

SALICYLIC ACID.

BY JOHN WILLIAMS, F.C.S.

The paper is printed at p. 785, and gave rise to the following discussion :—

The CHAIRMAN in proposing a vote of thanks to Mr. Williams said the Society would no doubt have a further paper from him on the same subject, as he was continuing the investigation.

Professor REDWOOD said the paper was an interesting contribution and one of no small importance. Mr. Williams had done a great deal towards affording the explanation of a fact which many had been aware of, namely that the artificial salicylic acid sometimes failed in producing the effects anticipated, such as would be produced by the natural acid. He had had very little practical experience of its use, but he knew that difficulties had attended the use of the artificial acid.

Mr. PLOWMAN could fully confirm what Mr. Williams had said with reference to the statement that artificial salicylic acid frequently caused considerable derangement to the system. It had been given in St. Thomas's Hospital in doses of 20 grains every two or three hours and the result had frequently been to cause delirium, so much so that in one case the patient got under his bed and moved about with it upon his back, and in another case the patient pulled the leg off the bedstead and threatened the attendant. The subject had been brought under his notice but he had not yet had time to investigate it. He was therefore interested to learn from Mr. Williams that there was probably a new acid existing in combination in the commercial artificial acid. The salicylic acid used in St. Thomas's Hospital was colourless and distinctly crystalline. He had not examined the nature of the crystals but they were somewhat minute, perhaps one-third or one-fourth the size of a pin's head. He did not know the history of the acid used, but he thought from the price paid it was probably artificial. Although it sometimes appeared to derange the system, at the same time it had the required effect of lowering the general temperature.

Mr. NAYLOR having given some attention to this subject would ask Mr. Williams whether he could explain to what the colour was due in the alkaline compounds of salicylic acid; was it to a chemical or a physical change? He had some reason to believe it was a chemical change. The way in which he had operated on a small scale, was to mix the salicylic acid with the alkali in contact with carbonic acid gas, and continue the current during the process of evaporation. By that means, after recrystallization, he got a fairly colourless body, but this process was too expensive to work commercially. He next tried to get the same effect by evaporating the solution *in vacuo*. But the dry salicylate of sodium had then a distinct rose tinge, and when exposed to the air at 120°F. the air being somewhat moist it deepened in colour. Then he tried if he could obtain this deep colour by exposure during evaporation to a limited quantity of air, and the same colour was produced. The coloured portion appeared to him to resemble rosolic acid, although the quantity was too small to enable him to be certain, but it answered to many of the tests. He could neither explain the reaction nor how the rosolic acid could originate except on the ground that the salicylic acid which he employed contained some carbolic acid. He carefully tested it, therefore, and found that the salicylic acid was commercially pure; at any rate, free from carbolic acid.

Mr. PLOWMAN asked how Mr. Naylor determined that the salicylic acid was free from carbolic acid.

Mr. NAYLOR said he was quite aware that it was very difficult to assure one's self that salicylic acid was free from carbolic acid, but he thought the process given in the Journal some time ago might be fairly relied upon, not the one by recrystallization, but by the action of hypochloric acid, or chlorinated lime, on a feeble alkaline solution. At any rate if it contained any carbolic acid it could not contain sufficient to give rise to rosolic acid.

Mr. CLEAVER said it was extremely difficult to evaporate a solution of artificial salicylic acid without decomposition taking place the carbolic acid being formed.

Mr. WILLIAMS in reply said the evaporation of the salicylic acid in water was not desirable or proper, for it was very volatile in the vapour of water and a great deal might be thus lost. He was in the habit of neutralizing it and making it into a soda salt before attempting to evaporate the mother liquor. Respecting the colour produced by salicylic acid in the presence of an alkali, it was a well known fact and there was some difficulty in preventing it. It would be found that if the process were begun, not in an aqueous solution but in an alcoholic, the colour would be avoided to a great extent. In fact he had found that it was better to use alcohol for the purpose of making white salts. The salicylic acid was chemically closely allied to gallic acid and pyrogallic acid, and others of a class which when united with an alkali absorbed oxygen and became brown.

Mr. HILLS then resigned the chair to the President, who called on the Curator to read a—

NOTE ON GRINDELIA ROBUSTA.

The paper is printed on p 787, and gave rise to the following discussion :—

Mr. MARTINDALE said he had received a letter some twelve months ago from Dr. Squibb, together with a present of some *Grindelia*. In the letter Dr. Squibb said the *Grindelia hirsutula* had been used as a remedy for rhus poisoning, but not for asthma, but the *G. robusta* was used for the treatment of that symptom, and he knew of one house which had sold over 1000 lbs., and during the last two years all sold more or less of it. He had, however, only heard of one physician who had used it, and did not know with what results. He inferred, therefore, that it was chiefly used in self-medication. With proper skill in diagnosis of the causes of asthma the plant would be well worth a trial on such as should be relieved by nitrite of amyl but were not. He had much pleasure in forwarding a sample, which he believed to be the plant as described by Torrey and Gray, their best botanical authorities, but whether gathered at the period of greatest activity he could not say. He (Mr. Martindale) had examined the drug a little, but not with any definite results, and whether it was the resin present on the flower-heads which formed the active principle he could not say. He had made an alcoholic extract, and, exhausting this with water, had tried it with different reagents to see if he could get any alkaloidal reaction. With a solution of iodohydrargyrate of potassium he got no result; with an aqueous solution of iodine there was a dark brownish precipitate, and perchloride of platinum gave a minute quantity of crystalline precipitate. With solution of ammonia this aqueous solution, obtained by treating the alcoholic extract, gave but little reaction, so that whether it was a neutral or an alkaline principle to which the action was due he could not say. A full abstract of a paper on this drug, by Mr. Steele, appeared in the sixth volume of the present series of the Journal. It was very difficult to treat the drug pharmaceutically, for it was very tough and difficult to reduce to a state of comminution, and it could hardly be percolated or macerated with success, the stems and other parts of the plants causing great waste. It had been used to some extent in America, but very little in England as yet.

Professor BENTLEY said that so far as he could judge from reading the American publications, this plant was worthy of more trial than it had yet received in this country. It was by no means a new remedy, for it was more than ten years since attention was first called to it in California as a remedy in asthma, and it had been used to some extent in the United States since. He was glad, therefore, that Mr. Holmes had called attention to the different species of Grindelia. Another question was that started by Mr. Martindale as to the active principle. At present it seemed natural to conclude that the activity was due to the resinous matter which covered the flowers heads. There was a very good paper on the preparations of Grindelia in the 'Proceedings of the American Pharmaceutical Association' about four years ago,* and he might add that this volume was a most valuable annual publication, from which he had received great assistance with regard to medicinal plants. Particular reference was made in that paper to the great benefit derived from the use of a decoction of the *Grindelia* in relieving the cutaneous eruptions caused by the emanations of the poison oak. The effects described were very marked, and probably the drug might be useful in other cutaneous affections.

The last paper read was a—

NOTE ON THE ALKALOID OF DUBOISIA MYOPOROIDES.
BY A. W. GERRARD, F.C.S.

The paper is printed on p. 787, and gave rise to the following discussion:—

The PRESIDENT said the paper had interested him very much, but he observed that the quantity operated upon was very small, and therefore many of the reactions mentioned as differing from those of atropine, might possibly be accounted for by the product obtained not being quite pure. He had worked a good deal on atropine and knew how difficult it was to get it to crystallize unless it were perfectly pure. He did not say that the alkaloid was atropine, because they now knew that daturine and other alkaloids of the same class, which were once supposed to be the same as atropine, were different, and it might be the same with this, but they could not feel quite certain about the matter without further experiments.

Dr. PAUL said some portion of the alkaloidal substance mentioned by Mr. Gerrard had been forwarded to him, and he had submitted it to some examination. He could confirm almost entirely Mr. Gerrard's statements with regard to the reactions and general chemical behaviour of this substance. It was in the state almost of a treacly mass, and so far as he had been able to work with it at all it refused to crystallize. There was so much vagueness about the chemical characteristics of atropine that it was somewhat hazardous to say whether this was identical with it or not; but his own opinion was decidedly that it was not. It was totally destitute of any signs of crystallization, and by any means he had been able to apply to it could not be provoked into crystallization. Again, its solubility in water was far in excess of that of atropine, and the alkalinity was also very marked, the reaction being almost as strong as that of a weak solution of caustic soda. Of course it was useless to attempt the combustion of such a material. He had therefore attempted to obtain a compound of it, but had hitherto failed in obtaining anything which could be called definite. The platinum chloride and the iodohydrargyrate were both oily, viscid masses which were very unpromising to deal with. The compound with auric chloride as he first obtained it was also of the same character, and it was not until after several trials that he succeeded in getting a crystallization of this compound. At first there was a considerable tendency to a reduction of gold, and on that account it was necessary to evaporate without heat. In looking at the solution on the previous day he noticed that there was a distinct crystallization

* See *Pharm. Journ.* [3], vol. vi, p. 566.

commencing, and that morning he found this was gradually developing as the evaporation went on. There was every reason to believe, therefore, that a definite crystallizable auric chloride compound was to be obtained from it, and that they might expect to get some definite data as to the composition and the relation of this alkaloid of atropine.

Mr. HOLMES said he had received a note that morning from Mons. A. Petit, of Paris, which might throw some light on this matter. M. Petit said that this alkaloid appeared to be different from atropine, being crystallizable with great difficulty, and ten times more soluble in water. He did not think this great solubility was due to impurity, because what he had operated with had been twice treated with ether in the presence of an excess of bicarbonate of potash. Aqueous solutions of this alkaloid were fluorescent and dichroic, being yellow by transmitted, and bluish green by reflected light. The double chloride of gold and of the alkaloid crystallized well and would permit of its being analysed and its constitution determined. The alkaloid was easily obtained by treating an aqueous solution of the extract with bicarbonate of potash until an alkaline reaction was produced, and then agitating with ether. He had obtained 1·10 gramme of the alkaloid from 60 grammes of the extract. Mr. Holmes further stated that Dr. Bancroft, of Brisbane, who discovered the properties of duboisia, was present, and he hoped would say something upon it.

Dr. BANCROFT was glad to find that the results just described agreed so well with those obtained by the chemist in Brisbane, who had worked hard at this question for six months for him. He could make no crystals, except that occasionally a chance crystal or two would appear. At first it was thought the extract had decomposed, and on one occasion the chemist worked with 50 lbs. of fresh leaves, but the result was the same. He (Dr. Bancroft) was not sure that the physiological action would not be found to be different from that of atropine; it was certainly much stronger, for the watery extract alone was equal, weight for weight, to atropine. One very peculiar physiological effect was this. If a dose were given to a dog subcutaneously, he would walk straight forward, and if he got into a corner he would struggle and cry for a long time, and paw at the walls, but it appeared never to occur to him to turn round. The same thing would happen if he got mixed up with the legs of a chair; he would fight with them for some time before he got out, and seemed to have no notion of going anywhere but straight forward. On cats, however, it had not this effect. *Pituri* was another very remarkable drug which he hoped before long to be able to bring before the Society. He believed it had more curious effects than any other drug. The natives chewed it before undertaking anything desperate, such as a fight. It was a strong poison, and a single drop of the prepared drug would kill a cat in a minute with symptoms very like tetanus. It was very difficult to get; the natives carried it about in bags ground up into a kind of powder, and traded with it in the interior. He had brought to this country a few ounces of the extract, but he hoped to get some seeds and grow the tree. It grew on the borders of Queensland, about a thousand miles from where he lived, and since 1872 he had been trying to get seeds and had not yet succeeded; but he still hoped to do so, and if he were able to cultivate it he had no doubt that a very curious medicine, which might prove of great value, would be obtained.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The twelfth general meeting was held at the Royal Institution, March 28, 1878. The President, Mr. T. Fell Abraham, in the chair. The minutes of the previous meeting were read and signed.

The donations to the library were duly acknowledged.

Mr. J. H. Owens, 52, St. Anne Street, was unanimously elected an associate.

The following paper was read on—

LIQUID DIFFUSION AND DIALYSIS.

BY CHARLES SYMES, PH.D.

The publication of Professor Graham's masterly paper on "Liquid Diffusion Applied to Analysis"* in which he not only brought together such meagre and disconnected facts as were already known concerning it, but added much original matter, the result of a large number of experiments and careful observations, establishing the whole on a sound and scientific basis, directed special attention on the part of chemists and physicists to the subject. Seeing the extensive field of inquiry which this appeared to open up it is rather surprising that so comparatively little has resulted from the investigations by others; and here we are, after sixteen years, with, as far as I am aware, very few new facts added and but little practical benefit accruing therefrom. It will not require much logic or argument to prove that this must be due either to the unsatisfactory nature of the process itself or the imperfect work of those who followed Graham in its investigation; be that as it may, one after another appear to have dropped the inquiry for an apparently more profitable, more interesting, or less worked field of inquiry. On reading the paper I was impressed, as doubtless were others, with its probable utility in toxicology, and in my own small way commenced a series of experiments in that direction which were not attended with a reasonable amount of success, and I arrived at the conclusion (correctly or otherwise) that as a means of separating small quantities of poisonous substances from large quantities of organic matter with which they were mixed and more or less combined, the process was not superior, and in most instances not equal to, already recognized methods; nevertheless I gained a conviction that it was a subject capable of further development, and want of time is my only reason for not having prosecuted the inquiry still further until a more recent date. I bring before you (prematurely perhaps) the following remarks, hurriedly put together, in the form of a paper, because our president had kindly placed this evening at my disposal for a short lecture on sound, accompanied by an exhibition of my phonograph, but up to the present it has stubbornly refused to give anything more than a faint mimicry of an articulate sound and that with some uncertainty.

Graham divides all substances into two classes; the first, such as sulphate of sodium, nitrate of potassium, sugar, etc., being more or less crystalline in character, readily soluble, and highly diffusive, are called crystalloids. The second, such as hydrated peroxides, silicic acid, gum, starch, tannin, gelatine, vegetable and animal extractive matter, etc., being marked by their low diffusibility, comparative inertness as regards chemical action, gelatinous character of their hydrates, and feebleness with which they are held in solution. Physically the first class possess more or less static, the latter dynamic, characters, always in a condition of change they readily pass into the pectous form, and from their plastic and impressible character they are permeated by crystalloids almost as readily as water itself; to this latter class the name of colloid has been given. In illustration of their permeable nature I have here a tall jar of gelatine in a hydrated condition, the lower stratum (which has been coloured red to distinguish it) forming one-fifth of the whole, contained when introduced five per cent. of sodium chloride. This was allowed to solidify, and on it was poured a cold solution of gelatine only, near its point of solidification, a tube funnel being used to prevent any disturbance or admixture of the two; it quickly set, and now at the expiration of five days we will examine it to different depths, and I doubt not but a little solution of nitrate of silver will reveal the fact that the chloride has risen at least through

* Philosophical Transactions, Part 1, 1862.

one half of the colloid without any change in the position of the latter. Here is another jar in which the sodium chloride has been replaced by potassium dichromate; in this we have ocular demonstration of the height to which the salt has risen by diffusion. No fixed line of demarcation exists between these two classes of bodies, but a peculiar property exists between any two strictly colloidal bodies of impenetrability to each other. What is it now which causes this denser body, in opposition to the laws of gravitation, to rise up through the lighter one in this remarkable manner? Can it be a special diffusive force existing in the crystalloid? We find that though possessed of chemical activity this class of bodies are physically static and more or less unchangeable. Not so the colloid; its molecules are loosely held together, its existence is a constant, though somewhat slow metastasis; and this has led me to the conclusion that it is no new force but a special form of a well recognized one; that it is in fact *molecular capillarity*, the molecules of the colloids being so feebly aggregated that the molecules of the crystalloid are drawn up between them, just as a fluid might be drawn up in a fine capillary tube, the only difference being that in the former we have capillarity between molecules, in the latter between masses of matter.

In gases we have Graham's well-known law that "the rate of diffusion is inversely as the square root of the density;" with the less mobile fluids under consideration no such law obtains. Hydrochloric acid is found to be amongst the most diffusible of bodies, and its time for the diffusion of a given quantity being taken as 1, that for a similar quantity of sodium chloride is found to be 2·33, for sugar and magnesium sulphate 7. As a rule, chlorides diffuse more rapidly than sulphates or nitrates; potassium salts more readily and rapidly than the corresponding ones of sodium. From these and other facts I have ventured to deduce the following law, which will doubtless be found subject to some, it might be many, exceptions, viz.:—*That the rate of diffusion is directly as the solubility of the crystalloid in the liquid atmosphere in which it is diffused.*

Diffusion in alcohol is much slower than in water; indeed alcohol is itself a crystalloid, although lower in the scale than the substances we have been dealing with. Here is an arrangment for diffusing coloured alcohol through an aqueous solution of sugar. Seeing that it is assisted by its lesser gravity it rises very readily, first forming small vortex rings and then spreading out into a laminated and finally arborescent appearance.

Let us now pass on to the second part of our subject, which has a more practical bearing on pharmacy, viz., dialysis. Certain substances possessing colloidal properties, such as hydrated metallic oxides, silica, alumina, etc., which under ordinary circumstances are insoluble in water, are by this means rendered perfectly soluble, but they are held in solution by a very feeble force and in consequence readily pectise or form an insoluble jelly.

The process consists, as you will be aware, of placing a liquid, in which the colloid is held in solution by the presence of a crystalloid, over a floating diaphragm or septum of a colloidal nature, when the crystalloid passes through and diffuses itself through the watery medium beneath, whilst the colloid (otherwise insoluble) is retained above in solution. The septum first recommended and that generally used is parchment paper, and Graham's view as to the rationale of the process is that it has no power to act as a filter and resist the passage of the fluid as a whole, but is permeated by crystalloid molecules capable of de-hydrating it; so that the process is one of continual hydration and de-hydration of a wetted membrane. Now if this view is correct, no such septum would be suitable for dialysis in any other than an aqueous medium and the process would exclude all substances soluble in alcohol only. But this theory has been challenged by M. Guignet, who obtained satisfactory results by the use of unglazed earthenware as a septum. Flat battery cells answer remarkably well for this purpose and a series of these arranged in a trough make a convenient and efficient dialyser. I have varied the septum by using asbestos cardboard, split sheepskins, thick French filtering paper, and also fine muslin saturated first with a solution of gelatine and subsequently with a solution of chrome alum, which renders the gelatine insoluble; at present, however, it would be premature to report on their comparative value. I have also substituted a hoop of glass for the ordinary one of gutta percha as being more cleanly and not liable to get out of shape, which is frequently the case with the latter after being a short time in use.

The chief preparation which has come into use as a medicine is dialysed iron. This, which is some ten or twelve years old, at least as a pharmaceutical preparation, has during the last few months been quoted in medical journals as a new or quite recent remedy. That it has been so largely prescribed of late is due I feel satisfied to an erroneous idea on the part of the medical profession as to its mode of preparation. Dialysis is performed either for the sake of the diffusate (the substance passing through) or for the dialysate (the portion remaining behind); these two have been more or less confused, and dialysed iron is not unfrequently prescribed under an impression that it will be readily absorbed into the system because it has passed through wetted membrane. Now the only merit possessed by dialysed iron, as far as I am aware, is that it is tasteless. But were it not that its condition becomes changed in the stomach it would pass through the system unabsorbed; but that some change does take place is certain, and at the request of several medical men I have undertaken to ascertain as far as possible to what extent it does so. The usual dose is one teaspoonful containing 3 grains of oxide of iron, and as far as my experiments take me at present, it is probable that the whole of this becomes converted into a crystalloid condition (chiefly perchloride) by the action of the gastric juice. A convenient and satisfactory working formula for its preparation is as follows:

Hydrated peroxide of iron is prepared by pouring, say four pints liquor ferri perchlor. B.P. (not the strong) into one pint liquor ammoniæ previously mixed with three pints of water (the exact quantities will vary somewhat according to the acidity of the iron solution), well wash the precipitate so obtained and drain on a calico filter; this is now dissolved to saturation in liq. ferri perchlor. fortior by the aid of a gentle heat. The necessary quantity will vary from half a pint to nearly a pint. The solution so obtained is placed in the dialyser to the depth of half an inch, and the latter is floated in a vessel of water where there is an arrangement for keeping up a constant flow underneath the parchment or other septum. The process is continued until the solution in the dialyser is almost or entirely free from styptic taste, and the strength should be such that on evaporating 100 grains in a tared capsule five grains of ferric hydrate remain, in other words it should be a five per cent. solution. In the *Canadian Pharmaceutical Journal* for October Mr. E. B. Shuttleworth writes an excellent paper on this subject, indicating a thoroughly practical acquaintance with the processes; he there gives two formulæ, one of which as nearly as possible accords with the one I have given. It is usual to place the dialyser on still water which is changed daily, but dialysis (a slow process at the best) is certainly facilitated by constant change of the liquid into which the diffusate passes. This I first proved experimentally in the following manner. Into two small dialysers, each possessing a superficial area of 100 square centimetres, was placed 100 c.c. of a two per cent. aqueous solution of common salt and gelatine; one of these was set to float on a litre of distilled water at rest, the other in such an arrangement as I have here, where a slow but constant current of water was passed under the diaphragm by means of capillary attraction. When one litre of water had flowed through, nearly the whole of the salt had been separated from the gelatine, whilst in the dialyser over the same quantity of still water about 30 per cent. of the salt remained. The experiment was repeated with similar results.

In France a successful application of dialysis is made to sugar refining. It is a well known fact that partially refined beet sugar contains a large percentage of potash and other salts. Now these (and the potash in particular) are not only objectionable as an impurity, but tend to prevent the sugar from crystallizing; its separation being somewhat difficult.

A saturated solution of sugar is placed to a shallow depth in large dialysers and a rapid current of water is made to flow underneath. So greatly superior is the diffusive power of the potassium salts to that of the sugar that the former is largely got rid of without any considerable loss of the water; indeed it is found an economic process for the purpose. Where the process is performed for the sake of, or with a view to preserving the diffusate, a large quantity of water cannot be used and the time occupied is increased. The purer the dialysed product the more readily does it spoil. Dialysed iron, as usually prepared for pharmacy, contains a small quantity of basic chloride, and it is this which enables it to remain unchanged for some length of time. Caramel might be dialysed till its colouring properties for a given quantity are considerably increased; but unfortunately it will not keep when thus purified more than a few days and will sometimes pectise in a few hours.

Dialysis is a process going on to a vast extent in nature, and is, I believe, capable of further development in the arts.

A lengthy discussion on the subject followed, in which the President, Messrs. A. C. Abraham, Michael Conroy, F.C.S., A. G. Haddock, Edward Davies, F.A.S., A. E. Tanner and others took part. Dr. Symes replied to questions asked and on the points of the discussion. A hearty vote of thanks to the author, which was carried by acclamation, brought the meeting to a close.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

March 30th, Anniversary Meeting, Dr. Gladstone, F.R.S. President, in the chair. The President in his address, after referring to the general history of the Society during the last twelvemonths, mentioned that the whole subject of the bye-laws had received the very careful attention of the council. The verbal alterations recommended were very numerous but the real alterations affected mainly the mode of electing fellows and of appointing auditors. The constitution of the publication committee has been entirely altered; it will for the future consist of six members in addition to the five officers of the Society. Various arrangements have been made for expediting the publication of papers, and the editor has made a successful effort to bring the work of abstracting up to date. This has involved the printing of an extra number of the Journal, which is on the point of being issued. As the duties connected with abstraction are increasingly laborious the Society has determined to appoint a sub-editor and has been fortunate in securing the services of Mr. C. E. Groves for the post.

The "Research Fund" now amounts to about £4000. Already two papers resulting from assistance rendered by its means have been received, viz.:—"On some points in Chemical Dynamics," by Dr. Wright and Mr. Luff, and "On certain Poly-iodides," by Mr. G. S. Johnson. It is to be hoped that many other chemists, especially those to whom the pursuit of chemistry has become a source of wealth, will contribute handsomely to this important fund.

Since the last anniversary meeting an independent institute of professional chemists has been formed and has been incorporated (October 2nd), under the title of the "Institute of Chemistry of Great Britain and Ireland," with the two following objects:—*a.* To promote and encourage a thorough study of chemistry and all branches of science allied thereto in their application to the arts, to agriculture, to public health, and to technical industry. *b.* To adopt such measures as may be necessary for the advancement of the profession of chemistry, and particularly for the maintenance of the profession of the consulting and analytical chemist on a sound and satisfactory basis. It will thus be seen that the two Societies are perfectly distinct, but may be mutually helpful; the President therefore wishes all prosperity to the new Institute.

Sixty-five papers have been read before the Society during the past year, and two lectures have been delivered. There are at present 965 fellows, 49 have been elected during the past year. The Society has lost by death one eminent foreign member, M. Regnault, whose name is so well known by his researches on specific heat, etc., etc., as well as R. Apjohn, late Prælector of Chemistry in Caius College, Cambridge, who died in his thirtieth year from the results of a fall from a bicycle; J. J. Griffin, the founder of the well known firm of chemical instrument makers; W. Gossage, alkali and soap manufacturer; J. Hall, late Science Master at the City of London School; E. L. Koch, M. Murphy, Dr. H. M. Noad, late Professor of Chemistry at St. George's Hospital, author of a 'Manual of Electricity;' and E. F. Teschemacher, of the firm of Denham-Smith and Teschemacher.

A vote of thanks to the President for his able address was proposed by Mr. De La Rue.

Dr. Frankland, in seconding the vote, referred to the establishment of the Institute, stating that he was at first anxious to have it founded in connection with the Chemical Society. This was found, however, to be impossible, and he was at one time afraid that a separate body might injure the interests of the Society. He was glad to say that his fears were groundless, and he had every reason to believe that the founding of the Institute would furnish the Society with many welcome fellows.

The vote of thanks was then put and carried.

The President, in returning thanks, said that he had endeavoured to do his best for the Society, and thanked the members of council, the officers and fellows for their constant and unremitting kindness to himself.

The Treasurer, Dr. Russell, then gave a statement as to the condition of the Research Fund.

At the conclusion of the report it was announced that Mr. De La Rue had offered a sum of £100 to be given to the Research Fund, on the condition that it was to be devoted to any one important research.

A vote of thanks to the Treasurer for his report, and to Mr. De La Rue for his handsome donation, was proposed by Dr. Odling, seconded by Mr. Neison, and carried unanimously.

The Treasurer then read his report of the condition of the funds of the Chemical Society.

A vote of thanks to the Treasurer for his lucid and satisfactory statements was proposed by Mr. Abel, seconded by Mr. E. Riley, and carried unanimously.

Dr. Odling then rose to move that the report of the President be received.

Mr. Neison, in seconding the motion, referred to the want of reagents in the preparation room, and the desirability of distributing the general index of papers to all fellows free of charge. He also made some remarks as to the present mode of electing and admitting fellows.

In reply, Dr. Russell said that there had been no demand for reagents, but if such a demand did arise there would be no difficulty in supplying them.

Dr. Armstrong also said that he always made a point of communicating if possible with authors, so as to have anything they might want ready for their use.

Mr. Crookes then proposed a vote of thanks to Mr. Watts, "our talented and conscientious editor."

Mr. Howard seconded the vote, which was carried unanimously

Before electing the council, etc., Dr. Odling asked the Secretary for information as to an alternative, which he ventured to designate an opposition list, which had been circulated; it was such an exact copy of the list issued by the council that many fellows thought that both lists had come from the same source.

Dr. Armstrong replied that the persons issuing the list were unknown to him.

Mr. Riley thought that the name of the fellow who issued the list ought to have been attached to it, to prevent mistakes.

Mr. Neison said that he had issued the list on his own responsibility, and that he much regretted if anyone had been deceived by it. He thought as he had proposed Mr. Kingzett at the last meeting that everyone would have known where the list came from, besides an additional name on the list would have rendered the balloting-paper illegal.

The election of officers was then proceeded with, Messrs. Beale and Thomson having been appointed scrutators. The following were elected:—President, J. H. Gladstone, Ph.D., F.R.S.; Vice-Presidents, F. A. Abel, C.B., Sir B. C. Brodie, W. De La Rue, E. Frankland, A. W. Hoffmann, W. Odling, Lyon Playfair, A. W. Williamson, T. Andrews, W. Crookes, F. Field, N. S. Maskelyne, H. E. Roscoe, R. Angus Smith; Secretaries, W. H. Perkin, H. E. Armstrong; Foreign Secretary, Hugo Müller; Treasurer, W. J. Russell; Council, Lothian Bell, M. Carteighe, A. H. Church, W. N. Hartley, C. W. Heaton, D. Howard, G. Matthey, E. Riley, W. A. Tilden, R. V. Tuson, R. Warington, C. R. A. Wright.

The meeting then passed the bye-laws as amended by the council with a few verbal alterations.

Parliamentary and Law Proceedings.

Opium Eating Extraordinary.

Samuel Wilkinson, a young man, not quite twenty, was on Friday, March 29, brought up before Mr. Huntriss and Captain Rothwell, at the Halifax Borough Court, on a charge of attempting to commit suicide.

The chief constable stated that the young man was an articled clerk to a solicitor, and was apprehended on Thursday night on a charge of attempting to commit suicide, but he had made inquiries since, and was under the impression that he had no such intent. It appeared that he was an opium eater, and could take 180 grains, which would be sufficient, he believed, to kill sixteen people. He went to a chemist's shop in Northgate where he bought some cocculus indicus as a substitute for opium, and took it on Wednesday night, in consequence of which a man with whom he lodged fetched a police-officer. He was found in a bad state, and taken to the Infirmary, but discharged on Thursday.—The Bench dismissed the case.—*Bradford Observer.*

Singular Action Against Mine Owners.

In the Nisi Prius Court at the Cornwall Assizes on March 27, before Sir James Fitzjames Stephen, a case of considerable importance to the owners of mines was tried. An action was brought by Mr. Reynolds, of Trevenson, near Pool, to recover £50, the value of a horse said to have been killed by means of arsenical deposits coming from the arsenic burning houses of East Pool Mine, and falling upon the grass in the field in which the animal was grazing. The stomach of the horse was analysed, and grains of arsenic were found in it, and evidence was called to show that there were not those arrangments existing in the mine which would condense the arsenic gases into arsenious acid, or the sulphuric acid, but that these escaped from the shaft, and poisoned the surrounding vegetation. The mine adventurers were made to be defendants, and they produced evidence to prove that no appreciable quantity of arsenic escaped, and that everything was done that could be done to prevent the outflow of any poison. It was also argued that there were scores of these works in the country, and that if they were subject to actions of this character, no mine could go on making arsenic or raising the tin stone from which the acid was obtained. Dr. Otland and Mr. Collins, the county analyst were examined in support of the defendants' case, and the jury gave a verdict for the defendants.—*Daily News.*

Alleged Adulteration of Soda Water.

On Wednesday, March 27, at the Borough Police Court, Humphrey Wood, South Street, Huddersfield, aerated water manufacturer, was charged with having, on the 8th inst., sold to the Sanitary Inspector three bottles of soda water which was not of the nature and substance demanded by the purchaser.—Mr. W. Armitage appeared for the defendant.

Mr. Kirk, the Sanitary Inspector, stated that on the day in question he went to the defendant's shop, at the corner of New North Road and West Parade, and asked to be supplied with three bottles of soda water. The defendant told him he had none there, and requested witness to accompany him to his manufactory in South Street, which he did. There the defendant supplied him with three bottles of soda water, and he offered the defendant a part, but the defendant said he did not require it, as he had plenty more in the works. Witness afterwards submitted the soda water to Mr. Jarmain, the borough analyst, who gave a certificate, showing that the sample he had analysed consisted of a solution of carbonic acid gas and there was no bicarbonate of soda in it at all. The solution contained lead amounting to about one-fortieth part of a grain, but it was in too small a quantity to have any injurious effect on health.—Mr. Jarmain gave evidence to this effect.

Dr. Cameron, the medical officer of health, stated that proper soda water should have thirty grains of bicarbonate of soda to each pint. If he ordered soda-water for a patient, he should expect to have certain definite actions as a result of the drug—actions which he never could expect to have from simply aerated water.

For the defence it was urged that the affair was the result of an accident, pure and simple.

Mr. Armitage explained the mode in which soda water and ginger beer were made, and said that after the ginger beer had been made some of the pure filtered water must have been left in the receiving pan, and when the soda water making was resumed the pure water got charged in the usual way, and was put into the soda water bottles without really having any bicarbonate of soda in it.

The defendant gave evidence to the effect that he bought the best bicarbonate of soda, giving 1s. per pound for it, and he put 12 ounces to 125 gallons of water. He said he had never manufactured soda water without soda knowingly, and he never knew an accident similar to this.

The bench fined the defendant 20s. and the expenses, but said they did not believe that the defendant had any intention of being dishonest, the affair having arisen more from carelessness that anything else.—*Leeds Mercury.*

Reviews.

Papers on the Plant Gynocardia Odorata, from which the Chaulmoogra Oil is obtained. By R. C. Le Page. Trübner and Co. 1878.

This little pamphlet is a compilation of papers relating to Chaulmoogra Oil from various sources. It is practically an advertisement of Chaulmoogra Oil, for on page 6 the author states, The first object of myself and those associated with me in making the sale of this oil a commercial adventure, will be to import it of undoubted purity." In the introduction it is stated that "the purport of this pamphlet is to bring together all that has yet appeared in scientific and other publications of the plant from which the Chaulmoogra Oil is obtained." Instead of containing a *précis* of all that is known of the plant, the author has simply extracted the papers as they stand, from various works such as the *Pharmaceutical Journal*, 'Pharmacographia,' etc., with the result of leaving the non-botanical reader very much puzzled as to what family of plants *Gynocardia odorata* really belongs. Thus on page 10 it is referred to Pangiaceæ; on pages 18 and 22 to Flacourtiaceæ; and on page 23, to Bixineæ, and to tribe Pangieæ (ord. Bixinæ). There can be doubt that the oil really possesses valuable properties, and that it has been found useful in leprosy, various skin diseases, and the incipient stages of consumption, and that it is well worthy of extended trial in this country. If the oil does come into use here Mr. Le Page's pamphlet will doubtless prove useful for reference. A few explanatory remarks, and a summary of the botanical details would, however, have much enhanced the value of the pamphlet.

New Commercial Plants, with directions how to grow them to the best advantage. No. 1. By Thos. Christy, F.L.S. London, 1878.

The author of this little pamphlet is known as an energetic contributor to the introduction of useful plants into new countries. Though it must be looked upon primarily in the light of a trade advertisement, it will be found to contain some useful information on the cultivation of the Liberian Coffee (*Coffea liberica*, Hiern), the West Tropical African Rubber Tree (*Landolphia florida*, Benth.), and Turkish Tobacco. The first-named bids fair to supersede the ordinary coffee in tropical countries, as it can be grown at the sea level, and yields a larger crop of berries, which, it is said, are also of a finer flavour; moreover the destructive coffee-fungus is not known to attack it. The Government of Liberia has recently placed a prohibitive export duty on the seeds and young plants, but the species is not confined to the small portion of West Tropical Africa occupied by that Republic. The pamphlet is illustrated by copies of the plate illustrating M. Hiern's original botanical account of *Coffea liberica* in the 'Linnean Transactions,' and of that accompanying the description of *Landolphia florida*, in Kotschy's 'Plantæ Linneanæ.'

Notes on the Treatment of Skin Diseases. By Robert Liveing, A.M. and M.D. Cantab., etc., etc. Fourth edition. Longmans. 1877.

When the first edition of Dr. Liveing's little work appeared it was very favourably received, and the fact of a fourth edition being so soon issued is convincing proof of the estimation in which it is held.

Clear and concise in its description and treatment, well printed and neatly bound, it constitutes a portable clinical guide, useful to practitioners and students. An index appears for the first time in the present edition, and adds materially to its value.

The collection of formulæ—from various sources—is a good one, and includes many convenient recipes for administration and application of medicaments, but we fail to notice the production of any novelties calling for special remark.

Dispensing Memoranda.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be considered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.

---

[92]. In answer to T. F. E., I beg to state that I always use the heavy oxide (B.P., page 201), when magnesia is ordered.

A. Billington.

---

[93] This is a case of undue concentration and cannot be dispensed satisfactorily, owing to the resin of the bark being precipitated. The only way I see out of the difficulty is to send out the solution of iodide in one bottle and the bark in another, with full directions for mixing each dose. If the prescriber could not be communicated with, a note should be made on the prescription for the guidance of future dispensers.

George Brown.

---

[94]. Will some reader kindly give the best excipient for making carbolic acid pills?

Dispenser.

---

[95]. I had the following prescription handed to me this week to be dispensed and am fairly puzzled by the second article. Can you or any of your readers enlighten me?

℞ Hydrarg. Bichlor . . . . . gr. iv.
Tr. Sap. Virid. Co. . . . . . ℥ss.
Aquæ . . . . ℥iss.

For external use night and morning.

I may add it was written in New York, but I cannot find any such article in the U.S. Pharmacopœia.

G.

---

[96]. Will some one kindly give me a formula for the following prescription?

Ol. Hydrarg. et Morph. . . . ℥ss.
(Ten per cent.)

A. S. R.

---

[97]. Will you kindly insert enclosed in the Dispensing queries?

℞ Potassii Bromidi,
Potassii Bicarb. . . . . . . āā ℥ss.
Sol. Taraxici . . . . ℥j.
Aquæ . . . . ℥iij.

Sig. Shake the bottle and take two teaspoonfuls three times a day in water after food.

What is meant by Sol. Taraxici? Does not "shake the bottle" seem to indicate something thicker than Succus Taraxici, perhaps a solution of the extract? Some of your correspondents may perhaps say what is intended, and oblige,

Glasgow, March 30, 1878. Euryowie.

Notes and Queries.

[581]. IRISH SLATE (LAPIS HIBERNICUS).—The following is the description of this Irish slate as given in Gray's Supplement:—"An argillaceous slate, said to contain iron and sulphur. It is found in different parts of Ireland, in masses of a bluish-black colour, which stain the hands. When powdered, it has a light bluish tint, which becomes darker with keeping. When exposed to the fire it acquires a pale red colour, and emits a sulphurous smell. The powdered slate is sometimes administered by the poor as a remedy for internal bruises."—F. P.

A similar answer has been received from J. F. R.

[584]. PREPARED SILICA.—Can any reader inform me where the fine levigated silica is to be obtained for cleaning plate, lenses, etc.?

A. D.

[585]. BALSAM OF ANISEED.—Would any reader be kind enough to inform me of the formula for balsam of aniseed as I am continually asked for it? With dose and how sold.

THE EXAMINATIONS.

Sir,—I have been expecting that some senior member of the trade in Scotland would take up in the Journal the defence of Scotch chemists and druggists against the literary missiles projected weekly by some from the south of the Tweed. Mr. Duncanson, Stirling, has been harshly criticized by some of your correspondents, and I am sure no one with any knowledge of that gentleman's status in the trade would venture to attribute to him motives having a tendency to introduce a lower class or a less educated set of youths to it. Our friends south of the Tweed apparently know very little of the exact position occupied by Scotch chemists and druggists, else we would have heard less about their "standard of perfection." The only gentlemen who have ventured to defend the position are Mr. Fairlie and Mr. Mackay. The latter gentleman is, I presume, a "real Mackay," and he deserves the best thanks of the Scotch druggists for his defence of them and the Edinburgh Examining Board.

It is intolerable to have slurs continually cast at this Board, and it appears to be only a *ruse* to get all the examining machinery removed to London, to further enrich and elevate the institution there and endeavour to lead members of the trade to believe that nothing is genuine unless what emanates from that great centre direct. Scotch druggists have managed their trade affairs very well in the past, and I can see no reason why the same may not continue. Of course the centralization system and tendency is in active operation, and it may be a "wire pulling" dodge, these insinuations against the Scotch Board of Examiners. However this may be, I say, let the examiners take courage and the Scotch chemists and druggists do the same, and insist on being left free from the literary projectiles from across the border. I have not one word to say against the examinations, but am rather pleased to know they are so fair and practical. We in Scotland cannot get genteel apprentices, as such prefer being bankers' or lawyers' clerks, for what reason I do not understand unless the short hours and the fact of being in an office instead of a shop. Provincial druggists in Scotland do not, as a rule, either from the nature or extent of their trade, keep a porter, and messages and the like have to be done by the younger apprentices. It will be at once understood, then, that we have to take our pupils from the working class, but not from that stratum of it which supplies "errand boys." It is almost impossible for a Scotch tradesman to afford keeping his son at school beyond the time he is between thirteen and fourteen years of age, which is the very time to set a lad to the study of higher education. Now what remains to be done—and I do it myself and can recommend it to others—is to enter the lad immediately he leaves school and arrange for him prosecuting the higher branches at certain hours under the same master to whom he is accustomed. I have found the plan work well, and those who have left my service to fill assistantships have all passed their Preliminary examination a year or more before their apprenticeship was finished. Of course they did not attend school as ordinary schoolboys, to put in the time and shirk their lessons when too lazy to learn them, but as with a well defined object in view, and by my interesting myself in their school work and encouraging them therein I have had the best results. It is a pleasant thing to turn out a young man well grounded in the rudiments of a business by which he is to earn his daily bread, and I feel that it is the duty of all those who train apprentices to provide for their passing the Preliminary examination before they are sent out as assistants. It may be that at the present time there is a little too much made of the scientific branch of our trade and too little heed given to being really useful and valuable assistants on the part of young men, but this is merely a personal matter, and employers usually succeed in weeding out suitable and profitable assistants only.

I hope these remarks may be taken in good part, and that they may assist in leading to good results is the sincere wish of

WM. R. KERMATH.

St. Andrew's, Fife, April 2, 1878.

THE PATENT MEDICINE QUESTION.

Sir,—In my opinion the only remedy to prevent patent medicines being sold by grocers, etc., is to have the sale of them restricted to registered chemists and druggists, and let the licence be increased. Here, in this city we have many grocers selling patents at $9\frac{1}{2}d.$ and 2*s.* 3*d*, sweet nitre, camphor, senna, and other drugs at the same proportionate low price, and injuring the fair legitimate trading of the chemist to a fearful extent; in fact, the sale of patents to our customers is becoming quite an unpleasant affair. Customers inquire how is it they have to pay 1*s.* $1\frac{1}{2}d.$ for a box of Cockle's pills at the chemist's while at the grocer's they only pay $9\frac{1}{2}d.$; any explanation is received with a "peculiar shrug of the shoulders."

Another source of mischief is, we unfortunately have among us some wholesale houses who do not hesitate to supply these and any other parties not connected in any way with the trade, and then they have the cool assurance to wait upon the "poor chemist" and solicit his orders, knowing they are at the very time supplying his "unfair" "cheap," and I may add, "illegal" rivals. Now, sir, I ask, is such a mode of doing business fair?—for my part I consider it scandalous. I should be glad to see a better "*esprit de corps*" spring up among both retail and wholesale chemists. I enclose you, sir, a list of prices at which patents are sold by these "cheap jacks" in this city.

Trusting the time will soon return when fair and legitimate trading will be the order of the day.

EXCESTRENSE.

Exeter, April 1, 1878.

Sir,—A great deal has been said of late with respect to drapers, grocers, hairdressers, printers, etc., selling patent medicines, cutting down prices, and, under cover of the patent medicine stamp, vending all kinds of poisons indiscriminately. This to a very great extent is carried on in this district, greatly to the annoyance of myself and brother chemists. When first commencing business, some six years ago, I strongly objected to lowering the prices peculiar to the district (for every county varies a little in a few things) of anything, as is done at the present time, but suffered so much from want of legitimate patent medicine retail, through a certain printer, nearly next door, who keeps the stamp office, cutting down the prices to 1*s.*, 2*s.* 6*d.*, 4*s.*, and so on, *i.e.*, taking off, as he said, the stamp duty, making the public believe he had not such duty to pay since he was the vendor by appointment of such stamps. My customers for 2*d.* of hair oil, etc., would bring in their hands 11*s.*

chlorodyne obtained of Mr. Printer, and for which was paid 10s. This sort of thing so annoyed me that in self-defence I commenced to sell below him and advertised well; now I may say I do a fair (but must own not legitimate altogether) amount of patent medicine trade. This is the only remedy, so far as I can see at present, left to us poor grumbling chemists; but so soon as an Act can be passed, either for the chemist's exclusive right of vending patent medicines or compulsion of selling at proprietors' advertised prices, I for one shall exclaim well done. Until then, laudanum, opium, etc., etc., will be sold, as it is done in this neighbourhood, to anybody and everybody by any one who pays 5s. for a licence, and under cover of the patent medicine stamp by some such name as So and So's opiate, opiates, mass, etc.

PATENT.

Sir,—I see in the Journal of the 30th March, some remarks of "Tento" on the sale of patent medicines by merely licensed persons, and no doubt what he says is true. Chemists and Druggists have a grievance in that as well as many other respects, and in my opinion it can only be remedied by an Act of Parliament; the country members suffer more, I think, than the town chemists and druggists. Will "Tento" say how, in his opinion, this state of things can be remedied?

No doubt he thinks, with many others, a chemist is to be found in every village; if so, so far as my personal observation goes, I can very soon dispel any such illusion if it exists. In one direction from here there are over seventy large villages besides numerous hamlets, and in all this number there are only eight registered chemists, and these are located in only five of these villages; in another direction from here, though not so large an area, having over forty villages, there are only two registered chemists.

I would ask "Tento" whether he would suggest a chemist in every village? If so, I may tell him that even in the larger of these villages it is not possible for a chemist to live, unless he deals in a most heterogeneous and sundry kind of goods as well as drugs, and in that case he must necessarily encroach upon many other trades,—and what would they have to say to those who want to monopolize the sole trade in drugs?—or would he suggest the "dog in the manger" policy, and neither serve them himself nor let others do so. He surely does not mean to say the public have no rights to consideration in this matter. I think they have, and all who know the country will, I think, agree with me. In many of these villages a person would have to send ten or twelve miles for a box of Cockle's pills, chlorodyne, or any other of this class of medicines. Can he show how this want can be met, as no chemist could (suppose no one else sold any medicine of any kind) live in these villages.

I would suggest an amendment of the Pharmacy Act registering some one, the most intelligent in every village, not only for the sale of patent medicines but poisons as well (what right have we as chemists to cause any persons to send ten or twelve miles for a pennyworth of laudanum or any other needful drug?), and none but registered persons should sell either patent or any other medicines.

Having met the public requirements, the chemists would have a good case to prevent any infringements on their business as chemists and druggists. I feel sure the public must be considered as well as the chemists, and till this is done any Act of Parliament, however stringent, will be a dead letter; the sooner this is understood the better it will in my opinion be for the trade. This I feel sure will never be done till we have a Council who thoroughly understand the country trade, and I would suggest all candidates for seats on the Council, as I did a year ago, should state their views. No one should, I think, vote for any member whose views he does not know. This is well put by a Provincial C. and D. this week, and deserves the consideration of all members and readers of the Journal. Many changes, I think, must be made the next few years, and the examinations be more practical and less scientific; by all means let those who have good attainments and higher aims get a higher class certificate.

Chesterfield, March 30. A. G.

Safety Matches.

Sir,—It may interest some of your readers to learn that these matches, if quite dry, may be ignited by friction on most hard rather smooth surfaces, such, for instance, as that of a composition mortar.

This fact was communicated to me some two years since by E. Tyler, Esq., F.R.S., but I do not know if he himself first observed it.

I am led to mention it now by the remarks in "The Month" of this week, which seem to show that the circumstance is not, as I supposed, a well known one.

Exeter. W. A. SHENSTONE.

To the Benevolent.

Sir,—I thought to have seen in your obituary a record of the melancholy death of Mr. George Dixon, aged forty-nine, who committed suicide at Bristol, with prussic acid, about a fortnight since.

I would fain enlist the sympathy of any who may be charitably disposed on behalf of his widow, who, left with eight children, is in great pecuniary distress. Five of the children are dependent upon her for support, the youngest of whom is three years old and the eldest thirteen, who has just been removed from school because of the mother's inability to keep him there.

Mr. Dixon was educated at Christ's Hospital. He carried on the business of a pharmaceutical chemist in Southampton for nine years, and during three of those years (1871–3) was a member of the Town Council. In 1864, owing to pecuniary difficulties, he was obliged to resign his business. For two years afterwards he obtained no employment, and during the past sixteen years the family experienced, more or less, much trouble and suffering. I am in a position to state that throughout all those sad years Mrs. Dixon has been most devoted as a wife and a mother. I will say no more than that any subscriptions on behalf of her and her family will be thankfully received by me, and with your permission, acknowledged in the Journal. Mr. Dixon was a freemason, and as members of the craft, and old blues, and pharmaceutical chemists are proverbial for their generous sympathy with distress and suffering, I feel sure I shall not have appealed in vain.

I have already received the following:—

A FAST GROWING CINCHONA WHICH PRODUCES MUCH QUININE.

BY DR. J. E. DE VRIJ.

The last letter, dated April 6, 1876, which I received from my lamented friend, Mr. McIvor (deceased on June 8, 1876), contained in answer to a question of mine as to "which species of cinchona produces the largest amount of bark in a given time," the following reply:—

"Up to the present time *C. succirubra* has produced in the same period of growth more than twice as much stem-bark as any of the other species we have in cultivation, and *C. pubescens*, Howard, will produce nearly twice as much stem-bark in the same period of growth as *C. succirubra*."

When I received some weeks later a box containing amongst other specimens a specimen of *C. pubescens*, Howard, first renewal, I was much pleased by the possession of a bark produced by such a fast-growing species, variety or hybrid of cinchona, and very anxious to undertake its analysis. Unhappily, however, I have been obliged to postpone the analysis till a few weeks ago, when I contrived to perform it with the following result:—

Total amount of alkaloids in the dry bark, 9·47 per cent., yielding—

5·728 of pure quinine = 7·637 of crystallized sulphate.
0·926 of cinchonidine.
0·937 of cinchonine.
1·111 of amorphous alkaloid.

This result seems to me so satisfactory that it is desirable to know something more about this fast growing cinchona. As Mr. McIvor wrote upon the specimen of bark which he sent me, *C. pubescens*, Howard, I have some hope that the distinguished author of the 'Quinologia of the East Indian Plantations,' Mr. J. E. Howard, may be able to give some explanation about this interesting subject. This hope is based on the following sentence in the 'Quinologia,' page 79:—"I am watching with considerable interest the development of some young plants of the pubescent form sent me by Mr. McIvor, but I must confess that I am led to suspect in these the result of mixture of pollen of other plants of cinchona."

I am inclined to suppose that the fast growing cinchona in question is a hybrid with pubescent form, to which Mr. McIvor, in consequence of his correspondence with Mr. Howard on this subject, has given the name of *C. pubescens*, Howard. A botanical specimen of this cinchona, which was sent to me together with the bark by Mr. McIvor, is actually in possession of my friend, Dr. F. A. Flückiger, in Strassburg.

The Hague.

NOTE ON LUBAN MATI AND OLIBANUM.

BY PROFESSOR FLÜCKIGER.

In the course of the investigations intended for working out the 'Pharmacographia,' the authors were led to the conviction, as stated there (pp. 121, 131, and 135), that the *Elemi* of the mediæval writers agreed with the old gum of the "Ethiopian Olive," and that under the latter name not an *Olea*, but *Boswellia Frereana*, Birdwood, is to be understood. Although it is impossible to prove absolutely the correctness of our view, it was especially the firm belief of my late friend Daniel Hanbury that the *Luban Meyeti* or *Mati*, as described in 'Pharmacographia' (p. 135), was the drug originally designated Elemi. I may only add that I have no new facts to present in support of that opinion, but we had repeatedly considered the question and never met with any statement which would be in contradiction with our suggestion.

Luban Mati, so well known to-day in the East, must very likely have been used there in the remotest antiquity (see 'Pharmacographia,' p. 131). Probably it was sometimes confounded with Olibanum, especially by western authors. Neither Luban Mati, nor any sound resembling it, is quoted in the famous 'Periplus' of the Erythrean Sea (mentioned in Phcogr. 126, 541), but frankincense, Libanos, is enumerated as a product both of Arabia and Somali land. The author of the 'Periplus' alludes to the difficulty of reaching the trees (in the steep slopes, where they are growing?). Yet in the 'Periplus,' another incense, Μοκρότον, is spoken of as an aromatic, θυμιάμα, likewise exported from the Somali coast. Are we permitted to identify this substance with Luban Mati? I think there is some probability in favour of this idea; olibanum and myrrh are expressly and unmistakably mentioned; what else can Mokroton mean than Luban Mati?

It is to be supposed that the physicians and pharmacologists of the famous medical school of Salerno, in the early middle ages, were acquainted with elemi, yet, strange to say, I am not aware of any such evidence. In the history of drugs, elemi is interesting for the curious fact that its name was given in later times to other drugs coming from a far distant country, and that the various kinds of elemi of the new world, and again of the Philippine Islands, are yielded by trees of the order of the Burseraceæ, like Luban Mati. An analogous transmission of an appellation is exhibited by the word Brazil, originally applied to the wood of the Indian tree, *Cæsalpinia Sappan*, now attributed to that of *Cæsalpinia echinata*, and its native country the Brazilian Empire.

I have had the opportunity of getting some new information on the drugs under notice, not relating at all to their history but to their production, and on the other hand, Captain Hunter, now of Aden, has very obligingly supplied me with excellent specimens, not only of olibanum but also of Luban Meyeti. The latter agrees perfectly with that described in the 'Pharmacographia,' except the fragrance, which is more powerful in the fresh drug. The accurate description given in a few words by Mr. Holmes, in *Pharm. Journ.* vii. (4 Nov. 1876), page 383, likewise points out the characteristic features of Luban Mati. Captain Hunter, in the letters he favoured me with, once more states that Luban Mati or Maieti Amshat, is the product of the Yegaar tree, *Boswellia Frereana* of the Somali coast range, and that it is shipped from the ports east of Karam, or Kurrum, 45° 41′ E. long. In the year 1875 to 1876 there were imported into Aden 1928 cwt. of Luban Mati, of which one half went to Egypt and Trieste, one fourth to the Red Sea ports, one eighth to the United Kingdom, and the rest to Bombay and the Dankali (or Danakil) coast, north-west of the strait of Bal-el-Mandel, opposite Yemen. The latter statement leads to the supposition that the Yegaar tree is not growing on the Danakil coast, but only in the extreme north-eastern part of the African coast lands. The external appearance of Luban Mati, of the finest description, is on the whole very different from the various sorts of olibanum, its bulk being not constituted of separate tears, but of stalactitic masses. It is, moreover, different inasmuch as it is an oleo-resin, not a gum-resin. There occurs, it must be granted, in some specimens of Luban Mati, a very little gum, as I have ascertained since I stated in the 'Pharmacographia' (p. 135) the absence of gum. Water is able to extract from 2·5 to 3·8 per cent. of gum from various specimens of Luban Mati, especially from the inferior kind sent me by Captain Hunter, under the name of "Dookoo," or refuse. But the question arises whether this gum is really to be considered as a constituent of the drug; I doubt that it is so, for gum is occasionally found in form of *single grains* in the remainder of Luban Mati, which has been exhausted by alcohol. This refuse, amounting to about 5 per cent., consists, besides the gum just alluded to, of pieces of the thin papery cork which is so very characteristic of the Boswelliæ, and other fragments of the bark.

As an oleo-resin, Luban Mati is analogous to elemi, but as recently shown in papers of mine and Dr. Buri (see *Pharm. Journ.* 22 Aug. 1874; 19 Aug. 1876), the resin of elemi is constituted partly of crystallizable resins, one of them, which we term elemic acid (*Pharm. Journ.* Feb. 2, 1878, p. 601), being of undoubtedly acid properties. The amorphous resin of elemi is a mixture of a largely predominant indifferent substance and a small amount of an amorphous resinoid acid. But as to Luban Mati, it yields no acid constituent, nor is it capable of affording any crystallizable substance.

The fragrant essential oil of Luban Mati is briefly described in 'Pharmacographia,' (p. 135); the greater portion, boiling at 165°, is to be considered as one of the innumerable modifications of oil of turpentine. That under examination possesses in a high degree the agreeable odour of Luban Mati, reminding of lemons. The resin nearly agrees with the resins of the Coniferæ; I found it to contain on an average, C 79·55, and H 9·58 per cent. This answers to the formula $C_{20}H_{30}O_2$:

20 C	240	79·47
30 H	30	9·93
2 O	32	11·60

To the resin of olibanum Hlasiwetz assigned the formula $C_{20}H_{32}O_4$ (*not* as erroneously printed in the 'Pharmacographia,' p. 124, $C_{40}H_{30}O_6$). It would thus appear that these two resins are not identical; neither of them is probably an individual substance, both being, no doubt, mixed bodies. Many other amorphous resins, like those of coniferæ, of copaiba, elemi, mastich, and sandaraca, correspond with the above formula, or with $C_{20}H_{32}O_3$; all these belong to that class of resins which are unable to yield any aromatic compounds if melted with caustic potash.

Luban Mati is not an article of European trade, but as a chewing material it is quite familiar to eastern dealers and travellers. It is also mentioned —to point out only one instance—in a recent paper on the trade of the Arabs, by Goergens, in the German periodical 'Das Ausland,' 1877, Part. II., p. 668, without any further information.

Captain Hunter informs me, in the written remarks he obligingly sent me in transmitting the specimens of Luban Mati, that in Aden, in July, 1877, the price of Luban, that is common good olibanum, varied from ¾ of a dollar to 1¾ dollars per 28 lbs. (dollars in Aden = 3*s.* 6*d.*) Mati (Luban Mati) fetching from ¾ to 2 dollars for the same quantity. The latter would certainly prove to be well fitted for any purpose for which now common resin, common American frankincense, Burgundy pitch, or galipot and barras (see 'Pharmacographia'), are used. Perhaps larger supplies of Luban Mati will some day reach Europe, if the port of Berbera, now like the whole coast under the dominion of the Khedive, becomes a still more important and regular place than it is at present, for eight months every year, on account of its famous fairs.

As to recent information about Luban Mati alluded to above, there is to be mentioned the account of the German botanist, J. M. Hildebrandt, in the 'Zeitschrift der Gesellschaft für Erdkunde zu Berlin,' 1875 (p. 277). The paper is shortly abstracted in Just's 'Botanischer Jahresbericht,' 1875 (p. 752). Starting from Aden, Hildebrandt paid a visit to the district of the Wer-Singelli, one of the Somali tribes, and the Alh mountains near Cape Chansireh, 45° 41′ E. long. This is a very steep range, as high as 2000 metres, running parallel to the coast, towards which lower hills are gradually descending.

Near the little port or road of Dobbru, not far from Lasgori,* Hildebrandt met with the "Gekar" tree, the Yegaar of other travellers. Its thick low trunk grows out of the nearly perpendicular rocks; the branches were just blossoming the 25th of March. The Somali men and women reach the trees by very dangerous paths, make a large number of incisions in their soft stems, and allow the oleo-resin to flow out. Within the next six days it is collected from the bark, and afterwards each tree is in succession again visited and incised. It would appear that by heavy rains the exudation is sometimes swept away and lost. This kind of olibanum, called *Meithi*, by the people there, is sometimes thrown in the fire by the Somalis, in order to lighten and perfume their huts; they likewise chew it when they are tired. This, however, occurs but exceptionally; most of the commodity is brought down to the sea, and bartered for rice and other food offered there by Arabian merchants. These then sell the Luban Mati in Aden and Gedda (Djedda), whence it finds its way, principally as a masticatory, into the harems. Hildebrandt correctly adds that mastich, used in the same way by the inhabitants of Eastern harems, is a quite different substance.

In that journey to the Somali country, the author had not met with the true olibanum tree (*Boswellia Carterii* probably intended). He says that its exudation requires a fortnight for drying, a statement which appears perfectly intelligible with reference to the large amount of gum present in frankincense. Luban Mati, consisting only of resin and essential oil, will no doubt, much more readily exude and dry on the stems, as above stated. In the Somali country the best kind of olibanum, according to Hildebrandt, is called Nachu, that is pure; in Arabic, and commonly in commerce, it is termed Fusus, tears. The second kind is known under the name of Upis Katjar (middling). Bentley and Trimen, in their 'Medicinal Plants,' Part XX., No. 58, give a good figure of *Boswellia Carterii*, as collected, apparently in another journey, by Hildebrandt, in Somali land.

The position of the places just alluded to may be found in the large map of the Gulf of Aden, as com-

* Ras Gorce, 48° 20′, or another cape, 49° 45′, of exactly the same name (?). Probably the former. Dobbru is not met with in the map before me.

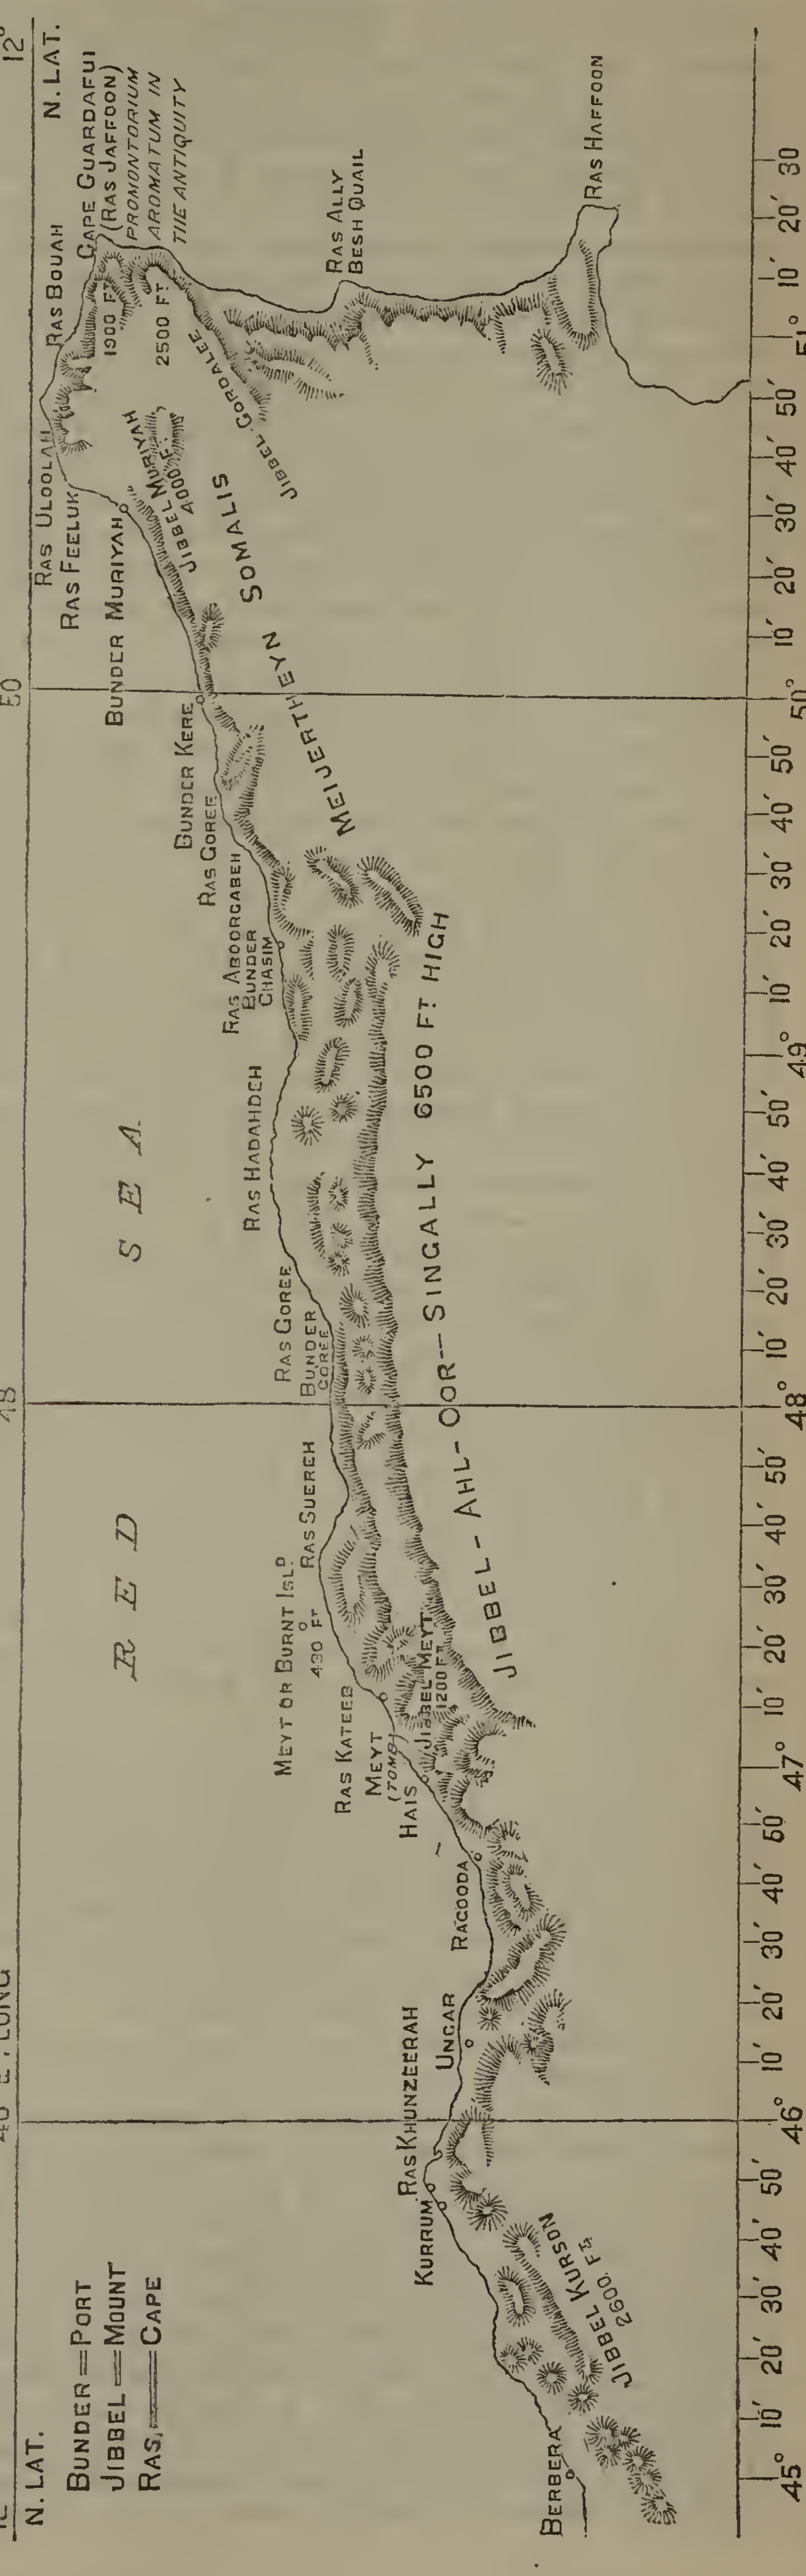
piled in 1874 by James F. Imray, F.R.G.S., chiefly from the surveys made by order of the East India Company. The rough sketch accompanying the present paper is an abstract of that map. The range, Jibbel-Ahl-Oor-Singally there extends from 49° to 47° E. only; Cape Khunzeerah is met with in about 45° 50′ E.

In this map the name of Meyt occurs three times near the western part of the said range: (1) Jibbel (mountain) *Meyt*, in 47° 10′, 1200 feet high, is one of the hills running down to the sea from the high range, which ascends as high as 6500 feet, according to the map; (2) a place *Meyt* is marked on the shore as a "tomb." North-north-east from this, in the open sea, there is (3) a cliff or small island, 430 feet high, called *Meyt* or Burnt Island—perhaps a volcanic formation. To these names, I presume, the appellation of Luban *Mati* or *Meyeti* may possibly bear some relation. In the pamphlet 'Botanische Erläuterungen zu Strabon's Geographie' (Königsberg, 1852, p. 135), Ernest Meyer, the learned author of an excellent history of Botany, also mentions Wellsted's account on Luban Mati (Travels in Arabia, 1833). Meyer then goes on to suggest that it is a superior kind of olibanum, for, says he, mati in Arabic means exquisite. But, as above shown, Luban Mati is not or not much more appreciated by the Somalis or Arabs than Olibanum. And as to the word Mati, it does not appear to belong to the Arabic idiom at all, and at all events, as I learn from eminent Arabic scholars, there is no such expression in the Arabic language meaning exquisite or excellent.

Some further particulars on olibanum are due to the unfortunate Swiss traveller, G. A. Haggenmacher. He had made an exploration in the Somali country shortly before he was killed, in the interior west of the gulf of Tedjura, by the Gallas, towards the end of November, 1875, together with our mutual friend Munzinger Pacha. Haggenmacher has devoted an interesting paper to the Somali country in the supplement, No. 47 of Petermann's 'Geographische Mittheilungen,' 1876, p. 19. In the coast region the more prominent plants are the Mimosæ, Euphorbiæ, Colocynth (Phcogr. 263), and *Calotropis procera* (Phcogr. 380). The hilly region exhibits the richer foliage of Sycomorus and Tamarinds (Phcogr. 197), and a lot of climbing plants growing amidst thorny shrubs. In the high lands of the interior, *Acacia arabica*, Willd. (*A. nilotica*, Desfont., Phcogr. 207) abounds, yet the most interesting plants, in the author's opinion, are the frankincense trees. According to him there are three kinds of it growing in the Somali country, viz.: (1) the tree called *Djau Der*, $\frac{1}{4}$ to $4\frac{1}{2}$ metres high, having a strong straight trunk, the foliage resembling that of the walnut tree, is equally abundant, and much appreciated on account of the dense shadow it affords. The bark is used for tanning, the wood as an incense; its resin constitutes the best kind of olibanum and is exported under the name of Liban Mascati or Liban Maheri. It appears that in summer a round incision is made through the bark into the wood. Towards the end of the rainy season the hole is found to be filled with the precious exudation. Haggenmacher does not state whether the wound or hole is stopped—as it is practised for instance in the collection of larch turpentine ('Pharmacographia,' p. 550).

It is not possible to identify Haggenmacher's tree Djau Der; this name does not occur in any other

Sketch of the Somali Coast.



account as far as I know. Luban Maheri or Mascati, however, no doubt refers to the coast of Arabia between Ras Fartak (52° 10′ E.) and Ras Morbat (54° 34′), where it is exported from the Somali coast. One of the varieties of olibanum, No. 9, sent me by Captain Hunter, is stated by him to be known in the Mahara country under the name of Sheehaz; the tree itself "Magharot." Whether it agrees with *Boswellia Carterii*, Birdwood, as I am inclined to think, must remain unsettled; Sheehaz is an Arabic name applied to that tree. Its exudation, also called Fasous Dhafari by Captain Hunter, is before me and agrees with the best commercial olibanum; he also tells me that Luban Shehri is no longer gathered in Arabia (49° 20′), but that this name is now applied to olibanum coming from the Somali coast. This is to be borne in mind in order to explain how it occurs that olibanum of the Somali coast bears the names of Arabian places.

(2) The *Beyo* tree, says Haggenmacher, is much more abundant than the Djau Der, and yields much more frankincense, which is collected twice a year. Its stem is never straight, but distorted, and only attains the height of a man; the umbelliform branches are bent down and touch the soil. The leaves are similar to those of the Djau Der, but larger. The exudation of this tree is of three kinds, distinguished by the designations of Fesus, being afforded by the first harvest; Naghua is that of the later season, and the impure drug picked out of both is termed Madjendel. Very likely the latter drug is the same which Captain Hunter has sent me under the name of Jandul, that is refuse (No. 11); it is indeed a variety of olibanum, consisting of brownish large fragments and tears, much papery bark (cork) adhering. Another variety (No. 8) is of better appearance and mostly consists of large bright tears; it is called Fasons Sehri in Arabia, and Nakwa on the Somali coast. The tree from which it is derived is known there as Beyo or Mohradd; probably Beyo means the same, and also perhaps Birdwood's *Boswellia Bhau-Dajiana* includes it. The exudation of the Beyo tree, according to Captain Hunter, is exported from the Somali coast, especially from the following small ports: Mait (above mentioned), Bunder Kassim (Ghasim, 49° 15′, in Imray's map), Bunder Khor (nearly 50°), Aloola (Ras Uloolah, 50° 46′).

(3) Muchos is the name of the third olibanum tree affording a resin, which is commonly sold under the name of Fesus, although it is not equal to that. The Muchos tree is nearly as large as the Djau Der; it has small white thorns (?) and a silver white bark.—I have no means of identifying the tree thus alluded to by Haggenmacher; his notice on it plainly shows that he was not a botanist.

The following notice is also in accordance with the above statements.

In an account on the trade of Berbera and the Somali coast, contained in the 'Preussisches Handelsarchiv,' 1875, Part II. 42, four varieties of olibanum are stated to be exported, viz.: (1) Fessous, a dry, pure drug consisting of tears, not chiefly of large fragments, of an intense odour. It is exported from Ongar (Ungar in Imray's map, 46° 16′ E. long.), being paid there 30 dollars (Austrian Maria-Theresa dollars = 32 Annas = 3*s.* 6*d.*) a bahar. One bahar = 14 ferasla; 1 ferasla = 28 robel = 12·73 kilogrammes. (2) Naghua, less pure, 20 dollars a bahar. (3) Wodjendel, very impure, containing much bark, 15 dollars a bahar. (4) Liban Maheri, quite white, a very rare article, fetches 3 dollars a ferasla (that is 42 per bahar). Myrrh is still more costly, being paid from 4 to 6 dollars one ferasla.

In concluding, I may say that the origin and nature of Luban Mati is now satisfactorily settled; there can be no doubt that it is produced by the Yegaar tree, which Dr. Birdwood has described as *Boswellia Frereana*; it appears to be confined to the Somali coast range. Its exudation is entirely different from olibanum by not being constituted of resin, essential oil, and gum, but almost exclusively of the two former. I have ascertained on the other hand, that all the various specimens of olibanum, for which I am obliged to Captain Hunter, the exquisite whitish tears, as well as the refuse, largely contain gum, and not resin and essential oil alone.

As to those species of *Boswellia* which afford olibanum, complete authentic and numerous specimens provided with leaves, flowers, fruits, and the exudation of the stems, collected with exact reference to the plants, are highly desirable, for, in its botanical aspect, the question is still remaining in the same state which I pointed out in the 'Pharmacographia' in common with my lamented friend. In the beginning of similar investigations, Dr. Birdwood had thought the Arabian frankincense trees to be identical with *Boswellia papyrifera*. I was originally of the same opinion until, in 1867, in my 'Lehrbuch der Pharmacognosie,' p. 31, I stated that this was an error, and I accordingly gave the name *Boswellia sacra* to the tree which on the Arabian coast yields olibanum.

Whether this tree is identical or not with that afterwards described by Dr. Birdwood as *Boswellia Carterii*, cannot yet be plainly decided (see 'Pharmacographia'). He was, therefore, not quite correct, when, in 1869 (or 1871) in 'Transactions of the Linnean Society,' XXXI. iii., he stated that I still indentified *Boswellia sacra* with *Boswellia papyrifera*. Nor is there the least reason for attributing any commercial kind of olibanum to *Boswellia papyrifera*, although in the recent French translation of the 'Pharmacographia,' I. p. 268, this is expressly alleged. I know of no authority in favour of this statement, and have even ascertained that the branches of *Boswellia papyrifera*, as contributed in 1867 from the Upper Nile to the Paris Exhibition, were provided with some tears of a resinous exudation, which, however, I found destitute of gum. Richard ('Voyage en Abyssinie,' 1839–1843), as well as Th. von Heuglin ('Reise nach Abessinien,' Jena, 1868, p. 174) were well aware of the abundant oleo-resin of *Boswellia papyrfera*, but without referring commercial olibanum to it.

THE VERATRUM ALKALOIDS.*

BY ALEXANDER TOBIEN.

This interesting essay, of which we can publish only a brief abstract, opens with an historical introduction citing the literature of the chemical investigations made with different species of veratrum. The poisonous properties of veratrum album were known in Spain in the sixteenth century, the rhizome being called *de balestera* or *de jerva*, and it is possible that the *charbak abjadb* of the Arabian

* Beiträge zur Kentniss der Veratrum Alkaloide. Inaugural Dissertation. Dorpat, 1877, 8vo., pp. 38. Translated in *The American Journal of Pharmacy*, March, 1878.

physicians was the same drug. Since veratrum is not indigenous to Greece, the helleboros of the ancient Greeks was most likely not identical with the former.

Pelletier and Caventou examined *V. album* in 1819, and announced the presence of veratria. In 1837, Edward Simon corroborated the presence of veratria, and found another alkaloid which he called *barytin* (from its behaviour to sulphuric acid), changing the name afterwards to *jervia*. H. Will (*Ann. der Phar.*, xxv.) examined jervia, and from his elementary analysis gave it the formula $C_{66}H_{45}N_2O_5$, which was changed by Limpricht *Grundriss d. Org. Chem.*, 1862) to $C_{60}H_{46}N_2O_6$. In 1842 A. Weigand confirmed the presence of veratria and jervia in *V. album*. The same results were arrived at by Herm. Weppen, in 1872, and in the same year Schroff, Jr., announced the presence of veratria in *V. Lobelianum*, while Dragendorff, in 1871, found the second alkaloid (beside jervia) to differ from veratria, and subsequently announced the presence of jervia also in *V. nigrum*.*

The author first examined the rhizomes of *V. Lobelianum*, partly collected from wild plants in Austria, partly from cultivated ones in Russia, in both of which Dragendorff had already found notable quantities of veratroidia. The process adopted was as follows:—

Two kilos of the coarsely powdered rhizome were mixed to a soft mass with sufficient water containing 36·8 grm. phosphoric acid, sp. gr. 1·23, macerated for twenty-four hours, mixed with 7·5 kilos alcohol of 95 per cent., the mixture digested in a water-bath for eight hours, cooled and expressed; and the press cake similarly treated with 12 kilos alcohol of 70 per cent. and 15 grams phosphoric acid. The united liquids were filtered, the alcohol distilled off *in vacuo*, the residue concentrated to a syrupy consistence, mixed with three times its weight of water, the resin filtered off after several hours, and the filtrate rendered alkaline by sodium carbonate. The precipitate was separated from inorganic salts by solution in alcohol, the filtrate diluted with an equal part of water, digested with recently ignited animal charcoal, and the faintly wine-yellow filtrate evaporated, when a yellowish crystalline mass, *a*, was left. The alkaline filtrate from the above precipitate was agitated with chloroform, this solution separated and the chloroform evaporated, leaving an amorphous light-yellowish residue, *b*.

A proved to be jervia, containing some veratroidia, while *b* was a mixture of veratroidia with some jervia. *A* was dissolved in dilute acetic acid, filtered and mixed with dilute sulphuric acid until a distinct turbidity appeared. The yellowish white granular precipitate, collected after several hours, was jervia sulphate not yet quite pure. The filtrate was rendered alkaline by ammonia and agitated with chloroform which left but a slight amorphous pale-yellow residue.

B was contaminated with wax, and contained so little jervia that its solution in acetic acid gave no precipitate with sulphuric acid; through an accident it was lost.

The resin collected as above from the concentrated liquid, after dilution with water, still contained alkaloid. To obtain this, Bullock's method (*Amer. Journ. Phar.*, 1876, p. 147) was tried with indifferent success. The powdered resin now mixed with an equal weight of lime, enough water was added to produce a soft mass, and this dried at 40° C. (104° F.). From the powdered lime resin soap the alkaloid could be extracted with ether, but hot 85 per cent. alcohol was also found serviceable. The alcohol was partly distilled off, then dilute acetic acid added and all alcohol evaporated; the filtrate was treated with sodium carbonate, the precipitate *c* washed, freed from lime by dissolving in alcohol, and this solution evaporated.

The alkaline filtrate from *c* was agitated with chloroform, which, on evaporation, left an amorphous light coloured residue, consisting of veratroidia with a little jervia.

C, consisting of veratroidia with larger quantities of jervia, was dissolved in dilute acetic acid, the solution divided into three parts, which were precipitated respectively with muriatic acid, sp. gr. 1·2, nitric acid, sp. gr. 1·13 and diluted sulphuric acid (1 to 7 water). The filtrates were mixed and marked *d*, the brown-red soft granular precipitates were, after Bullock's recommendation, freed from resin with 95 per cent. alcohol, and the residue dissolved by boiling in strong alcohol, previously diluted with an equal part of water. The filtered solutions left on spontaneous evaporation crystals agreeing with those figured by Bullock and by Wormley (*loc. cit.*).

Pure jervia was obtained from the nitrate by treating it with a warm solution of sodium carbonate, and purifying the alkaloid with strong alcohol, when it formed perfectly white needles, which by ultimate analysis gave results leading to the formula $C_{13}H_{23}NO_4$, or, more closely to $C_{27}H_{47}N_2O_8$ ($O=16$). The sulphate and hydrochlorate have the composition $C_{27}H_{47}N_2O_8$, H_2SO_4 and $C_{27}H_{47}N_2O_8$,HCl.

The acid filtrate, *d*, was precipitated with sodium carbonate, and the precipitate freed from jervia, as recommended by Bullock, by dissolving in acetic acid, and treating with potassium nitrate; the filtrate was rendered alkaline by sodium carbonate and agitated with chloroform; a small quantity of light yellow amorphous veratroidia was obtained, having the following reactions:—

Concentrated sulphuric acid gave a yellow solution, passing through light brown-red into deep raspberry red.

Concentrated muriatic acid yielded a light yellowish rose-red solution, which, on heating, became dirty yellow, and with sulphuric acid and heating brown-red.

Concentrated nitric acid produced a light yellow solution, which, with sulphuric acid and on being heated, turned transiently orange-red and passed into lemon-yellow.

The author observed that small quantities of veratroidia, also of veratria, will materially modify the reaction of jervia, and commercial jervia seems often to contain one or both of these alkaloids. Veratroidia is dissolved by cold concentrated muriatic acid with a pale rose-red colour, which, when heated, is rapidly discoloured. Veratria, on the contrary, dissolves in cold muriatic acid colourless, an intense and lasting red coloration being produced by heat, and this is likewise the case with sabatrina and sabadillia.

Veratroidia is rather freely soluble in water, freely in alcohol, ether and chloroform, little in petroleum spirit (gasolin), somewhat more in benzin and amylic alcohol. It dissolves in water to about the same extent as sabadillia, less than sabatrina, and more freely than veratria; it differs from sabadillia by its greater solubility in ether.

The two alkaloids, jervia and veratroidia, were also found in cultivated old and recent rhizomes, and in the young leaves of *Veratrum Lobelianum*, and in the dried rhizome of *V. album*, which yielded little jervia and more veratrordia.

Jervia is very sparingly soluble in water and in solution of sodium carbonate, freely in alcohol and in chloroform, less in amylic alcohol and benzin, very little in ether, and almost insoluble in petroleum. When pure it is dissolved by concentrated sulphuric acid with a yellow and finally light green colour. Concentrated muriatic and nitric acids cause no change in the colour, but muriate of jervia, thrown into concentrated nitric acid, produced an evanescent rose colour. Potassium nitrate indicates jervia when in dilution of 1 in 1200.

* The literature on the investigation of *V. viride* is given in full. We omit it here, since our readers are familiar with it from the papers of Ch. L. Mitchell ('Proc. Am. Phar. Assoc.,' 1874; *Pharm. Journ.* [3], vol. v., pp. 768, etc.), Chas. Bullock (*Amer. Journ. Phar.*, 1875, p. 449; *Pharm. Journ.* [3], vol. vi., p. 1009) and Professor Wormley (*Ibid.*, 1876, p. 1).

The elementary analyses of veratroidia point to the formula $C_{51}H_{78}N_2O_{16}$ or $C_{24}H_{37}NO_7$. Its action upon frogs is similar to veratria, but much more energetic than either sabadillia or sabatrina.

The composition of the above alkaloids, as ascertained by Weigelin and Tobien, is the following:—

Veratria	$C_{52}H_{86}N_2O_{15}$, W.
Veratroidia	$C_{51}H_{78}N_2N_{16}$,
or	$C_{24}H_{37}NO_7$, T.
Sabatrina	$C_{51}H_{86}N_2O_{17}$, W.
Sabadillia	$C_{41}H_{66}N_2O_{13}$, W.
Jervia	$C_{27}H_{47}N_2O_8$, T.

Even if the molecular value of the formulas should, on further investigation, be altered, this is evidently a natural group of alkaloids, somewhat similar to those of opium and cinchona. The first four show a great similarity in their behaviour to sulphuric acid, but with sugar and sulphuric acid pure veratria yields a green, afterwards blue, coloration, while veratroidia gives a black-brown colour, which lasts for some time.

Veratria, sabatrina, and sabadillia agree in their behaviour to muriatic acid, but veratroidia and jervia differ very widely from it. In their action veratria, veratroidia, and perhaps jervia, are nearest related to each other, but the latter is distinctly characterized by its behaviour to sulphuric, muriatic, and nitric acids.

THE BROMINE PRODUCTION OF THE UNITED STATES.*

BY HENRY S. WELLCOME.

The only available source of bromine supply in the United States is the residual liquor from the salt works, technically known as bittern.

A brief description of the process employed by our leading manufacturers in separating this important element from the salt liquors, may be of interest to you. The original salt liquor or brine is pumped out of the ground at 9° B., evaporated to about 15° in long iron pans; then allowed to settle, and is further evaporated in wooden tanks, heated by steam pipes, to the point of crystallization. The first crystallization yields the best salt of commerce; these tanks, five in number, are placed one above another; each day the liquor is run off from No. 1 to No. 2, next day to No. 3, and so on until it reaches No. 5, the crystallized salt being removed from each tank or so-called grainer, after draining off the liquor. The brine, when it reaches No. 5, is bittern, and consists chiefly of chlorides of calcium, magnesium, sodium, and some aluminum, with varying percentage of bromides of sodium and calcium.

Tank No. 1 is each day filled with fresh brine, and thus the process becomes continuous. The bittern marking 30° to 38° B., is evaporated to about 45° B. By this further evaporation an additional percentage of impure salt is removed, the liquor is then run into stone stills, material for generation of chlorine added, and heat applied by means of steam injected directly into the still, until all the bromine has been eliminated and vaporized, which is conveyed through a condenser into a receiver.

Several recent improvements have been made in the process of bromine manufacture, most of which consist in the form of the bottom of the still, and appliances for condensing the vapour. The most important of these are the devices of F. W. Arvine.

The principal bromine producers in America are: Victor G. Bloede and Co., Parkersburg, W. Va. (have recently disposed of their works); Herman Lemer, Mason City, W. Va.; John J. Jubler, Pomeroy, Ohio; Mason City Salt and Mining Company.

The production of bromine was first commenced in the vicinity of Parkersburg, by Hegeman, a Danish chemist, formerly employed by the Pennsylvania Salt Manufacturing Company.

Mr. Hegeman's operations were of an experimental character at first, and he produced but a limited quantity. As there was at that time very little demand, he realized four dollars to eight dollars per pound for all he made. Mr. Hegeman patented the use of stone stills and steam in the manufacture of bromine and preparations. His claims and patents, as well as the small demand, prevented others from attempting to enter into competition. However, as the use of the bromides became more general, others began to manufacture bromine, their processes varying but little from Hegeman's, though modifications in details have been introduced by each.

Herman Lemer is now supposed to be the largest producer of bromine. He was, formerly, a poor shoemaker at Natrona, Pa., of limited education, but with rare energy, and has developed fine executive ability, which has led him to his present position.

The Ohio and Kanawha salt region yields bittern at least twice richer in bromine than any other yet discovered, and hence holds the balance of power over the whole world.

It is a remarkable fact that the Syracuse and other New York and Western bitterns do not contain any or but a slight trace of bromine.

The quality of bromine produced annually varies greatly, due to the extreme depression and uncertainty of the salt trade, upon which the bromine business is entirely dependent.

The salt interests have suffered much during several years past, as more salt is made than can be sold, and for the last two years it has sold steadily for less than actual cost of production. The uncertainty of the salt furnaces working has induced bromine manufacturers to erect and operate bromine works at every furnace, so that when one shuts down on the production of salt, they may not be wholly thrown out of the production of bromine.

The capacity for producing bromine has risen, during the years 1875 and 1876, to about three times that of 1874 (owing to the facts given above), while the actual production has not materially increased. The capacity at present is estimated by manufacturers at 3000 pounds per day, while the actual production does not exceed 1000 pounds. These figures are intended to convey the average production. There are indications that the production will be lessened for a time, yet that it will be sufficient to supply all demand.

The exportation of bromine has been reduced to a very small matter. The cost and risk of transportation are so great that European makers of bromides cannot compete with the American manufacturers; no steamship company will carry bromine, and it is becoming very difficult to induce vessels to take it at any price.

Recently, owing to the very high prices at which bromides are held in the European market, several lots have been exported, in all about 50,000 pounds this year.

Owing to the great advantage possessed by American manufacturers in the production of the bromides, it is believed that the exportation of bromine will soon entirely cease. The consumption of bromine in the form of the bromides has greatly increased during the past twelve years, the bromide of potassium being the principal salt, but, during the last three or four years, the bromide of sodium, bromide of zinc, and several other bromides are becoming very popular.

The only really new and very recent application of bromine is its use by a Paris firm, within a few months, in the production of a new aniline colour.

I will here express my obligations to Mr. Victor G. Bloede, who has very kindly furnished me the principal points used in this paper, as also to other parties who have furnished me valuable information on the subject.

NOTES ON INDIAN ROSES AND THEIR PRODUCTS.*

BY J. DOUGLAS, B.A.

In the ancient literature of India the rose is never mentioned, and its names in the modern languages of the country prove that the natives became acquainted with it much later than their neighbours of Persia and Arabia, by whom it was undoubtedly first introduced to their notice. The genus, represented by numerous species, is now generally met with in most parts of the country, and its extension is only restricted by high temperature and a moist atmosphere along with heavy clayey soil. In the Deccan, where they are favoured by a decrease in the tropical heat, roses are very common, and present many new forms in species and varieties. There is no similar increase of forms in the region of the Neilgherry Hills, where the rainfall is very large and the atmosphere excessively moist. In Bengal one of the commonest species is *R. involucrata*, Roxb., which is plentiful in a wild state; other species with numerous varieties are also widely distributed through this province, where they were probably introduced from the north-west. In the mountainous regions of Northern India and Thibet numerous species of the rose are found in a wild state, but, except in Cashmere, they are rarely cultivated either for profit or ornament, as the civilization of the natives of these regions is generally too low to admit a demand for gardens and flowers as such. The highest situation in which roses are found upon the northern side of the Himalayas is in Kumaon, about 13,650 feet above the level of the sea. The average annual winter and summer temperatures in Kumaon are 59°, 47°, and 76° respectively. Roses are very abundant in Thibet, where they present a great variety of forms, and are found at a much greater elevatiou than upon the northern slopes. Ladak and Gnari Khorsum, at heights of 14,625 and 15,112 feet above the level of the sea, are the highest situations in which roses are found in Thibet. The average annual winter and summer temperatures of Gnari Khorsum are 58°, 40°, and 75° respectively. The two species which are found at the greatest height in this region are *R. macrophylla*, Lindl., and *R. Webbiana*, Wall., both of which flourish in Ladak, while the latter extends to Gnari Khorsum. The greatest variety of forms within the species is shown by *R. Webbiana*, which varies markedly not only with the temperature and moisture, but also with the nature of the soil. The most striking differences in the size of the flowers are found in *R. macrophylla*. These differences are directly dependent on the climate, and the greatest dimensions are attained with the greatest degree of warmth and moisture consistent with the existence of the species. In Sikkim, at from 5850 to 7800 feet above the level of the sea, the flowers are more than $3\frac{1}{4}$ inches in diameter; but at their highest limit the surfaces of these roses are scarcely one-tenth as large, and their diameter is little over half an inch.

The production of rose-water and rose-oil is of great importance in India, where the art of preparing them was introduced by the Persians and Arabs. In Cashmere roses are largely cultivated, and the manufacture of their products is a very general branch of industry. They flourish up to an elevation of 5850 feet. In India rose culture is confined chiefly to the districts along the Ganges, and is especially vigorous in the environs of Ghazipore. The greater part of the large quantities of rose-oil consumed in Western and Northern India is imported to Bombay from Persia.

Rose-water is called in India "Gulab," which is the Persian word for rose. Sometines the word "Gulab" means rose alone, and then rose-water is styled "Gulab-pani." "Pani" is a Sanscrit word; but I am not aware of any corresponding Sanscrit term being used for "Gul" or "Gulab." In Pehlevi the rose is called "Rurd," the original meaning of which is "flower" or "flower-leaf." In modern Persian this word has undergone a phonetic change into "Gul," but it is still employed in its original form to designate the rose in Arabic, Armenian, and Hindi. The Western nations became acquainted with the word "Rurd" through the Phœnicians, and from the Arabic "Brovon" it passed into the Greek "Rhodon" and the Latiu "Rosa." The Arabic word "Atr" or "Hatr," meaning "fragrance," is the name of rose-oil in India. The commercial and general used form of the word is "Attur," and it is also found in the forms "Utter," "Odo," and "Otto."

Rose-water is obtained by means of distillation. The rose leaves are placed in clay or metal retorts, with water in the proportion of two to three. The metal retorts generally hold upwards of 100 lb. of water and leaves. The steam passes through bamboo pipes, and condenses in long-necked vessels, which stand in tubs filled with water, which is renewed as often as it gets too warm. About one-third of the vapour is lost, so that 1 lb. of roses is required to produce the same quantity of rose-water. The price of the best rose-water is from 1*s*. 6*d*. to 2*s*. per pound. The sorts usually sold in the bazaars are much cheaper, but are greatly diluted and mixed with various fragrant ingredients. Amongst the cheaper sorts is the liquid which remains after the extraction of the rose-oil. Rose-water is used by the natives of all India as a grateful perfume, and is also one of their commonest medicines. A favourite sweet preserve is also made from the rose leaves, which is called "Gulub-kand," or rose-sugar. The first process in the preparation of the rose-oil is the production of strong rose-water by mixing the results of one distillation with fresh rose leaves and then distilling a second time. The liquid thus obtained is poured into shallow metal basins, which are placed in holes in the ground, previously well saturated with water, and is then left to cool during the night. A thin layer of oil gathers on the surface, and in the morning is skimmed off by means of feathers or thin pieces of wood, and collected in phials. Another method of preparing this oil is to place layers of oiled cotton, or, better still, of oleaginous reeds, such as those of the sesame, between thick layers of rose leaves, and then to bruise the mass in an oil press. The oil prepared in this way contains comparatively little attar, although it generally smells very strongly of it. The quantity of roses required to produce 152 grains of pure attar is estimated at from 10 to 12 lb. In general the dark red varieties of rose are cultivated, *R. indica* and *R. centifolia* being the two favourite sorts. The colour of the oil is not, of course, affected by that of the leaves. When freshly collected it is thick and of a greenish yellow hue, but when it is clear and in a liquid condition it is sparkling and of a very bright yellow. The price of attar is very high, and generally much more variable than that of rose-water; the price of 1 tola, or about 184 grains of oil, has often been known to reach £8 or £9. The maximum is probably that mentioned by Hooker, who, in March, 1858, found the price of rose-oil in Ghazipore to be £10 per tola; the ordinary value of a tola is from £4 to £5, but the cheapest sorts are sold at 30*s*. These sums are not, however, to be understood as prices in the ordinary sense of the term, but rather as estimations of the value of pure oil. The quantity which is sold as quite pure attar is proportionately very small, as it is seldom bought, except as specimens by the wholesale merchants, or by the European inhabitants. The common cheap sorts of rose-oil, which are much used by the natives at their festivals and in their religous ceremonies, are greatly adulterated.

The climate of Ghazipore, which is situate 341 feet above the level of the sea, is subtropical, with intense heat from April to the end of August, the month of May being the warmest in the year. The roses are in bloom from the end of February to about the second week in April. The annual temperature averages 106°. At the end of February the average mid-day temperature is 101°, but at the beginning of April it reaches 108°. Benares is the chief mart for the sale of the rose products of Ghazipore.

---

* From the *Gardeners' Chronicle*.

THE PRACTICAL USES OF ELECTRICITY.*

Dr. Siemens, in his recent presidential address to the Society of Telegraph Engineers, made the following remarks on recent practical applications of electricity other than telegraphic :—

Electricity has hitherto rendered service as the swift agency by which our thoughts are flashed to great distances, but it is gradually asserting its rights also as a means of accomplishing results where the exertion of quantitative effects are required. Much has been said about the application of electricity for producing light, and the French Alliance Company, as well as the Gramme Company, have, it is known, for some years been establishing magneto-electric apparatus to illuminate the lighthouses upon the French coast and for galvano-plastic purposes. By an ingenious combination of two magneto-electric machines with Siemens armatures, Mr. Wild, of Manchester, succeeded in greatly augmenting the effects produced by purely mechanical means; but the greatest impulse in this direction was given in 1866-67 by the introduction of the dynamo-electrical principle, which enables us to accumulate the current active in the electric circuit to the utmost extent permissible by the conductive capacity of the wire employed. Dr. Tyndall and Mr. Douglass, chief engineer to the Trinity Board, in reporting lately to the Elder Brethren upon the power of these machines and their applicability to the lighthouses, gave a table showing that a machine weighing not more than 3 cwt. is capable of producing a light equal to 1250-candle power per horse-power expenditure of mechanical energy. Assuming that each horse-power is maintained with an expenditure of 3 lb. of coal per hour (which is an excessive estimate), it would appear that 1 lb. of coal suffices to maintain a light equal to 417½ normal candles for one hour. The same amount of light would be produced by 139 cubic feet of gas of 18-candle power, for the production of which 30 lb. of coal is consumed. Assuming that of this quantity, after heating the retorts, etc., 50 per cent. is returned in the form of gas-coke, there remains a net expenditure of 15 lb. of coal in the case of gas-lighting to produce the effect of 1 lb. of fuel expended in electric lighting, or a ratio of 15 to 1 in favour of the latter. Add to the advantages of cheapness in maintenance, and of a reduced expenditure in favour of the electric light, those of its great superiority in quality and its freedom from the deleterious effects of gas in heating and polluting the atmosphere in which it burns, and it seems not improbable that it will supersede before long its competitor in many of its applications. For lighthouses, for military purposes, and for the illumination of large works and public buildings the electric light has already made steady progress, while for domestic applications the electric candle proposed by Jablikoff, or modifications of the same, are likely to solve the difficulty of moderating and distributing the intense light produced by the ordinary electric lamp. The complete realization of all the advantages of the electric light remains, however, a problem to be solved, and it would be extravagant to expect from applications on a small scale, such have hitherto been made, anything like the amount of relative advantage indicated by theory. The dynamo-electric machine has also been applied with considerable success to metallurgical processes, such as the precipitation of copper in what is termed the wet process of smelting. The effect of one horse-power expended in driving a dynamo-electric machine of suitable construction is to precipitate 21 lb. of copper per 24 hours, equivalent to an expenditure of 72 lb. of coal, taking a consumption of 3 lb. of coal per horse-power per hour. Electrolytic action for the separation of metals need not be confined, however, to aqueous solutions, but will take, perhaps, an equally important development for the separation in a state of fusion of the lighter metals, such as aluminum, calcium, and of some of the rarer metals, such as potassium, sodium, etc., from their compounds. Enough has been shown by Professor Himly, of Kiel, and others, to prove what can be done in this direction, although there remain practical difficulties (chiefly the rapid destruction of the vessels containing the fused masses), the removal of which will require patient perseverance, but they are not likely to prove of an insuperable character. In an inaugural address which I had occasion to deliver to the Iron and Steel Institute a twelvemonth ago, I called attention to another application of the dynamo-electric current, that of conveying mechanical power, especially the power of such natural sources as waterfalls, to distant places, where such power may find useful application. Experiments have since been made with a view to ascertain the per-centage of power that may thus be utilized at a distance, and the results of these experiments are decidedly favourable for such an application of the electrical conductor. A small machine, weighing 3 cwt. and entirely self-contained, was found to exert 2·3 horse-power as measured by a Prony's brake, with an expenditure of five-horse power at the other end of the electric conductor, thus proving that about 40 per cent. of power expended at the distant place may be recovered; the 60 per cent. lost in transmission includes the friction of both the dynamo-electric and electro-motive engines, the resistance of the conductor, and the loss of power sustained in effecting the double conversion. This amount of loss seems considerable, and would be still greater if the conductor through which the power were transmitted were of great length and relatively greater resistance; but, on the other hand, it must be remembered that the power of a natural motor is obtained without expenditure of coal, and that a small caloric motor, which the electric motor is intended to supplant, is inconvenient and very extravagant in fuel. The electric motor presents, moreover, this great advantage, that it requires hardly any installation, and would be available at any time by merely closing the electric circuit without incurring the risk and inconvenience inseparable from steam and gas engines. Without considering at present the utilization of natural forces, let us take the case of simply distributing the power of a steam engine of say 100 horse-power to 20 stations within a circle of a mile diameter, for the production of both light and power. The power of 100 horses can be produced with an expenditure of 250 lb. of coal per hour, if the engine is constructed upon economical principles, or of 250-20=1·25 lb. per station. In the case of the current being utilized for the production of light 2·3+1200=2760, or say, 2000-candle power, are producible at the station, whereas, if power is desired, 2·3 horse-power may be obtained, in both cases with the expenditure of 12·5 lb. of coal, representing 1*d.* per hour for cost of fuel, taken at 15*s.* a ton. The size of the conductor necessary to convey the effect produced at each station need not exceed half-an-inch in external diameter, and its cost of establishment and maintenance would be small as compared with that of gas or water pipes for the conveyance of the same amount of power. Electricity, which in the days of Franklin, Galvani, Volta, and Le Sage was regarded as an ingenious plaything for speculative minds, and did not advance materially from that position in the time of Oersted and Ampère, of Gauss and Weber, and not indeed until the noonday of our immortal Faraday, has, in our own times, grown to be the swift messenger by which our thoughts can be flashed either overland or through the depths of the sea to smaller or greater distances, circumscribed only by terrestrial limits. It is known to be capable of transmitting, not only language expressed in conventional cipher, but facsimile copies of our drawings and handwriting, and at the present day even the sound of our voices, and of resuscitating the same from mechanical records long after the speaker has passed

* From the *Journal of the Society of Arts*, February 1, 1878.

away. In the arts it plays already an important part throughout the creation by Jacobi of the galvano-plastic process, and in further extension of the same principle it is rapidly becoming an important agent in the carrying out of metallurgical processes upon a large scale. It has now appeared as the formidable rival of gas and oil for the production of light, and, unlike those inferior agents, it asserts its higher nature in rivaling solar light for the production of photographic images; and finally it enters the ranks as a rival of the steam engine for the transmission and utilization of mechanical power. Who could doubt, under these circumstances, that there remains an ample field for the exercise of the ingenuity and enterprise of the members of that society I have just had the honour of addressing?

COLLECTION OF CANADA BALSAM.*

In the Report of the Committee on the Drug Market to the American Pharmaceutical Association at its meeting at Toronto, are given the following interesting details respecting the collection of Canada balsam in the Dominion.

This article is largely collected in the province of Quebec, where the *Abies balsamea* grows in great abundance. It is gathered there not only in quantities sufficient to supply the needs of the Dominion, but also to export to a sufficient extent to form an important article of commerce. The writer is indebted to the kindness of Mr. W. E. Brunet, chemist, of Quebec, who is a large dealer in this balsam, for the following details in reference to the collecting of it:—

The whole family of balsam gatherers go into the woods in the Laurentine Mountains, at a distance of from seven to ten miles from the villages. There they encamp for two months, their baggage consisting of canisters, packages of pork, flour, a stove, and bed-covering. The mother remains in the camp to do the cooking and to strain the gum, and it is she who transports it, upon her back, in canisters of 5 gallons each to the village, where she sells it at the rate of one dollar twenty cents a gallon in exchange for flour and pork, which, on her return, she carries also on her back, to the camp. The father, with his boys, goes to pierce the trees, each furnished with a small can with a tube proceeding from it at the top. This tube is of iron, sharpened, and with this portion of the instrument the blisters of gum are pierced, one by one, the liquid flowing down the tube until the vessel is full. The children mount into the branches while the father works about the lower part of the tree. A large balsam tree, rich in gum, will yield as much as a pound of balsam; but one with another the yield of each tree is not usually more than eight ounces. The father, with the help of two children, can gather from sunrise to sunset a gallon of balsam, but the man who works alone has done a good day's work when he has collected half a gallon.

One cannot gather the balsam when it rains, or even on the same day, for the branches let fall drops of water, which, mixing with the gum, render it milky and unsaleable. The collection of the balsam is made from the 15th of June, or about the time that the snow disappears from the mountains, up to the 15th of August or 1st of September, the date when the snow usually begins to fall, or the weather turns cold and the gum no longer flows. Near the villages and upon partially cleared land it is gathered in May, but this is only in small quantities. It is only the poorest inhabitants and the Indians who do this business. There has been gathered in the mountains nearly 3000 gallons this year; the largest crop ever gathered was 5000 gallons. A tree should not be pierced two years running, and requires two or three years' rest before being tapped again, and then it always yields very much less than the first time.

Spirit of Turpentine and *Rosin* were made in Canada during the time of the civil war in the United States, when prices ruled high. They were prepared from the common red pine, *Pinus resinosa*, which grows in abundance in the northern counties of Ontario. The turpentine obtained from this source, although not identical with that made from the *Pinus palustris* and other pines of the South, yet served as a convenient substitute in the various uses to which that article is applied in the arts. At the close of the war, when Southern turpentine resumed its old figures, this manufacture in Canada was abandoned, because it was found impossible to produce it at a price to compete with that from the South.

* From the 'Transactions of the American Pharmaceutical Association.'

THE ROOT OF EPILOBIUM ANGUSTIFOLIUM.*

BY C. J. BIDDLE.

The *Epilobium angustifolium*, L., *E. spicatum*, Lam., is a common plant growing very abundantly in many parts of the United States, north of the 39° of north latitude, and in British America, as far north as Behring's Straits; it is also indigenous to the northern portions of Europe and Asia.

It has a simple erect stem, often branched above, from four to six feet high, leaves scattered, lanceolate, subentire, with a marginal vein, sessile, smooth, acuminate, with pellucid veins; flowers in a long terminal spike, numerous and showy, all parts coloured; petals deep lilac-purple; they appear in July and August. Seeds numerous, in linear four-cornered and four-valved capsules, to which are attached long silky hairs.

The root penetrates the soil quite deep, and is much branched; it is from three to six lines thick, and is covered with quite a thick bark; the ligneous portion is very tough and fibrous.

As to the therapeutic value of the root, as a remedy for the cure of aphthæ, there is no doubt.

It has been used by Dr. H. A. Smith, resident physician of the Philadelphia Hospital, with success.

The form in which it was used was the infusion, made one part of the contused root to sixteen parts of boiling water.

A qualitative analysis of the root was attempted, but owing to the difficulty of securing a large quantity I was unable to treat it as thoroughly as the subject requires.

The dried contused root, when treated with water, either hot or cold, causes small white crystalline masses to separate, which appear under the microscope to be close bundles of needle-shaped crystals; these were separated mechanically, and on testing proved to be a calcium salt.

No preparation of the root when treated with Mayer's test for alkaloids showed evidence that one existed.

A saturated decoction treated with the precipitants mentioned in the 'U. S. Dispensatory,' under Gallæ, page 430, produced very similar results. The root contains large quantities of tannin, gum, and mucilage; it also contains starch, sugar, resin, gallic acid, extractive, etc.

The tannic acid is the kind which produces a bluish-black colour with ferric salts. Its remedial action I do not think is to be attributed to any *one* principle in the root; in my opinion it is in its combined demulcent and astringent properties.

For the cure of aphthæ an infusion of any herb having the above properties is recommended, and as a never failing remedy of easy access we have the "mel sodii boratis" of the Pharmacopœia.

* Paper read before the American Pharmaceutical Association. From the 'Transactions.'

NOTES ON THE OLIVE.

Dear Mr. Editor,—The olive crop has now almost all been gathered in; perhaps a few notes on the cultivation of the tree, and preparation of the oil in this district, may not be without interest.

The produce of the tree forms the staple of the country, and although it is the fruit which absorbs the chief attention of the cultivator, it is not with it the useful products of the tree stops: the leaves have been used in medicine; the wood takes a high polish and is much valued by cabinet makers, and moreover forms the chief, almost the only fuel used by the people; the crushed stones of the fruit when washed and dried also are used for fuel, while the residue left after the extraction of the oil is excellent manure.

The whole country, covered as it is with these trees, possesses a character peculiar to itself. Everywhere the lower hills present the dark dead green colour of the leaves, but seen from an elevated point, when miles of olive groves lay below and the tree tops toss and wave in the wind, the scene can only be compared to the billows as they come rolling in from the sea, as the colour changes from green to grey and then to green again, as first the dark upper side of the leaf, and then the silvery grey of the under is presented to view. Much has been said of the monotonous effect of olives seen in masses, and the want of variety in the landscape, but soon the beauty of the view grows on the visitor, and such complaints die on the lips. The twisted and gnarled trunks would make capital studies for an artist. Nothing can be more beautiful than a vista of olive trees, with their variegated and fantastic shapes, covered as they are with a grey lichen.

On every available spot of ground a tree has been planted; terraces have been built on the hill sides to hold the soil and prevent it being washed away by rains. Every spring each tree is carefully examined and decayed branches cut off, and the earth round is dug so as to give air to the roots. At least once in three or four years the trees are well supplied with manure, the kind most valued for this purpose being the hoofs and horns of cattle, and woollen rags, of the latter those collected from amongst the Neapolitan lazzaroni are most prized, as having peculiar virtue. It will be seen from this that the cost of cultivation, together with the constant repairs needed by the walls of the terraces that support the soil, is no slight tax on the yield, while the expense of gathering the fruit and making the oil is calculated at twenty-five per cent. on the net produce.

From November to the end of March the work of gathering in the olive harvest goes on; the mode followed is to shake the trees and pick up the fruit that falls. This is done from time to time, and towards the end of the season the few drupes that still hang on the branches are gently thrashed off with poles, and very carefully must this operation be conducted, for the young wood formed one year bears fruit the next, so that if the shoots are destroyed by a merciless thrashing in the winter or early spring but little chance is left for a good crop the following season. In some parts the fruit is entirely hand gathered, so careful are the cultivators that the young wood shall not be injured.

Only once in three years is a good crop expected, and bearing in mind that the fruit hangs on the tree from April or May, when it forms, until almost the following March, and as the trees are of very delicate constitution, equally likely to be injured by extremes of climate, heat or cold, long drought, rain or wind, it is not to be wondered that two out of three crops should fail. An enemy is found also in a small insect which lays its eggs in the young fruit, the grub hatched from these feeds on the drupe and prevents it attaining maturity. Those trees occupying the higher grounds are in some degree free from this pest, but are at the same time more exposed to changes of the weather. For this insect plague the people have in a great measure themselves to blame; such is their love of sport that they stalk down every small bird they see, much in the same manner as we at home would stalk a stag in the wilds of Scotland.

The olives when gathered are taken to the mills, where they are first crushed under a stone to a pulpy mass, then placed in bags which, stacked one above another, are subjected to gentle pressure in a screw press; the oil thus obtained is filtered through cotton wool and forms the finest quality. The residue is again ground in a trough through which a constant stream of water is kept running; the stones of the fruit are by this process perfectly cleaned, and fall to the bottom, while the pulp and oil is held in suspension and washed away by the water, which is made to run through a series of cisterns. On the top of the water in each of these a scum rises, which skimmed off and pressed yields a second quality of oil used for lamps and machinery purposes; the residue of this second pressing is boiled with water and the oil as it rises is removed and used eventually by the soap manufacturer. The residue left is most excellent manure; the crushed stones removed in the grinding are sold as fuel. Hanbury, in the 'Pharmacographia,' mentions a report, that in some districts, the mill stones are so mounted as not to break the olive stones, but crush only the pulp. When making inquiries on this point, I was told such was the practice here, the oil yielded by the kernels being supposed by the manufacturers to have a bitter taste, but in the mills I have seen working the stones are broken in the first grinding.

The oil mills here are all worked by water, this scarce but necessary motive power being collected far up in the mountains and carried along the hill sides for great distances in channels or gutters, some foot wide by half that depth; this little stream is made to work the mill by an overshot wheel, is again collected and carried on to another mill lower down, and so performs its work three or four times over before being lost in the sea.

This season's olive crop has been very plentiful, though the drupes are smaller than usual, from the want of rain during the summer; those gathered from the higher grounds are somewhat finer than those grown lower, having been subject to the heavy dews and mists that sometimes cover the mountains in early morning.

I have been informed that the oil made here is of so fine a quality that the whole is exported, and only an inferior quality used for home consumption. How that may be I cannot say, but some twenty thousand quintals of oil are made annually in this district alone, a quantity which considerably exceeds four hundred thousand gallons.

March 20. San Remo.

THE ROYAL GARDENS AT KEW.

AMONG the institutions of which scientific Englishmen have reason to be proud none can justly lay claim to a higher reputation than the Royal Gardens at Kew. This is the more remarkable because their great reputation is of quite modern growth; for only about five-and-thirty years ago, when they were committed to the charge of the late Sir WILLIAM J. HOOKER, they were comparatively unknown. But, first under the able management of that celebrated botanist and subsequently under that of his no less distinguished son, the collections of plants, both living and dead, have been so perfected that it is scarcely exaggeration to describe them as the cynosure of the botanical world. To the establishment at Kew botanists in every country under the sun are continually making contributions of the rarest gems of the vegetable kingdom, and within its walls visitors from many lands meet to compare its treasures with their own. Moreover, some of the most important and practically useful works on botany published during recent years have been issued under its auspices.

But whilst the gardens at Kew have been growing more and more a household word with scientific men, they have also been steadily growing in favour with the public. The wonders of the palm and orchid houses, and the beauties of the flower beds, have been sufficiently obvious to afford even to non-scientific minds the most exquisite enjoyment, and for several years past this has been made increasingly manifest by the numbers of holiday folk who flock to see the gardens. Unfortunately this has led to temporary unpleasantness, and the very excellence of the service done to the public has virtually contributed to raise discontent in some quarters with those who have rendered it.

The point in dispute is quickly stated. The Directors of the Gardens have hitherto considered it necessary, in order to the furtherance of the objects which the gardens are primarily intended to serve, to keep them closed to the public until one o'clock in the afternoon. Against this practice there is just now a very strong current of public opinion running; meetings have been held, memorials have been presented, and the subject has been brought under the notice of Parliament. Indeed, Mr. GERARD NOEL fairly epitomized what may be presumed to be the official line of defence in a reply to a question put in the House, when he said that the opening of the gardens at an earlier hour could not be conceded without a large increase of expenditure and a material interference with the daily work in the gardens. In fact, it was urged that the change demanded would involve the question whether Kew should continue what it was originally intended to be, a scientific utilitarian institution, or become merely a resort for pleasure seekers. On the other hand, it has been argued that there would be nothing inconsistent with the gardens retaining their scientific character if they were opened at ten in the morning, and instances have been quoted, such as the gardens in Dublin, Edinburgh, and Paris, where the public are admitted at a still earlier hour.

The dispute with the public is hardly suitable for argumentation in these columns, and we would only express a hope that the strongly expressed view of the Director, whose name is so closely associated with the fame of the gardens, may not meet with an unfair antagonism in the shape of clamour about the rights of the people to use the public parks, a right that we presume is not all disputed by Sir JOSEPH HOOKER. But when the plea is put forward that it is necessary that the gardens should be closed during the early part of the day to enable students to pursue their studies unmolested we do feel warranted in asking whether such facilities are afforded to a large number of students as might be expected? For instance, the Royal Botanic Society acts in a most liberal manner towards students wishing to study in its gardens between the hour of opening and 1 o'clock, and the privilege is widely appreciated; but we know of no analogous facilities afforded in the public gardens at Kew. It is true that it has been stated that some such privilege is granted upon proper application, but it is evident from the number of failures that have been recorded that there is at least considerable obscurity as to the form in which the application is to be made.

Again, there is another direction in which we think the services rendered to science by the establishment at Kew might be profitably extended. For the proper illustration of the numerous courses of botanical lectures now delivered in the metropolis and its neighbourhood, in connection with medical and pharmaceutical schools and other institutions, a large supply of typical plants is requisite. For this we believe lecturers in the metropolis are chiefly again indebted to the liberality of the Royal Botanic Society at Regent's Park, and in some measure to the Apothecaries' Garden at Chelsea, but we are not aware of a single instance in which these wants have been supplied from Kew. This may be contrasted with the fact that in one of the suburbs of Berlin there is a garden under the control of the educational authorities from which upwards of four millions of fresh plants are supplied to the schools during the year. In our case no special garden is required, as in the immense grounds at Kew there is room for the cultivation of an ample supply for present requirements.

In conclusion, we need scarcely say that these opinions are not put forth in a cavilling spirit, but because we believe that the arguments of the Kew authorities would have been stronger had they rested on a wider basis.

THE PHARMACEUTICAL SOCIETY OF ST. PETERSBURG.

THE publication in the *Pharmaceutische Zeitschrift für Russland* of the Annual Report of the Pharmaceutical Society of St. Petersburg for 1877, furnishes some details that give interesting indications as to the position of associated pharmacy in the chief city of the Russian empire. But their bearing will perhaps be better understood if we repeat briefly some statistics that have already been quoted in these columns from the same source, to the effect that in 1874 there were in that city 54 free pharmacies and 3 branch establishments, giving employment to 4 magisters, 74 dispensers, 934 assistants, and 77 pupils, or just upon 1100 persons, and dispensing upwards of one million and a half of prescriptions annually.

At the close of 1877, according to the report, the Society consisted of 275 members, of whom only 122 were effective members, 46 were corresponding members, and no less than 107 were honorary members. Of the 122 effective members 65 were not resident in St. Petersburg. During the year, 21 new members had been elected.

In connection with the Society at St. Petersburg there is a Pharmaceutical School, but it does not appear to draw many pupils, only six having presented themselves at the commencement of the course. The report confesses that notwithstanding many attempts to infuse a greater amount of life into the School, these have hitherto been unsuccessful. There can be little doubt, however, that a great part of the unfavourable result last year is due to the fact that the number of practising pharmacists in St. Petersburg has been considerably diminished in order to supply the needs of the war department. The St. Petersburg pharmaceutical students appear also to be suffering under some disadvantage in consequence of obstacles that exist in the way of completing their course of education at the Medico-Chirurgical Academy.

The St. Petersburg Pharmaceutical Society further possesses an analytical laboratory, in which analyses in connection with legal investigations are made for the local authorities, the receipts on this account during the year amounting to 1165 rubles. It has also a library of about 5000 volumes, and a museum. The *Pharmaceutische Zeitung für Russland* is the organ of the Society for the diffusion of pharmaceutical information, and some admirable papers that it contained during the past year had been first read at the Evening Meetings of the Society. At biennial intervals a gold medal, known as the "Suworoff Medal," is awarded by the Society for the best memoir on a subject connected with pharmacy; the subject for the next competition, to be held in 1879, is a "Critical Review of the Methods used in the Separation and Estimation of the Different Cinchona Alkaloids." Finally, the Society has its Benevolent Fund.

The Report also incidentally reveals the effect of the war upon pharmacy in another direction. In Russia the pharmacist is protected to a much greater extent than in this country. For instance, the number of pharmacies is strictly limited, only one being allowed to, we believe, each twelve thousand inhabitants. On the other hand they are placed under considerable restriction, and as in Germany the prices for the articles sold or dispensed in them are fixed by the State. The commercial disturbance caused by the war has led to an enormous rise in the price of drugs, so that in some cases the price allowed to be charged does not cover the cost of the drug. A deputation from the Society therefore waited upon the Medical Council and asked that the tariff might be revised. The suit was, however, not granted, the revision being somewhat ironically deferred until the close of the war.

It is also not without interest to notice, in connection with the position of pharmacists in Russia, that in Russian Poland complaints have been made that the pharmacists do not always possess a sufficient acquaintance with the language of their conquerors. The Council of the Warsaw University has therefore ordered that each pharmaceutical student at the close of each course as well as at the final examination shall be tested as to his knowledge of the Russian language. Lectures in the Russian language are also to be obligatory at this institution in future.

THE DENTAL BILL.

IN looking over the amendments on the notice paper of the House of Commons we observe that Sir JOHN LUBBOCK has given notice of his intention to move the omission of the words "either separately or in conjunction with the practice of medicine or surgery" from the 5th clause.

THE ANNUAL MEETING.

IT is proposed that the Seventh Annual Dinner of the Members and Friends of the Pharmaceutical Society shall take place at the Grosvenor Gallery, New Bond Street, on Tuesday, May 14th, the day preceding the Annual Meeting of the Society. Gentlemen willing to act as Stewards on that occasion are requested to forward their names at once to the Honorary Secretary, Mr. RICHARD BREMRIDGE, 17, Bloomsbury Square.

PROFESSOR BENTLEY'S LECTURE.

WE would remind our readers that on Wednesday evening next, April 17, Professor BENTLEY will deliver a lecture at 17, Bloomsbury Square, on "Eucalyptus globulus and its Uses." The chair will be taken at half-past eight o'clock.

BEQUEST TO THE YORKSHIRE COLLEGE, LEEDS.

THE late Mr. HENRY BROWN, of Bradford, has bequeathed the sum of £5000, free of legacy duty, to the Yorkshire College. It is understood that this is intended for scholarships.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

A lecture was delivered in the Rooms of the above Association, at No. 4, Halford Street, on the 2nd inst., by J. E. Weatherhead Esq.; subject, "The house I live in."

The President, Mr. Garrett, occupied the chair and briefly introduced the lecturer.

The number of members present was very small, but the visitors, including several ladies, made up a fair audience.

Mr. Weatherhead, before commencing the lecture, presented to the Association a chart of the osseous structure of the lion. The chart was prepared by himself to explain the parts of a skeleton of a lion in the town museum. The lecturer then called attention to the human skeleton suspended against a black cloth, and spoke of the goodness and power of the Creator in producing such a structure, also of the usefulness of this special study to surgeons. Each bone of the skeleton was then fully explained, the bones of the head being illustrated by a skull taken to pieces so that the internal structure could be examined. The skull of a monkey also showed the same arrangement of bones as in the human skull. The teeth were named and described by diagrams, and a very large tooth of a rhinoceros was exhibited. The usefulness of the ulna and radius bones of the arm were shown, without which the hand could not turn as it does. The curved shape of the back bone was shown to be less liable to be strained or broken than if it was straight.

The lecturer, in concluding, illustrated the similarity of the bones of a horse's foreleg with the human arm. He called attention to the common error the public have got into by saying, when a horse has fallen down, that it has broken its knees. The knees he showed to be upon the hind leg close to the stomach, and therefore not liable to injury, the parts commonly called the knees in the horse being truly the wrist bones, the elbow being just under the shoulder, and the bone from the wrist downwards being the metacarpus bones coalesced into one. The toes, or bones corresponding to human fingers, terminate in the hoof.

A vote of thanks was proposed by Mr. Garrett, and seconded by Mr. Shuttlewood, and carried.

Mr. Garrett in announcing the next class, called the attention of the members present to the very small number attending the classes, and hoped to have a great improvement in the future.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

Assistants' Section.

The fifth meeting of the present session was held in the Andersonian College; Mr. Wm. Simpson, President, in the chair.

After the minutes of the previous meeting had been read and confirmed, Mr. C. Macmillan (Vice-President) read a paper on "Food."

He began by pointing out the necessity of food to the animal organism in order to repair the continual waste going on, and showed how the plant absorbed nutriment from the inorganic kingdom to form, with the aid of heat and light, its own tissues, and how it in turn contributed to the formation of animal tissues. He then went on to describe how a certain quantity of food represents not only so much material to repair the waste of the body, but has bound up in it a certain amount of energy, waiting to show itself as heat and mechanical force. After briefly describing the process of digestion, and the various theories regarding assimilation, he divided foods into five classes, viz., nitrogenous or tissue forming, fats, carbohydrates, mineral substances and water, and specified certain staple articles of food in connection with their nutritive value as articles of diet. He made some interesting observations on some of the more important beverages in common use, and concluded by showing how much knowledge concerning the functions of the different kinds of food had increased during recent years, chiefly owing to the investigations of the German school of physiologists, and how much there was yet to learn.

At the close of the paper, the reader was awarded the usual vote of thanks.

The Secretary then intimated that the Council had agreed not to proceed with the formation of a botany class this year, and recommended students to take advantage of the one about to be opened in the Andersonian College, as being perfectly sufficient to furnish all that was required by any one in the botany examination in the Minor. He also intimated that the final meeting of the present session would take place on the 10th April, when the new office bearers would have to be elected.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The last ordinary evening meeting of the session was held in the Memorial Hall, on Monday the 8th inst., the chair being occupied by the President, Mr. W. S. Brown.

In the absence through illness of Mr. A. N. Palmer, who was to have read a paper, Mr. J. T. Slugg, F.R.A.S., Vice-President, delivered a short lecture on "Glass," treating especially of its application to the construction of optical instruments.

At the close of the lecture Mr. F. B. Benger showed and explained some new and interesting forms of Geissler's tubes.

A cordial vote of thanks to Messrs. Slugg and Benger having been passed, the President announced that owing to his numerous engagements in Manchester he had decided to decline to accept nomination for re-election as a member of the Council of the Pharmaceutical Society, but was glad to say that Mr. G. S. Woolley had consented to become a candidate. Alluding to the state of pharmaceutical affairs in 1870, when Mr. Woolley and himself had been elected members of the Council, and reviewing the subsequent legislation and events, he proposed the following resolution:—"That this meeting considers Mr. G. S. Woolley to be the most suitable person to represent Manchester and the surrounding district on the Council of the Pharmaceutical Society, and pledges itself to use every legitimate means to ensure his election."

Mr. Benger having seconded the resolution,

Mr. J. B. Payne begged to be allowed to support the resolution, as he considered that it was very important that Manchester and the district should be thoroughly represented. He took this opportunity of expressing his regret at the retirement of Mr. Brown, a feeling which he was sure was shared by every member of the Association, as they all knew what valuable assistance Mr. Brown had rendered to the Association. He (Mr. Brown) was a gentleman who had a large experience in committee and council work, and the Manchester Chemists' Association was especially indebted to him for the kind and able manner in which he had supported and assisted it in his capacity as a member of the Pharmaceutical Council. As he had just previously remarked it was essential that so important a district as this should be properly repesented. He supported the resolution, believing that Mr. Woolley, who had always taken a large interest in this Association, as well as in all matters connected with the trade generally, would prove a very able representative.

The resolution was carried unanimously, and the meeting then terminated.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Thursday April 4th, Dr. Gladstone, President, in the chair. After the announcement of visitors, etc., the minutes of the last ordinary and of the anniversary meeting were read and confirmed. The following certificates were read for the first time: B. Gregory, A. E. Tucker, and T. Slinger. The undermentioned gentlemen were balloted for and declared duly elected: R. H. C. Nevile, R. H. Jude, T. H. Norton, A. K. Huntington, G. H. Rutter, S. S. O. Norris, J. Spencer, T. W. Drinkwater, A. N. Pearson, W. J. Macadam, W. A. H. Naylor, J. Tchermiac, M. Zingler, S. A. Goldschmidt.

Mr. H. C. Sorby, F.R.S., then delivered a lecture—

On the application of the Microscope to some special branches of Chemistry. The lecturer stated that he felt himself placed in a difficult position; if he gave a full account of his subject he feared that every one would be wearied; if on the other hand he contented himself with a summary he was afraid that he would not be understood. He did not propose to touch on the general use of the microscope for magnifying small crystals or examining the minute structure of larger ones, but to confine himself to an application of the microscope to certain branches of chemistry in which it had not hitherto been employed. He would therefore give a rough general sketch of this application and dilate on subjects which were especially interesting to chemists. Lines and circles have long been looked at through doubly refracting media, such as Iceland spar, but until lately no one seems to have systematically studied the appearances which present themselves when appropriate objects are observed with a *microscope* through various crystalline substances. These appearances are quite different because the object-glass of the microscope collects the diverging rays, and we have new conditions. Dr. Royston Pigott described in 1876* his refractometer. The principle made use of in this instrument was the increase of the focal length of the object-glass of a microscope, caused by looking through media of different refracting power. Dr. Royston Pigott measured this displacement by means of a micrometer screw fixed under the stage in such a manner that it became unsuitable for its ordinary use. The author has succeeded in contriving an arrangement which, while it gives sufficient accuracy of measurement, allows the microscope to be used for general purposes. Practically the application of this method is very simple. If an object be placed on the stage of a microscope and the focus adjusted accurately, on placing over the object a plate of some highly refracting substance the object will be invisible, and to bring it into focus the body of the microscope must be moved farther out. If this distance be d and the thickness of the plate be T, Royston Pigott has shown that—

$$\mu, \text{ the index of refraction} = \frac{T}{T - d}$$

Now this distance can be measured either by means of a scale and vernier attached to the body of the microscope or by having the head of the screw which works the fine adjustment graduated. To take an example, suppose we wish to determine the refractive index of water. A short piece of barometer tube is firmly cemented to a glass slide, and the cell thus formed filled with water; the cell is then covered with a cover-glass (which must be larger than the tube, and the surface of the cover-glass must be parallel with that of the glass slide). If the apparent thickness of water t (T-d) = 0·2360 inch, whilst $d = 0{\cdot}0790$ inch, then $\mu = \frac{\cdot 2360 + 0{\cdot}079}{\cdot 2360} = 1{\cdot}335$. A second determination gave 1·334. In order to determine "T" and "d," we proceed as follows:—First to get T, we focus to the upper surface (any dust or scratches will do for focussing) of the glass slide, and read off the position of the body of the microscope, then focus to the under surface of the cover-glass and read off: the difference between these two readings evidently gives us the thickness of the stratum of liquid, *i.e.*, T. Secondly, to obtain "d," the image of a grating or circle is formed under the cell by means of a condenser under the stage, and the microscope focussed to it; the cover-glass cell and slide are now placed on the stage so that the observer looks through the cover-glass and slide but not through the cell; the image is again focussed, the difference between this reading and the first gives the displacement due to the slide and cover-glass. The cell is now pushed over the image and the latter focussed; the difference between this reading and the second gives the displacement due to the stratum of liquid, *i.e.* "d." A two-third's inch objective and No. 2 eyepiece are usually employed. To obtain accurate measurements many precautions are necessary, but with care "T" and "d" can be determined to one-thousandth of an inch. Red light is employed. For small quantities of liquid the ordinary live box is most convenient. The author has determined the refractive index of water with a film one-fiftieth of an inch in thickness, and obtained the number, 1·338. In a similar way the refractive indices of solids can be determined, the only conditions being that suitable slices be cut which are transparent, more or less, and whose surfaces are flat and parallel. If we look at the image of a grating, *i.e.* two systems of lines at right angles to each other through a plate, with flat parallel surfaces, of glass, or any transparent mineral which has no double refraction, both systems of lines are seen at once. The image thus formed is said to be *unifocal* and the index of refraction thus determined is that of an ordinary ray. If, however, the mineral possesses double refraction, the phenomena presented may be totally different; the ordinary ray has the same properties and is strictly unifocal, but the characters of the extraordinary ray differ according as the section is cut perpendicular, oblique, or parallel to the principal axis. Let us take calcite as an example, if we examine the image of the grating through a section parallel to the axis when the extraordinary ray is alone transmitted, the ordinary ray being cut off by a Nicol's prism, it will be found that there are two points separated from one another by an interval somewhat more than one-eighth of the thickness of the section, at each of which only one system of lines can be seen at once; *i. e.*, at one focus, only the lines, say from right to left are visible, at the other only those from top to bottom can be distinguished. The image is thus truly *bifocal.* If we examine a circular hole, furnished by an iris diaphragm, through a unifocal and a bifocal crystal respectively in the first case, the image is seen undistorted and well-defined at one focus, whereas in the bifocal image there is no focal point at which the hole can be seen of its true size and shape; it is either drawn out into a long vertical band with curved ends, or a horizontal band, or forms a large circle without any definition. Crystals like aragonite, which have two optic axes, have no ordinary ray and no permanently unifocal images, but two bifocal images. With such a crystal a circular hole is drawn out into a cross. The lecturer then showed in what direction such crystals must be cut in order to obtain their true indices of refraction. The forms taken by gratings and circles were illustrated by models, and by means of the latter it was demonstrated how it was possible to tell at a glance in what direction a mineral had been cut, in order to furnish the sections under observation. The lecturer then proceeded to explain the application of this method of observation to rock sections, and showed how valuable and simple the process was for identifying minerals—even with sections one five-hundredth of an inch in thickness and one one-hundredth of an inch in diameter good results have been obtained. The sections must be flat and have parallel sides; they can be examined loose or mounted in Canada balsam, the method of observation being very

* 'R. S. Proc.,' xxiv., 393, and *Monthly Micros. Journ.*, xvi., 294.

similar to that described above in the case of liquids. Thus in the meteoric irons of Krasnogarsk and Rittersgrün a clear mineral was proved to be olivine; the three indices were found to be—

Krasnogarsk . . .	1·71	1·68	1·68
Rittersgrün . . .	1·70	1·68	1·66
Olivine . . .	1·70	1·61	1·66

In some cases it is better to compare the index of refraction of the unknown mineral with that of a known mineral, *e. g.*, quartz, which is lying close to it. Even with very black hornblendes good results can be obtained, by using very thin sections, although the mineral is in moderately thin sections quite opaque. As an instance of the marvellously delicate nature of the method, the lecturer gave the examination of a section of a dolerite from near Glasgow one-four hundredth of an inch thick. In this extremely thin section a zeolite, probably analcime, labradorite, calcite, and augite were identified with almost absolute certainty. In a similar way in sections of shells of Pinna $\frac{1}{1000}$th of an inch thick calcite was recognized, whilst in a section of the shell of *Haliotis tuberculata* arragonite was identified. In conclusion the lecturer referred to the connexion between the indices of refraction and chemical composition. The subject is beset with difficulties, principally from defective data, but some points come out clearly; the fluorides have low indices of refraction; all the zeolites have indices less than that of quartz. All the earthy carbonates, sulphates, and borates have indices between those of quartz and corundum. All minerals with an index greater than that of corundum are metallic or metalloidal; sulphur and sulphides have indices above 2·000 and the arsenides above 2·500. A mineral containing calcium instead of the alkalies has a higher index, *e.g.*, adularia 1·52, labradorite 1·61. Again, a mineral containing iron has a higher index than one in which calcium is substituted for that metal: thus in the lime garnet $\mu = 1·74$, in the precious garnet $\mu = 1·79$.

The lecturer finished by stating that much information might be obtained in a very short time by a qualitative examination of a mineral, *e.g.*, whether it was unifocal or bifocal, etc.

The principal appearances described above were illustrated by specimens exhibited.

The President said that he was struck with the great extension of power with which this beautiful research of Mr. Sorby had furnished us. Good results seemed possible with even one drop of liquid.

Mr. Duffy asked if the method had been applied to crystals, raphides, or liquids in vegetable cells.

Mr. Sorby replied in the negative, and pointed out that the cell walls would have to be perfectly flat in order to obtain results.

A hearty and unanimous vote of thanks was then given to Mr. Sorby for his elaborate and important communication, and the Society adjourned to April 18, when the following papers will be read: on Terpin and Terpinol, by Dr. W. A. Tilden; the Poisonous Principal of *Urechites suberecta*, by J. Bowrey; on the Temperature at which a few of the Alkaloids Sublime, as Determined by an Improved Method, by A. Wynter Blyth.

THE SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held at 17, Bloomsbury Square, on Thursday evening, March 28, Mr. J. F. Savory, Vice-President, in the chair.

The first paper read was a "Note on the Various Kinds of Valerian," by Mr. W. R. Atkins. The paper opened with a botanical description of the valerians in general, giving the characters diagnostic of these plants, followed by the various varieties, and the peculiarities of these latter by which they may be distinguished from one another, including the marsh, common, and Pyrenean valerians, the plant known as American valerian belonging to the order orchidaceæ, and bearing no resemblance to the true valerian. *Valeriana officinalis* was, according to the author, extensively produced on the borders of Wiltshire and Dorsetshire. Of the chemical constituents supposed to be contained in valerian root, that known as valerianic acid was most largely treated of. Formerly obtained from the root by distillation, it is now artificially produced by the oxidation of amylic alcohol. The manufacture, tests for purity, and the products of decomposition of this acid were fully detailed. In its dry state the root appears to yield no volatile oil, but after treatment with water does, resemblance being here shown to the production of oil of bitter almonds in presence of water. The paper concluded with details for making the more important valerianates, and the therapeutical action they exert.

A paper by Dr. Senier and Mr. A. J. G. Lowe, on "The Action of Glycerine on Borax," was then read by Dr. Senier.

The Action of Glycerine on Borax.

BY DR. A. SENIER AND MR. A. J. G. LOWE.

Solutions of borax in glycerine are used in medicine, and have to be prepared by the pharmacist—indeed such, a solution finds a place in the British Pharmacopœia. It has sometimes been required to dispense sodium bicarbonate together with borax and glycerine, when effervescence has taken place. This phenomenon has been reported occasionally in the query columns of various journals. The authors of this paper have made a few experiments, which lead at least to a very probable explanation of this reaction, and these they think will be of interest to the Students' Association.

To a solution of borax in water a few drops of tincture of litmus were added, colouring the solution deep blue. The addition of some glycerine to this solution caused it to change from blue to red, the characteristic wine red of free boracic acid. An experiment was then tried using sodium monoborate in place of ordinary borax or biborate; in this case no red colour was developed. The ordinary acid borates of silver, mercuric-mercury, lead, barium and calcium were next employed. In each of these cases the red colour or acidity was developed in the same manner as when borax was employed. Water seems to act in a manner opposed to glycerine, for when added in excess to the acid solution the blue colour returns. It is said that a large excess of water renders even an aqueous solution of borax more alkaline to litmus. It is well known also that solution of sodium carbonate is decomposed by boiling with aqueous solution of borax. In this case carbon dioxide is evolved, and a more basic borate is produced. In like manner sodium bicarbonate or carbonate, or even calcium carbonate is decomposed by solution of borax in glycerine, and there can be little doubt that the reaction is the same; that is to say, that the glycerine separates the biborate into free boracic acid and a more basic borate. This more basic borate is probably not strongly alkaline in glycerine, at least our experiments show that while sodium biborate is acid in glycerine sodium monoborate is alkaline.

We next endeavoured to ascertain the amount of carbon dioxide evolved when carbonate of sodium is added to a solution of borax in glycerine. In these experiments the glycerine, borax, and sodium carbonate all free from notable impurities, were employed in the anhydrous state, it having been ascertained that water lessened the evolution of gas. Solutions of anhydrous salts in anhydrous glycerine are, of course, viscid, and as might be expected little action takes place until the temperature is raised to 100° C. At this temperature part of the carbon dioxide is evolved, but the greater part comes over at a somewhat higher temperature, and in order to ensure complete action the mixture was generally heated at the close to about 180° C. Using concentrated solutions we obtained carbon dioxide in the proportion of one-half an equivalent of carbon dioxide to one equivalent of sodium biborate. Using dilute solutions we obtained rather less carbon dioxide, that is instead of ·044 gram carbon dioxide we obtained ·038 gram. These experiments show that at least in concentrated solutions a sodium borate midway between biborate and monoborate would answer the requirements of the free acid, doubtless boracic, which exists in glyceroles of borax. Very many experiments, not here detailed, were conducted with the view of separating the free acid, either directly or indirectly, all of which gave negative results.

In answer to Mr. Naylor, Dr. Senier described the apparatus used and means employed to estimate the boracic acid liberated.

This was followed by a paper, by Mr. Mason, on "The Flame Tests for Boracic Acid." The author reviewed the flame tests for boracic acid in general use; first, by the use of sulphuric acid and spirit, secondly, by fusing with bisulphate of potash and fluoride of calcium; thirdly, by the use of glycerine; and fourthly, of sulphuric for other acids. All the tests appear to depend upon the liberation of boracic acid, and the author was in favour of the use of glycerine for this purpose.

In the discussion which ensued, however, in answer to a question from the Secretary, Dr. Senier remarked that monoborates will not show the green colour with glycerine, a fact which would limit the applicability of the glycerine test, and which would confirm the opinion previously expressed by Dr. Senier, that the action of glycerine on borax resulted in the liberation of boracic acid and formation of a more basic borate.

In replying to the discussion, Mr. Mason was of opinion that, all things considered, the use of strong sulphuric acid in the blowpipe or Bunsen flame was the best of the flame tests for boracic acid.

Specimens of the leaves, flowers, and fruits of *Eucalyptus globulus*, sent from San Remo by Mr. Hardwicke, a member of the Association, were exhibited by Mr. Parker, accompanied by a description of the plant and the uses to which it was applied.

The meeting was then adjourned till April 25.

LONDON INSTITUTION.

The Analogies of Plant and Animal Life.*

BY FRANCIS DARWIN, M.B.

(*Continued from p.* 781.)

The other tendency, which may be also compared to an instinct, is the power possessed by the growing parts of plants of perceiving the position of the chief source of light. This tendency of course interferes with the geotropic tendency, for if the tip of a growing shoot bends towards the light it deviates from its vertical course. This contest between two instincts is well shown by placing a pot of seedlings close to a lamp or a window, in which case the heliotropic beats the geotropic tendency and the young plants curve strongly to the light; now if the pot is removed to a dark room the geotropic tendency reasserts itself, and the seedlings become once more upright. One might fancy from this that the darkness of night would be always undoing any good gained by heliotropic growth in the day. An imaginary case in the life of a seedling will show that it is not so. A seedling germinates under a pile of sticks: having few competitors it makes a good start, but in consequence of the darkness it begins to starve as soon as it has exhausted the supply of food given it by its mother plant stored up in the seed from which it sprang. It starves because it is dark under the pile of sticks, and without light it cannot decompose the carbonic acid of the air and make starch; carbonic acid may be said to be the raw material from which a plant makes its food—but without the help of light the plant is powerless to make food—it starves in the midst of plenty. So that the power of knowing where the light is and of moving towards it may be just as necessary to prevent a young plant starving as the power of knowing a grain of corn when it sees one and of snapping it up are to a young chicken. Luckily for our imaginary plant a ray of light streams in between two sticks—if the plant insisted on growing straight up in obedience to the geotropic instinct it would lose its chance of life. Fortunately the other light-seeking instinct wins the day and the plant thrusts its summit between the sticks and reaches the light. And now it is clear that when the plant has once got between the sticks the tendency to straighten again in the night will not be able to undo the advantage gained in the day by heliotropism. Besides the tendency to seek the light, there is in some plants another exactly opposite tendency to grow away from it. Just as in the case of geotropism no reason can be given why two organs should be affected in exactly an opposite manner by the same cause; no difference of structure can be perceived and no difference in manner of growth can be found between a tendril which grows away from the light and one which grows towards it. The convenience of the plant seems to dictate the result. Thus the virginian creeper climbs by forming little sticky feet at the end of its tendrils, and as it climbs up a support each new tendril is enabled by its power of seeking for darkness rather than light to find out little dark crannies in which to place its feet. On the other hand a bryony climbs by seizing anything it can get hold of, and as each tendril reaches out towards the light the whole plant will tend to be dragged towards the lighter side of the bush or hedge on which it clambers.

It looks as if the case might be put thus: Given the fact that light produces some kind of movement, the convenience of the plant shall decide whether it be towards the light or away from it; or in other words, grant the plant the power of knowing where the centre of the earth is, and grant it the power of knowing where the light comes from, then the plant itself can decide what course of growth is most advantageous.*

We may find a kind of analogy for these cases of contradictory action—for they really strike one as contradictory.

The chameleon and the frog are both affected in a peculiar manner by light; they both change colour in accordance with variations in the intensity of the light. Moreover, the change of colour is produced by the same mechanism in the two cases; by a kind of contraction and expansion of certain coloured cells in their skin. But the curious fact is that chameleons† become darker in sunshine, while frogs‡ become pale in sunshine and darker in darkness. No doubt both these changes are in some way serviceable to the frog and the chameleon, and we may suppose that the whole phenomenon is really analogous to the opposite effects of light which occur in plants.

To quit the paths of science for those of another region of "Wonderland," it has been pointed out by Mr. Lewis Carrol that dogs wag their tails when they are pleased, whereas cats do so when angry. Seriously the principle is the same—given that emotion produces disturbance of the tail, it will depend on the surrounding circumstances in which the creatures live as to whether a given emotion shall produce a wagging or a rigid tail.

Let us once more consider what needs will arise in the life of an animal, and then see how the same needs are

* A lecture delivered at the London Institution on March 11 by Francis Darwin, M.B. From *Nature*, March 14, 1878.

* I have spoken as if the existence of positive and negative helio- and geotropism could be simply explained by considering the convenience of the plant. But in details many difficulties arise; for instance, some roots are heliotropic. (Sachs' 'Text Book,' p. 755.)

† Brücke, *Wein. Denkschrift*, 1851; v. Bedriaga, 'Die Entstehung der Farben bei den Eidechsen,' 1874.

‡ Lister, Cutaneous Pigmentary System of the Frog. (*Phil. Trans.*, 1858; v. Wittich, Muller's *Archiv*, 1854.)

supplied by plants. An animal needs to be alert to changes going on in the world around it; it needs delicate sense-organs to perceive the approach of enemies or the whereabouts of its food. In fact it is evident that to prosper in the varying conditions of life an animal must be sensitive to these changes. By sensitiveness one means that an animal must be capable of being affected by changes which, considered as mere physical agents, are insignificant. A fly living in the same room with an active-minded boy will depend upon its safety on its rapidly appreciating the approaching shadow of the boy's hand. Now the changes produced in the arrangement of forces in the universe are not perceptibly affected by this shadow—it is utterly insignificant—yet what a violent effect it has on the fly. It is because the nervous system of the fly possesses the property of magnifying external changes so that apparently slight disturbance causes large results.

The power of being strongly affected by apparently slight changes is a very important character of living matter. The processes which occur within the fly have been likened to the explosion of a pistol, the force used in moving the trigger being utterly insignificant when compared with the result produced. I do not mean that this exploding power is a distinguishing mark of living matter, but it certainly is a well marked feature. Besides the power of magnifying or intensifying external changes, which we have described as the exploding power of irritable tissue, there is another, the power possessed by nerves of transmitting a stimulus wave from one part to another. We will first look for this transmitting power as it exists in plants.

The leaf of the sundew, or drosera, consists of a shallow, slightly saucer-shaped disc covered over with short glands, and fringed all round with projecting tantacles which also terminate in glands. The glands secrete a sticky fluid, which hangs in drops on them, hence the name of sundew, because the leaves seem to be covered with dew in sunshine, when other plants are dry. Insects are caught by the sticky secretion, and are also embraced and held fast by the outer tentacles, which possess the power of moving. When the insect has been killed by being drowned in the sticky secretion, it is digested by the acid juice poured out by the glands and subsequently absorbed.

The external or movable tentacles may be made to bend inwards, either by insects alighting on the centre of the disc of the leaf, or on the sticky glands of the tentacles themselves. In the first case, when an insect is caught on the middle of the leaf, and the external tentacles bend in and surround it, we have a true transmission of stimulus, a message sent, like a message is sent along a nerve. The insect may be struggling to free itself, and will probably succeed in doing so, unless the external tentacles give their help. The external tentacles can be made to bend not only by insects or other objects placed on the centre of the leaf, but also by anything placed on the gland at the end of the tentacle itself. In this case the meaning of the movement is equally obvious. If a gnat or fly lights on one of the external glands, it will probably escape, unless carried to the centre of the leaf, where it will be also held by the small sticky glands. Here also there is a true transmission of stimulus. The message has to be sent from the gland at the top to the place where the tentacle bends; a message is sent from the gland to the bending part of the tentacle, just as a message goes through nerve tissue from our skins to our muscles.

In this case the tentacle always carries the fly it has caught to the actual centre of the leaf. But if a fly has been caught by the disc of the leaf, and not quite in the centre, then the messages are sent in accordance with the position of the fly, and all those tentacles within reach move to the point of irritation with marvellous precision. This transmission of messages is all the more wonderful, because, as far as our powers of observation go, there is no special structure to convey the stimulus. It is true that waves of stimulation do travel with special facility along the fibro-vascular bundles, or what are usually called the veins of the leaf. But in this case, where tentacles converge to a given point in the disc of the leaf, this mode of transmission is impossible, because the veins are few in number, and could not cause so nice an adaptation of movements. Moreover, stimuli can travel across a leaf of drosera after the vascular bundles have been cut through.* So that we have the wonderful fact of a wave of stimulation travelling with great accuracy transversely through a number of cells with absolutely no structure like nerve-fibre to guide the course in which the stimulus-wave shall flow.

One other curious phenomenon may be alluded to as showing the extraordinary power of stimulus-transmission. If a piece of meat is placed on an external tentacle, the gland on which it rests sends forth an acid secretion; and if a piece of meat is placed on the centre of the leaf, the tentacles, as before said, bend in and ultimately touch it; but if the external glands are tested with litmus paper before they reach the meat in the centre, they will be found to be covered with acid secretion, proving that not only had a message been sent to the moving part of the tentacles, but also to the secreting cells in the gland.

One might find a parallel to this in the action of the human salivary glands. The gland nerves may be excited either by the stimulus of food placed in the mouth, or by the voluntary action of the muscles of mastication. Here the saliva is poured out, although there is no food to act on, just as the drosera-gland secretes during the movement of the tentacle before there is anything for its secretion to digest.

Having briefly considered the transmission of stimulus-waves as shown in drosera I will pass on to consider what manifestation may be found of the other general property of nerve tissue, the property which I have called exploding power. It is chiefly manifested in drosera by the extreme sensitiveness of the glands on the external tentacles. It is found not to be necessary to place meat or insects on the glands, but that bits of glass, wood, paper, or anything will excite them. Smaller and smaller atoms were tried and still the glands were found to be sensitive to their presence.† At last a minute piece of a human hair, about one-hundredth of an inch in length, and weighing just over $\frac{1}{80000}$ of a grain, was placed on the gland of a tentacle and it caused unmistakable movement. The case is yet more wonderful than it sounds, because the piece of hair must be partly supported by the thick drop of secretion on the gland, so that it is probably no exaggeration to say that the gland can perceive a weight of one-millionth of a grain. This degree of sensitiveness is truly astonishing, it seems to us more like the sense of smell than that of touch, for to our most delicate tactile organ, the tongue, such atoms are quite imperceptible.

The power which drosera has of perceiving the presence of ammonia is perhaps still more astonishing. A solution of phosphate of ammonia in pure distilled water in the proportion of one part to over two million of water, caused inflection of tentacles.‡ One may form an idea of this result by making a solution of a single grain of the phosphate and thirty gallons of distilled water, and then finding out that it is not pure water. Considering the water-supply which we at present enjoy, we may well be grateful that our senses are duller than those of a sundew.

As examples of simple sensitiveness these facts are sufficiently striking, but the powers of discriminating between different kinds of stimuli are equally curious. The tentacles having proved so extraordinarily sensitive to light bodies resting on them, one would expect that the slightest touch would make them bend. But it is not

* See Batalin, 'Flora,' 1877, who has correctly pointed out the importance of the fibro-vascular bundles as conveying stimulus-waves.

† 'Insectivorous Plants,' p. 32.

‡ 'Insectivorous Plants,' p. 170.

so; a single rapid touch, though it may be violent enough to bend the whole tentacle, does not cause inflection. The meaning of this is clear, for in windy weather the glands must be often touched by waving blades of grass, and it would be a useless labour to the plant if it had to bend and unbend its tentacles every time it was touched. It is not excited except by prolonged pressures or quickly repeated touches. This is also quite intelligible, for when an insect is caught on the sticky secretion of the gland it will give a somewhat prolonged pressure, or a number of kicks to the sensitive gland, unless indeed it flies away after a single struggle, and in that case the tentacle will be also saved from uselessly bending.

In another carnivorous plant, dionæa, the specialization of sensitiveness is exactly the reverse; thick and comparatively heavy bits of hair can be cautiously placed on the sensitive organs without causing any movement, but the delicate blow received from a cotton thread swinging against the hair causes the leaf to close.* Dionæa catches its prey by snapping on it like a rat-trap—there is no sticky secretion to retain the insect as in drosera till the slowly closing tentacles can close on it. Its only chance of catching an insect is to close instantly on the slightest touch. The specialization of sensitiveness in dionæa is therefore just what it requires to perfect its method of capture.

In describing the sensitiveness of drosera and dionæa I wish rather to insist on a wide and general similarity to the action of nerves. There may be said to be an analogy between the specialization of extreme sensitiveness in drosera and dionæa and the nervous tissues of animals, because these properties play the same part in the economy of the plant that is supplied through some kind of nerve machinery in the higher animals. Closer analogies could be pointed out. There are, for instance, the well-known researches of Dr. Burdon Sanderson, in which he compares the electrical disturbances which occur in the leaf of dionæa to those which take place in nerve and muscle. Again Mr. Romanes has, in a recent lecture in this place, compared the peculiar sensitiveness of drosera to repeated touches with the phenomenon known in animal physiology as the summation of stimuli. But I have merely sought to show that we find in drosera a power of conduction of stimuli, an extreme sensitiveness to minute disturbances, and a power of discriminating between different kinds of stimuli which we are accustomed to associate with nervous action. To establish this analogy I believe that the examples already mentioned may suffice.

(*To be continued.*)

Parliamentary and Law Proceedings.

Sweet Spirit of Nitre at a Cooperative Store.

At the Huddersfield County Police Court, John Balmforth, manager of the Equitable Cooperative Store at Marsden, has been fined 10*s.* and the expenses for having on the 8th inst. sold to Mr. Superintendent Sykes four ounces of sweet spirits of nitre which on analysis by Mr. Allen, of Sheffield, analyst to the West Riding, was found to be 43·2 degrees over proof, whereas it should have been 52·4 degrees over proof.

Poisoning by Cyanide of Potassium.

On Wednesday April 10, Mr. W. Carter held an inquiry at the Duke of Clarence Tavern, Penton Street, Newington, as to the death of Mr. Stephen Stammers Austin, 47, who resided in apartments at Lambeth. On Saturday afternoon last, Mr. Austin entered the Queen's Head Tavern, Lock Square. After a short time he picked up a bottle from the corner near the fire place and drank a portion of its contents. He then said to a Mr Hughes, "I have drank some cyanide of potassium." He appeared to be sober and collected. He was afterwards attacked with a fit of trembling, and taking a document from his pocket he asked a man named Ross to hand the paper over to Mr. Cowley, the landlord. Mr. Austin then fell down and died. Mr. Carter read the following document written by the deceased, dated April 8:—"I die from the effects of partaking of cyanide of potassium, prussic acid. I take it through necessity, as I have been suffering from neuralgia of the brain. There is no necessity of making a *post-mortem* examination." The jury returned a verdict of "Temporary insanity."

Dispensing Memoranda.

[80]. Boracic Acid Ointment (Lister's).—The suggestion in the "Month" in regard to this to dissolve one ounce of "boracic acid in a little water" (three ounces of boiling or twenty-five ounces of cold water would be required) "in a test tube," add to five ounces of melted fatty basis "and stir constantly till cold," is impracticable. The formula is quite correct unless specially ordered by Professor Lister to be made with half the quantity of boracic acid. It is applied more like a plaster than an ointment as a dressing to burns, etc. The use of spirit as suggested by one of your correspondents is inadmissible. Let "Quærens" try labour and let him *warm* his powdered boracic acid before adding to it the melted fats. Wm. Martindale.

[92]. T. F. E. will find on referring to the B. P. that there is only one preparation designated "Magnesia;" the other identical in composition but differing physically is described as Magnesia Levis. The former of course would be the correct one to use in dispensing the above prescription, and neither Magnes. Carb., Magnes. Carb. Levis, nor Magnes. Levis could be substituted with propriety. E. Mann, *Halifax*.

[93]. H. G. C. thinks the mixture will answer if the ext. cinch. liq. be first shaken with a little mucil. acaciæ and the water, and the potass. iod. be then added. He has found this plan answer well in mixtures containing tr. cannab. indic. and tinct. tolut.

[94]. A good excipient is a mixture of one part of powdered soap and five parts of powdered liquorice root. Three grains of this will take up one grain of carbolic acid or one minim of creasote, or of any essential oil, without any other addition, making a firm pliable mass, easily rolled. Moule.

[95]. It is quite evident that "Tr. Sap. Virid. Co." (New York prescription), as given by "G." in the "Memoranda" of April 6, is either some proprietary article or, what is more likely, the Tr. Verat. Virid. is the preparation meant. Some men are so careless in writing, and some so ignorant of the Pharmacopœia and its preparations, that many do not know the difference between a compound and a simple tincture. This will account for the very stupid prescriptions so constantly written. The prescription (95), besides the Tinct., contains Hydrarg. Bichlor. and Aq. It is evidently for some skin affection, such as acne, and the Tr. Verat. Virid. is used as a discutient and anodyne preparation externally, as well as in various diseases internally; but with its internal use we have nothing to do at present. Sap-green, the juice (succus) of buckthorn evaporated with lime so as to form a solid, cannot be meant, and I never heard of a tincture of green soap. I therefore think the compounder would be justified in using Tr. Verat. Virid.

The U. S. formula is stronger than that usually made in England. I know of no tincture prepared from any of the sapotaceæ or sapodilla order of plants that could be meant. The seeds of *Achras sapota* are aperient and the bark used as a febrifuge. *Bassiă butyracea* furnishes a kind of oil or butter; *Chrysophyllum* supplies fruit for dessert. *Isonanara gutta* is the gutta percha tree in Singapore; and the kernels of *Lacuma mammosa* abound in hydrocyanic acid, etc.—H. BROWN.

---

[95]. In reply to G., I beg to say that Tr. Sap. Virid. Co. is a solution of green soap in spirit of wine (one of soap in two of spirit), scented with oil of lavender (ʒij in Oj). As green soap is seldom to be procured in this country I use freshly prepared soft soap, B.P. The form as given by G. I have often prepared for some kind of ringworm and scabies. C. J.

Bury St. Edmunds.

---

[96]. A. S. R. asks for the formula of Ol. Hydrarg. et Morph. I may state it is prepared of various strengths after the formulæ of Mr. John Marshall, F.R.C.S., and was prominently brought before the notice of the medical profession in a lecture delivered by Mr. Marshall on the 16th of March, 1872, and reported in the *Lancet* of the 25th of May following.

In the said lecture a full history is given, but, perhaps, A. S. R. may not have easy reference to the above-named source. Mercury is dissolved in nitric acid, and caustic potash or soda added, and the yellow impalpable oxide well dried. It is found that the precipitated oxide readily dissolves in oleic acid at a temperature of 300° F. A 5 per cent. solution is clear and fluid as olive oil, a 10 per cent. is as clear but dark as linseed oil, and a 20 per cent. unctuous, and not unlike resin ointment. To each drachm one grain of the muriate, acetate, or meconate of morphia is added, and constitutes the Ol. Hydrarg. et Morph. It will be observed the 10 per cent. applies to the oxide of mercury, not to the morphia. The oleate is applied instead of the old Ungt. Hydrarg. by means of a brush to inflamed joints, etc., or the stronger preparations are smeared over the affected parts by the finger. Strong preparations require caution.

Northallerton. HENRY BROWN, L.R.C.P., etc.

---

[96]. OLEATE OF MERCURY.—The following formula for oleate of mercury, first introduced by J. Marshall, F.R.S., and manufactured by Messrs. Hopkin and Williams, is from the University College Pharmacopœia. To each drachm of it add one grain of morphia (pure alkaloid) for Ol. Hydrarg. et Morph. (10 per cent.):—

15. *Linimentum Hydrargyri Oleatis* (10 *per cent.*).
Precipitated Peroxide of Mercury . 1 drachm.
Oleic Acid . . . . 10 drachms.

To the oleic acid, kept agitated in a mortar, sprinkle in the peroxide gradually, and triturate the mixture frequently during twenty-four hours until the peroxide is dissolved and a viscid solution is formed.

WM. MARTINDALE.

---

[97]. This is another instance of stupidity in writing a prescription. Sol. Taraxaci is evidently Liquor Taraxaci, a preparation at one time largely used. Some wholesale houses send out a very elegant Liquor Taraxaci.

HENRY BROWN.

---

[98]. Would some reader kindly inform me how to dispense the following prescription?—

℞ Liniment. Opii post Bowes . . ℥iss.
M. Sig. For external use.

EDINBURGH.

---

[99]. TINCT. QUINÆ.—Can you inform me through the medium of the Journal why tinct. quinæ, B.P., after being made and bottled some time, forms a feathery-looking sediment round the bottom and neck of the bottle?

R. S. T.

---

[100]. CREASOTE PILLS.—Can any one inform me as to the best method of dispensing a prescription, of which the following is a copy?—

℞ Creasoti . . . . gtt j.
Panis . . . . q.s.
Mucilag. Acaciæ . . . . . . gtt j.
Ft. pil. mitte xij, silvered.

The bread on coming in contact with the creasote immediately becomes dry and crumbles.

R. S. T.

---

[101]. AQUA MENTHÆ.—When aqua menthæ is ordered in a prescription should aq. menth. pip., or aq. menth. virid. be used?

DUBIUS.

Notes and Queries.

[579]. MIST. FERRI COMP. CONC.—Just make the Griffith's Mixture (Mist. Ferri. Co., B.P.) eight times stronger, omitting the ferrous salt. If made with the "fat gum" the solution is somewhat milky. But an inferior quality gives a reddish-coloured fluid more clear than the above. Probably the addition of spirit caused the increased transparency of one of the samples.

J. B. L. M.

---

[581]. IRISH SLATE.—The question of your correspondent, W. L., in the Journal of March 30, is not replied to in the statements of F. P. and J. F. R. in the Journal of April 6. I have noticed the description in Gray's 'Supplement' referred to, but my answer would be, "Irish Slate!" I should give what is asked for. Having about two cwt. of the article in stock, I shall be happy to send W. L. some if he will apply to

W. T. MARTIN.

16 *and* 17, *Cliffe, Lewes.*

---

[582]. GINGERADE.—Use Essence of Ginger deprived of its resin. Such a preparation by several makers is now before the public. That manufactured by Mr. Hay of Hull, advertised in Journal, No. 405, I have seen. It is very good and has been well recommended.

J. B. L. M.

---

[583]. CELLAR LABELS.—In my experience sized writing paper, coated (after inscription) with solution of orange shellac, has most effectively resisted damp.

J. B. L. MACKAY.

---

[584]. PREPARED SILICA can be obtained from the principal wholesale houses or from the importers, Read and Co., Cope Street, Coventry.

---

[586]. ESSENCE OF GINGER.—Will any one oblige with a recipe for making a strong Essence of Ginger, to be miscible with water without being opaque?

ASSOCIATE.

---

[587]. COD LIVER OIL EMULSION.—May I ask through the medium of the *Pharmaceutical Journal* for any good recipe for Cod Liver Oil Emulsion that will not separate?

Patent Medicines.

Sir,—Permit me to offer a few remarks in reply to the letter of A. G. in the Journal of last week. He admits the truth of what I said in my letter of the 30th March, and that the "Chemists have a grievance in that as well as many other respects, which he says can only be remedied by an Act of Parliament." I quite agree with this, but to the insinuation, that "I with many others think a chemist is to be found in every village," I have only to say that I never for a moment entertained such a thought; nor do I think any chemist in his right senses would.

As to the seventy large villages and hamlets which A. G. says exist in his neighbourhood, I do not doubt but that the eight registered chemists there will be fully competent and able to supply all patent and other medicines without the interference of any unqualified person.

I would not suggest a chemist for every village, as it would neither be sufficiently remunerative, nor necessary, and I would inform A. G. that it is not only the country chemists who are obliged to deal in a "most heterogeneous and sundry kind of goods as well as drugs" to make a living, but many of his town brothers also; a state of things to be deplored, and for which it is difficult to find a remedy. But I believe if we were to get our full and legitimate trade (which at the present time we do not) many would confine themselves purely to dispensing and the sale of drugs. I myself have a strong objection to selling groceries, hardware, and other things foreign to our calling.

The purport of my letter was simply to advocate the sale of patent medicines by qualified and registered persons only, and in doing that I think I am not only considering the rights of the chemists, but the wellbeing and safety of the public.

What I am most grieved at, is the low prices for which patent medicines may be obtained; in fact it is extremely unpleasant to be told by customers that they can save threepence by getting a box of Holloway's pills at so and so's the draper; and it is only a week ago that a lady told me that she had got two 2*s.* 9*d.* bottles of Eno's fruit salt at my shop, but that a friend had got another bottle for her at 2*s.* 4*d.* elsewhere. Now, sir, I ask if this is not interfering with our interests, what is? Surely the chemists might agitate, get an Act passed, or do something to put an end to this sort of things, which if allowed to go on, must certainly lead to very serious results, as far as the pockets of chemists are concerned.

Tento.

Sir,—I have been astonished by the reasoning and conclusions of your correspondent A. G., who, after remarking that in his neighbourhood in one direction there are seventy large villages, besides numerous hamlets, wherein there are only eight registered chemists; and in another direction forty villages with but two registered chemists; goes on to say that because of competition and the difficulty of making a living in those large villages, the registered chemist must needs retire from the field of competition and allow his friends (also registered), who style themselves wholesale druggists, to amend the Pharmacy Act and register the most ambitious man in every village, not only for the sale of patent medicines, but poisons as well, and thereby legislate not for the educated pharmacist, but for some one or other whom he is unfortunate enough to come into collision with in his legitimate calling as a chemist and druggist. Now, I do know this much about the matter, that if our brethren on the register were true to one another, and that if it were not the fact that in all those villages in question the carts of small wholesale druggists are to be seen delivering their goods, including poisons, during several days of every week; and that if they did not compete so eagerly with one another by sending their young men into every one of those places for orders, life would soon become to the chemist more of a pleasure, and we would hear less of those distressing appeals to the

Manchester. Benevolent.

Sir,—I am glad to find that the "patent medicine question" is beginning to be fairly discussed. It is a matter of the greatest importance to the majority of chemists, and I consider it is the duty of all chemists to use their influence to gain by Act of Parliament the sole right of vending patent and all other medicines. If necessary let the cost of licence be increased or even doubled. It may be urged that inconvenience would be caused to the public by their not being able to get pills, castor oil, etc., in country villages. I do not consider this would be the case as in emergency a surgeon would be called in and as a rule simple medicines would be kept at hand, and very few places are without railway communication or carriers once or more a week to the market town. To show the necessity of legislation on this question, I enclose a list of patent and other medicines sold by an advertising "tailor" in Liverpool at prices which would prove a bait that many would greedily swallow. I trust our representatives on the Council of the Pharmaceutical Society will bring this matter under discussion and endeavour to stop this evil and injustice.

Lancaster, April 4, 1878. Treu und Fest.

To the Benevolent.

Sir,—In addition to the sum of £10 16*s.* which you kindly announced in last week's Journal that I had received on behalf of Mrs. Dixon and her family, I have since received the following contributions:—

	£	s.	d.		£	s.	d.
Frederick Barron	3	3	0	P. C.	0	5	0
John Attfield, Ph.D	2	2	0	W. H. Rogers, J. P.	0	5	0
George Dowman	1	1	0	J. S. B.	0	2	6
Thomas Summers	1	1	0	J. D.	0	2	6
W. Patterson	1	1	0	J. Pearce	0	2	6
Thos. Juves	1	0	0	B.	0	2	0
Miss White	1	0	0	L. C. "domestic servant"	0	1	6
William Barron	0	10	6	"Sundries"	0	2	0
G. B.	0	10	0	J. Adams	0	1	0
H. Abraham	0	5	0				
"Charity"	0	5	0				

I desire to express my best thanks to all the kind donors.

Robert Chipperfield.

Southampton, April 9, 1878.

H. G. C.—Messrs. Hopkin and Williams, Cross Street, Hatton Garden.

A.P.S—The paper on Physic Mass will be found on p. 481 of the present volume. We do not think the time has yet arrived for republication of the formula.

W. R. Fowler.—The Act makes it penal to wilfully and unlawfully administer or cause to be administered to horses, cattle or domestic animals "any poisonous or injurious drug or substance," but it does not contain a poison schedule or any definition of what is to be deemed a "poisonous or injurious drug or substance."

G. C.—St. Ignatius' Bean is official in the United States Pharmacopœia. Its physiological action is described as being very similar to that of nux vomica seeds, but more energetic. The dose of the powdered seed, according to the American Dispensatory, is one or two grains.

"*A Swedenborgian.*"—The bearings of the subject are too purely medical to allow of its discussion in this Journal.

A. G. R.—The Paris Society's formula for Syrup of Bromide of Potassium is printed on p. 68 of the present volume.

W. Wing.—The specimen appears to be a variety of lancifolia bark.

H. L.—A formula for an emulsion of cod liver oil and the hypophosphites will be found in vol. v., p. 770 of the present series of this Journal.

H.—The letters F.C.S. can be used only by members of the Chemical Society.

Communications, Letters, etc., have been received from Mr. Howard, Mr. Cathcart, Mr. Wright, Mr. Rayner, Mr. Kitchen, Mr. Barnes, Mr. Blaikie, Mr. Buck, Mr. R. F. Smith Alpha, Nepos, H. G. C., R. S. P., H. M. H., S. W.

THE FAST GROWING VARIETY OF CINCHONA CALLED PUBESCENS.

BY J. E. HOWARD, F.R.S.

I send a few facts to complete (thus far) the history of the above promising sort, to which Dr. de Vrij has very properly called attention in your columns; and respecting which I had much correspondence with the late Mr. McIvor.

It is about ten years since this skilful cultivator raised from seed two sorts of *officinalis*, which for some reason he considered to be hybrid with *C. succirubra.* The two were alike distinguished by strong and vigorous habit of growth, and at a little distance it was difficult to discriminate between them. As they developed, however, it was found that the one with slightly pubescent leaves yielded much more quinine in the bark than the other. I suggested, for distinction's sake, calling this the *var. pubescens*, which has unfortunately since become changed into *C. pubescens*, How., an entirely erroneous designation.

Referring to the bark sent both to Dr. de Vrij and to myself in 1873, Mr. McIvor says, "This bark is taken from a hairy leaved variety of *C. officinalis.* It is a tree of wonderful growth. It produces enormously thick bark, and the tree is not injured by wind. The tree from which I now send you the bark is only five years old. It is twenty-six feet high and has a stem of sixteen inches in circumference at the ground, and the bark now sent you is taken in a strip from the stem to the height of about twelve feet from the ground. This tree grows at least twice as fast as *C. succirubra.* The bark of this variety which I sent to Dr. de Vrij was taken from a tree grown at a high elevation and with a N. W. exposure. The bark now sent you is taken from a tree growing at a low elevation with a N. E. exposure. Dr. de Vrij found the bark of this species to yield 10·67 per cent. of total alkaloids with 4·72 of crystallized sulphate of quinine. If under all conditions this bark is found to yield this amount of alkaloids, and especially quinine, it is certainly the best plant we can grow; being hardy and of rapid growth and perfectly free from canker and other diseases to which the *officinalis* and especially the *calisaya* are liable. I therefore sincerely hope that you will be able to confirm Dr. de Vrij's results, and if this occurs in the two barks taken from different positions of elevation it will establish the value of the species beyond doubt."

The examination which I made quite confirmed and even surpassed the results obtained by Dr. de Vrij, as the notes I have preserved indicate a produce equal to 6·00 sulphate of quinine, 5·00 sulphate of cinchonidine, cinchonine and amorphous alkaloid 1·20 per cent. Even this was exceeded after an additional year's growth. In June 1874, Mr. M. writes, "I take the liberty of again sending you some bark of *C. pubescens.* This sample is of the narrow strips left on the same tree from which I took the bark sent to you in December last. If not giving you too much trouble I would very much like to know what this bark yields, the more so [as some persons] have been trying to impress on the Government here that mossing does not improve the bark on the tree generally and that the renewing bark draws the alkaloids from the natural bark adjoining, *i. e.* that the alkaloids in the natural bark are transferred to the renewing bark. I do not believe this to be the case, but if it is so in any degree the bark now sent you will show exactly to what extent this takes place; as the narrow strips of bark were surrounded on all sides by renewing bark."

The examination of the above "strips" was therefore of special interest in connection with an important problem in vegetable physiology. They gave equal to—

	Per cent
Sulphate of Quinine	6·94
" Cinchonidine	4·48
" Cinchonine	0·20
" Quinidine	0·14
Amorphous alkaloid	1·14
	12·90

Thus disproving the transferrence theory.

It will be noticed that my friend de Vrij has recently obtained more quinine and less cinchonidine than I have done. This is no doubt owing to his having described the results of examination of renewed bark. I have also a small specimen of this, but have not subjected it to examination.

It is obvious that a plantation of this kind is likely to be very profitable. Mr. McIvor wrote me in August, 1875, that 20 acres had been planted in the previous year, and that in the year above named they had planted out 60 acres on the Kartairy estate. The next year occurred his lamented decease, and I am unable to continue my record in consequence.

The great question is, how far is it possible to count upon the propagation of this sort. Mr. McIvor speaks with a varied amount of certainty. In the last letter I had from him he says, "You are quite correct as to the danger of relying on plants raised from seeds of our hybrids; of course to be certain we must propagate from cuttings only, but *pubescens* comes pretty true. Still I would not rely on a plantation formed by seedlings even of this variety."

In 1874, Mr. M. sent me a few seeds, from which I have one plant * remaining which reproduces all the character of vigorous growth and promising aspect of the parent plant. It is already between six and seven feet in length, and the leaves reach the length of 9 or 10 inches by 6 inches in width. The plant may be a hybrid; but if so, as admitted by Mr. McIvor, it has much more the characteristics of *C. officinalis* than of *C. succirubra.* I send for the Museum of the Pharmaceutical Society a section of a tree of this sort sent me by Mr. M., from which those who are conversant with the characteristics of the wood of these different species will easily discern what I have stated to be true. A good botanical specimen in a collection given me by McIvor does not appear to settle the question of hybridity.

It remains that I add a parting word about *Cinchona pubescens.* This very distinct species was named by Vahl, and has been described and figured by Dr. Weddel. Not much is known about the β form, but in its form *Pelletierana* it is the source of the bark from whences aricine was procured, and from whence I have myself many times obtained this much contested alkaloid. Its whole chemical constitution is distinct from other cinchonæ, the cinchona red being superseded by an intensely yellow substance. It is no longer to be met with in commerce, as it is useless except for scientific investigation, and has certainly never been introduced into India. So I hope we have heard the last of *C. pubescens*, Howard, though not of the promising sort of *officinalis* which obtained this erroneous name.

* Another has diverged.

COMPARATIVE ANALYSES OF RHUBARBS.

BY PROFESSOR DRAGENDORFF.*

The following analyses were undertaken by the author in order to compare some varieties of rhubarb with one another. Five samples were examined.

I. *Rheum Moscovicum*, imported in 1860 with the last consignment of "crown" rhubarb, and supplied to the author from the Crown warehouse in Moscow.

II. *Rheum Chinense*, as this kind occurred in commerce in 1877, and was delivered from the Crown warehouse in St. Petersburg.

III. Rhubarb from *Rheum palmatum Tanguticum*. A sample of the drug brought by Przewalski from Kansu, the origin of which was the subject of a communication by Maximowicz.

IV. *Rheum anglicum cultum*, purchased in Moscow and corresponding externally with the Rhapontic rhubarb.

V. *A Rhubarb cultivated in Siberia*, of a kind formerly used there in the hospitals, etc., and supplied to the author through Dr. Duhmberg of Irkutsk.

The author describes the process of analysis adopted in examining the Siberian drug, No. V, giving only the analytical data for the other four, except where any variation was made. The drug was in each case reduced by rubbing upon a fine grater and the powder was passed through a sieve having 169 meshes to the square centimetre. In the experiment similar quantities both of the powder and the solvents were used.

(1). *Moisture*.—Upon drying the loss of moisture was as follows:—

No. I.	0·9954 gram	lost 0·0948	gram =	9·52 per cent.
No. II.	0·9807 „	„ 0·1103	„ =	11·25 „ „
No. III.	0·9883 „	„ 0·1023	„ =	10·35 „ „
No. IV.	0·9800 „	„ 0·1086	„ =	11·09 „ „
No. V.	0·9921 „	„ 0·0863	„ =	8·69 „ „

(2). *Ash*.—The foregoing quantities of powder yield the following quantities of light grey ash:—

No. I.	yielded 0·0823 gram	=	8·27 per cent.
No. II.	„ 0·0620 „	=	6·32 „ „
No. III.	„ 0·2379 „	=	24·07 „ „
A second experiment yielded		=	24·03 „ „
No. IV.	yielded 0·0314 gram	=	3·20 „ „
No. V.	„ 0·1030 „	=	10·38 „ „

(3). *Watery Extract*.—Five grams of the powder were macerated for two days with sufficient water to make the volume equal 100 c.c., the mixture being frequently shaken at first, but allowed to stand during the last few hours. The swollen powder now occupied 35 c.c. divisions in the cylinder (No. I. occupied 34 c.c., No. II. 44 c.c., No. III. 44 c.c., and No. IV. 28 c.c.), and yielded upon filtration through a well covered filter about 55 c.c. of extract, this was used in the experiments described in paragraphs 4 to 9. The marc in the cylinder was then washed out with sufficient water to bring the product up to 100 c.c., so that the smallest quantity possible of the solid residue should come upon the filter. Subsequently the entire undissolved portion was placed upon the filter which was laid in a second filter cut from a close gauze material. After draining, the filter and residue were dried at 30° C. until the powder could be conveniently removed from the gauze and the paper, and the remainder of the moisture was driven off at the above temperature. The further operations upon the portion insolubl in water are described in paragraphs 11 to 16.

(4). *Combustible Substances Soluble in Water*.—Upon evaporating in a platinum dish 5 c.c. of this watery extract (0·25 gram of powder), 0·0679 gram, or 27·16 per cent. of dry residue was obtained. The ash in this amounted to 0·0053, or 2·12 per cent. of the powder. The combustible portion of the drug soluble in water amounted to 25·04 per cent. in No. 5.

No. I. yielded 0·1045 gram less 0·0049 gram of ash = 39·84 per cent.

No. II. yielded 0·1044 gram less 0·0069 gram of ash = 39·00 per cent.

No. III. yielded 0·0694 gram less 0·0032 gram of ash = 26·48 per cent.

No. IV. yielded 0·0830 gram less 0·0060 gram of ash = 30·80 per cent.

No. V. yielded 0·0679 gram less 0·0053 gram of ash = 25·04 per cent.

(5). *Mucilage*.—Twenty c.c. of the watery (= 1 gram of the powder) was mixed with 60 c.c. of 95 per cent. alcohol, and after 48 hours thrown upon a tared filter, the precipitate washed with alcohol, dried at 110° C., and weighed. It amounted in No. 5 to 0·0329 gram, containing 0·0021 gram of ash, the mucilage was therefore 0·0308 gram, or 3·08 per cent.

No. I. yielded 0·0347 gram precipitate, with 0·0012 gram ash = 3·35 per cent.

No. II. yielded 0·0167 gram precipitate, with 0·0009 gram ash = 1·58 per cent.

No. III. yielded 0·0183 gram precipitate, with 0·0012 gram ash = 1·71 per cent.

No. IV. yielded 0·0259 gram precipitate, with 0·0004 gram ash = 2·55 per cent.

No. V. yielded 0·0329 gram precipitate, with 0·0021 gram ash = 3·08 per cent.

(6). *Cathartic Acid*.—The filtrate and alcoholic washings were rapidly distilled in a partial vacuum until 5 c.c. of residue remained. This was mixed with 40 c.c. absolute alcohol. Cathartic acid was precipitated, which was washed with alcohol, dried, weighed, and incinerated.

No. I. yielded 0·0548 gram precipitate, with 0·0023 gram ash = 5·25 per cent.

No. II. yielded 0·0513 gram precipitate, with 0·0025 gram ash = 4·88 per cent.

No. III. yielded 0·0223 gram precipitate, with 0·0020 gram ash = 2·03 per cent.

No. IV. yielded 0·0260 gram precipitate, with 0·0010 gram ash = 2·50 per cent.

No. V. yielded 0·0244 gram precipitate, with 0·0184 gram ash = 2·26 per cent.

(7). *Tannin and Chrysophan*.—To another 20 c.c. of the watery extract solution of acetate of copper was added, great excess being carefully avoided; the brown precipitate was at once collected on a tared filter, rapidly washed with the least possible quantity of water, dried and weighed. Its weight, after the amount of copper oxide present had been deducted represented the tannin and chrysophan present. Chrysophan is the glucoside, soluble in water, from which chrysophanic acid is formed.

No. I. gave 0·0298 gram precipitate, less 0·0385 gram copper oxide = 17·13 per cent.

No. II. gave 0·1627 gram precipitate, less 0·0210 gram copper oxide = 14·17 per cent.

No. III. gave 0·1302 gram precipitate, less 0·0480 gram copper oxide = 8·22 per cent.

No. IV. gave 0·0830 gram precipitate, less 0·0347 gram copper oxide = 4·83 per cent.

No. V. gave 0·0976 gram precipitate, less 0·0192 gram copper oxide = 7·84 per cent.

* From a paper in the *Pharmaceutische Zeitung für Pharmacie*, February, 1878.

(8). *Malic Acid, etc.*—With the filtrate of No. 7 neutral lead acetate gave a precipitate consisting principally of malic acid.

No. 1 precipitate weighed 0·0007 gram, about 0·0004 gram of which was malic acid, or 0·04 per cent.

No. 2 precipitate weighed 0·0204 gram, containing 0·0095 gram lead oxide, or 1·09 per cent. of acid.

No. 3 gave only a slight turbidity.

No. 4 precipitate weighed 0·0072 gram, containing 0·0055 gram lead oxide, or 0·17 per cent. of acid.

No. 5 precipitate weighed 0·0229 gram, containing 0·0105 lead oxide, or 1·24 per cent. of acid (malic acid with a little phosphoric acid).

(9). *Sugar.*—The filtrate from No. 8 still contained sugar. It was therefore freed from arabin and cathartic acid with basic lead acetate, excess of lead removed with sulphuretted hydrogen, filtered, the filtrate distilled in a vacuum to a few c.c., the residue made up to 30 c.c. and tested with Fehling's solution.

No. 1	contained equal to	5·55	per cent. glucose.
No. 2	,,	,, 4·27	,, ,,
No. 3	,,	,, 3·94	,, ,,
No. 4	,,	,, 4·40	,, ,,
No. 5	,,	,, 3·66	,, ,,

(10). *Arabic Acid (?) and Undescribed Substance Soluble in Absolute Alcohol.*—Of the 25·04 per cent. of combustible dry substance from the watery extract of No. 5, 18·80 per cent. has been accounted for in pars. 5 to 9. The remaining 6·96 per cent. consisted partly of a modification of arabic acid (?) not precipitated by alcohol, but after treatment with absolute alcohol becoming insoluble, and partially of a substance readily soluble in absolute alcohol; probably a carbohydrate, but not further described.

In No. 1 the total of the substances accounted for in pars 5 to 9 out of the 39·84 per cent. of combustible dry substance was 31·32, leaving 8·52 per cent. of arabic acid (?), etc. In this case the filtrate of par. 6 was evaporated; the residue treated with ether gave only traces of fat, absolute alcohol dissolved 0·2570 gram; 25·76 per cent. (The total of the sugar, chrysophan and tannic acid in pars. 7 and 9 was 29·68 per cent.: difference 3·08 per cent.). Water dissolved the entire remainder of the residue, and gave upon evaporation 0·0687 gram residue with 0·0105 gram ash = 5·82 per cent., indicating here 2·70 per cent. of the substance freely soluble in absolute alcohol.

In No. 2 the results obtained by similarly treating the filtrate of par. 6 were arabic acid (?), 6·23 per cent.; substance freely soluble in absolute alcohol, 6·47 per cent.

No. 3. Arabic acid (?), 2·83 per cent.; substance soluble in absolute alcohol, 7·41 per cent.

No. 4. Arabic acid (?), 8·38 per cent.; substance soluble in absolute alcohol, 8·21 per cent.

(11). *Chrysophanic Acid, Emodin, Erythroretin, Phæoretin, Resin, etc.*—After deducting the moisture, ash, and substance soluble in water there remained of No. 1, 42·37; No. 2, 43·43; No. 3, 39·12; No. 4, 55·89, and No. 5, 55·89 per cent. of combustible substances insoluble in water. The marc from the watery extract was left during six days in contact with absolute alcohol, the tincture filtered through the filter mentioned in par. 3, and the residue washed with alcohol. The filtrate and washings were evaporated in a tared glass dish, and yielded 0·3652 gram, or equal to 7·30 per cent. of residue, containing, besides free and combined chrysophanic acid, emodin, and phæoretin, a considerable quantity of a crystalline dark brown resinous substance, which was also soluble in ether, but difficultly soluble in dilute soda solution. As a subsequent experiment (par. 16) showed that the amount of chrysophanic acid in this sample was equal to 1·01 per cent., there remained for emodin and phæoretin, which was present in only very small quantity, together with the brown resin equal to 6·29 per cent.

The residue from No. 1 gave up to alcohol 0·1110 gram, or after deducting 0·0047 gram of ash equal to 2·13 per cent. of erythroretin, phæoretin, emodin and resin, but no brown crystalline resin; 0·0521 gram was soluble also in ether.

The residue from No. 2 gave up to alcohol equal to 1·15 per cent., containing no crystalline resin or free chrysophanic acid.

The residue from No. 3 gave up to alcohol equal to 3·67 per cent., containing no crystalline resin or free chrysophanic acid; 0·1050 gram of this was also soluble in ether.

The residue from No. 4 gave up to alcohol equal to 5·89 per cent., in which brown crystalline resin was present; 0·0543 gram of this was soluble in ether.

(12). *Metarabic Acid.*—The residue insoluble in alcohol was again dried at from 30° to 40°, powdered, and macerated with frequent stirring in sufficient 1 per cent. soda solution to measure 100 c.c. Of this 50 c.c. (=2·5 gram of the root) were filtered (through the filter mentioned in pars. 3 and 11), neutralized with acetic acid, and mixed with 100 c.c. of 95 per cent. alcohol. After standing 24 hours the precipitate was collected on a filter, dried, and the weight, after deducting ash, represented metarabic acid.

No. 1 gave 0·0869 gram precipitate, with 0·0014 gram ash = 3·82 per cent.

No. 2 gave 0·1438 gram precipitate, with 0·0013 gram ash = 5·70 per cent.

No. 3 gave 0·0656 gram precipitate, with 0·0018 gram ash = 2·57 per cent.

No. 4 gave 0·0826 gram precipitate, with 0·0020 gram ash = 3·22 per cent.

No. 5 gave 0·2118 gram precipitate, with 0·0040 gram ash = 8·47 per cent.

(13). *Starch.*—The remaining 50 c.c. of the mixture was diluted with water to 150 c.c., boiled in a flask, cooled to 50°, a few centigrams of very active diastase added and digested for 24 hours at 40° C. After replacing the evaporated water, 50 c.c. (=1·64 gram of the root) was filtered, and boiled with 8 c.c. of dilute sulphuric acid (1 in 8). After cooling it was tested with Fehling's solution (10 c.c.=0·044 starch).

No. 1	contained equal to	8·40	per cent. of starch.
No. 2	,, ,,	6·20	,, ,,
No. 3	,, ,,	6·32	,, ,,
No. 4	,, ,,	16·50	,, ,,
No. 5	,, ,,	11·95	,, ,,

(14). *Pararabin and Calcium Oxalate.*—The residue after the saccharification of the starch was mixed with sufficient 1 per cent. hydrochloric acid to make 100 c.c. This was macerated for 24 hours, and then rapidly boiled. After making up the evaporated water 50 c.c. was filtered, saturated with ammonia and 150 c.c. of 95 per cent. alcohol added, which precipitated a mixture of a pararabin-like substance and calcium oxalate. This was collected on a filter, washed with alcohol, dried and weighed, and afterwards incinerated.

No. 1 gave 0·2143 gram of precipitate, yielding 0·910 gram $CaCO_3$ = 3·28 per cent. oxalic acid and 3·91 per cent. pararabin.

No. 2 gave 2,179 gram of precipitate, yielding 0·1277 gram $CaCO_3$ = 4·59 per cent. oxalic acid and 2·18 per cent. pararabin.

No. 3 gave 0·2374 gram. of precipitate, yielding 0·1163 gram $CaCO_3$ = 4·19 per cent. oxalic acid and 3·54 per cent. pararabin.

No. 4 gave 0·0886 gram of precipitate, yielding 0·0130 gram $CaCO_3$ = 1·12 per cent. oxalic acid and 1·95 per cent. pararabin.

No. 5 gave 0·1520 gram. of precipitate, yielding 0·0597 gram $CaCO_3$ = 2·15 per cent. oxalic acid and 3·02 per cent. pararabin.

(15). *Cellulose.*—The residue from the powder still remaining was mixed with sufficient concentrated nitric acid to make the mixture correspond with an acid of 1·16 sp. gr., and potassium chlorate added. After macerating several days it was diluted with water, washed, exhausted with dilute ammonia solution, and finally with alcohol. The cellulose was then dried and weighed.

No. 1 yielded	0·3274 gram	=7·45	per cent.
No. 2 ,,	0·3822 ,,	=7·64	,,
No. 3 ,,	0·2456 ,,	=4·91	,,
No. 4 ,,	0·2143 ,,	=4·29	,,
No. 5 ,,	0·4304 ,,	=8·61	,,

(16). *Chrysophanic Acid and Fat.*—Of the substances insoluble in water (see par. 11) there have been accounted for by experiments 11 to 15, No. 1, 28·99, No. 2, 27·46, No. 3, 25·20, No. 4, 32·97, and No. 5 40·49 per cent. This left for further examination in No. 1, 13·38, No. 2, 15·97, No. 3, 13·92, No. 4, 21·94, and No. 5, 15·40 per cent. 1·0133 gram of powdered root (No. 5) was therefore macerated during eight days with 12·5 of petroleum spirit having a low boiling point, afterwards filtered, the undissolved portion washed with petroleum spirit and the liquid evaporated. It left a yellow crystalline residue of chrysophanic acid with a little fat.

No. 1, 1·0446 gram left 0·0005 residue, almost entirely fat = 0·05 per cent.

No. 2, 0·9976 gram left 0·0015 residue, almost entirely fat = 0·15 per cent.

No. 3, 1·0083 gram left 0·0032 residue, fat with a little chrysophanic acid = 0·32 per cent.

No. 4, 1·0041 gram. left 0·0017 gram residue, fat with a clearly recognizable quantity of chrysophanic acid.

No. 5, 1·0133 gram left 0·0103 gram residue, chrysophanic acid with a little fat = 1·01 per cent.

(17). *Colourless Crystalline Resin Soluble in Ether.*—The residue from experiment 16 was treated with absolute ether.

No. 1 gave up to ether 0·0118 gram, of which 0·0015 gram was insoluble in alcohol, and consisted of almost colourless crystalline resin = 0·15 per cent. The portion soluble in alcohol was taken to be erythroretin, phæoretin, and emodin.

No. 2 gave 0·0070 gram, the greater part insoluble in alcohol = 0·70 per cent.

No. 3 gave 0·0167 gram, of which 0·0049 gram = 0·49 per cent. was insoluble in absolute alcohol, leaving 1·18 per cent. of erythroretin, etc.

No. 4 gave 0·0236 gram, the greater part insoluble in alcohol = 2·32 per cent.

No. 5 gave 0·0279 gram, consisting of emodin, erythroretin, resin, and traces of combined chrysophanic acid; the greater part was undissolved by alcohol and left as an almost colourless crystalline resinous mass = 2·75 per cent.

(18). The portion of No. 5 insoluble in ether was macerated with absolute alcohol during six days and lost 0·2094 gram. = 20·75 per cent. As the total substance soluble in alcohol accounted for in experiments 7, 9, 11 and 16 amounted to 18·80 per cent., the difference 1·95 per cent. was reckoned as the substance easily soluble in alcohol, obtained from the watery extract (see experiment 10).

No. 1 gave up to absolute alcohol equal to 26·84 per cent. Experiments 7, 9, 11 and 16 had yielded a total of 23·67. Difference 3·16 per cent.

No. 2 gave to absolute alcohol equal to 26·65 per cent. Experiments 7, 9, 10, 11 and 16 had given a total of 26·08 per cent. soluble in alcohol.

No. 3 gave to absolute alcohol equal to 22·15 per cent. The earlier experiments gave a total of 22·06 per cent. soluble in alcohol.

No. 4 gave to absolute alcohol equal to 26.17 per cent. The earlier experiments gave a total of 23·33 per cent. soluble in alcohol.

The residue from experiment 18 was extracted with water and yielded quantities of mucilage, arabic acid, cathartic acid, and salts, corresponding closely with the previous experiments.

(20). *Albuminoid Substances.*—The mean of the nitrogen determinations indicated the following proportions of albumenoid substances: No. 1, 4·37 per cent ; No. 2, 4·39 per cent. ; No. 3, 4·33 per cent. ; No. 4, 3·17 per cent. ; No. 5, 3·92 per cent. The small quantity of nitrogen present in the cathartic acid was not taken into consideration.

(21). *Insoluble Residue.*—The portion remaining undissolved the author considered to be a mixture of pectose, paracellulose, vasculose, lignin, etc. It amounted in the different specimens to: No. 1, 8·81 per cent. ; No. 2, 10·90 per cent. ; No. 3, 8·68 per cent. ; No. 4, 16·10 per cent. ; No. 5, 10·72 per cent.

The foregoing results are brought together for comparison in the table printed at the end of the article on the following page.

Before comparing the results obtained with each other to assist in forming a judgment as to the relative value of the rhubarbs examined, the author briefly discusses the question as to which are the active constituents of rhubarb.

The active constituent upon which the purgative properties of rhubarb depend the author considers to be cathartic acid, a glycosidal nitrogenous substance, possessing the closest resemblance to the active substance occurring in senna leaves and black alder bark.

The tonic action of the rhubarb probably finds its principal explanation in the tannic acid present. But the high value rhubarb has in practice is in the third place dependent upon the existence of substances which, like chrysophan, by an easily initiated decomposition yield chrysophanic acid, or, like emodin, erythroretin, phæoretin, etc., standing so near to the latter that their similarity in action might be presumed. But since through the study of araroba, etc., attention has been turned to the strongly antiseptic property of chrysophanic acid, and its power to suppress abnormal decomposition processes in the body, probably it would not be a mistake to attribute the frequently surprising action of rhubarb in intestinal catarrh, for the greater part, to the action of these last mentioned substances.

In respect to the amount of cathartic acid, as well as of tannin and chrysophan, the Moscow "Crown rhubarb, No. 1," stands highest among the rhubarbs analysed. If it be considered that the sample examined was already upwards of seventeen years old, and that the easily decomposed cathartic acid would probably during that time have become somewhat diminished, it appears to be subject for regret that the former source of this rhubarb cannot be reopened.

Next to the "Crown rhubarb" in respect to the peculiar constituents, come the best varieties of *Rheum chinense* (No. 2) as at present occurring in commerce, and which so far may be considered a useful substitute for it.

At a considerably wider interval from it stands the *Rheum palmatum* of Przewalsky (No. 3). In the face of the fact that the better sorts of rhubarb show by their structure that they are derived from the stem, whilst the root of *Rheum palmatum* is used, it is not probable that Przewalsky's rhubarb could be identified with them, and this opinion is also supported by the chemical analysis. The rhubarb from *R. palmatum*, which was remarkable also for the large amount of ash it yielded, contained only about 40 per cent. of the amount of cathartic acid present in the Crown rhubarb and about 48 per cent. of the chrysophan and tannin.

In respect to cathartic acid Przewalsky's rhubarb had no advantage over the cultivated English and Siberian rhubarbs (Nos. 4 and 5), but the English was considerably poorer in chrysophan and tannin. The English and Siberian, probably both derived from *R. Rhaponticum*, contained especially a much higher proportion of starch than the other three, and a smaller proportion of cellulose than the crown and the Chinese, but instead a larger proportion of the brown and the white crystalline resins. Finally, the English and Siberian samples were characterized by containing free chrysophanic acid, dissolved out by treating it with petroleum spirit, but which was absent from the other three samples. An admixture of the powder of a Rhapontic rhubarb with that of a better class Chinese rhubarb could therefore be easily detected by exhausting with cold petroleum spirit. Good rhubarb after standing several days would give a colourless extract, whilst one sophisticated with a Rhapontic rhubarb would yield an intensely yellow extract.

CINCHONA CULTIVATION IN CEYLON.

BY J. LAKER MACMILLAN.

Pharmacist at the Victoria Hospital (late Superintendent Ouvah Coffee Company's Service, Ceylon).

Cinchona cultivation in Ceylon is yet in its infancy, but in that transition phase verging from the experimental to the practical.

Statisticians have found it rather difficult to get other than a rough estimate of the area under cultivation, because of the mode adopted of interspersing the cinchona plants amongst those of tea and coffee.

This rough approximate was in 1877 computed at 4000 acres, and I have reason to believe that out of some 3500 acres of land, sold in the vicinity of Newara Eliya, 2000 will by this time have been planted out.

Several millions of plants exist in nurseries ready for planting.

The demand for plants from the director of the Pendeniyá and Hakgallá gardens, and from private sources, is annually computed by the million, and greater than can be met.

The total number of trees planted out must now be close on 7,000,000.

The entire cultivation is carried on by private companies and private proprietors; government so far having only given its attention to the propagation, nursing, and classification of the plants.

Succirubra is the variety in favour, the variety in demand, the variety that pays, and the variety that thrives, it requiring little attention in propagation, and costing next to nothing to rear. It may be found growing luxuriantly everywhere, in the mountain provinces, on fertile estates, and on the poorest patená soils, around government rest houses and remote police stations, in the various Kacheri grounds and gardens of government residences; from the ancient kingdom of Kandy to the confines of the principality of Ouvah. So familiar indeed has it become to the eye of both colonist and native, that it is looked upon as indigenous; the latter, having now the fullest confidence in it as a remedy and not hesitating to help himself to a strip of bark from the nearest tree when occasion necessitates it.

This variety seems to thrive best at an elevation of from 3000 to 5000 feet.

Mr. Wood's remarks in his interesting paper read before the society on the 6th Feb., in regard to the varieties calisaya and officinalis, hold good for Ceylon, that is, success has not hitherto attended their development. Every attention, however, is still being given to their culture by experienced planters, and I doubt not but by the end of the present year definite information will be given as to probable future results.

Ceylon planters have not followed the late Mr. McIvor's instructions as to propagation by seed; that is steeping, cleansing, straining, mixing with dry sand and charcoal, etc. Boxes of an average depth of twelve inches are simply filled with virgin jungle soil and the seeds carefully strewn on the surface, when, with due regard to temperature and moisture, they germinate within twenty days.

The embryo plants are picked from the germinating box and carefully placed in baskets containing a mixture of virgin jungle soil and sand, or placed in carefully prepared beds of the same mixture within a tent of coir matting. At this state of their existence careful nursing is essential, when their development is, comparatively speaking, rapid. When they have attained the height of from twelve to fifteen inches they may be planted out.

Propagation by layering, or by cuttings has not been attended with success in the few instances which have came under my own observation, nor do I believe that such methods are now followed.

Mossing, as recommended by the late Mr. McIvor, after the first harvest, has been tried, but not adopted in Ceylon, for the reason that moss cannot be obtained unless at a considerable expense. There is no doubt however, but that such is the most rational method yet put forward, and the method that must ultimately be adopted, providing that moss, or a substitute for such, can be obtained in sufficient quantity and at a reasonable cost.

It is estimated that by this process of stripping and mossing a yield of 14 to 17 per. cent. of quinine would be the probable limit from good dry bark of the calisaya varieties, and from succirubra bark a proportionate percentage.

This probable limit may look alarmingly large, but if I mistake not, Dr. de Vrij corroborates the statements of the Indian quiniologists on this point, viz., that the renewed bark is progressively richer in alkaloids than the virgin bark; moreover, under the mossing system it is believed that a cinchona tree will go on yielding crop after corp of bark, increasing in richness, for the space of fifty years, that is, providing the operation of stripping and mossing is carefully performed and the condition of the soil attended to. At any rate past experience does not furnish a limit, each succeeding crop predicting a next and a next of greater value. There is reason to anticipate then the large yield of quinine estimated, however alarming the figures may look.

Crops of marketable bark may be collected in the fifth year after planting, but Mr. McIvor has wisely remarked that such bark, "costs more to collect and more for freight," because it is light, and "that the renewed bark produced under the moss becomes to the cultivator fully eight times the value of natural red bark."

A bark realizing from 1*s*. 3*d*. to 1*s*. 6*d*. per lb. costs 1*s*. per pound to place it in the market, including all charges. The profit on this bark is 3*d*. and 6*d*. per lb.; on a bark realizing 5*s*. the profit is 4*s*. per lb.* The red bark collected on the Nediwuthum government plantations realised the following prices in 1875: first crop, eight year old trees, 1*s*. 6*d*. per lb., first renewed bark produced under moss 2*s*. 3*d*. per lb., second ditto 4*s*. 3*d*. to 4*s*. 5*d*. per lb. One thousand trees treated by this method of mossing yielded 8727 lb. of dry bark, that is equal to 8·72 lb. per tree.

In face of this argument, however, in favour of mossing I may give the following facts, which can be corroborated. A three and half acre lot of succirubra, on Sherwood Estate, Hapootela, which I from time to time, for a number of years, had an opportunity of carefully observing, yielded in its eleventh year, an average of nearly 14·5 lb. per tree, a small parcel of which in its ninth year yielded as much as 3*s*. 6*d*. per lb. At the latter age, the superintendent, Mr. Andrews, requested me to collect an average sample of the trunk bark for assay. Strips from twenty trees were taken, dried, powdered, and thoroughly incorporated; this powder yielding me 9·2 per cent. of mixed alkaloids, which, on treatment with ether, gave 2·14 per cent. of soluble alkaloid, representing 0·423 per cent. of quinine.

I recommended that a year or more should be allowed it to mature, which recommendation was acted upon, the result being, as aforementioned, a yield of 14·5 lb of bark per tree. In all, from 406 trees ($3\frac{1}{2}$ acres) 53 cwt., or 1700 lb. per acre. I have not up to the present time learned what this lot realized.

Subsequently I made an analysis of the soil on which the above was grown, which may be worth placing on record:—

Organic Matter	10·29
Phosphoric Acid	·27
Carbonate of Lime	1·28
Sulphate of Lime	·27
Magnesia	·72
Potash	·30
Soda	·11
Oxide of Iron	3·15
Alumina	11·13
Insoluble Silica	72·48—100

This is the mean of the results obtained from the examination of one picked sample and a homogeneous mixture of ten samples taken indiscriminately.

Ceylon planters have much to learn yet in regard to collecting the bark, as well as to curing and sorting it for shipment. Hitherto trunk and branch barks have been simply dried in the sun, and bundled indiscriminately together, rendering it liable to considerable damage in transport. In some instances I have seen it crammed into sacks, whereas, were it piled, classed, and done up into neat bundles, not only would it present a better appearance in the market, and command a better price, but nearly half the amount paid for freight would be saved.

It would be unfair at present to comment on the rough methods used for collecting the bark. Having got over the difficulties of cultivation, I feel confident that planters will now turn their attention to the operations of harvesting, collecting, curing, and classing of the bark, and above all to the conservation of the trees themselves. The method of coppicing or cutting down the trees has many advocates (all easy methods will find advocates); the general feeling, however, is that it is a system of deliberate waste. I myself venture to assert that the loss incurred by the cultivator, though unfelt, is incalculable.

The exports of bark from Ceylon to this country have of late been considerable, and the prices obtained fair. I therefore venture to believe that in a few years this "el dorada" of the ancients will prove a formidable rival to either and all of the continental presidencies in the production of this material alone.

No attempt has as yet been made towards the production of either quinine or mixed alkaloids, there being no active demand for a cheap febrifuge, or even for quinine sulphate itself. The day is, however, not far distant when Ceylon must prove an important factor among the sources of supply of this drug (mixed alkaloids) for the thousands of fever stricken people on the vast neighbouring continent.

* '*Ceylon Times*' Summary.

The Pharmaceutical Journal.

SATURDAY, APRIL 20, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE CINCHONA FEBRIFUGE.

THE letters from Dr. BIDIE and Mr. CORNISH, which are published in the present number of the Journal, will serve to throw additional light upon the subject of febrifuge alkaloid manufacture in India. It was naturally to be supposed that the remarkably indiscreet way in which Mr. WOOD dealt with this subject in the paper he read at the Evening Meeting of the Pharmaceutical Society, and still more in the remarks he made in the course of the subsequent discussion, would not remain without reply from those who were so recklessly impeached by him and by Dr. DE VRIJ. Accordingly, we find in Dr. BIDIE'S letter a statement of the circumstances under which the "cinchona febrifuge" was subjected to trial in Madras, put forward to show that on the part of Surgeon-General SMITH the trial of this article was conducted just in the same manner as that of any other new drug. The report which appeared in this Journal was simply an epitome of the results arrived at by various medical officers, who had given the proposed remedy careful and patient trial. The Surgeon-General had nothing to gain either by praising or by condemning the preparation, and there does not seem to have been the slightest justification for the insinuation made by Mr. WOOD that the unfavourable character of Dr. SMITH'S report was merely a consequence of the disposition of "the Madras people" to find all the fault they could with the cinchona febrifuge made in Bengal. At the time of this singular view of the influence of human nature upon official action being put forward we were indisposed to accept it, but thought its refutation would come more effectually from "the Madras people" themselves.

As regards the comments of Dr. DE VRIJ, we think Dr. BIDIE is quite justified in objecting to them, and to the assumption they involve that the "cinchona febrifuge" really consists of alkaloid to such an extent that its power of neutralizing acids and its capability of being dissolved can be measured by a theoretical standard. In face of the positive statements that the preparation did not dissolve as cinchona alkaloids would do, and the *primâ facie* probability of such a preparation containing extraneous substances that would affect the solubility, there does not seem to be any sufficient ground for the unqualified declaration that the objection as to sparing solubility was not true. Dr. BIDIE reiterates the statement that three drachms of dilute hydrochloric acid of the Pharmacopœia failed to dissolve completely one drachm of the febrifuge sent to Madras for trial, and he adds that no judgment can be formed as to whether that sample was of average character or not, since repeated applications for further supplies have never been responded to.

Mr. CORNISH, the Sanitary Commissioner for Madras, is even more emphatic and circumstantial in his condemnation of the statements made by Mr. Wood, for leaving aside any question as to good taste he does not hesitate to describe those statements as being garbled and incorrect. In support of this view Mr. CORNISH has sent to us a report made by himself to the Madras Government, in which we find many passages that we should have been glad to place before our readers on an earlier occasion had we had an opportunity of doing so. But unfortunately there seems to be some reluctance to furnish copies of these reports at the time they are issued; in our own case, at least, we have failed hitherto to obtain them, and we were enabled to publish the report of Surgeon-General SMITH only in consequence of it having been copied into an Indian newspaper which was forwarded to us.

As Mr. CORNISH was appointed by the Madras Government to report upon the whole subject of alkaloid manufacture in Madras, his account of the matter may be accepted as being based on due familiarity with the facts, and one of the most important points to which he refers is the relative cost of the "cinchona febrifuge" and of the pure sulphates of the alkaloids obtainable in the market. In regard to this point he says that on comparing the out-turn of alkaloids "with the prices at present charged for sulphates of conchonidine and cinchonine, the disadvantage of local manufacture will be still more apparent. Mr. HOWARD'S recent price list quotes sulphate of cinchonidine at 40*s*. per pound, and, at this rate, assuming the drug to cost 50*s*. per pound, landed in Madras, 1233 lbs. might have been bought for the sum which we calculate Government has expended in producing 445½ lbs. of mixed alkaloids. Or, if we look to the price of the cheaper salt, sulphate of cinchonine, quoted at 24*s*. per pound, and assume its value, landed in Madras, at 30*s*., we see that Government might have purchased 2055 lbs. of this preparation for the same sum that 445½ lbs. of mixed amorphous alkaloids has cost."

Another very important point is the waste of alkaloid attending the manufacture of "cinchona febrifuge." According to Mr. BROUGHTON'S results in Madras this loss amounted to as much as 35 per cent. of the alkaloid present in the bark operated upon. This is of course a point of considerable influence in regard to any calculated cost of production based upon the results of analyses and upon the assumption that there is no manufacturing loss. When Mr. Wood's operations are examined in regard to this point, it appears from the official reports that he only obtains something less than two per cent. of "cinchona febrifuge" from bark which he declares to contain on the average from 4 to 5 per cent. of total alkaloids.

Perhaps this relation between the quantity of bark supplied to Mr. Wood for his operations and the quantity of "cinchona febrifuge" obtained from it may be capable of explanation in some way, for with our knowledge of Mr. Wood's ability and skill as an operative chemist, we can scarcely imagine him to be content with results which were attended with such extravagant losses.

However this may be and whatever chance there may be of avoiding such loss in the future it is clear that the result of the "cinchona febrifuge" manufacture has been much less advantageous than the sale of the bark would have been, and to illustrate this Mr. Cornish points out that if the bark used in the manufacture of the Bengal product had been sold in the market it would have realized from £30,000 to £40,000 that might have been spent in purchasing febrifuge preparations of a definite character, whereas the value put upon the "cinchona febrifuge" obtained from that quantity of bark was, according to Mr. Wood's own valuation, only £9000 or £10,000.

But in addition to these questionable aspects of the "Indian home made quinine" business there is very much reason to doubt the soundness of the estimates put forward as to the cost of growing the bark from which it is proposed to make "cinchona febrifuge." The sum of sixpence per pound appears to leave so many things unprovided for that it is merely a fancy amount, having no kind of significance in a commer- point of view, but whatever credit may be assigned to the estimate of cost it does not in any degree reduce the certainty that more can be made of Indian grown bark in the English market than can be made by the attempt to extract from it the alkaloids it contains under all the disadvantages with which chemical manufacture has to be conducted in India.

THE WEIGHTS AND MEASURES BILL.

This Bill has now undergone the ordeal of consideration by a Select Committee of the House, from which it has come in a somewhat modified form. The alterations are not very extensive, but one of them will require the serious attention of chemists and druggists. On a former occasion (see p. 709) it was stated that clause 20 of the Bill, apparently in deference to the wish of the Council of the Pharmaceutical Society, made it permissive to use the "apothecaries' weight" when selling drugs by retail; but it was also pointed out that no provision was made for a scruple or drachm standard, although to be in possession of a weight not of the denomination of some Board of Trade standard was to render a person liable to a fine of five pounds. The Select Committee has removed the inconsistency by expunging the permission to use apothecaries' weight, and in doing so has so far decided that henceforth to sell a drug by the apothecaries' drachm or scruple shall be deemed an offence.

The Bill is now set down for consideration in Committee of the whole House on the 9th of May, and before that time the Parliamentary Committee of the Pharmaceutical Society will no doubt decide whether there is a promise of sufficient gain through the proposed simplification to outweigh the obvious inconveniences that would attend it, or whether an attempt shall be made to restore the permissive sentence. It may be remarked, however, that should the Bill pass in its present form not only will it be illegal to use or even to be in possession of an apothecaries' drachm or scruple weight, but it will be an offence to print any return, price list, or price current in which such weights are quoted, the offence being punishable by a fine not exceeding ten shillings for every copy of such price list or price current published.

With respect to metric weights and measures it will be remembered that as the Bill originally stood it was permissive to keep and use them for scientific purposes, but not for the purposes of trade. The Select Committee has shown a slight increase of favour towards the metric system, by introducing a clause that would allow the Board of Trade, should it think fit, to verify by the standards in its possession such metric weights and measures as might be submitted, provided that the Board be satisfied that such weights and measures "are intended for the purpose of science or of manufacture, or for any lawful purpose not being for the purpose of trade within the meaning of this Act."

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association will be held at 17, Bloomsbury Square, on Thursday evening, April 25, when a paper will be read by Mr. Graham on "Explosives."

The Medical Act Amendment Bill was read a second time on Tuesday evening; the amendments are to be brought forward in Committee, and we shall take the earliest opportunity of publishing any of them which have an interest for our readers.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

At a Meeting of the Board of Examiners for England and Wales, held in London, on Tuesday, April 16, 1878, the report of the College of Preceptors on the examination held on April 1, was received.

Three hundred and twenty-four candidates had presented themselves for examination, of whom *one hundred and forty-three* had failed. The following *one hundred and eighty-one* passed, and the Registrar was authorized to place their names upon the register of Apprentices or Students:—

(Arranged Alphabetically.)

Alderton, James ....Leamington.

The questions for Examination were as follows:—

FIRST OR PRELIMINARY EXAMINATION.

April 1, 1878.

(*Time allowed: Three hours for the three subjects*).

I. LATIN.

1. Translate into English the following passages:—

Cæsar suos a prœlio continebat, ac satis habebat in præsentiâ, hostem rapinis, pabulationibus, populationibusque prohibere. Ita dies circiter quindecim iter fecerunt, uti inter novissimum hostium agmen et nostrum primum non amplius quinis aut senis milibus passuum interesset.

Nam etsi sine ullo periculo legionis delectæ cum equitatu prœlium fore videbat, tamen committendum non putabat, ut, pulsis hostibus, dici posset eos ab se per fidem in colloquio circumventos.

2. Decline throughout *hostem, agmen, eos*; and together *legionis delectæ*.

3. Give the present, perfect, infinitive, and supine (where found) of *habebat, prohibere, fecerunt, interesset, dici, posset*.

4. Parse fully—"*Cæsar suos a prœlio continebat.*"

5. Translate into Latin:—*He hastens to set out from the city. On the next day they move the camp from that place. Cæsar makes an end of speaking.*

II. ARITHMETIC.

(The working of these examples, as well as the answers, must be written out in full.)

6. Find the quotient of 9313702853 by 1987, and the product of 46481 and 936, and express the difference in words.

7. Define the terms *gramme* and *litre*, and give as nearly as you can their English equivalents. How many pints are there in 6 décalitres?

8. Simplify $\dfrac{(1\frac{1}{2}+\frac{2}{3}+\frac{3}{4})\times(\frac{4}{15}-\frac{3}{20})}{2\times21\frac{7}{9}}$.

9. Multiply ·0235 by 8·08; and find the value of 3·275 of £10.

10. Find the difference between the simple and compound interest on £41 13*s*. 4*d*. for 2 years at 5 per cent.

III. ENGLISH.

11. State any reasons for considering the English alphabet to be defective.

12. Define *comparative degree* and *superlative degree* in adjectives. What is the usual mode of forming these degrees? Mention six adjectives which do not conform to the rule.

13. Parse the following sentence:—

"Who will undertake it, if it be not also a service of honour?"

14. Write a short essay on *one* of the following subjects:—*Athletic Sports, Cruelty to Animals, The Force of Example, The Advantages of Travelling.*

The following is a list of the Centres at which the examination was held, showing the number of candidates examined at each centre and the result:—

	Candidates. Examined.	Passed.	Failed.		Candidates. Examined.	Passed.	Failed.
Aberdeen	5	3	2	Leeds	11	5	6

EXAMINATIONS IN LONDON.

April 10, 1878.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall and Umney.

Dr. Greenhow was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

Seven candidates were examined. *Two* failed. The following *five* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Greenough, Hugh Fairhurst ...Manchester.
Heywood, John Henry ....Lincoln.
Hutton, Harry ....Warwick.
Mather, John Henry ....Newcastle-on-Tyne.
Tompsett, Leighton Stovold ...Strood.

MINOR EXAMINATION.

Sixteen candidates were examined. *Three* failed. The following *thirteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Capern, Francis T. Mesmer ...Weston-super-Mare.
Crooke, Charles Gibbins ....Walsall.
Davies, Hugh ....Machynlleth.
Dawson, George Robert ....Southend.
Graham, Andrew Ward ....Brighton.
Gravill, Edward Day ....Gainsborough.
Greensill, William Joseph ......Birmingham.
Jepson, Alfred ....Swansea.
Phillips, John Edwards ....Cheltenham.
Richards, William ....Nottingham.
Sutcliffe, George Hargreaves ...Bacup.
Tunley, William Henry ....Guernsey.
Wing, William ....Sheffield.

MODIFIED EXAMINATION.

Five candidates were examined. *Two* failed. The following *three* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bradshaw, Charles Henry ......London.
Garrett, James Oliver ....Newport, Mon.
Ramsey, Joseph ....Mansfield.

April 11, 1878.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss and Southall.

MAJOR EXAMINATION.

Seven candidates were examined. *Three* failed. The following *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Collinson, Frederick William ...Alnwick.
Mead, Charles John..............Wimborne.
Stephenson, George Herbert ...Hull.
Vernon, William Henry ....Boston.

MINOR EXAMINATION.

Twenty-one candidates were examined. *Seven* failed. The following *fourteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Barrat, Reuben ....Kingston-on-Thames.
Bevan, William.....................Ipswich.
Fowler, George William ....Hackford.
Glaisyer, Edmund ....Brighton.
Hoyle, Richard Ashworth ......Rawtenstall.
Kent, Benjamin John ....Boston.
Parker, Thomas ....Preston.
Roberts, Thomas ....Margate.
Sadler, William, jun. ....Margate.
Sangster, John Graham ....Southsea.
Smith, Peter ....Runcorn.
Stonham, William Burne ......Maidstone.
Street, Walter Charles ....Lincoln.
Thompson, John Hartley ......Sheffield.

April 12, 1878.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss and Southall.

MINOR EXAMINATION.

Twenty-six candidates were examined. *Eleven* failed. The following *fifteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bosher, Alexander ....London.
Chadwick, William ....Lytham.
Chalmers, John.....................Newport, Salop.
Cole, Samuel John ....Exeter.
Higson, John.........................Blackburn.
Holmes, Charles Newman ......Battersea.
Jennings, Francis Rice ....Falmouth.
Madeley, Edward Stanbury ...Barnes.
Morley, John Thomas ....Barton-on-Humber.
Nicholson, Charles ....York.
Pearson, Thomas Styan ....York.
Robinson, Charles Bradshaw ...Great Bridge.
Shaw, William Bourne ....Bridgnorth.
Thomason, Thomas Watson ...Birmingham.
Walton, Henry.....................Manchester.

April 16, 1878.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall and Umney.

MAJOR EXAMINATION.

Seven candidates were examined. *Two* failed. The following *five* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Barrow, Frank Arthur ....Newmarket.
Brown, George German ....Dresden.
Greenhill, Samuel Osborne......Colchester.
Jackson, Henry John ....Bawtry.
Pumphrey, John Henry ....Evesham.

MINOR EXAMINATION.

Nineteen candidates were examined. *Eleven* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Aston, Walter ....Tarporley.
Dashwood, James.................Portsmouth.
Davies, John.........................Newcastle Emlyn.
Dodd, William Ralph ....Market Drayton.
Ellis, James ....Southsea.
Griffith, Samuel ....Weston-super-Mare.
Leigh, Marshall ....Middlesborough.
Smith, Joseph ....Salford.

April 17, 1878.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall and Umney.

Dr. Greenhow was also present on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-four candidates were examined. *Seventeen* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Blaymire, Thomas Croskell......Kendal.
Broadhead, Richard..............Levenshulme.
Clayton, Christopher ....Market Rasen.
Jones, William Forsyth ....Notting Hill.
Middleton, Christopher ....Thirsk.
Stevens, Henry George Lewis Bury St. Edmunds.
Whitrod, Henry Frederic ......Diss.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's examination:—

Certificates of the College of Preceptors.

Cripps, Richard Augustus ......Upper Holloway.
Jackson, Walter ....Catterick.
Pritchard, Edward Thomas......South Norwood.
Taylor, Alfred J. ....Swansea.
Thomas, Henry Owen ....Rhyl.

Certificates of the University of Cambridge.

Bush, Robert ....Swardeston.
Swift, Augustus Dickerson......Spalding.

Certificate of the University of Durham.

Low, David ....Hexham.

Certificate of the University of Oxford.

Thomas, Richard ....Llanfyllin.

Provincial Transactions.

THE REGISTERED CHEMISTS' ASSOCIATION OF LIVERPOOL.

The Annual Dinner of this Association took place on the 2nd inst., at the Adelphi Hotel. Forty-five gentlemen were present.

After dinner the President of the Association, Mr. J. Abraham, in felicitous terms proposed the loyal toasts.

Mr. A. E. Tanner having given a recitation of "The Raven,"

Mr. J. A. Turner, in a humorous speech, gave the toast of "The Registered Chemists' Association of Liverpool." This was responded to by the Hon. Secretary, Mr. B. Dickins, and by Messrs. Parkinson and Mackinlay. The object of the Association in promoting friendly co-operation for the common benefit was dwelt upon. The Secretary mentioned the gratifying demand that there had been from all parts of the country for the new edition of the price list; and said the Association trusted that the issue of a list generally applicable may be found a service to the trade at large.

The toast of "The Liverpool Chemists' Association" was then proposed by Mr. J. Shaw, who sketched its history, recalling the names of eminent men who in different departments had taken part in its educational work. The President of the Association, Mr. T. F. Abraham, in responding said that although the Chemists' Association from its constitution could not discuss the purely trade matters for the consideration of which the Registered Chemists' Association was formed, yet the more scientific society very much conduced to the welfare of the trade by indicating as occasion arose matters connected with adulteration, etc. Mr. Williams, F.C.S., the Hon. Secretary of the Chemists' Association, also acknowledged the toast.

The Chairman then gave the toast of "The Pharmaceutical Society." He said that its success abundantly proved the wisdom of its founders. He alluded to the able discharge of its duties as an educating and examining body, recalling the names of illustrious men who had been among its lecturers and its councillors. The names of its present lecturers were received with applause which showed that pleasant recollections of Bloomsbury Square were potent with many of the gentlemen present. The work of the Society as a legislative body, by its Benevolent Fund, and by its publication of the *Pharmaceutical Journal* were recognized, and the mention of the last recalled the obligations of the trade to *The Chemist and Druggist* as a trade journal. The toast was responded to by Dr. Symes and by Mr. George A. Redford. The former in eloquent terms recalled the interest of old days at the School of Pharmacy, and the latter fresh from the passage of the Major examination, said that nothing more than steady, patient work was needed to pass what seemed to some a formidable ordeal. Hearty tributes were paid to the kindness of the lecturers and examiners.

Mr. Woodcock proposed the toast of "The Chemists of Chester and Birkenhead." Mr. Shepherd, President of the Chester Chemists' Association, responded for Chester, giving an account of the Society. He alluded with approval to the recent issue of the Liverpool price list, and gave some practical business advice advocating firmness in dealing with objectors. Mr. A. Stewart, in responding for Birkenhead, gave pleasing testimony to their reasonable hour of closing, 8 o'clock; and to the fact that all were closed on Sunday. For other places this is "a consummation devoutly to be wished."

The toast of "The Wholesale Trade" was given by Mr. Fingland in a most happy manner, and responded to by Mr. R. Summer,

The Vice-President, Mr. Redford, proposed "The Health of the esteemed President of the Association, Mr. J. Abraham." This was received in a manner which testified to the appreciation of the services which in an eminent degree Mr. Abraham has rendered to the Association.

The toast of "Our Musical Friends" was responded to by Mr. A. H. Mason, and "The Health of the Vice-President, Mr. A. Redford" having been received with honours, the company broke up, having spent an evening about which there was only one regret, viz., that "it only comes once a year."

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

The first election of General Committee for this Associatian has been held. The following is a list of the gentlemen elected:—

England.

Anthony, J. L., Bedford.	Greenish, Thomas, London.
Stevenson, James, Reading.	Hampson, Robert, London.
Turner, John, Aylesbury.	Owen, John, London.
Throssell, John, Cambridge.	Preston, Alfred, London.
Bates, W. J., Macclesfield.	Slipper, James, London.
Blades, C. M., Northwich.	Urwick, William W., London.
McNeill, J. M., Crewe.	Wade, John, London.
Prockter, John, Penzance.	Pearman, Henry, Newport.
Thompson, Andrew, Carlisle.	Atmore, George, Lynn.
Greaves, Abraham, Chesterfield.	Corder, Octavius, Norwich.
Frost, George, Derby.	Poll, W. S., Yarmouth.
Symons, William, Barnstaple.	Bingley, John, Northampton.
Balkwill, A. P., Plymouth.	Carr, W. G., Berwick-on-Tweed.
Delves, George, Exeter.	Proctor, B. S., Newcastle-on-T.
Tucker, C., Bridport, Dorset.	Parker, W. H., Nottingham.
Mays, R. J. J., South Shields.	March, W., Newark-on-Trent.
Nicholson, J. J., Sunderland.	Prior, G. T., Oxford.
Robinson, James, Darlington.	Cross, W. G., Shrewsbury.
Cole, F. A., Colchester.	Commans. R. D., Bath.
Smith, Nathaniel, Cheltenham.	Prince, Henry, Taunton.
Stafford, William, Chester.	Jones, Charles, Hanley.
Stroud, John, Bristol.	Averill, John, Stafford.
Clift, Joseph, Dorking, Surrey.	Brevitt, W. Y., Wolverhampton
Randall, W. B., Southampton.	Anness, S. R., Ipswich.
Pollard, H. H., Ryde, I. of W.	Whaley, E., Kingston-on-Tham.
Ellwood, M. J., Leominster.	Cortis, A. B., Worthing.
Durrant, G. R., Hertford.	Vizer, E. B., Brighton.
Provost, J. P., Huntingdon.	Rossiter, Frederick, Hastings.
Green, Robert, Woolwich.	Arblaster, C. J., Birmingham.
Barnaby, Henry, Rochester.	Barclay, Thomas, Birmingham.
Bing, Edwin, Canterbury.	Jones, William, Birmingham.
Cotterell, W. H., Dover.	Walker, George, Coventry.
Bagnall, W. H., Lancaster.	Jones, S. U., Leamington.
Hogarth, William, Preston.	Severs, Joseph, Kendal.
Farnworth, Wm., Blackburn.	Atkins, S. R., Salisbury.
Thomas, Richard, Burnley.	Hollier, Elliott, Dudley.
Dutton, Francis, Bolton.	Johnson, T. S., Great Malvern.
Phillips, Jonathan, Wigan.	Thompson, T., Richmond, Yorks.
Robinson, Ralph, Rochdale.	Robson, J. E., Middlesboro'-on-T
Hargreaves, H. F., Oldham.	Whitfield, John, Scarborough.
Benger, F. B., Manchester.	Davison, R., Holgate-Hill, York.
Brown, W. S., Manchester.	Earle, Francis, Hull.
Slugg, J. T., Manchester.	Coupland, Joseph, Harrogate.
Woolley, G. S., Manchester.	Reynolds, Richard, Leeds.
Beecham, Thomas, St. Helens.	Yewdall, Edwin, Leeds.
Abraham, John, Liverpool.	Thornton, Hezekiah, Bradford.
Dickins, Benjamin, Liverpool.	Jessop, Jonathan, Halifax.
Woodcock, Joseph, Liverpool.	Hunter, James, Dewsbury.
Clark, W. B., Leicester.	Hick, M. B., Wakefield.
Palmer, Enoch, Great Grimsby.	Hall, George, Huddersfield.
Maltby, Joseph, Lincoln.	Shaw, H. W., Doncaster.
Pilley, H. T., Boston.	Cubley, G. A., Sheffield.
Andrews, Frederick, London.	Jervis, William, Sheffield.

Wales.

Roberts, Meshach, Bangor.	Davies, D. J., Aberystwith.
Edisbury, J. F., Wrexham.	Davies, R. M., Carmarthen.
Jones, Evan, Bala, Merioneth.	Williams, Thomas, Cardiff.

Scotland.

Storrar, David, Kirkaldy.	Kinninmont, Alex., Glasgow.
Mackenzie, James, Edinburgh.	McAdam, Robert, Glasgow.
Napier, Alexander, Edinburgh.	Strang, Peter, Perth.
Raimes, Richard, Edinburgh.	Burns, D. H., Arbroath.
Borthwick, A. J., Selkirk.	Kerr, Charles, Dundee.
Allan, William, Dumfries.	Ritchie, David, Aberdeen.
Borland, John, Kilmarnock.	Strachan, Alex., Aberdeen.
Davison, Thomas, Glasgow.	Ettles, John, Elgin.
Fairlie, J. M., Glasgow.	MacRitchie, David, Inverness.

Additional Members.

Churchill, W. J., Birmingham.	Shaw, John, Liverpool.
Holdsworth, T. W., Birmingham.	Southall, William, Birmingham.
Laird, G. A., Edinburgh.	Walker, Robert, Birmingham.
Matthews, William, London, W.	

Proceedings of Scientific Societies.

LONDON INSTITUTION.

The Analogies of Plant and Animal Life.*

BY FRANCIS DARWIN, M.B.

Concluded from p. 822.)

We will now inquire whether among plants anything similar to memory or habit, as it exists among animals, may be found.

The most fruitful ground for this inquiry will be the phenomenon known as the sleep of plants. The sleep of plants consists in the leaves taking up one position by day and another at night; the two positions for night and day following each other alternately. The common sensitive plant (mimosa) is a good example of a sleeping plant. The leaf consists of a main stalk from which two or more secondary stalks branch off; and on these secondary stalks are borne a series of leaflets growing in pairs. The most marked character of the night or sleeping position is that these leaflets, instead of being spread out flat as they are in the day, rise up and meet together, touching each other by their upper surfaces. At the same time the secondary stalks approach each other and ultimately bring the rows of closed-up leaflets (two rows on each stalk) into contact. Besides this well marked change the main stalk alters its position. In the afternoon it sinks rapidly, and in the evening it begins to rise, and goes on rising all night, and does not begin to sink until daylight. From that time it sinks again till evening, when it again rises, and so on for every day and night. In reality the movement is more complicated, but the essential features are as I have described them.

In comparing the sleep of plants with anything that occurs in animal physiology, we must first give up the idea of there being any resemblance between this phenomenon and the sleep of animals. In animals, sleep is not necessarily connected with the alternation of light and darkness, with day and night. We can imagine an animal which by always keeping its nutrition at an equal level with its waste would require no period of rest. The heart which beats day and night shows us that continuous work may go on side by side with continuous nutrition.† Mr. Herbert Spencer has suggested that since most animals are unable to lead a life of even ordinary activity during the night because of the darkness, therefore it answers best to lead an extremely active life in day when they can see, and recover the waste of tissue by complete rest at night. On the other hand, certain animals find it more to their profit to sleep in the day and work at night. But there is nothing of this kind in plants; their sleep movements are not connected with resting. Although the leaflets close up, yet the main stalk is at work all the night through.‡ Moreover, owing to the closing up of the secondary stalks of the leaf, the length of the whole organ is increased, and therefore the work done by the main stalk is also increased. So that, far from resting at night, the main stalk is actually doing more work than in the day. Besides this, instead of being more or less insensible, as a sleeping animal is, the primary petiole of the mimosa remains fully sensitive at night, and displays the same property which it shows by day, viz., that of falling suddenly through a large angle on its irritable joint being touched. Besides these points of difference, there is the important distinction that the movements of sleeping plants are strictly governed by light and darkness without any reference to other circumstances.

* A lecture delivered at the London Institution on March 11 by Francis Darwin, M.B. From *Nature*, March 14, 1878.

† Leaving out of the question the repose during diastole.

‡ In mimosa at least.

In Norway,* in the region of continual day, the sensitive plant remains continually in the daylight position—although no animals probably remain continually awake.

There is one—but only a fanciful—resemblance between the sleeping plants and animals, namely, that both have the power of dreaming. I have been sitting quietly in the hot-house at night waiting to make an observation at a given hour, when suddenly the leaf of a sensitive plant has been seen to drop rapidly to its fullest extent and slowly rise to its old position. Now in this action the plant is behaving exactly as if it had been touched on its sensitive joint; thus some internal process produces the same impression on the plant as a real external stimulus. In the same way a dog dreaming by the fire will yelp and move his legs as if he were hunting a real instead of an imaginary rabbit.†

I said that in the regions of perpetual light the sensitive plant remains constantly in the day position. We might fairly expect, therefore, that we should be able to produce the same effect by artificial light constantly maintained. This experiment has, in fact, been made by A. de Candolle,‡ Pfeffer, and others with perfect success. But before the leaves come to rest a remarkable thing takes place. In spite of the continuous illumination, the sleeping movements are executed for a few days exactly as if the plant were still exposed to the alternation of day and night. The plant wakes in the morning at the right time and goes to sleep in the evening; the only difference between these movements and those of a plant under ordinary circumstances is that under constant illumination the movements become gradually smaller and smaller, until at last they cease altogether. When the plant has been brought to rest it can be made to sleep and wake by artificial alternations of darkness and light. This fact seems to me extremely remarkable, and one which, in the domain of animal physiology, can only be parallelled by facts connected with habit. The following case is given me by a friend and is probably a common experience with many people:—Having to be at work at a certain time every day, he has to get up at an early hour, and wakes with great regularity at the proper time. When he goes away for his holiday he continues for a time waking at the proper hour to go to work, but at last the body breaks through the habit, and learns to accommodate itself to holiday hours.

It seems to me that this case may fairly be likened to that of the sensitive plant in constant illumination. There is the same continuance of the periodic movement on the first removal of a stimulus, and the same gradual loss of periodicity consequent on the *continued* absence of the stimulus.

From this kind of habitual action there is but a small step to those actions in which we say that memory comes into play. Dr. Carpenter§ relates the case of a boy who, in consequence of an injury to his brain, never acquired the power of speech or of recognizing in any way the minds of other people. In spite of this mental incapacity he had an extraordinary sense of order or regularity. Thus although he disliked personal interference, his hair having been one day cut at ten minutes past eleven, the next day and every following day he presented himself at ten minutes past eleven, as if by fate, and brought comb, towel, and scissors, and it was necessary to cut a snip of hair before he would be satisfied. Yet he had no knowledge whatever of clocks or watches, and was no less minutely punctual when placed beyond the reach of these aids.

It is hard to say whether this boy actually remembered at ten minutes past eleven that now was the time to have

* Schübler, quoted by Pfeffer ('Die periodische Bewegungen der Blattorgane,' 1875, p. 36).

† This curious phenomenon was first observed by Millardet, who describes it as of rare occurrence. (Millardet, *loc. cit.*, p. 29.)

‡ Quoted by Pfeffer ('Periodische Bewegungen,' p. 31).

§ 'Mental Physiology,' p. 349.

his hair cut, or whether it was an unconscious impulse that made him do so. But whether we call it habit or memory, there is the same knowledge of the lapse of time, the internal chronometry, as Dr. Carpenter calls it, which exists in the sensitive plant, and the same tendency to perform an action because it has been done previously. There is, in fact, hardly any distinction between habit and memory; if a man neglects to wind up his watch at night, he says that he forgot it, and this implies that memory normally impels him to wind it; but how little memory has to do with the process is proved by the fact that we have often to examine our watches again to see that they are wound up. It is the old problem of conscious and unconscious action. If a friend, in order to test our powers of self-control,* moves his hand rapidly near the face, we cannot help winking, though we know he will not hurt us; and when we are breaking through a hedge or thicket, we close our eyes voluntarily to keep twigs out. Here are two actions performed with the same object by the same muscles under command of the same nerves, yet one is said to be directed by the will, and the other by instinct, and a great distinction is drawn between them. It seems to me that the presence of what Mr. Lewes calls "thought consciousness" is not the crucial point, and that if it is allowed that the sensitive plant is subject to habit (and this cannot be denied), it must in fact, possess the germ of what, as it occurs in man, forms the groundwork of all mental physiology.

I am far from wishing to make a paradoxical or exaggerated statement of this resemblance between the periodic movements of plants and memory of the human mind. But the groundwork of both phenomena seems to be the repetition of a series of acts, or the recalling of a series of impressions, in a certain order at a certain time, because they have been repeated in that order and at that time on many previous occasions.

I will mention one more fact in connection with the movements of mimosa, in which the formation of habit is illustrated. Every one knows that a noise regularly repeated ceases to disturb us; that one becomes habituated to it, and almost ceases to hear it. A boy fast asleep inside an iron boiler whilst riveting is going on, is an example of this power of habituation. The same thing occurs with the sensitive plant. A single violent shake causes the main stalk to drop, and the leaflets to shut up; in a minute or two the leaf recovers, and will again react on being disturbed. In order to test the power of habituation, I fastened one end of a thread to the leaf of a sensitive plant, and the other to the pendulum of a metroneme, and placed the plant just at such a distance from the instrument that it received a pull at every beat. The first shock caused the leaf to shut up, but after a few repetitions it became accustomed to it, and I had the curious sight of a highly-sensitive plant unaffected by a series of blows. In nature this power no doubt enables the plant to withstand the constant shaking of the wind.

In spite of the amount of time which has been spent on the study of sensitive and sleeping plants, no satisfactory explanation of the use which the movements are to the plant has ever been given. In the case of the carnivorous plants, we saw that the movements of plants may be offensive, and like the movements of animals in securing their prey. In the case of certain flowers which we will now consider, the movements are defensive, like the closing of a sea anemone. I shall describe these movements with a view to showing the existence of periodicity or habit, and some other general resemblances to animal physiology.

The crocus is perhaps the best example of a flower which opens and shuts in accordance with changes of external circumstances. The crocus is especially sensitive to changes of temperature. If a light index is fastened into one of the petals or divisions of the flower, very small movements are made visible, and in this way it has been shown that the crocus actually appreciates a difference of temperature of one degree Fahrenheit.* I have seen a crocus distinctly open when a hot coal was brought near it. The use of this power of movement is connected with the fertilization of the flower. In the warm sunshine the flower opens wide, and the bees are soon hard at work, and carry pollen from one flower to another. If, now, a cloud hides the sun, the temperature falls, and the crocus begins to close, and by the time the sky has become overcast, and the first drops of rain fall, the precious pollen is housed safe beneath the roof of petals. The crocus is warned of the coming danger by the shadow of the cloud just as the fly is warned by the shadow of the approaching hand. The crocus is sensitive to changes of light and darkness as well as to changes of temperature, and the sum of these influences alternately acting by night and day produces a periodic opening and shutting which resembles the periodic movement or sleep of the sensitive plant. Corresponding to the regular repetition of the stimulus of light and heat, an internal periodicity has arisen in the flower which shows itself in a curious manner. This phenomenon is best shown by certain flowers which are not so sensitive to temporary changes, but which open and close regularly by day and night. Raising the temperature in the evening does not produce nearly the same amount of divergence of the petals as a similar rise in the morning. With the white water-lily, *Oxalis rosea*, and some other flowers, the same thing is well seen.† If the flowers have been allowed to close at the natural hour in the evening it is hardly possible to perceive the least opening of the petals even when the temperature is raised from 50° to 82°. On the other hand a considerable lowering of temperature does not produce so much effect in the morning as it does towards evening. In all biological problems it is necessary to consider the internal condition of the organism quite as much as the other element, viz., the external condition. It is a familiar fact that similar external causes do not produce like results. A man may fall ill after exposure to wet and cold at different times of his life and the kind of illness may be very different. Once it may be rheumatic fever, another time pleurisy, or some other malady, so that in the case of the flowers which, under a given change of temperature, behave differently at different times of day, we see the variability in the internal condition or receptive state of the organism exemplified, the most interesting fact being that the receptiveness varies not capriciously but with periodicity.

The same phenomenon may also be seen when the cycle is a yearly and not a daily one. A German physiologist has lately made a long and patient research on the yearly periodicity in the growth of buds.‡ The method consisted in ascertaining the weight of one hundred cherry buds gathered at frequently repeated intervals throughout the year. In order to discover whether the growth of buds would be equally increased in rapidity at all times by a given increase of temperature, branches were cut and kept in a greenhouse at a temperature of 60 to 70 at various times of the year. This experiment showed that branches thus treated in the beginning of December were hardly at all hurried on in growth, while the rise of temperature at once produced energetic growth in buds in the middle of January. If this fact is to be classed with the very similar effects of temperature on the daily periodic changes in flowers—and I can hardly doubt that it ought to be so classed—a difficulty arises. The buds being new growths, have never experienced a previous winter or spring, so that the periodicity cannot originate in their tissues; it must, therefore, depend on some property common to all the branches, some periodicity common to the nutrition of

the tree. Askenasy describes the case as the occurrence of some chemical change which goes on in the buds, rendering them sensitive to rise of temperature at a certain period. The case bears a resemblance to the hybernation of animals. Thus, Berthold* says that when the dormouse, *Myoxus avellanarius*, first goes to sleep in the autumn it can be partly awakened, and then sent into deep sleep by alternations of temperature, answering, like the crocus, to alternations of heat and cold; but when the winter sleep has fairly set in, no effect could be produced by raising the temperature,—just as the oxalis and water lily when once shut for the night could not be made to open.

I have no doubt that many closer analogies will some day be shown to exist between the behaviour of plants and animals, as regards nerve-physiology. The after-effect of stimuli seems to be represented in the movements of plants. If a stimulus is suddenly applied and then removed, the nerves acted on do not cease to be disturbed the instant the stimulus ceases. The molecular change, whatever it is, which goes on in the nerve, cannot leave off directly the stimulus ceases. The molecular action goes on like the vibration of a bell after it has been struck. When a wheel is turned round rapidly before our eyes the image of a new spoke strikes the retina before the image of the old one has died away, so that we cannot distinguish one from another. In the same way a burning stick whirled round looks like a circle of fire. This after effect of stimuli is represented in plants by heliotropism and geotropism. I have myself observed it in the latter. I took a young growing shoot and put it through a hole in a cork, so that it was firmly fixed into a bottle of water. I then put the bottle on its side in a vessel filled with wet sand, and fixed it firmly by piling wet sand over it. The shoot thus projected horizontally from the vessel of sand. It now began to straighten itself by geotropism, that is to say, the tip of the shoot began to curve upwards. I applied a delicate means of measuring this upward movement, and allowed it to continue for some time. I then turned the bottle round on its axis, so as to rest on what had been its upper surface, and the action of gravity being now reversed as far as the shoot went, the tip ought to have reversed its direction of growth, and curved upwards, but instead of this it went on curving towards the earth in consequence of the after-effect of the old stimulus. And it was more than an hour before it could reverse its movement, and again grow upwards.

With this case I conclude my comparison of plants and animals. Some of the points of resemblance which I have attempted to point out are purely analogical. Nevertheless, I have tried to show that a true relationship exists between the physiology of the two kingdoms. Until a man begins to work at plants, he is apt to grant o them the word "alive" in rather a meagre sense. But the more he works, the more vivid does the sense of their vitality become. The plant physiologist has much to learn from the worker who confines himself to animals. Possibly, however, the process may be partly reversed—it may be that from the study of plant-physiology we can learn something about the machinery of our own lives.

Parliamentary and Law Proceedings.

PROSECUTION OF AERATED WATER MANUFACTURERS AND RETAILERS.

At the Huddersfield Borough Police Court, on Tuesday, April 9, before J. F. Brigg (in the chair), W. R. Haigh and J. A. Brooke, Esqrs., John Ellis, Fruiterer, Westgate, appeared in answer to a summons charging him with selling to Mr. E. G. Kirk, sanitary inspector, a certain quantity of food called potass water, to wit four small bottles, which was not composed of the ingredients demanded by the purchaser; and also to answer another charge of selling soda water which was not of the nature and quality demanded by the purchaser.

Mr. E. G. Kirk, sanitary inspector, stated that an information had been laid under two different sections, because he thought he should be able to prove that two distinct offences had been committed. On the 13th of last month, in company with William Jessop, he visited the defendant's shop, and asked to be supplied with four bottles of soda water, and four bottles of potass water, which were served to him by Mr. Ellis himself, and for which he paid 1*s.* 4*d.* After completing the purchase he said to Mr. Ellis, "I am purchasing these samples in my official capacity, for analysis," and asked him if he wished to retain a part, offering at the same time to divide it, according to the terms of the Act of Parliament. He replied "No, I bought it of the South Yorkshire Aerated Water Company, and I sell it in the same way that I receive it. If it's wrong it's the company's fault, not mine, and if I am fined I shall sue them for any damages that they may have caused me." After that he (Mr. Kirk) made the bottles secure, and subsequently numbered the potass water 21, and delivered it to the borough analyst, Mr. George Jarmain, and requested him to analyse it. He had since received Mr. Jarmain's certificate, which stated that the sample was a solution of carbonic acid gas in water, that it contained no bi-carbonate of potass, but ·42 gr. of metallic copper per gallon, which would be injurious to the health of a person in the habit of drinking potass water frequently.

George Brighouse and others, trading together in Fitzwilliam Street, Huddersfield, as the South Yorkshire Aerated Water Company, were summoned for selling, to the prejudice of the purchaser, Mr. E. G. Kirk, sanitary inspector, a certain quantity of food called soda water, to wit, six bottles, which was not of the nature, substance, and quality demanded by the purchaser. The defendants were also charged with selling a certain quantity of food called soda water, to wit, six bottles, which was not composed of ingredients demanded by the purchaser. Mr. S. Learoyd appeared for the defendants.

Mr. Kirk, the sanitary inspector, stated that on the 4th of last month, in company with William Jessop, he visited the manufactory of the defendants, and asked the manager if he would sell him six bottles. Witness paid 1*s.* 6*d.* for the soda water, and paid for the bottles separately. After completing the purchase witness told the manager that he was the sanitary inspector, and that he had purchased the sample for analysis. Witness sealed the bottles, and handed the manager two, two he retained, and afterwards he took two to Mr Jairmain for analysis.

Mr. George Jarmain identified the certificate produced by Mr. Kirk as that of his analysis. In that certificate he stated that he was of opinion that the sample was a solution of carbonic acid gas in water, and contained no bicarbonate of soda, but ·23 gr. of metallic copper per gallon, which would be injurious to the health of a person in the habit of drinking it frequently.

In cross-examination Mr. Jarmain said that 23 gr. to the gallon would be about a 300th part of a grain to half a pint. It was possible that if there was an accident in the joining of the apparatus some of the copper might have come off through the tin being worn off. Excluding the metallic copper the article he analysed was probably very nice; but he did not take it himself, and he did not think there was much in it. It might be a pleasant drink on a hot summer day, but it was not soda water. There was nothing injurious in it excluding the copper. The soda water of the British Pharmacopœia contained 30 gr. to one pint of water. Soda water of that standard was too alkaline for common taste. It was medicinal, and distasteful to the palate. He knew that the quantity of soda in Schweppe's soda water bottles varied, but not that some contained none. He was not aware of any soda water that had ever been sold as a beverage that contained more than five grains to the bottle. Soda water did not properly describe aerated water which had no soda in it. The B.P. soda water was introduced into the British Pharmacopœia in order that medical men might have an article of a standard strength. He thought soda water with thirty grains of soda to the half-pint would be deleterious if taken constantly as a beverage, but he would not say very deleterious. He should call an article soda water because it contained soda. If there was one grain in it he should call it soda water, but he must fix his limit at one grain. If it contained seventy-five grains to the bottle it would still be soda water, but there would be too much soda in it. They had soda water made in the town that contained from three to five grains of soda to the bottle. A pound of soda, which cost 1*s.*, would make 1200 bottles.

Richard Henry Inman, aerated water manufacturer, Huddersfield, said he had not come there to give evidence against the South Yorkshire Aerated Water Company; he came to the court to hear the cases, but having heard Mr. Learoyd say that in the trade soda water was universally understood to contain no soda at all, he entirely objected to that, because it was not so understood by his firm nor by other firms. His firm's soda water always contained five grains of soda to the bottle, and it was totally impossible for it to vary. The soda cost very little, and made very little difference to the cost of the article.

Mr. Learoyd addressed the Bench for the defence, and contended that there was no standard of soda water as a beverage, and that the name of soda water did not indicate the ingredients at all. The standard of British Pharmacopœia was altogether unpalatable. One of the offences charged was that no person should sell any compound, article of food, or compound any drug—which this was—which was not composed of ingredients in accordance with the demand of the purchaser. Before a person knows the ingredients demanded the purchaser must ask for the ingredients. Asking for soda water was not asking for the ingredients, and what was called soda water was understood to be aerated water without soda in it. With reference to the copper, where anything arose from mere accident the person who was the creature of the accident was not accountable for it. This was purely an accident from the machinery having got out of order.

In reply to the Bench,

Mr. Kirk said he could not admit that, because from three months prior to and three weeks after he obtained these samples the same state of things continued, which showed it was negligence.

Mr. Learoyd said the defendants had had no notice of the facts.

The Chairman said at present the Bench thought it was an accident.

Mr. Kirk remarked that Mr. Ellis told him he purchased his before Christmas, and that actually contained more copper than the sample he got at the company's works.

The Bench, at this stage, decided to hear all the evidence before deciding on this point, and at this stage the case was adjourned until Saturday morning.

At the adjourned hearing—

Mr. Mills, the magistrates' clerk, said there were two summonses in this case—one under section 6, which was for selling soda water which was not of the nature and quality demanded, and to the prejudice of the purchaser; and the other under section 7, which was for selling a compounded article—a food or drug—which was not composed of the ingredients demanded by the purchaser; but, as both summonses had relation only to one set of circumstances, he thought it was quite clear the magistrates would not inflict penalties, assuming the charges to be proved, under both those sections. He thought the charge under section 6 should be abandoned, and that they should rely on that under section 7, in accordance with the argument used on the previous day.

Mr. Haigh pointed out that the charges were distinct—one was in relation to prejudice, meaning that a consumer would be liable to suffer in health if he continued taking the water; and that referred to the copper part of the business.

Mr. Mills said at all events he thought it clear that the Bench would not convict under both sections. If they were going on with the case as regarded prejudice the gin case was of very great importance; but they would remember that the evidence of Mr. Jarmain was that there was no injury whatever. Under section 7 Mr. Learoyd's argument was, as he understood it, that it only——

Mr. Learoyd said section 6 referred to the sale of an article of food which was not of the nature and substance demanded by the purchaser; and section 7 related to not supplying the ingredients which were specified at the time the order was made.

Mr. Mills said his interpretation of section 7 was that it related to a specifically compounded article. Soda water was a general name by which an article was supposed to be composed of certain ingredients; and if a purchaser demanded soda water he assumed, and had a right to assume, that that soda water contained ingredients which soda water properly made did contain. In answer to this Mr. Learoyd quoted the gin case, and said that aerated water was generally sold in this town and neighbourhood under the name of soda water, and that, therefore, was a commercial article, that persons who asked for soda water were supplied with aerated water, and that there was no offence under either of the sections. But there was a case under the old Act which seemed to him (Mr. Mills) to throw considerable light upon this Act of Parliament (the Sale of Food and Drugs Act)—namely, the case of Roberts *v.* Edgerton (9 L. R., Q. B.), in which a man had sold as unadulterated green tea which had been adulterated. It was faced with gypsum and Prussian blue for the purpose of colouring it. This was not known to the public. Pure green tea was imported from Japan. It was contended that as green tea was sold in the trade this coloured green tea that came from China was a commercial article, and, therefore, the purchaser who got it got [what he demanded; but it was also shown that pure green tea came from Japan, and, as the public did not know that there was this adulterated green tea, they had a right to assume that when they asked for green tea they got the pure article. The judges—Cockburn and Blackburn—both held that the public had a right to be supplied with the pure article when it was demanded, even though they only asked for green tea; and applying the same principal to the case now under consideration, his (Mr. Mills) opinion was that although to those who were in the trade, and made it, it might be perfectly well known that what was known as soda water had no bicarbonate of soda in it, yet if the fact were not known to the general public then the defendants were not relieved from the charge under the section 7. A person who asked for soda water believed, and had a right to believe ,that there was bicarbonate of soda in it in some proportion.

Mr. Learoyd: Even though it had the name and was known by the name of soda water.

Mr. Mills again said that a person asking for soda water had a right to assume or believe that there was some proportion of bicarbonate of soda in it; but if Mr. Learoyd could show that the public did not so believe, and that they were not prejudiced by the sale, then it would be another matter, but, in his opinion, what the magistrates had to decide was this, whether or not, when Mr. Kirk asked for soda water, he was served with that which correspond with what he demanded, there being in the water no bicarbonate of soda whatever.

Mr. Learoyd: There is the question of law.

Mr. Mills said it was rather a question of fact. The public, when they ordered soda water, assumed that there was some proportion of soda in it: in this case there was none, and he considered that upon that fact there must be a conviction. If the magistrates, however, found that the public must know that there was sold under the name of soda water that which contained no bicarbonate of soda then that would be another matter, as he before remarked; but he did not think that the mere fact that it was known to the trade that what was sold as soda water contained no bicarbonate of soda got the defendants out of the difficulty. He considered that they must go further, and show that the knowledge extended to the general public, and that the purchasers were not misled at the time. His interpretation of clause 7 was that inasmuch as the soda water contained no bicarbonate of soda there was an offence within the meaning of the Act of Parliament, unless upon the facts the magistrates found that the fact was so generally known to the public that they could not be misled by it, in which case there would be no offence.

Mr. Haigh pointed out that if a person wished to have a drink as a beverage without any soda in it he would not ask for soda but for aerated water.

Mr. Learoyd said he thought that if his client knew that they must have another christening day. He bowed to the decision of Mr. Mills, who was supreme in that court, but there were two points which struck him in the case quoted by Mr. Mills; the first was that the article in question was a natural one, and was not compounded; and the second was that the article was adulterated by the addition of something to it.

Mr. Mills said that was so. The whole tenor of the decision was that there were two classes of tea, both known in the market as green tea. It was perfectly known to the trade that one class of the green tea was coloured, and that there was pure green tea; and Justice Blackburn held that as this was so the fact of its being known to the trade did not relieve them from liability, because the general public were not aware of the distinction.

Mr. Learoyd: That is actual adulteration.

Mr. Mills said it was not a question of adulteration here—it was a question of omitting the potass or soda from the water sold as potass or soda water.

Mr. Learoyd said the sixth section had reference to the article, and the seventh to a person asking for certain ingredients.

Mr. Mills: Section six would apply to milk.

Mr. Learoyd said that soda water was both a drug and a beverage. As a drug undoubtedly it must contain soda. As to the soda water supplied by the defendants, all he could say was that it was highly appreciated, and he believed that it was very agreeable even without soda in it. He thought there would be no controversy between scientific men on this, that one or two grains of soda would make no difference whatever, and that it would not make it more beneficial. He might point out that in the soda water their worships were accustomed to drink there was not more than a grain and a-half to a certain quantity of water. All he could say was that it was well known to the trade.

Mr. Brigg (the chairman): Well known to the makers.

Mr. Haigh said that 99 out of 100 persons who asked for soda water expected to get it.

Mr. Learoyd: They would expect to get what they liked.

Mr. Mills said that Mr. Inman stated that some makers put soda in, and some did not.

Mr. Learoyd said his clients were only anxious to do what was right. They paid very great deference to the views of the magistrates, and if the Bench thought there should be a new christening day, as he had suggested before, they were quite willing to have it, and not to let anything go out of their place as soda water unless it had soda in it. It was no benefit to the defendants, and he thought the Bench would have come to the conclusion that there had been no intention whatever to impose upon the public, or to obtain any advantage over the public, or to adulterate any article to the prejudice of the public. The question of cost was nothing—had nothing to do with it; and the defendants had done nothing affirmatively wicked, he hoped, under the statute, having only sold this to the public as soda water, that name having been given to it by the public.

Mr. Haigh said the name had not been given to the article by the public, but by the makers of the article, and when the name had been given to it, the public asked for it under that name undoubtedly.

Mr. Learoyd said that when the case started he thought there was a standard for soda water—a standard according to the British Pharmacopœia. Of course it came to this now, that they would have to sell either soda water or water without any soda at all—and in future they would sell nothing as soda water which did not contain bicarbonate of soda.

The Bench: That which you sell as soda water must have soda in it.

Mr. Learoyd said that as regarded the other water, they would undertake to sell it as aerated water. Considering that his clients had done nothing which was intentionally wicked or wrong, or been guilty of adulteration, and that they would undertake to pay the costs, he hoped the Bench would not regard it as a case for a penalty.

Mr. Kirk said that as far as he was concerned he did not wish to show any vindictive spirit towards these people; still the offence was of a serious nature, and he really must press the case.

Mr. Brooke: The serious part of the case is the copper. That is prejudicial to health.

Mr. Mills said that as the case stood, upon the interpretation he had given to section seven, Mr. Learoyd confessed that there was an offence; and he asked had he anything to say to the magistrates with reference to the copper?

Mr. Learoyd said that all he could say was, that the best makers had made the machine; that a crack had been found in the joining, which was not found without the most careful examination.

The Chairman said that although the company had not been guilty of any underhand work in manufacturing the soda water, the case was of such importance that they must convict. The conviction would be in no way excessive, they would make only one conviction, namely, under section 7.

Mr. Learoyd said he could call a number of persons to prove that the aerated water was known as soda water, and he should ask the Bench to find upon a question of fact. He could call overwhelming evidence to shew that this was known to the trade as soda water, and upon that the question of law would turn.

Mr. Haigh remarked that Mr. Kirk might call 300 ignorant people, who were not supposed to know anything about the matter, and the question arose did the public when they asked for soda water expect to get aerated water.

Mr. Kirk said he thought he could call 300 intelligent people to prove that they expected to get soda water when they asked for it.

After some further conversation, in which Mr. Learoyd assured the Bench that he was not going to take counsel's opinion on the matter, it was arranged that the case should be adjourned to the 24th inst.

Mr. Kirk asked that in the meantime the defendant's might be restrained from selling any water they had now in stock.

Mr. Learoyd said the cylinder was in London with the makers undergoing an entire supervision, and the defendants were making nothing at all just now.

Mr. Kirk said there might be a large quantity in stock.

Mr. Learoyd: We shall sell no more copper.

Mr. Mills: It has all been made out of the same machine.

It was arranged that a sample from each kind of water in stock should be submitted to the analyst in order that it might be tested, and if it was found that there was any copper in any of the samples the whole of the stock should remain unsold.

The cases against the other persons who had been summoned for a similar offence were adjourned.

Dispensing Memoranda.

[54]. Creasote Pills.—Lest silence on my part as well as on the part of the writer of the "Month," from whom I expected some explanation, should convey consent to the views of "Pil. Creasoti" and others on this subject, as a Pharmaceutical Examiner in Dispensing, I again utter my protest to the use of light calcined magnesia as an excipient for making creasote into pills. If magnesia may be used in the case referred to where two minims of creasote have to be combined with two grains of compound rhubarb pill with the sanction of the *Pharmaceutical Journal*, it will naturally be inferred by dispensers generally that magnesia may be used as an excipient to make creasote into pills whenever it is ordered, and with the results I have stated, that the pills will in most cases be insoluble. It is true that two minims of creasote can be made into a pill with one grain of magnesia, but it takes hours before the mass becomes sufficiently firm to form pills; but creasote is generally "used with success to arrest certain forms of vomiting" (Garrod), and either the patient for whom creasote pills are ordered must endure this for some hours, when he expects to have his pills in ten minutes—or, which is much more probable, the dispenser will expedite the process by putting more magnesia to the mass, sufficient to enable it to be rolled out quickly. Yet either in the case of a pill made with one grain of magnesia and two minims of creasote, or with two grains of magnesia and two minims of creasote (such as I referred to before), both of which I have made and tried by boiling with water in a test tube with no perceptible action;—only a very slight odour of creasote was evolved—they were not disintegrated, and both are indigestible, as I have experimentally proved. Mr. Savage also has shown that pills so made are insoluble in boiling water.*

"Pil. Creasoti" says in his first letter, "When creasote is prescribed in the pilular form it may be assumed that the writer has a definite object in view and desires the slower action of the pill as compared with that of an emulsion." I think this is erroneous. Creasote is mostly prescribed in a pilular form, because it is the only way in which physicians can get their patients to take it. In my large experience in dispensing I do not remember once having to dispense it in a liquid form for internal administration.

But setting aside the solubility and the slower or quicker action of the pills of creasote with magnesia, I hold that the addition of magnesia to creasote pills is not justifiable. Creasote is not creasote when combined with magnesia any more than epsom salt or plaster of paris is sulphuric acid, and no dispenser of medicines is justified in substituting a salt of a corrosive acid for the acid itself in either case. If the physician wanted the salt he would have ordered it. "Pil. Creasoti" in effect says they are the same thing, or that one will do as much good as the other. The onus rests with him to prove this, not with me the negative.

My object is not hair splitting with an anonymous correspondent about metallic oxides or "caustic alkalies decomposing creasote" when they combine with it (let the "prentice hans" try it with oxide of silver), but to point out the glaring diversity of results which will be obtained by a patient having his creasote pills made up at different establishments, or by different dispensers in the same establishment, if the Journal of the Pharmaceutical Society says magnesia may be used. Such diversities, where uniformity is expected by the public, are too frequently complained of as it is. "Honour and good faith toward the customer, or patient, will not permit defects in the consistence or plasticity of a pill mass to be remedied by additions unauthorized by the prescription, as is unfortunately too often done by careless, inexperienced, and unscrupulous manipulators" (Cooley).

Wm. Martindale.

* *Pharm. Journ.*, 2nd series, vol. xi., p. 200.

[92]. Undoubtedly Magnesia, B.P., known in the trade as Mag. Calc. Pond., unless the prescription was written prior to 1864, in which case the light calcined variety would be meant. Unfortunately this change in nomenclature has caused much confusion, so that the ponderous kind is unknown in many pharmacies.

J. B. L. M.

[93]. Dissolve the salt in the requisite quantity of water and add the fluid extract of bark in successive portions, shaking on each addition. A flocculent deposit separates, but is readily diffused throughout the liquid on agitation without adhering to the sides of the bottle.

The Bengal "Cinchona Febrifuge."

Sir,—Having just seen in your Journal of February 9, 1878, the report of the discussion which ensued on the reading before the Society of Mr. Wood's paper, on "The Progress of Cinchona Cultivation and Alkaloid Production in Bengal," I have to request permission to offer a few remarks on some of the statements made on that occasion by Dr. De Vrij and Mr. Wood.

But before entering on these it seems necessary to explain the exact position which Dr. Smith, Surgeon-General, Madras, occupies with respect to experiments such as those conducted with the Bengal "cinchona febrifuge." It must be clearly understood that he is purely an administrative officer, standing in the same relation to the State Medical Department of Madras as the Director-General at the War Office does to the Army Medical Department in London. When a new drug, therefore, is sent by Government for trial he has neither the means nor the leisure to conduct the experiments under his own personal observation. In such cases the article is issued to hospitals presided over by officers of experience, whose judgment can be relied on, for trial and report. This is precisely the course which was adopted in the case of the Bengal "cinchona febrifuge," and Dr. Smith's report, which appeared in the *Pharmaceutical Journal*, vii., page 499, was simply an epitome of the replies received from the executive medical officers, who had given the remedy a patient and most careful trial. The Surgeon-General had no object to gain either by praising or condemning the preparation, but simply as the head of the medical department had to communicate to Government a plain, unvarnished report of the results of the trial as communicated to him by his subordinate medical officers. It seems rather ungenerous, therefore, on the part of Mr. Wood, in referring to Dr. Smith's remarks on the drug, to say, that "it was in human nature that the Madras people should be prepared to find all the fault with it they could," inasmuch as, according to Mr. Wood, the Madras Government had tried to make a similar preparation and failed. Such a statement does not say much for Mr. Wood's ideal standard of official integrity, and is hardly one that should be directed by one gentleman against another, besides against an officer holding the highest office of trust and responsibility in his department which Government can confer on him. I might also mention here, as an illustration of the feeling created in Bengal by the adverse Madras report on the "cinchona febrifuge," the fact that since its publication no further supplies of the preparation have been sent down for experiment, although repeatedly asked for by the Madras authorities. In other words, Madras is prepared to give the drug another fair trial, but the friends of the preparation have apparently shrunk from this fresh ordeal.

With regard to Dr. De Vrij's remarks that "it was well known that 324 parts of quinine required 36·5 parts of pure HCl, and that 308 parts of cinchonine or cinchonidine required the same quantity for solution," and that therefore Dr. Smith's statement as to the insolubility of the "cinchona febrifuge" could not be correct, I must say that I fail to see the force of the argument. Apparently Dr. De Vrij's logic amounts to this: Because the pure alkaloids only require so much HCl to effect their solution, therefore the Bengal preparation can only require the same amount. Dr. De Vrij seems entirely to forget that the "cinchona febrifuge" does not consist merely of mixed alkaloids, but contains a large quantity of extraneous matter. It is quite possible that the supply of the "cinchona febrifuge" sent to Madras for trial was not of the best quality, but the fact remains that three drachms of dilute hydrochloric acid failed to dissolve completely one drachm of the febrifuge in two ounces of water. The acid used was the ordinary dilute acid of the Pharmacopœia, and there can be no doubt about the results, as I witnessed the experiment, and can affirm that the statement is absolutely correct.

In conclusion, let me remark that Surgeon-General Smith is *officially* as much interested as Dr. De Vrij and Mr. Wood are *personally* in securing a cheap and efficient cinchona febrifuge for the people of India, but the way to obtain this is not for interested parties to carp when their pet preparation receives adverse criticism, but rather to accept this in a generous spirit, and try to produce something better.

G. Bidie, M.B.,
Surgeon-Major,
Secretary to the Surgeon-General, I.M.D., Madras.
Surgeon-General's Office, Indian Medical Department,
Fort St. George, Madras, March 22, 1878.

Sir,—Your issue of the 9th February, contains a paper by Mr. C. H. Wood, F.C.S., "On the Progress of Cinchona Cultivation and Alkaloid Production in Bengal," and a report of the discussion of the Society on that paper. As a question of taste, it seems to me that Mr. Wood might have acknowledged the labours of Mr. J. Broughton, the late quinologist of the Madras Government, inasmuch as those labours directly led to the modified process adopted by Mr. Wood in his extraction of the rough alkaloids of the cinchona bark, and as Mr. Broughton, since his mysterious disappearance in 1875, is not present to assert his own claims; but on this score Mr. Wood is responsible only to himself. What I have to complain of is that Mr. Wood has given a garbled and incorrect account of the reasons which induced the Madras Government to discontinue local manufacture of the rough alkaloids. He says, according to the report, "Madras had produced a similar preparation from its plantations, and this preparation had failed and had been abolished because the Madras people could not make it pay."

As I was appointed by the Madras Government in the year 1874 in conjunction with the Commissioner of the Neilgherries to report on the whole question of local manufacture, I have forwarded by the present mail a copy of our joint report on the subject, from which you will see that Mr. Wood, in the above summary, has not given a correct account of the matter. The report is too long to be reprinted *in extenso*, but I will ask you, if you have space, to give such extracts as may be of interest to the pharmaceutical world, and which will serve to justify the action of the Madras Government in suspending its manufacturing operations during a period when its cinchona barks were fetching abnormally high prices in the open market.

Mr. J. Broughton, in his experimental manufacture of rough alkaloids, found that there was a considerable waste of product and that his operations on a large scale failed to yield the amount of alkaloid ascertained to be present by analysis of samples. On the whole his out-turn of alkaloid was about 35 per cent. below the quantity present in tested samples.

Mr. Wood's operations on a larger scale, and by his modified process, show even more unfavourable results than Mr. Broughton's, but I observe he has studiously avoided touching on this aspect of the question in his paper.

Mr. Wood tells us that the bark of the roots of the *C. succirubra* in Bengal gives from 7 to 8 per cent. of alkaloids, and that the stem bark yields from 5 to 6 per cent., while the branch bark gives a smaller yield. Taking the average product of the bark used up in his manufactory in fair proportions of root, stem and branch bark, Mr. Wood says that "the average bark of the plantations contains from 4 to 5 per cent. of total alkaloids."

I observe that in the year 1876–77, the bark operated on was in the following proportions—root and stem bark 57 per cent., and branch bark 43 per cent. It is assumed by Mr. Wood in his paper throughout, that the annual supply of bark from Bengal will yield 4 per cent. of his cinchona febrifuge.

Now please observe the practical commentary on this estimate. In the last two years Mr. Wood has had delivered over to him by the superintendent of the plantation, and has actually used up, 297,928 lbs. of dry bark of the *C. succirubra*, and his official reports show that he has made out of this quantity of material, 5739 lbs. of impure alkaloids, or just 1·9 per cent. By his own showing he has lost in the process of extraction more than one half of the total alkaloids present in the bark.

Mr. Broughton's losses in this respect were only 35 per cent. and latterly much less, but we now find Mr. Wood taking credit to himself for an improved process of manufacture whereby he loses, by his own showing, not far short of 60 per cent. of the febrifuge his analyses show to be present in the bark.

Mr. Wood has not thought proper to allude to these facts, the data for which are taken from the official reports of Dr. G. King, the superintendent of the Bengal cinchona plantations; I have ventured to do so for him, and shall be glad to learn how Mr. Wood can reconcile the estimates in his paper of a 4 per cent. yield, with the actual out-turn of 1·9 (less than two) per cent. of alkaloids. Would any manufacturing chemist depending on his skill and experience for remuneration be content with such results? Surely any chemist working with a view to profit would not be content with so great a waste of valuable material, yet Mr. Wood passes the subject by in silence, just as if his operations had resulted in a great financial success to the Bengal Government, and as if he had really produced a "cheap" febrifuge.

If the bark used in this crude manufacture had been sold in the market, the Government of Bengal might have had from £30,000 to £40,000 to spend in providing crystalline salts of alkaloids, of known and definite composition, for the fever stricken population of the country, in the place of the product you graphically describe as a "*mischmasch.*"

Let me, in conclusion, say that in my judgment the method of keeping the accounts of the cinchona estates in Bengal is such as to render extremely fallacious the estimate that dry bark can be produced and sold at a profit for sixpence a pound. This very question was inquired into by myself and colleague in regard to similar estimates made for the Madras plantations, and when we came to cross-examine the late Mr. McIvor, he was obliged to admit that his estimate had reference only to the expenses of up-keep and bark collection, and that it had been made without any reference to outlay in forming the estates, interest on unproductive capital, rent, taxes, etc. No data, in fact, yet exist showing the cost of production, and the whole question of a cheap febrifuge hinges on the problem whether bark can be cultivated at a profit on commercial principles.

The Government of India is naturally very anxious that the product of its cinchona gardens should be placed within the reach of the people of India with the least possible delay, but unless the cultivation is of a nature to yield a profit, it is very evident that any measures traversing the well established laws of supply and demand would discourage private enterprise and thus protract indefinitely the advent of the time when every man shall be able to buy a dose of quinine just as he now buys his daily supply of opium or hemp. A fictitious cheapening of cinchona can serve no useful or lasting purpose, and no crude and wasteful extraction of alkaloid can help on the cause we all

have at heart—the benefit of the Indian people and the human race at large. W. R. CORNISH, F.R.C.S.,
Sanitary Commissioner for Madras.
Madras, March 23, 1878.

THE ELECTION OF COUNCIL.

Sir,—The election of an efficient Council is a matter of some importance to the Society. It has often appeared to me an anomaly that we should be called upon to vote for men whose opinions are utterly unknown to us until after their election they are reported in the Journal, and therefore it seems an advantage to have anything in the shape of an address. Such an address is now before me, and I take it to be a document of such a public character that it is fit subject for comment in your columns. It is signed by the "principal" of a "college" in London, who says that he should, if elected, consider himself the special representative of country chemists. Without disputing the truthfulness of the *ipse dixit*, it may be permitted me to ask what support the assertion has in the nature of things; what connection is there between a professorial chair in the metropolis and the business of a country chemist. The address proposes to take measures "to stop the unauthorized practice of dispensing medicines, selling poisons, patent medicines, etc., by co-operative societies and other unqualified bodies." So far as the illegal compounding of medicines and vending of poisons is concerned, it simply means the action which the Society has endeavoured to take for some time, and which time has not "now arrived"; but as to the sale of patent medicines, does the professional gentleman propose that chemists should take the responsibility of them ?. and if not, if the liability is to be thrown back upon the proprietors ? Wherein do chemists differ from the grocer or huckster who may deal in them ? and what advantage to the public—the sole ground for legislation—will accrue from any proposed restrictions?

But these matters may be left in other hands. I desire rather to call attention to the omissions of the address. From such a quarter I should have expected a word on the education of young men, some utterance on "cram." I have heard of a trainer of assistant chemists, who professed to teach Latin by giving only the nominative and genitive cases of nouns, as that was "all that is necessary." When I was first introduced to the trade, the last 'London Pharmacopœia' was just out. I wonder how a student in those days would have managed the directions of the chemical compounds, or the descriptions of the materia medica, with only two cases. Is the present age so deteriorated ? I look upon the palming off of such teaching as worse than the quackest of medicines or the lowest price at co-operative stores, and I marvel that nothing has been said on this point, which is too notorious to be overlooked. Further, I think it highly undesirable that persons engaged in training candidates for examination should have anything to do, however remote, with the appointment of examiners, and therefore I not only decline to give the requested support, but think it right also to draw the attention of chemists generally to the subject.

April 15, 1878. A COUNTRY CHEMIST.

NOT ONLY PATENT MEDICINES, BUT ALSO GENERAL PHARMACY IS COMING TO GRIEF!

Sir,—Please allow me space through the medium of your pages to state my utter repugnance at the present fearfully injurious low price system, having read with interest in your valuable Journal the free discussion of several correspondents upon the subject, and fully approve of many statements knowing that they are too true.

Shortly after this nineteenth century had risen out of her "teens," I ventured my lot amongst the C's and D's, and after a long and hard apprenticeship of seven years in a country town I emerged into London, and about that time chemists were springing up like mushrooms, but never was the business so degraded and such a rush of ruinous competitions carried out in almost all quarters as it is at the present day. And I beg to add that not only our patent medicine trade suffers from the village grocers, drapers, and advertising tailors, co-operative stores, and a host of other "dabblers" in medicines, but the whole of our legitimate dealings are now curtailed to the utmost extreme, even by (the worst of them all) pharmaceutical and other qualified chemists by examination calling themselves co-operative drugs companies, who are fiercely "clipping" (especially in our county) this our respectable business into shreds, barely allowing a grocer's margin of profit, who may be supposed to return their five to ten thousand sterling per annum. Can there possibly be no remedy for this monstrous malady, which is spreading so widely all round us thick and fast?

I have read that once upon a time "a mouse could release a lion from its snare." Let us registered chemists under the Pharmacy Act of 1868 rise up ourselves—unity is strength—and lawfully agitate, petition, and strive altogether against this cruel monopoly. Might against right! for so it meaneth. The man who happens to have the most cash or falls in with a rich wife, says "Here goes in for a dash! I intend to make all the trade my own," while his smaller neighbour and brother tradesmen may starve.

But where is this ingenious mouse is to be found? Well, I think and hope that something could be broached amongst our affluent brethren to alleviate, or even to release us poor little hard strugglers from the very heavy pressure which these evil doings are at the present time causing. Have not the chemists of Plymouth and surrounding towns, Birmingham, Liverpool, and other large towns, done some good by combination and societies, and why should not Brighton, a very large town and neighbourhood, do the like? Pray let some attempt be made by the parent society, or by some C's and D's society, to save us from these suicidal prices, namely, for 1*s*. 1½*d*. articles, sold at 7½*d*., 8½*d*., 9½., 10½.; 2*s*. 9*d*. articles at 2*s*. 3*d*., and 2*s*. 6*d*. articles for 2*s*., 1*s*. 9*d*., etc., and for drugs, perfumery, pomades, and sundries, at proportionate low charges, and prescriptions dispensed at 50 per cent. below the usual table or list of prices. There can be no defence at these ridiculous figures, and they are advertised in this locality almost daily.

April 15, 1878. SUSSEX.

P.S.—I now hold in my hand a circular from a candidate for my vote at the approaching election for the Council of the Pharmaceutical Society, who says: "You may rely upon my best endeavours to further in every way the interests of pharmacy, especially with reference to the retail trade." This the man I would support.

J. B.—We do not know; but the date of becoming a member is placed against each name in the list in the Society's Calendar, and such names might be counted.

W. J. W.—Glycerole of subacetate of lead is prepared by substituting glycerine for water in the official liquor plumbi subacetatis, using the heat of an oil-bath to effect solution, and filtering while hot. The method of operating is described in a paper by Mr. Balmanno Squire, published in the *Pharmaceutical Journal* for May 6, 1876. The product is diluted with pure glycerine to the strength required.

J. S.—No; except as a trustee.

"*Radix*" is recommended to address his question to the Registrar.

"*Preliminary*."—We should think not; but if you think there has been any irregularity you are advised to communicate with the Secretary, 17, Bloomsbury Square.

"*Aberdonia*."—It would require a stamp if recommended in any way for the relief of disease, or put forward as an occult or proprietary preparation.

R. F. Smith.—The lectures should have our careful consideration if we were furnished with a report and the lecturer's permission to publish them.

"*Nepos*."—*Ruscus aculeatus*.

N. Lincoln.—The following has been recommended by a correspondent:—Iodine and iodide of potassium, of each, ʒss; hydrochloric acid, ʒj; water to Cj. M.

"*Incog*."—Novargent is prepared from recently precipitated chloride of silver by dissolving it in a solution of either hypophosphite of sodium or cyanide of potassium.

W. H.—You will find the information you require in Cooley's 'Cyclopædia of Practical Receipts,' a new edition of which useful work is now being issued in monthly numbers by Messrs. Churchill.

"*Occidens*."—(1) We cannot say the exact number, but the British species are certainly under 700. (2) We do not know. (3) The question shall receive attention.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Smith, Mr. Hallor, Mr. Stowell, Professor Flückiger, Mr. Burn, Mr. Morris, Mr. Reynolds, Mr. Williams, Dr. Lewis, Mr. Mudie, S. J. T. M., A. E. J., A. G., Glycerinum.

"THE MONTH."

Notwithstanding the cold weather experienced during the early part of April, flowers have made such rapid progress that the botanical list for this month is quite as long as the one for the same date last year. The woods are already gay with anemones, primroses, bluebells, and the delicate blossoms of the wood sorrel and wild cherry, while other welcome harbingers of spring, the golden saxifrage, the handsome marsh marigold, the pretty cuckoo flower or ladies' smock, and the favourite cowslip, are everywhere brightening the damp pasture with the profusion of their blossoms.

The *Daphne Laureola* may still be found in blossom in chalky woods. It is very curious with regard to the berries of this plant that they are said to be poisonous to all animals except birds, which are very fond of them. Some of our spring flowers are perhaps worthy of more notice than they generally receive. Thus the marsh marigold (*Caltha palustris*) will be seen upon examination to have its petaloid sepals folded in such a manner as to answer the purpose of both calyx and corolla, for while three sepals overlap only at one edge, and fulfil the duty of a corolla, the two outer sepals overlap the others at both edges so as to cover the lines of junction of the other three, and thus effectually protect the pollen from moisture. Darwin quotes Lecoq's statement that sometimes specimens of this plant are found with only staminate flowers. We have never been fortunate enough to meet with such specimens. An infusion of the flowers was formerly used for fits, this use having arisen, according to Withering, from the fact that a large quantity of the plant having been placed in the bedroom of a girl afflicted with fits, the fits afterwards ceased.

The pretty little moschatel, which may here and there be met with on shady banks in lanes and woods especially on a sandy soil, is well worth examination. The small head of flowers consists of five flowers, of which the four lateral flowers usually have five parts, and the top flower only four parts. The two stamens are alternate with each petal, and the anthers are one-celled only, hence each of these stamens is regarded by some botanists as consisting of a single anther lobe, separated from its fellow by a long forked connective. The white coral-like rhizome, with its abortive scale-like leaves and slender stolons proceeding from their axils, are also worth notice. The plant is also interesting on account of the difficulty in finding out the exact position it should occupy. Although possessing somewhat the habit of a saxifragaceous plant, it was formerly placed in the ivy family, and now it is placed in the *Caprifoliaceæ*.

The cuckoo flower was used in the time of Ray for hysteria and epilepsy, and is recommended by Withering for worms. It may be profitable, as showing the progress made in medicine and pharmacy during the last century, to recall the fact that it is little more than one hundred years ago that Sir G. Baker read a paper before the Royal College of Physicians, on the use of the flowers, in which it is stated that the flowers should be toasted on pewter dishes over a fire, powdered, and the powder boiled in bottles covered and *stopped with leather, and on no account with a cork.*

The elegant little wood sorrel (*Oxalis Acetoseall*), to which oxalic acid and salts of sorrel owe their names, is worth examining, as it is one of the plants producing cleistogamous flowers; these may be recognized by looking like buds, and having short stalks bent downwards. In these flowers the upper stamens are on a level with the stigma, and the petals are minute. According to Darwin, these produce a few more seeds than the open flowers. This is one of the plants which claims the honour of being the Irish shamrock.

The dark blue flowers of the *Anemone Pulsatilla* may now be looked for in chalky districts in the eastern countries, as near Hitchin and Cambridge. Although when in blossom it is conspicuous only from the size of the flower, the flower stalk being very short, yet after flowering the stalk lengthens very considerably, and the head of long tailed achens forms a very conspicuous object. The juice was formerly used for paralysis, and the plant is now much valued by homœopaths as a remedy in various female disorders. Its name of Pasque flower is said to have been given to it by Gerarde on account of its flowering at Easter-tide.

At the Kew Gardens, several medicinal plants are now in blossom. In the economic house may be seen the ipecacuanha plant with its condensed cymes of small white flowers just coming into blossom. The Maltese orange and the capsicum present both flowers and fruits. The lime (*Citrus Limetta*) and the cinnamon are in bud, and the West Indian ipecacuanha (*Asclepias curassavica*) is in full flower.

In the open ground the American mandrake, or may apple (*Podophyllum peltatum*) is now just unfolding its leaves and flower buds. In this state it presents a curious appearance, the leaves being folded closely around the leaf stalk so that they look like little closed umbrellas. *Jeffersonia diphylla* is now in full foliage, the flowers being over, and the kidney-shaped leaves form a striking object. *Sanguinaria canadensis*, with its pretty white flowers, and the rosemary may be seen in blossom in front of the No. 2 museum. The leaves of the former on the slightest touch exude drops of fluid of a much more blood-red colour than that of the celandine; indeed, so close is the resemblance that a drop of the juice on the hand might easily be mistaken for blood. The caraway also is in full blossom in the umbelliferous bed, and we are glad to see in the same locality a healthy young plant of the sumbul, carefully tended. In one of the hothouses may be seen a splendid plant of the *Datura sanguinea* of Peru, covered with its handsome orange-red flowers, each of which is about six inches long, and wide enough to admit a full-sized finger. Those who are interested in British plants, may find the following rare plants in blossom:—*Muscari racemosum, Euphorbia hiberna* and *E. pilosa, Fritillaria Meleagris*, and Solomon's Seal. Among less rare plants now in flower may be seen *Geum rivale, Myrrhis odorata*, and *Smyrnium olusatrum*, all of which formerly had their medicinal uses.

Students of botany will be glad to learn that in future there will be no difficulty in obtaining admission to these magnificent gardens before 1 o'clock. The *Gardeners' Chronicle* for April 20th, p. 500, publishes an authoritative statement to the effect that "all persons visiting the gardens for study and improvement of whatever kind may in future, on calling at the Curator's office, signing their names and stating the object of their visit in a book kept for the purpose, enter the garden by the office gate."

For the benefit of those who may not know where the Curator's office is, we may state that it will be found a few doors to the left of the main entrance on the Kew Bridge side of the gardens. Dr. Hooker's letter, which is well worth reading by all who think that the gardens should be opened to the general public at 10 a.m., is published in full. The advantage likely to be taken of such a concession has already been manifested by applications which have been made to the Office of Works for permission to erect in the gardens a photographic establishment and a shooting gallery!

Some interesting remarks on the leaf of *Conium maculatum* formed the substance of a paper recently read before the Linnean Society by Mr. J. Gorham. From observations which he had made it was shown that in a piece of the leaf, one-third of an inch long by one-fifth wide, the veinlets were arranged in exactly the same way as the venation of the entire leaf. This was found to occur in the other umbelliferous plants which were examined, so that it was possible to detect and recognize each from the merest fragment. This is something like describing an animal from a bone. These facts open a new field to students of botany, besides promising to be of valuable service in medico-legal investigation. The relation of the venation of leaves to the branching of a tree may yield more interesting facts upon investigation.

In Edinburgh Botanical Gardens we learn, through the kindness of Professor Balfour, the following medicinal plants are now in blossom:—*Ipecacuanha*, *Asarum Europœum*, *Sanguinaria canadensis*, *Sarracenia purpurea*, *Jeffersonia diphylla*, *Quassia amara*, *Coptis trifoliata* and *Symplocarpus fœtidus*. The curious Californian pitcher plant (*Darlingtonia californica*) is also in blossom. Those who have the opportunity of visiting these gardens should not forget to look at the curious blossoms of *Mantisia saltatoria*, a zingiberaceous plant which derives its generic name from the singular resemblance of the flowers of some of the genus to the mantis insect; the specific name saltatoria is derived from the fanciful resemblance of the flower of this species to a ballet dancer, whence the popular name of "Dancing Girls" is applied to this flower. The curious flowers of *Musœnda frondosa* are also worth examining. Some of the flowers of this cinchonaceous plant produce a white leaf-like sepal, which is remarkable for having several veins converging towards the top of the sepal, instead of the pinnate venation of the leaves, for which reason it is sometimes regarded as a modification of the petiole rather than of the lamina of a leaf.

The present month is perhaps the best time of the year to study the Trilliaceæ, several species of which are now in blossom in the various botanical gardens, as well the curious Herb Paris (*Paris quadrifolia*), which may now be found in blossom in damp woods in several of the Eastern counties. This plant is remarkable for having the parts of the flower in multiples of four, and net-veined leaves, although it is a monocotyledon. The rhizome, which has a pleasant nutty flavour, is said to be poisonous.

From the annual report of the Botanical Gardens at Calcutta, we learn that the Para rubber and vanilla will not flourish there, but that it is intended to try the former in Burmah, and that seedling plants are being now grown for exportation to Burmah. The cultivation of ipecacuanha, although still continued, does not seem likely to be carried on to any great extent.

The crop of the cinchona plantation at Sikkim during 1876–7, according to the Government report, appears to have been a very good one, amounting to 207,782 lbs., and consisting of 201,455 lbs. of dried red bark, and 6326 of yellow and pale bark.

It is intended to discontinue the process of mossing the bark at Sikkim for the future, it not being applicable to that locality.

During the last year 406,600 more plants of red bark were planted.

It may be hoped that the valuable Calisaya of Santa Fé, which has recently been brought to this country, will be tried both at Sikkim and in the Nilghiris,—although the latter district is more likely to prove favourable,—this species having the remarkable property of producing a large quantity of quinine in its young shoots, and being thus most valuable for coppicing.

The operation of stopping or filling teeth is attended with so much discomfort that any improvement of practical value must be a great boon to the suffering public. Dr. Weil, of Munich, has recently advocated the method of first extracting the tooth, filling it and then replacing it. The tooth is only kept out of the socket for one or two hours and the results are said to be excellent, as the teeth so treated ultimately become firmly fixed and can be freely used. It is said to be applicable both to bicuspids and molars. As to whether the replacing of the filled tooth causes much pain no information is given.

Chinese materia medica is well known to include many curious substances, but the following paragraph, extracted from *Nature* will show that the list of curiosities in medicine is by no means exhausted:—"Dr. F. Wong gives us some curious particulars respecting a strange remedial agent used in China for Cynanche tonsillaris. The remedy in question is called How-tsao and is apparently a soft stone not unlike a biliary calculus. It is said to come from Siam, and is worth twenty times its weight of silver. Twenty or thirty grains of this taken in water is thought to be very efficacious, and Dr. Wong mentions having seen a case where this remedy was given and certainly appeared effective after gargles and astringents had been applied in vain. The way in which the structure of the remedy is accounted for is very curious. The story goes that when a monkey is wounded, it picks out the proper medicinal herbs, masticates and applies them to the wound, so that successive layers are in this way laid on so as to form a mass. In time the wound heals, and the lump of dried herbs falls off; it is then picked up by the Siamese and sent in small quantities to China as a drug." From the brief description of the character of this curious remedy it seems probable that it is a biliary calculus like the oriental bezoar. If its properties are found to have a basis in facts, it would be worth while to examine How-tsao for ellagic acid, which is one of the principal constituents of oriental bezoar; the medicinal properties of this acid might perhaps be worth examination.

In France an attempt has recently been made to revive the old reputation of the purple loosestrife (*Lythrum Salicaria*), as an astringent in diarrhœa and all diseases which require a mucilaginous astringent. The infusion is made in the proportion of 30 or 40 parts of the leaves to 1000 of water; the decoction with 30 to 60 parts to 1000 of water. The decoction is used for injections, etc. The powdered leaves are applied to atonic ulcers.

The poisonous properties of the yew tree appear to have attracted the attention of various correspondents of the *Gardeners' Chronicle.* The present number contains a note from Mr. W. Robins, of Slough, who notices the curious fact that the deer crop freely the yew and laurel, but will not touch the rhododendron.

In 'Medicinal Plants' for this month, the following are described and figured, *Garcinia Indica*, *Citrus Bergamia*, *Butea frondosa*, *Carum ajowan*, *Pinus Tæda*, *Pinus balsamea*, and *Alpinia officinarum.* The first is perhaps better known under the name of *Garcinea purpurea*, and is the plant from which "kokum butter" is obtained. The authors state that 'Pharmacographia' errs in describing the embyro as having thick inseparable cotyledons, the fact being that the seed consists almost entirely of a thickened radicle, at the apex of which is a slight depression indicating the plumule, the cotyledons being entirely absent. *Alpinia officinarum*, the source of the galangal root of commerce, has not been figured before. Although many of the plants which have been figured from time to time in 'Medicinal Plants' have been figured elsewhere, yet it is only in works which are by no means easily accessible, except to the dwellers in large cities, and hence this work should form a standard work with every pharmaceutist.

Amongst recently introduced preparations may be mentioned one that is now being advertised in the American journals as "Ingluvin, from the Ventriculus Callosus Gallinaceus; superior in all cases to pepsin from the hog." This substance is prepared from the gizzard of the domestic fowl, and is described by Dr. Shelley, of Philadelphia, and Professor Wallace, of Jefferson Medical College, as a specific for vomiting in pregnancy. It is also said to be a powerful and reliable remedy for indigestion, dyspepsia, and in all cases where pepsine or pancreatine is usually employed, but to give more certain results. This would appear to open up a new field for experiment, and already there has been announced an analogous preparation from the stomach of the ostrich!

It will be remembered that Berthelot prepared a number of extremely interesting conjugated compounds by the reaction of fatty and other acids upon certain sugar-like principles. Thus from mannite and stearic acid he obtained tetrastearomannide and hexastearomannide, bodies resolvable into mannitane and stearic acid by boiling with dilute acids. Again he prepared a number of so called saccharides and glucosides; for instance, by the following reaction, $C_6H_{12}O_6 + 2C_4H_8O_2 = C_{14}H_{22}O_7 + 3\,H_2O$, he obtained butyric glucose.

Recently L. Prunier* has obtained similar compounds from quercite and butyric and acetic acids. The substance termed by him monobutyrin decomposes as follows under hydrating influences:—

$$C_6H_{10}O_4(C_4H_8O_2) + H_2O = \underset{\text{Quercite.}}{C_6H_{12}O_5} + \underset{\text{Butyric Acid.}}{C_4H_8O_2}.$$

Tributyrin is similarly affected:—

$$C_6H_6O_2(C_4H_8O_2)_3 + H_2O = C_6H_{12}O_5 + 3\,C_4H_8O_2.$$

So also is pentabutyrin, $C_6H_2(C_4H_8O_2)_5$. Prunier also prepared the corresponding acetins in a similar manner, namely, by heating quercite with the acid in sealed tubes at about 110° to 112° for twelve hours.

* *Compt. Rend.*, lxxxiv, 1318.

C. Reischauer* has analysed a substance ("nucin") prepared from the green shells of walnuts (*Juglans regia*), and assigns to it the formula $C_{36}H_{12}O_{10}$. It is soluble in alcohol, and forms a copper compound, which is of a bronze colour and is crystalline. Its composition is not yet worked out.

From determinations of the vapour density of cantharadin, J. Piccard† gives to this substance the formula $C_{10}H_{12}O_4$. Its vapour density is about 6·5 and its fusing point 218°. Under the influence of hydriodic acid it forms a derivative of identical ultimate composition with cantharadin, but differing in its properties. Its constitution has not been thoroughly established by the author, who terms it cantharic acid, forming salts of the general formula $C_{10}H_{11}O_3OR$.

It has been recently suggested,‡ by Mr. Thomas Douglas, that gas lime could be utilized for the production of ferrocyanides. He arrived at this conclusion from an experiment in which he mixed gas lime with 5 per cent. of carbonate of sodium, extracted with water, and evaporated the solution to dryness. The dry extract when mixed with iron filings, and heated in a covered crucible, seems to produce ferrocyanide of sodium. If this process for utilizing the sulphocyanates in gas lime could be carried out commercially, it would incidently free the gas lime from at least a part of its sulphur compounds.

In a paper§ read before the Society of Public Analysts, Mr. A. Wynter Blyth explains certain discrepancies exhibited in the analyses of milk made by different analysts, as due to a decomposition of its albuminous constituents with the production of fats. In this way, a milk analysed at two different periods would yield different amounts of fat on analysis, and thus the proportion of the other constituents would be distorted. The author quotes an old memoir of Blondeau in confirmation of his results. M. Blondeau showed that Roquefort cheese when kept undergoes certain changes, which are initially attributed to mycoderms; these changes result in the production of fat, so that a sample of cheese, containing originally 1·85 per cent. of fat, showed after keeping two months as much as 32·30 per cent. of fat, with a corresponding diminution in the amount of caseine, viz., from 81·03 per cent. to 43·28 per cent. This subject is interesting, and in view of our slight knowledge regarding the chemical constitution of albuminous substances, and recent attempts to elucidate their structure, deserves more complete study.

The discovery of sulphocyanides in saliva is due to Tiedemann and Gmelin, and some time afterwards Leared found indications of their presence in urine and other liquids. These observations were confirmed by Gschleiden (in 1870), who estimated the sulphycyanic acid in urine at about 0·0225 grm. per litre. It is somewhat startling in face of these facts to find the *Medical Record* of to-day referring to Gschleiden's observations as recent ones. Our contemporary has, moreover, corrupted his name to Gschleidew, and points out that Munk arrived at the same results independently. It is more to the point to observe that recently Thudichum || seems to have disproved every statement made by Gschleiden,

* *Deut. Chem. Ges. Ber.*, x, 1542–1548.

|| 'Pathology of the Urine,' p. 300.

who relied upon reactions of sulphocyanic acid which are by no means peculiar to that body.

In the *Quarterly Journal of Science*, for April, there is contained a most interesting article on the "Economy of Nitrogen," in which the anonymous author describes the various sources of certain elements either of great use to mankind in a commercial sense or essential to his subsistence by entering into the composition of foods. He then enters into the question of "waste," as, for instance, of phosphorus in the use of matches, and of nitrogen in gunpowder, and adduces strong evidence to show that our stores of these materials will presumably in the future, distant though that may be, run short. Many of the forms which waste products take are so far removed from the original and available forms that, in spite of the indestructibility of matter, our supplies may be cut off through mere lack of time (if not for any other reason) required to transmute waste substances into available sources. The author, after warning of these and other matters, concludes as follows :—"Meantime, to economize nitrogen, phosphorus and potash, to recover these bodies from waste, and to find substitutes for their present profligate applications, is the most sacred task which the chemist can take in hand. The reforms which may shield us from occasional pestilence sink into insignificance compared with those required to guard posterity, in a not very remote future, from chronic scarcity, from recurrent famine, and from a wolfish struggle for food, in which man must relapse into a worse savagery than that from which he has emerged."

Our consolation is that, before to-day, supplies of certain materials have been cut short, and yet man's ingenuity and chemical knowledge have yielded new sources. When during the French Revolution nitre could not be got for love or money, men extracted the common earth under their door-steps with water in order to obtain the small but widely distributed quantities thus available; and when a monopoly of the sulphur trade was granted to a house in Marseilles, technology found pyrites to be a suitable material; moreover nearly two hundred patents were secured in the meantime to obtain sulphur from gypsum.

The *Brewers' Guardian* is reprinting a translation and abridgment of Dr. Lintner's article on the Manufacture of Beer, from Hofmann's 'Reports on the Recent Development of Chemical Industries,' and the following table showing the production of beer and the consumption per head is taken from this article. The table refers to the year 1872 :—

	Production of Beer in Litres.	Consumption per Head in Litres.
Bavaria	920,700,000	219
Wurtemberg	280,100,000	154
Belgium	700,000,000	145
Great Britain and Ireland	3,568,200,000	118
Saxony	154,500,000	60·5
Baden	41,900,000	56
Alsace Lorraine	83,600,000	51
Other German States	200,300,000	48·5
Prussia	972,200,000	39·5
Holland	135,600,000	37
Austrian Hungary	1,221,200,000	34·5
Sweden and Norway	77,300,000	27
North America	998,200,000	26
France	700,000,000	19·5
Russia	974,000,000	14

It is so common now-a-days to write and think of beer as a mere alcoholic solution, produced by the fermentation of sugar, that some very important matters are nearly left out of consideration. Beer not only contains alcohol and certain other comparatively simple ingredients, but it likewise contains a mass of extractives of the nature of which chemists are as ignorant as they are of the extractives derived from muscular tissue or meat, and it is really a question how far the substances comprised in this list take part in producing the effects which collectively are termed drunkenness. If anyone takes the trouble to free beer from alcohol by distillation, it will be found that although the residual solution is not nearly so pleasant to the taste, it is, when consumed, still capable of producing extraordinary effects on the human system. That these effects are due to the presence of alkaloidal or other matters there can be little doubt, and when it is remembered what powerful influences certain alkaloids exert in the human body, it is still further surprising that scientific enterprise should not extend to the elucidation of these interesting and important matters. That alkaloidal principles do exist in beer is beyond question, and if anyone doubts this statement a simple experiment will remove the doubt and substitute conviction in its place. The experiment referred to consists in the precipitation of beer by means of a solution of phospho-molybdic acid acidified with nitric acid. There are some persons who cannot drink a single glass of mild ale in the day without feeling certain effects—giddiness and so on—which are ordinarily comprised in the phenomenon of intoxication, and it would be absurd to suppose these effects due only to the small percentage of alcohol that is contained in the beer. It thus arises that in all probability there may be produced a most intoxicating beer quite free from alcohol.

But to pass from the consideration of beer to that of another and equally favourite beverage, namely, tea.

Professor Sewell, of Quebec, has recently made a communication to the Surgical Society of Ireland, in which he states that green tea counteracts the poisoning effects of opium. There are many points, however, requiring confirmation and explanation upon this subject, and Dr. Cameron, of Dublin, has undertaken some experiments to better decide them.

The *Medical Press and Circular* (April 10) calls attention to a disease to which sorters of alpaca, camel-hair, and mohair are exposed. This disease, known as "sorters' disease," oftentimes proves fatal to persons without the exhibition of any previous distinguishing symptoms; that is to say, it acts so suddenly at times that men who are apparently in good health in the morning are dead by evening of the same day. It seems to be a preventible disease, resembling septicæmia in some respects, although its precise nature and cause are unknown. If the cause were known, then the *Medical Press* believes that chemistry might assist by submitting the fleeces to some agent which would destroy the poison without injuring their texture or value.

Before taking up the thread of the "Dispensing Memoranda" it may be as well just to refer to the suggestions of some correspondents with reference to one or two prescriptions which received the usual notice in last month's summary. One of the prescriptions referred to (No. 72) was composed of calomel, Dover's powder and bismuth with oil of caraway, and for these ingredients a good excipient was required to form a satisfactory pill; more than one correspondent recommended ext. gent. for this purpose. A little reflection must convince a dispenser that a medicinal extract of the Pharmacopœia, like that of gentian, is inadmissible as an excipient, except in those cases where it may be specially ordered by the writer. If made use of in the prescription just referred to, the patient in taking the pills would be very likely to detect the presence of a bitter that had no place in the prescription, more especially if the pills had been previously prepared with a more suitable excipient. Glycerine of tragacanth may be used, and to its use there can be no objection.

Again, in the carbolic acid and lead lotion with rose water (No. 91) it is remarkable that so many correspondents should have overlooked the necessary formation of carbolate of lead, and have attributed the deposit to carbonic acid present in the rose water. One or two experiments would have determined this point, and it is to be regretted that this course is not more frequently adopted in the presence of a difficulty such as the one in question.

Several replies have been received with reference to Lister's boracic acid ointment (No. 80), and an acknowledgment is due for the practical suggestions contained in them. It was an error to conclude that the principle generally applicable to compounds of this nature, that of solution of the salt, is practicable in this case. The boracic acid must be rubbed very fine and then stirred into the other ingredients previously melted together. From the observations of hospital dispensers on this preparation, perhaps the formula may be considered somewhat of a spécialité in hospital practice.

The glycerole of belladonna also has elicited several replies, and in almost every instance hospital formulæ have been quoted. The object in view in these memoranda columns is rather to shadow forth certain principles that shall assist in guiding a dispenser placed in a responsible position, and in presence of a difficulty, than to issue an unalterable "fiat" that shall assume the character of a dogma. In this instance it is perfectly possible that the glycerole of belladonna, made in accordance with any one of these hospital formulæ, may be a more active and efficient preparation, but in case of inconvenience from an undue absorption of belladonna, the dispenser of the prescription would be in a better position if he had made the glycerole of belladonna in strength corresponding to a formula having official sanction than any other, especially stronger, used in hospital practice, and probably under special circumstances.

The first question for consideration is that of No. 92, Where "magnesia" is prescribed, what preparation of magnesia should be used? On reference to the Pharmacopœia it will be seen that there is only one magnesia, made by calcining carbonate of magnesia, the other is magnesia levis, made by calcining light carbonate of magnesia; this differs from the preceding preparation only in its greater levity.

The prescription No. 93 contains equal parts ext. cinch. liq. and aqua with pot. iodid. The bark is said to separate and stick to the sides of the bottle, violent shaking having no effect upon it. The pot. iodid. should be dissolved in the water and the bark added gradually with repeated shaking. There is a flocculent separation, but this is readily diffused and does not adhere to any extent, or with appreciable tenacity, to the sides of the bottle. There is no necessity for the addition of mucilage; after moderate shaking there will be no difficulty in dividing the doses. Cinchona bark contains very little resin, and the fluid extract being an aqueous preparation a separation of resin as suggested by a correspondent would scarcely be expected.

The inquiry No. 94 is not definitely stated, and this makes a satisfactory reply the more difficult. It would have been better to have sent a copy of the prescription, or to have stated how much carbolic acid was required in each pill. The reply of one correspondent, recommending soap and powdered liquorice root, may be a sufficient answer, if only one drop be required in each pill, but a more satisfactory result will be obtained by using two grains of bread crumb to each grain of crystallized carbolic acid. A correct copy of the prescription should be sent where practicable, as it places correspondents in a better position for replying, and the suggestions offered will generally be the more valuable.

The tinct. sap. virid. co. (No. 95) may be a preparation of soft soap, but it may also be an ingredient in one of those obscure prescriptions which are occasionally met with straying from the special establishment to which they were directed. This one apparently hails from New York, and, if a resident there, may be a representative of elegant pharmacy. It is not quite clear if, as one correspondent has suggested, it is merely a solution of green soap in spirit, why it is called a compound tincture; and further, it is scarcely probable that the bichloride of mercury would be combined with tincture of soap. Neither can it be tr. verat. vir. Most probably it owes its origin to some private formula.

In reply to the question No. 96, relating to oleate of mercury with morphia, correspondents have furnished very detailed replies to which nothing further need be added. It is a satisfactory feature in connection with the "Dispensing Memoranda" that the various questions are being so fully answered by correspondents as on many subjects to leave little for remark in the month's review.

Indefinite preparations are now and then, and probably always will be, met with in prescriptions. A case in point is that of No. 97, where sol. taraxaci is prescribed, there being no official form for this preparation. It may mean succus taraxaci or a solution of the extract, and is very likely a preparation of the latter kept for convenience in dispensing by some practitioner who makes up his own prescriptions. If the dispenser is unable to refer to the writer he would be on the safe side in using the official succus taraxaci; but it must be admitted that the sol. taraxaci is not *evidently* the same as liq. taraxaci, as has been suggested by a correspondent. It may be a preparation of the extract introduced to some members of the profession and made proprietary by certain establishments.

The answer to No. 98 must be sought for in the locality whence the prescription emanated. Lin. opii post Bowes, may be an illegitimate offspring, resulting from the union of the prescriber and the chemist, to which the general name of "bastard forms" would be applicable. "Bow's Liniment" is a preparation enjoying a certain amount of popularity, formulæ for which will be found in the numbers of this Journal for Feb. 19, March 1, and March 8, 1876. The orthography of the name is, however, different. The dispenser in this instance must use his discretion, and in case of any inconvenience or disappointment resulting from the employment of lin. opii, B.P., in lieu of lin. opii post Bowes, the writer will be more to blame than the dispenser of the prescription.

It is very difficult to give a definite reply to query No. 99. For sulphate of quinine to crystallize out of tinct. quinæ is unusual if it be made according to the B.P. and the directions for dissolving the quinine be attended to. The cause must be looked for in some imperfect manipulation, provided that the several ingredients were of the proper quality and strength.

The creasote ♏j in each pill, as in No. 100, may be satisfactorily combined by using bread crumb in the proportion of two grains to each minim of creasote. Should the bread crumb be crumbly a little glycerine of tragacanth will give it a pilular consistence. These pills may be almost immediately silvered.

Aq. menthæ referred to in No. 101 is mint water, the product of *Mentha viridis.* Mint water was formerly more frequently met with in prescriptions than is the case at the present time. Sowerby says "the peppermint was not introduced as a medicinal plant until the beginning of the last century, the green mint being usually preferred by the older physicians." Mint water is still a favourite with some members of the medical profession; at the same time it is just probable that in this instance the writer may have intended Aq. Menth. Pip., but the dispenser without positive knowledge to this effect has no alternative, he must use the Aq. Menth. Viridis.

NOTES ON A FEW AMERICAN DRUGS.*

BY JOHN M. MAISCH.

Pterocaulon pycnostachyum, Ell.—An imperfect specimen of the subterraneous portion of this plant was received from Georgia, where it is known as *Blackroot,* and enjoys some local reputation as a valuable alterative. The plant belongs to the natural order Compositæ, has a nearly simple stem, with decurrent lanceolate wavy-margined leaves, which are smooth above and densely tomentose beneath. The inflorescence is spicate, the imbricated involucral scales are deciduous, the ray florets are white, and the achenes are crowded with a long hairy pappus. The plant grows in the damp pine barrens of the Southern States, from North Carolina to Florida.

The portion used is the rhizome, which is horizontal or oblique in the ground, and when viewed from above has a compact but knotty and somewhat contorted appearance. Its most striking peculiarity is that on the lower side it divides into a number of closely-set tuberous branches, which are nearly perpendicular and somewhat conical, grow to the length of about an inch, and are then suddenly contracted, each into one thin, wiry rootlet of about one to two inches. The rhizome has a thin bark, which is externally of a black colour, internally of a greyish brown, and adheres but loosely to the tough wood, which is greyish or blackish brown, and divided into numerous very narrow wedges, loosely connected by the shrunken, narrow medullary rays from which the tangential surface, after the removal of the bark, assumes a lace-like appearance. The rootlets have a similar character, only the bark is relatively thicker. The recent rhizome branches, from which over-ground stems had grown, are scarcely one-quarter inch in diameter, but on their lower surface show already the disposition of sending off the perpendicular, cylindric-conical branches described, and as the latter increase in size the stem bases become almost obsolete, and are reduced to mere scars, more or less concave. The entire rhizome is inodorous, and the wood tasteless, while the bark has a slightly acrid and peculiar bitterish taste.

"Blackroot" resembles in colour the rhizomes of *Cimicifuga racemosa* and *Leptandra virginica,* both of which are easily distinguished from it by the total absence of the perpendicular tuberous branches, and more particularly the former, by its stout ascending rhizome branches and the cross-shaped disposition of the meditullium of its rootlets; and the latter by the horizontal branches of the rhizome, its hard wood and rather large pentagonal or hexagonal central pith.

In regard to its medicinal properties, Dr. F. P. Porcher ('Resources of the Southern Fields and Forests,' p. 460) says that much use is made of it as an alterative, and that it is supposed to be possessed of decided value; also, that it is well known as the blackroot of the negroes, and is given in the form of decoction (how strong?) several times a day. Nothing is known of its chemical constituents.

Ledum latifolium, Ait.—About nine months ago specimens from a shrubby plant were received from Michigan, in the northern part of which State the Indians claim for it great healing virtues, it being regarded to possess soporific and cathartic properties, and externally used as a sovereign remedy in fevers, sores, bruises and rheumatism. The dry fruit capsules still attached to the plant made it not difficult to recognize it as a member of the Ericaceæ, and the above mentioned species of Ledum. Subsequently, the same plant was received from Canada, with the statement that it was popularly used to some extent and considered a valuable medicine; its supposed properties, however, were not mentioned.

The plant is known by the name of James Tea and Labrador Tea, and occurs in British North America, and in the United States, from New England to Wisconsin and southward to the mountains of Pennsylvania. It occurs in cold bogs and damp woods, grows to the height of 2 to 5 feet, and has alternate leaves about one inch in length, somewhat aromatic when bruised, elliptical or oblong, with an entire somewhat revolute margin, dark-green and shining above, whitish beneath, and covered with a rusty wool. The small white flowers have five or sometimes six stamens, and are in umbels situated at the end of the branches; lateral branchlets with a smooth bark, growing from the base of the umbel. The fruit forms a five-celled capsule, which splits from the base upwards, and contains many minute seeds.

In Redwood's 'Supplement to the Pharmacopœia,' it is stated that the leaves are used for tea, and when infused in beer render it unusually heady, producing headache, nausea, and even delirium, but they have, nevertheless, been used, it is said, in tertian agues, dysentery and diarrhœa.

This little shrub is very similar to the *Ledum palustre,* Lin., which is indigenous to Northern Asia, Eastern and Northern and some parts of Central Europe, and likewise to British America. It differs from the former mainly by its linear-lanceolate leaves, the ten stamens of its flowers and its more oval capsules. It was formerly known as *Rosmarinus sylvestris,* but the leaves are readily distinguished from the rosemary leaves by the dense, rusty, felt-like hairs on the lower surface. The young and fresh leaves have an agreeable aroma and a bitter and astringent taste; the old and dry leaves are less aromatic. They have been employed in intermittent and other fevers, in cutaneous diseases, croup and other complaints.

L. latifolium has been analysed by Bacon, but I have not been able to consult his essay. The other species has been repeatedly examined. The most complete, though now not satisfactory, analysis is by Meissner ('Berl. Jahrb.,' xiii., p. 170), in which, besides the more generally distributed principles, he found notable quantities of

* From the *American Journal of Pharmacy,* February, 1878.

tannin and 1·5 per cent. of volatile oil. Rauchfuss (1796) had previously obtained 3 per cent. of volatile oil. G. W. Grassmann (1831) noticed for the first time the stearoptene, which he obtained to the extent of nearly seven-tenths per cent. of the weight of the fresh plant, and which L. A. Buchner subsequently (1857) subjected to elementary analysis, and found to be a hydrate of a terpene agreeing with the formula $5C_{10}H_{16}.3H_2O$. Willigk also examined the volatile oil, and besides the stearoptene, determined it to consist mostly of a hydrocarbon of the same composition as turpentine. Grassmann's ledum camphor volatilizes readily, its vapour producing headache and vertigo.

It is not improbable that our indigenous species may contain similar principles, and, aside from the volatile oil, may possess the tonic, somewhat astringent and diuretic properties of the leaves of other Ericaceæ.

Dioscorea villosa, Lin.—This is the only representative in the United States of the natural order Dioscoreaceæ, and is known by the name of *wild yam*. A number of species of the same genus occur in the East and West Indies, the most important of which are *Dioscorea alata*, Lin.; the white negro yam, *D. triphylla*, Lin.; the buck yam, *D. trifida*, Lin., or Indian yam, *D. bulbifera*, Lin., the Ceylon white yam and several others comprised in *D. sativa* of Linnæus. They are generally cultivated in tropical countries for their tubers, which attain a considerable size, weighing frequently thirty to forty pounds, and, though quite acrid in their fresh state, are cooked and used as food. They contain starch as their valuable constituent, which appears generally to be about 15 to 18 per cent. of the weight of the fresh tuber, but may occasionally reach 24 per cent., according to Sheir (1847), or according to Grouven (1856) fall to 8 per cent.

The rhizome of the indigenous species has a very different appearance.

The wild yam occurs throughout the United States from New England southward to Florida and westward to the Mississippi, and is quite common in the southern section. It grows in thickets in moist localities, its slender herbaceous stems running over bushes and attaining a length of 10 to 15 feet and more. The plant is diœcious, the greenish staminate flowers are in paniculate hanging bunches, the pistillate flowers in simple drooping racemes. The leaves are quite variable, frequently alternate, but sometimes opposite or even in whorls of four to six; the latter appears to occur oftener in the South. The leaves are broadly ovate, with a heart-shaped base, entire or wavy at the margin, conspicuously pointed, with nine to eleven ribs, nearly smooth above and more or less downy but never villous beneath. The fruit forms a triangular capsule, which is conspicuously winged on the angles, and the pendulous bunches of which are quite striking and make the plant easy to identify.

The rhizome is horizontal, about one half inch in diameter, somewhat flattened from above, repeatedly forked or branched in various directions, so that the entire rhizome covers a space six to twelve inches in diameter, the branches bearing a slight resemblance to ginger. Upon the upper surface at irregular distances are the circular, more or less concave scars, left by the overground stems; beneath and on the sides, at a distance of about half an inch, are the simple wiry rootlets about two to four inches long. Rhizome and rootlets are of a light or yellowish-brown colour, and break with some difficulty, exhibiting a compact white tissue with numerous scattered wood bundles of a yellowish colour. Odour is absent; the taste, at first insipid, soon becomes strongly acrid.

It is regarded to possess antispasmodic, diaphoretic, expectorant and emetic properties, and has, among other complaints, been recommended in bilious colic in the form of an infusion, made with one ounce to the pint, one half being taken at a dose. In Virginia, and probably in other States, it is known among the negroes as *rheumatism-root*, it being considered a sure cure in that complaint.

Continued boiling impairs the acrid properties of wild yam, the principle being either volatilized or altered by heat; it has not been investigated. The rhizome contains also a considerable proportion of starch.

COMPOUNDS OF SALICYLIC ACID WITH ALBUMINOIDS.*

BY FR. FARSKY.

The author has prepared compounds of egg-albumin, casein, fibrin, and syntonin with salicylic acid by several methods. Either the albuminoid and the acid were mixed together and allowed to stand with constant stirring, or the two were combined in a dialyser, or the vapour of the acid was made to act on the finely powdered substance. Whichever method of preparation was adopted, the solid substance was finally extracted by pure ether, which was shaken up with it as long as the filtrate gave a reaction with ferric salts. The albumin-compound was then washed with hot water, and dried in an air-bath at 120—130°.

Analyses showed that on the average 14·16 per cent. of salicylic acid was combined with 85·84 per cent. of the albuminoid, which points to the formula $C_{72}H_{112}N_{18}SO_{22} + 2C_7H_6O_3$. These compounds are found to be quite as easily digestible as the uncombined albuminoids, so that salicylic acid might possibly be used for the preservation of feeding-stuffs.

In connection with the above researches the author has been enabled to make a more accurate investigation of salicylic acid, and he gives the following account of it. It crystallizes from concentrated solutions in slender, almost colourless needles, from dilute solutions in larger prismatic, very hard crystals, often very prettily grouped. If, however, other bodies are present in the solution, and more especially if they are organic bodies, regular crystals are not formed, but, according to the nature and quantity of the admixed body, either crescent-shaped, annular, or tufted forms which scarcely resemble crystals, are obtained.

When the foreign body is removed the acid gradually regains the capability of forming acicular crystals. Freezing the solution also brings about the change. The acid melts at 157·5°, and sublimes at 200°, but even at 80° a considerable quantity volatilizes. Perfectly pure crystals may be obtained by heating a solid body containing the acid, or a solution of the acid, at this temperature in the air- or water-bath. The acid, as is well known, splits up on boiling into carbon dioxide and phenyl-alcohol; but it is quite sufficient to heat the solution of the acid or certain salts, especially in presence of other acids, for a long time on the water-bath, to bring about this change. Hydrated sulphuric acid decomposes salicylic acid only when it is added all at once to the solid acid or its solution.

Permanganate of potassium, especially in presence of sulphuric acid, oxidizes salicylic acid, and among other products of the decomposition are found formic and carbonic acids and water. A similar decomposition is effected by boiling the acid with potassium bichromate and sulphuric acid. If the solution of the acid is heated with the bichromate without addition of sulphuric acid, a body passes over with the steam which has an unpleasant odour; it has not been examined. When salicylic acid is brought into contact with ferric acetate, it combines with the iron, the liquid becomes of a violet colour, and deposits a dirty violet precipitate of $Fe_2H_2O_4$.

This hydrate dissolves in water and forms a golden-yellow liquid, which can be concentrated, but is decomposed by contact with acids, bases, salts, alcohol, ether, and even filter-paper, and rendered insoluble. If, however, the solution of the ferric salt is tolerably concentrated, and especially if the mixed solution is not too acid, a brown salicylate separates out. The acid behaves in a

* *Chem. Centr.*, 1877, 148. From the *Journal of the Chemical Society*, March, 1878.

similar way to lead acetate; lead salicylate is formed, and very strong vapours of acetic acid are evolved in the cold.

Salicylic acid forms three salts with ferric oxide, a normal salt, a basic salt, and a so-called ferric ferro-salicylate.

Compare the author's paper on the "Application of these salts to acidimetry and alkalimetry" (*Wien. Sitzungsber*, lxxiv, 49).

MUSTARD.*

Mustard was, according to the belief of the ancients, first introduced from Egypt, that country which claims the honour of being the birthplace of Ceres, the goddess of seeds, and Æsculapius, the god of medicine, through whose means this plant was made known to mankind as an agreeable and wholesome herb in its green state; while the seed was used as a medicine, and occupied the first rank among alimentary substances which exercised a prompt influence on the brain. Mustard is mentioned by Pythagoras, and was employed in medicine by Hippocrates, B.C. 480. Pliny states that there were three kinds of mustard cultivated in his day; the first of a thin and slender form, the second with a leaf like that of the rape, and the third with that like the rocket. The best seed, he says, was imported from Egypt, but that this plant grew in Italy without sowing. The Romans made great use of the seed in medicine; the oil extracted from it, mixed with olive oil, was used by those who suffered with stiffness of their limbs after a cold bath. Pounded with vinegar it was employed as a liniment for the sting of serpents and scorpions, and a dose of it effectually neutralized the poisonous properties of fungi. The Romans, and other nations after them, used to ferment mustard-seed in new wine, which converted it into a kind of inferior brandy, and was known by the name of *Mustum ardens*, burning wine.

The mustard seed mentioned in the Scripture has of late years been a matter of considerable controversy, some authors supposing it to be quite a different plant from the one we are now treating of; but it is generally believed by the best authorities in the present day that the plant referred to was *Sinapis nigra*, the common mustard, which is indigenous to Palestine, as it is to Britain. Dr. Thompson, in his 'Land and the Book,' records that he has seen this plant as tall as the horse and his rider in the rich plains of Acre.

"As small as a grain of mustard seed," appears to have been a proverbial expression for any small object among the Jews; and this seed, which was the smallest the husbandman was accustomed to sow, produced the largest results by becoming the greatest of the husbandman's herbs.

We have no record when mustard was first used in this country, but in the household accounts of the thirteenth and fourteenth centuries we find that mustard was known to our forefathers under the name of "Senapum," and appears to have been used in large quantities, for in that interesting Household Book of the Earl of Northumberland, in the reign of Henry VII., it is stated that 160 gallons of mustard-seed was the allowance per annum to his servants and retainers. In those days the seed was not manufactured, but brought to table whole, when it was bruised and mixed with vinegar, according to the taste of the eater. It was not only used as a condiment, but also, no doubt, for medicinal purposes. Tusser, who wrote his 'Five Hundred Points of Good Husbandry" in the reign of Queen Mary, says in the direction for February—

"Where banks be amended or newly upcast,
Sow mustard-seed after a shower be past."

From this it appears that mustard was cultivated as a field crop; we also find it mentioned as an agricultural produce in Rogers's 'History of Agriculture and Prices in England,'' as far back as 1285. It must then have been *S. nigra*, black mustard, or *S. arvensis*, the charlock, for Gerarde tells us that the garden mustard, which produces the whitest of seeds, had not become common in the days of Queen Elizabeth, but that he had distributed the seed into different parts of England to make it known. He says, "Mustard makes an excellent sauce, good to be eaten with gross meats, either fish or flesh, because it promotes digestion and sharpens the appetite." Thomas Cogan, M.D., of Manchester, who published his 'Haven of Health' in 1605, says, "The force of the seed is well perceived by eating mustard, for if it is good in making to weep we are straightway taken by the nose and provoked to sneeze, which plainly declareth that it soon pierceth the brain. Wherefore as it is a good sauce and procureth appetite, so it is profitable for the pulse, and for such students as be heavy-headed and drowsy, as if they would fall asleep with meat in their mouths. And if any be given to music, and would fain have clear voices, let them take mustard-seed in powder, work the same with honey into little balls, of which they must swallow one or two down every morning fasting, and in a short time they shall have very clear voices." Shakspere mentions mustard as a condiment in his play, "Taming the Shrew," act iv., scene 3, where *Grumio* says to *Katharina*, "What say you to a piece of beef and mustard?" It is also mentioned in his play "As You Like It,'' in connection with pancakes (act i., scene 2). In Evelyn's time, Tewkesbury was famous for its mustard. The seed, Coles tells us, in 1657, used to be ground there and made up into balls, which were brought to London and other remote places as being the best the world affords. Mustard used formerly to be largely cultivated and manufactured in the county of Durham; but until the year 1720 the seed used to be pounded in a mortar and coarsely separated from the black integuments of the seeds, and in that rough state prepared for use. About the year mentioned an old woman of the name of Clements, resident at Durham, conceived the idea of grinding the seed in a mill, and to pass the meal through the several processes which are resorted to in making flour from wheat. The secret she kept for many years to herself, and in the period of her exclusive possession of it supplied the principal parts of the kingdom, and in particular the metropolis, with this article; and George I. stamped it with fashion by his approval. Mrs. Clements used to travel twice a year to London for orders, and was able to pick up a small fortune. From this woman's residence at Durham, it acquired the name of "Durham mustard" (*Mechanics' Magazine*, vol. iv., p. 87). The seeds of *Sinapis arvensis*, charlock, and *Raphanus raphanistrum*, the wild radish common in our cornfields, are often sold and used as a substitute for mustard-seed. The seed of the black mustard, like that of the wild sort, and also of the wild radish, if sown below the depth of three or four inches, will remain in the ground for ages without germinating: hence when once introduced it is difficult to extirpate. Whenever they throw the earth out of their ditches in the Isle of Ely, the banks come up thick with mustard, and the seeds falling into the water and sinking to the bottom will remain embalmed in the mud for ages without vegetation (Loudon's 'Encyclopædia of Agriculture').

Sinapis alba appears to be a native of the more southern countries of Europe and Western Asia. It is now cultivated not only as a garden herb, but is grown very largely as an agricultural crop, chiefly as food for sheep or to be ploughed in for manure in its green state. Mustard is extensively cultivated in the Fen lands of Lincolnshire and Cambridge, also in Essex and Kent. Its medicinal properties are well known; in its action it is an irritant, stimulant, emetic, and stomachic.

Some authors think *Sinapis* is derived from *sino* to hurt, and *opis* the eyes, from the pungency of the plant causing the eyes to water; others from the Celtic *nvp* (modern

Gaelic *neup*) a turnip, which belongs to this tribe. Our word "mustard" is derived from the French *moutarde*, but in early times it was, both here and on the Continent, *sauve* or *seneré*. Some authors assert that the etymology of this plant was changed from the following circumstance. In 1382 Philip the Bold, Duke of Burgundy, was marching against his rebellious subjects of Ghent, and the city of Dijon, which traded largely in *seneré*, supplied him with a thousand men-at-arms, for which service the duke granted that city many privileges, amongst others that of bearing his arms, with his motto "*Moult me tarde*" in old French (I long or wish ardently), which was carved on the principal gate of Dijon. By some accident the middle word was destroyed; the other two, *moult tarde*, caused many a smile at the expense of the citizens, and in derision the *seneré* in which they traded was called *moutarde*, a name it has preserved ever since.

IODIDE OF ETHYL, OR HYDRIODIC ETHER.*

A communication made recently to the Academy of Medicine by M. G. Sée has directed attention to the iodide of ethyl or hydriodic ether, a body of which the therapeutic action has not hitherto been much studied. In 1850 M. Huette briefly indicated the advantages attending its use as an inhalation in phthisical dyspnœa, but M. Sée has extended the inquiry in a different direction and finds that in asthma inhalations of iodide of ethyl produce most remarkable effects.

Iodide of ethyl was discovered in 1825 by Gay-Lussac; and is represented by the formula C_2H_5I. It is a colourless liquid, having a very strong peculiar ethereal odour and a sp. gr. of about 1·95; it commences to boil about 72° C., and inflames with difficulty. It decomposes slowly in contact with air and more quickly under the influence of sunlight, becoming coloured through iodine set free.

In preparing iodide of ethyl according to Wurtz's method 25 parts of alcohol are introduced together with 7 parts of phosphorus into a flask; to the neck of the flask is fitted a prolongation nearly filled with iodine and coarse fragments of glass; the orifice of the prolongation is closed by a cork, through which passes one end of a glass tube, the remainder of which after a slight curve is enveloped in a Liebig's condenser. The flask is heated in a water-bath and upon distillation of the alcohol the vapour after condensation flows back into the prolongation where it dissolves iodine before falling into the flask. There under the influence of the iodine and the phosphorus the alcohol is decomposed, iodide of ethyl being formed and an oxygen compound of phosphorus. When the whole of the iodine has been dissolved, indicated by the condensed liquor falling into the bottle colourless, the operation is stopped and the product in the flask separated from any excess of phosphorus for purification. The precautions necessary during the operation are to regulate the heat so as to produce a gentle ebullition and to use a relatively capacious vessel.

M. Personne substitutes amorphous for ordinary phosphorus, using 30 parts of phosphorus, 120 parts of absolute alcohol and 100 parts of iodine. The phosphorus and alcohol are placed first in a tubulated retort, next the iodine in two successive portions at a minute's interval; the mixture is then distilled and condensed. In this way, according to Personne, a kilogram of hydriodic ether may be obtained without danger in less than an hour.

Prepared by either method the product requires to be purified before use in medicine. This is done by redistilling it over a water-bath, shaking the distillate with water and then with an alkaline solution, dehydrating it over calcium chloride, and submitting it to a final rectification.

At present iodide of ethyl is only administered in inhalations, 6 to 10 drops being used six or eight times a day against attacks of asthma.

SAPO VIRIDIS.*

BY HERMAN BETZ.

This preparation is used to some extent in Europe, and many pharmacists here are obliged to keep it for their customers, who make use of it in itch and allied affections, for which it is by some considered quite an efficacious remedy.

As found in the market, it is often very impure, being prepared from common animal fats and coloured with various substances. Animal fats are not advisable for this purpose, but any vegetable fatty oil, such as oil of hemp or linseed can be very properly used. In countries where oil of hempseed is a common article of commerce, green soap is usually made from this oil, and is obtained of a nice dark green colour.

One reason why green soap in this country is so often adulterated may be found in the scarcity and high price of oil of hempseed. Oil of linseed has the same properties in making a soap for the purpose before mentioned, and on account of its cheapness would not offer so much temptation for adulteration; it would be advisable to use it altogether, when we would always have a uniform and reliable preparation. As it is now, one can hardly find two samples alike.

In making green soap, one or two points have to be taken into consideration. In the first place the colour; this green colour is one of the most difficult to obtain from vegetables. I have made a number of experiments, and found none to answer so well as the green colouring matter precipitated from a solution of indigo by lime.

Another point is the disagreeable odour which green soap usually has, but this is easily overcome by a few drops of essential oil, for instance, the oil of citronella.

The following formula may be found useful in preparing the soap:—

Take of Oil of Linseed, U. S. P.,
Solution of Potassa . . . . āā Oi.
Colouring Matter . . . . . q. s.
Oil of Citronella . . . . . gtts. x.

Place the oil and potassa in a porcelain dish; mix thoroughly and boil with a regulated heat until the mass becomes thick or stringy; then add the colouring matter and the oil of citronella, with constant stirring.

If the oil is perfectly saponified the mass must be homogeneous and transparent; opaqueness may be due to want of water, or to an excess of fat, or of solution of potassa. The first and the last can be remedied by a small quantity of water, and if the proportion of oil was too large, an addition of solution of potassa will render the mixture clear.

ATROPIA AND DATURIA†.

A. Poehl has investigated the cause of the well-known and generally acknowledged difference in the medicinal activity of commercial atropia and its salts, which Hager has been inclined to attribute to the presence of another alkaloid, probably belladonnia. The supposed chemical identity of atropia and daturia, asserted by Planta, has led to the practice of preparing atropia not only from the roots and leaves of belladonna, but, likewise, from the leaves and seeds of stramonium. Poehl has recently again examined the two alkaloids prepared by himself and found the following differences:—

Atropia is optically inactive, but daturia turns polarized light to the left, its specific rotating power being 14·12°. Atropia salts are precipitated by platinic chloride, but daturia salts are not affected by the same reagent. Atropia salts are not precipitated by picric acid, which, however, precipitates daturia salts. The two alkaloids are therefore chemically not identical, and the difference in the physiological action of commercial atropia is doubtless due to the absence or presence, in larger or smaller proportion, of daturia.
