NOTE ON THE DISTRIBUTION OF THE ALKALOIDS IN CINCHONA TREES.

BY DAVID HOWARD, F.C.S.

In the *Pharmaceutical Journal* of June 26, 1875, I called attention to the constant presence of quinidine in renewed bark of *Cinchona succirubra* and *C. officinalis*, and in the root bark of *C. officinalis*, in much greater quantities than in the natural stem bark. Since that time I have had many opportunities of confirming those observations, the renewed bark of both species invariably showing a greatly increased percentage of this alkaloid. I find, however, that by very careful testing of considerable quantities of the alkaloid from the *C. succirubra* it is possible to obtain quinidine in quantities from a minute trace to ·06 per cent. of the bark in that from Ootacamund, Darjeeling, and Java.

Recent importations of the root bark of *C. succirubra* and *C. officinalis*, from Darjeeling, and of *C. succirubra*, *C. Ledgeriana*, and *C. Hasskarliana*, from Java, have given an opportunity to extend our knowledge of root bark. The specimens from Darjeeling are of special value, as the root, stem, and branch bark sent over together may safely be taken as representing the produce of the same trees, whereas we have no information as to which of the various parcels of stem bark sent from Java the small quantities of root bark sent with them belong.

In examining the root bark from Darjeeling we are at once struck by the high percentage of alkaloids, which is in all cases much greater than that given by the stem bark of the same trees, usually in the proportion of about eight to five, and by the great difference in the proportion of the different alkaloids in the stem and the root.

In all the specimens that I have examined of the *C. succirubra*, the great increase is in the dextrogyrate alkaloids, quinidine and cinchonine, and to a small extent in the slightly dextrogyrate amorphous alkaloid. The percentage of quinine and cinchonidine in the bark averages slightly less in the root than in the stem, but more than in the branches; but the total variation in these alkaloids between the stem and root of the same tree is much less than between different samples of either from different plantations; the percentage of cinchonine, on the other hand, seems invariably in the root bark from twice to three times as great as that in the stem bark; and that of quinidine is increased from the minute quantity I have mentioned to ·2 to ·3 per cent.

The increase of the amorphous alkaloids is much smaller, being usually in the proportion of eleven to ten.

A comparison with the quill bark from the smaller branches shows even more decidedly this difference in the distribution of alkaloids. Not only do we find the total quantity of alkaloids much less than in the stem bark, but the proportion of the dextrogyrate alkaloids is distinctly less. One example will suffice to illustrate these remarks as well as the whole series, which all present similar variations; and I therefore add the percentage of alkaloids in the branch, stem, and root bark from one plantation, and the percentage composition of the alkaloid of each.

The composition of the alkaloid in the root fibre shows, as will be noticed, an even higher percentage of quinidine than that of the root bark. It is impossible to separate the bark from the wood in these small roots, which are from the thickness of a quill to a mere fibre, and therefore impossible also to give the percentage of alkaloids in the bark without the woody portion.

	Branch.	Stem.	Root.	Root Fibres.
Total alkaloid . . .	3·3	5·5	7·6	2·0
Composed of :—				
Quinine	23·5	20·2	11·5	13·0
Quinidine	·6	·6	2·9	11·4
Cinchonidine . . .	25·3	23·6	19·9	11·7
Cinchonine	19·4	32·8	47·3	46·7
Amorphous	31·2	22·8	18·4	17·2

The crown bark from Darjeeling is interesting both in its resemblance to and difference from the red bark. This species has not flourished there; a large proportion of the trees died, and those that survived were stunted and weakly. The stem bark is of fair quality, though far inferior to that grown at Ootacamund, yielding 3 to 4 per cent. of alkaloid, of which 60 per cent. is quinine, with small quantities of quinidine and cinchonine. The root bark contains about twice as much total alkaloid, of which 50 per cent. is quinine, 9 per cent. quinidine, 9 per cent. cinchonidine, and 16 per cent. cinchonine; the increase in the quinidine and cinchonine being even more marked than in the case of the succirubra.

The root barks from Java which I have examined of the *Cinchona succirubra*, *C. Ledgeriana*, and *C. Hasskarliana*, all show the same tendency to the development of the dextrogyrate alkaloids. As has been mentioned, we are not informed what stem bark belongs to the root bark sent over, but it is interesting to observe that in each case the root bark contains more of these alkaloids than any single specimen of stem bark of the same species, and greatly more than the average.

Thus, in the *C. Ledgeriana* the increase of alkaloid in the root is very slight, but the proportion of quinidine is doubled, and of cinchonine trebled, the amorphous alkaloid being also increased.

In the *Hasskarliana* the total alkaloid is decidedly increased, the proportionate increase of the dextrogyrate alkaloids being similar to that in the *Ledgeriana*. In both these species the quantity yielded of these alkaloids is but small, but the marked increase is not less interesting on that account. In the *C. succirubra*, also, the increased quantity of alkaloid in the root is chiefly cinchonine, the quinidine increasing from ·01 to ·05 per cent.

There has been no opportunity of comparing the root bark of the cinchonas from Ootacamund, for the great success which has attended the system of renewing the bark puts the destruction of the trees out of the question; but it is interesting to observe that the specimen of root bark from *C. officinalis* from this district, which I described in 1875, shows an increase in the dextrogyrate alkaloids equal to that in the *C. officinalis* from Darjeeling; there is also an increase in the quinine, but much less than in the Darjeeling bark.

A specimen of root and stem bark from the Wynaad district has reached me. In this case the total alkaloid is increased from 5·0 per cent. to 6·5 per cent., the quinine being diminished and the cinchonidine increased; but, as might be expected, the cinchonine is increased from 2·2 per cent. to 2·8 per cent., and the quinidine from a trace to ·3 per cent.

It seems, therefore, that there is an invariable tendency in the bark of the root of the various species of cinchona to produce the dextrogyrate alkaloids in greatly increased proportions, and this is the more noteworthy as the production of the lævogyrate alkaloids in the root bark varies exceedingly, according to the species and habitat, being sometimes greater and sometimes less than that in the stem bark of the same trees.

The same tendency is shown in a much slighter degree by a comparison of the bark of the branches with that of the large stems, the proportion of the cinchonine and quinidine increasing as we approach the root more rapidly than that of the quinine and cinchonidine; but it is not till we reach the root that we see the sudden and well-marked change in proportion of the alkaloids that we have been considering.

The constitution of the alkaloids of the renewed bark affords curious points, both of resemblance and contrast to that of the root. There is seen in the renewed bark also an increased yield of alkaloids, but in this case the increase of the more oxidized alkaloids, quinine and its isomers, is accompanied by a distinct diminution of cinchonine and cinchonidine.

This is most evident in the *C. succirubra*, the proportion of quinine and cinchonidine being inverted by the process, while the slight diminution of the cinchonine is accompanied by an increase of the quinidine from ·03 per cent. to ·14 per cent., but the same change takes place in the bark of the *C. officinalis*, where the cinchonidine almost disappears, and the quinidine is markedly increased in quantity, the amorphous alkaloid being in each species increased by the process.

The renewing of the bark has only been carried on as yet on the Neilgherries, but it is to be hoped that the great commercial success which has attended the experiment will lead to its adoption, if practicable, elsewhere, when we shall see if the modification of the alkaloid follows the same rule under all circumstances.

The variations shown by the *C. succirubra*, under the influence of climate and soil, are also very interesting. This species of cinchona alone seems to be sufficiently hardy to adapt itself to varied circumstances, growing alike at Darjeeling where the other species have proved almost total failures, in the Neilgherries where the climate seems the best suited for the *C. officinalis*, and in Java in the habitat so singularly favourable to the *C. Ledgeriana*.

The proportion of the alkaloids varies, however, very distinctly under these varied circumstances. Except under the artificial treatment of renewing the bark, it is never rich in quinine, but the cinchonidine and cinchonine show very interesting variations.

In Java the cinchonidine predominates in a most marked degree. On the Neilgherries, though cinchonidine is still predominant cinchonine shows an increase. On the Himalayas the bark shows a deminished yield of cinchonidine, but a marked increase of cinchonine and amorphous alkaloid.

Not having been able to get particulars of the various elevations at which bark is grown in Ceylon, I cannot speak with certainty as to the different specimens obtained from that island, but as far as I can judge, the bark from the lower elevations approximates nearly to that from Darjeeling, while the higher plantations give bark of similar characteristics to that from Ootacamund.

All these considerations point out the great care that should be exercised to choose suitable situations for cinchona plantations, as well as the importance of selecting the best species for cultivation. The experience of the plantations in Java shows that under the most favourable circumstances the wrong tree will not produce rich bark, and that of the Darjeeling plantations shows that the right tree in the wrong situation will either dwindle away or produce a distinctly inferior bark.

The result of cinchona cultivation at Darjeeling thus agrees with the experience earned in some districts of South America, somewhat similarly situated in too damp a climate at too low an elevation. There also, instead of the calisaya and micrantha barks, rich in quinine, of the higher slopes, we find what are either degenerate varieties or different species, in which cinchonine, and in some cases quinidine, take the place of quinine.

A vast proportion of the "flat yellow bark" now imported is from these regions, and though certainly flat and yellow, resembles in little else the flat calisaya bark of a few years back, and must certainly lead to disappointment if substituted in medicine for the true calisaya.

THE ACTIVE PRINCIPLES OF CALABAR BEAN.*

There is scarcely another modern drug which has been subjected to such frequent and exhaustive investigations as the seeds of *Physostigma venenosum*; but at the same time there is a surprising difference of views and theories in regard to its physiological action. All authors are agreed on *one* property of the drug, namely, that of contracting the pupil, but in all other respects they differ widely. Ever since Fraser's classical investigations (1863)

* From *New Remedies*, June, 1877.

it has been customary to regard the Calabar bean as a poison directly paralysing the spinal cord, and from this view arose its employment as a remedy in tetanus, where it was found (by Watson and others) to be so exceedingly effective that most other previously used remedies were henceforth discarded. But lately statements have been published, in reference to the action of the commercial extract of calabar and of "physostigmin," which would make their usefulness in tetanus appear exceedingly problematical. Rossbach and Nothnagel, for instance, assert that extract of calabar is not a paralysing but a tetanising poison, and the latter adds that it resembled strychnia in so far as its paralysing effect was a secondary symptom depending upon an exhaustion of nerves and muscles by preceding violent convulsions. Martin Damourette thought he had solved the problem by supposing that the drug excited the spinal marrow and paralysed the peripheral nerves. But such compromises, unsupported by evidence, are inadmissible in exact science, and Rossbach was unable to obtain any paralysing effects upon the peripheral nerve with Merck's physostigmin. It was left to chemistry to throw light upon these apparent discrepancies. Hitherto it had been supposed that calabar contained only *one* alkaloid, namely, physostigmia, as Hesse called it, or eserina, as Vé and Leven termed it. But, according to the researches of Harnack and Witkowsky, conducted in the pharmacological laboratory at Strassburg, Calabar bean contains *two* alkaloids, one of which entirely resembles strychnia in its effects, while the other produces the previously known central paralysis. The new alkaloid, named by the discoverers *calabarine* (calabaria), differs from physostigmia by its insolubility in ether, and easier solubility in water; it is also soluble in alcohol. A further difference is the fact that the precipitate produced by potassium iodohydrargyrate in calabarine solutions is insoluble in alcohol. The commercial preparations of calabar are, according to the same authorities, mixtures of the two alkaloids in varying proportions, and therefore produce such discordant effects. Whenever physostigmia preponderates, it appears to suppress the effects of calabarine; this fact explains why most investigators merely took notice of the paralysing effects. On the other hand, there are preparations in the market which scarcely contain any physostigmia at all, as was proved directly by Harnack and Witkowsky in the case of an English specimen. The purest commercial preparation was Duquesnel's eserine, which appears to be absolutely free from calabarine.

Since, therefore, commercial preparations of calabar may contain comparatively large percentages of calabarine, the administration of which is positively injurious and highly dangerous in tetanus, it is desirable to possess a means of control, or to employ preparations which make the presence of the dangerous alkaloid impossible. As the latter is absolutely insoluble in ether, it appears advisable to introduce, in place of the present officinal alcoholic extract of calabar, an ethereal extract, although the same drawback, which Hager points out as inherent to the officinal preparation, is not unlikely to attach to this, namely, a proneness to speedy deterioration. Indeed, physostigmia is very readily decomposed, with formation of Duquesnel's rubeserine, which appears to be formed not only under the influence of alkalies, but even spontaneously, as may be suspected from the change of colour observable in old Calabar beans. Duquesnel's eserine has an especial tendency towards this decomposition, according to Harnack and Witkowsky. But rubeserine cannot contaminate the ethereal extract prepared from the beans, since it is insoluble in ether. (*Pharm. Zeit.*, 1877, Nos. 16, 30.)

In No. 21 of the same serial we find a communication by O. Hesse, commenting on the above article, in which he states that he has succeeded in extracting from Calabar beans a substance crystallizing from alcohol in probably the same form as the so-called crystallized eserine, and appearing to be a much more definite and stable substance than the latter. It crystallizes from ether, chloroform, and petroleum-ether in white silky needles, melts at 133–134° C., is indifferent, and greatly resembles cholesterin and iso-cholesterin in appearance, though not in properties or composition. Hesse also adds that the substitution of an ethereal instead of an alcoholic extract would be of but little use, as Calabar beans contain physostigmia in such a combination that it appears insoluble in and incapable of extraction by pure ether.

The well-known manufacturing chemist, E. Merck, in Darmstadt, has heretofore prepared and sold a substance which was supposed to be the only active principle of calabar, and which he called calabarine, but which was really eserine or physostigmine. He now accepts and confirms the results of Harnack's and Witkowsky's researches, and has put both of the active principles upon the market labelled with their correct names, namely, "*physostigmin*" (or eserine, being the same substance which he formerly sold as calabarine), and "*calabarin*," distinguished by the addition of Harnack's name ("Harnack's calabarin"). *The attention of physicians and pharmacists is particularly directed to this change of appellations.*

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of assistants was held in connection with the above on June 28, at 17, Bloomsbury Square. Mr. A. W. Postans occupied the chair.

The Hon. Secretary pro. tem. read the following report from the Preliminary Committee.

"Gentlemen—The Committee have reason to congratulate the supporters of the movement on their success hitherto. It is only about two months since the projectors determined to put their idea into a practical form by founding a Chemists' Assistants' Association. Donations to defray expenses have been received from eighty-two gentlemen amounting to £10 12*s.* 6*d.* The balance sheet shows the amount in hand to be £3 13*s.* 8*d.*, but this is not the actual state of the fund; there are debts to pay off, viz.: Messrs. Lockwood's account and the reporter.

"The Committee have met several times and considered various ways of rendering the new association a success; the resolutions to be proposed, and the rules, copies of which have been distributed, will clearly show what the promoters wish to do.

"Nearly 1000 circulars have been distributed containing a request for opinions and suggestions to be sent to the Hon. Secretary. Very few replies have been received, but such as have come in have received due consideration by the Committee. Letters of invitation to this meeting have been sent to the principal chemists; replies have been received from several expressing regret that they are unable to attend, and wishing success to the undertaking."

The Secretary announced that Mr. John Williams, President of the Pharmaceutical Society, had forwarded a cheque towards the funds of the Association.

The Chairman in the course of his introductory remarks said the meeting that evening was one of unusual interest and pleasure, and also for congratulation specially to the committee and honorary secretary, who had so persevered in the preliminaries of organization as to steer the ship safely at last into the time-honoured Lecture Theatre of the Pharmaceutical Society. He advised the members to avoid all reference to or interference with the early closing movement, and to banish trades unionism entirely from their debates. In order to do young men good, it was necessary to bring them together and make them feel their desires and wishes to be one—and this new society would by its social gatherings help on and develop good work. He considered the meetings of the Pharmaceutical Society all that could be desired in their way, but knew that after business, assistants liked to be away from employers and have a little society of their own to feel free from restraint. He referred to an association which had existed about eleven years ago, supported by gentlemen from Messrs. Bell's, Corbyn's, Allen's, Savory's, Morson's, etc., from whose meetings much good had resulted, although conducted under great disadvantages. How much more might be done by the new association, which he trusted would have the support of all employers. He told those present that the meeting was intended to give them, one and all, an opportunity to express their opinions, and to simplify matters he drew their attention to several points he thought they should discuss. He suggested that some of their meetings should if possible be held at Bloomsbury, that their rooms should be supplied with daily papers, and the refreshments be confined to tea and coffee.

Mr. Biddiscombe thought that all assistants had at one time or another felt the want of a meeting place, especially during their weekly or bi-weekly relaxations from their duties. He had long been interested in the matter, and tried some two years ago to establish an association similar to the one now proposed. Numerous obstacles had presented themselves, and objections had been raised as to its usefulness. One objection was that there was no need for it, as the Pharmaceutical Society supplied all the wants that assistants ought to feel; another that London assistants were so migratory. These he trusted had been removed and he now asked those who had reached the top of the tree in assistantship to remember the time when they would have appreciated the formation of an Association for Chemists' Assistants. He begged to propose, "That this meeting feels the desirability of an organization for the purpose of social intercourse and promotion of good feeling among chemists' assistants, and the discussion of all matters affecting their welfare."

Mr. Stephenson, in seconding the motion, thought that had present employers had social meetings, such as this Association was intended to produce, there would be much less jealousy now, and less difficulty about the early closing matter.

Mr. Princep proposed the second resolution—"That this want will be best supplied by the establishment of an association to be designated 'The Chemists' Assistants' Association,' which shall provide rooms for the occasional discussion of scientific subjects, and at other times to be used as reading and smoking rooms by the members." He said associations of this kind existed in many country towns and were productive of much good, promoting good feeling not only among assistants but also between employers and assistants. He accounted for the fact that no association existed in London by stating that the majority of assistants had their time so fully occupied by business that none was left to think of organization, or that they were too indifferent. He thought they required the services of Dr. Ox with his oxygen to instil a little life into them. A letter had been read from Mr. Greenish suggesting the amalgamation of the new Association with the School of Pharmacy Students' Association. He was certainly in favour of such amalgamations, if practicable. It would be to their mutual benefit, for union was strength.

Mr. Fox seconded the motion.

Mr. Hampson, in supporting it, said he was glad the Association had been started. He imagined there were rocks ahead, but was sure nothing but good could come from their meeting together, and the energy and tact required to steer their craft successfully would but strengthen them for far more serious conflicts. It was a good thing to unite—union was strength—but they must remember everything depended on themselves individually. Each must do his share, and if they had a dozen good men and true he felt sure they would carry the Association to a triumphant success.

Mr. Wallis proposed, "That having heard the intentions of the promoters of the Association explained, this meeting pledges itself to do the utmost to secure the desired objects." He said that when he came to London he felt strongly the lack of that sociality among assistants which was conspicuous in the provinces. He had seen great good come from one or two provincial associations for both employers and assistants. Some people said the proposed association would not answer, for they would never get assistants to come together. He could only say that if they would not meet for their own benefit they ought to be ashamed of themselves. He was pleased to see so many there to refute that objection by their presence. He then briefly stated the objects of the Association, and trusted those present would show their interest in the movement by aiding it as much as possible.

Mr. Stuart, in seconding the motion, said that having so unanimously passed the first and second the meeting was bound to pass the third resolution, which was the logical outcome of the two former ones. The first stated that there was a want; the second showed how that want could be supplied, and this they were bound to support. He urged his hearers to come forward and join the ranks, and to induce their friends to do so too, and unite, not against their employers, but for their own welfare and advancement; in one word, for the triumphant establishment ofthe Chemists' Assistants' Association.

The resolution was unanimously carried.

Mr. McKnight proposed "That the thanks of this meeting be accorded to those gentlemen who had so willingly subscribed towards the expenses of formation." He said several employers had subscribed, who candidly told him they did not think the Association would succeed; nevertheless they had liberally paid their subscriptions, and he would like to see many who had as yet only expressed sympathy, assist the promoters in the way Mr. Williams, the President of the Pharmaceutical Society, had done.

Mr. Moon, in seconding this resolution, said he thought a thorough canvass would greatly increase the number of members, as several of his friends, notwithstanding the number of circulars sent out, had heard nothing of the movement.

Mr. Long (Notting Hill), in supporting the motion, said that for one night he had left the public to take care of itself. He had no assistant, so if any one came to his shop he would have to go without medicine that night. He thought the movement a good one, for even when they had time to amuse themselves, assistants did not known how to set to work about it; and a bond such as this Association would form would be a very good thing. He thought masters were sometimes like the monkey in the fable, and made cat's paws of their assistants to rake a few chestnuts out of the pockets of the public. That public would never think well of them until they thought well of themselves, and he did not think that they should let the public look upon chemists as its slaves. Let them free their business from their chains, and the public would respect them for it.

Mr. Bull proposed "That the Secretary be instructed to convey the thanks of this meeting to the President and Council of the Pharmaceutical Society for the loan of the lecture theatre." He hoped they would soon have rooms they could call their own and spend many pleasant and instructive evenings.

Mr. Baker seconded the motion, and it was carried unanimously.

Mr. Hetherington then proposed and Mr. Bath seconded a vote of thanks to the Chairman, which was carried unanimously.

After a suitable reply from the Chairman the meeting broke up.

Many assistants were enrolled as members at the close of the proceedings.

The Secretary stated that a meeting would be held on July 10th, if possible, to consider the rules, and that the preliminary committee would then resign, and a President and Council be elected.

The Pharmaceutical Journal.

SATURDAY, JULY 7, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W.* *Envelopes indorsed "Pharm. Journ."*

THE COUNCIL PRIZES.

COMPLAINTS against existing regulations not unfrequently arise from some misunderstanding, or from careless observation, and unpleasant as they are to hear they have the advantage of affording an opportunity to the complainant of increasing his information and modifying his too often distorted views by the correspondence evoked.

It is now little more than a year ago that the rules for the competition for the Council prizes were definitely settled, and it is therefore a matter of regret that already distant mutterings of dissatisfaction should have made themselves heard. The letter of "AULD REEKIE," which appeared in our last issue, commenting upon the character of the questions given at the last competition, has naturally enough elicited a strong protest from "ARATOR," who evidently looks at the subject from another point of view.

Since the time of ADAM it has always been a feature in human nature that he who deserves blame should try to cast it upon another, and we must confess that "AULD REEKIE" is no exception to this peculiarity. His criticisms betray that the writer of them is not in the habit of perusing the scientific portion this Journal, and imply that many others on the opposite side of the Tweed are guilty of the like abstention, an implication which we should be sorry to regard as correct.

The statement made by "ARATOR" that an admirable research upon some of the alkaloids of Melanthaceæ has already appeared in this Journal, is, unfortunately for "AULD REEKIE," quite correct. Not only so, but the classical paper on Pareira Brava, of which only a *résumé* is given in 'Pharmacographia,' appeared first in former numbers of the Journal.

If students belonging to the Society in Scotland prefer to use such a work as SCORESBY-JACKSON'S 'Note Book' (the deficiencies of which as regards Pareira Brava, etc., were pointed out in our review of the last edition), and if they do not supplement the knowledge so acquired by reference to more recent information in the Society's Journal and in works which are acknowledged by all authorities to be the best of their kind, among which 'Pharmacographia' deservedly ranks, they must not expect to be able to compete with those who take the trouble to do so. Fault-finding is very easy work, but it is particularly ungracious when the fault is found with those who work gratuitously and who are authorities on the subjects in which they examine.

The two last questions to which "AULD REEKIE" objects are such as any student would be able to answer who has read ATTFIELD'S 'Chemistry,' a work which is well known in England and America and surely cannot be unknown in Scotland. The fact that SCORESBY-JACKSON classes oil of bitter almonds under materia medica must have been overlooked, or our correspondent could not with any degree of fairness have expected it to be excluded from questions on that subject.

We feel convinced that those who carefully examine the questions proposed last year must come to the conclusion that they are carefully framed so as to give sufficient scope to various classes of students to exhibit the character of their knowledge. It is only by questions of this kind that the difference between information carefully digested and that which has been lazily and superficially accumulated can be ascertained. A little consideration must bring with it the reflection that the Council Medals, which are the highest rewards the Society offers, should rightly be bestowed upon those who have taken pains to gain information and who have made the most of their opportunities.

We regret to find upon examination that "ARATOR'S" statement as regards the success of Major candidates at Edinburgh is correct, and a reference to the Registrar's Report for 1876 shows that even during that year only one candidate succeeded in passing the Major examination, and he might not have been eligible to compete. We should gladly welcome a better report from Scotland; but until the Major candidates in Scotland can satisfy their own examiners as to their claims to compete for the Council Medals, complaint seems both premature and uncalled for.

SCIENCE v. SUPERSTITION IN JAMAICA.

WE have been favoured by Mr. CLAYTON of Birmingham with a perusal of a communication from Mr. J. STURGE of Montserrat, in which it is stated that in consequence of the impression that acts of poisoning are associated with the increasing belief in witchcraft in Jamaica, the government has appointed a chemist, Mr. BOWREY, to investigate the vegetable poisons of the Island. One of the plants examined by Mr. BOWREY has been the *Echites suberecta,* from which he has obtained an alkaloidal salt, one thousandth part of a grain of which is capable of poisoning a cat. The operation was a very unpleasant one in consequence of the pain caused when small particles of this substance came into contact with the skin.

ORANGES AND LEMONS.

GREECE and the Levant are countries in which lemons and oranges grow in abundance, and Dr. LANDERER of Athens, in a communication received from him on the subject, estimates that more than 100,000,000 of lemons, oranges, and citrons are consumed or exported by the inhabitants of various parts of Asia Minor. There are also met with all the other sorts of fruits of the family Hesperidæ, such as *Citrus Indica*, commonly known as mandarins.

The fruits of *Citrus Cedro* and *Citrus Decumana* are collected for the preparation of the confection Citrinate. The fruit known under the name of Adam's apples and Paradise apples, called in the Levant *Trappes*, are there employed by the Jews for ornamenting their synagogues on festival days. At certain times these fruits are exported in little barrels preserved in brine.

The parings of these millions of fruits have hitherto been thrown away as useless. But recently some Sicilians have introduced into the island of Poros the art of preparing the essential oil. Steps are also being taken to condense the juice and send it to Europe under the name of *Agro Condensato*.

CULTIVATION OF JALAP IN JAMAICA.

ACCORDING to the last report on the Jamaica Botanic Gardens it seems that nearly two acres of land attached to the cinchona plantation is now systematically cropped with jalap, the crops during the past year amounting to 1700 lbs., and it was estimated at the time the report was written, about the middle of February last, that at least 3000 lbs. additional would be obtained in the course of a few months, which produce would be sent to England.

ITALIAN CASTOR OIL.

THE following appears in a recent report from Italy relative to the manufacture of castor oil in the neighbourhood of Forli. The oil, it is said, is obtained by an improved method. Besides the common oil, a double quality is produced of which the average consumption is 14,000 bottles, each containing 54 grams; the residuum after the extraction of the oil forms a very useful manure, well suited for the cultivation of hemp, and it is also used in the composition of almond paste for the hands, which is sold in packets of 160 grams. The annual consumption amounts to about 5000 packets, of which 2000 are sold in the city of Bologna.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of the above Association will be held at 17, Bloomsbury Square, on Thursday evening next, July 12, at eight o'clock, when a paper on "The Theories of Darwin concerning Evolution," will be read by Mr. EDWIN RICHARDSON.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, July 4, 1877.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atherton, Atkins, Betty, Bottle, Brown, Churchill, Cracknell, Gostling, Greenish, Hampson, Hanbury, Hills, Mackay, Owen, Rimmington, Robbins, Sandford, Schacht, and Shaw.

The minutes of the preceding meeting were read and confirmed.

THE INAUGURAL SESSIONAL ADDRESS.

The SECRETARY reported that Mr. Southall had acceded to the request of the Council to deliver the Inaugural Address to the Students in October next.

THE CHEMISTS' ASSISTANTS' ASSOCIATION.

The SECRETARY read a letter of thanks from the Secretary of the Chemists' Assistants' Association, for the use of the lecture theatre for a preliminary meeting, and a further letter asking the use of the room on July 10th, for the purpose of electing a committee and officers.

The request was ordered to be complied with.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

The following Pharmaceutical Chemists were elected Members of the Society:—

Brayshay, Thomas ....Stockton on Tees.
Bullen, George William ....London.
Glover, William Kensit ....London.
Greenish, Henry George.........London.
Gutheridge, George Frederick..Falmouth.
Harrison, William Hopper ......Newton Abbot.
Parker, Robert Henry............Barnstaple.

Chemists and Druggists.

The following registered chemists and druggists were elected Members of the Society:—

Garrow, William ....Keith.
Smith, John ....Charlestown of Aberlour.
Walker, John Henry ....Hull.

ASSOCIATES IN BUSINESS.

The following having passed their respective examinations and being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Edwards, James ....Chelsea.
Moore, John Ernest ....Loughborough Junction.
Tweedie, Alexander ....Innellan.

Modified.

Alexander, William...............Banff.

ASSOCIATES.

The following having passed their respective examinations and having tendered their subscriptions for the current year, or having paid the subscriptions of Apprentices or Students, were elected "Associates" of the Society:—

Alcock, Joseph Pitman ....Worcester.
Bell, Henry ....Newcastle-on-Tyne.
Brearey, Arthur William ......Douglas.
Hill, Arthur ....Cheltenham.
Hinks, John ....London.
Lunn, Alfred.........................Spalding.

Marshall, George Thomas ......Newcastle-on-Tyne.
Nicholson, Richard ....Darlington.
Savory, Arthur Ledsam ....London.
Stubbs, Edwin ....Hull.
Troughton, Henry ....Lancaster.
Wright, George.....................Park, Sheffield.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination, and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Alldridge, Charles Harry ......Bath.
Blades, William Wrench.........Northwich.
Bunting, Frank Alexander......Witney.
Caton, Edwin Charles............Shepherd's Bush.
Hughes, Evan ....Chelmsford.
Laughlin, Edwin Drewery ......Ramsey.
Perkins, Thomas Frampton......Clifton.

The names of the following persons were restored to the Register of Chemists and Druggists:—

William Witchellow, 35, East Street, Walworth, Surrey.
James Lyon, 102, Kingsland High Street, Middlesex.
George Bassett Hutchinson, 8, Station Road, Westgate-on-Sea, Kent.

One individual was restored to his former status in the Society upon payment of the current year's subscription and a fine.

Reports of Committees.

FINANCE.

The report of this Committee was read and various accounts ordered to be paid.

Mr. Sandford asked what further liabilities were due in respect of the Conversazione, because the amount already charged was very small compared to that in previous years.

The Secretary said the accounts were not completed, but there would be, he thought, a saving of more than £100, compared with the amount expended last year.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£15 to the widow of a registered chemist and druggist, who has had a previous grant of £10.

£10 to the widow of a former member, aged fifty-four.

£10 to a registered chemist and druggist, suffering from incurable disease.

£10 to a registered chemist and druggist who has been in business about twenty-seven years.

Another application was referred for further inquiries.

The report and recommendations were received and adopted.

Benevolent Fund Dinner.

The Secretary read the report of this Committee, from which it appeared that the number of persons attending the dinner was 245, and the principal figures in the accounts were as follows:—Donations, £1579 14*s.* 10*d.* New Annual Subscriptions, £92 7*s.* Dinner Tickets, £306 12*s.* The total expenses were £382 18*s.* 8*d.*, leaving a balance of £1595 15*s.* 2*d.* Further payments, amounting to £10 10*s.* had been since received, raising the total proceeds to £1606 5*s.* 2*d.*

The report was received and adopted and the sum of £1606 5*s.* 2*d.* ordered to be invested immediately.

The President, in putting the resolution, said there was one omission he had made in his remarks at the dinner, for he certainly ought to have said something in the way of thanks to the officers of the Society, especially the Secretary and the Assistant-Secretary, for the very efficient manner in which they had carried out the work in connection with the dinner. He thought it would not be too late even now to pass a resolution to this effect.

A resolution was afterwards passed on the motion of Mr. Brown, seconded by Mr. Greenish—

"That the best thanks of the Council be tendered to the Secretary and Assistant-Secretary for their services in carrying out the arrangements which so largely conduced to the success of the Benevolent Fund Dinner."

The Secretary, in thanking the Council, said the Benevolent Fund had always been a hobby of his, and it was very satisfactory to him to find its sphere of usefulness being enlarged.

Provision for an Orphan.

Mr. Owen, referring to the case mentioned last month of an orphan whom he had endeavoured to get elected into an asylum by the aid of twenty guineas voted by the Benevolent Fund Committee, now asked for an additional thirty guineas, to ensure the child's success at the ensuing election. According to the rules, the Council might, if it thought fit, provide for an orphan by purchasing an entry into an asylum; but he did not ask for so much as that, because the mother and friends had done a great deal; but he believed that if thirty guineas were now voted, in addition to the twenty already granted, he could make sure of the child's election. He would therefore move that this be done.

Mr. Hills seconded the motion.

Mr. Betty objected, as a matter of form, that this was a grant of money of which no notice had been given, and also that the application came before the Benevolent Fund Committee on the previous day, when it was fully considered.

Mr. Owen: No.

Mr. Betty said the matter was gone into certainly.

Mr. Brown was very loth to say anything against the exercise of benevolence, but he must agree with Mr. Betty that the method of bringing this forward was totally out of order; it was clearly committee work, and the grant ought to be recommended by the Benevolent Fund Committee before it was brought before the Council. Besides, it ought to have been brought forward before the report of the Benevolent Fund Committee was adopted.

The President said Mr. Owen did mention the matter to the Benevolent Fund Committee on the previous evening, but he was then told that he was out of order, and that the matter should be brought before the Council. If the money were not granted now it would be of no use, because the election would take place on Tuesday next.

Mr. Atherton suggested that Mr. Owen should withdraw his motion, until after Mr. Robbins' motion had been discussed.

Mr. Owen said this was not necessary. The purchase contemplated by Mr. Robbins would require £120 to £150 in each case, according to the age of the child, while he simply wanted thirty guineas to help.

Mr. Shaw said the matter had been discussed on the previous evening. He understood that at the former election the lowest successful candidate obtained 650 votes, whilst theirs had only 134, leaving a deficiency of 525 which would cost £130 to obtain.

Mr. Owen said a large additional number of votes had been already obtained.

Mr. Shaw said he was quite willing that this sum should be placed in Mr. Owen's hands, provided it were not expended unless success could be guaranteed. But he must say he did not like the principle on which these elections were conducted, for they partook so much of the nature of gambling as to be in his view very detrimental to the morals of the country.

Mr. Greenish supported the motion, which was then carried, Mr. Owen saying he should not expend the money unless he felt something like certainty that the candidate would be successful.

Mr. Betty desired that his protest should be recorded against a money vote being passed without previous notice being given.

Library, Museum and Laboratory.

Professor Redwood had reported to the Committee that the attendance in his class was about as usual.

Professor Bentley had reported that his class at the Botanical Gardens contained about the average number, and the conduct of the students that was highly satisfactory.

Professor Attfield had reported 86 entries during the session, 44 students being now at work.

The Librarian had reported the average attendance during the previous month to have been, day 21, evening 10. Circulation of books, in town 207 : country (to 21 places) 43. He had also reported donations from the British Pharmaceutical Conference; Mr. A. Rivers Willson; the School of Pharmacy Students' Association; the Surgeon General, U. S. War Department; the Philadelphia College of Pharmacy; the American Pharmaceutical Association; the Smithsonian Institution; the University of London; Mr. F. W. E. Shrivell; Monsieur A. Petit; Professor Dragendorff; Dr. Lionel Beale, and Professor Soubeiran.

It had been ordered that letters of thanks should be sent to the respective donors.

The following books were recommended to be purchased:—

General Fund.—Everett's 'Elementary Physics.'

Hanbury Fund.—Continuation of Pfeiffer's 'Nomenclator Botanicus;' Lemaout and Decaisne's 'Botany,' translated by Mrs. Hooker.

It was recommended that a subscription of 10*s.* 6*d.* be paid, and that the Librarian be requested to attend the proposed conference of librarians, to be held in October next.

The Curator had reported the average attendance in the museum to have been, morning 17; evening 6. The whole of the catalogue was now in the printer's hands; and the Curator had been instructed to prepare an estimate of the cost and labour required to prepare a catalogue of the Hanbury Collection. The Curator had also reported the receipt of another case of Indian drugs from Professor Dymock of Bombay, illustrating his papers published in the Journal.

The revised list of Local Secretaries had been presented by the Secretary, and it had been approved subject to the further supervision of the President after communication with the persons nominated.

The Committee had considered and discussed the question of arrangements for the evening meetings, but the further consideration of this matter had been deferred until the next meeting, when the Professors and Editor would be requested to attend.

The report and recommendations were received and adopted.

It was also resolved that the persons named in the following list be appointed Local Secreteries for the ensuing year.

List of Local Secretaries, 1877-8.*

Towns eligible.	Names of persons appointed.
Aberdare	Thomas, Watkin Jones.
Aberdeen	Davidson, Charles.
Abergele	Hannah, John.
Aberystwith	Wynne, Edward Price.
Abingdon	Smith, William.
Altrincham	Hughes, Edward.
Arbroath	Shield, George.
Ashbourne	Bradley, Edwin Silvester
Ashby-de-la-Zouch	Johnson, Samuel E.
Ashton-under-Lyne	Bostock, William.
Aylesbury	Turner, John.
Banbury	Ball, George Vincent.
Banff	Ellis, Bartlett.
Bangor	Roberts, Meshach.
Barnsley	Badger, Alfred.
Barnstaple	Goss, Samuel.
Barrow-in-Furness	Steel, Thomas.
Bath	Commans, Robert Dyer.
Bedford	Cuthbert, John M.
Belper	Ashton, John.
Berwick	Carr, William Graham.
Beverley	Hobson, Charles.
Birkenhead	Nicholson, Henry.
Birmingham	Southall, William.
Bishop Auckland	Leigh, John James.
Blackburn	Pickup, Thomas Hartley
Blackpool	Harrison, John.
Blandford	Bird, Matthew Mitchell.
Bodmin	Williams, Joel Drew.
Bolton	Dutton, George.
Boston	Fowler, W. R.
Bournemouth	Duncan, Alexander.
Bradford (Yorkshire)	Rimmington, Felix W. E.
Brecon	Meredith, John.
Bridgnorth	Deighton, Thomas Milner.
Bridlington	Forge, Christopher.
Bridport	Tucker, Charles.
Brighton	Gwatkin, James Thomas.
Bristol	Stoddart, William W.
Buckingham	Sirett, George.
Burnley	Thomas, Richard.
Burslem	Blackshaw, Thomas.
Bury St. Edmunds	Youngman, Edward.
Buxton	Barnett, Alexander.
Cambridge	Deck, Arthur.
Canterbury	Bing, Edwin.
Cardiff	Proctor, S. J.
Cardigan	Jones, John Edward.
Carlisle	Thompson, Andrew.
Carmarthen	Davies, Richard M.
Carnarvon	Lloyd, W.
Chelmsford	Baker, Charles Patrick.
Cheltenham	Smith, Nathaniel.
Chester	Grindley, William.
Chesterfield	Greaves, Abraham.
Chichester	Long, William Elliott.
Chippenham	Coles, John Coles.
Christchurch	Green, John.
Cirencester	Mason, Joseph W.
Clevedon	Martin, J.
Cockermouth	Bowerbank, Joseph.
Colchester	Shenstone, James B. B.
Congleton	Goode, Charles.
Coventry	Wyley, John.
Crewe	McNeil, James Norton.
Croydon	Barritt, G.
Darlington	Robinson, Alfred Francis.
Deal	Green, John.
Denbigh	Edwards, William.
Derby	Frost, George.
Devizes	Evans, John.
Devonport	Codd, Francis.
Dewsbury	Gloyne, C. G.
Diss	Gostling, Thomas Preston.
Doncaster	Dunhill, William W.
Dorchester	Evans, Alfred John.
Dorking	Clift, Joseph.
Dover	Bottle, Alexander.
Droitwich	Taylor, Edmund.
Dudley	Hollier, Elliot.
Dumfries	Allan, William.
Dundee	Hardie, James.
Dunfermline	Seath, Alexander.
Durham	Sarsfield, William.
Eastbourne	Provost, James A.

* Local Secretaries are appointed in all towns in Great Britain which return a Member or Members to Parliament, and in such other Towns as contain not less than Three Members of the Society or Associates in Business.

Towns eligible.	Names of persons appointed.
Edinburgh	Mackay, John.
Elgin	Robertson, William.
Ely	Pate, Henry Thomas.
Evesham	Dingley, Richard Loxley.
Exeter	Delves, George.
Eye	Bishop, Robert.
Falkirk	Murdoch, David.
Falmouth	Newman, W. F.
Fareham	Batchelor, Charles.
Faversham	Underdown, F. W.
Flint	Jones, Michael.
Folkestone	Goodliffe, George.
Gateshead	Elliott, Robert.
Glasgow	Kinninmont, Alexander.
Gloucester	Meadows, Henry.
Gosport	Hunter, John.
Grantham	Whysall, W.
Gravesend	Bulgin, William.
Greenock	Fraser, Charles.
Grimsby, Great	Palmer, Enoch.
Guildford	Martin, Edward W.
Haddington	Watt, James.
Halifax	Dyer, William.
Harrogate	Davis, R. Hayton.
Hartlepool	Jackson, William G.
Harwich	Bevan, Charles F.
Hastings and St. Leonards	Jameson, William E.
Haverfordwest	Williams, William.
Helston	Troake, Marler H.
Hereford	Jennings, Reginald.
Hertford	Lines, George.
Heywood	Beckett, William.
Hitchin	Ransom, William.
Horncastle	Kemp, William.
Horsham	Williams, Philip.
Huddersfield	King, William.
Hull	Bell, Charles Bains.
Huntingdon	Provost, John Pullen.
Huntly	Prott, William.
Hyde	Wild, Joseph.
Hythe	Lemmon, Robert Alce.
Inverness	Galloway, George Ross.
Ipswich	Anness, Samuel Richard.
Jersey	Ereaut, John, jun.
Kendal	Severs, Joseph.
Kidderminster	Hewitt, George.
Kilmarnock	Borland, John.
King's Lynn	Atmore, George.
Kingston-on-Thames	Walmsley, Samuel.
Kirkcaldy	Storrar, D.
Knaresborough	Sindall, John William.
Knutsford	Silvester, Henry Thomas.
Lancaster	Bagnall, Wm. Henry.
Launceston	Eyre, Jonathan Symes.
Leamington	Jones, Samuel Urwick.
Leeds	Reynolds, Richard.
Leek	Johnson, William.
Leicester	Cooper, Thomas.
Leighton Buzzard	Readman, William.
Leith	Finlayson, Thomas.
Leominster	Davis, David Frederick.
Lewes	Martin, Thomas.
Lichfield	Perkins, John Jaquest.
Lincoln	Maltby, Joseph.
Liskeard	Young, Richard.
Liverpool	Abraham, John.
Llandudno	Williams, Thomas.
Longton	Prince, Arthur G.
Loughborough	Paget, John.
Louth	Hurst, John B.
Lowestoft	Sale, Thomas J.
Ludlow	Cocking, George.
Lyme Regis	Thornton, Edward.
Lymington	Allen, Adam U.
Macclesfield	Bates, William Isaac.

Towns eligible.	Names of persons appointed.
Macduff	Henry, James Hay.
Maidenhead	Walker, Robert.
Maidstone	Rowcroft, Albert Edward.
Maldon	Wallworth, David.
Malmesbury	Brown, Francis James.
Malton	Hardy, George.
Malvern	Metcalfe, Edmund Henry
Manchester, etc.	Wilkinson, William.
March	Davies, Peter Hughes.
Margate	Knight, Alfred.
Merthyr Tydvil	Smyth, Walter.
Middlesborough	Robson, James Crosby.
Montrose	Burrell, George.
Neath	Hibbert, Walter.
Newark	March, William.
Newbury	Davis, Frank Pratt.
Newcastle-under-Lyne	Cartwright, William.
Newcastle-on-Tyne	Proctor, Barnard S.
Newport (I. of Wight)	Orchard, Herbert Joseph.
Newport (Mon.)	Pearman, Henry.
Newtown	Owen, Edward.
Northallerton	Warrior, William.
Northampton	Bingley, John.
Norwich	Sutton, Francis.
Nottingham	Atherton, John Henry.
Nuneaton	Iliffe, George.
Oldham	Hargraves, H. Lister.
Oswestry	Saunders, George James.
Over Darwen	Hargreaves, Wm. Henry.
Oxford	Prior, George T.
Paisley	Hatrick, William.
Pembroke	John, David William.
Pembroke Dock	Andrews, Charles.
Penrith	Kirkbride, W.
Penzance	Cornish, Henry Robert.
Peterborough	Heanley, Marshall.
Petersfield	Edgeler, William B.
Plymouth	Balkwill, Alfred P.
Pocklington	Cundall, Robert.
Pontefract	Bratley, William.
Poole	Penney, William.
Portsmouth, etc.	Rastrick, J. L.
Preston	Barnes, James.
Ramsgate	Morton, Henry.
Reading	Hayward, William G.
Redcar	Little, Henry.
Redditch	Mousley, William.
Retford	Clater, Francis.
Richmond (Yorks)	Thompson, John Thomas.
Ripon	Judson, Thomas.
Rochdale	Taylor, Edward.
Rochester	Harris, Henry William.
Ross (Herefordshire)	Stafford, John.
Rotherham	Horsfield, John M.
Rothesay	Duncan, William.
Runcorn	Whittaker, William.
Rugby	Garratt, John C.
Ruthin	Bancroft, John James.
Ryde (Isle of Wight)	Pollard, Henry Hindes.
Rye	Waters, William Allen.
St. Albans	Martin, Henry Gilham.
St. Andrews	Govan, Alexander.
St. Austell	Hern, William Henry.
St. Ives (Cornwall)	Young, Tonkin.
Salisbury	Atkins, Samuel Ralph.
Sandwich	Baker, Frank.
Scarborough	Whitfield, John.
Seacombe	Shaw, Ralph Horwood.
Selby	Colton, Thomas.
Shaftesbury	Powell, John.
Sheerness	Bray, John.
Sheffield	Ward, William.
Shields, South	Mays, Robert, J. J.
Shipley	Dunn, Henry.
Shoreham	Barker, John.

Towns eligible.	Names of persons appointed.
Shrewsbury	Cross, William Gowen.
Slough	Griffith, Richard.
Southampton	Dawson, Oliver R.
Southport	Walker, William Henry.
Spalding	Shadford, Major.
Stafford	Averill, John.
Stalybridge	Brierley, Richard.
Stirling	Duncanson, William.
Stockton-on-Tees	Brayshay, Thomas.
Stoke-on-Trent	Adams, Jonathan Henry.
Stourbridge	Bland, T. F.
Stratford-on-Avon	Hawkes, Richard.
Stroud	Blake, William F.
Sudbury	Harding, James John.
Sunderland	Nicholson, John J.
Swansea	Brend, Thomas.
Tamworth	Allkins, Thomas Boulton.
Taunton	Prince, Henry.
Tavistock	Gill, William.
Teignmouth	Cornelius, Joseph.
Tenby	Davies, Moses Prosser.
Tewkesbury	Allis, Francis.
Thirsk	Thompson, John.
Tiverton	Havill, Paul.
Torquay	Smith, Edward.
Totnes	Keen, Benjamin.
Truro	Serpell, Samuel.
Tunbridge	Wibmer, Lewis Michael.
Tunbridge Wells	Howard, Richard.
Uttoxeter	Johnson, John Borwell.
Wakefield	Hick, Matthew Bussey.
Wallingford	Payne, Sidney.
Walsall	Highway, Henry.
Waltham Abbey	Marshall, Jas. Ainsworth.
Wareham	Randall, Thomas.
Warrington	Woods, Joseph Henry.
Warwick	Pratt, Henry.
Watford	Chater, Edward Mitchell.
Wednesbury	Gittoes, Samuel James.
Wellington	Langford, John Brown.
Westbury	Taylor, Stephen.
West Bromwich	Laugher, William.
Weston-super-Mare	Gibbons, George.
Weymouth	Groves, Thomas Bennett.
Whitby	Stevenson, John.
Whitehaven	Kitchin, Archibald.
Wick	Miller, Kenneth.
Wigan	Phillips, Jonathan.
Winchester	Hunt, Richard.
Windsor	Russell, Charles J. L.
Wolverhampton	Brevitt, William Yates.
Wokingham	Spencer, Thomas.
Woodbridge	Clarke, G. E.
Woodstock	Griffits, John Alonza.
Worcester	Virgo, Charles.
Worthing	Cortis, Charles.
Wrexham	Edisbury, James Fisher.
Wycombe	Furmston, Samuel C.
Yarmouth, Great	Poll, Wm. Sheppard.
York	Davison, Ralph.

House.

The report of this Committee was read. It recommended certain small matters to be done to the Society's premises during the recess, for which an estimate had been obtained.

The President thought the Committee had been rather too economical on the present occasion, and that some of the work proposed to be done now would have to be repeated in a very short time, when the whole outside of the house would have to be painted. He thought it would be wiser to reconsider the matter.

Mr. Greenish said it was not usual to send back a matter to the Committee after it had been fully considered, unless there was good reason for doing so.

Mr. Robbins said there had been fresh light thrown on the matter, and it might very well be reconsidered.

Mr. Betty thought it would be a slur on the Committee if their report were sent back.

The Vice-President agreed with Mr. Betty that the views of the Committee ought to be carried out.

Mr. Churchill asked if the small amount of outside work proposed to be done could not wait for another year.

Mr. Gostling thought the wood-work now proposed to be painted would be all the better for the additional coat, even if it were redone next year.

After some further conversation the report of the Committee was received and adopted.

Poison Regulations for Ceylon.

The President read some correspondence which had passed between the Home Office and himself relative to poison regulations which the Colonial Office proposed to introduce into Ceylon, he having been compelled, by considerations of time, to act with the assistance of some of the London members of the Council without waiting for the present meeting. The proposed ordinance had been based upon the Pharmacy Act of 1868, and he had pointed out the additions which had since been made to the schedule of poisons, and enclosed a copy of the printed paper on the subject issued by the Council. He had also informed the authorities at the Home Office that the question of adding chloral hydrate to the schedule of poisons was at present under the consideration of the Council.

Mr. Shaw said he had some time ago suggested that a reference to the additional schedule of poisons should be added to the Pharmacy Act.

The President said such a reference had been inserted in the Calendar, at Mr. Shaw's suggestion, but they had no power to make any additions to the Register, which was an official document.

Mr. Schacht remarked on the fact that the poisons proposed to be inserted in the schedule to the ordinance were only those the sale of which was prohibited in England. He should have thought that some other poisons would have been locally used in Ceylon.

The President added that according to the proposed ordinance, there would be no examinations, but respectable persons would be licensed for one year to sell poisons at the discretion of the magistrates, penalties and even imprisonment being imposed on any unlicensed person who sold poison.

Personation at the Preliminary Examination.

The Secretary drew attention to the proceedings at the Police Court in regard to personation at the Preliminary examination, as reported at page 18, and a conversation upon the subject ensued.

The Preliminary Examination.

The Secretary presented a list of centres and table of attendances of candidates at each centre, since July, 1874, which is printed on the opposite page.

Superintendents of Written Examinations.

It was resolved that the appointment of Superintendent of the Written Examinations at the various local centres during the ensuing year should be offered to the Local Secretaries at those centres.

Mr. Schacht remarked on the very satisfactory average of candidates at nearly all the local centres, which he viewed with considerable pleasure, having proposed the introduction of the present system. There was only one centre which he should like to omit from the list, viz., Dorchester.

Some conversation followed as to the desirability of erasing Dorchester from the list, or substituting another town for it, but it was ultimately resolved to leave the list as it was at present.

PRELIMINARY EXAMINATION.

List of Centres and Table of Attendances of Candidates at each Centre.

	1874. July Oct.	1875. Jan. April. July. Oct.	1876. Jan.	1876. April.	1876. July.	1876. Oct.	1877. Jan.	1877. April.	1877. July.	Total number of attendances at each Centre.

Mr. CHURCHILL thought it would be desirable in a few places to engage two superintendents, because it sometimes happened that more candidates were present than could be efficiently superintended by one person. He also wished to know if any means had been considered to prevent cases of personation occurring in future. It occurred to him that by communicating with the employers of the candidates, the handwriting might be identified.

Mr. MACKAY, with all deference, could not agree with Mr. Churchill in either point. A superintendent could ask for additional assistance if he wanted it, but this would very seldom be necessary, and so far as personation was concerned he thought by the time Mr. Hunter received his sentence it would so deter others that the Council might feel perfectly safe.

APPOINTMENT OF PROFESSORS AND CURATOR FOR THE ENSUING YEAR.

Professor Redwood was reappointed Professor of Chemistry and Pharmacy for the ensuing year.

Professor Bentley was reappointed Professor of Botany and Materia Medica for the ensuing year.

Professor Attfield was reappointed Professor of Practical Chemistry for the ensuing year.

Mr. Holmes was reappointed Curator of the Society's Museum for the ensuing year.

EXAMINERS FOR THE COUNCIL PRIZES.

Mr. MACKAY having referred to the regulations for the Council prizes as given in the Calendar, said these regulations were very freely discussed at the time, and it was then supposed that the result would be that either two gentlemen belonging to the London Board of Examiners would be appointed, or one from that board and one from the board in Scotland. It was evident, however, that there would be some difficulty in this, inasmuch as those two gentlemen would have to act together. Still he did not suppose the members of the Scotch board would care to be entirely ignored in the matter, and he would suggest that if two members of the English board were appointed this year to examine the answers, another year two gentlemen in Scotland might be nominated to the same office.

The PRESIDENT said he thought it was understood that the Council would occasionally appoint two members of the North British Board, but inasmuch as the Council knew more of the London Board than of their colleagues in Scotland, they would have to rely on Mr. Mackay to suggest the most eligible names.

Mr. BOTTLE then moved and the VICE-PRESIDENT seconded,

> "That Messrs. Carteighe and Linford be requested to conduct the examinations for the Council prizes in the present month."

The PRESIDENT remarked that there was no fee attaching to this duty—it was purely honorary.

Mr. SCHACHT expressed his concurrence in the suggestion of Mr. Mackay, that once in three years, or even every alternate year, this duty should be delegated to two members of the Scotch board. There was no occasion for a personal interview. When this matter was discussed before he was very anxious that the places of examination should not be limited to London and Edinburgh, but that an opportunity should be given to all eligible candidates to compete without the expense of a long journey. He now ventured to raise the question again, and wished to know what proportion of those eligible were likely to come up.

The PRESIDENT said the question was a much wider one than that of mere expense. These prizes were the most important given by the Society, and it was considered that candidates ought to be ready to undergo some inconvenience in competing for them.

Mr. SCHACHT asked how many competed last year.

The SECRETARY replied, eight in London, and one in Edinburgh.

Mr. SCHACHT said this was a serious matter. The prizes cost a good deal of money and nothing ought to be done which tended to limit the number of competitors.

The resolution was then put and carried.

REPORT OF EXAMINATIONS.

LAW AND PARLIAMENTARY.

The report of this Committee was read. It included letters from the Solicitor stating the progress made in various cases which had been placed in his hands, in some of which a penalty had been paid. It also included a communication from the Chemists and Druggists' Trade Association giving particulars of alleged infringements of the Pharmacy Act, 1868, and a letter from Mr. Churchill expressing a hope that cautionary letters would not be sent before commencing proceedings. The question of placing chloral hydrate in the schedule of poisons had been discussed, but its further consideration had been deferred. A motion had been made in committee by Mr. Churchill that a letter should not be sent to alleged offenders before commencing proceedings, but it was lost. The remainder of the report consisted of correspondence with the Board of Trade relative to the "Institute of Chemistry."

Mr. HILLS moved that the report be received and adopted.

Mr. HAMPSON moved as an amendment—

> "That the report be received and adopted save and except the recommendation giving power to the Registrar, according to the alleged rule in existence, to write letters of caution in all cases of alleged infringement of the Pharmacy Act."

Mr. SANDFORD said there was no such recommendation in the report of the Committee.

The PRESIDENT said it had been rather by custom than by any law, that such letters had been sent, but it had been acted on by the authority of the Council and the Committee, on all occasions for some considerable period.

Mr. HAMPSON withdrew his amendment and—

Mr. BROWN moved in lieu thereof,

> "That the proceedings of the Committee be adopted save and except the portion referring to alleged infringement of the Pharmacy Act, and that this be referred back for further consideration."

He did not think it desirable in every case that a preliminary letter should be sent, and it was the first time he had heard of a rule being in existence that such a course should be followed. Had there ever been a resolution to the effect that this should always be done?

The PRESIDENT said it was the custom, but he did not know of any rule being on record. There ought to be one, however, for he remembered the Secretary being so instructed.

Mr. BROWN thought it was quite a throwing away of courtesy to send a cautionary letter in some of these cases. Some parties, calling themselves general dealers, were selling laudanum without a label, or any of the precautions prescribed by the Pharmacy Act, and it was a perfect farce to write to them; they would probably express their sorrow and promise not to offend again, which promise would probably be worth very little. Again in the case of unregistered chemists and druggists, he would at once commence proceedings, because they must be aware they were breaking the law. The case of widows carrying on business was a different thing altogether.

Mr. HAMPSON seconded the amendment. His only desire was that each case should be considered on its own merits. All information submitted should be treated on an equal footing. Local Secretaries found it very difficult in many cases to obtain information, and when information was brought to them ready cut and dried it saved an immense deal of trouble, and ought to be impartially considered and acted upon if necessary. In the meantime the cases ought to stand over for inquiry without a letter of caution being sent.

The VICE-PRESIDENT said the custom of sending these letters arose in great measure from an expensive bill sent in by the Solicitor, as it was felt that every preliminary object could be accomplished by a letter from the Secretary. He quite agreed that it was very important for the Council to avail itself as far as possible of the information furnished, and there were some cases which ought to be proceeded against, while there where others where some judgment ought to be exercised. Some cases had been before the Council previously, and the offenders ought to be proceeded against immediately on the information now furnished.

Mr. CHURCHILL said he was much surprised in Committee to find the way in which information, which had been obtained at some trouble and cost, had been treated, for the matter seemed practically shelved. He did not think it wise to persist in sending cautionary letters in all these cases, but each one should be considered on its merits. He was far from saying that every case should be prosecuted, but some ought to be, and the effect of sending a letter was to prevent the Council afterwards prosecuting for the offence. He mentioned several cases in which from his knowledge of the circumstances he was satisfied that no preliminary letter ought to be sent, but proceedings at once commenced.

The PRESIDENT having read the form of letter which was sent, said it might be deemed desirable to modify its terms, but he certainly thought a letter of some kind ought to be sent in each case.

Mr. SANDFORD thought it unfortunate that Mr. Hampson's original amendment had been altered by Mr. Brown, because it put two questions before the Council for consideration; in the natural course of things these cases would go back to the Committee. The present practice arose in this way: At a meeting of the Law and Parliamentary Committee there had been a report on a a long string of cases sent in by the Solicitor to all of which he had sent letters, and in some cases the parties had consequently desisted from infringing the Act. On inquiry it appeared that in some cases the Committee had not authorized the reference to the Solicitor, and it was then determined that in future the Secretary should in all cases write a premonitory letter, which might abate the offence without expense. The Council did not want to punish people by imposing penalties, but to prevent illegal trading. It was then a question whether the Secretary should write these letters without the authority of the Committee, but it was decided that to wait three weeks or a month was undesirable, and the Secretary was therefore authorized to write on his own responsibility. He thought it would be a very sensible course to propose that this should be discontinued, and that each case should come in the first instance before the Committee, who should decide what action should be taken.

Mr. HAMPSON said he had accepted Mr. Brown's amendment, because Mr. Sandford assured him there was no such rule as he had supposed.

Mr. BOTTLE said Mr. Brown objected to cautioning general dealers who sold laudanum without a label, but he thought these people were much less culpable than the wholesale traders who induced them to undertake the sale of such things. He entirely endorsed Mr. Hampson's sentiment, that every case should be treated in the same way, no matter where the information came from, but he had never known of a prosecution being undertaken on such evidence as had been furnished by the Trade Association. The Committee had not had the laudanum before it or any proof that the substance sold was really a poison at all. The objection had been raised that if the Solicitor were not instructed to take up these cases the chain of evidence would be broken, but he would rather see such a case fall through, than for the Council to undertake a prosecution for selling something which might turn out after all to be only treacle and water. If the Council treated these cases in the same way as those reported by private individuals there must be something more tangible to go upon before commencing proceedings. Mr. Churchill spoke of the matter being shelved, but he could not agree that there was any such intention.

Mr. SCHACHT said he could not allow Mr. Churchill's most unwarrantable assertion to pass, that the treatment of these cases was practically shelving the matter introduced by the Trade Association. He did not see the smallest evidence of anything which would justify such a statement. If it was the rule to send a letter in every case, the Council ought, treating all information received in the same way, as Mr. Hampson had said, to follow the same course with those presented by the Association as they would if he or any other individual had supplied the particulars.

The PRESIDENT said two propotions had been moved in Committee in reference to the action to be taken in the cases reported by the Trade Association, but both were withdrawn, and he believed it was understood that there was no disposition to shelve these cases, but that they should be treated in the ordinary way.

Mr. BROWN here said he would withdraw his amendment with his seconder's permission, understanding that Mr. Sandford would propose another.

Mr. SANDFORD then moved,

"That the report of the Law and Parliamentary Committee be received and adopted, with the exception of the negative passed on the motion proposed by Mr. Churchill; and with reference to that proposition this Council is of opinion that all reports of infringements of the Pharmacy Act should be brought first to the notice of the Law and Parliamentary Committee, and that it should rest with that Committee to send premonitory letters to the alleged offenders or not, according to its discretion."

He thought that would be a reasonable and proper course to adopt.

Mr. CHURCHILL seconded the amendment.

Mr. BROWN said he felt that the Committee had rather dealt with the cases *en bloc*, instead of considering each case on its merits. He by no means advocated the prosecution of all general dealers, but there were some cases which would justify such a course without any preliminary letter being sent.

Mr. BETTY regretted Mr. Brown's absence from the Committee meeting, which accounted for the error into which he had fallen. The Committee did not receive the report *en bloc*, but followed the usual practice which had been in operation for about two years. Some cases were recommended for prosecution at once, as they had heard in the report just read, but the Committee did not entertain first cases, of which they had no proof, until a letter had been sent. It was quite open to the Council, however, to give the Committee fresh instructions. Old offenders would be prosecuted at once if sufficient evidence were adduced.

Mr. HAMPSON said his impression of what passed did not agree with that of Mr. Betty.

Mr. ATKINS agreed that all information should be treated exactly alike, but he did not see his way at once to the conclusion that every case must come before the Committee before a letter was written, though it should do so before any legal proceedings were commenced. Several reasons might be mentioned, but the loss of time would suffice.

Mr Mackay saw no reason for altering an arrangement which had worked well during the last two years. The point had been rather overlooked that the Secretary only sent out these letters on his own responsibility in first cases, but where an offender did not desist after receiving such a letter proceedings were commenced without further notice. Even if the cases were placed in the hands of the Solicitor he would begin by sending such a letter, and it was in consequence of a long bill for similar letters that the Secretary had been requested to undertake the duty.

The Secretary said the Council had no idea of the enormous number of cases constantly reported to him. There was scarcely a day which did not bring information of some alleged infringement, and though he should be glad to be relieved of the trouble, he must say that these letters did a great deal of good. If all these cases were submitted to the Committee it would have to meet in the middle of the month and spend a whole day over them.

Mr. Schacht said that probably the Committee would order a preliminary letter to be sent in every case of a first offence, and he could quite see that these letters sent by the Secretary greatly lightened the labours of the Committee by sifting the cases. The object of the Society was to protect the public, not to inflict punishment, and he thought it a pity to disturb an arrangement which had worked well.

On the amendment being put the following voted:—

For—Messrs. Betty, Brown, Churchill, Gostling, Greenish, Hampson, Owen, Sandford, and Shaw.—9.

Against—Messrs. Atherton, Atkins, Bottle, Cracknell, Hills, Mackay, Rimmington, Robbins, Savage, Schacht, and Williams.—11.

The amendment was therefore lost, and the original motion adopting the Report was then put and carried.

Reporting the Council Meetings.

Mr. Hampson next moved the resolution of which he had given notice, as follows:—

"That it is desirable that the proceedings of the Council be reported by a reporter or reporters from the recognized journal or journals representing pharmacy and the trade, as well as by a reporter of the Journal of the Society."

He said an apology was almost due from him to Mr. Betty, who had moved so actively in this question some time ago. He felt the question would now be better in Mr. Betty's hands, but no doubt it would receive ample support from him. Five years ago Mr. Betty moved a resolution to the effect that the proceedings of the Council should be genuinely reported, in order that there should be full confidence attached to the proceedings of the Council. His action had certainly been very valuable, and the reports had very much improved in consequence. Years ago the Council met and its constituents and members of the trade knew very little of what occurred. Now they knew more, no doubt, but he was anxious that there should not be a shadow of a doubt as to the character of the proceedings, that there should not be any feeling in the body they represented that the proceedings were not properly reported. What was the character of the arrangement which now existed? It was certainly a very pleasant one, but, he did not think it was perfect or healthy. The Council had its own reporter, and he must certainly compliment him on the manner in which he carried out his duties; he had not a shadow of complaint to make against him, but it was almost impossible for him to give an absolutely genuine report. After he had written down what he considered to be important, the remarks of each speaker were sent to the Editor, and were put into type, and were then sent to the town members, and they had an opportunity—a very pleasant one he might admit—to amend, to improve, or to add to, or possibly to suppress a portion of the report. At any rate, it was an opportunity which he certainly had been tempted to take advantage of, for it was almost impossible for any person receiving such a report to altogether ignore it. But that was not such a report as he desired should be published. He believed that by having an independent reporter members of the Council would see themselves as others saw them, and that it would be very much healthier and better for them in every way, so that there could be no possibility of any one outside even whispering the suggestion that they reported themselves. It was his attachment to the Society that made him bring this matter forward. It had been said, and with truth, that the members had taken very little interest in the proceedings of the Society, and if the number of voters who exercised the privilege of voting indicated interest, it was certainly very small. He would rather increase that interest by producing perfect confidence, and that he believed would be the effect of carrying out his motion. He saw no objection to having the kind of report he alluded to. The Council had always the opportunity when anything very special was being considered of a private nature to do so in Committee, and there was also the General Purposes Committee which could discuss any important and delicate question which it was not desired to publish. He would also call attention to the fact that other bodies occupying a similar position allowed independent reports to be published. This was the case with the Medical Council, which did not report itself; and what he wished was that there should be no obstacle to the introduction of an independent reporter from any journal or journals, because there might be two or three pharmaceutical journals, and it would be very desirable that each journal should have an opportunity of reporting the proceedings. He recommended the resolution to the Council as the natural result of what had taken place in the past; and besides the advantages he had named, he thought there would be less desultory talk, and the business would be got through better and more quickly.

Mr. Churchill had much pleasure in seconding the resolution. Since he had sat at the Board he had been able to see that the debates appeared fairly reported, but there was an impression amongst the people outside that the members of the Council reported themselves, and and he thought the best way to rebut such an idea would be to admit accredited reporters from any other pharmaceutical organs who might wish to attend. The only argument he need use was to point out a little correspondence which had taken place relative to the last election, the observation having been made by several members of Council and others how small a proportion of the Society voted in these important elections.

Mr. Schacht entirely concurred with the proposition introduced by Mr. Hampson, though he should say it was not from the smallest idea of any better report being given of the proceedings which took place there. It was because of the excellence of the reports which were prepared by the reporter, that he wished all reports of their proceedings to come through the same sort of channel. Now it was a fact that there was another journal, which more or less professed to represent pharmacy, in which there were so-called reports of what took place at the Council Board. From whom the editor received the inspiration was a mystery to him, but it was an inspiration of a very curious sort indeed. He had often seen the most extraordinary exaggeration and misrepresentation of what speakers had said, which he was quite sure the editor would never have sanctioned with his eyes opened. This had always presented itself to his mind as a strong reason why he should have an opportunity of sending his accredited reporter to the meeting, and then the Council would have a right to call him to account for what he did report, and he was quite certain he would be only too glad to avail himself of the opportunity. He could not, however, allow the observation made by Mr. Hampson to pass entirely unchallenged. It appeared from what he said that individual members had an opportunity of correcting the reports of their observations before they were published. It might be that Mr. Hampson, or the members living in London, had the good fortune to be so treated, and no doubt they deserved that privilege, and he was not at all jealous of it, but he certainly never had the opportunity himself, and he rather thought that gentlemen in the country were left to the tender mercies of the reporter, of which, however, he personally had no reason whatever to complain.

Mr. SHAW supported the motion. He said he need not go over all the reasons for doing so, though he thought they might be proud of the manner in which their proceedings had been reported for the past five years, during which time the matter had been left entirely to the reporter. At the same time he thought it would be satisfactory to that gentleman if he had a colleague. There would not be more than one or two extra reporters who would make application under this resolution, so that he did not think any inconvenience would arise. He was not aware previously that London members had the privilege of revising their remarks.

Mr. GOSTLING, who said he was obliged to leave early, stated that he should have voted for the resolution if he had been able to remain.

The PRESIDENT said that Mr. Hanbury, who had been obliged to leave, had told him that he should have voted against it, so that those two gentlemen might be considered to have paired.

Mr. BROWN said he should support Mr. Hampson's motion. He need not repeat the satisfaction which had been expressed by every member who had already spoken with the character of the reports prepared for the perusal of the public, but which did not always go forth to the public. He considered the proceedings of the Council ought to be public property, and that there should be no revision of the report after it was written by the authorized reporter of any journal connected with the trade. He thought if they had reporters generally admitted, every member of the Council would speak under a sense of responsibility, and the work of the committees would be infinitely better done, and better prepared for the Council. At the present time many things were left undecided by the committees, to be afterwards discussed at length in Council, which might be avoided if the committee work were better done. He did not think the Council would lose in dignity by the course proposed, or that any improper revelations would be made.

Mr. SANDFORD said it would be a most excellent thing if they could save time, but he was not at all sure the plan now proposed would enable them to do so. He was sorry to hear Mr. Brown say that the reports of the Committees were not fully and properly drawn up, but however fully and properly that might be done in future he hoped the Council would never forego its privilege of acting on its own discretion whatever the report of the committee might be, for he should not like to see the Council bound hand and foot by the report of any Committee. It would often place the Council in a difficulty if there were reporters from other journals present, though it could not be said in any way that now the reports were cooked for publication. The reporter took notes and sent them to the Editor, who published just what he liked, and the members of Council themselves had no authority to interfere. Sometimes he thought it would be well if they had authority, because he had seen matters published which ought not to have been published. The Council was in a certain sense a private body and often had private business to discuss. If it were always known when these little private matters would come on, and the Council could resolve itself into Committee, well and good; there might then be as many reporters as they liked, but it would be necessary to ask them to leave the room on such occasions. It often happened that the Council did not feel the necessity of going into Committee until something had been said which it was felt the public ought not to read. Therefore he thought it was a matter for grave consideration whether other reporters should be admitted or not, and he was not prepared to vote for such a course.

Mr. MACKAY thought a good deal might be said on both sides of the question. It was in his recollection that some time ago it was remarked by some outsiders that the reports of the Council meeting were very short, and it was said that they were so short sometimes as not to give the members at a distance a fair idea either of the opinions or of the work done by the Council. He did not share that feeling, but still it became so clamant that a reference was made to the Editor whose reply was that he printed what he received, and that he could neither alter it, lengthen or shorten it unless he was allowed a seat in the room along with the reporter, when he might perhaps be able to give a longer report, and one which might give more satisfaction. That was, at the time, fully considered, but it was decided that the Editor should not be allowed to sit at the reporter's table. With all due deference he thought they might with some advantage follow a middle course on the present occasion, and admit the Editor, and give him and the reporter a fair chance for another twelve months and see the effect of that before throwing open the Council door to other journals.

Mr. ATKINS said he had come quite open to conviction and wished to hear all that could be said before making up his mind. It appeared to him, however, that the tendency of the age was rather towards publicity than secrecy. He thought the Council could scarcely call itself a private body; it was, in his opinion, pre-eminently a public body, and being returned by a large constituency it owed a duty to the constituents, the making its action at the Board, as far as reasonably and safely could be, known to them. If there were greater publicity some of those errors which did occur respecting the matter of the report might be avoided. He was not speaking of the report in the Journal, except this, that he was not satisfied with the length of the Journal report. He could not say he thought all that he had witnessed and heard there had been fully reported in the Journal, but he must bear testimony to the admirable way in which the *precis* or condensed report had been furnished. Still if a more full report had been given a great many of those unjust and unwise criticisms which had been made, never would have been written. Therefore he thought publicity might tend to avoid some of those mistakes. He scarcely understood the relation of their own reporter to their own members, and was going to ask whether it would not be possible that one reporter should furnish a more varied report if need be, to other journals. The answer would be probably readily forthcoming that such a thing would not be practicable. Still the Council was not a private body; it owed so far as was safe a report of what was done and said there to its constituents as was the case with other representative bodies. Mr. Brown, as a member of the Town Council of Manchester, could no doubt speak as to the publicity given to proceedings of that body; and he might say that in his own neighbourhood an effort was being made to have the local press represented at the meeting of the Board of Guardians, and he had no doubt that these efforts would before long be successful. The ratepayers said the guardians were bound to let them know the grounds on which they spent public money, erected buildings, and so on. He must say, therefore, the balance of his judgment rather went towards the admission of other reporters.

Mr. HILLS suggested that Mr. Hampson should alter the terms of his resolution to the effect that the proceedings of the Council be reported more fully, and that the reporter of the *Chemist and Druggist* be invited to attend.

Mr. Brown remarked that the motion simply enunciated the proposition that it was desirable that certain things should be done, and it would be necessary afterwards to refer it to the General Purposes Committee, or to pass a further resolution to say how it should be carried out.

The President said he had had an amendment put into his hand to be moved by Mr. Mackay, and seconded by Mr. Bottle:—

"That in the future meetings of the Council Dr. Paul be admitted to sit at the reporter's table with a view to more fully report the proceedings."

Mr. Brown questioned if this was really an amendment.

The President said it might easily be made so by adding a word or two, if necessary, saying that it was at present undesirable to admit more reporters.

Mr. Betty asked if other reporters were admitted, how the Council would proceed in case of going into Committee. Would those gentlemen be allowed to remain or would they be asked to leave the room each time the Council went into Committee?

Mr. Mackay here said he would withdraw the amendment referred to by the President.

Mr. Betty repeated the question he had put.

Mr. Bottle said he was one of those who had previously expressed a desire that the proceedings of the Council should be made public in every way, but he could not go with Mr. Hampson in the present motion. He had been under the impression for many years that their own Journal represented pharmacy and the trade; but the motion seemed to ignore that and look abroad for some other journal which did so. He should be prepared to admit the reporter of the *Chemist and Druggist*, but the Council should not go begging here and there asking people to send reporters to publish its proceedings, more especially so seeing the Society was interested in a Journal which was a valuable property and of which the proceedings at the Council formed a very attractive portion. Was the Council prepared to ignore the existence and the property it had in that Journal? He should be extremely sorry to see that advantage thrown away, especially as there had been no application from any other journal to admit a reporter. When there was, let it be dealt with upon its own merits. Every one of the gentlemen who advocated the admission of other reporters expressed his satisfaction with the way in which the report was prepared, and was it not well therefore to be satisfied? If the reporting was being done well why should there be a desire to go abroad and do something more? Another reason why he was not prepared to admit the reporters of medical journals or others, was that he did not think the proceedings had hitherto been carried on in that strictly formal way which would be creditable to the Council. Only that day he had had to call attention to the standing orders in order to obtain more regularity in the proceedings, and one gentleman had even interposed with remarks in the middle of the minutes of one of the Committees.

Mr. Betty here repeated his former question.

The President said it must be decided hereafter by the resolution of the Council or some Committee what regulations should be made if reporters were admitted.

Mr. Betty said it seemed to him a matter of public convenience to know whether the Council should have strangers in its midst when it was doing confidential work.

The President said he could give an opinion as a private individual on the question put to him.

Mr. Betty said the President could not occupy the chair as a private individual.

The President said he could not answer the question as President until the Council had decided upon it.

Mr. Betty replied that if he were in the chair, he thought he should have given a very explicit answer to such a question. He did certainly entertain some years ago the idea that the proceedings of the Council should be made as public as the proceedings in Parliament, but he must confess that at that time he did not fully appreciate the delicacy of many matters that came before the Council, and he could now acknowledge the better judgment of those older members who had in this respect modified the somewhat radical constitution of the motion originally brought forward by him, the result of which had been to put a drag on the wheel of the vehicle which perhaps otherwise he should have sent into a position he would not describe. The longer he sat on the Council the more he was convinced that it was necessary in this matter to argue as to what would practically be to their advantage as members of Council. The general opinion expressed by all who had spoken was that the proceedings were fully reported. Persons outside did not think they were; but what had the members of the Council to do with what others thought if their consciences told them they were in the right?—and no one could say they were not. Was the Council to be like a criminal at the Old Bailey, afraid of what people might say of him, and constantly on his defence. A more subservient argument to adduce for altering the mode of procedure he never heard. So long as the Council did its duty and was well represented by the Journal, why in the name of independence should it trouble itself about what other people said? He thought it would show much greater dignity if it were content to face any such position rather than to show itself subservient to every rumour it heard. Considering there was no actual necessity for a change, and no one said it was a necessity, why should not the arrangements remain as they were? One great complaint was that certain London members had an opportunity of seeing a slip of their speeches and making any corrections, but if that was the case he did not see that it was at all an argument against a system which had worked so well, No one on the Council had theoretically a greater love of fairness than Mr. Hampson, but when he wished to influence a certain number of votes he tried to show gentlemen from the country that those in London had some slight advantage over them. What did that signify? It ought not to weigh as an argument on the main point in dispute, and he thought it very unfair to introduce this question as between country and town. Rather than that should be made a bone of contention every town member of the Council would be ready to say he would stand in the same position as the country members. This statement had been repeated again and again until it would almost appear that the London members cooked their speeches, but nothing of the kind took place; a verbal alteration here and there was all that was ever done. It was proposed to give the editor and proprietor of the *Chemist and Druggist*—for no one else would want to come there—the privilege of sitting there and providing matter for that journal out of the reports of the Council meetings. He contended that their own Journal represented pharmacy and the trade, that it properly reported the proceedings of the Society, and that it in fact was the only journal which did represent pharmacy free from the commercial element. He then proceeded to make some further comments which he expressed a desire should not be reported, and concluded by saying he believed that if reporters generally were admitted members would feel such a restriction in speaking that the report would lose both in length and interest.

Mr. Greenish said he should vote against the motion. He thought at the present time the proceedings were reported sufficiently fully and quite fairly. There was a great deal more talk there than need be in proportion to the work done, and he feared that if another reporter were present there would be no end to the speeches which would be made,

Mr. Cracknell quite agreed with the general principles of publicity advocated by Mr. Atkins, but he thought his remarks hardly applied to the present case.

The Council was a public body in one sense, but in another sense it was not. It was the governing body of a trade, and trade interests would very frequently be best served by not being paraded too publicly. It was very desirable, therefore, that the Council should have an amount of control over the reports of its proceedings which it would not have if reporters were admitted indiscriminately, whilst their presence would much hamper the proceedings.

Mr. Robbins said he had come to the conclusion to vote against the motion. This matter came before the Council a short time ago, when it was said that several matters which had been reported were mischievous and were never intended to be reported. The answer to that was that the Council exercised no control over its reporter. That was quite correct, but the reporter was always anxious not to report what would be mischievous. If there were a number of other reporters there, however, what control could be exercised over them? It frequently happened that observations were made which, if reported, might lead to an action at law, or, at all events, would be highly injudicious. In debating a large number of subjects it was impossible sometimes not to mention names and other matters which it was necessary should not be reported. He could not see any advantage in having more reporters, because it appeared to him the reports of their meetings were fully given. In reading them over in the evening he could fancy he was sitting at the table and listening to his colleagues' observations. He could see a great disadvantage in having a large number of reporters present, but no advantage whatever.

Mr. Owen said he came perfectly unbiassed, determined to listen to every argument on every side, and he could only say that he was quite satisfied with things as they were.

The President said he had made up his mind to vote against the motion. He thought the time had not arrived when it would be expedient to introduce this change. He wished to see a good, full, faithful report of what occurred, and he was not prepared quite to go with all the gentlemen who were so perfectly satisfied with the reports. He thought they might be, and ought to be, fuller, with more colour in them. If their reporter could infuse a little more soul into them without giving any opening to those who were apt to cavil at them, it would often be an advantage. He could see many disadvantages that would follow the adopting of the motion. It might often happen that medical journals would wish to send their reporters, and when private matters were discussed they would have to be sent out of the room and great delay and inconvenience would arise.

Mr. Hampson, in reply, said he should have rather a long task if he took up all the arguments, and so-called arguments, both for and against him, and therefore he should not attempt to do so at length. Mr. Sandford, in the first place, distinctly said it would not save time to have an independent reporter, but it was found in all public bodies, as a rule, that business was facilitated by having an independent reporter present, because speakers then felt fully responsible for the views they enunciated. It would have this advantage, that gentlemen would come prepared to express their opinions, and they would not have so much desultory conversation. It was also said by Mr. Sandford that the Editor published just what he liked; but that was an eminently unsatisfactory condition of affairs. Mr. Mackay thought the Editor might be introduced in a sort of nondescript capacity; he would not be reporter, he would simply be an auditor. He did not think that would be an improvement. Mr. Atkins and Mr. Schacht it would appear were both ignorant of the advantages the town members possessed. He would like to particularize some of those advantages in reply to Mr. Betty who thought he had given unfair prominence to the privilege, although he utterly denied having done so. It was one he did not desire, and thought it was one which few men could use with satisfaction to themselves, because it placed a temptation in their way. They might think they could alter the turn of a sentence so as more completely to express their views, but that was not fair towards other members who had spoken, and who had not the same opportunity. Every man ought to be responsible for the views he enunciated at the time under the particular circumstances of the moment and to bear the consequences of his utterances, and he thought an arrangement so unfair with respect to country members eminently unsatisfactory. Mr. Betty illustrated the disadvantages which would accrue from carrying his resolution by stating that the proceedings of the Council were not of such a character as to bring credit to its members, and Mr. Bottle had likewise spoken in a somewhat similar strain. But he maintained that if that were so, by having an independent reporter the character of their discussions would be improved and time would be saved; so that on the whole those arguments were in his favour. Mr. Betty himself had undertaken to-day most unwarrantably to instruct the reporter as to how he should report his part of this discussion, and the President in the same spirit had also taken upon himself to give advice as to how the report should be prepared, recommending that he should "infuse a little soul into their reports." He had not the least objection to accept Mr. Bottle's amendment if he desired to press it, but he had made his resolution as comprehensive as possible, not wishing to single out any particular journal. If the principle were adopted arrangements could be made accordingly; but he was quite willing to accept the amendment.

Mr. Bottle said his amendment was that the Editor of the Society's Journal should be introduced, and that had been withdrawn.

Mr. Hampson, continuing, said he thought it undignified for any member to speak of the proceedings of the Council in a depreciatory style, and he believed that any journal which sent a representative there would in all probability act with perfect fairness and would not sow discord or introduce that state of havoc which Mr. Betty so much feared.

The motion was then put with the following result:—

For—Messrs. Atkins, Hampson, Schacht and Shaw.

Against—Messrs. Betty, Bottle, Cracknell, Greenish, Hills, Mackay, Owen, Rimmington, Robbins, Sandford and Williams.

The motion was therefore lost.

———

The Secretary presented further returns respecting the number of students attending the classes and the expenses in connection therewith, which, on the motion of the President were referred to the Library, Museum and Laboratory Committee, to put into a more convenient shape for discussion.

———

Mr. Robbins said that at that late hour he would postpone the motion of which he had given notice, with regard to making provision for orphan children, until the next meeting, and the Council then adjourned.

Parliamentary and Law Proceedings.

THE RIGHT OF CHEMISTS TO PRESCRIBE.

At the Birmingham County Court, on Monday, before Mr. J. Motteram, Q.C., judge, an action was brought by the Society of Apothecaries, London, against James Harrison, chemist, of 73, Stafford Street, Birmingham, to recover the sum of £20, for that after the 1st of August, 1815, in contravention of an Act of George III. for the better regulation and practice of apothecaries, he did unlawfully practise as an apothecary without having the necessary certificate.

Mr. Nathan (instructed by Mr. Reeves) appeared for the plaintiffs, and Mr. Jesse Herbert (instructed by Mr. Glaisyer) for the defendant.

The case for the plaintiffs was that on the 27th of November, 1876, a woman named Julia Caddick went to the defendant's shop and asked him if he could make her up something for a weakness left on her since her confinement. Defendant inquired her symptoms, looked at her, felt her pulse, and gave her some medicine, which he said would do her good. She paid a shilling for the medicine and departed.

Mr. Charles Suffield, surgeon, said after hearing the evidence of the woman Caddick he was of opinion that she was suffering at the time she applied to the defendant from anæmia, which was a dangerous complaint and frequently ended in death if not properly treated.

After some discussion Mr. Herbert said it was clear that chemists and druggists might furnish and supply medicines, and as to attending and advising, there had been none in the present case, according to the evidence given. It was strange that for sixty years the Apothecaries' Company had allowed chemists and druggists all over the country to do what the present defendant had done without interfering in any way.

His Honour said, in his opinion, a man might go to a chemist and say "I have got the toothache, or I have the headache; will you give me some sal volatile for the headache or some tincture for the toothache?" That was one thing; but whether the chemist could take ordinary means of finding out the headache or the toothache, and then prescribe the medicine for the disease which he himself had found out, was quite another matter. If a person told the chemist that he was suffering from some disease or other, he knew not what, and the chemist felt his pulse and said, "I will give you something," surely that would be an infringement of the Act. If Mr. Herbert meant to contend that a chemist should prescribe, he would give him a case upon it.

Mr. Herbert said no examination was made by the defendant. He simply supplied the woman with what she required.

The defendant was then called. He stated that Julia Caddick asked for some medicine for general weakness. He did not examine her neither did he feel her pulse. The label on the bottle (produced) was one of his labels, but having tasted the contents of the bottle, he swore that no such stuff had ever been sold at his shop. It was not necessary to examine the woman. He prescribed for her by "instinct." He gave her a mixture of quinine and iron, which was a common remedy for anæmia.

Mr. Thomas Parsons said that when he was an apprentice in 1809, the practice adopted by the defendant in the present case was the general custom Later on he had prescribed and given medicines in simple cases. In more serious cases the prescribing was attended to by the principal at the shops where witness had been employed.

His Honour said it was still more dangerous for a man to practise if he took simply the word of a patient, who was admitted to be suffering from a serious disease. It was almost impossible to conceive how important it was that the Act should be carried out.

The case was then adjourned.

On Tuesday the case was again brought forward. Several witnesses were called, and formal evidence given with a view to disprove the statement made by the defendant to the effect that the medicine produced in Court was not that with which he supplied the woman Caddick at his shop, in November last.

His Honour said he should not have allowed such evidence to be given had it not been that the defendant's statement was a reflection upon the persons who got up the plaintiffs' case.

Mr. Herbert said his client had spoken in a moment of excitement, and he would not deny that the medicine produced was supplied at his establishment. Proceeding to address the Court for the defence, Mr. Herbert contended that a chemist had a right to prescribe small remedies in his own shop, and that he contravened the law only when he undertook to visit and prescribe for patients at their own homes.

His Honour pointed out that the Act of Parliament distinctly laid down that a chemist's duties were to "buy, compound, dispense, and vend," and said that when a chemist exceeded these duties he undoubtedly made himself amenable to the law. Baron Bramwell held that if a man went to a chemist's shop and asked for something for a headache and a medicine was supplied to him, the chemist technically infringed the terms of the Act. He (Mr. Motteram) did not put so strict an interpretation upon the law as that, but he held that if a person went to a chemist and explained certain symptoms of a disease with which he or she was not acquainted, and the chemist prescribed for such disease after an examination of any kind whatever, he made himself liable to an action under the Act of Parliament.

A lengthy argument followed, and Mr. Nathan having replied on behalf of the plaintiffs, his Honour said that as there was an appeal in a similar case pending in a higher court at the present time, he would defer judgment until after decision had been given on the appeal, for it would be unnecessary to put the defendant to the expense of taking a second case to be decided before a higher tribunal.

THE CHARGE OF PERSONATION AT THE PRELIMINARY EXAMINATION.

On Tuesday last, George Frederick Webb, was charged at the Bow Street Police Court, before Mr. Vaughan, on remand, with fraudulently procuring his registration under the Pharmacy Act, 1868, and Andrew Ritchie Hunter was charged with aiding and abetting him in the same. They were also jointly charged with conspiracy. Mr. Douglas Straight, instructed by Messrs. Flux and Co., appeared for the Pharmaceutical Society.

Evidence was given by a detective officer as to the arrest of Hunter at Wolverhampton, and to the effect that Hunter then acknowledged that he had passed the Preliminary examination for Webb, but asserted that at the time he was not aware that the proceeding was a criminal offence.

Mr. William G. Hayward, pharmaceutical chemist, of Reading, deposed that he was the Local Secretary of the

Pharmaceutical Society in Reading, and that in July, 1876, he superintended the local Preliminary examination held in that town. On that occasion five persons were present as candidates, of whom the defendant Hunter was one, and when the names were called over, Hunter answered to the name of George Frederick Webb.

Mr. Nockolds, chemist and druggist, said that the defendant Webb was in his employ when arrested. He knew that Webb had failed to pass the Preliminary in April, 1876. On the morning following the arrest witness had an interview with Webb at Bow Street, and pressed him to tell the truth and meet the charge properly. Webb then told him that after his failure to pass he was being "coached" by a Mr. Ramsay, living in Gower Street. On one occasion the class was taken by Hunter. After the close Hunter walked with Webb to the station. On the way Hunter proposed to Webb that he should pass the examination for him. Hunter said that it could be done for he had done it before. Hunter said he should require three guineas for his trouble.

The defendants being told that they were at liberty to put any questions to the witness, Hunter said that probably witness had only stated what Webb had told him, but that there were several inaccuracies in the statement. Webb made a statement in which he reiterated what he had before said to his employer.

Webb was then committed to take his trial at the Central Criminal Court, and Hunter was remanded till Friday, by which time it was expected that the prosecutors would be able to proceed against him on another charge in connection with a person for whose arrest a warrant was issued. Meanwhile Mr. Vaughan said he would admit both prisoners to bail.

On Friday, as the expected arrest had not been made, Hunter was again remanded until Monday.

We are informed that the arrest has now been made.

Poisoning by a Mercurial Powder.

Mr. Donaldson has held an inquest at the London Hospital, relative to the death of Catherine Watson, aged eight weeks. Mary Ann Watson, wife of a labourer, stated that on the previous Wednesday she took deceased to the London Hospital, as it was suffering from skin disease, and two powders and some ointment were given her. On arriving home at twelve o'clock she gave deceased one of the powders, when it became very cross and vomited. The next morning at six o'clock she took the deceased to the hospital, when it was pronounced dead. The doctor had told her to administer the powder every morning. There was something written on the paper, but she could not read. Mr. William Howes, dispenser at the London Hospital, said he gave the mother two papers of powders, there being six doses in each packet, which was marked on the outside. There was one grain in each of mercury and chalk, called grey powder. A juryman said he considered that the powders ought to be made up separately. Mr. Rees, house surgeon, said he had made a *post-mortem* examination. The quantity of mercury acting on a weak child had caused death. If the powders had been made up separately, and only one administered, it would not have caused death. The jury returned a verdict of "Accidental Death."

Poisoning by Prussic Acid.

At Kendal, Richard Braithwaite, a brazier, has committed suicide by taking prussic acid. Deceased was defendant in an action for libel which was to have been tried at the Appleby Assizes, and this appears to have weighed heavily on his mind.

Suicide of a Medical Student.

On June 26, Mr. Bedford held an inquiry at St. George's Hospital, respecting the death of Walter Hugo, a medical student, aged twenty-two. Deceased was known as a student at Charing Cross Hospital by the name of Victor Hugo. On Thursday afternoon, about four o'clock, he left Charing Cross Hospital in apparent good spirits, and at seven the same evening his dead body was found in Hyde Park, near the Reformers' Tree. The *post-mortem* examination clearly proved that death was caused by a large quantity of prussic acid.

An open verdict was returned of "Death from poison," and "that there was not sufficient evidence to show how it came into the stomach of the deceased."

Dispensing Memoranda.

[6]. Chloric Ether.—In answer to this query it is my opinion that spt. chloroformi would be the correct article to dispense when spt. æth. chlor. is ordered. When æth. chlor. is ordered I dispense a preparation mixed according to the formula given in Gray's 'Supplement," p. 633:—Chloroform 1 part, S.V.R. 8 parts.

An Assistant, *Exeter.*

[6]. Chloric Ether.—In reply to Mr. Leigh's query, I venture to say that spt. chloroformi has no more right to be substituted for æther. chlor. in a mixture than "sulph. præcip." has to be given instead of "lac sulphuris," which, in accordance with the decision in reference to the much vexed "sulphur question," are regarded as two distinct preparations. So ought the others to be looked upon; the former of B. P. strength (one in twenty), the latter with more than double the proportion of active ingredient, viz., one part of chloroform to seven of S.V.R. Unfortunately, difficulties of this nature do spring up in certain establishments—right of usage overruling the intention of the prescriber. There should be no dubiety in the matter (although considerable controversy frequently occurs upon the subject), for all young physicians are sufficiently well versed in the British Pharmacopœia nomenclature to know what "spt. chloroformi" represents, whilst the older members of the medical fraternity are not like to discard the names or despise the remedies they have, for years, been accustomed to prescribe. I suppose the best plan where disputes arise, is to go upon the principle "of two evils choose the lesser," and dispense the article insisted on by the master (if he cannot be persuaded to change his opinion), so that, in repetitions, uniformity may be adhered to, but, in all cases, the date of the formula ought to be observed, and if written prior to 1864, there is no alternative but to employ æther. chloric. (one in eight). It is a pity, however, that the younger members of our craft should be subjected to the mortification of being compelled to act in direct opposition to their conscientious and correct convictions—or otherwise lose their situations—owing to the dogmatic opinions of their employers, who have been trained in a different school.

J. B. L. Mackay.

[8]. CARBOLIC ACID MIXTURE.—Can any reader inform me how to mix the following recipe, so that the carbolic acid will not separate when more water is added?—

Ac. Carbol., Calvert's (No 5) . . . ʒj.
Hyd. Bichlor . . . . ℈ij.
Aq. ad . . . . ℥viij.

J. W. Hayton.

[9]. MISTURA FEBRIFUGA.—Would "Mistura Febrifuga," the formula for which is given in Beasley, p. 285, be the correct article to dispense in the following prescription?

℞ Liq. Morphiæ . . . . . ʒj.
Vini Ipecacuan. . . . . ʒiss.
Mist. Febr. . . . . . . ℥viij.

An eighth part every four hours. An Assistant.

Correspondence.

The Council Prizes.

Sir,—In the last issue of the *Pharmaceutical Journal*, a letter appears with the signature "*Auld Reekie*," commenting on the examination for the Council prizes offered for competition to those who have passed the Major examination during the preceding year. Some people exist who are never happy unless they have a grievance to air. "*Auld Reekie*" seems to be one of these. I consider that the very facts which he adduces as ground for complaint should really be productive of the liveliest satisfaction. He quotes some of the questions asked at the last examination, and thinks that those who studied in a London school of pharmacy would be better able to answer half of one of the questions, than others who had not done so, or even than those who had attended a course of Sir Robert Christison's lectures: that another question "smelt" strongly of the 'Pharmacographia,' and was not to be found in Scoresby-Jackson, and that "cram" is the only means of gaining the required information, and that the questions are really "catch" questions. Again that a third question under the head of materia medica really belonged more to the chemistry department, and that it is of "no consequence" to remember the proper solution of a fourth.

With regard to the first objection I venture to assert that no course of lectures alone would give the knowledge required to fully answer the half question. Within a period of eighteen months previous to the examination, an admirable research upon some of the species of the natural order Melanthaceæ had appeared in the *Pharmaceutical Journal*, and without a knowledge of which no candidate could hope to fully answer the question. I consider this highly satisfactory, as it gives direct encouragement to self-help and the acquirement of knowledge of the most valuable kind, viz., the results of modern research. The second objection is almost too trivial and absurd to require an answer. Is not the 'Pharmacographia' as easily obtainable in Scotland as in England? If a certain text-book does not contain the results of recent research, are the examiners to abstain from asking questions on that matter? Further, has not an elaborate paper on the very subject of the question appeared in the *Pharmaceutical Journal* within the last few years? Surely the *Journal* is as accessible to Scotchmen and Countrymen as to Londoners. It is intolerable to think that, because certain valuable matter does not appear in a certain text-book, and is not mentioned in a certain course of lectures, it should be gravely suggested that examiners should not select questions from that matter.

Turning to the third objection, I would simply ask "*Auld Reekie*"—How is it possible in the matter of the adulteration of drugs, to draw a line so that chemistry shall not be introduced? With regard to the question selected for criticism from the chemistry paper, I think it is of considerable "consequence" to have some knowledge of the body by the combustion of which artificial light is commonly produced. It is impossible to give its exact per centage composition, since it constantly varies from different causes, such as the amount of heat employed in its manufacture, etc. Here is a field in which a well-informed candidate might display his knowledge by stating what the chief variations and their causes are.

"*Auld Reekie*" puts forth his complaint in great measure on behalf of Scotch Students. The reality of his grievance and the quality of his championship can be judged from the fact that there has not been a single successful Major candidate at Edinburgh up to the present time during this session.

Finally, "Auld Reekie's" letter would be simply productive of amusement, did it not rouse one's indignation to the utmost by connecting the odious words "cram" and "catch questions," with the highest prize of the year. Let all intending candidates cast all thoughts of any such connection from their minds, and honestly gird up their loins for the contest. I enclose my card.

London, July 3, 1877. ARATOR.

The Testing of Tannin.

Sir,—My attention has just been directed to the correspondence in your Journal, as to my paper on "Some Methods of Estimating Tannins," and I think Mr. Allen's courteous letter demands a few words of explanation.

I did not of course imagine that a chemist of Mr. Allen's standing could be ignorant of the fact that acetate of lead precipitates gallic acid and colouring matter, as well as tannin, but although, as he remarks, this is rather an advantage than otherwise for the analysis of teas, it is fatal to its value for the estimation of tanning materials. Mr. Allen will not be surprised to learn that other and less experienced chemists had proposed it for this latter purpose, and writing simply as a tanner, it never occurred to me that it was necessary to point out its special applicability to tea-testing, as perhaps I should have done.

I had no expectation in writing the paper that it would find its way into the *Pharmaceutical Journal*, and in my experiments simply aimed at the unambitious though useful end of deciding which of the processes at present in use was most suited to the technical requirements of my trade.

It seems to me that Mr. Allen scarcely takes enough credit to himself for the indicator he proposed, for on it much of the value of the process depends, and in fact I believe that Prilram had previously suggested the use of acetate of lead.

North Shields. H. R. PROCTER.

J. B. L. Mackay.—(1) In an auriculate leaf the lobes are separated almost entirely from the blade, in a hastate leaf they are not. See Bentley 'Man. Botany,' p. 160, fig. 345, 346. (2) *Matricaria chamomilla* has a hollow conical receptacle, and *M. Parthenium* a shallow convex one. If our correspondent will compare the receptacle of a dried chamomile flower with that of the common garden feverfew, he will understand what is the difference between conical and convex. See also Pharm. Journ. [2] vol. i., p. 448, 449. (3) For the sake of uniformity the names adopted in Babington's 'Manual of British Botany' are those we prefer to use in speaking of British plants. (4) *Tanghinia venenifera*, Poir. (*a*) The contraction stands for Poiret, who is the author who described the plants. See Bentley, 'Man. Botany,' p. 379. (*b*) See 'Treas. Botany,' p. 1123, for description of its use, etc. (5) All the 29 forms of *A. Napellus* do not possess characters sufficiently distinct to be classed as *species*, and therefore do not rank as such. De Candolle describes 21 other *species* of *Aconitum*, most of which have also one or more forms. (6) The Linnæan system is scarcely ever used by British botanists at the present day.

"*A Student.*"—Apply to the Secretary for a copy of the pamphlet "Hints to Apprentices and Students."

"*Syrupus.*"—*Orobanche Picridis.*

W. H. P.—We are not prepared to decide "which is the best and most reliable application to produce whiskers," amongst so many competitive compounds.

W. Richardson.—*Myrrhis odorata*

F. A. Brown.—We are informed by the Secretary of the Chemists and Druggists' Trade Association that the appeal on the Apothecaries' Company *v.* Shepperly is entered for hearing in the Exchequer Division of the High Court of Justice on the 2nd of November next.

"*Inquirer*" is thanked for his correction. Ammonium bromide would be formed.

"*Chemicus.*"—(1) There is nothing to prevent a chemist and druggist mixing the ingredients of coloured fires, but he should be careful that in so doing and in their storage and sale he complies with the provisions of the Explosives Act. (See vol. vii. p. 417.) (2) We know of no law to compel you to label the bottle on the grounds stated.

L. Thompson.—*Lithospermum officinale.*

Errata.—In the number for June 23, p. 1040, col. i., line 19, *for* "anhydrous salicylic acid," *read* "anhydrous salicylate of soda;" line 13 from bottom, *for* "CRYSTALLIZED ACONITE," *read* "CRYSTALLIZED ACONITINE."

J. C. T.—Variations not unfrequently occur in these plant

A. P. Baker.—Probably the sale of the quinine at the low figure quoted was due to its purchase by the seller before the last rise in price. We have reason to believe that an alteration has now been made.

Picea taxifolia, Hort.

E.: Pectinate Fir Tree; Silver Fir; Spanish Fir.—G.: Weisstanne; Edeltanne, Pechtanne.—F.: Sapin de Lorraine; Sapin des Vosges; Sapin de Normandie; Sapin pectiné; Sapin argenté; Sapin à feuilles d'If; Sapin commun; Sapin blanc; Sapin en peigne.

This fir-tree is one that inhabits almost all the mountains of Central Europe, the Alps, Apennines, Pyrenees, certain mountains in the Forez and Loire departments, etc. It is very common in the Vosges, and in the Black Forest, where it constitutes high forests; sometimes it is met with in Transylvania. It is worked especially in the Vosges and in the Alps. A variety (*β. Cephalonica*) is met with in continental Greece and in the Islands of Eubœa and Cephalonica. The greatest elevation it attains is in Corsica at 1700 metres, in the Pyrenees at 1950 metres, in the Jura and Auvergne at 1500 metres. It seeks particularly fresh soil formed of detritus from granitic rocks, or in a state of transition and mixed with humus.

The bark of the silver fir loses its epiderm from the first year, laying bare its suberous envelope, which forms a superficial, thin, shining, tensile and smooth periderm, sometimes of a brownish yellow, but more often of a characteristic silver grey colour. The mesophlœum, which is below, is sprinkled with hollow glands in which the turpentine is elaborated and accumulated, the glands becoming ruptured and transformed into irregular lacunæ. The fluid in these glands is very limpid, colourless and viscous, and raises slightly the covering periderms in the form of a small tumour or blister, which, upon being pressed with the nail or a pointed instrument, is ruptured, allowing the contents to run out. Finally, the liber is composed of thin pearly white layers, the most superficial of which, when six to eight years old, are transformed into a reddish thick and ligneous cellular tissue.

The bark remains smooth and bright on the surface until an advanced age, 80 to 100 years, varying with the individuals. Then an internal periderm is developed on the exterior of the active layers of the liber, through which all that is outside becomes dry and constitutes a persistent increasingly cracked rhytidoma, the thickness of which increases with age, but rarely exceeds three to four centimetres.

The production of the internal periderm, by drying the green envelope, naturally arrests the secretion of turpentine, the volatile portion of which is evaporated. The resin becomes concrete, and, remaining in the rhytidoma, makes the bark of the fir one of the best of wood fuels.

The wood of the fir has only fibres and rays; the canals and resiniferous cells are absent, and consequently it has no decided odour.

Extraction. — It has been mentioned that the interior layer of the bark is furnished with a large number of resiniferous ducts, and that in the most external layers of the trunk there are formed larger lacunæ, called cellules or utricules, which in distending raise the suberous portion. These utricules are ruptured with the edge of a steel instrument and the oleo-resinous juice escapes. The turpentine is afterwards collected in bottles and filtered through bark funnels.

Characters.—This turpentine, when freshly collected, is liquid, whitish and milky, but it becomes clear after standing some time in the sun. It resembles Canadian balsam pretty closely, its colour being a pale yellow, but its odour is more agreeable. This odour is very pleasant and citron-like, which has given rise to its French name of "térébenthine au citron." Its taste is less acrid and less bitter than that of Canada balsam. It has the specific gravity of distilled water. It rotates the plane of polarized light 3° to the left, when examined either in the pure state or previously diluted with one-fourth of its weight of benzine. It is soluble in ether, chloroform, benzine and hot amylic alcohol.

---

* L = Latin, E = English, G = German, F = French names.

† The name *Térébenthine de Venise* has no foundation, except it may be that the substance passed as an article of commerce through that city when at the height of its splendour. Possibly, however, this name should be borne by Strassburg turpentine and not by the larch turpentine. In fact, Dodonœus and most ancient authors designate it thus, and give the name "*larice*" to the larch turpentine.

‡ In the Botanical Synonymy here given the author has followed closely Carrière, 'Traité Général des Conifères,' 1867. He also desires to express his indebtedness to the authors of 'Pharmacographia," for assistance derived from that work in the compilation of these papers.

In glacial acetic acid, absolute alcohol and acetone, it dissolves without giving an abundant flocculent precipitate. Its solution in ordinary alcohol, also, is only slightly turbid, a granular precipitate separating upon standing. All the solutions have an acid reaction. Examined under the microscope it shows, especially with polarized light, the presence of numerous crystals of abietic acid.

Strassburg turpentine possesses very marked siccative properties. When exposed to the air there is formed on its surface after a short time a hard brittle crust. If spread out in thin sheets it hardens and solidifies completely. Mixed with one-sixth of its weight of calcined magnesia it acquires a pilular consistence.

Composition.—In 1830, Caillot, who discovered abietine, a crystallizable principle, in Strassburg turpentine, represented the composition of this product as follows:—

Volatile Oil	33·50
Resin, insoluble in Alcohol	6·20
Abietine	10·85
Abietic Acid (resin acid)	46·39
Aqueous Extract (containing succinic acid)	0·85
Loss	2·21
	100·00

Flückiger has found in it 72·4 per cent. of resinous matters (sylvic acid, pinic acid, etc.) and 24 per cent. of an essential oil, boiling at 163° C. and rotating the plane of polarized light 8° to the right. The proportion of essential oil contained in Strassburg turpentine would appear therefore to be very variable. In 1865, Rochleder found in the leaves of the plant a kind of sugar approaching to mannite, to which he gave the name "abietite;" its composition is represented by the formula, $C_{12}H_{16}O_6$.

II.—CANADA BALSAM.*

Synonyms. — E.: Canadian Turpentine. — G.: Canada Balsam.—F.: Baume du Canada; Térébenthine du Canada; Térébenthine du Sapin baumier; Faux baume de Giléad.

E.: Balm of Gilead Fir; American Silver Fir; Balsam Fir.—G.: Balsamtanne; Balsamfichte.—F.: Baumier de Giléad; Sapin baumier de Giléad.

The *Abies balsamea* is a fine tree, which attains a height of 20 to 40 feet, the trunk having an average thickness of 6 to 12 inches. It grows abundantly in the United States, in Nova Scotia, and in Canada. It resembles the *Abies pectinata* of Europe, but the cones are more acute at the summit.

The turpentine of the *Abies balsamea* is also yielded by the *Pinus Fraseri*, the small-fruited or double balsam fir of the Americans. Pursh found this tree on high mountains in Carolina, resembling the *Pinus balsamea* in several respects, but differing at first sight in being a smaller tree, the leaves shorter and more erect, and the cones not one-fourth the size.

The *Pinus* or *Abies Canadensis* (Canada Pine or Hemlock Spruce Fir), grows in the same countries as the *Abies balsamea*, and appears to contain an analogous turpentine.

Extraction.—In this plant the secretory canals are distributed in nearly the same manner as in the *Abies pectinata*, and the turpentine is extracted in a very similar way. Upon piercing the utricules, which cause a protuberance in the exterior layers of the bark, the oleo-resinous juice runs out, and it is filtered in the sunlight.

Characters.—When it is fresh, Canada turpentine is turbid, like Strassburg turpentine, but like it gradually clarifies and becomes transparent. Its colour is pale yellow, with a greenish tinge, becoming duller and darker in time, but still retaining its transparency. The odour is stronger and more agreeable than that of Strassburg turpentine; to the taste it is slightly acrid and bitter, but not disagreeable. Exposed to the air it dries like Strassburg turpentine, but its colour becomes perceptibly darker. This modification in the colour and its odour, constitute the characters by which it can be distinguished from the preceding species.

When examined carefully in direct sunlight Canada turpentine exhibits a slight green fluorescence like other turpentines, or copaiba balsam. This optical property becomes more pronounced when the turpentine is previously heated to a temperature of about 200° C. Examined under the microscope it does not present the crystalline and granular structure observed in some other turpentines, and in this respect it resembles Venice turpentine.

At 14·5° C. the specific gravity of Canada turpentine is 0·998, distilled water having a specific gravity of 1·000 at the same temperature. Mixed in the proportion of 4 parts of the turpentine with 1 part of benzine, and examined in a 50 mm. tube, it rotates the plane of polarized light 2° to the right. This dextrogyre power is also characteristic of the resin, which, according to Flückiger, rotates the polarized beam 8·5° to the right, whilst the essential oil has a rotatory power in the contrary direction.

Canada turpentine is soluble, in all proportions, in chloroform, benzine, ether and hot amylic alcohol; in each case the solution is acid and reddens litmus.

* Although this turpentine is known best by this name, the author, together with most pharmacologists, protests against the term balsam being applied to other substances than drugs containing an essential oil, and one or more volatile acids, such as benzoic or cinnamic acids. It is therefore in error that the name of balsam has been retained in commerce for this Canadian turpentine, since it contains no volatile acid. In consequence of its pleasant odour, it has also been called "balsam of Gilead," but this is equally wrong, as that name applies to the "Mecca turpentine," yielded by the *Balsamodendron Gileadensis*, belonging to the order Terebinthaceæ, and growing in Arabia.

It dissolves readily in carbon bisulphide, but this solution is a little turbid. Glacial acetic acid, acetone, and absolute or 70° to 75° alcohol dissolve it partially, and after boiling followed by a slow cooling give up a large quantity of amorphous residue. Colophane and Venice turpentine dissolve completely in these menstrua. One-fifth of its weight of recently calcined magnesia readily brings it to a pilular consistence; the mixture treated with dilute alcohol and kept during some days at a temperature of 93° C., with very frequent agitation, yields a hard mass that at last becomes transparent.

Composition.—Several analyses of this oleo-resin have been published, that of Bonaster being the oldest, and that of Flückiger the most recent.

Bonaster's Analysis.

Volatile Oil	18·6
Resin soluble in Alcohol	46·0
Sub-resin, slightly soluble in Alcohol	33·4
Soft Resin, similar to the sub-resin	4·0
Bitter Extractive, Salts, and traces of Acetic Acid	4·0

Flückiger's Analysis.

Volatile Oil	24·0
Resin, soluble in Absolute Alcohol	59·8
Resin, insoluble in Absolute Alcohol, but soluble in Ether	16·2
	100·0

Wirzen, who has also made a recent analysis, found 16 per cent. of volatile oil and three amorphous resins, one of which had the composition of abietic acid.

These analyses show that the composition of Canada turpentine is not constant. Flückiger made the quantitative determinations of the volatile oil by heating the turpentine in a water-bath during several days; the same specimen distilled with water yielded only 17 to 18 per cent. of volatile oil.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from Vol. VII., page* 979.)

POLYPODIUM QUERCIFOLIUM.—*Local Names*, KADIC PAN, *and* KALI PANDAN.

A parasitic fern, found upon the roots of trees and widely distributed. The part used medicinally is the rhizome, to which are attached the bases of the fronds and numerous thick radicles, all of a black colour. The rhizome is about as thick as the little finger; when broken across it is seen to consist of a black parenchyma in which are several bundles of vessels of a lighter colour. These can be separated from the canals in which they are situated without much trouble when the rhizome is fresh. Under the microscope the cell walls of the parenchyma appear of a dark brown colour, and the vascular bundles are seen to consist of large scalariform vessels. When at Goa a short time ago, I found this drug in all the shops, and was informed that it is considered a valuable alterative in cases of prolonged malarious fever: it has an astringent and slightly bitter taste. It does not appear to be known as a medicine in Bombay.

PRANGOS PABULARIA.—*Local Name*, FATURASALIYUN.

The fruit consists of a pair of mericarps about ¼ of an inch long, which together form an elongated oblong body crowned by the stylopodium and calycinal teeth; each mericarp has five very prominent convoluted ridges. The margins of the seed are curved inwards, so that a transverse section shows a horseshoe-shaped object, surrounded by about forty vittæ, full of yellowish brown essential oil. The taste is at first somewhat like anise, but afterwards bitter. It is used by the Hakeems as a stimulant and carminative; it is also said to promote the expulsion of the fœtus. Faturasaliyun is an Arabic corruption of Petrosilinum; it is still further corrupted by the Bombay druggists into Phuttersalum.

ACONITUM, Sp.?—*Local Names*, WAKMA *and* BIKHMA

Tuberous roots of a light brown colour, resembling those of *Aconitum Napellus* in size and shape; they break with a short fracture, and the interior is either white and farinaceous, or horny and yellowish. Both the horny and farinaceous roots have a pure bitter taste, as persistent as that of quinine, without any acridity. The roots when soaked in water have a pungent smell like nasturtium. They do not resemble any of the varieties of aconite described by Mr. Moodeen Sheriff ('Supplement to Pharmacopœia of India,' pp. 25, 32, 265). They may or may not be included in the numerous varieties of aconite noticed in the Makhzan ul Adwiya and other Persian and Arabic works on Materia Medica, under the heads Bish and Judwar. The descriptions are not sufficiently minute to determine this point. Microscopic structure:—The parenchyma is composed of large oblong thin-walled cells loaded with starch; the vascular bundles, which consist of scalariform vessels, are about twelve in number. In the young tubers they are crowded together towards the centre; in the old ones they occupy the circumference. This drug is new to me, and is little known in Bombay. A considerable parcel was brought here a short time since by a Brahmin from Maugrole, who would not say where it came from. He has written a pamphlet to explain its properties, the most remarkable of which are, that it is said to stop vomiting or purging, and allay pain in the abdomen. The dose, according to our Brahmin, is two grains. Dr. Sakharam Arjun, a graduate of the University of Bombay, practising here, tells me that he is acquainted with the drug, and that he considers it to be a powerful bitter and antiperiodic. He believes it to be the root of *Aconitum palmatum*.

NAREGAMIA ALATA.—*Local Names*, TINPANA *and* KAPUR BHENDI.

This is the country Ipecacuanha or Trifolio of the Portuguese at Goa. It is a small woody shrub, seldom more than 6—8 inches high, consisting of several slender stems, sparingly branched, rising from a spreading root-stock, which is contorted, knotty, and warty. The leaves are alternate, mostly situated at the ends of the branches, and consist of a narrow winged petiole ¾ to 1 inch long, at the end of which are articulated three small cuneate obovate leaflets. The ends of the shoots and buds are seen under the microscope to be thickly covered with white simple hairs; the petiole and leaflets are nearly free from them. The flowers are large and white, on axillary peduncles; the capsules 3-angled and 3-valved. The drug consists of the creeping root with the small stems attached, the leaves having been stripped off. A section of the root examined microscopically presents a tolerably thick dry suberous layer of a brown colour; immediately within this, the parenchyma, which is composed of thin walled cells, is much loaded with a yellowish oil. In the inner portion of the bark the cells contain starch; the wood is very hard and of a greenish yellow colour. The drug has a somewhat pungent aromatic odour, but hardly any taste; it is given as an emetic in doses of from 12—18 grains. Trifolio is abundant in the Southern Concon and Goa territory on the banks of nullahs.

METHONIA SUPERBA.—*Local names*, VINDAI *and* NAGKARIA.

This beautiful climbing plant, which adorns the hedges at the end of the rainy season, has a tuberous cylindrical or flattened root, often 7—8 inches long, and about one inch in diameter. It consists of two tubers which unite at a right angle, one being much smaller than the other. At the point of union may be seen, on the upper surface, a circular scar marking the attachment of the stem, and on the under surface immediately beneath it another, to which a tuft of thin rootlets is often attached. The tubers are covered with a brown epidermis except at the point, which is tapering and nearly white, like the growing part of a young kidney potato. Internally they are juicy, white and farinaceous, and have a faint acrid odour like potatoes. The taste is mucilaginous, feebly bitter, and a little warm and acrid. Examined microscopically, the root is seen to consist of large starch granules, principally oval, contained in very delicate thin-walled cells. The vascular bundles are few, and are composed of spiral and pointed vessels. The epidermis is an exuvium of the delicate cellular structure compressed and discoloured. Mr. Moodeen Sheriff finds this drug to act as an alterative tonic and antiperiodic. He has given it in 12-grain doses without its producing any disagreeable symptoms. Popularly it is considered poisonous, and is said to be sometimes criminally administered to cattle in this neighbourhood. A small piece is said to be a certain remedy for worms in cattle.

TRIBULUS TERRESTRIS.—*Local name*, CHOTA GOKHROO.

This plant is well described by Ainslie, he says: "The species in question is a common plant near the Dardanelles, and called in modern Greek Τριβόλια; it has a slender fibrous root, from which spring four to five delicate stalks, spreading flat on the ground; these are hairy and extend 2½ feet in length; the leaves are pinnated, leaflets five to six pairs nearly round. The flowers are axillary on short peduncles, and composed of five broad obtuse yellow petals; these are succeeded by a roundish five-cornered fruit, about the size of a marble, armed with prickles, the bane of travellers; this ripening divides into five cells, each armed with four strong sharp thorns, and containing several seeds." The latter part of this description has been slightly altered, as it was incorrect. The cocci are wedge shaped, yellowish when ripe; the external convex surface being rough between the thorns. When all five are *in situ* the fruit presents ten thorns pointing towards the peduncle, and ten pointing outwards round the circumference; the latter are developed first. This may account for the statement in some books, that each coccus has only two spines. The seeds are oily, and enclosed in very hard stony cells. Chota Gokhroo is always to be obtained in the shops. It is valued as a diuretic. The taste is rather agreeable.

POLYPODIUM VULGARE.—*Local name*, BASFAIJ.

The dried rhizome occurs in pieces of various lengths, and of the thickness of a quill. It is flattened, of a yellowish-brown colour externally, green internally, but when old, yellowish; the upper surface is studded with tubercles, to some of which a portion of the base of the frond still adheres. The under surface is more or less spinous from the remains of broken radicles. The taste is sweetish, astringent, nauseous, and somewhat acrid; odour ferny. Under the microscope the rhizome is seen to consist of a delicate cellular structure containing much starch and green granular matter; it is traversed by large bundles of scalariform vessels. Analysed by Dêsfosses, it was found to contain a complex substance, partly resinous and partly oily, a fermentable sugar, a substance analogous to sarcocolla, an astringent matter, gum, starch, albumen, and salts of lime and magnesia. Confer. Guibourt, vol. 2, p. 71, where there is a good figure of the drug. Basfaij is aperient and deobstruent, and is considered to act as an expellant of peccant humours; it is also used as an alterative in a variety of disorders; it is frequently combined with cassia pulp and honey. The Mahomedan Hakeems use it largely. It is the Polupodion of the Greeks, and the Azras ul Kalb of the Arabs; the latter name, which may be translated Dog's Tooth Fern, is given to it on account of the toothed appearance of the fronds.

MELIA SUPERBA.—*Local names of drug*, KALA KHAJUR, or KURROO KHAJUR.

The dried fruit of this tree is sold in all the shops under this name, which means black or bitter date. In size, shape, and colour it is very much like that fruit, but upon closer examination the pulp is found to adhere firmly to a large and very hard stone. The remains of the peduncle may also be seen to be different from that of a date. When soaked in water it soon loses its shrivelled appearance, and becomes like a large oval yellowish green plum. The skin is now seen to be thick and easily separated from the pulp, which consists of a delicate parenchyma supported by fibrous bands attached to the stone. The apex of the fruit is blunt, and studded with small tubercles. At the base is attached the five-partite calyx and a small portion of the fruit stalk. The stone is an inch in length, obscurely five-furrowed, oblong, perforated at both ends; apex five-toothed round the perforation, five-celled; seeds solitary, lanceolar, attached from the apex; perisperm in small quantity; embryo straight, inverse; cotyledons lanceolate; radicle oval, superior. The seed is ¾ of an inch long, and ⅛ of an inch broad; testa dark brown or black, polished; kernel very oily, sweet tasted. Under the microscope the cells of the fruit pulp are seen to be full of oil globules and fine granular matter, and the skin to consist of one row of columnar cells covered by a horny epidermis. This drug has a bitter nauseous taste. It is a favourite remedy amongst the labouring classes for colic; half a fruit is the dose for an adult. It appears to have hardly any purgative properties, but is said to relieve the pain most effectively. The *Melia superba* is a native of Soonda, and a large forest tree.

PERISTROPHE BICALYCULATA.—*Local name*, GHATI PITPAPRA.

The whole herb is gathered when in flower and dried. Stem much branched, six sided, rough, covered with white jointed hairs; leaves ovate, acuminate, rough, a few jointed hairs scattered here and there; peduncles axillary; branches dichotomous; flower heads 1–1½ inches long, flowers small, pink; root slender, long, woody, straight, with numerous slender stems rising from the crown. This is a small plant, and very abundant in the rainy season. It has a faintly bitter disagreeable taste, and is used as a substitute for *Fumaria parviflora*, the true Pitpapra.

(*To be continued.*)

SANTONIN.*

BY E. MARLETT BODDY, F.R.C.S., ETC.

There is no doubt that santonin is, for many reasons, by far the most efficient anthelmintic which can possibly be administered to children, and its combination with calomel I have found to be most advantageous in every respect. Santonin, like every other therapeutic agent, requires care in its administration; and if it is allowed to remain in the system it acts deleteriously, like certain cumulative medicines. This pernicious after-action one of course seeks as much as possible to obviate, and the only way to do so as regards santonin is to combine it with some purgative, such as calomel, which carries it off.

According to Falck of Marburg, if santonin is allowed to remain in the system we get a substance called xanthopsin, into which santonin is supposed to be transformed under certain circumstances which at present are not well ascertained. This xanthopsin is excreted by the urine, giving it a remarkable yellow colour, causing a similitude to that secretion passed in jaundice, and its presence there is easily detected by caustic alkalies, which redden the urine. No doubt it is this xanthopsin which gives rise to those dangerous symptoms that have been so largely dilated on of late, and which many attribute to santonin only, forgetting or ignoring the presence of xanthopsin; and this mischievous action I have found from experience to be entirely counteracted, or rather prevented, by administering calomel at the same time.

I generally administer santonin combined, as I have just said, with calomel, or I give it preceded and then followed by that drug; but one plan is as good as the other. The results of so giving this anthelmintic in either of these two modes have been most happy, and I have very seldom found it necessary to repeat the dose, for such treatment is thorough, and consequently precludes the necessity of repetition.

I myself have never had a case where convulsions or retention of urine have originated from santonin; in fact, I have never seen any untoward symptom resulting from it in any way whatever, which I attribute to my combining it with calomel, or preceding and following it up by that purgative.

My experience has convinced me that nothing of a deleterious tendency can possibly accrue from santonin if it is combined with calomel, for by so doing we do not allow sufficient time to elapse for the xanthopsin to act on the system, for when the santonin has done its work the calomel removes it. The latter drug is a more searching purgative than castor oil; being likewise a cholagogue, it causes a greater secretion of bile, which, as my readers know, is the natural purgative. Giving the santonin in one of these two methods aforementioned will entirely prevent all dangerous symptoms arising; there will be no convulsions and no retention of urine, nor will that secretion appear like that found in jaundice, for this one simple reason: the santonin, when it has done its work, is eliminated from the system by the calomel, and consequently the poisonous xanthopsin has not sufficient time to form. Perhaps this substance is the cause of patients seeing objects either yellow or green in colour.

* From the *Medical Times and Gazette*, July 7, 1877.

FORMULÆ FOR NEW MEDICAMENTS ADOPTED BY THE PARIS PHARMACEUTICAL SOCIETY.

(*Continued from Vol. VII., page 1064.*)

DIASTASE.

Malt, the germination of which is two-thirds the length of the grain, and which has been dried at 50°C., is ground in a mill and treated with two parts of water at the ordinary temperature, stirring from time to time; after six hours' contact it is strained and pressed, and the liquor filtered is added to twice its volume of 95° alcohol. The precipitate formed is collected on filters, spread in thin layers upon glass plates, and dried rapidly in a current of air at a temperature of 45°.

Test.—0·05 gram of diastase added to 200 grams of paste containing 10 grams of starch yields a liquid filtering very rapidly, and decolorizing five times its volume of Fehling's solution.

CRYSTALLIZED DIGITALIN (*Digitaline cristalisée*).

Digitalis Leaves, from the Vosges, in rather fine powder, 1000 grams; Neutral Lead Acetate, 250 grams; Distilled Water, 1000 grams. The digitalis should be collected in its second year just when the first flowers appear. With respect to the lead acetate, it is very important that it should not have an alkaline reaction; a slight acidity would be preferable. The lead salt is dissolved in the cold water, the powder added and thoroughly mixed, the whole passed through a sieve and left in contact twenty-four hours, taking care to mix it from time to time. The mixture is then packed sufficiently in a displacement apparatus, and exhausted with 50° alcohol until it no longer yields any bitterness. About six parts of liquor are thus obtained, and this is neutralized exactly with sodium bicarbonate dissolved to saturation in cold water; about 25 to 30 grams will be required. When effervescence ceases, the alcohol is distilled, and the liquor remaining is evaporated in a water-bath down to 2000 grams; it is then left to cool and diluted with its weight of water. Two or three days afterwards the clear liquor is decanted off by means of a siphon, and the precipitate drained upon a linen filter. When freed from the extractive liquor the precipitate weighs about 100 grams. It is suspended in 1000 grams of 80° alcohol and the whole passed through a metal sieve or fine cloth; the turbid liquor obtained is heated to ebullition, and to it is added a solution containing 10 grams of neutral lead acetate; the heating is continued a few moments, and the liquor is then left to cool and filtered. The deposit on the filter is washed with alcohol to remove any liquor it may retain and then pressed. To this liquor is added 50 grams of finely powdered vegetable charcoal that has been washed with acid and afterwards with water until quite neutral, and it is then distilled, the residue being heated for some time in a water-bath, it being very important that all the alcohol should be driven off. A little water is added to replace what may evaporate. The residue is allowed to cool, then drained upon the cloth that was used to separate the precipitate, and the carbonaceous mass is washed with a little water to remove the last portion of the coloured liquor. The carbonaceous residue is then dried completely in a stove at a temperature not exceeding 100°C., and exhausted by displacement with pure chloroform until it passes colourless. This liquid is distilled to dryness, and a few grams of 95° alcohol are placed in the retort and evaporated to drive off the last traces of chloroform.

The residue is crude digitalin with viscous and oily matter. It is dissolved with heat in 100 grams of 90° alcohol, and 1 gram of neutral lead acetate dissolved in a little water added, together with 10 grams of animal charcoal in fine granules without powder that has been treated with hydrochloric acid and washed until the washings are no longer acid. After boiling for ten minutes it is allowed to cool and settle, and then filtered in a glass cylinder furnished with a tight cotton plug, through which it passes quickly and clear. The black deposit is added last, and exhausted of all bitterness with alcohol. After distillation, the digitalin remains as a grumous crystalline mass, now only contaminated with the coloured oil. A little aqueous liquor that occurs with it is separated and the weight of the impure digitalin is taken in the previously tared vessel. The digitalin is then dissolved with heat in exactly sufficient 90° alcohol for its solution (from 6 to 12 grams). Any alcohol evaporated is replaced, and then to the cooled solution is added sulphuric ether, rectified at 65°, to half the weight of the alcohol employed; after mixing, distilled water equal to the weight of the alcohol and ether combined is added, and the flask is closed and shaken. Two layers are formed: the upper is coloured, and consists of the ether which has taken up the fat oil; the lower is colourless, and contains the digitalin, which being now free, quickly crystallizes. The flask is placed in a cool place. Two days afterwards the whole is thrown into a small cylinder furnished with a moderately tight cotton plug: the mother liquor runs off, and then the coloured layer, and the small quantity that remains adherent to the crystals is removed by a little ether.

Thus obtained, this first crystallization of digitalin is slightly coloured; it is sufficiently pure, however, for its weight to be taken in an analysis, one-tenth being deducted for the digitalin it still contains. To obtain it perfectly white two purifications are necessary, but first a treatment with chloroform is indispensable to separate the remainder of digitalin which injures its purity.

The digitalin, well dried and reduced to a fine powder, is dissolved in 20 parts of chloroform and the solution is filtered in a cylinder through a tight cotton plug. The liquor passes limpid; it is distilled to dryness, and a little alcohol is poured into the retort and evaporated to remove the last traces of chloroform. This digitalin is dissolved in 30 grams of 90° alcohol, 5 grams of washed granular animal black added, and the whole boiled for ten minutes; the liquor is filtered and the charcoal exhausted as before indicated; and lastly it is distilled: the digitalin in dry crystals is found on the sides of the vessel, but it is still slightly coloured. To obtain it perfectly white it is dissolved with heat in exactly sufficient 90° alcohol (about 6 to 8 grams); to the solution is added ether equal to half the weight of alcohol employed and double the quantity of distilled water, and the flask is closed and agitated; the crystallization commences quickly. The ether does not separate. It is exposed to the coolness of the night, and by the next day nearly the whole of the digitalin is deposited in small groups of white needles, that which retains colouring matter remaining in the mother liquor. The whole is thrown into a cylinder and the crystals washed with ether as before described.

1000 grams of Vosges digitalis of good quality yields about 1 gram of crystallized digitalin.

Digitalin occurs under the form of very white light crystals, consisting of short slender needles grouped around the same axis. It is very bitter, and scarcely soluble in water. 90° alcohol dissolves it well; anhydrous alcohol dissolves it less freely. Pure ether dissolves only traces. Chloroform is its best solvent. Brought into contact with a small quantity of concentrated hydrochloric acid digitalin is coloured emerald green, and this reaction is favoured by a very slight heat.

Granules (Granules de digitaline cristalisée).—Crystallized Digitalin, 0·025 gram; Powdered Sugar of Milk, 4 grams; Powdered Gum Arabic, 0·90 gram; Syrup of Honey, q.s. Triturate the digitalin in a porcelain mortar for some time with the milk sugar, and make 100 silver-coated granules each containing ¼ milligram.

Emulsion of Medicaments insoluble in Water.

In these preparations a tincture of quillaya (1 to 5) is employed. It is prepared by digesting together 100 grams of bark of *Quillaya saponaria* and 500 grams of 90° alcohol, heated by a water-bath for half an hour at nearly boiling temperature; after this the ingredients are allowed to macerate for forty-eight hours, with occasional stirring, and filtered.

Emulsion of Tolu Balsam.

Dissolve 2 parts of Balsam of Tolu in 10 parts of 90° alcohol, add 10 parts of Tincture of Quillaya, and then 78 parts of hot water.

Emulsions of copaiba balsam, tar, oil of Cade, etc., may be prepared by the same method.

Eucalyptus Globulus.

All the parts of this tree, but especially the leaves, are impregnated with an aromatic volatile oil, having the odour of oil of peppermint, but of a special character. It breaks up into two principles: eucalyptol ($C_{12}H_{18}$) and eucalyptene ($C_{12}H_{20}O$). This latter substance, which is the most important in the treatment of pulmonary catarrh, appears to be free from the irritant properties presented by the undecomposed volatile principle. Eucalyptol is miscible in water, and soluble in ether and alcohol.

The *Powder*, *Infusion*, *Wine*, *Elixir* and *Extract* are prepared in the same way as the corresponding preparations of coca (see vol. vii., p. 1064.

Distilled Water (Eau distilée).—Dry leaves 1 part, and sufficient water to yield 4 parts of product.

Syrup (Sirop d'Eucalyptus).—Infuse 50 grams of Eucalyptus Leaves in 250 grams of Water; after three hours strain and press; filter the product and bring it up to 250 grams; then add 100 grams of Distilled Eucalyptus Water, and melt in it 650 grams of sugar under a covered water-bath.

Bromide of Iron.—$FeBr_2$.

Iron Filings, 40 grams; Distilled Water, 216 grams; Bromide, 80 grams. Introduce first the water and then the bromine into a flask, and add the iron filings a little at a time. Towards the end, to complete the reaction, heat should be applied until the liquor is of a fine green colour. When the combination is complete, pour the whole, including the excess of iron, into a stoppered bottle. This normal solution cannot be preserved long without alteration. It should therefore be used as promptly as possible under the form of syrup and especially of pills. 1 gram of pure bromide of iron is completely precipitated by 1·56 gram of silver nitrate.

Pills (Pilules de bromure de fer).—Normal Solution (filtered) 15 grams; Porphyrized Iron Filings, 0·10 gram; Powdered Gum Arabic, q. s.; Liquorice Powder, q. s. Place the solution and the iron in a porcelain capsule, and evaporate quickly until the liquor has lost two-thirds of its weight; then pour it still hot into a very dry and slightly warmed porcelain mortar; add the powders previously mixed and in quantity sufficient to form a tolerably consistent pill mass, which divide into 100 pills and roll in lycopodium. The pills can also be covered with a mixture of gum and sugar and kept in a well dried flask.

Each pill contains 0·05 gram of bromide of iron.

Syrup (Sirop de bromure de fer).—Normal Solution, 15 grams; Syrup of Gum with Orange Flower, 985 grams.

20 grams of this syrup, or one tablespoonful, contains 10 centigrams of bromide of iron.

FERROUS CHLORIDE (*Protochlorure de Fer*) $FeCl_2$.

Dilute pure hydrochloric acid with its volume of water, add pure iron filings, and heat slightly towards the end of the operation. When the evolution of hydrogen has ceased, filter and evaporate to dryness as rapidly as possible. The product is anhydrous ferrous chloride.

If the liquor suitably concentrated be left to cool, greenish crystals, derivatives of an oblique rhomboid prism, are formed, having for a formula, $FeCl_2,4H_2O$.

Syrup (Sirop de protochlorure de fer).—Syrup of Gum, 800 grams; Syrup of Orange Flowers, 175 grams; Orange Flower Water, 20 grams; Dry Ferrous Chloride, 5 grams. Dissolve the ferrous chloride in the orange-flower water, and add the solution to a mixture of the two syrups.

20 grams of this syrup, or one tablespoonful, contains 0·10 gram of iron salt.

Pills (Pilules de protochlorure de fer).—Dry Ferrous Chloride, 10 grams; Powder of Marsh Mallow Root, 10 grams; Mucilage, q. s. F. S. A. 100 silvered pills, each containing 0·10 gram of iron salt.

DIALYSED IRON (*Oxide de fer dialysé*).

Solution of Ferric Chloride (sp. gr. 1·245), 100 grams; Solution of Ammonia (sp. gr. 1·169), 35 grams. Add the ammonia in small quantities to the ferric chloride; at first the precipitate formed is redissolved very rapidly, but afterwards disappears more slowly. When the liquor has again become transparent it is introduced into the dialyser; the distilled water in which the vessel containing the ferruginous solution is placed must be frequently renewed. After a time the highly coloured solution is no longer precipitated by silver nitrate and gives no acid reaction. It is then absolutely free from the disagreeable taste of certain ferruginous preparations. A small quantity of hydrochloric acid always remains in the liquor, which may be shown by precipitating the oxide of iron by a slight excess of ammonia, filtering, adding an excess of nitric acid, and then silver nitrate. 10 c.c. are evaporated, and from the residue must be calculated how much distilled water is required to be added to produce a 10 per cent. solution.

SOLUTION OF FERROUS CHLORHYDROPHOSPHATE (*Solution chlorhydrique de phosphate de protoxide de fer*).

Ferrous Chloride, 5 grams; Phosphoric Acid (sp. gr. 1·45), 5 grams; Distilled Water, q. s. to make a litre.

20 grams of this solution contain 0·10 gram of salt of iron.

SYRUP OF FERROUS CHLORHYDROPHOSPHATE (*Sirop de chlorhydrophosphate de protoxyde de fer*).

Ferrous Chloride, 5 grams; Phosphoric Acid (sp. gr. 1·45), 5 grams; Distilled Water, 350 grams; Powdered Sugar, 640 grams. Dissolve the ferrous chloride in the distilled water, add the phosphoric acid, and melt the sugar at a gentle heat.

20 grams, or a tablespoonful, of this syrup contains 0·10 grams of salt of iron.

The Syrup and Solution of Ferric Chlorhydrophosphate may be obtained by substituting the ferric for the ferrous salt.

SOLUTION OF PYROPHOSPHATE OF IRON AND SODA.

Pyrophosphate of Soda, 25 grams; Dry Ferric Sulphate, 5 grams; Distilled Water, q. s. to make 1 litre. Dissolve the pyrophosphate of soda in 250 grams of water and the ferric sulphate in 100 grams; add, while stirring, the ferric solution to the solution of pyrophosphate, and to the limpid and colourless solution add sufficient distilled water to make a litre.

20 grams of this solution contain 0·10 grams of salt of iron.

SYRUP OF PYROPHOSPHATE OF IRON AND SODA.

Pyrophosphate of Soda, 25 grams; Dry Ferric Sulphate, 5 grams; Distilled Water, 350 grams; Sugar, 620 grams. Make the solution and dissolve the sugar in it by the aid of a water-bath.

20 grams of this syrup, or a tablespoonful, contain 0·10 of salt of iron.

CALABAR BEANS.

Powder.—Crush and dry the beans in a stove. Then triturate in a covered mortar and pass the powder through a sieve of fine silk. The pulverization leaves scarcely any residue.

Tincture (Teinture de fèves de Calabar).—Powder of Calabar Bean, 100 parts; Alcohol (80°), 500 parts. Macerate during ten days, strain with pressure, and filter.

ESERINE.

Powder of Calabar Bean, 100 parts; Tartaric Acid, 1 part; Potassium Bicarbonate in powder q. s.; Alcohol (90°), q. s.; Rectified and Washed Ether, q. s. Exhaust the bean mixed with the tartaric acid by several digestions in alcohol at the heat of a water-bath, alcohol equal to about three times the weight of the powder being used for each maceration. Distil the combined liquors and filter; heat the residue in a water-bath exposed to the air until it contains no more alcohol. After cooling suspend the extract in a small quantity of distilled water and filter through paper to separate the insoluble resin. Agitate the filtrate with rectified and washed ether until the ether is no longer sensibly coloured; two or three treatments are usually sufficient. Treat the aqueous liquor, which contains the eserine in the state of acid tartrate, with a slight excess of potassium bicarbonate, until the reaction is alkaline. Shake this liquor several times with ether, which removes the liberated eserine and deposits it upon evaporation. The product is purified by fresh crystallizations from ether.

Pure eserine is colourless, or slightly rose coloured; it crystallizes in thin laminæ having a rhomboid form. Most frequently it occurs in commerce under the form of yellowish spangles, or amorphous masses more or less coloured by the action of the air.

It is slightly soluble in water, but dissolves freely in alcohol, ether, and chloroform. When a 1 per cent. solution of it is treated with potash or soda it rapidly acquires a characteristic rose colour. Heated in a flask in a water-bath in contact with excess of ammonia, it gives upon evaporation of the liquor in the open air a magnificent blue colour, very soluble in the water. This solution, treated with acids, produces a very fine dichroic liquor, violet and transparent by transmission and carmine red and turbid by refraction. Eserine has the property of contracting energetically the pupil of the eye.

A kilogram of Calabar beans yields on the average one gram of eserine.

NEUTRAL HYDROBROMATE OF ESERINE (*Bromhydrate neutre d'ésérine*).

This body is prepared with colourless hydrobromic acid in the same manner as the sulphate. The solution, evaporated to a syrupy consistence, crystallizes in the course of a few days in fibrous masses, rarely colourless and non-deliquescent.

The neutral hydrobromate of eserine is employed like the sulphate and in the same doses, although it contains a little less eserine.

NEUTRAL SULPHATE OF ESERINE (*Sulphate neutre d'ésérine*).

This salt is obtained by saturating directly and exactly a known quantity of eserine with dilute sulphuric acid (1 in 10); or better still, by shaking a solution of the eserine with a titrated solution of sulphuric acid, so as not to exceed the point of saturation. The filtered solution of sulphate of eserine is evaporated rapidly to dryness by the aid of a gentle heat.

Sulphate of eserine can be crystallized in long prismatic needles combined in radiating groups, but it is very difficult. It is preferable to preserve it in the amorphous state and in well stoppered bottles, as it is very deliquescent.

Sulphate of eserine is employed, like eserine, internally under the form of granules containing up to 1 milligram. It is employed also for the eyes as a solution containing 2 to 5 centigrams of the salt to 10 grams of distilled water.

Solutions containing eserine, pure or combined, alter rapidly in contact with the air, becoming red; they should only be prepared in small quantities as required.

GLYCERATE OF CALABAR BEAN.

This is prepared by dissolving, with the aid of a gentle heat, the alcoholic extract of Calabar beans in glycerine, which should dissolve it entirely.

(*To be continued*).

A NEW METHOD FOR THE QUANTITATIVE DETERMINATION OF SUGAR IN BLOOD.

BY F. W. PAVY, F.R.S.

Dr. Pavy read a paper on Thursday, the 14th June before the Royal Society, in which he described minutely his new method for the quantitative determination of glucose, and its application to physiological relations of sugar in the animal system. Dr. Pavy claims that the accurate results which he has succeeded in obtaining by means of his new gravimetric process of analysis are such as will tend to advance materially our knowledge, and hence will substantiate and extend the position with regard to the treatment and pathology of diabetes.

The paper consisted chiefly of a description of the method which the author adopted for accurately ascertaining the amount of sugar in the blood of animals, and formed the prelude to a second one which was read on Thursday the 21st June, in which Dr. Pavy gave the results obtained by the application of his method as follows:—

1. The natural state of the blood.
2. The comparative state of arterial and venous blood.
3. The spontaneous change ensuing in blood after its removal form the system.

Before describing his own gravimetric system Dr. Pavy proceeded to criticize Bernard's new volumetric process, which has been described fully in recent issues of the *Comptes Rendus*. This method the author considers to be not only devoid of precision as a quantitative analytical process, but in itself calculated to give rise to fallacious results, inasmuch as keeping the suboxide of copper dissolved by means of organic matter is fundamentally wrong. The entire system was based on errors, and the results were necessarily incorrect; two of these errors the author dealt with somewhat in detail. The first was in the assumption that the volume of trial liquid corresponds in c.c. with four-fifths of their weight in grams of the mixture of sulphate of soda and blood. In practice it was found that the actual relation between the volume of liquid obtained and the weight of the mixture employed must vary in each individual case, according to the solid matter existing in the particular specimen of blood and the loss of liquid by evaporation during the separation of the coagulum by heat. The other error in Bernard's method arose from the influence which organic matter exerted in preventing the deposition of suboxide. The large addition of potash which is employed in this process, viz., from 20 to 25 cubic centimetres of a concentrated solution to one c.c. of the copper test, acts upon some one or other of the organic principles left in the liquid obtained from the blood, and prevents the deposition of suboxide of copper.

The author then proceeded to describe his own new gravimetric process, in which he adopts the use of a galvanic battery for effecting the deposition of copper which has been reduced by the sugar in a form to be susceptible of weighing. The details of this method are, shortly, as follows:—

A certain volume of blood—about 20 c.c. forms a convenient qnantity—is taken for analysis, and first mixed with 40 grams of sulphate of soda; the whole must be subjected to weighing in detail, so that the precise weight of the blood taken may be known. To this mixture, in a beaker of about 200 c.c. capacity, about 30 c.c. of hot concentrated solution of sulphate of soda are added, and the whole contents heated until a coagulum is formed.

Filtration is then performed, and the coagulum thoroughly washed, so that all traces of sugar may be removed. The liquid thus obtained, from having been run and squeezed through muslin, is slightly turbid, and must be boiled again and filtered through paper to render it perfectly clear. It is now ready for the application of the copper test. Being brought to a state of ebullition about 10 c.c. of the potassio-tartrate of copper solution, or sufficient to secure that the test liquid is left in excess, are added, and brisk boiling continued for a minute, but not longer. In this way a reduction of the oxide to the suboxide of copper is effected by the action of the sugar present in the solution.

The liquid is then filtered through a plug of asbestos, or, what is better, glass wool. The suboxide having been collected and washed from excess of the copper test liquid is next dissolved by a few drops of nitric acid, a small quantity of peroxide of hydrogen having been previously added in order to effect oxidation and consequent ready solution.

The copper present in the liquid is now deposited by the agency of galvanism. The positive pole of the battery is formed by a platinum spiral coil around which and forming the negative pole is a cylinder of platinum foil; upon this the copper is slowly deposited in a pure metallic form. This operation is continued until the appropriate test shows that the whole of the copper has been thrown down. The period ordinarily required to effect this does not exceed twenty-four hours.

The platinum cylinder is next removed, and instantly plunged first into distilled water, and then into alcohol. After drying in a water oven it is ready for weighing; the difference in the weight of the cylinder before and after the operation gives the amount of copper deposited.

The battery used is a modification of Fuller's Mercury Bichromate Battery, and has been selected on account of the constancy of its action.

From the amount of copper deposited, that of the sugar existing in the blood analysed may be accurately calculated. Five atoms of the cupric oxide of the test solution are reduced by 1 atom of glucose, it follows that 317 parts of copper represent the equivalent of one part of glucose, or the relation stands as 1 of copper to 0·5678 of glucose. Therefore to ascertain the amount of sugar the weight of the copper has to be multiplied by 0·5678. This application of the copper test solution yields a gravimetric instead of a volumetric process of analysis, and one which has no uncertainty belonging to it. There is nothing for the mind to decide, and no opportunity for error of judgment, as may be the case to a slight extent where a gradual fading of colour—as in the volumetric process—has to be watched until the attainment of the proper point of the decoloration has been effected.

The accuracy and reliability of the foregoing process are strongly supported by the uniformity in the results obtained from a large number of experiments. Compared with the results yielded by this gravimetric process, those obtained by Bernard present the greatest discordancy. The figures he gives are invariably too high, and there is no intelligible relation in the differences noticeable, suggesting that there is something radically wrong in taking decoloration without precipitation of suboxide as a means of estimating the amount of sugar. Dr. Pavy supports this assertion by the conclusions derived from a large number of experiments.

In his second communication, Dr. Pavy dealt with the question of the quantity of sugar in the system under the following conditions:—

1. The amount which exists in blood in its normal condition.

2. The comparative state of arterial and venous blood.

3. The spontaneous change which takes place in blood after its removal from the system.

The author pointed out that the very rapid changes which take place in blood under altered conditions of the system render it essentially necessary that the greatest precaution should be observed in order to obtain blood in its natural condition. If taken during life the animal should be in a perfectly tranquil state. If after, it should be procured as instantaneously as possible after the death of the animal, so that no opportunity could be afforded for the blood to be affected by the *post-mortem* production of sugar in the liver.

The experiments now under notice were made on dogs, sheep, and bullocks' blood, and a series of six, in one case seven, examinations of each kind instituted, and two analyses made for every sample taken.

In quoting Dr. Pavy's figures we are giving the mean of the two separate analyses. It is necessary, however, to state that the extremes of each show but trifling variations, and these are rarely so great as to effect more than the second figure in decimals. The differences were so slight indeed that had the results been obtained by rival analysts no dispute could have arisen, as the variations were within the recognized range.

Dr. Pavy detailed the precautions which he adopted in order to secure blood from the various animals in its natural state. In the case of the dog the painless and instantaneous mode of destroying life by pithing was performed. The larger vessels in the chest were immediately freely incised and the blood collected and analysed before coagulation could take place.

With the sheep the blood was obtained from animals slaughtered in the ordinary way, viz., by division of the vessels of the neck; and the time which elapsed between collection and the commencement of the analysis was not more than a quarter of an hour.

The blood of bullocks was obtained from animals slaughtered by the Jewish method; this consists of a sudden severance of the soft structures of the neck down to the vertebral column. The incision yields arterial blood, and the time which elapsed between collection and the commencement of the analyses was one hour.

The mean results of seven examinations of dogs' blood showed the amount of sugar which it contained in parts per 1000, to be as follows:—0·751, 0·786, 0·700, 0·766, 0·786, 0·921, 0·803, respectively. This gives an average of 0·787 on the whole series.

The blood of sheep yielded 0·470, 0·490, 0·517, 0·559, 0·569, 0·526, respectively, or an average of 0·521 parts of sugar per 1000.

The bullocks' blood gave 0·703, 0·525, 0·492, 0·456, 0·499, 0·588, or an average of 0·543.

In each of these experiments every care was taken to secure the blood in such a manner that it was a reliable representation of its ordinary condition during life. Unless such precautions are taken the results obtained will be, in a physiological point of view, worthless and misleading.

This fact was strikingly illustrated by a comparison of results which Dr. Pavy obtained from four bullocks killed in the ordinary way, viz., by felling the animal with a poleaxe, and breaking up the spinal cord by means of a cane. In the first two of these observations the opening into the blood vessels was made as speedily as possible after the animal had been felled. In the next two Dr. Pavy had reason to believe that this necessary condition had not been complied with, and that some little time was allowed to elapse between the felling of the bullock and the opening of the vessels. The effect of this delay in the *post-mortem* production of sugar is shown by the following results:—

Blood of the first two bullocks (mean of two analyses) yielded 0·596, 0·688, parts of sugar per 1000, respectively. In the second two a mean of 1·053 and 1·094 parts of sugar per 1000 were given.

The conclusions to be drawn from this various experiments are, that the amount of sugar contained in the blood of sheep and bullocks is about ½ per 1000, or 1 in 2000, and in a dog about ¾ per 1000, or 1½ per 2000. The results of the whole series of observations show a remarkable uniformity and harmony in the amount of sugar contained in the blood of the respective animals.

In striking contrast to this uniformity and consistency of the results attained by Dr. Pavy are the figures given by Bernard, who states (in *Comptes Rendus*, June 19th, 1876, p. 1409) that the lowest limit of sugar in the blood is 1 per 1000, and that in the normal state the amount of sugar varies from 1 to 3 per 1000.

Comparative State of Venous and Arterial Blood.

The author next considered the comparative states of the arterial and venous blood. This part of the subject is one which possesses the greatest importance from a physiological point of view.

One of the effects of anæsthetics on animals is to occasion an abnormal amount of sugar in the blood. In order to attain accuracy, therefore, it is indispensable that blood should be taken at a time when the animal is not under such influence.

In the first observation made on the blood of a dog, life had been instantaneously destroyed by pithing, and collections were made immediately after from the jugular vein and crural artery. No time was allowed for the effect of *post-mortem* formation of sugar in the liver to influence the blood. The results obtained by this method were as follows: crural artery, ·799, ·791; *mean*, ·795. Jugular vein, ·793, ·791; *mean*, ·792. In order, however, to obtain evidence to which no exception could be taken, Dr. Pavy adopted another method of procedure, which he was enabled to do just prior to the meeting of the society from having a restriction previously imposed under the Vivisection Act removed. This enabled him to collect the blood under the natural conditions of life both from the carotid artery and the jugular vein. The animals operated upon were placed under an anæsthetic, during which time the vessels were exposed and a thread placed loose round each. After they had regained tranquillity, and the effect of the anæsthetic passed off, the vessels were drawn forward and openings made into them to allow of the simultaneous escape of blood. So quietly and painlessly was this operation of collection performed, that the animals themselves manifested no signs of consciousness of what was taking place. The analyses of the blood obtained in this manner were commenced before coagulation had time to occur, and the results were as follow: No. 1, carotid artery, ·806, ·817; *mean*, ·811. Jugular vein, ·808, ·788; *mean*, ·798. No. 2, carotid artery, ·854, ·873; *mean*, ·863. Jugular vein, ·863, ·896; *mean*, ·879.

From these figures it is clearly evident that no material difference exists in the amount of sugar contained in arterial and venous blood.

Compared with these results the figures given in *Comptes Rendus*, lxxxiii., 373, by Bernard, stand in direct opposition. His volumetric process tends to show that a disappearance of sugar takes place largely while the blood is passing from the arterial to the venous system. In the journal referred to he gives the results of five observations referring to the crural artery and vein, and three to the carotid and jugular.

The mean of these several observations shows an apparent difference between arterial and venous blood of ·300 parts of sugar per 1000. The least difference stands in an observation in which the figures are 1·100 parts per

1000 for arterial, and 1·080 for venous, showing a variation of ·020. The greatest difference is in an observation where the figures stand 1·510 for arterial and ·950 for venous. This comparison relates to the carotid artery and jugular vein, and the difference amounts to ·560 parts per 1000, which represents actually altogether a larger proportion of sugar than Dr. Pavy has found exists naturally in the blood of the sheep and the bullock.

Spontaneous Disappearance of Sugar from Blood.

Turning to the third part of his subject, viz., the spontaneous disappearance of sugar from blood after its removal from the system, Dr. Pavy gave the results of a series of analyses he had conducted, and which are as follows:—

No. 1.	Taken immediately after death	mean	·786
	„ after 1 hour	„	·739
No. 2.	Taken immediately after death	„	·700
	„ after 1 hour	„	·670
No. 3.	Taken immediately after death	„	·766
	„ after 1 hour	„	·751
	„ „ 23 hours	„	·285
No. 4.	Taken immediately after death	„	·786
	„ after 1 hour	„	·728
	„ „ 24 hours	„	·302
No. 5.	Taken immediately after death	„	·921
	„ after 1¾ hours	„	·793

A somewhat parallel series of experiments made by Bernard, and published in *Comptes Rendus*, June 19th, 1876, show a remarkable discrepancy with the foregoing. Bernard's figures show—

Amount of Glucose immediately after death	1·070
„ „ after 10 minutes	1·010
„ „ „ 30 „	0·880
„ „ „ 5 hours	·440
„ „ „ 24 „	0·000

Dr. Pavy pointed out that there was nothing new in the suggested discovery that a gradual destruction of sugar takes place with blood after its removal from the system. He himself had brought the fact before the notice of the Royal Society so far back as 1855, when he stated that under the changes of the decomposition of blood normal animal glucose is very readily metamorphosed. The rapidity of the metamorphosis depending on the activity of the decomposition of the animal substances present.

In conclusion the author stated that the evidence adduced in this communication shows that the results which Bernard has obtained by the experimental *modus operandi* he has been recently employing are erroneous and consequently the inferences he has drawn from them are equally in error. The cause of truth and the interests of science demand that what he has recently been advancing should be eliminated from physiological literature.

ACCLIMATIZATION EXPERIMENTS WITH MEDICINAL PLANTS.

The following extracts relating to articles of the materia medica are quoted from "The Annual Report on the Progress and Condition of the Royal Gardens, Kew, for the Year 1876, which has just been issued":—

"*Balsam of Copaiba.*—Some well ripened seeds of the Para copaiba (*Copaifera multijuga*) have been brought by Mr. Cross from the forests of Para, and germinated freely. The tree which produces it is described as gigantic, the trunk sometimes rising to a height of eighty feet before branching. The Para balsam, called *Copaiba blanca*, is chiefly sent to France, where it obtains the highest price of any. A single tree, if tapped at the right season, is said to yield about eighty-four imperial pints of balsam. Very little is known of the history or botanical characters of this plant, which has been only imperfectly described. It is greatly to be desired that this tree should be introduced into the East Indies."

"*Balsam of Peru.*—This beautiful tree (*Myroxylon Pereiræ*) was introduced into Ceylon in 1861 by the exertions of the late eminent pharmaceutist, Daniel Hanbury. It has succeeded there admirably, and last year I received several parcels of seeds from Dr. Thwaites, which I have distributed to various tropical colonies. Dr. Thwaites speaks in warm terms of the beauty of its foliage and habit."

"*Ipecacuanha.*—Dr. King reports that he fears this drug cannot be grown profitably so far north in India as Bengal; but that the secret of its successful propagation being now perfectly understood any quantity of seeds can be sent out. A quantity of the dried root has been prepared by Dr. King for use in the Medical College Hospital of Calcutta, and found to be quite as efficient as the best South American drug. The disadvantage attributable to the extreme slowness of the growth of this plant, and hence small annual return of root wherever it has been cultivated, must be met by a greater extension of the cultivation, as to which there should be no difficulty, seeing that the plant is increased with astonishing facility by ordinary cuttings, root division, or by merely pegging a leaf to the earth."

"*Castor Oil in Bahamas.*—A correspondence has taken place with the Colonial Office on the subject of the cultivation of the castor oil plant in the Bahamas. Governor Robinson states that 'the castor oil plant grows here as a weed, but no endeavour yet has ever been made to express the oil. Thousands of gallons might be exported from here annually.' A supply of the best castor oil seed was obtained from Calcutta and forwarded to the Bahamas. Governor Robinson now reports: 'The yield of this variety of the castor oil plant is, we should say, fully three times greater than that commonly found amongst us, the heads and the beans themselves being very much larger than those produced by the native variety. As the East India Plant can be cultivated quite as easily and readily as our own, and as it possesses such a marked superiority in the matter of yield, we hope to see it speedily and widely introduced into the colony, so as to supersede the indigenous kind altogether.'"

"*Burmese Cardamoms.*—A sample of these seeds was sent to Kew by the India Office for identification. Burmese cardamoms fetch a low price in the market compared with Malabar cardamoms, and it was supposed that this might be due to the intermixture of the seeds of this plant with those of a spurious kind. It was, however, quite certain from their microscopic structure that the seeds sent were not those of *Elettaria Cardamomum*, and it was not improbable that they might belong to *Amomum xanthioides*, the wild cardomom of Siam, but about which scarcely anything is known. In this, as in so many other cases, the materials sent to Kew for an opinion were from a botanical point of view lamentably insufficient, and this was in this particular instance the more to be regretted, because a scientific department like the Indian Forest Service might easily obtain such a series of specimens for transmission to England as would enable the whole history of the Burmese cardamom, which at present is very unsatisfactorily known, to be entirely cleared up."

With regard to the *Cinchona Cultivation in St. Helena*, Sir Joseph Hooker says,—"In my report for 1874, I pointed out that 'the suitability of the soil and climate of that island for cinchona cultivation has now been indisputably proved.' It is a melancholy conclusion to the efforts made by Kew on behalf of this doubtless dispirited, but I am afraid I must add, spiritless colony, that nothing has been done to utilize so easy a source of revenue. In a private letter recently received, I am informed, 'up to within a few months since a man was paid by the colony to look after the cinchona plants on Diana's Peak, but even he has been disestablished, and the plants are overgrown and almost hidden in ferns and dense undergrowth of native vegetation.'"

The report, which deals largely with other plants of economic value, will be found of more than usual interest.

The Pharmaceutical Journal.

SATURDAY, JULY 14, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

EXTRA-JUDICIAL SENTENCES.

THE trial of a pot-boy at the Quarter Sessions held at Margate last week, for the offence of attempting to commit suicide by poisoning himself with laudanum, has furnished the opportunity for another extra-judicial utterance, similar to those which have on several previous occasions given rise to comment in these columns. A chemist's assistant, who had complied with all the legal requirements in the sale of two-pennyworth of laudanum, was admonished by the Recorder in such a manner as to suggest that had the would-be suicide succeeded in carrying out his intention, the chemist's assistant would in some way have been held legally responsible for his death.

It is far from our intention to suggest that there is no moral responsibility lying upon the registered chemist and druggist beyond an exact compliance with the provisions of the Pharmacy Act in the retailing of poisons to the public. The very position assigned to him under that Act implies that he shall be a person who will exercise his important trust with an intelligent regard to the safety of the public. At the same time it must not be forgotten that Parliament has, wisely or unwisely, made important distinctions as to the manner in which different poisonous substances are to be supplied to the public, and it may be presumed that the reason for not imposing the same restrictions upon the sale of articles included in Part 2 of the schedule as upon the sale of those in Part 1 was that these restrictions were not thought necessary. It may therefore be fairly disputed that the chemist and druggist is called upon to impose restrictions upon the sale of poisons not found in the statute, or to do more than to exercise ordinary care towards preventing, so far as he is able, poisons from coming into the possession of improper persons. Whether such carefulness was so wanting in the case in question as to justify the Recorder's remarks is, in our opinion, at least open to question.

The facts of the case, as they have reached us, will be found in the report quoted from a local paper on p. 37, and the letter from a correspondent on p. 39. A lad, described in the indictment as fifteen years of age—our correspondent says that he is now sixteen in age and appearance—asked to be supplied with twopennyworth of laudanum for his master, professing ignorance as to the purpose for which it was required. Applicant's master being known as a neighbour, and he himself proving cognizant of the fact that laudanum is a poison, the drug was supplied, bearing a red label with the words "Laudanum, Poison," and the seller's name and address. Some time afterwards the lad attempted to poison himself with laudanum, but this incident has no bearing on the point under discussion, as it does not affect the conduct of the person who sold the poison. The law, however, having been thus complied with by him, the question arises whether there were any circumstances that should have suggested extra precautions beyond those that were taken.

Of course the age of the person to whom the poison was supplied would have an important influence in the decision of this question, and the learned judge appears to have rather persistently associated the designation "child" with the prisoner. But although this may have been correct in point of law, it is hardly the name that would be applied popularly to a fairly grown lad of sixteen. Seen in the light of the subsequent occurrence it may appear that to have required some guarantee of the truth of the lad's story would have been an advisable course, but practically this could have only been done with certainty by interviewing his master—a course that was hardly called for. As to the suggestion of the Recorder that the laudanum should not have been delivered without a medical certificate, this is palpably absurd. On the whole, speaking after the event, and assuming the correctness of the information that has reached us, we think that very little censure, if any, can be fairly cast upon the person who sold the laudanum in this case.

In conclusion, we would again carefully guard ourselves from being supposed to assert that the chemist and druggist has no other responsibility than the use of a proper label in the sale of even so common a narcotic as laudanum. But this view does not bear pushing too far, and it would indeed be anomalous if chemists and druggists were bound to exercise such extreme precautions while selling two drachms of laudanum under its proper name, with the caution that it is a poison, whilst co-operative stores and hucksters are allowed to sell it by the quart, under cover of a *nom de plume* and a government stamp, without any precautions whatever.

THE ALLEGED BREACH OF THE APOTHECARIES ACT AT BIRMINGHAM.

WE are enabled by the courtesy of the executive of the Chemists and Druggists' Trade Association, who are defending the case, to lay before our readers a much fuller report of the proceedings in relation to the alleged breach of the Apothecaries Act at Birmingham than that printed in the last number.

The importance of the subject to most of our readers will, it is believed, excuse a partial repetition, although we regret that the necessity was not prevented by a little more promptitude in supplying the report.

BRITISH PHARMACEUTICAL CONFERENCE.

The following are the titles of papers already announced to the Secretaries for reading at the approaching meeting at Plymouth on Tuesday and Wednesday, the 14th and 15th of August.

1. The Supply of Cinchona Bark as Connected with the Price of Quinine. John Eliot Howard, F.R.S.
2. Report of the Committee on the Extraction and Investigation of the Aconitines of *Aconitum Napellus*. Dr. Wright, F.C.S., J. Williams, F.C.S., and T. B. Groves, F.C.S.
3. Report on the Active Principle of Capsicum Fruit. J. C. Thresh, F.C.S.
4. The Fats in Capsicum Fruit. J. C. Thresh, F.C.S.
5. Report of Continued Researches on Essential Oils. Dr. Tilden, F.C.S.
6. On a Product of the Oxidation of Barbaloin and Socaloin. Dr. Tilden, F.C.S.
7. Report on the Proximate Constituents of Ivy Berries. R. H. Davies, F.C.S.
8. Report of a Research (part 2) on Essential Oil of Sage. M. M. P. Muir, F.C.S., and Mr. Siguira.
9. An Impurity in Oxide of Zinc. W. W. Stoddart, F.C.S.
10. An Improved Preparation of Ergot. Mr. A. W. Postans.
11. The Microscope in Pharmacy. Mr. J. Cooke.
12. Additional Notes on the Assay of Opium.
13. Tincture of Acetate of Iron. Dr. C. R. C. Tichborne, F.C.S.
14. Sugar in Pharmacy. Dr. C. Symes.
15. A Point in Pharmaceutical Ethics. Mr. S. R. Atkins.
16. A Paper on Brucia will probably be read by W. A. Shenstone, F.C.S.

The Secretaries state that eight or ten other papers are expected.

WHAT DOES IT MEAN?

Our American contemporary, *New Remedies*, states that a number of Brooklyn physicians and pharmacists have connected their "offices" by means of a telegraph. This proceeding seems to have aroused suspicion of an intention to unduly influence business, as for instance when a person applied in an urgent case to a druggist for the address of a physician he would be able to ascertain which of the "ring doctors" might be at home. One explanation, however, is that the arrangement had its origin in a chess club, and was undertaken to enable the members to follow the game without being absent from their places of business!

THE SOCIETY OF ARTS MEDALS.

The Albert Medal of the Society of Arts, for distinguished merit in promoting Arts, Manufactures, or Commerce, has been awarded this year to M. Jean Baptiste Dumas, the distinguished chemist, who presided over the *commission de rédaction* of the French Codex in 1862. One of the Medals for papers read during the session has been awarded to Professor Barff for his paper on the treatment of iron for the prevention of corrosion, which was reprinted at the time in this Journal.

Parliamentary and Law Proceedings.

Apothecaries' Co. *v.* Harrison.

This case was heard at the Birmingham County Court, before Mr. James Motteram, Q.C., judge, on Monday and Tuesday, July the 2nd and 3rd. The plaintiffs were the Society of Apothecaries, London, and the defendant James Harrison, chemist and druggist, of 73, Stafford Street, Birmingham.

Mr. Nathan (instructed by Mr. W. J. Reeves) appeared in support of the case, and Mr. Jesse Herbert (instructed by Mr. Glaisyer) defended on behalf of the Chemists and Druggists' Trade Association.

In opening the case Mr. Nathan explained that the action was brought under the 20th section of the 194th Chapter, George III., entitled, "An Act for better regulating the practice of Apothecaries throughout England and Wales." The section provided "That if any person (except such as are then actually practising as such) shall after the said first day of August, 1815, act or practice as an Apothecary in any part of England or Wales without having obtained such certificate as aforesaid every person so offending shall for every such offence forfeit and pay the sum of twenty pounds." The action was now brought to recover the penalty named. He said it might be possible, if the Apothecaries' Company strained their powers, to bring an action against a chemist every time he gave a man over the counter a cooling draught or suggested a pill for stomach-ache. But if the respectable body he represented were to be guilty of such folly public opinion would step in. These actions were always a matter of great consideration, involving many inquiries and much correspondence before the company would allow their name to be used in any way whatever in connection with the same. Any person who had a knowledge of the facts connected with the previous actions could not help admitting that the discretion of the Society had been well exercised. It was perfectly clear that if a man practised as an apothecary he was liable to the penalty, the "practising" being professing to be a judge of internal complaints by external symptoms, and applying himself to their cure by medicine. If that was established in the present case it would be sufficient for the penalty. After detailing the evidence he purposed adducing, the learned Counsel called

Julia Caddick, who, having been sworn, returned the following answers to the following questions:—

Do you know Stafford Street, Birmingham?—Yes.

You know Mr. Harrison?—Yes, sir.

Did you go to his shop last November?—Yes, the 27th.

What did you tell him?—I asked if he could make me up something for a weakness left on me.

His Honour: What did he say?—He asked me what the weakness was from.

His Honour: Well?—And I told him.

His Honour:—What did you state?—I said it was weakness left on me from my confinement.

His Honour: Did he do anything; did he feel your pulse or look at your tongue?—Yes, sir.

His Honour: What did he do?—He looked at me.

His Honour: Will you be good enough to tell me all he said and did?

Mr. Nathan: Did you explain?—I told him, sir, and he gave me medicine.

What did you tell him?—I told him the womb came down.

Came down; did you describe anything else to him? did you tell him what you felt?—Yes.

His Honour: Did he inquire?—Yes, I said I was very weak, and he said the medicine would do me good.

His Honour: Will you begin from the time you went into the shop and tell me all you said, and what he said and what he did with reference to this matter?—I went to Mr. Harrison and asked him if he could give me something for a weakness, and he said, "what weakness?" and I explained, and he gave me a bottle of medicine.

His Honour: Did he examine you?—No.

His Honour: Did he feel your pulse?—Yes, I think he did.

His Honour: I don't mean a particular examination; did he look at your tongue or feel your pulse?—Yes, sir, he did feel my pulse.

Mr. Nathan: Did he look at your tongue?—No.

Did he ask you anything about how you felt or what you felt?—Yes, I told him I suffered very much from my back.

His Honour: "From my back?"—Yes; and he gave me the medicine and said he thought it might do me good.

His Honour: Did he say he knew what it was?—He said the medicine would do me good and I was to take it by the instructions on the bottle.

Mr. Nathan: Did you take some of it?—Yes, sir.

Did you pay him?—Yes; a shilling.

Afterwards, in April last, when the summons was served, did he come to see you?—Yes, sir.

Did he ask you to let him look at the bottle?—Yes; he came on the 7th of April, and asked to look at the bottle. He said, "Is your name Goodwin?"

His Honour: Never mind about that.—He said, did I remember going to Adcock's for a bottle of medicine, and I said no; then he said it was a very bad case for him to be fined £20 for selling a bottle of medicine.

His Honour: I said I did not remember going to "Adcock's."—No; not for a minute I did not remember where I had been.

Mr. Nathan: Was he the same man you saw at the shop?—Yes, Mr. Harrison; he looked on the table at the baby's bottle, and asked for the bottle, and I said I didn't know where it was.

Did he ask about the medicine and whether it had done you any good?—I said I had taken some of it.

Did he ask whether it had done you any good?—Yes; I told him I had taken some and that I did not know whether it had done me any good, and that I had taken enough of it. I knew I must take more than a bottle.

His Honour: Is that what you said?—Yes; and he came again on the 9th.

Mr. Nathan: What was that for?—He said that he had mentioned his case to a gentleman friend who would not believe him till he opened the case to him, and he wished to see me.

You would not go?—No; I said I would not on account of the baby's sickness.

Did he come again?—Yes; on the 16th of April and brought a cloak and wanted to fetch a cab to take me to his solicitor, but I would not go.

His Honour: Wanted to fetch a cab and take you to his solicitor?—Yes, but I would not go; I said all I could say was that I had the medicine.

His Honour: I told him it was no use my going, as I could only say I had the medicine. He asked me whether it was him or his assistant, and I said of course it was you, Mr. Harrison, who served me.

Mr. Nathan: You were very unwell I believe when you went there?—Yes sir.

Besides what you have said were you very pale and weak?—Yes; he asked me if I had mentioned it to Mr. Jones, and I said I had not.

Had you any conversation with him when you first went to him about what you were suffering from—what you felt?—No more than I told you.

Mr. Herbert (cross examining): You remember these circumstances though they occurred last November?—Yes.

All that took place when he came to your house?—Yes.

Did you say you could not go because you had not the clothes?—Well I had not the clothes, but I said the sickness of the baby.

Then why did he bring a cloak the second time?—I know I said I could not go then.

Did you say you could not go because you had not clothes to go in?—I said I could not go then.

Did you say you did not know the name of the shop you went to?—No; at the first time I did not remember the shop, but I told him the second time; I did not know him for a minute when he first came in, but I knew him after.

But did you tell him that you did not know which shop it was?—No; I said it was a little shop below Adcock's.

You did not say it was "Adcock's"?—No, because I knew it was not.

Where do you live?—In Allison Street.

How far is that from Stafford Street?—Not far.

Half an hour's walk?—No, it would not take me that long.

Had you been to Harrison's shop before?—Not for myself, I had not.

Have you been there at all?—I have been before, I know.

What made you go that day?—Because I was told he might do me good.

Who told you?—Mr. Goodwin.

Who is Mr. Goodwin?—The master of the house I live in.

Did you know why he wanted the bottle?—I did not.

Do you know whether he is going to give evidence?

Mr. Nathan: She does not know, I know.

Mr. Herbert: Why did you go to Mr. Harrison?—I would go anywhere I thought would do me good.

Was it not his assistant you saw?—No, I saw Mr. Harrison himself.

Did you not tell Mr. Harrison it was his assistant you saw?—No, I did not.

Did not you say you did not know which it was?—I said it was you, Mr. Harrison.

Oh, you knew Mr. Harrison when he first came in?—No, not for the minute, but I did when he sat down.

Did you not tell him you had never seen him before?—He said he did not remember serving me, and I said yes, it was you, Mr. Harrison.

How long were you in the shop with him?—I know I was not there long.

Were you there three minutes?—Of course I was.

Were you there five?—I dare say I was there quite that long.

When was the first time you saw Harrison?—The 27th November was the first time I could remember seeing him.

Where was the bottle when he came the second time, and you said you had given it to Mr. Goodwin?—I had given it to Mr. Goodwin.

Then you were sent by Mr. Goodwin to get it?—I was told it might do me good.

How was it you did not drink it all? After you had drunk a certain portion you gave it Mr. Goodwin?—Yes.

You said, you said you had not taken enough to do you good, because you knew you must take more than a bottle?—I did not take any more because it seemed to get me in pain.

Were you not sent for it on purpose to hand it over to Mr. Goodwin?—No, I went because I wanted it to do me good.

How old was the baby then?—Between two and three months.

Did he write you any prescription?—No, he made it up himself.

His Honour: I wish you would let me hear?—I said he did not write me any prescription.

I suppose he casually felt your pulse and said "very slow" or "fast"?—He said he could make me a mixture that would do me good.

His Honour: Felt your pulse and said he could make a medicine that would do you good?—Yes, sir.

Did you say your womb had come down?—Yes.

Charles Radford Suffield, M.D. and F.R.C.S., upon being sworn, was examined by Mr. Nathan as follows:—

Were you present in Court when the last witness was examined?—Yes, sir.

And you have heard her give her evidence?—Yes.

From the description she has given of what she suffered and what she told Mr. Harrison at the time what she was suffering from?—I should imagine that she was suffering from a disease called anæmia, deficiency of blood or of the red particles of blood.

Is it an internal complaint—constitutional?—Yes.

And a dangerous one?—Yes, unless treated properly.

I believe it may arise from a great number of causes?—Yes.

And common to both sexes?—Yes.

His Honour: Not so common to man as to woman?—No.

Is it in your opinion a constitutional complaint?—Yes.

In diagnosing a complaint of that nature would such an account as you have heard from the woman have been sufficient?—No, we might go a little deeper into particulars. A good deal would depend upon complexion, pulse, etc.

The appearance of the pulse is one of the symptoms from which you diagnose?—Yes.

Do you ever form a diagnosis from it alone?—No.

You don't consider it sufficient?—No.

Mr. Herbert: You would not consider it sufficient?—No.

Mr. Herbert: In the early stages it is not very dangerous, is it?—No.

Have you examined that mixture?—No. I have looked at it, and I imagine it is a preparation of iron which would be a proper medicine.

I believe this disease is not a common one?—No, by no means; it is a disease of poverty, if you like.

Is it a very common disease?—No, not a very common disease.

But I believe thousands have suffered from it?—Yes, the world is very large.

His Honour: And it has existed a long time.

Mr. Herbert: It is not an uncommon disease?—Certainly not.

Mr. Nathan remarked that the above was the evidence for the plaintiffs.

Mr. Herbert submitted that the case had not been proved. He contended that according to the Act, any person practising as an apothecary before 1815 may so practise now. It was for the prosecution to prove that the defendant was not in the business at the time the Act was passed.

His Honour: What do you say to that, Mr. Nathan.

Mr. Nathan: I say it lies on the defendant to prove that he was. It is impossible to prove a universal negative. The affirmative lies on him who affirms.

His Honour: You affirm as a fact that he was not an apothecary before 1815. You allege that he was not an apothecary before 1815.

Mr. Nathan: Then I say the onus does not lie on me; it is a negative, and no man is bound to prove a negative.

His Honour: I find the case has been tried twice in your favour, Mr. Nathan, and against you, Mr. Herbert. It would be for you, Mr. Herbert, to prove that he was practising previous to 1815. Feeling sure that no injustice will be done to the defendant, I shall hold that inasmuch as the affirmative is with you, Mr. Herbert, and within your own knowledge, that it is for you to establish and not for Mr. Nathan to prove a negative. If there is the slightest doubt about it I will adjourn the case until to-morrow morning. It is a matter which may be proved by subpœnaing the witness.

Mr. Herbert: In order that the case may go on I will admit as a fact that the defendant was not in practice prior to 1815.

Mr. Herbert: I am instructed by Mr. Glaisyer, the Solicitor of the Chemists and Druggists' Trade Association, to appear on behalf of the defendant. The defence is a very simple one, and it would be necessary that I should argue at some length. There have been many actions brought against unqualified men, but not against qualified chemists and druggists. The real question is whether chemists and druggists may recommend their wares over their counter to persons coming to buy. The point is a new one, and knowing that a case has gone up to the Court of Exchequer, knowing that it was a question whether properly qualified chemists and druggists could really recommend their drugs and medicines, and in the face of a special request for delay until the case had been decided, the Apothecaries' Company have pushed forward this action and for the penalty, when no possible good can result from it. The action cannot possibly serve any purpose, because, if your Honour is against me, it will be necessary to appeal to a higher Court to have the point decided, as in the previous case. After quoting various sections of the Act, the learned counsel submitted that chemists were legally entitled to conduct their business in the manner adopted prior to 1815, and that as he should prove by a witness who had been in the trade since 1809—six years before the passing of the Act—that such a procedure as that alleged to have been taken by the defendant for the recommending of drugs or medicines upon an expression of certain symptoms was the custom before 1815. But now, after a lapse of sixty years, there was a sudden outburst of feeling, it being probably thought by the Company that all witnesses who could prove the custom prior to 1815 had become decrepit or died out. The 28th section provided "That nothing in this Act shall extend or be construed to extend to prejudice or in any way to affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing and vending drugs, medicines and medicinable compounds, wholesale and retail." It was, therefore, perfectly clear that chemists properly qualified might furnish and supply medicine, and, he submitted, there was no evidence to show that the defendant had either attended or advised in the present case.

His Honour: Do you mean to say any person may go to a chemist and say, "I am suffering from some disease or other, but I don't know what it is; I have not been well for a month and am getting worse," and the chemist prescribe for him?

Mr. Herbert: In simple minor ailments.

His Honour: You admit no chemist can attend at a patient's house and supply medicine?

Mr. Herbert: Yes.

His Honour: But you say he may prescribe?

Mr. Herbert: I don't like the word prescribe.

His Honour said in his opinion a man might go to a chemist and say, "I have got a toothache, or I have got a headache, will you give me, say, some sal volatile for the headache and some tincture for the tooth." His Honour had not the slightest doubt that a chemist might sell what was required, but whether he might take the ordinary means of finding out the headache or toothache and then prescribe medicines for the disease which he himself had found out, was quite another matter. He ventured to put it that if a man went to a chemist's shop and said he was suffering from some disease, the nature of which he did not know, and the chemist took the ordinary means of feeling his pulse and examining him, and then saying, "I know what's the matter with you," and supplied him with some medicine, he would be infringing the Act.

Mr. Herbert: I might consult with one of my friends and say, "I think a little quinine would do you good; go to Southall Brothers and get it there." If I may say that, why may not a chemist say it?

His Honour: You have no interest in the sale of the quinine. You may as a friend offer advice, but gratuitous advice is seldom worth receiving. It was lest a man not being qualified should give a wrong medicine that the Act was passed.

Mr. Herbert: But defendant is qualified, and the Act was never intended to apply to properly qualified chemists and druggists. The woman goes to the defendant, says, "I am weak; my womb is down owing to weakness left in my confinement," and Dr. Suffield says the medicine given by the defendant is the right stuff.

His Honour: Dr. Suffield said it was probably a preparation of iron, and if so it would be a proper medicine. Did Mr. Herbert think that supposing his client was properly qualified that such a man would have prescribed medicine which might have had serious effects without inquiries as to the particular state of that woman, when she herself said she was suffering from weakness. In my opinion there is no difficulty in the law, but in applying it. If there is "prescribing" the chemist infringes the Act, but if there is no "prescribing" he does not do so. If he sells his medicine simply because he is asked for the same I think there is no infringement.

Mr. Herbert: He writes no prescription, and simply on the statement of the woman, he makes a medicine and gives it her. A simple charge of one shilling was paid for the medicine, the same amount as would have been required had the woman sent for the bottle instead of going for it herself. If the Act touched Mr. Harrison it should touch Mr. Goodwin, for on his advice the woman fetched the medicine.

His Honour: If you can put Mr. Goodwin on a level with the chemists and druggists, for the Act says they shall not prescribe.

Mr. Herbert proceeded to argue that defendant had acted in accordance with the custom prior to the passing of the Act, as the learned counsel contended he had a perfect right to do. Not allowing chemists and druggists to give advice would prevent the poor scarcely ever getting advice.

James Harrison, the defendant, examined by Mr. Herbert, replied as follows:—

Are you a registered chemist and druggist?—I am.

Do you carry on business in Stafford Street, as a chemist and druggist?—I do.

Will you look at that register of chemists and druggists?—I have not my glasses.

Your name appears in it, does it not?—Yes, sir.

How long have you been a chemist and druggist?—Thirty years.

During that time have you ever been charged for precribing?

Mr. Nathan: That is not fair.

Do you remember Julia Caddick visiting your shop stNovember?—Yes, sir.

I believe it was in the afternoon?—Yes, it was.

What then took place?—She came to me and asked for a bottle of strengthening medicine, which I supplied her for a weakness.

Did you examine her at all?—No, it was not necessary.

Did you feel her pulse?—Certainly not.

Did she say anything about her womb?—No, nothing whatever.

Have you told us all the conversation that took place between you?—She asked me for a bottle of medicine for a weakness, and I said "Is it in connection with your lying-in, you mean?" and she said. "No." Seeing that she had been recently confined I asked her that.

His Honour: You asked her if the weakness had anything to do with her confinement?—Yes, sir.

His Honour: Do you say she had been recently confined?—She had a baby in her arms, which was a proof of it. I asked her if it was hers, and she said "Yes." I said, "What kind of weakness is it?" and she said, "I mean weakness of the body."

His Honour: That does not come in very well.—Yes; she said, "I mean, weakness of the body."

Mr. Herbert: What did you say in reply to that?—I said, "Do you mean general weakness of your constitution?" and she said "Yes."

What was done then?—I then mixed up some stuff.

Will you look at that; is that the stuff?—No; I never sold such rubbish out of my shop. I never sold such rubbish in my life.

What kind of weakness was she suffering from?—You might call it anæmia.

Mr. Nathan: How did you know which kind of medicine to supply her with—did you take it at random?—I supplied it in the ordinary way that chemists and druggists do.

You saw the woman and judged that she was suffering from debility and anæmia?—Yes.

How did you know which of the tonics to prescribe?—From instinct.

Mr. Nathan: What did you give her?—To the best of my belief, tincture of iron with quinine.

When you were served with the summons you went to see Mrs. Caddick?—I did.

Did you ask whether she recollected fetching a bottle of medicine from Mr. Adcock's?—No, I did not.

You went to the woman when you were served with the summons?—Yes; I said to her "Do you know me?" and she said, "No;" and I said, "Did you ever go to a chemist and druggist for any medicine?" and she said, "Yes;" and I said, "Where did you go to?" and she said, "I went to a shop in Stafford Street." Then I said, "If you went to a shop in Stafford Street and it was not me, was it Adcock's?" and she said, "Yes, it was;" and I wrote it down.

Did you say I don't recollect serving you?—No.

You did recollect her perfectly, did you?—Yes, I did.

Did you ask her whether she was sure it was you or your assistant.—Yes, I did.

And you did not feel her pulse?—No.

Why did you go to the woman?—I went to her and wanted her to go to a solicitor's office, and say what she thought proper. I wanted her to state what she said to me.

In selecting this medicine you selected it by instinct?—Well, I gave it her from many others.

Mr. Herbert: You gave a common remedy?—Yes.

His Honour: She did not tell you she was suffering from anæmia?—She told me she was suffering from weakness, and I gave her some medicine, but not that rubbish.

Thomas Parsons stated that he was eighty-four years of age, served his apprenticeship to a firm of chemists and druggists, and had remained in the trade till about twelve or fourteen years ago.

Mr. Herbert: If a person, prior to 1815, came to the shop and described her symptoms, did you give her medicine for the complaint?—I was accustomed to give medicine as well as advice.

Did you give advice?—Yes; in an important or serious case the head assistant or one of the principals attended to it.

In simple cases you prescribed?—Occasionally.

And in more difficult cases one of the principals?—Yes.

Was that the custom of the trade at that time?—Yes.

Do you know whether it was done in other shops?—It was.

His Honour remarked that according to defendant's own admission, he took the woman's word for what was the matter. If a chemist would take the simple word of a patient for what was the matter with her, and without making any examination, supply medicine, it was almost impossible to conceive how important it was that the Act should be properly observed. In the present case a chemist and druggist of thirty years' standing was simple taking the statement of his patient's case and without feeling her pulse, supplying medicine, as he said, by instinct.

At this stage the case was adjourned till Tuesday morning, when James Harrison, the defendant, was recalled by Mr. Herbert.

How much did you charge for the medicine?—For the medicine I supplied I charged one shilling.

One shilling?—Yes.

Did you charge anything for consultation?—No.

Was it or was it not the value of the medicine alone?

His Honour: No one says it was not.

Mr. Herbert: I want it to be particularly on your notes that nothing was charged for advice.

His Honour: The reverse is not on my notes, therefore I shall take it there was not. If you mean that one shilling was charged for the medicine, and nothing charged for advice, I have that fully; but whether the medicine which was sold was the consequence of the prescribing is quite another thing. There is no doubt at all he charges nothing in that sense; he does not say, so much for your visit to me, nor so much for the advice given you.

The witness being asked what was in the bottle, his Honour remarked that it was a pity the question had been raised. Defendant, he said, had denied on the previous day that the bottle of medicine produced was the one he supplied. He considered that a serious imputation upon the plaintiffs and one that ought to be withdrawn.

Mr. Herbert withdrew the alleged imputation and the witness proceeded to describe what the mixture supplied was composed of, evidence which His Honour held to be utterly irrelevant to the question at issue.

Julia Caddick, recalled, said in answer to Mr. Nathan, that in mixing the medicine defendant weighed something in the scale and poured something from a bottle.

The bottle given to you, you say you gave to Mr. Goodwin; did you take any of it?—I took some two draughts.

How long was it before you gave the bottle to Mr. Goodwin?—I took one draught the day I had it, and one the next day, and then gave it to him.

Did you put anything into it, or alter it in any way?—No, I did not.

Did Goodwin ask you for the bottle?—Yes.

And what did you say?—I told him it did not agree with me, and gave it to him.

His Honour: Who is Mr. Goodwin?

Mr. Nathan: I am going to call him.

William Henry Goodwin, examined by Mr. Nathan, returned the following answers to the following questions:

What are you?—A commercial porter.

In whose service?—Different gentlemen engage me.

Where do you live?—20, Allison Street.

Did Julia Caddick live with you in November last?—Yes, she did.

How long have you lived there?—Twelve years.

How long has Julia Caddick?—About three years.

You remember when she gave you the bottle of medicine?—I received the bottle on the 28th, which she brought on the 27th.

How long did you keep it in your possession?—One night, sir.

On the 28th did you take it to Mr. Reeves?—Yes, sir.

Did you put anything with it or alter it in any way?—No.

I suppose you had been told by Mr. Reeves to get it?—Instructed by Mr. Reeves.

Instructed to do what?—To procure the bottle.

His Honour: How did he know you had it?—I was engaged by Mr. Reeves to send for it.

And you sent Julia Caddick to Mr. Harrison's?—Yes.

Mr. Herbert: She being very weak?—Yes, and ill.

Three months after her child was born?—Yes.

Suffering after a confinement?—Yes.

You simply told her to go and get it, to say she was weak, and you to take it to Mr. Reeves?—I did not tell her that.

Is Julia Caddick living with you as your wife?—I expect to make her my wife.

And in that capacity you sent her for the medicine?—Yes, she not knowing what my intention was.

Then you are the informer in this?—I received instructions from Mr. Reeves to do it.

To get up the case?—To do what I did.

This was the whole of the evidence, and at the invitation of his Honour, Mr. Herbert again addressed the court.

The learned counsel contended that the defendant had in no way infringed the Act, and the statement of the woman. The chemist had a right to consult with his customer and supply what was best for her. Surely the defendant might suggest to her, persuade her to take (in the sense of buying) or dissuade her from buying; such consultation was part of the sale.

His Honour: That is contrary to the opinion of Baron Bramwell. His lordship stated that if a person entered a chemist's shop and asked for something to cure the headache, and the chemist gave him some medicine, he would be technically infringing the terms of the Act, although it would be very unreasonable for the Society to interfere in such a case. I am not prepared, however, to adopt in its entirety the view of the learned Baron. I draw the line, and say, if a person goes to a chemist, suffering under a disease the nature of which he does not know, but believes the chemist does, and he takes the ordinary means of ascertaining what that disease is, and then prescribes medicine to cure the disease, which by examination in any way you like is found out, then he steps beyond his province as a chemist, and adopts that of a medical man. I should be very wrong indeed, however, in saying that such a learned judge as Baron Bramwell is not right; nevertheless, my own view is that it is too strict an interpretation of the Act. If Mr. Herbert contends that a chemist is entitled to prescribe I should like to know the object for passing the Act.

Mr. Herbert: To prevent unqualified persons from practising. On the face of the 28th section, it is shown that a chemist is qualified for something.

His Honour: No doubt that Act proceeded upon the assumption that only those who had received a proper education and had passed the Apothecaries' Company were persons who ought to treat diseases. If you are right, Mr. Herbert, in supposing that a chemist could do so before, after the Act was passed so doing would be an infringement.

Mr. Herbert: Apothecaries might attend patients at their residences and chemists at their own shops might prescribe in minor cases.

His Honour: What authority is there for saying that the chemist might prescribe for minor ailments, and where would you draw the line?

Mr Herbert: By exercising discretion as we did prior to 1815.

His Honour: The section to which reference has been made, provides against the trade of a chemist in buying, preparing, compounding, dispensing, and vending medicines, nothing is said about prescribing. It appears a very good Act, and ought not to be infringed. I did not think the Apothecaries' Company intended to interfere in trifling cases, and I am not of opinion that if a chemist gave a man something for the toothache or headache, he would be infringing the Act. I think they should take it for granted that the company have grounds for taking these proceedings in the interests of the public, for whose real benefit the Act was passed.

Mr. Nathan remarked that as long as chemists confined themselves to the buying, preparing, compounding, dispensing, and vending of drugs, they would not be open to any interference. All cases he said were taken up by the Society after careful consideration.

His Honour: Do I understand you to say there is an appeal now pending relative to a similar case?

Mr. Herbert: There is.

His Honour: On this very point.

Mr. Herbert: Yes.

His Honour: Then probably you will wish that no judgment shall be given until that appeal is decided?

Mr. Herbert: That is what we should like.

His Honour: Then I shall not give judgment in the case until that appeal is decided, unless the defendant applies himself for judgment. Mr. Nathan will, however, have a right to ask for judgment supposing the appeal is not prosecuted with due diligence.

THE PERSONATIONS AT THE PRELIMINARY EXAMINATIONS.

On Monday last, July 9, Frank Oates, to whose arrest reference was made last week, was brought up on remand at Bow Street Police Court, charged with fradulently procuring his registration under the Pharmacy Act, 1868, and Andrew Ritchie Hunter was charged with aiding and abetting him in the same. They were also jointly charged with conspiracy. Mr. Douglas Straight, instructed by Messrs. Flux and Co., appeared on behalf of the Pharmaceutical Society.

Evidence having been given as to the arrest of Oates, the forms of application sent in on behalf of Oates were put in, and it was deposed that they were filled in in the handwriting of Hunter.

Mr. James Thomas Gwatkin, the Local Secretary of the Pharmaceutical Society at Brighton, deposed that in April, 1876, he superintended an examination on behalf of the Society, in the Pavilion, and that a person named Frank Oates was one of six candidates then to have been examined. One of the candidates who attended that examination now deposed that he saw Hunter present.

Upon this evidence, the defendants, who made no answer to the charge, were committed to take their trial at the Central Criminal Court. Bail was allowed.

THE SALE OF LAUDANUM—CENSURE OF A CHEMIST'S ASSISTANT.

At the Margate Quarter Sessions, on Wednesday, July 4, James Thomas Rowe, 15, a pot-boy, was indicted for attempting to commit suicide by taking a quantity of laudanum on the 18th June. On being placed in the dock and charged in the usual way the boy pleaded guilty, and began to cry.

Mr. Duckett, the boy's master, said that the only reason he could give for the boy taking the laudanum was that he had occasion to find fault with him about an hour and a half before the boy took the poison.

Addressing the chemist's assistant (Mr. F. S. Morton, of Zion Place), who served the poison, the Recorder (F. J. Smith, Esq.), asked him how he came to sell a lad like that poison, to which the assistant replied that there was a discretionary power.

The Recorder: But do you think it was exercising a wise discretion to sell poisonous drugs to a boy like this?

The Assistant: He told me it was for his master.

The Recorder: Should you let him have it without a medical certificate?

In answer to this the assistant stated that laudanum was principally used in this part of the country for external applications, and they never got asked for it to be used internally; it was largely used internally in the Midland Counties and the North, but not in Kent. Witness was now assisting his father, who was carrying on business at Ramsgate.

The Recorder: Well, unfortunately you have sold laudanum to this child, and he bought it for the purpose of making an improper use of it. Perhaps it will be a caution to you in the future not to sell it to a child. If a child comes for a poisonous drug, even if he is sent by his master, there ought to be some note from the master to satisfy the chemist that it is to be used for a proper purpose. Fortunately for you and the boy in this case it did not take effect. If he had died it would have been a matter of very serious moment to you in having supplied the drug to him without due caution.

In reply to the Recorder, Mr. Duckett said that he ascertained the boy had taken the poison a few seconds after he had obtained it, he believed.

The Recorder: I see it was taken in beer.—Mr. Duckett: I do not know anything about that. I sent for the medical man, and he came directly.

Mr. Mosse (Counsel for the prosecution): He vomited freely, and that no doubt saved the boy's life, and the chemist as well.

Mr. King, surgeon, on being called by the Recorder, said that when he was called in to attend the accused the effects of the poison had then passed away.

The Recorder: Would twopennyworth have been sufficient to take away the boy's life if it had taken effect?

Mr. King: Yes, it would. I believe he took two drachms of laudanum, and that is the minimum dose to destroy the life of an adult. I believe twopennyworth would be about two drachms and be quite sufficient to destroy life. It is however a very uncertain poison. I asked him why he took it, but he gave me no answer, only admitting that he did it.

The Recorder dismissed the lad on his father entering into recognizances of £50 for him to keep the peace for twelve months.

POISONING BY CARBOLIC ACID IN A WORKHOUSE.

On Monday last, Dr. Hardwicke held an inquiry at St. Pancras Coroner's Court as to the death of John Page, aged 77, a patient in one of the male infirm wards of St. Pancras workhouse. From the evidence of Eliza Powell, nurse of the ward, it appeared that carbolic acid in bottles labelled "Poison, carbolic," was kept in the ward for disinfecting purposes, in a cupboard among other bottles containing black draughts and other house medicines. On the morning in question deceased asked Jane Connelly, the pauper helper, for some house medicine, whereupon Connelly, who could neither read or write, poured a large dose of carbolic acid into a wine glass and gave it to deceased. Dr. Dunlop, the medical officer, was immediately sent for, but death took place in about five minutes.

Mr. Fildew, on behalf of the guardians, said there had evidently been a fatal mistake. He could not understand how the paid officer could have allowed the carbolic acid to pass into the hands of a scrubber or pauper help. He would bring the whole matter before the guardians, who would thoroughly investigate it, and take steps to prevent the recurrence of a similar calamity. The jury, on Mr. Fildew's assurance, agreed to a verdict of "Death from misadventure.—*Daily News*.

SINGULAR CHARGE OF POISONING.

On Tuesday, July 10, at the Manchester Assizes, Martha Barker, a domestic servant, was charged with administering poison to her mistress, a Mrs. French, with intent to murder her. Mrs. French being ill, the prisoner was sent to the doctor's for some medicine for her, and she returned with a bottle of medicine which she said the doctor had told her she must make her mistress take, and that it would probably make her ill. Mrs. French took two doses of the medicine and became very ill, and it was afterwards found that there was red precipitate in the medicine, and the doctor said he did not keep this poison in his surgery at all. There was not, however, sufficient poison to prove fatal, according to Taylor's 'Medical Jurisprudence,' which the Judge consulted on the point, and the jury acquitted the prisoner.—*Daily News*.

ALLEGED ATTEMPT TO POISON WITH SALT OF LEMONS.

At Salisbury, on July 6, in the Crown Court, before Mr. Justice Lindley, John Smith Flemmon, aged fifty-six, a labourer, was indicted for attempting to poison his wife. The case for the prosecution was that in May the wife of the prisoner, a young woman of twenty-one, had made a pot of rhubarb jam, and that on the evening of the 11th the prisoner had pressed her to take some of it and again the next morning: that she then noticed something white in the jam, and immediately took the pot to two neighbours to show it to them; that one of them retained a small quantity of the jam, while the rest, which the wife took into her house again, was thrown into the fire by the prisoner. It was proved that the prisoner had purchased a pennyworth of salts of lemon on the 7th or 8th of May, saying it was to take ironmould out of his shirts. It was also proved that the prisoner and his wife, who had been married about a year, lived very unhappily together. The jam which was not thrown into the fire was analysed, and found to contain oxalic acid in sufficient quantity to be dangerous to life. The prisoner, when apprehended, said that he had bought the powder to take ironmould out of his shirts, and that if the powder found in the jam was the same, his wife had put it there to kill him.

For the defence it was urged that the only evidence to connect the prisoner with the placing of the powder in the jam was that of the wife, who might have found the packet (which was labelled "Poison") and herself placed the powder where it was discovered for the purpose of founding a charge against her husband.

The prisoner was acquitted.

Dispensing Memoranda.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible considerable latitude will be given to the definition of wha, may be considered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.

[5]. Sulphur Hypochlorite.—In part answer to this correspondent I may say that I have several times dispensed the prescription ung. sulph. hypochlor., in the proportion of one drachm of the sulphur preparation to one ounce of benzoated lard. This was according to the direction of one of our leading surgeons. The sulph. hypochlor. used was in ℥j stoppered bottles, but I forget the name of the maker. In regard to its explosive properties, I have never known it to explode spontaneously, but a slight tap on the bottle is generally sufficient to set it off. On one occasion (the first I believe), the stopper of the containing vessel was fast, and on tapping it with a knife the bottle exploded and the contents took fire at a gas jet near which I was standing. There was a flash of blue flame and I found myself minus the greater part of my eye-lashes and eyebrows, and with an incrustation of what appeared to be sulphur upon my face and coat, while the counter was covered with small pellets of the same substance. Whether the flame was simply due to the particles of dust coming into contact with the gas flame, or whether it was caused by the liberation of some combustible gas I leave to be decided by abler hands, but I believe in all probability the latter, as you can have no explosion without chemical action.

S. L. S.

[5]. Sulphur Hypochlorite.—I fancy that "Occident's" experience of that highly inconvenient as well as malodorous substance, sulph. hypochlor., can be paralleled by many similar instances. About a month ago my stock of it blew a piece out of the shoulder of the bottle and emitted a large volume of the offensive vapour which he describes. It was bought in May, 1876, and the bottle had been only partially filled, for as soon as I received it I mixed some with an equal weight of benzoated lard, securing it as well as I could in a covered pot. This has undergone no change in colour or consistence but is quite free from smell, although I well remember the disagreeable effects which accompanied its preparation. I have a dim suspicion that the chemical energies of the hypochloride, so called, are usually expended on the unhappy dispenser to whose lot it falls to open the stock bottle and compound the ointment therefrom; and that the patient's needs would be as effectually served by simple sulphur ointment.

J. F. Brown.

[5]. Hypochlorite of Sulphur.—There is no test for the strength or purity of sulphur hypochlor., it being a very indefinite compound. The explosion was probably due to volatilization of the sulphur chloride, and I have always found the odour more pungent when the chloride of sulphur is mixed with powdered sulphur than when prepared by passing chlorine over the surface of sulphur till no longer absorbed. The formulæ for the unguents may be found in Beasley. More information will probably be given before the Conference.

E. S. Balchin.

[6]. Chloric Ether.—With respect to this question one of your correspondents draws a distinction between æther chlor. and spt. æth. chlor., which I think is not usually admitted, the two names being considered synonymous. When chloric ether is ordered generally a stronger solution of chloroform than that of the Pharmacopœia is used. The use of this stronger solution of chloroform for prescriptions written before the 1864 Pharmacopœia was published, would be correct, but it is questionable whether it should be used for prescriptions written after that time. Previous to the 1864 Pharmacopœia spirituous solutions of chloroform (so called chloric ether) of strengths varying from 1 part of chloroform to 6, 7, 8, and 9 of spirit were in use. Spirit of chloroform was, I believe, introduced into the Pharmacopœia to supply a want felt for a definite solution of chloroform and which would be more readily miscible in ordinary mixtures than the strong solutions formerly in use. By "æther chlor." a spirituous solution of chloroform is meant, and as we have an authorized formula, I think it should be used in preference to a variable solution there is no authority for. With regard to the case of lac sulphuris quoted by your correspondent (Mr. Mackay), I think scarce any one would object to the use of precipitated sulphur any more than they would hesitate to use spt. ætheris nitrosi for sweet spirit of nitre when ordered. In both cases the distinctions were made on technical grounds to set aside what was looked on as arbitrary prosecutions, but not to establish their absolute adoption.

E. M.

[8]. Carbolic Acid Mixture.—Mix the acid. carbolic. (No. 5, Calvert's), ʒj., well together with mucilage of gum acacia, ℥j, in a mortar, then gradually add (stirring) the water with perchloride of mercury, ʒij, previously dissolved to ℥viij. This mixture can be added afterwards to any quantity of cold water, and it will not separate.

C. Campbell.

Notes and Queries.

UNUSUAL SPECIMENS OF ATROPA AND HYOSCYAMUS.—Two years ago an unusual monstrosity in *Atropa belladonna* came into my hands. It was from a garden plant growing at Stanninghall, Norfolk, and is an example of what are called fasciated branches. It consists of a long, flattened, ribbon like-branch with the following dimensions: length of the flattened part, 43 inches; breadth at the apex, 4 inches; at the base, 1¾ inch; circumference at apex, 9 inches; at base, 4⅝ inches. As these measurements show, it tapers gradually from apex to base, losing at the same time its flattened shape and becoming rounded just above its point of union with the root. On each of the flattened sides were about fourteen faintly marked rounded ridges; these ridges were marked with scattered scars arranged in an obscurely spiral manner. These scars were probably produced by fallen or aborted branches. Along the edge of the apex at least forty-three branches were arranged in two rows; the two rows diverged from each other at an angle of about 60°, and between them a tolerably distinct naked path was visible. Outside the rows of branches and inserted on the flattened part were a few leaves and flowers, one pair of leaves being situated about six inches from the end of what I may call the ribbon. The branches were from one to two feet long, and were covered with leaves; numerous flowers and immature fruit being also present. This form of monstrosity is comparatively common among various plants. Several examples of it have occurred to me during the past two or three years. But as I have seen no record of its occurrence in *Atropa belladonna* I have thought it worth while sending this note.

A remarkable specimen of Hyoscyamus is described in Johnston's 'Botany of the Eastern Borders,' (London, Van Voorst, 1853) in the following words: "In a garden of Mr. Allanton, surgeon, there is now growing a plant of *Hyoscyamus niger*, of the following extraordinary dimensions and fecundity. It is 5 feet 4 inches in height, and in breadth its branches spread out to the same extent. It bears above 1000 seed vessels, and if we reckon each of these vessels to contain 300 seeds (which is a moderate computation, as I counted the seeds of one of the pods, not of the largest size, and found it to contain 326 seeds) the amount of the whole will be 300,000.—Geo. Henderson."

These dimensions are very remarkable and as they are recorded in a book which does not come much into the hands of pharmacists I have ventured to give them greater publicity.

WALTER G. PIPER.

REMEDY FOR DANDRIFF.—A French physician recommends that a solution of chloral hydrate containing five per cent. should be applied to the scalp by means of a sponge every morning. The quantity employed should be from one half ounce to one ounce. A slight burning sensation and reddening of the scalp occurs, disappearing after two minutes. If the hair has fallen off in consequence of the dandriff, it will be renewed in about a month.—*Cincinnati Lancet.*

[549]. GREY AND WHITE LIME.—"*Bricklayer*" would be glad to have the difference, if any, between "Grey Lime" and "White Lime" explained. Also whether Grey Lime would do equally well for the manufacture of Lime water.

[550]. TINCT. COLCHIC. C. MORPHIA.—I should be much obliged if some one could give me a form, in the Journal, for Lavill's Tincture of Colchicum with Morphia.

R. MODLEN.

[551]. MARKING INK FOR SACKS.—Can any one oblige by giving me a receipt in Pharm. Journ. for marking ink for sacks?—INQUIRER.

Obituary.

Notice has been received of the death of the following:—

On the 7th of May, 1877, Mr. George Pitt Foster, Pharmaceutical Chemist, Tetbury, Gloucester. Aged 60 years. Mr. Foster had been a Member of the Pharmaceutical Society since 1855.

On the 14th of May, 1877, Mr. John Harper, Chemist and Druggist, Leamington. Aged 35 years.

On the 28th of June, 1877, Mr. William Geldart, Chemist and Druggist, Boroughbridge. Aged 23 years. Mr. Geldart had been an Associate of the Pharmaceutical Society since 1873.

On the 2nd of July, 1877, Mr. William Williams, Chemist and Druggist, Coedpoeth, Denbighshire. Aged 36 years. Mr. Williams had been a Member of the Pharmaceutical Society since 1872.

On the 4th of July, 1877, Mr. Thomas Figg, Chemist and Druggist, Lewes, Sussex. Aged 69 years.

Correspondence.

**** No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE SALE OF LAUDANUM.

Sir,—I have taken the liberty of sending, by a preceding post, a copy of Keble's *Margate Gazette*, containing a report of the trial of a boy for attempting suicide by taking laudanum.

I should not have called your attention to the circumstance (especially as the assistant now in charge of the business is my son, whose aid was sought in the sudden and alarming illness of the late principal, and who is now acting under my supervision until the business shall be transferred to a successor) but for the remarks of the learned Recorder and others, reflecting severely on the assistant for supplying laudanum to a boy of fifteen years old, apparently arising from an imperfect acquaintance with the relation in which a chemist stands to the public when called upon to supply a preparation in such frequent demand as laudanum, and with the regulations to be complied with in meeting the applicant's requirement.

The facts are as follows:—

A boy apparently not under sixteen years old, asks for twopennyworth of laudanum.

Assistant: What is it for?

Boy: I don't know.

Assistant: Who is it for?

Boy: My master, Mr. Duckett.

Assistant: Do you know it is poison?

Boy: Yes.

Two fluid drachms were then supplied, labelled "Laudanum," Poison, with the seller's name and address, printed in black letters on a red ground. The boy was also told to be careful with it as it was poison.

Mr. Duckett being the proprietor of a respectable house within a minute's walk of the shop, no further hesitation was felt in supplying it.

About a week after, a policemen brought part of the broken bottle with the label entire, inquiring respecting it, and was informed of the particulars related.

The officer then stated that the boy had that morning (about a week having intervened since obtaining it) drunk it, and that the assistant's evidence would be required, as the boy was in custody for the attempt on his life.

The examination of the boy before the magistrate led also to similar severe remarks (parts only reported) about the carelessness and indiscreet mode of supplying poison to children.

I ought to say that the boy in question, called a "child," has attained his sixteenth birthday, and was in receipt of sixteen shillings per week with a regular daily allowance of three glasses of beer, and was not considered by the assistant as a "child" to whom he could refuse to supply the laudanum, especially as the boy was known to be in the employ of the person for whom he stated it was required.

The boy it seems had provided himself with the poison fearing detection of some delinquencies.

It seems to me that where the legal requirements in supplying laudanum have been complied with, and the schedule showing such requirements had, as in this case, been produced, and due caution also given to the purchaser, a better understanding of the state of the law might save from these castigations those who have really complied therewith.

HENRY MORTON.

The Elms, Ramsgate,
July 9, 1877.

PHARMACY IN AUSTRALIA.

Sir,—In the hope of preventing distress I am induced to indite a few lines on the subject of the emigration to Australia of English chemists, which you will much oblige by inserting in the next issue.

Nearly three years ago I came to Australia. I had passed the Minor examination and was seeking a berth as a chemist's assistant. I had several letters of introduction to leading houses, and fortune favoured me, for before a month had elapsed I found a home in a bush town in Victoria, at a salary of 30*s*. per week for first six months, and £2 per week afterwards. Three months before my arrival here I had been earning only £30 per annum, consequently, I thought Australia a "grand place," and wrote glowing accounts home to my professional friends urging them to follow my example. Fortunately not one of them took my advice, for I have since found out that it was only by a piece of good luck that I was not kept waiting for months; and since I have been up here, although it is only a small town, three young chemists (two qualified) have begged money for a night's lodging, and told doleful tales of going unsuccessfully over the colonies in search of employment. Also several cases have come under my immediate notice, where men educated as chemists have had to go on a station (sheep tending) or do any menial work they could obtain, in consequence of their inability to get a situation in their own trade. My advice to intending emigrants is, "Do not come unless you have sufficient money to live without work for six months, and if you have enough capital to open a business at home do not come at all—unless it be a question of health—for a more remunerative business can be had in England for £500 than here for £800." Chemists in proportion to the population are much more numerous here than at home, and although the fact of surgeons seldom dispensing their own medicine is one advantage over the old country, yet that is quite counterbalanced by nearly all the stores selling drugs and patent medicines at low prices; in some parts 1*s*. $1\frac{1}{2}$*d*. articles sell at 1*s*, when the advanced wholesale price leaves only an apology for a profit.

I have made these remarks in a friendly spirit and not for the sake of discouraging those who would like to see the other side of the world On the contrary, I say to any one who has some spare cash and does not mind working harder and roughing it that he can do better here (as an assistant) than at home; but beware of coming out and leaving too much to chance, for the demand is very limited.

I may add that in Victoria, N. S. Wales, and Tasmania, pharmacy acts have been passed and examinations are necessary.

AN AUSTRALIAN.

"NO DISSENTER NEED APPLY."

Sir,—I consider "Fraternity" has given the right solution to "Equality's" problem in a recent number, and I fully intended sending a reply of a similar purport, last week, but forgot. I know that churchmen (like Methodists) are very conservative in patronizing tradespeople of their own denomination, particularly if the shopkeeper acts as a Churchwarden. This custom is more prevalent I believe in agricultural districts than in manufacturing cities, so that if the case in question be of the former type, *a dissenter* would run a poor chance of retaining the customers of his predecessor.

JAMES B. L. MACKAY.

Newcastle-on-Tyne, 3rd July, 1877.

"*Œnanthe.*"—(1) *Epilobium montanum*; (2) *Artemisia vulgaris*; (3) Not in flower: it looks like *Circæa lutetiana;* (4) *Œnanthe crocata*; (5) *Veronica officinalis*; (6) *Scrophularia nodosa*; (7) *Alisma Plantago*; (8) *Lysimachia nemorum*; (9) *Sisymbrium officinale.*

"*Claviceps purpurea.*"—We presume the prescriber had some object in view, but what that was is not perceptible to us.

"*Syrupus.*"—(1) *Ranunculus flammula*; (2) *Melilotus officinalis*; (3) *Prunella vulgaris*; (4) *Ceratodon purpureus*; (5) The outer stamens are longest in the tribes mentioned.

F. C. B.—*Habenaria chlorantha*; *Equisetum sylvaticum*; *E. arvense*; *Lychnis Flos-cuculi*; *Senecio aquaticus*; *Carduus pratensis.* The *Senecio* and the *Carduus* we cannot name with certainty; no leaves are present. *F. C. B.* should send better specimens and attach numbers to each.

"*R. Spro.*"—*Essence of Smoke.*—Crude pyroligneous acid, 1 pint; sugar colouring, 2 ozs.; dissolve, and in a week decant the clear portion. Other recipes for essence of smoke may be found in Cooley's Cyclopædia.

A Warning.—We have received from Mr. L. Dotesio, of Bilbao, a communication giving an account of "an accomplished rascal who by his artful blandishments has succeeded in transferring some £25 from his soft-hearted friends' pockets into his own." The means of introduction to Mr. Dotesio was a prescription ordering potass. bromid., syrup. aurant., and aq. menth. pip., which now bears the mark of the English Pharmacy at Bilbao, No. 8193, 1877.

"*Inquirer.*"—(2) The answer to your question would possibly depend upon what would be implied by such a name.

Herr Platz.—(1) See Gmelin's 'Chemistry,' art. "Sugar." (2) A candidate must comply with the regulations in force at the time of his presenting himself to enter for an examination.

"*Alpha-Beta.*"—Not unless it otherwise comes under the provisions of the Medicine Stamp Act by its being represented to be a proprietary or occult preparation, or useful in the cure or relief of disease.

W. Young.—We quite agree with you that comment is needless and that competition with such prices is out of the question.

Gadus Morrhuæ.—The subject of your first question is dealt with on another page. With respect to the second we are unable to give you the information you ask for.

H. Humphry.—Darby prepared bichromate of ammonia by partially saturating chromic acid with ammonia, and evaporating to the crystallizing point (Gmelin's 'Chem.', iv., 142).

"*Inquirer.*"—The reaction of bromine with ammonia does not give rise to the formation of bromate, and is represented by the following equation:—

$$4NH_3 + 3Br = 3NH_4Br + N.$$

"*Syrupus.*"—A table of the percentage of cane sugar in aqueous solutions of different densities will be found under the article "Sugar," in Watts' 'Dictionary,' vol. v., p. 47

D. B. Dott.—Your note has not been overlooked, and shall receive attention at the first opportunity.

"*A Candidate.*"—We are not in a position to say with certainty, but we presume that the words should have been *venation* and *vernation*, and that by a printer's error the letters at the commencement of each word were transposed.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Young, Carlsbad Mineral Water Company, Mr. Vizer, E. M., Philomas, Atom, Spes.

COSTUS.

BY M. C. COOKE, M.A., A.L.S.

Botanical Origin.—*Aplotaxis auriculata*, D.C. (*Aucklandia costus*, Falc.), is a composite plant inhabiting the North Western Himalayas. According to Stewart it grows at from 10,500 to 13,000 feet in parts of the basins of the Jhelam and Chenab. Under the name of *Saussurea hypoleuca*, Spr., it is included in Clarke's 'Compositæ Indicæ,' and is said to extend from Sikkim to Kashmir at an elevation of from 7000 to 12,000 feet. The "Koot" or "Costus" root of which we have any knowledge at the present day has no relation whatever to the plant *Costus speciosus*, Sm., or *Costus Arabicus*, Linn., with which it is sometimes confounded. Dr. Falconer was the first to trace the drug to its true source, and although Dr. Royle at one time seems rather to have considered it the produce of an umbelliferous than a composite plant, there appears to be no ground for the suspicion.

Native Synonyms.—The native names determined by Surgeon Moodeen Sheriff are—

Qust, *Arab.* Kosht, Kost, *Pers.* Pachak, Kut, *Dukh.* Goshtam, *Tam.* Goshtamu, *Tel.* Koshtam *Sans.* It is the orris root, patchuck, putchuck, or ooplates, of the trade lists and returns, and the Pachak of Bengal. In China it is known as Muh-hiang and Kwang-muh-hiang.

History.—Costus was well known to the ancients, and the account given of it by Dioscorides is to the effect that "Arabian Costus is best; it is of a white colour, and light, and emits a very grateful and sweet odour. Indian Costus holds the second rank; it is thick and light like ferula. The third sort is the Syrian, which is heavy, in colour like boxwood, and emitting a strong odour. The best Costus is that which is fresh, light coloured, compact, and of firm texture, dry, not worm-eaten, devoid of an acrid smell, and which tastes hot and biting."

The Persian Hukeems have founded their account of Costus upon that of Dioscorides. In the Toftehool-moomineen, cited by Falconer, it is stated that "Koost is a root resembling in appearance that of the Mandragora, and comes from the borders of Hindoostan. The plant which yields it is humifuse and stemless, and has broad leaves. There are three sorts; the first, called Arabian or Ocean *Koost* (Koost Arabee and Koost buhree), is sweet, light, white, and fragrant. The second called Indian *Koost*, is of a dirty yellowish colour, light, thick, bitter to the taste, and having but little fragrance. The third is of a dirty red colour, and heavy, and in weight (or colour) like boxwood, and fragrant, and without a bitter taste. What follows refers to the first sort, or sweet Koost. The best is what is fresh, white, not worm-eaten, and having a hot, biting taste. It retains its virtues good for four years; and the difference between it and Elecampane (*Rasun*) or Damascus Koost is in this, that Elecampane is harder, and has not the fragrant odour and biting taste of Koost. Koost is hot and dry in the third degree; it is diuretic, revulsive, emmenagogue, hepatic, deobstruent, a universal antidote to animal poisons, attenuates the secretions, a powerful aphrodisiac, vermifuge, lithontriptic," etc., etc.

Dr. Falconer maintained that the *Aplotaxis* was the Costus of the ancients for the following reasons:

1. It corresponds with the descriptions of the *Costus* given by the ancient authors.

2. Coincidence of names: in Kashmir the root is called *Koot*, and the Arabic synonym is said to be *Koost*, both given as synonyms by the Persian Hakeems, and names by which the medicine is known in all the bazaars of the Hindoostan Proper; in Bengal the Kashmir *Koot* is called *Putchuk*, and it appears by a note in Dr. Royle's illustrations that Garcias ab Horto gives *Pucho* as the Malay synonym of Costus Arabicus.

3. Koot is used at the present day for the same purposes in China as Costus was formerly applied to by the Greeks and Romans.

4. The direct testimony of the Persian authors that *Koost* comes from the "borders of India," and that it is not a production of Arabia.

5. The commercial history of the root gathered in Kashmir under the name of *Koot*. It is collected in large quantities and exported to the Punjab, whence the larger portion goes down to Bombay, where it is shipped for the Red Sea, the Persian Gulf, and China; a portion of it finds it way across the Sutlej and Jumna into Hindoostan Proper, whence it is taken to Calcutta, and bought up there with avidity, under the designation of *Putchuk*, for the China market. Upon these grounds Dr. Falconer held that the plant described by him under the name of *Aucklandia* was undoubtedly the source of the Costus of the ancients.

Although but little reliance is to be placed on Honigberger, he repudiates the idea that the plant described by Falconer yielded the Costus of the ancients. He says it may be the *Costus niger Cashmereanus*, but that the true *Costus*, the *Costus veterum*, was *Costus Arabicus*; which is probably brought from Arabia into India, and is used by the Hakeems in a variety of diseases. After a residence of many years at Lahore it is surprising that his knowledge on this subject is so confused. The drug of the Hakeems is undoubtedly the Kashmir "Kut."

Still more curious is the account of *Costus* contained in Pomet's 'History of Drugs,' in which it is stated that the Arabian Costus is the root of a shrub very like an elder tree, which grows plentifully in the happy Arabia, from whence it takes its surname. The chief use of this root, he adds, at present is in the composition of Venice treacle and others of that kind. In a similar vein he discourses of *Costus Indicus*, with a like result.

Although preceding in time of publication the above remarks from Dr. Falconer, it will be of interest to associate with them, in full, the observations of another equally celebrated writer on Oriental materia medica.

Dr. Royle, in his 'Illustrations' (pp. 360), says that "in the bazaars two or three kinds of root are met with, having a general resemblance to one another, and known by the name *Kooth*, Arabic *Kust*; to this *Koostus* (κοστος) is assigned as a Greek, and *Koshta* as a Syriac name. Three kinds are described—(1) sweet, light, and white; (2) black, light, bitter, without fragrance; (3) reddish, and heavy like boxwood. These evidently refer to the three kinds described by Dioscorides, under the the names of (1) Ἀραβικος λευκος; (2) Ἰνδικος; (3) Συριακος. I was only able to meet with two kinds, one called *Koost hindee*, and *Koost tulkh*, Indian or bitter Costus, and said to be brought from Mooltan. This is probably the κοστος ινδικος of Dioscorides. The other kind is called *Kust sheeren*, with the synonyms of *Koost-buhree* and *Koost-arabee*, which is of a light yellow colour, with a very pleasant fragrant odour, said to be brought into India from Caubul and Cashmere. It is said by the native authorities to be produced by a plant having a root like *Atropa mandragora*, without stem, with spreading succulent leaves. This root is found in every bazaar, and is what, I believe, is commonly called Indian orrice (iris) root, and must form an extensive article of commerce. It does not appear to be produced in any part of India, though I am inclined to think that under the name *puchuk* it forms one of the exports from Calcutta to China, where the substance is probably employed as incense. On comparing the specimens of the sweet Costus in my collection of materia medica with those of *Puchuk* bought in the Calcutta bazaar, I am unable to perceive any difference, either in appearance or flavour." Afterwards, in a note on the same page, the author writes: "I have been favoured with a visit from Mr. Beckett, long resident in Allygurh, who informs me that he used to procure this Indian orrice root from Umritsur, under the name of *Koot*, to send to Calcutta, where it was sold by the name of *puchuk* or *puchook* for export to China. He also states that the roots frequently had attached to them pieces of the stem, which were hollow and angular, and appear from description to be those of a channelled umbelliferous plant."

In 'Punjab Products' (p. 356) the writer says, quoting from Dr. Johnstone, "When in Kashmir last year, I endeavoured to trace the Costus, and after toiling up many a rugged mountain pathway, was rewarded; but the root stock alone existed buried in snow, which clothed its habitat so late as June. Leaving the valley, I directed two intelligent servants, one on the Indus, the other on the Punjab side of Kashmir, to wait until it had bloomed, and was seeding. Owing to the unusual severity of the season, a good collection of plants was not obtained until the end of September. Eight of those were carefully removed, imbedded in their natural soil, and safely landed at Gujrat, when I replanted them." As the snow melts in the end of March the root stock appears, its caudal leaves develop in the beginning of June, and it comes to full fruition in September. It is a perennial, leaves and stem dying yearly to the root stock; the exstipulate caudal leaves rise in threes, the two lateral spathing the centre; the centre sheathing the stem as it shoots above ground. The stem, two or three of which may arise from the root stock, stands in adult growth forty inches, is fluted, lined internally with pith, and sheathed with exstipulate tristichous leaves. The root stock varies in size from nine to fifteen inches in length, and from three to twenty-one inches in thickness. The caudal leaves spring straight from the root stock, and are supported on petioles eighteen inches long. The leaves are simple, obcordate, eight by five inches in adult growth and strongly veined."

At the present day we have heard of no other *Kut* which is known in India than that which comes down from Kashmir, and its substitutes or adulterations. Prefixes and affixes to the name appear to indicate only minor differences, as of age or locality. Three of Dr. Royle's original specimens have been consulted. One of these (No. 148) is identical with the false *Kut*, hereafter described; this is merely marked "Koot;" another is the *Aplotaxis* root (No. 150) marked "Koot Tulkh" from Umritsur. The third specimen (No. 147) is so far advanced in decay that it is impossible to say what it is. It is marked "Koot, Aucklandia costus." It is possible that the farinaceous, inodorous root (No. 148) may be the "Koost shirin" of the natives, but of this there is no direct evidence. It is not uncommon to find the same native name applied to two or three similar substances.

Description.—The root, as met with in the bazaars, consists of irregular pieces from two to three inches in length, and scarcely an inch in diameter, cylindrical, with a rough and somewhat reticulated surface, and very compact and brittle. Internally it is dirty white, with radiating bundles leaving numerous small cylindrical channels filled with a brownish resin. There is no distinct bark or central medulla. When cut or rubbed it has a strong and definite odour resembling that of violets or orris root. In taste it is at first camphoraceous, and then bitter with a slight pungency, but by no means unpleasant. The genuine root does not appear to be at all subject to the attack of insects, although fragments of foreign roots introduced as adulterations are nearly destroyed. Of the two varieties of root that called *Kut tulkh* is probably the old and *Kut shirin* the young root. Dr. Stewart hazarded the opinion that *Kut shirin* is the produce of a different and unknown plant. Two specimens collected in Kashmir under the names respectively of *Tet Khot* and *Muder Khot* do not appear to differ except in size.

Composition.—Hitherto we have found no record of any chemical examination of this root, although it is one which certainly offers many points of interest. At present our own microscopical examinations have been very superficial, sufficient only to show that starch only exists in very small quantities, and of a character quite different from that of the false root hereafter alluded to.

Collection and Preparation.—The roots are dug up in the months of September and October, when the plant begins to be torpid; they are chopped up into pieces from two to six inches long, and exported without further preparation. The quantity collected is very large, amounting, as far as Dr. Falconer could learn, to 10,000 or 12,000 khurwars (of 192 lbs., or about two million pounds per annum). The commodity is laden on bullocks, and exported to the Punjab, whence it finds its way to Bombay, and a portion gets to Calcutta through India. In Dr. Falconer's time the cost of collection and transport was about half a crown per hundredweight.

Commerce.—The Sanscrit name, *kashmirja*, of the root indicates the chief place whence it was brought. Cleghorn states that it is also exported from Pangi on the Upper Chenab to the plains. The loads of it when passing scent the air to some distance. A great part of the imports into the Punjab pass through to be sent to China. Davies' 'Trade Report' gives twenty maunds as exported to Affghanistan *viâ* the Bolan. Royle mentions that in one year (1837-8) 6697 maunds of this root, valued at Rs. 99,000, were exported from Calcutta to China, and in 1867-8 347 cwt., nearly 10.000 maunds, were exported from Calcutta to China. In Kashmir territory the Maharaja is said to take it over from the collectors at half the price at which he sells it again. In 1864 his income from this source was put down on good authority (according to Dr. Stewart) at 300,000 chilki, equal to nearly 190,000 rupees; but this, he adds, is scarcely credible. Koot is imported into Leh in small quantities from Kashmir for exportation to Lhassa, where it is called, as well as by the Bhotes, *Rusta*, and is used for incense. In 1871, 33 maunds were imported into Leh from Kashmir, valued at Rs. 672. According to Dr. Falconer, at the time he wrote the cost of collection and transport to a depôt at Kashmir was 2*s.* 4*d.* per cwt.; on entering India its value was enhanced to from 16*s.* 9*d.* to 23*s.* 4*d.* per cwt., whilst the commercial value at Canton was 47*s.* 5*d.* per cwt., an immense increase upon the cost in Kashmir. As this drug is not enumerated in the recent trade returns of Bombay or Bengal the amount of exports cannot be ascertained.

From the consular reports we find that in the year 1875 the imports of Costus into two Chinese ports only were for Hankow 1270 piculs, valued at £5224 6*s.* 3*d.*, and Chefoo 277 piculs, valued at £1197, so that it is clearly no insignificant article of Chinese commerce.

Uses.—Dr. Irvine states that formerly, when opium was not produced in Rajwarra, this root was extensively smoked as a stimulant. He adds that it is said to be narcotic when thus used, and that formerly great quantities went to China for smoking purposes. At the present time it is chiefly used as a perfume, as a protection of bales of cloth from insects. In the Punjab it is applied in powder to ulcers, for worms, in wounds, etc., and for toothache, and it is also given in rheumasm. Locally it is used also for hair powder. Assistant-Surgeon Raheem Khan says that it acts as a diuretic, emmenagogue, absorbent, and as an antidote for animal poisons. It also acts as an aphrodisiac and anthelmintic. He adds also that it is a good tonic for the liver and stomach. A summary of the uses of this drug is given by Baden Powell in his 'Punjab Products,' in the following terms.

1. Dried and powdered as the principal ingredient in an astringent stimulant ointment, applied to severe ulcerations.

2. Dried and powdered as a hair wash.

3. As a stimulant in cholera, an infusion is made of Cardamoms 1 dr.; Fresh "Kut" 3 dr.; Water 4 oz. One ounce every half hour. It is doubtless a powerful aromatic stimulant, and would be serviceable in any spasmodic disease.

4. It is universally employed by the shawl merchants, as a mechanical protector of Kashmir fabrics from the attacks of moth and other vermin.

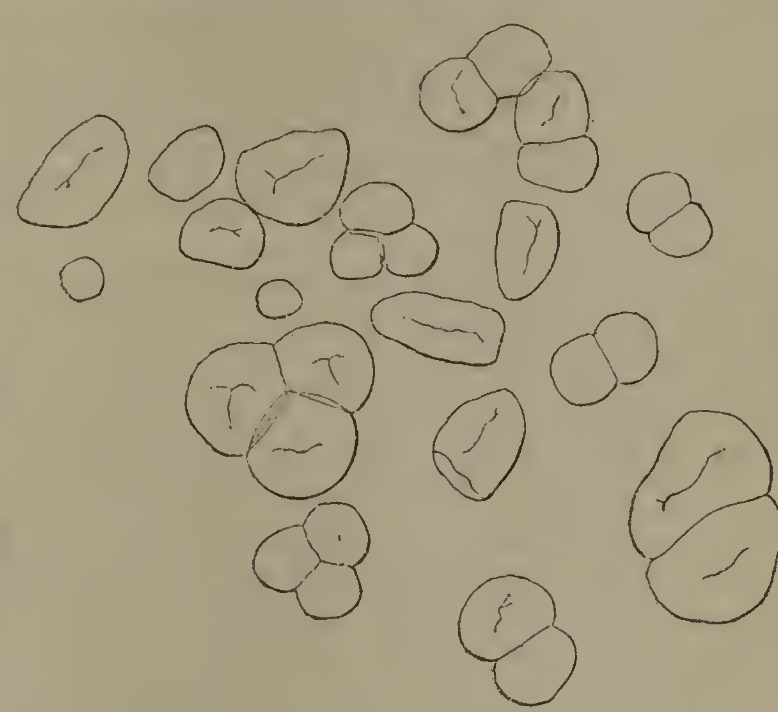
5. The dried root is an agreeable fumigatory, and yields excellent pastilles which burn fairly.

6. It is exported in enormous quantities, to China, where it is used as an incense. Lines of camels may often be met passing down to Multan, the "Kut" perfuming the air for a considerable distance; in every hong it is found; no mandarin will give an audience until the "pachak" incense smokes before him; in every joss house it smoulders before the Tri-Budh Deity; in every floating junk in the Chinese rivers, the only house of countless hordes, Budh's image is found, and the smoke of the "pachak" religiously wends its way heavenward; with the bulk of the Chinese, this ceremony is regarded as sufficient to propitiate the gods, while their merchants by substituting a spurious pungent article, endeavour even to mephitize their frowsy deity.

7. It is a crown monopoly, each village in the vicinity of the "Kut" fields is assessed at a fixed amount yearly, which must be delivered in the capital, the Maharaja's agents buy up the surplus at one maund per chilki rupee, and retail it double rate.

As to its uses in China, Dr. Porter Smith says that it is used in making incense in the south, or to preserve clothes from the attacks of moths and other insects. It is said to have the power of turning grey hair black. Carminative, stimulant, antiseptic, prophylactic, astringent, sedative, and insecticidal properties are referred to this remedy. The Chinese apply it with musk, which it resembles in odour and properties, to aching teeth.

Substitutes.—The Kashmiris say that this drug is apt to be adulterated with five or six other kinds of roots. Dr. Birdwood remarks that the root of a plant with the native name of *poshkar*, believed to be a species of *Ligularia*, is used for adulterating *Koot*, and the Kashmiris at Lahore make the same statement. A sample of false Costus in the Indian Museum, under the name of *Kut mitha*, consists of pieces of a cylindrical root from 1 to 3 inches in length and from ½ to 1½ inch in thickness, externally



Starch of False Costus.

nearly smooth, or longitudinally striate with transverse paler scars. It is much lighter and less compact than Costus, friable and farinaceous internally, very much subject to attack from insects, with little or no apparent odour or taste, and containing a large quantity of starch, the granules of which are very variable in size, attached to each other in twos and threes, as in the figure (drawn by camera lucida to a scale of 500 diameters). Although sometimes called "Orris root," and so named in some of the trade returns, Costus must not be confounded with the rhizomes of *Iris*, which are also to be met with in India and other oriental countries, and are the true "Orris root," though perhaps the produce of a species of *Iris* differing from *Iris florentina*.

In 1859 a communication was made to the Agri-Horticultural Society of India of two roots, one called *Koot* and the other *Thooth*. They were from the hills of that part of the Kangra district which borders on Chumba. The "Koot" was identified as the "Costus," the subject of this communication; and the other was believed by Dr. Thomson to be the root of *Salvia lanata*, which was said to be common also in Kashmir, where it is used to adulterate "Kut."

Subsequently Mr. H. Cope of Umritsur contributed some remarks to the same society on the adulterations of this drug. "This adulteration," he says, "is now (1860) carried to such a pitch with the assistance not only of the Toot (which so closely resembles the genuine article in every respect but its qualites, that it is difficult to distinguish the one from the other after admixture, which imparts to the false the odour of the true drug) but with other foreign substances, of which cow-dung is one, that I have ascertained as a fact that the more unscrupulous dealers use some 20 seers of the Koot to flavour 100 seers of trash. When *Toot* was first found useful as an admixture, it was sold at Rs. 1—8 per maund; being now the main ingredient of the Putchuk of commerce, it has risen to Rs. 4—8. I am told that two other substances resembling the genuine article in exterior appearance have been ascertained to serve as ingredients in the mixture sent to Calcutta and Bombay for exportation to China, under the name of *Putchuk*. They are a root called *Chog*, brought from the hills, which is generally reported to be a deleterious drug; and *Nirbisi*, the root of a species of *Aconitum*, probably a virulent poison.

BUTYL-CHLORAL HYDRATE.

The following are the concluding paragraphs of a paper on butyl-chloral hydrate—otherwise known as croton-chloral hydrate—which appeared in the *Medical Examiner* for June 28.

"Gathering up our own experience, and comparing it with that of others, we are inclined to think butyl-chloral hydrate will be of value when we learn accurately to discriminate the cases to which it is most adapted. We have seen some remarkable successes. Neuralgia and toothache have both disappeared after a dose or two of the remedy as if "by magic," as the victims said. On the other hand, we have been completely disappointed in similar cases in which it was given in the same way. For one case of toothache, due to an exposed nerve, we have carried it as far as seemed right, and produced its full constitutional effect without obtaining the slighest relief. We have known it give immediate relief in exactly similar cases. It appears to us that a nerve recently irritated is not to be appeased by a moderate dose of such a drug, though other conditions giving rise to similar pain may more readily yield to its influence. For the intense pain set up by mechanical irritation or chemical injury there yet remains the question of its local use, and here we look to dentists to give us information. Some important facts have been recorded which should lead them to give it a fair trial. Thus Dr. Cleborne, of the U.S. Naval Hospital, Portsmouth, has lately employed a mixture of equal parts of the hydrate, crystallized carbolic acid and solid Japanese oil of peppermint as a plug in caries, and says it very speedily removed sensitiveness. Of course, here we have the effect of the carbolic acid to consider. This is a decided anæsthetic when applied locally, and so also oil of peppermint has a very ancient reputation for the same property. This experiment is therefore by no means conclusive, and it would be well to try the butyl-chloral hydrate pure. But as a remedy for toothache the compound recommended by Dr. Cleborne might soon be tried on a large scale. He recommended it to his dentist, who he says confirmed his opinion of its value, and pronounces it the best "obtunder" for use when stopping, as well as to remove soreness and pain after dental operations. In toothache from caries he advises that after the mouth has been washed with a weak solution of bicarbonate of soda in warm water, the cavity should be dried with cotton wool, and then a pledget of this soaked in the "obtunder" be gently introduced into the cavity and covered with fresh wool—either dry or soaked in styptic colloid. Further, he says that stopping may be effected without pain when it is not desirable to destroy the pulp with arsenic by the use of the remedy. This is the plan advised: a fine brooch armed with a pledget of wool soaked in the remedy is introduced into the cavity and retained in position by a second plug of wool. In from five to ten minutes the application is removed, and the excavation of the cavity proceeded with until it produces pain; then the operation is suspended, and a renewed application made. The process may, it is said, be repeated until the cavity is ready for the permanent stopping, and it is suggested that this may be introduced without causing any pain, and without destruction or injury of the pulp.

"We should feel considerable doubt as to the propriety of pushing its use thus far, but it certainly seems desirable that a fair trial should be given to any drug which promises to be unusually efficacious in relieving toothache or neuralgia; whether butyl-chloral hydrate alone, or in combination, is trustworthy for such a purpose might soon be determined, and so too it might easily be shown whether ordinary chloral possesses similar properties. It is well known that camphorated chloral—prepared by rubbing together equal parts of camphor and chloral hydrate—is useful for relieving the pain of toothache and neuralgia, when applied locally, and probably other combinations might be found equally or even more effectual.

"With regard to the internal administration of butyl-chloral it may, perhaps, be given in larger doses than the drug for which it is proposed as a substitute. It is said that as a hypnotic from twenty to forty-five grains may be administered at bed-time. For the purpose of producing sleep, however, we prefer ordinary chloral, unless under special circumstances, and then we should decidedly object to the larger doses mentioned. Probably when chloral is contra-indicated by heart disease it would be well to forego butyl-chloral also. In all cases it would be safer to give a smaller dose and repeat it than to charge the system with the full quantity at once. The effect of a small dose passes off frequently in about two hours, when it can be repeated if need be, with safety; or if no effect whatever were produced another dose could be given even earlier. An alcoholic solution is liable to undergo some change which is said to impair its anti-neuralgic power. This is probably true of all solutions, and we should therefore advise it in all cases to be freshly prepared. It is commonly given in syrup, but a good solution may be readily made with glycerine. The following mixture contains enough to supply at once, and is not likely to be dangerous:

℞. Butyl-chloral Hydrat. . . . . ʒss.
Glycerinæ . . . . ℥ss.
Aq. destil. ad . . . . ℥vj. M.

"Two tablespoonfuls of this, containing only five grains, can be repeated in half an hour two or three times in succession until the pain is relieved, and then less frequently. It should be still further diluted when taken, as the taste is very pungent. Some have recommended grain or two grain doses to be given, but we cannot report favourably of these small quantities; nor can we understand how those who advise large does as a hypnotic can expect insignificant ones to assuage the pain of tic. We prefer to avoid the use of massive doses on the one hand, or to trifle with pain on the other. It is better to trust to the local action than to minute doses internally for the relief of pain; while as a hypnotic butyl-chloral is not so effectual as chloral, which is accordingly in most cases to be preferred. But a combination of the two drugs sometimes induces sleep when either alone fails. If a few doses of butyl-chloral give no relief to pain it is seldom advisable to continue it."

FORMULÆ FOR NEW MEDICAMENTS ADOPTED BY THE PARIS PHARMACEUTICAL SOCIETY.

(*Continued from page* 28.)

Cataplasm of Fucus crispus.

A sheet of wadding, simply carded, about one metre square, is stretched upon a frame and a concentrated mucilaginous infusion of *Fucus crispus* is diffused over it. Above this is placed another sheet of wadding of the same dimensions, and this is struck lightly with a brush in order that the mucilage may penetrate the wadding equally throughout. The whole is then exposed to a moderately heated stove, and the mucilage losing its water of hydration returns gradually to the state of dry *Fucus*. When taken from the stove the cataplasm resembles a sheet of thick cotton, and notwithstanding the time it has been kept in a warm atmosphere it has not contracted the least odour.

When required for use it should be placed in a large plate and treated with nearly boiling water. The *Fucus* swells considerably, and in this state the wadding contains under the form of mucilage a large quantity of water saturated with the emollient principles of the plant.

Glycerates (*Glycérés*).

Glycerate of Subnitrate of Bismuth (*Glycéré de sous-nitrate de bismuth*).

Glycerate of Starch, 90 grams; Subnitrate of Bismuth, 10 grams. Mix carefully in the cold.

Glycerates of Lead Carbonate, Zinc Oxide, and Calomel are prepared in a similar way.

Laudanum Glycerate (*Glycéré laudanisé*).

Glycerate of Starch, 90 grams; Sydenham's Laudanum, 10 grams. Mix.

Glycerate of Lead Acetate is prepared in a similar way.

Glycerate of Rhatany (*Glycéré d'extrait de ratanhia*).

Glycerate of Starch, 90 grams; Extract of Rhatany, 10 grams. Dissolve the extract of rhatany in the smallest possible quantity of glycerine and add the glycerate of starch.

Tar Water (*Eau de Goudron*).

Choice Vegetable Tar, 5 grams; Pine Wood Sawdust, 10 grams; Distilled Water, 1000. Divide the tar by mixing it intimately with the sawdust; leave it in contact with the water 24 hours, stirring from time to time, and filter. Vegetable tar of good quality should be red-brown, transparent, free from resinous lumps, and derived either from Norway or the Landes department. If common water or water containing selenite be used the product will not keep and contracts an odour of sulphuretted hydrogen.

1000 grams of this water contains at least 1 gram of extract of tar.

Syrup of Tar (*Sirop de Goudron*).

Choice Vegetable Tar, 15 grams; Pine Wood Sawdust, 30 grams; Distilled Water, 1000 grams; Sugar, q. s. Divide the tar by mixing it with the sawdust. Pour it upon the water heated to 60° C., agitating occasionally. At the end of two hours filter upon the sugar, and in a closed vessel, by the aid of a water-bath, make a syrup in the proportion of 100 grams of liquid to 190 grams of sugar.

Iodized Cotton (*Cotton Iodé*).

Mix 25 grams of fine carded cotton, thoroughly dried in a stove, with 2 grams of finely powdered iodine so as to destribute the iodine powder as uniformly as possible throughout the cotton. Place the mixture in a litre flask, having a large mouth and a ground class stopper. Keep the flask with the mouth open for some minutes in nearly boiling water, so as to expel a portion of the air, then close it and tie down the stopper. The flask is then submitted for two hours at least to a temperature near 100°. The iodine vapourized condenses upon the cellulose. The flask ought not to be opened before it is quite cold, when all the iodine, about 8 per cent., will remain fixed upon the cotton.

This preparation should be kept in a well-closed bottle.

Iodoform (CHI_3).

Pure Carbonate of Potash, 2 parts; Iodine, 2 parts; Alcohol (84°), 5 parts; Distilled Water 15 parts. The potash, water, alcohol and the iodine reduced to powder are placed together in a flask. and the whole heated in a water-bath, until the decoloration of the liquid. Another $\frac{1}{2}$ part of iodine is then added, and heat again applied, and the addition of the metalloid is repeated until the liquid remains slightly brown coloured. It is then decolorized by the addition of one or two drops of caustic potash solution, and upon cooling crystals of iodoform are obtained. These are collected upon a filter, washed lightly with cold distilled water, then dried upon blotting paper and enclosed in well-stoppered bottles.

By evaporation of the mother liquor iodide of potassium is obtained.

Iodoform crystallizes in hexagonal lamellæ of a beautiful citron-yellow colour; it has a pungent saffron-like odour. It volatilizes without residue at a gentle heat; but a temperature of 120° partially decomposes it. It is almost insoluble in water; soluble in alcohol, and especially soluble in ether. It is almost entirely decomposed by potash. Pure iodoform ought not to dissolve in solutions of fixed salts. It should dissolve completely in boiling alcohol. Calcined strongly in contact with air it should not leave any residue.

Iodized Syrup of Horseradish (*Sirop de Raifort Iodé*).

Iodine, 1 gram; Alcohol (90°), 11 grams; Compound Syrup of Horseradish (Codex), 988 grams. Dissolve the iodine in the alcohol, filter, and mix the solution thoroughly with the syrup. After about 24 hours of contact at the ordinary temperature, the combination will be complete and the syrup will have recovered its original colour.

In this preparation the iodine is concealed from ordinary reagents. The syrup contains one-thousandth of its weight of iodine.

Iodotannic Syrup (*Sirop iodotannique*).

Iodine, 1 gram; Alcohol (90°), 11 grams; Syrup of Rhatany (Codex), 988 grams. Proceed as with Iodized Syrup of Horseradish.

If it be desired to obtain the preparation at once it will be sufficient to heat the mixture to 30° or 60° C.; the combination is quickly completed, and is indicated by the return of the original fine red colour of the syrup of rhatany.

This syrup contains one-thousandth of its weight of iodine.

Syrup of Iodide of Starch (*Sirop d'iodure d'amidon*)

Soluble Iodide of Starch, 10 grams; Distilled Water, 350 grams; White Sugar, coarsely powdered, 640 grams. Dissolve the iodide of starch in distilled water and filter. Use this liquor to dissolve the sugar with the aid of a very gentle heat.

20 grams of this syrup contain about 2 centigrams of iodine.

The soluble iodide of starch is prepared by dissolving 1 part of iodine in sufficient 90° alcohol, adding 9 parts of starch previously washed in water acidulated with nitric acid and air dried, and then drying the mixture in a water-bath at a moderate temperature. This product is triturated with sufficient distilled water to make a soft paste, which is heated in a flask by means of a water-bath until it becomes entirely soluble in water, which may be ascertained by removing a small quantity and suspending it in pure water.

Jaborandi (*Pilocarpus pennatifolius*).

The leaves and the cortical parts of this shrub are alone employed in medicine. They contain, besides pilocarpine, a peculiar essential oil composed principally of a carbide of hydrogen and various other substances as yet unstudied.

The leaves of Jaborandi are employed in medicine under the same forms and in the same doses as Coca leaves (see before, vol. vii., p. 1064).

Pilocarpine.

Exhaust the leaves or bark of Jaborandi with 80° alcohol, to which hydrochloric acid has been added in the proportion of 8 grams per litre; distil and evaporate to the consistence of an extract. Re-dissolve the extract with a small quantity of distilled water, and filter; treat with ammonia in slight excesss and a large quantity of chloroform. Distil off the chloroform, dissolve the residue in distilled water acidulated with hydrochloric acid, and filter. Treat afresh with chloroform and ammonia. The chloroformic solution is then shaken with water to which hydrochloric acid is added drop by drop up to the quantity sufficient to saturate the pilocarpine. The foreign matters remain in the chloroform, and upon evaporation of the aqueous liquid the hydrochlorate is obtained well crystallized in long needles radiating from a common centre. The hydrochlorate, dissolved in distilled water and treated with ammonia and chloroform, yields the pilocarpine upon evaporation of the chloroform solution.

Pilocarpine appears under the form of a soft viscous substance; it is slightly soluble in water and very soluble in alcohol, ether and chloroform. It presents all the chemical characters of an alkaloid and rotates the plane of polarized light strongly to the right.

Lithium Benzoate (*Benzoate de Lithine*). $LC_7H_5O_2,H_2O$.

Benzoic Acid, 122 grams; Lithium Carbonate, 37 grams. Suspend the benzoic acid in 10 parts of water, add the lithium carbonate, and heat. Solution takes place with effervescence, and upon evaporation handsome, much flattened, more or less elongated prismatic crystals are obtained.

Lithium benzoate is very soluble in water. One gram of the salt calcined, and then treated with slight excess of sulphuric acid, and heated to redness, should give 0·376 gram of lithium sulphate.

Lithium Bromide (*Bromure de lithium*). LBr.

Bromine 80 grams; Iron Filings, q.s.; Distilled Water, 300 grams; Lithium Carbonate, 38 grams. Prepare iron bromide as before indicated (see p. 26), filter, and add the lithium carbonate to the filtrate whilst still hot; heat toward the close of the operation to complete the double decomposition. The liquor ought to be feebly alkaline. Filter to separate the precipitated carbonate of iron, and wash the precipitate with q.s. of distilled water, evaporate and run into flakes, which should afterwards be enclosed in well-dried flasks.

One gram of lithium bromide is entirely precipitated by 1·95 gram of silver nitrate.

Lithium Carbonate (*Carbonate de Lithine*). L_2CO_3.

Lithium carbonate is prepared on the large scale from lepidolite. It is a white powder soluble in 100 parts of cold water. Treated with dilute hydrochloric acid it dissolves with effervescence, and the solution evaporated to dryness leaves a residue which, dissolved in alcohol, communicates to flame a beautiful purple colour. The chloride dissolved in water gives a precipitate with sodium phosphate.

One gram of this salt treated with sulphuric acid, then evaporated and heated to redness, should give 1·48 gram of lithium sulphate, which, re-dissolved in distilled water, is not precipitated by calcium oxalate or lime water.

Effervescent Salts.

Effervescent Lithium Carbonate.

Citric Acid, 40 grams; Sodium Bicarbonate, 50 grams; Lithium Carbonate, 10 grams. Mix the powders, and place them in a flat-bottomed vessel having a large surface; heat to about 100°C., stirring the powder continually until it takes the granular form; then by means of appropriate sieves obtain granules of suitable and uniform size, and preserve the preparation in well-closed bottles.

Effervescent Citrate of Lithium, Effervescent Citrate of Iron, Effervescent Potassio-Tartrate of Iron, etc., may be prepared in a similar manner.

Lithium Citrate (*Citrate de Lithine*). $L_3C_6H_5O_7,2\,H_2O$.

Citric Acid, 186 parts; Lithium Carbonate, 100 parts. Dissolve the citric acid in ten times its weight of water, saturate while boiling with lithium carbonate, and evaporate with a gentle heat. Handsome elongated prismatic crystals are thus obtained, containing two equivalents of water.

The citrate dried at 100° C. retains half a molecule of water. To obtain it anhydrous it is necessary to raise the temperature to 115°C. This salt is soluble in 25 parts of cold water.

One gram of crystallized lithium citrate calcined, and the residue treated with sulphuric acid and heated to redness, should yield 0·223 gram of lithium sulphate.

Lithium Iodide (*Iodure de lithium*). LI.

Iodine, 127 grams; Iron Filings, 35 grams; Lithium Carbonate, 38 grams; Distilled Water, 300 grams. Prepare a solution of iodide of iron with the whole of the distilled water; filter, add the lithium carbonate to the liquid while still hot, and raise the temperature to boiling to complete the double decomposition; the liquor ought to be slightly alkaline. Filter; wash the precipitate, evaporate, and run the melted lithium iodide into flakes.

Lithium iodide is white, and very soluble in water and alcohol. One gram, dry and pure, is entirely precipitated by 1·27 gram of silver nitrate.

Magnesium Lactate (*Lactate de Magnésie*).
$MgC_3H_5O_3,3\,H_2O$.

Dilute Lactic Acid with ten times its weight of water, and saturate while boiling with Magnesium Carbonate. Filter and leave to evaporate at a moderate temperature.

Magnesium lactate is white, and crystallizes in small flat elongated prisms. It is soluble in about 20 parts of cold water, much more soluble in boiling water, and insoluble in alcohol.

Magnesium Sulphite (*Sulfite de Magnésie*).

$MgSO_3, 3\,H_2O$.

This salt may be obtained by double decomposition between magnesium sulphate and neutral sodium sulphite; but it is preferable to prepare it by passing a current of sulphurous acid gas into water holding magnesium carbonate in suspension. When effervescence is no longer produced, and when the liquor after being strongly agitated retains the odour of sulphurous acid, the current of gas is suspended. The precipitate is collected on a filter or cloth, slightly washed, then pressed and dried rapidly at a very moderate temperature. It should be preserved sheltered from the air.

The salt is white, with an earthy flavour and an after-taste of sulphurous acid. It is soluble in 20 parts of water. It dissolves more easily in a solution of sulphurous acid, which deposits it on evaporation in transparent prismatic crystals. Exposed to the air it absorbs oxygen rather rapidly.

100 c.c. of a solution containing 0·79 gram per litre of pure magnesium sulphite, to which starch paste is added, absorbs 10 c.c. of a solution containing 12·7 grams of iodine to the litre before giving a persistent blue colour.

Extract of Malt.

Malt dried at 30° C., the germ of which equals two-thirds the length of the grain, is ground in a mill, treated with two parts of water at the ordinary temperature, stirring occasionally, and after five or six hours' contact, strained and pressed. The product is filtered and evaporated in vessels exposing a large surface, at a temperature not exceeding 45° C.

Bibasic Mercurous Nitrate (*Azotate mercureux bibasque* or *Turbith nitreux*). $Hg(NO_3)_2, Hg_2O + H_2O$.

Crystallized Mercurous Nitrate (Codex), 1 part; Boiling Water, 10 parts. Powder the salt as finely as possible and suspend it in the boiling water, shaking it for some time. When the powder has become greenish yellow allow it to deposit at the bottom of the vessel; decant the supernatant liquor and wash the deposit several times with cold water. Finally dry it and preserve it sheltered from light.

Nitrous turbith is pulverulent, pale greenish yellow, insoluble in water, but completely soluble in pure nitric acid. The powder is blackened by potash. When calcined strongly it gives off rutilant fumes, the mercury condenses in metallic gobules, and no fixed residue is left.

Mustard Paper (*Papier moutarde*).

The preparation of sinapisms in leaves demands two conditions for its success: (1) the employment of a mustard deprived of all fatty matter; (2) the use an agglutinant liquid that contains no water, alcohol, resin, or fatty matter.

The mustard powder is separated from the fatty matter it contains by washing with carbon bisulphide or petroleum spirit. The agglutinant liquid consists of a solution of 4 to 5 per cent. of caoutchouc in a mixture of carbon bisulphide and petroleum spirit. A uniform layer of the viscous solution is spread by means of an ordinary plaster spreading machine. As the sheet covered with the varnish issues from the machine a sieve containing mustard flour is shaken over it. The flour, retained by the viscosity of the fluid, remains fixed upon the paper after the vaporization of the volatile liquids by the heat of a stove. It will be understood that it is necessary to combine with a certain amount of precision the movements of the sieve and the progress of the sheet of paper. The leaf is afterwards cut into pieces of the size desired.

(*To be continued*).

NOTE ON GARDENIN.*

BY JOHN STENHOUSE, LL.D., F.R.S., AND CHARLES E. GROVES.

Gardenin was discovered by one of us (*Stenhouse, Phil. Trans.*, 1856, cxlvi., 155, and *Ann. Chem. Pharm.*, xcviii, 316) some twenty years ago in "dekamali gum," a resinous exudation from the *Gardenia lucida*, but the amount of gardenin obtained at that time was insufficient to make a satisfactory analysis, the quantity of resin operated on being but limited. About three years ago, however, we had a larger sample of the resin, enabling us to obtain a few grams of the gardenin in the pure state. The resin from the *Gardenia lucida* has been fully described both by Dymock (*Pharm. Journ.* [3], vii., 491), and by Flückiger (*ibid.*, p. 589), the latter of whom, moreover, extracted the gardenin and analysed it.

We found that the best method of obtaining the crude gardenin was to boil the resin with alcohol, filter the solution to separate the insoluble residue, consisting chiefly of small fragments of bark and wood, and allow it to cool. It then deposited almost the whole of the gardenin in slender, pale-yellow needles, which were collected and washed with cold spirit, to free them from the amorphous greenish-yellow resin, which forms by far the larger portion of dekamali gum. These needles, however, even after several crystallizations from alcohol, were found to be still impure, being contaminated with a colourless substance of low melting point, somewhat resembling a fat in appearance. After repeated trials in various ways, it was found that this impurity might be removed by means of light petroleum. A boiling saturated solution of the gardenin in alcohol was allowed to cool, and the almost pasty mass of crystals was agitated with light petroleum at a temperature of about 30°, the clear liquid poured off, and the residue again agitated with petroleum, repeating the operation several times. The gardenin was finally purified by alternate crystallization from hot benzene, in which it is readily soluble, and from alcohol.

When pure, gardenin forms brilliant deep yellow crystals, which melt at 163—164°. Dried at 100°, and burnt in a current of oxygen it gave the following results:—

I. ·249 gram of substance gave ·567 gram carbonic anhydride, and ·119 gram of water.

II. ·202 gram of substance gave ·457 gram carbonic anhydride, and ·102 gram of water.

		Theory.	I.	II.	Mean.	Fluckiger
C_5 . . .	60	61·86	62·12	61·70	61·91	59·47
H_5 . . .	5	5·16	5·31	5·60	5·45	6·71
O_2 . . .	32	32·98	——	——	——	——
	97	100·00				

Flückiger's numbers do not agree with these, but as the specimen he analysed had merely been purified by repeated crystallization from spirit, it is not impossible that it was contaminated with traces of the colourless fatty substance mentioned above. This is rendered very probable by the much lower melting point (155°) which he obtained.

It was stated in the earlier paper (Stenhouse, *loc. cit.*) that when gardenin is digested with concentrated nitric acid, it is rapidly decomposed, picric acid, but no oxalic acid being produced. On repeating the experiment, however, we found this to be incorrect: gardenin, when boiled with nitric acid, dissolves with evolution of nitrous fumes, forming a yellow solution, which, on evaporation, leaves a yellowish residue; this, however, on careful examination, proved to be quite free from trinitrophenol. It was noticed, in making this experiment, that at the moment the gardenin came in contact with the nitric acid, it assumed a brilliant crimson colour before dissolving. The attempts made to isolate the red substance thus

* From the *Journal of the Chemical Society*, May, 1877.

formed were ultimately successful: 1 part of gardenin was dissolved in about thirty times its weight of boiling glacial acetic acid, and after being rapidly cooled two parts parts of nitric acid of sp. gr. 1·45 were added to the clear solution. In a few seconds hair-like crimson needles began to form, very different in appearance from gardenin. At the expiration of five minutes, the mixture, which was kept cold, had solidified to a pulp of needles. It was then mixed with about 150 parts of cold water, and the gelatinous precipitate collected after it had stood a few minutes. The pasty red mass, after being well washed, was pressed into a cake and removed from the filter before drying, for it was found that if allowed to dry on the filter it adhered so firmly to the paper that it was very difficult to remove it. Gardenin yields nearly 90 per cent of its weight of this substance, which is insoluble in water and dilute acids, but readily soluble in alkaline solutions, and reprecipitated, on the addition of an acid. We have provisionally named it *gardenic acid.* It is free from nitrogen, and after being purified by boiling with spirit, in which it is but very slightly soluble, and crystallization from glacial acetic acid, it was found to melt at about 236°. If the nitric acid is allowed to act on the glacial acetic acid solution of gardenin for a considerable time, or on the gardenic acid itself, it becomes changed to an orange-coloured substance much more soluble in alcohol than in gardenic acid.

At present the amount of gardenin at our disposal is too small to permit a thorough examination of these new compounds, and other derivatives of gardenin. As they appear, however, to be of some interest, we have made arrangements to obtain a considerable quantity of dekamali gum from India, and hope ere long to be able to continue the investigation.

DIALYSED IRON.

BY ANDREW AND H. C. BLAIR.

This preparation has attracted the attention of many of the pharmacists and medical profession of Europe for some time past, and the experience resulting from its use is so satisfactory, peculiar and wonderful, that it is probably destined soon to become one of our most valued therapeutic agents in a large class of diseases where the ordinary iron preparations are objectionable. "With this preparation," says an author, "we are able now to avoid all inconveniences which arise from the employment of ordinary ferruginous preparations."

Our attention was called to it some months ago through correspondence with a customer residing abroad, who spoke so highly of it, and mentioned such peculiar and wonderful properties it possessed, that led us to inquire more particularly into it. Further correspondence stated that this party had taken it as a remedial agent for a protracted period without the least inconvenience or unpleasant effect, and while under treatment in this country for the same ailment, the ordinary iron preparations were prescribed, but could not be taken for any considerable time without experiencing the common trouble so frequently complained of—headache, constipation, etc. Being interested in the matter, we obtained from a prominent French chemist a formula by which he was in the habit of making it, which is in substance as follows:

Take 10 parts liq. ferri per. chlor. (Br. Ph.), precipitate by aqua ammoniæ and wash the precipitate thoroughly. Mix this with 12 parts of liq. ferri perchlor. (Br. Ph.), and place in a dialyser. The dialyser is placed in a suitable vessel with distilled water, the water under it renewed every 24 hours. The operation is continued until no trace of chlorine exists, at which time the preparation is found to be neutral. It usually takes from 12 to 15 days to complete the process.

The resulting preparation is, or should be, of a deep dark-red colour, and contains about 5 per cent. of the oxide of iron. As to the chemical condition of the iron in solution, M. Bravais, of Paris (who claims to produce the only genuine), says, "It consists of liquid peroxide of iron, *i. e.*, iron merely united with oxygen and water to the exclusion of all acids;" but it is, no doubt, in fact a neutral solution of an oxychloride of iron in a concentrated form, and the theory of its production is nothing new, and is very simple. The oxychloride (which is the substance retained in solution in the dialyser) is a colloidal substance. The chloride (which is the principal substance rejected, or washed out as it were) is a crystalloidal substance. These two substances—crystalloid and colloid—are separated by dialysis, the former from the latter by diffusion through a septum, such as parchment paper.

Other formulæ more recently have been suggested, differing somewhat from the above, and it has been the subject of no little discussion abroad as to the particular merits of the one or the other of these. By some it has been suggested to pursue the following formula: Take a given quantity of liq. ferri perchlor. (Br. Ph.), and precipitate by ammonia, wash well the precipitate, and mix with sufficient quantity of the same preparation of liq. ferri perchlor. to saturation, and dialyse. It is remarkable how large a proportion of this freshly precipitated sesquioxide of iron will be taken up or dissolved. For example, the precipitate obtained from one pint of our officinal liquor ferri chlor., representing 3 ounces and 6 drachms of dry oxide, is entirely taken up by about 5 fluid ounces of the same liquor. In the magma this precipitate seems a very great quantity, so bulky is it; and, as stated before, it is quite surprising to see it disappear into solution under the influence of so small a quantity of the liquor.

By following the above method, we have found that it shortened the process considerably. It became thoroughly dialysed in one week, while the other takes about twice that time.

Still another method has been suggested, namely, to take a given quantity of the liquor ferri chlor., and add aqua ammoniæ almost enough to produce the precipitate of the sesquioxide. When the precipitating point is reached the whole solution is placed in the dialyser. The chloride of ammonium is thus extracted from the solution, and the peroxide of iron, or oxychloride, retained.

If either of these processes were pursued carefully, we have found the same result to be reached. If the solution, after completion of the operation, should contain more than 5 per cent. of iron, it may be diluted with distilled water till it reaches that point. There are some dialysed irons in the market which we have examined, containing no more than from $3\frac{1}{2}$ to 4 per cent. When the preparation has become thoroughly dialysed, it is tasteless and neutral; the operation should then be discontinued, as by further dialysis the liquid is converted into a gelatinous condition.

We may say in closing, that the above formula furnishes an article precisely similar to the original Bravais' Dialyzed Iron, which we have imported and had ample opportunity for comparison. By manufacturing it in this country, it can be produced for about one-half the cost of the imported.

The manner of taking the pure concentrated dialysed iron is generally in drops, ranging from 15 to 50 daily, in divided doses, on sugar or in sugar and water; suitable vehicles can be used for administration without fear of decomposition. Being without taste and odour, compatible with syrup and alcohol, and communicating no taste to any suitable vehicle, it is easy to construct formulæ for elixir, syrup, etc.; a glycerite we find to be an excellent preparation.

These preparations, besides being more acceptable to the delicate palate, are perhaps preferable on account of the dose being brought up to the more popular measure of tea- and tablespoonful, and avoiding the necessity of the patient mixing them with any other liquid before taking.

THE BRITISH PHARMACEUTICAL CONFERENCE.

IN a circular issued by the Local Committee of the Conference in respect to the meeting to be held in Plymouth on the 14th and 15th of next month, attention is called to the many "natural beauties of "scenery of hill, dale, and moorland heath" for which Devon is famous, and to the tin, copper and iron mines, and china clay works of Cornwall. Nor is this unwarranted. Plymouth Sound, perhaps the largest harbour in the world, with its famous breakwater; the beautifully wooded heights and grounds of Mount Edgcumbe, which most Englishmen have heard of if they have not seen; the Hamoaze, where the wooden, or rather iron, walls of Old England ride at anchor; and the river Tamar, which has been called the "English Rhine," and is crossed by BRUNEL's tubular suspension bridge, form a very tempting conglomeration of the natural and the artificial, which should not be without its influence on the decision of the pharmacist as to whether he will attend the coming meeting of his craft in the West. If his tastes lie in other directions, he may inspect the dockyard and the vast Government works of the victualling yard, the gun wharf and the Keyham factory, or the naval and military hospitals, or the fortifications by which three towns, and £100,000,000 worth of public property, are to be protected in the event of an attack by a foreign enemy.

Of course we do not doubt that the list of papers to be read, of which we were able to give an instalment last week, will be the most interesting of the preliminary notices. The Conference being established primarily for the encouragement of pharmaceutical research it is only natural that this should be so. But even the most stoically scientific pharmacist will not have failed to notice that the second object of the Conference, the promotion of friendly intercourse amongst those engaged in pharmacy, is not to be lost sight of, and that the members of the Local Committee have announced their intention to furnish the opportunity for this friendly intercourse by inviting the visitors to accompany them on an excursion, on Thursday, the 16th of August, the day following the meetings.

We understand that, as at present arranged, it is intended that this excursion shall include a trip up the river Tamar. Passing, on the way, through the Hamoaze, with its fighting ships of every class, Saltash will be reached, where the Cornwall Railway bridges the river in two enormous spans at a height that will permit the largest vessel to pass under with all her sails set. Next running past the mouth of the Tavy, with the beautifully wooded hills of Warleigh and Budshead crowning either side of the adjoining creek, and equally varied scenery on the opposite shore, Carr Green, with its tea gardens will be seen on the left, and soon after a large silver and lead mine on the right. A little further on, on the same side, are the celebrated cherry gardens, and then, beyond a sharp bend of the river, Pentillie Castle, the picturesque seat of Colonel CORYTON, comes into view, perched in the midst of magnificent woods, on an eminence commanding a grand view of river scenery. From this point the river begins to narrow, and here and there may be seen on its bank the solemn-looking heron waiting for its finny prey.

The next place to be visited is Cothele, a granite built mansion of the Earl of MOUNT EDGCUMBE, dating from the time of HENRY VII. Here, besides enjoying the rich woods sloping down to the river, visitors possessing antiquarian tastes may revel in a magnificent accumulation within the mansion of ancient tapestry, ancient armour, ancient carvings, and dragon china. Then, still winding between the leafy banks, the village of Calstock, and Harewood House, the scene of the tragedy of 'Elfrida,' will come into view, and, further on, Morwell Ham Quay, where a canal brings the Tavy again into communication with the Tamar. Lastly, the Morwell rocks, near the Weir Head, and the limit and crown of the trip in this direction, will be reached. On the return, passing through Plymouth Sound, a glance will be given at the Breakwater and then a landing will be made at Mount Edgcumbe, where the wonderfully beautiful park and gardens will, by the kindness of the noble owner, be thrown open to the Members of the Conference. If the day be fine, probably at its close there will be few of the visitors disposed to question the taste of the Spanish grandee who is said to have selected this seat as his share of the spoil that did not fall to the lot of the Invincible Armada.

To turn now to the more serious portion of the business of the Conference it will be seen that we are enabled to announce the titles of six other papers beyond those published last week. With this bill of fare, and the certainty of its being supplemented by something substantial from the veteran President, Professor REDWOOD, no great prophetic power is needed to predict a successful meeting.

One word in conclusion. Perhaps the most important contribution to the enjoyment of a holiday is being lodged and fed well. It is thought probable that the large number of visitors to Plymouth next month will severely tax its powers in this respect. We have failed hitherto to get any very definite information upon this subject, either from the local Conference executive or that of the British Association. We understand, however, that if Members of the Conference desiring hotel accommodation will communicate with the Local Secretary, Mr. R. J. CLARK, 77, Old Town Street, Plymouth, he will attend to each application as it comes to hand. It is urged that such applications should be made at as early a date as possible. But the issue of a list of the hotels and their tariffs would much facilitate arrangements and probably relieve the Local Secretaries from a deal of unnecessary labour.

AN ERROR IN THE PHARMACOPŒIA.

IN the reprint of the *British Pharmacopœia* recently issued, an error has crept into the text on p. 180 that was not present in previous issues. In the formula for Liquor Arsenicalis, the quantity of Compound Tincture of Lavender to be taken should be "5 fluid drachms," and *not* "5 *fluid ounces*" as there printed. This correction becomes the more necessary, because our contemporary, the *Medical Press and Circular*, in calling attention to the error, has itself erroneously reversed the conditions and given "5 fluid ounces" as the correct quantity.

THE ROYAL GARDENS AT KEW.

SIR JOSEPH HOOKER'S Report on the Progress and Condition of the Royal Gardens at Kew during the year 1876, from which we quoted some extracts last week, contains also other very interesting details. In the first place the number of persons visiting the gardens shows a decrease as compared with the previous year, the figures being 596,865 against 678,002. On the 7th of August, however (which was Bank Holiday) the gardens were visited by 64,163 persons, the largest number ever recorded for one day. The visitors themselves appear, in the Director's opinion, to have shown indications of degeneracy, their appetite for quiet study having been somewhat impaired by previously feasting on the frivolities of Kew Green.

During the year there was received from 244 contributors living in all parts of the globe no less than 2,487 packets of seeds, 2,129 stove and greenhouse plants, 1,962 herbaceous plants, and 1,942 trees and shrubs. On the other hand there have been distributed 3,354 packets of seeds, 11,770 stove and greenhouse plants, 1,179 herbaceous plants, and 7,480 trees and shrubs to 164 recipients.

Those of our readers who have not been able to understand the enhanced price of coffee during recent years may find an explanation here. After reading the description of the leaf blight of Ceylon and Southern India, the coffee fly of the Antilles, the "borer," the "coffee bug," the "canker," and other vague diseases attributable to climatic causes, the wonder will be that the plant survives anywhere. In fact, in Dominica, where once the finest West India coffee was produced, the cultivation is now abandoned, and British Guiana, once the home of the "Berbice" coffee, now imports the berry. At present it is somewhat undecided how far the Liberian coffee plant, from which so much was expected, will be able to withstand the leaf blight.

With respect to the scourges from which economic plants suffer so much, Sir J. D. HOOKER remarks, that the conditions under which they are grown are extremely favourable for the rapid extension and development of parasitic plants and insects. When these have only native plants in small quantities to prey upon they pass unnoticed, and their appearance on a large scale is one of the penalties man must expect to pay for such an enormous disturbance of natural conditions as is implied in replacing a tropical forest of the most varied and mixed vegetation by a plantation of a single economic plant.

Considerable efforts are being put forth to secure the acclimatization of plants producing good varieties of india rubber in countries having suitable climates. Plants of *Hevea brasiliensis* and *Castilloa elastica* have been distributed to Ceylon, West Coast of Africa, Burmah, Jamaica, Java, the West Indies, etc. But at present our knowledge of the india-rubber producing plants is very imperfect; whilst as to the botanical history of the plants yielding the commercial varieties of gutta percha literally nothing is known, though there is reason to believe that they are very local and restricted in their geographical occurrence.

Another interesting point in these bellicose times is, that the large consumption of dogwood (*Rhamnus Frangula*) in the preparation of charcoal for gunpowder has produced a scarcity, and supplies of this material are now drawn from Germany. The use of the hornbeam (*Carpinus Betulus*) as a substitute has in consequence been proposed.

There are many other points of interest in this little pamphlet, but we must content ourselves with adding that the estimated number of specimens in the Herbarium is considerably over a million, and it is claimed that the collection of economic plants is now probably one of the most complete series of medicinal and useful plants ever brought together.

THE CONFERENCE PAPERS.

THE following titles of papers have been received in addition to those published last week:—

17. An Examination of Water from the Mineral Districts lying between Plymouth and Penzance. Dr. S. T. Rowe.
18. Proximate Principles of the *Narcissus Pseudo-narcissus*. Mr. A. W. Gerrard.
19. The Alkaloids of Japanese Aconite. Dr. Paul, F.C.S., and C. T. Kingzett, F.C.S.
20. Preserved Foods and Copper. Dr. Paul, F.C.S., and C. T. Kingzett, F.C.S.
21. Analyses of Preserved Carrots, Potatoes, Cabbage, and Mixed Vegetables. Professor Attfield.
22. Scammony Root. C. T. Kingzett, F.C.S.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

THE Annual General Meeting of the above Association will be held at 17, Bloomsbury Square, on Thursday evening, July 26th, at eight o'clock; Professor ATTFIELD, President, in the chair.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held in London on Wednesday, July 18th, 1877, the Report of the College of Preceptors on the Examination held on July 2nd was received.

Two hundred and fifty-one candidates had presented themselves for examination, of whom *one hundred and twelve* had failed. The following *one hundred and thirty-nine* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

(Arranged alphabetically).

Addis, Thomas Joseph............Bath.
Atkinson, Richard....................Penrith.
Bailey, John Streets...............Nottingham.
Batchelor, Frederick James......Swansea.
Beaumont, Edmund ....Wath-upon-Dearne.
Beaven, Baron Bruce ....Newport, I. of W.
Bell, Henry ....Ambleside.
Bennett, Frederick Birtwell ...Whitehaven.
Bennett, Joseph John ....Southsea.
Borkwood, Edward Turner......Boston.
Bowman, William Powell ......Brixton.
Brooks, John.........................Manchester.
Brown, Alexander...................Motherwell.
Brown, James ....Halifax.
Brownlee, George...... ....Edinburgh.
Burnett, Joseph Fearon.........Hyde, Cheshire.
Caffyn, Ernest John...............Crawley, Sussex.
Campbell, Hugh ....Glasgow.
Capper, Henry ....Liverpool.
Challans, John William ....Spilsby.
Clarke, Henry Robert Stanhope Malvern.
Clay, Charles.........................Clay Cross.
Clayton, John ....Scorton.
Clowes, William Cubitt ....Attleborough.
Cole, William ....West Cowes.
Cook, John Webster... ....Chapel-en-le-Frith.
Cowie, George ... .Glasgow.
Cowper, Charles Frederick......Wakefield.
Cox, Robert ....Bolton.
Cross, Charles H. ....Lancaster.
Currie, William Little............Glasgow.
Damant, Arthur Alfred ....Stowmarket.
Davies, Thomas Louis Kenrick Llandudno.
Davies, William ....Llantrisant.
Day, Arthur Joseph................Maidstone.
Desborough, James George, jun. Stamford.
Dickie, John ....Whitehaven.
Dickson, John ....Dumfries.
Dodds, Benjamin Bellamy ......Upper Clapton.
Edwards, Rees William ... .Brecon.
Evans, John Robert.................Carnarvon.
Evans, Robert Frederic ....Manchester.
Farman, Bartholomew Robert...Norwich.
Fenwick, John Clarke.............Bishopwearmouth.
Fisher, Henry ....Bingham.
Ford, William Crossley ....Dudley.
Fraser, James ....Edinburgh.
Gabbert, Thomas Martindale...Ulverston.
Gifford, Ebenezer ....Cambridge.
Gill, Reginald ....Yeovil.
Goss, Sidney Francis ....Plymouth.
Gott, Alfred Thomas ....Bradford.
Gowans, John Bruce ....Perth.
Graham, George Leslie ....Maidstone.
Greaves, William Thomas ......Nottingham.
Greenall, Thomas Holdsworth Ashton.
Greig, David..........................Arbroath.
Gribble, Edmund Arthur.........Stockwell.
Griffiths, David......................St. Davids.
Harris, William Thomas ... .Merthyr Tydvil.
Harrison, Henry Haseldine......Pickering.
Hatton, Frederick William......London.
Hayward, Luther....................London.
Headdey, Hervey Parry ....Oxford.
Hirst, Herbert Nelson............Bradford.
Hornblower, Joshua Thomas ...Birmingham.
Hutchins, Edward Coxhead ...Bath.
Hutton, William ....Portobello.
Jackson, George Granger ......Buxton.
Jeavons, Joseph ....Bradmore.
Jones, Penrhyn Vaughan ......Kirton.
Jubb, Robert..........................Howden.
Keene, Frederic John ....Oldbury.
Kett, George Robert ....London.
Keys, William Hall ....Birmingham.
Laing, Alexander ....Kelso.
Langton, William Crowder. Epworth-by-Rotherham.
Lawrence, Matthew Scott ......Stapleton.
Ley, David ....Alnwick.
McInroy, James ....Edinburgh.
MacManus, Josephine............Berkswell Rectory.
Mallinson, Joseph..................Wigton.
Marsh, Edward......................Luton.
Meacham, Vincent Whittenbury. Ledbury.
Mead, Theophilus William ......Yeovil.
Miller, John Wilson ....Perth.
Miller, Wm. Philip Faulkner...Folkestone.
Milnthorp, Joseph ....Altofts.
Morris, John Jones ....Cardigan.
Mowat, John Watt ... .Coatbridge.
Neale, George ....Spilsby.
Oliver, Frederick Josiah ....Tunbridge Wells.
Owen, Robert Garonwy ....Ruthin.
Painter, William, jun. ....Broadstairs.
Parker, Charles......................Lancaster.
Paterson, Walter ....Aberdeen.
Perry, Arthur William ....Birmingham.
Pidduck, William Joseph ......Southport.
Porter, Samuel Edward ....Southery.
Powell, Francis Edward ....Camden Road.
Prentice, Frank ....Ipswich.
Pringle, George......................Pathhead.
Procter, Henry Raithby ....Boston.
Prosser, Frank Henry ....Birmingham.
Rainey, James Jarvis ....Spilsby.
Rawes, William......................Hulme.
Rees, John ....Aberystwith.
Reid, Robert..........................Aberdeen.
Reynolds, Richard Freshfield...Leeds.
Richards, Benjamin ....St. Dogmells.
Ripley, Edward ....Cambridge.
Robertson, George ....Portsoy.
Roe, Robert ....Scotforth.
Schofield, Frederick Elston..... Morpeth.
Sergeant, Furlow Ross ....Goxhill.
Shackleton, Thomas................Accrington.
Slicer, Walter ....Bingley.
Stedman, Frank William ......Ashford, Kent.
Taylor, John Cleasby ....Kendal.
Thistleton, Hugh ....Preston.
Thomas, Benjamin ....New Inn.
Thompson, Charles Letchford...London.
Thomson, Ernest Andrew ......Plymouth.
Thomson, George ....Dumfries.
Turnbull, William S. ....Edinburgh.
Walshan, Richard Carnelly ...Wakefield.
Watts, George William ....Clapham.
Wheldon, James Alfred ....Darlington.
White, Henry Lancaster.........Pimlico.
White, Herbert William.........Manningham.
Whitelaw, Robert...................Bonhill.
Whitwam, Joe ....Leeds.
Wilding, George James ....Preston.
Wilkins, Walter Sidney ....Wimbledon.
Williams, John Harris ....Cardigan.
Willis, William......................Chadlington.

Wood, James Arthur ....Barnsley.
Wyatt, Samuel.....................Brimscombe.
Yeatman, Frederick James......London.

The following is a list of the Centres at which the examination was held, showing the number of candidates examined at each Centre, and the result:—

	Candidates. Exa-mined.	Passed.	Failed.		Candidates. Exa-mined.	Passed.	Failed.
Aberdeen	5	3	2	Hull	4	3	1
Aberystwith......	4	1	3	Leamington	1	1	0
Barnstaple	1	0	1	Leeds...............	16	9	7

Hereford	2	2	0				

The Questions for Examination were as follows:—

First or Preliminary Examination.

July 2*nd*, 1877.

(*Time Allowed: Three hours for the three subjects.*)

I. LATIN.

1. Translate into English:—Interim quotidie Caesar Haeduos frumentum, quod essent publice polliciti, flagitare. Nam propter frigora, quod Gallia sub septentrionibus, ut ante dictum est, posita est, non modo frumenta, in agris matura non erant, sed ne pabuli quidem satis magna copia suppetebat; eo autem frumento, quod flumine Arare navibus subvexerat, propterea uti minus poterat, quod iter ab Arare Helvetii averterant, a quibus discedere nolebat. Diem ex die ducere Haedui; conferri, comportari, adesse, dicere.

2. Decline in the singular and plural *frigora, agris, copia, iter*. Explain the cases of *pabuli, frumento, flumine*.

3. Select from the above passage, and arrange in three columns:—(*a*) the pronouns, with their cases; (*b*) the adverbs; (*c*) the prepositions, and the cases governed by them.

4. Give the present, perfect, infinitive, and supine of *flagitare, subvexerat, averterant, ducere, dicere*; and the present of *polliciti, posita, poterat*.

5. How are expressions denoting *at, in*, or *on a place*, usually rendered in Latin? Write in Latin, if you can:—*In the midst of the city; in the morning; to protract from day to day*.

II. ARITHMETIC.

(The working of these questions, as well as the answers, must be written out in full.)

6. Multiply 574689 by 354; divide the product by 177, and express the result in *words*.

7. Find the value of $\frac{4\frac{4}{15} \text{ of } 2\frac{5}{8}}{5\frac{1}{5}-4\frac{1}{2}}$ and reduce 3*s*. $3\frac{3}{4}$*d*. to the decimal of £1 6*s*. 6*d*.

8. If 8 men earn £9 wages for 5 days' work, how much would 32 men earn for 24 days' work, at the same rate?

9. What is the basis of the Metric system? Reduce 12 kilog. 5 gr. to decigrammes, and prove the accuracy of your result.

III. ENGLISH.

10. State the rules for the formation of the plurals of nouns, giving *one* example only of each rule; and convert the following adjectives into their corresponding adverbs:—*first, good, hopeless, pretty*.

11. Give the past tense and past participle of the verbs *begin, throw, lie, lay*; and the present infinitives of *brought, flung, shorn, stricken, frozen*.

12. Parse the following:—

"He spoke of love, such love as spirits feel,
In worlds whose course is equable and pure."

13. Write a short life, in the order of the chief incidents, of Cardinal Wolsey, Admiral Nelson, *or* Mary Queen of Scots (*one only*); *or* an account of a visit to an Aquarium, *or* an outline of Dr. Schliemann's recent excavations and discoveries in Asia Minor.

EXAMINATIONS IN EDINBURGH.

July 12*th*, 1877.

Present—Messrs, Ainslie, Borland, Buchanan, Kemp, Kinninmont, Stephenson, and Young.

Professor Maclagan was present on behalf of the Privy Council.

MAJOR EXAMINATION.

Three candidates were examined. *One* failed. The following *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Clark, William Inglis ....Edinburgh.
Dick, Robert Gibson ....Edinburgh.

MINOR EXAMINATION.

Nine candidates were examined. *Two* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Blacklock, Philip Walton ......Brighton.
Boa, Peter.. ....Stranraer.
Cook, Frank.........................Herne Hill.
Curle, David.........................Partick.
Dodge, William ....Marple.
Fisher, John Hutchinson.........Edinburgh.
Warburton, Walter ....Middlesborough.

July 13*th*, 1877.

Present—Messrs. Ainslie, Buchanan, Kemp, Kinninmont, Stephenson, and Young.

MINOR EXAMINATION.

Ten candidates were examined. *Three* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bruce, William Balfour ....Kirkwall.
Nicholson, John Hastie ....Moffat.
Ogilvie, William Ogilvie.........Arbroath.
Pattinson, William ....Hexham.
Starkey, George Thomas.... ....Stratford-on-Avon.
Tipper, Jonathan Edward ......Evesham.
Walker, James ....Auchmull.

MODIFIED EXAMINATION.

One candidate was examined, but failed to pass.

PRELIMINARY EXAMINATION.

The undermentioned certificate was received in lieu of the Society's Examination.

Certificate of the Royal Colleges of Physicians and Surgeons of Edinburgh.

White, James ....Edinburgh.

Provincial Transactions.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

Law Committee Meetings held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on July 13th, 1877, at 1 p.m. The President in the chair.

Present: Messrs. Barclay, Churchill, Hampson, Holdsworth, and the Solicitor of the Association. The minutes of the previous meeting of this Committee were read and approved.

The Secretary stated that in compliance with a resolution passed by the Executive Committee, he had collected evidence of several cases of infringements of the Pharmacy Act, 1868, and forwarded particulars of the same to the Secretary and Registrar of the Pharmaceutical Society.

The following letters were then read:—

"Chemists and Druggists' Trade Association,
"23, Burlington Chambers,
"New Street, Birmingham.
"30th June, 1877.

"The Secretary and Registrar,
"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square,
"London, W.C.

"Dear Sir,

"Herewith please find particulars of thirteen cases of illegal trading under the Pharmacy Act, 1868, which kindly submit to the Council of your Society at their next meeting.

"In the first twelve cases, I made purchases of the poisons named within the last twelve days, and the parcels still remain in my possession.

"You will doubtless remember that in the case of L———, No. 4 on the sheets, I forwarded you on Nov. 27th last, particulars of a previous purchase of poison I had made from this person.

"I am, dear sir,
"Yours faithfully,
"W. F. Haydon,
"Secretary."

"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, London, W.C.
"5th July, 1877.

"The Secretary,
"Chemists and Druggists' Trade Association,
"23, Burlington Chambers,
"New Street,
"Birmingham.

"Dear Sir,

"Your letter of the 30th ult., with particulars of thirteen cases of alleged infringement of the provisions of the Pharmacy Act, 1868, was laid before the Council at its meeting yesterday.

"In the case of C——— a prosecution has been ordered.

"In each of the other cases, with the exception of L——— (with whom we are already in correspondence), a letter will be sent giving notice that if the infringing of the provisions of the Act of Parliament be not discontinued forthwith, legal proceedings will be taken without further notice.

"I am,
"Yours obediently,
"Elias Bremridge,
"Registrar."

Some considerable discussion then took place, when it was moved by the President, seconded by Mr. Holdsworth, and unanimously resolved:—"That this Committee regrets the action which the Council of the Pharmaceutical Society has thought best to adopt in reference to the cases of illegal trading, evidence of which has been supplied by this Association, particularly the resolution of the Council, by which it decided to give the Registrar power to warn in all cases of infringement of the Act, without receiving the instructions of the Council in each case."

The Secretary was instructed to forward a copy of this resolution to the Secretary of the Pharmaceutical Society.

Communications were read from two members, residing at Liverpool, stating that they had been threatened with legal proceedings by the clerk to the Apothecaries' Company, for alleged infringements of the Apothecaries Act, 1815.

The cases were fully discussed, when it was moved by Mr. Barclay, seconded by Mr. Hampson, and unanimously resolved:—"That the Solicitor be empowered to defend in either or both of these cases, at his discretion."

THE ASSOCIATION OF CHEMISTS AND DRUGGISTS FOR WOLVERHAMPTON AND DISTRICT.

A Special Meeting of the above Association was held on July 6th, 1877, at 69, Darlington Street, Wolverhampton, to take into consideration a letter that had been received from the Sanitary Committee of the Town Council, addressed to the President of the Society, Mr. Fleeming. There was a large attendance of members, the President occupying the chair. After the minutes of the last meeting had been read, the Chairman read the following letter:—

"Town Clerk's Office, Wolverhampton,
"27th June, 1877.

"Dear Sir,—My Sanitary Committee has during the last fortnight been engaged in the consideration of the fact that certain medicines of a public character have been sold in the town by druggists, under names which do not in the slightest degree represent the ingredients of which such medicines are supposed to consist.

"A very grave question arises, whether under such circumstances an offence has not been committed under the Adulteration of Food and Drugs Act; but my Committee feel desirous before instituting any proceedings that all the members of the profession should have full notice that the subject is still before them, and must be dealt with, unless a different course of procedure be adopted.

"My Committee understand that you are not only the oldest druggist in the town, but are also Chairman of the Wolverhampton and District Chemists and Druggists' Association, and they have instructed me to call your attention to the above circumstances, feeling quite sure that you will take the necessary steps through the organization of your Society to prevent a recurrence of the complaints which have been made, and the further necessity of my Committee attending to the matter.

"Yours truly,
"H. Underhill, *Town Clerk*.

"Wm. Fleeming, Esq.,
"Chemist and Druggist, Queen Square."

The Chairman said that as this letter contained nothing in itself that would lead the members to understand what were the medicines alluded to he had sent a letter to the Town Clerk, in reply, asking for further information in the matter, but the answer that he received was couched in similar terms to the first letter.

A long discussion ensued as to what the medicines referred to in the letter could be. It was generally thought that as action had been taken in some parts of the country respecting the sale of Castor Oil Pills, and the absence of any Castor Oil from them, the allusion might be to that article. As no other preparation could be suggested as coming under the remarks contained in the letter, the following resolution was passed unanimously.

It was proposed by Mr. T. A. Wedge, and seconded by Mr. R. H. Lawe:—"That this meeting, whilst feeling obliged for the communication received from the Sanitary Committee, and for the action taken by them, cannot without some definite complaint made about some *one* drug or medicine, at present enter upon further consideration of the subject."

After a vote of thanks to the Chairman, the meeting separated.

Proceedings of Scientific Societies.

KING AND QUEEN'S COLLEGE OF PHYSICIANS.

The Influence of Chemical Constitution on Physiological Activity.*

BY J. EMERSON REYNOLDS, M.D., F.C.S.,

Professor of Chemistry, University of Dublin, etc.

Introduction.

On the 6th of January, 1868, a very remarkable paper was communicated to the Royal Society of Edinburgh, by Drs. Crum-Brown and Frazer, "On the Changes produced by direct Chemical Addition on the Physiological Action of certain Poisons." In that paper chemical constitution was shown to be a factor of great importance in determining the physiological action of certain substances, chiefly belonging to the group of alkaloids, and some highly interesting results were obtained. Since the date just mentioned numerous researches have been published by eminent observers on the physiological action of medicinal and other bodies, but the results have usually been discussed from the pure physiologist's point of view rather than from the chemical side. In these lectures I propose to consider physiologically active substances, chiefly from the chemist's standpoint, and while following to some extent on the lines of the research of the distinguished pioneers of this branch of inquiry, I shall venture to draw special attention to some matters which have either been overlooked or passed by with trifling notice.

I need scarcely say that it would be impossible to deal exhaustively with the wide subject upon which I have the honour to address the College, in the short time at my disposal; but I hope, nevertheless, to satisfy my hearers of the truth of the chief propositions I have to state.

It will, no doubt, be readily granted that all chemical substances introduced into the animal organism during life, and which produce any sensible effect, act either physically or chemically, and that in many cases the same substance exerts a physical *and* a chemical action.

By *physical action* we mean that kind of effect which a body can produce without suffering change of composition, or directly causing any such alteration in bodies with which it happens to come in contact. Thus a saline solution of high specific gravity—a strong solution of Rochelle salt, for example—diffuses, as a rule, more slowly through an animal membrane than a weak solution of the *same* salt. Here the effect is almost purely physical, for the rate of diffusion is dependent on the proportion of saline matter in the solution. It is true that the composition of a body, as well as the strength of the solution and other conditions, influences its rate of diffusion; but the effect of composition is eliminated when, as in the case supposed, we compare strong and weak solutions of the same salt.

By *chemical action* we mean that kind of action which involves change in *composition* of the matter engaged.

As I have already stated, the same body may act both physically and chemically; hence we must always remember that the physiological activity of a body may be due in part to the purely physical action exerted by it.

Our aim in these lectures, however, being to trace a connection between chemicial constitution and physiological activity, we shall leave physical action, and, indeed, local corrosive action also, as much as possible on one side.

Let me now explain some chemical terms which must be used in the course of my remarks, but which may not be familiar in their modern sense to some of those whom I have the honour to address.

When we now speak of the *molecule* of a body, we refer to the physical particle of matter, and this is the analogue of the ultimate particle which was long ago called an "atom" by Dalton. Within this molecule of a compound, and, indeed, of most elements, we are compelled to recognize the presence of two or more smaller portions of the same or of different kinds of matter. It is to these intramolecular portions of matter that chemists now restrict the term "atom."

Now, the atoms of elementary matter have not all the same power of uniting with each other. Thus, the atom of chlorine cannot combine with more than one atom of hydrogen (as in hydrochloric acid, HCl), whereas the atom of oxygen can unite with two atoms of hydrogen (as in water, H_2O), but with no more; while the atom of nitrogen can combine with three atoms of hydrogen (as in ammonia, NH_3), and then with an additional atom of hydrogen and one of chlorine to form NH_4Cl, or salammoniac. Finally, the atom of carbon unites with four, but no more, hydrogen atoms.

We can thus arrange the chemical elements in groups according to the number of atoms of hydrogen that they can either combine with or displace from chemical combinations, and the elements are spoken of as monad, diad, triad, or pentad, according to their position in the series.

Atomicities of the Common Elements.

This so-called "atomicity" of an element is conveniently indicated by lines radiating from the symbol of the element, thus showing the total number of points of attraction, or "bonds," as they are often called, and consequently the total combining power of the atom.

The molecules of the elements are supposed to contain two elementary atoms of the same kind of matter in com-

* The substance of two lectures delivered before the King and Queen's College of Physicians in Ireland, being the first and second of the Annual Scientific Lectures for 1877. From the *Dublin Journal of Medical Science.*

bination with each other. According to this view the molecules of hydrogen and of oxygen may be thus represented :—

H—H   O—O

But this combination of an element with itself is feeble and very easily broken up, according to our present knowledge.

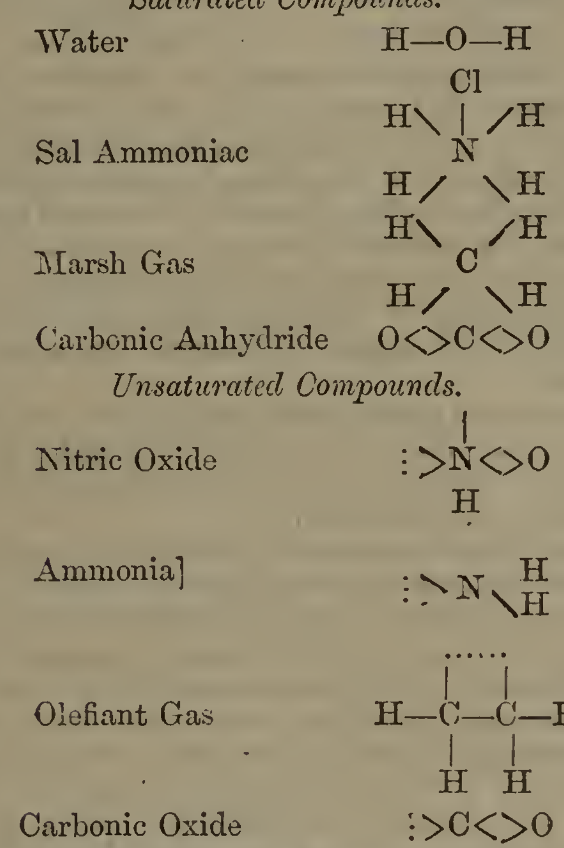
Having premised this much, I may now state that we can broadly subdivide chemical compounds into—

(*a*). Bodies in which all the "bonds" of all the atoms within the molecule are satisfied and are engaged in holding together the molecular edifice. These are called *saturated* compounds.

(*b*). Bodies in which the bonds are partially satisfied. These are called *unsaturated* compounds.

The differences between the two classes of compounds will be evident on inspection of the following diagram:—

Saturated Compounds.



Change can only take place in the molecules of *saturated* compounds by substitution. Thus the metal potassium can displace hydrogen from the molecule of water and form caustic potash; but we cannot, in any true sense, add anything chemically to water.

Change in unsaturated molecules can take place by addition as well as by substitution. Thus nitric oxide can unite with oxygen with extreme facility to form peroxide of nitrogen; ammonia gas with hydrochloric acid to form sal-ammoniac; olefiant gas with chlorine to form Dutch liquid; and carbonic oxide with oxygen, in order to produce the saturated compound carbonic anhydride.

The bonds not employed in holding together the elements of which an unsaturated compound is composed are said to become *latent*, owing, as some assert, to mutual satisfaction. This is indicated in the diagram by means of broken lines connecting the bonds.

From the statements already made, it will be easily gathered that the unsaturated compounds are, as a rule, the most energetic in their chemical relations. But I may go farther and assert that it is chiefly within the large group of unsaturated compounds that we meet with physiologically active bodies. I shall presently bring forward a good deal of evidence in proof of this assertion; but I propose to show, in addition, that the members of the group of saturated compounds which exert decided physiological action are bodies which either contain one or more atoms within the molecule capable of easy replacement by more energetic elements or groups of elements, or which are readily broken up, under certain conditions, into unsaturated molecules within the animal economy.

I hope thus to be able to satisfy you that the study of the chemical constitution of a body, or of the manner in which the elementary atoms are grouped within the molecule, is of the highest importance if we desire to explain the action of many bodies possessing physiological activity.

In seeking now to prove my case, it will conduce to clearness to state at once that I propose to bring forward evidence in support of the following propositions :—

1st. That bodies which contain the *same elements in the same proportions* can differ materially in physiological activity when compared under equally favourable conditions, and that the observed dissimilarity in action is due to difference in chemical constitution.

2nd. That bodies exist which contain the same elements *in different proportions, and are similar in chemical structure*, but which differ materially in degree of physiological activity; and that the observed alteration in action can be explained on chemical grounds.

3rd. That many bodies which are unlike in composition, but which agree in being either actually or constructively unsaturated, and are alike in certain marked chemical relations, often agree in physiological action.

4th. That the result of chemical addition to unsaturated molecules is either to destroy or materially to modify their physiological action.

Finally, I hope to show how far a knowledge of chemical principles and of the habits of chemical compounds enables us to trace the probable kind of action exerted within the living animal organism by physiologically active bodies:

FIRST PROPOSITION.

Our first proposition asserts *that bodies which contain the same elements in the same proportions can differ materially in physiological activity when compared under equally favourable conditions; and that the observed dissimilarity in action is due to difference in chemical constitution.*

We are acquainted with a considerable number of compounds which have the same centesimal composition, and amongst these I may mention the group of which acetic and lacetic acids and grape sugar are members:—

Acetic Acid	$C_2H_4O_2$.
Lactic Acid	$C_3H_6O_3$.
Grape Sugar	$C_6H_{12}O_6$.

These bodies have formulæ which are multiples by integer numbers of the group CH_2O (or formic aldehyde). Although these bodies differ in their physiological action, these differences are not very striking; hence I pass at once to the consideration of two cases which seem to have been unaccountably overlooked by physiologists.

There are two volatile liquids known to chemists which contain the same elements in the same proportions by weight, and which have the same number of atoms within each molecule. They have, therefore, the same empirical formula, which is C_2H_3N. These bodies are isomeric, or, strictly speaking, metameric,* and, strange to say, are often produced together in a single reaction. One of these bodies is poisonous; the other does not exhibit any strongly-marked physiological activity.

Both these remarkable compounds have the composition of *cyanide of methyl*, and a mixture of the two bodies was long regarded as that body. It has been shown, however, that the mixture referred to contains two volatile liquids having different boiling points. The liquid which possesses the highest boiling point (77° C.) is the true cyanide of methyl, or *nitrile*, and is a body which does not exhibit extraordinary chemical or physiological ac-

* Compounds which have the same percentage composition are *isomeric;* but we can recognize at least two classes of isomers—(1) polymeric bodies, or those whose molecular weights are different; (2) metameric bodies, or those whose molecular weights are the same, but which differ in constitution.

tivity. The other body boils at 59° C., and is called isocyanide of methyl, or the *carbamine*; this compound is very active chemically, and is poisonous.

The vapour of the *pure* nitrile* produces little discomfort when inhaled for a short time, but the vapour of the carbamine quickly produces considerable nausea, headache, and general depression. The carbamine is less easily miscible with water than the nitrile; nevertheless, the former quickly destroys life when a mixture of the body and water is injected into the blood of a dog, whereas a mixture of the same weight of the more soluble nitrile and water produces comparatively trifling effects.

It is evidently sufficient for our present purpose to know that one of these metameric bodies possesses much greater physiological activity than the other, and that the active body is one which is most energetic in its chemical relations. This marked difference in chemical and physiological activity is due to difference in chemical constitution, and the constitutional formula assigned to each body, on purely chemical grounds, sufficiently indicates their recognized difference.

Nitrile.	Carbamine.
$C \equiv N <^{\diagup CH_3}_{:}$	$:> N \equiv C <^{\diagup CH_3}_{:}$

In the nitrile the combining power of the carbon atom is represented as wholly satisfied, though two "bonds" of nitrogen seem to be latent. In the carbamine the carbon atom is shown to have but half its "bonds" satisfied. The nitrile cannot be regarded as a saturated compound because of the latent bonds of nitrogen, and the carbamine is still less so, because of the additional latent bonds of carbon. This difference in degree of chemical saturation of the atoms within the molecule evidently corresponds to the observed difference in physiological activity.

Although I leave these remarkable bodies for the present. as they have served my purpose in proving the truth of my first proposition, I would venture to commend them and their homologues to the study of physiologists. If time permitted I could bring forward a large amount of additional evidence bearing upon the same point, but I will now content myself by referring as briefly as possible to the metallic cyanides, as some members of the group are well known to be highly poisonous, while others which are easily soluble† in water, are inert or nearly so.

A metallic cyanide, or, indeed, hydrocyanic acid itself, may be regarded as the analogue of a carbamine or of a nitrile; thus—

Hydrocyanic Acid.		Cyanide of Potassium.
$C \equiv N <^{\diagup H}_{:}$	Nitrile,	$C \equiv N <^{\diagup K}_{:}$
$:> N \equiv C <^{\diagup H}_{:}$	Carbamine,	$:> N \equiv C <^{\diagup K}_{:}$

We have no means at present of determining with any degree of precision whether the cyanides of hydrogen and of metals are to be viewed as nitriles or carbamines. If we allowed physiological evidence to materially influence our opinion, we would probably conclude that they resembled the carbamines rather than the nitriles on account of their poisonous activity. It may be that the hydrocyanic acid we are acquainted with is the analogue of the carbamine, and that we may one day succeed in discovering a metameric body (another hydrocyanic acid) which will be almost inert. That day has not yet arrived however, and all we can say at present is that we know the soluble simple cyanides to be highly poisonous bodies; but we are acquainted with soluble metallic compounds rich in cyanogen, which are not poisonous; the most remarkable and best known of these is ferrocyanide or yellow prussiate of potassium.

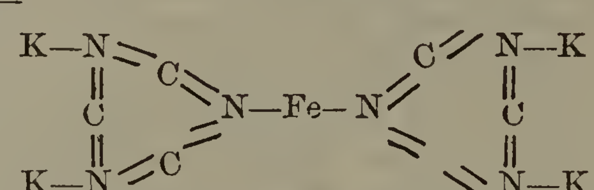
The fatal dose of cyanogen for a man is known to be two grains, if administered in the form of cyanide of potassium or as prussic acid; but five grains of cyanogen can be given to a man in the form of ferrocyanide of potassium without producing any more marked effect than slight diuresis. Ferrocyanide of potassium was at one time regarded as a double cyanide of iron and potassium, but in all true double cyanides the component metals can be recognized with more or less facility by ordinary chemical tests; in the ferrocyanide the iron cannot be detected by ordinary chemical reagents. For this and other reasons we conclude that the ferrocyanide is not a true double cyanide, but rather the salt of a new acid, into the radicle of which the iron has entered. The ordinary formula of the anhydrous compound may be thus written according to each view of its constitution.—

Double Cyanide . .	$Fe(CN)_2 + 4\,KCN$.
Ferrocyanide . . .	$K_4\overline{Fe(CN)_6}$.

If we take as much cyanide of potassium as contains two grains of cyanogen, and as much ferrous cyanide as contains one grain of cyanogen, mix the moist precipitate of the latter with the strong aqueous solution of the former, and immediately inject the mixture into the blood of a dog, the animal is almost immediately killed. If, however, we administer in the same way to another dog a quantity of pure ferrocyanide of potassium, likewise containing three grains of cyanogen, the animal survives the dose.

It is at least possible that in the first experiment we have to deal with a true double cyanide, while in the second it is certain that we have to deal with a very differently constituted body.

A true double cyanide of iron and potassium has not yet been obtained in the solid form, but if it exists for a short time in solution, its *unsaturated* cyanogen radicle is doubtless as free to exert its poisonous action as in other double cyanides. In the ferrocyanide, on the other hand, the unsaturated cyanogen groups have united with each other under the influence of the iron to form a compound in which all the atoms are fully engaged in binding together the molecular structure, and which need not be supposed to have within it any latent bonds, if we except the seemingly unimportant case of the iron atom. The developed formula of the ferrocyanide may be then written—



The instances I have now given in evidence of the truth of our first proposition might be largely supplemented but I apprehend that no one will doubt that the degree of saturation of the components of a molecule, and consequently its constitution, materially influence its physiological activity.

SECOND PROPOSITION.

Our second proposition asserts *that groups of bodies exist which contain the same elements in different proportions, and are similar in chemical structure, but which differ materially in degree of physiological activity; and that the observed alteration in action can be explained on chemical grounds.*

At the recent meeting of the British Association, at Glasgow, the results of some highly interesting experiments on the physiological action of the sodium salts of the three kinds of phosphoric acid were communicated by Professor Arthur Gamgee, who, in conjunction with Messrs. Priestly and Larmuth, discovered the existence of remarkable differences in activity between the three compounds. The details of this investigation have not yet been published, but the results obtained, if confirmed

* There is so much difficulty in obtaining the nitrile free from dangerous impurity that the experiment ought not to be unnecessarily repeated.

† Difference in solubility is often alone sufficient to account for difference of physiological activity; it is, therefore, of special importance only to compare bodies which can be absorbed with equal or nearly equal facility.

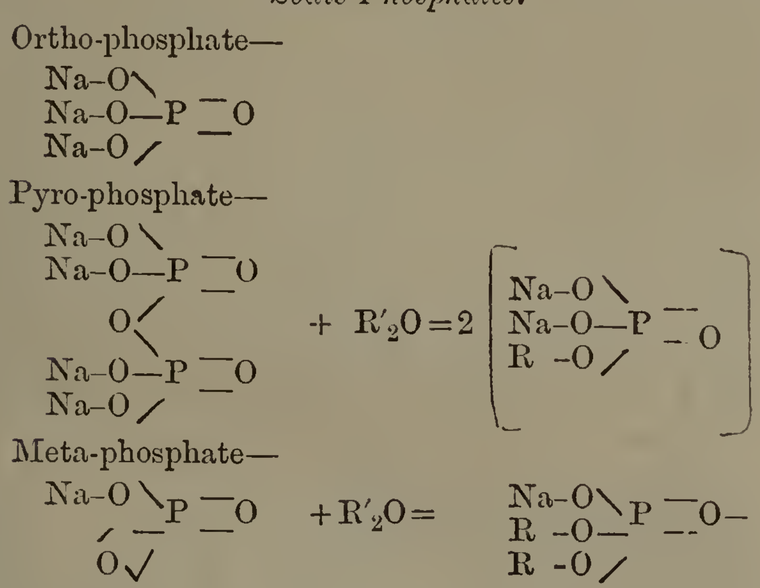
by further inquiry, constitute remarkably strong evidence in support of our proposition, though the authors do not seem to be aware of the special importance of their discovery, as I shall presently point out. The researches of Graham first made us distinctly acquainted with the well-marked group of phosphoric acids :—

Ortho-phosphoric Acid (Tri-basic) . H_3PO_4.
Pyro-phosphoric Acid (Tetra-basic) . $H_4P_2O_7$.
Meta-phosphoric Acid (Mono-basic) . HPO_3.

Corresponding sodic salts are obtainable in which the hydrogen of each acid has been replaced by the equivalent of the alkali metal. Messrs. Gamgee, Priestly, and Larmuth's experiments were conducted with the three sodic phosphates just referred to. Standard solutions of the salts were prepared of such strength that equal volumes contained the same weight of phosphorus. The action of each solution, when injected in the same proportion into the blood of an animal, was carefully noted, and it was found that the sodic ortho-phosphate is almost inert, while the pyro-phosphate is an energetic poison, and the meta-phosphate is also poisonous, but less active than the pyro-phosphate. The authors have shown that both the poisonous bodies act in nearly the same way on the animal organism. When either salt is injected subcutaneously into the system of a frog, it leads to paralysis of voluntary motion, to arrest of respiration, and soon to stoppage of the heart. The reflex functions of the spinal cord are very soon affected by the poison, but it has no action on the irritability of muscles or nerves.

We have here, then, evidence of a wide difference in degree of physiological activity between the sodic orthophosphate and the corresponding salts of the other two phosphoric acids, though all three bodies contain the same elements, and are similar in structure, but contain different proportions of their components. I understood Professor Gamgee to state at the meeting of the British Association that he attributes the poisonous action of the pyro- and meta-phosphates to a possible reduction of either compound in the organism to phosphoretted hydrogen or to elemental phosphorus.* The explanation I have now to offer is a very different one, and will be easily understood with the aid of the following diagram :—

Sodic Phosphates.



An examination of those developed formulæ will satisfy you that each of the phosphates may be consistently supposed to contain a triad nucleus, consisting of one atom of pentad phosphorus, and one atom of diad oxygen, both "bonds" of which latter are exclusively united with phosphorus. In the ortho-phosphate the three bonds of the nucleus are completely satisfied with the basic radicle Na′O, or, more generally R′O, when R is some monad metal, or metal-like body. In the pyro-phosphate two only of the three bonds of the nucleus are satisfied by the basic radicle, the third bond being connected with oxygen, which serves to tie it to another phosphoric group. Although all the bonds are saturated in this compound, they seem to be only fully satisfied when united with basic radicles—hence, on treating one molecule of a pyro-phosphate with one molecule of the oxide of any monad metal, two molecules of an ortho-phosphate are formed, as shown in the diagram. In the meta-phosphate but one of the three bonds of the nucleus is satisfied by a basic radicle, the remaining two being saturated by, but apparently not really *satisfied* with, one atom of oxygen; for one molecule of meta-phosphate, when treated with one molecule of an oxide, or a corresponding group, yields one molecule of ortho-phosphate.

As a matter of fact both the pyro- and meta-phosphates are unstable, especially in aqueous solutions, and tend to pass into the particularly stable ortho-phosphate by addition of the basic or allied material, provisionally represented in the diagram by R'_2O. According to the general principles already stated, the ortho-phosphate ought to be almost inert, and the other two phosphates physiologically active: *à priori* reasoning would, then, lead us to the conclusion already arrived at by the experimental method in the course of the valuable investigations of Messrs. Gamgee, Priestly, and Larmuth. Assuming now that further inquiry will confirm the opinion of those observers that the pyro-phosphate is more poisonous than the meta-phosphate, we have to account for the difference in activity of the two bodies. This difference is one of degree only and not of kind, as far as we can at present judge. The difference in intra-molecular satisfaction is also one of degree only, and we may reasonably conclude that the pyro- and meta-phosphates retain within the animal organism their tendency to attract and to be attracted by basic material. If, then, their poisonous action is due to the exercise of this power, the question arises whether or not both bodies poison by withdrawing basic material from some important organ. The experimental answer to this is a decided negative, for the pyro-phosphate is most poisonous; yet that body, for a given weight of phosphorus, is capable of withdrawing much less than the meta-phosphate (see diagram).

(*To be continued.*)

* Since the above was written, Professor Gamgee has published a paper on the subject in the *Journal of Anatomy and Physiology* for January, 1877, in which he expresses opinions more closely in accordance with the view taken by the lecturer.

Parliamentary and Law Proceedings.

Poisoning by Arsenic.

An inquest was held on the 4th inst. respecting the death of Sidney Caillier, aged 3, of Paradise Street, City Road. It appears that on the previous Saturday his brother picked up a piece of green chalk, which he put in his school bag. On Saturday the deceased went to the bag, and mistaking the chalk for a sweetmeat, sucked it. He immediately became so ill that he was taken to the Royal Free Hospital, where he died the same day. Dr. Sharpe said the green chalk contained arsenic, which had caused death. Verdict—Death from misadventure.

Review.

Aids to Chemistry, specially designed for Students Preparing for Examinations. Part I., Inorganic: Oxygen to the Metalloids inclusive. By C. E. Armand Semple, B.A., etc., etc., etc. London: Baillière, Tindall and Cox. 1877.

The author of this little book states in his preface, that his endeavour has been "to present the leading facts of the science in as systematic a manner as possible." The object of the treatise is sufficiently explained by its title-page. If this were not so, the very first line of the subject matter would suffice to show for what purposes the book was written. Thus it opens with Oxygen, "Symbol, O; Combining Weight, 16; Density, 16." That is to say it tells the reader of certain facts which without a previous knowledge of other matters he cannot understand. That is however a secondary consideration; the object of the book is to present facts; in short it is a "cram" work. The vast examinational system now so widely adopted in this and other countries is not an unmixed good. It leads to a system of cramming of whose magnitude many persons have no conception. Students preparing for examinations know that they will be questioned regarding facts and too often they acquire such a knowledge, which is utterly unmeaning to them, unacquainted as they are with the principles which underlie those facts. Hence so soon as they have passed their examinations and appeared duly on the lists, their facts are forgotten because they possess no mental appreciation, or at best an imperfect one, of the relations existing between the said facts. "Knowledge is power," but it is only a means to an end, and when it is disposed within the memory like bon-bons in a box, piled up piece upon piece, it constitutes only so much padding to the intellectual engine.

It may be urged that so long as the present examinational system lasts, so long will it be necessary to provide treatises such as the one before us. Be this as it may, we cannot recommend such works, and we therefore unhesitatingly condemn the use of Mr. Armand Semple's 'Aids to Chemistry.' Most of the facts communicated in it are correct enough so far as they go, but this is the "be all and the end all" of them; in arrangement they differ little from that displayed in other and similar works, many of which constitute but condensed abstracts of more complete and recommendable volumes. Macaulay once said that in a Turkey carpet there are all the colours which occur in a good picture, and that in Mr. R. Montgomery's poems, there are all the words which when properly arranged make poetry; so it might also be said that in Mr. Semple's 'Aids to Chemistry' there are all the facts necessary for the construction of a system of chemistry. They lack however that arrangement, display of concatenation and relationship so essential to the constitution of a systematic treatise on chemistry.

In the present part of his work, Mr. Semple describes, in brief language, the non-metallic elements, their sources, methods of preparation and tests. The more important compounds are similarly treated and represented by the abundant use of formulæ. Further on in the book, we come to the consideration of what Mr. Semple terms the metalloids,—sulphur, phosphorus, arsenic, boron, silicon, selenium and tellurium. We have seen that the book treats of those substances ranging from oxygen to the metalloids, but why oxygen and carbon should not be included among the metalloids, or why sulphur and tellurium should be, or again why arsenic and tellurium should not be reserved until Mr. Semple reaches the metals, we know not. It is about as interesting to mentally calculate the distance of oxygen from the metalloids, as that obtaining between infectious diseases and Professor Tyndall's germs. Mr. Semple brings his book to a conclusion with some observations upon the metric system of weights and measures; the measurement of temperature; expansion of gases by heat; the relation of the volume of gases to pressure; and the property of diffusion of gases.

There are errors in the work under consideration, as in all books. Thus we are told on page 1, that oxygen is "a dyad element replacing two monads as in the case of water $\left.\begin{matrix}H\\H\end{matrix}\right\}O$"; and this is a kind of error repeated frequently by our author. He also gives several methods of preparing ozone which are not correct, or at least doubtful, viz., the action of sulphuric acid upon potassic permanganate and the aerial oxidation of phosphorus in the presence of water (p. 2). It is certain that this last stated method gives peroxide of hydrogen. Writing on page 5, of the combination of oxygen with hydrogen, it is said "*the oxyhydrogen blowpipe* is employed to develop the great heat, evolved by the combination of the two gases."

Ammonia is described (p. 9) as a colourless, irrespirable gas with the "odour of hartshorn;" and on page 13, iron is stated to be unattacked by nitric acid. Chlorine is described as "never native" (p. 25), and bleaching powder receives the erroneous description of a *mixture* of chloride and hypochlorite of calcium (p. 27), whereas it is well known to be a definite chemical combination which is resolvable into these substances.

There is also a looseness of description exhibited in the book before us, which is very objectionable. For instance, on the second page of the book, one of the tests for oxygen, is given as follows:—"Phosphorus inflamed and placed in this gas exhibits dazzling brilliancy." This is quite true, but a student attempting to make this experiment, not having been previously informed of the dangerous nature of phosphorus, might not improbably witness the "dazzling brilliancy" under circumstances not altogether pleasant to his body.

Again, among the sources of sulphur (p. 34) Glauber's salts and gypsum receive mention, and in the next paragraph, under the heading of "preparation," we are told that to obtain pure sulphur, "the mineral in which it is contained is heated in earthenware pots," etc. Although this method would serve very well for pyrites, it would scarcely answer with gypsum. Further (p. 41), hydrogen disulphide is described as "an oily liquid, closely resembling H_2O_2." Enough has been said, to show the character of Mr. Semple's 'Aids to Chemistry.' The title itself is not free from objections; the work still less so.

Dispensing Memoranda.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageoue were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be conidered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.

[2]. DISPENSING QUERY.—Use dry measures. 1. Put the glycerine into a 4 oz. bottle. 2. Mix the Tr. Tolu and Tr. Opii Ammon. 3. Mix the Chlorodyne (Collis Browne's) and the Vin. Ipecacuan. 4. Add gradually, and shaking gently between each addition, first No. 3, and then No. 2,—to No. 1. A homogeneous brown mixture will result, which will not separate on standing.

Z. V. Z.

[10]. EXT. TARAX. LIQUID.—Which preparation of Taraxacum should be used when Ext. Tarax. Liquid. is prescribed in a mixture? The old fashioned treacly preparation made by dissolving Ext. Taraxaci in water, and adding a little spirit, the more elegant Liquor Taraxci prepared "in vacuo," or the Succus Taraxaci, B.P.? What rule is adopted in leading dispensing establishments?

S. J. W.

TURPENTINE EMULSION.—Mr. Louis Genois reports (*Amer. Journ. Pharm.*, vii., 346), that in a series of experiments on the emulsionizing of oil of turpentine, he obtained the best results with castile soap. The smallest proportions he found to answer were 10 grains of soap to 1 ounce of oil and any quantity of water. The soap is put into a round-bottomed mortar, the oil added by degrees with constant trituration; when well mixed, the product is placed in a bottle, half an ounce of water is added, the whole is shaken vigorously, a little more water is added, and the mixture is again shaken. The result is said to be a very white emulsion, which remains permanent almost indefinitely, and will not separate on the addition of a gallon of water. The soap should be dry and in very fine powder.

Admission of Reporters.

Sir,—I apprehend the discussion at the late meeting of Council upon the motion of Mr. Hampson, for "the admission of reporters from the recognized journal or journals representing pharmacy and the trade," will be read with considerable interest by many of our brethren; how far the majority will agree with the result is another question. I must confess my own entire disagreement both with the line of argument and its issue.

The whole gist of the matter rests upon the question whether the Pharmaceutical Council is a private or public body. This point being settled, the privacy or otherwise of its deliberations would follow as a matter of course.

Upon what basis any gentlemen can argue that it is a private body I cannot conceive; it is perfectly true the privilege of election rests with members of the Society alone, but once elected those gentlemen immediately lose their individuality as private representatives, and at once assume the position of legislators for the entire body of chemists and druggists; they are recognized by the Legislature, not as representatives of a private society, but as the executive of the trade at large.

I would refer your readers to the Pharmacy Act, 1868, the first and second clauses of which clearly set forth that "it shall be unlawful for any person to sell or keep open shop, for retailing, dispensing, or compounding poisons, or to assume or use the title "Chemist and Druggist" or Chemist or Druggist, or Pharmacist, or Dispensing Chemist, or Druggist, in any part of Great Britain, unless such person shall be a Pharmaceutical Chemist, or a Chemist and Druggist, within the meaning of this Act, and be registered under this Act, and conform to such regulations as to the keeping, dispensing, and selling of such poisons, as may from time to time be prescribed by the Pharmaceutical Society with the consent of the Privy Council." And again, "That the *Council* of the Pharmaceutical Society is herein referred to as the Pharmaceutical Society." Putting these two clauses together, we at once see that the Council is not recognized by the Legislature as a private, but as a public body. To guard the public safety is its one recognized office and duty.

The next question is—The Council being a public body, are its deliberations to be public or private? To this query I can see but one reply, and on what logical ground the opponents of Mr. Hampson's motion base their arguments I fail to see.

Mr. Sandford tells us "the Council often has private business to discuss, and therefore it is a matter for grave consideration whether other reporters should be admitted." Has the Medical Council no private business to transact? Has not every legislative council and board private business to transact? and yet perfectly able to conduct their general meetings under the flying pen of the reporter? For what purpose are committees formed but, among others, that such special subjects may therein have the benefit of private discussion and matters matured for the final settlement of the Board or Council?

Mr. Bottle repudiates the idea from a financial point of view, that the Society having valuable property in the *Pharmaceutical Journal*, it would be injurious to its interests to admit others to so rich a feast with which to fill their columns to repletion. Can it be that the merits of our Journal rests simply in these reports published once a month? I rather take this statement as an admission of the objection so often heard, that the Journal is far in advance of the requirements of the trade, rather than an argument against the motion. Mr. Bottle further argues that "hitherto the proceedings of the Council have not been carried on in that strictly formal way which would be creditable to the Council." Surely this is an admission which speaks volumes in *favour* of the motion. If after so many years' experience the Council has not yet learnt how to conduct its duties in a business-like manner, the sooner its delinquencies are removed the better for all parties.

Passing over the observations of other gentlemen I would draw attention to those of Mr. Betty, who comes before us in an entirely new character; he who in June, 1872, could say at the meeting of Council, "Last year on my own motion for the admission of reporters, the stronghold of secretness fell down like the walls of Jericho at the trumpet blast!" now, under the awakening influence of the Council Chamber, sees the danger of those fallen walls, and viewing with awe the steady advance of the hosts would fain restore those battlements and keep at bay the clamouring enemy of peace and quiet. The very idea of such an indignity as the admission of the reporters of the *Chemist and Druggist* fills his soul with horror. The *Pharmaceutical Journal* alone really represents pharmacy pure and simple; how, then, can we allow our scientific discussions on co-operative stores and trade interests to be defiled by insertions in the pages of such a commercial production as the *Chemist and Druggist*? Thus argues our oratorical representative and once warm advocate.

Allow me to ask, sir, Where is the argument adduced by the opponents of Mr. Hampson's motion which conclusively weighs against its adoption? The Council has important public functions to perform, the entire trade is by Act of Parliament put under its control and guardianship. Who, then, has a better right to a full knowledge of what passes at its meetings than those for whom it legislates? There still remains a ray of hope that the effort so well made by Mr. Hampson may yet result in success. It is suggested by more than one speaker that were the editor of the *Chemist and Druggist* to make a formal application for the admission of his own reporter it would not be disregarded. It is to be hoped that in the interests of the trade that gentleman may feel it his duty to make such an application, and that the Council may yet retrieve the false step so unfortunately taken at its last meeting.

Edwin B. Vizer.

Belgrave House, Cliftonville, Brighton.

The Council Prizes.

Sir,—The opinions of many, on the examination papers for the Council prizes, having been recently brought before the readers of this Journal in a letter from myself, it would be unnecessary for me to refer further to them, were it not that your editorial notes of them, and the letter from

"*Arator*," contain certain assertions and conclusions which I feel called upon to refute. "*Arator*" concludes that because I happened to express dissatisfaction with last year's questions, I am "never happy unless" I have a "grievance to air," an accusation as unjust as it is illogical, and in the same strain your editorial infers that I, deserving blame, am trying to cast it on others. Further, you state that my criticisms betray that I am "not in the habit of perusing the scientific portion of this Journal." Upon what do you base this assertion? Does it follow, because I think certain questions were ill-suited for Major candidates, that therefore I knew nothing about them. In opposition to your remarks, I beg to state that I rarely read any other part of the Journal, and farther that I take notes of all such papers as those referred to in my note-book, for further reference. It so happens that I did read the papers in question, and took notes on them, but surely no reasonable examiner can expect a candidate to keep all such facts in his head. It surely is carrying matters too far, to suppose that pharmacists must remember all the papers which have appeared in the Journal during the last few years, and be able to write statements on them if called upon. It is but true that candidates should apply to the best sources for information, but if he must get up the Journal for an examination, it is a question of best memory, and not of sound knowledge. I might enumerate many papers which have appeared in these pages, but which I very much doubt if "*Arator*" (whose *nom de plume*, if literally translated, would point out one of our best rising pharmacists) always carries in his mind. On this point at least, I trust many will agree with me. When writing my former letter, the paper on Pareira Brava in the Journal escaped my memory, and on this single point I crave toleration.

I was perfectly aware that the test for nitro-benzol in oil of bitter almonds is given under materia medica by Scoresby-Jackson, but this does not alter my views. In answer to "*Arator's*" question, I do not profess to draw any line between materia medica and chemistry, but think a question more purely relating to the former should have been given. The question itself is very simple. "*Arator*" has couched his language with regard to the quality of my championship, so as to leave it doubtful whether he refers to Scotch students, or to myself. If he refers to myself, my name and qualifications, already known to you, are at his disposal. I would in conclusion suggest that some evidence of original work, be it great or small, be required next year of each candidate; a far more searching test than the remembrance of certain papers in the Journal.

AULD REEKIE.

Edinburgh July 17, 1877.

MEANING OF THE WORD "MEDICINES."

Sir,—As distinguished from the word drug, medicine implies a curative relation to some definite bodily disorder.

If a druggist be not permitted to ascertain, or assist his customer to ascertain, what drugs are most suitable, then his right to prepare, compound, dispense, and vend them "as medicines" is extinguished, and he becomes a mere vendor of drugs. He may sell tincture of catechu as an astringent, because his doing so does not affirm it to be medicinal. In such case he may not prepare, compound, dispense and vend it as a diarrhœa medicine on his own judgment and responsibility.

Proprietors of patent medicines, through the medium of newspapers, almanacks, handbills and pamphlets, prescribe for the general public, and it certainly is inexplicable, if it be that a druggist may not address himself to the individual, and compound *impromptu* a specific to meet one case, as they address themselves to an aggregate—that is to say, the public—which is made up of individuals.

In your report of Apothecaries' Co. *v.* Harrison, Mr. Nathan remarked, "that as long as chemists confined themselves to the buying, preparing, compounding, dispensing and vending of drugs, they would not be open to any interference." Now, unfortunately for the Apothecaries' Company, the Act in the section quoted does not say drugs—it says medicines.

York, July 16, 1877.

MEANING OF THE WORD "DISPENSER."

Sir,—I have been waiting to see some further information about "the meaning of the word dispense," a topic started by J. W. at p. 956, of the previous volume, and continued subsequently, and which would probably have been of sustained interest had some of our respected authorities upon such subjects had the time and the will to have given their aid. By way of keeping the topic going, I beg to offer the following remark.

The dispenser of the present time derives his name from a very ancient source, but is now the only representative of a numerous family. Dr. Ash, a most careful lexicographer, in 1775, takes the term from the French *dispenser*, but we may go farther than that, as the French derived from the Latin, in which language the word has always an underlying meaning of administration as opposed to authoritative direction. For a long time, the Latin dispensator held the position of general adviser and agent in all sorts of matters requiring special knowledge and habits of business. Any gentleman anxious to analyse the dialectic value of the term will best find it in the three Greek forms—διέπω = administro, rego: διοικέω = ordino: and διανέμω = divido (Littleton, 1678; Scrivelius, 1805; Donnegan, 1846).

The elucidation of the value of the word dispense may not influence the legal decision in R. *v.* Shepperly, but, while wishing Mr. Shepperly and all others speedy relief, no harm can happen to him from our present little discussion.

THOMAS B. LANGRIDGE.

Midhurst, July 13, 1877.

J. T. Fox.—(1) *Euphorbia amygdaloides*; (2) *Lepidium campestre*; (3) *Galium cruciatum*; (4) *Lysimachia Nummularia*; (5) *Gnaphalium uliginosum*; (6) *Veronica Beccabunga*; (7) *Œnanthe crocata*; (8) *Matricaria Parthenium*; (9) *Galium aparina*; (10) *Scutellaria galericulata*; (11) *Juncus effusus*, probably, specimen imperfect; (12) *Juncus acutiflorus*, probably, specimen imperfect. Our correspondent must in future limit the number of specimens sent to six.

G. S.—*Euphorbia Paralias*; *Linaria repens.* The Curator would be glad of a good specimen of the latter.

H. C. Letty.—The Royal Dispensary for Diseases of the Ear is in Frith Street, Soho Square. The surgeons, according to the Medical Directory, are Messrs. W. Harvey and U. Pritchard, M.D. Probably the other information you require could be obtained by addressing the Secretary, at the Dispensary.

"*Hydrobromic Acid.*"—The use of the drachm is inconsistent with the inference that avoirdupois weight is intended. We notice that in our American exchanges, what is claimed to be the original formula, "containing 10 grains of bromine to the fluid drachm," is given thus, troy weight of course being used:—

"Bromide of Potassium . . .	120 grains.
Crystallized Tartaric Acid .	153 ,,
Water	1 fluid ounce.

"Dissolve the bromide in the water, then the acid. Place in cold water twelve hours for precipitation, and decant."

T. P. B.—We do not know what is designated under the name. If you send a specimen we will try and give you the information.

"*G.*" (1) *Crepis virens*; (2) *Œnanthe pimpinelloides*; (3) *Lepigonum marinum*; (4) *Lepturus incurvatus*; (5) *Brachypodium sylvaticum*; (6) *Schœnus nigricans*; (7) *Agrostis vulgaris.*

"*Fidelis.*"—(1) The colour is due to oxidation, and the liquid state to the attraction of a small quantity of moisture. It would not be worth while to attempt its restoration. (2) Twaddell's hydrometer, for testing liquids heavier than water, is so graduated that the number of degrees indicated multiplied by five, and added to 1000, gives the specific gravity with reference to water at 1000.

"*Quærens.*"—The nature of the crystals could be determined by analysis.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Lamplough, Mr. Wilks, Mr. Turnley, Mr. Anderson, Mr. Piesse, Mr. Ransom, Mr. Perks, A Dispenser, Mr. Gibbs, W. H. R., T. H. W.

Erratum.—On p. 27, col. i., line 31, *for* (sp. gr. 1·169), *read* (sp. gr. 0·924).

"THE MONTH."

The present is a time of year rarely characterized by great activity in scientific research, so far, at least, as the publication of results is concerned. Many scientific societies conclude their terms sooner or later in June, and not until the autumnal meetings of the British Association, the British Medical Association, and the Pharmaceutical Conference prepare scientific men for another session's work, do we hear of any great progress in those domains of science which are of special interest to the readers of these columns.

As is well known to most of them, an attempt has been in progress for some time past, to organize the chemical profession, or in other words those professional gentlemen who practise as analytical and consulting chemists. Though such a movement can only slightly affect existing individuals and interests, there can be no doubt that a professional institute might find its function in future years or in another generation to be one of no mean kind. The profession which could scarcely be said to have had an existence fifty years ago is to-day one of importance and dignity, justly comparable with other professions, such as those of law, medicine and the church. At the same time it cannot be disputed that the rate at which professional chemists are generated is one in great advance of the demand, and, in consequence, men have too often resorted to practices which are strictly speaking unprofessional and undignified, notably resulting in what is termed in trade "cutting down." Besides this evil there is another and a more serious one calling for rectification, namely, the want of a standard of knowledge, the possession of which constitutes the claim of a man to practise. Instances have constantly come before the public, where chemists have made mistakes and blunders, and even where professionally immoral conduct has been proved. The projected organization was therefore proposed to contend against and rectify these and other evils.

The originators of this movement were not certainly and strictly speaking, professional chemists—or at least some of them were not, and there was not a little danger at the onset that from this cause, and want of confidence in the whole project, it would come to the ground. However, after considerable explanations and concessions among those who joined or interested themselves in the organization movement, it was at last fairly started and has made considerable progress. It is not possible to enter into the matter at all in detail, because hitherto the transactions have been of a private nature in a large measure, and hence to do so would constitute a breach of confidence. After successfully surmounting several difficulties, a fresh one has arisen, consisting, so far as is known, in a protest against the registration of the Institute of Chemistry, on the ground apparently that the objectors gravely suspect they will be refused admission into the body. How far this is possible, it is difficult to say; whether their fear has its origin in a wavering conscience or in groundless apprehensions, they know best. At any rate a contemporary has taken up their cause and unduly magnified its importance. This so-called determined and powerful resistance may prove to be a pitiful wail against inner consciousness and outward circumstances, but if the men who participate in it have a genuine care for their profession and its practice, they should rather lend a helping hand than oppose a resistance which will, from its nature and cause, probably prove futile. But how our contemporary makes itself acquainted with the details of the proceedings and transactions of the Institute is not clear. It certainly seems to indicate a breach of confidence on the part of some officer of the Institute, and if this be so it would be only gracious on his part to resign office, more particularly if it be that he is not at one with his brothers in office, or satisfied with the objects of the organization controlled by the body of which he is a member.

While on this subject, we may take note of the formation of a Sanitary Institute during the past month. A sort of inaugural meeting was given at the Royal Institution on the 5th inst., when there was a great deal of talking, fussiness and effervescence. Dr. Richardson gave a general address and several well known foreign sanitarians were welcomed. Of course the objects of the association consist in the prevention of disease and the maintenance of health, but there are so many similar institutions already existing, having like objects, that it is not easy to see why this new one was formed. The founders propose to include sanitarians of both sexes as working associates, but we rather question whether the Institute will ever accomplish anything more successful than the dinner which was enjoyed at the Grosvenor Gallery Restaurant under the chairmanship of Dr. B. W. Richardson.

In chemical science there is little to note this month. In a contribution to the *Chemical News* of July 13th, Dr. C. R. A. Wright gives the analysis of two Australian wines, and devotes especial attention to the presence of iron as a natural constituent. Dr. Wright certainly admits knowledge in the past of the occurrence of iron in the ashes of some wines, but he is not "as certain as to how far this iron was precontained in the grape juice employed." To determine this point in an absolutely satisfactory manner, it would be well to employ grape juice in the investigation, and not wine itself, however genuine and carefully prepared. But the fact is that chemists at all experienced in wine chemistry were previously perfectly well acquainted with most of the facts brought forward by Dr. Wright. If a man drinks a cuprous solution, copper may be detected afterwards in his body, and it has been shown that plants assimilate with ease a great variety of matters not essentially, and in the truest sense unnatural therefore as constituents. Iron is one of these, and recently a striking instance was brought forward in these pages, of a case of lead poisoning caused by a person eating cabbages grown on a soil containing white lead. It is not at all likely that the traces of iron often found in wines (and other than Australian wines) exist there in a form at all analogous to blood hematin, and therefore it was not surprising that Dr. Wright found the iron to exist in wine in a state of combination admitting of dialysis. The amount of iron was in both cases ·01 gram (calculated as protoxide, FeO) to the litre, and he compares the wines containing it to "lactophosphate of iron" and "Parrish's Chemical Food," finally suggesting a medicinal value for the said wines as "highly agreeable tonics." No doubt the wines, if good, like all others which are good, are worth drinking, but that from the traces of iron contained therein they are any better as tonics or otherwise, this is too much even to suggest. Parrish's food consists of phosphates of iron and lime; the wine analysed by Dr. Wright contained ·01 gram FeO to the litre; to institute a comparison between such substances requires a certain amount of imagination, and when expressed sounds very much like a "puff."

Chemical elements have been cropping up of late, like new potatoes, and now Mr. Kern, an engineer of St. Petersburg, announces his discovery of yet another, which he calls Davyum. He has obtained it from some residues obtained in the working of platinum, by first precipitating the ruthenium, and heating the mother liquors with nitrate of ammonium. The red precipitate thus obtained yields davyum on calcination. From the theoretical considerations developed by M. Mendeleef, Mr. Kern ranks davyum between molybdenum and ruthenium, and assigns to it a hypothetical equivalent of 100. So far so good; but, as Mr. Allen points out in the *Chemical News*, of July 20, the characters of davyum yet ascertained are not particularly special or striking, and as Mr. Kern's contributions to analytical chemistry have not always been novel, or even correct, it would be well to exercise a wise reserve before accepting the existence of a new metal, although Mr. Kern may be prepared to stake "his Davy" upon it.

The Lavoisier medal of the Société d'Encouragement pour l'Industrie Nationale has been presented to Mr. Walter Weldon for his process now so largely employed in the manufacture of chlorine. By this process more than 100,000 tons of bleaching powder are made annually, besides a large quantity of potassic chlorate; whereas about ten years ago, the total make of bleaching powder in the world did not amount to more than 50,000 tons. M. Dumas, in presenting the medal, pointed out that through Mr. Weldon's process every sheet of paper and every yard of calico has been cheapened. The only other previous recipient of this medal is M. H. St. Claire Deville, to whom it was given in 1870.

The telephone is a physical instrument, which is at the present moment attracting much interest, and although it is only as yet a scientific toy, it may serve some useful purposes in the future. In construction it is really as simple as it is ingenious. By means of a battery an electric current is sent through a wire of any length, and to this wire may be communicated, by the agency of a key board, the vibrations of any one of a series of tuning forks (the whole forming a complete octave), kept in constant vibrations by means of the trembler of an induction coil. In this way the rate of vibration of any one fork, and consequently the pitch of any particular note, may be transmitted to the wire of the telephone. The wire terminates in an electric condenser and sounding disc, consisting of a thin sheet of gutta-percha coated on both sides with silver foil, the attractions and repulsions of which are communicated to the atmosphere as musical sounds. In some experiments which have recently been conducted, various popular airs have been transmitted by means of the instrument from one place to another. In the dim vista of the future the love-sick heart may ease its cares by cooing its plaintive song to the object of its affections, although oceans may roll between.

Just a word in relation to a paper which has been reproduced in the columns of this Journal, and which forms the subject of two lectures by Dr. Emerson Reynolds. As stated in these lectures, Drs. Crum-Brown and Frazer were the first to call special attention to the relations existing between chemical constitution and physiological action of substances. This subject was taken up by a number of physiologists, among them, by Dr. McKendrick and Mr. Dewar and more recently by Dr. Gamgee and some of his students. Now, although it must be granted that a subject of any merit presents a special interest when reviewed in a special light, it is open to question whether the results of experimental science in this direction have been of any considerable value or promise. But apart from this question the whole matter has nothing new in it and but reveals a slowly growing appreciation of the fact that the human body is constituted of chemical principles of like nature and properties with those more particularly studied in the laboratory. And as it is possible by our knowledge of the nature and properties of substances to predict in some measure their action one upon the other, and, in fact, to foretell their next states, so the same holds good when the substances entering into the composition of the animal body form one side or both sides of the equation. Hydrochloric acid acts upon chalk with the evolution of carbonic acid, and it matters not whether it happens in a beaker or in the human stomach, only the one reaction is regarded as a chemical one and the other too often as a purely physiological one. Granted sufficient knowledge of two bodies, and securing the contact of those substances, it is possible sometimes to predict the result. If one of those substances happens to form part of the brain or liver, or lung tissue, then if the other substance be swallowed and come into contact with it the same result will ensue to a certain extent. The retarding influence of vital force, as we are pleased to call it, arises from the state of combination already possessed by substances forming part of the human body, and any experiments which physiologists may perform, having reference to the physiological action of chemical substances, can only result in a more or less imperfect knowledge of this retarding influence. Even when that is known it cannot be considered an absolute advance, because in the first place the action of any substance, be it physical or chemical, is very difficult to localize, and a knowledge of the affected parts is equally difficult to ascertain; and then, after all, the composition of the substances so affected is at the best but very imperfectly known. Above and beyond all other matters affecting health and disease and a knowledge of life, a greater acquaintance with pure animal chemistry is necessitated.

"The Chemistry of the Future" is the title of a paper in the July issue of the *Quarterly Journal of Science*, but this is somewhat of a misnomer, dealing as the article does quite as much with the chemistry of the past and of all ages. In fact, it concerns itself with the theory of the evolution of the chemical elements out of a hypothetical primordial matter. Mr. Huggins' and Mr. Lockyer's researches into the chemical constitution of the sun and other planets are briefly alluded to, the bulk of the paper being concerned with M. Mendeleef's periodic laws regarding the chemical elements. The article by no means does justice to the theory of the homogeneity of matter and the question of its evolution, about which so much has been written since the days of Aristotle. This is a subject to which at an early opportunity we propose to devote some consideration in these pages.

A note contained in *Nature* of June 28th deserves mention by reason of its incorrectness and injustice. After alluding to the varied and cultured tastes of the Emperor of Brazil the note goes on to say that during his stay in London he "conversed with almost every man of science who has been doing any original work during the past few years." In the first place this is impossible, and in the second place it is unjust to those many scientific men who have *done* much original work of late years. It would be interesting to learn whom "almost every man of science" includes in the sense intended by *Nature.*

Dwellers in noisy and smoky cities are now everywhere hurrying away on the wings of steam to enjoy their well earned holidays in some pleasant nook in the country, or in some favourite seaside resort, each one bent on the pursuit of his peculiar hobby. The botanist with his well worn vasculum will probably be seen here and there eagerly stowing away floral treasures, while others preferring the study of fruits to that of flowers will be discussing the merits of different species through the medium of another sense than that of sight. In a few places, such as Hitchin, Mitcham, Banbury, Market Harboro', etc., the harvest time of medicinal plants is now drawing near, and the sweet odour of lavender and other fragrant herbs will soon be perfuming the air. Many of the plants alluded to last month are still in blossom, but Nature, always prolific at this time of the year, furnishes a number of fresh ones sufficiently ample for present discussion.

One of the most graceful objects to be seen in woods and on shady hedge banks is the male fern (*Lastrea Filix-Mas*, Presl.), with its elegant tufts of fronds grouped together in the form of a vase. It is easily distinguished by the kidney-shaped indusium, which covers each of the sori at the back of the frond. Ferns in other genera which have a somewhat similar appearance in the outline and division of the fronds have the indusium of a different shape. The only other species in the genus *Lastrea* with which it could be confounded is the sweet mountain fern, a much rarer plant, which visitors to the Conference at Plymouth will be able to find abundantly in the neighbourhood of Dartmoor. It is easily distinguished by the sweet odour which it gives off when rubbed with the hand, and by the fact that the pinnæ or leaflets decrease in size from the middle of the frond, and are continued down to the base of the stalk, whereas in the male fern they cease a short distance below the middle. Another difference which may be turned to practical account in the examination of the rhizome is that a transverse section of the leaf base is seen under a lens to be furnished with eight woody bundles, while the ferns which might be confounded with it contain only two. It is rather singular that the male fern, although found from Greenland to Natal, and from Japan to Peru, is absent from the Eastern United States.

The borage (*Borago officinalis*, L.) with its brilliant blue flowers bearing a considerable resemblance in size and shape to the flower of the potato, is now to be seen in waste places near villages, and very often it finds a place in the cottage garden. The scorpioid cymes and rough foliage characteristic of the family to which borage gives its name are well marked in this plant. The structure of the flower is rather peculiar. The petals, as in many other plants of the Boraginaceæ, are furnished at their base with a hollow "scale," formed by a small portion of the petal being inverted in the shape of a short tube, the opening into which may be seen by examining the back of the petal. At the back of each anther there is another black tongue-shaped scale, the object of which appears to be to cause the anthers to return to the shape of a cone immediately after they have been separated by the proboscis of the bee, the only insect, according to Lubbock, which is capable of getting at the honey-clad ovary. The stamens are mature before the stigma. The whole plant contains nitrate of potassium, and has been used in the form of infusion as a cooling drink.

The tall fennel (*Fœniculum vulgare*, Gærtn) with its finely cut leaves, capillary leaflets, and umbels of yellow flowers, may be found here and there on grassy slopes and hedge banks, chiefly on a calcareous soil. The sweet fennel (*F. dulce*, D. C.) which yields a larger, sweeter and more aromatic fruit, is distinguished by being a smaller plant, flowering earlier, and having stems compressed, not rounded at the base. It is questionable, however, whether it is anything more than a variety of the former plant, since the fruits diminish in size and change in shape every year, until after four or five years they are hardly to be distinguished from those of the wild fennel. Hanbury mentions, however, four commercial varieties distinguishable by shape, size, colour and flavour. The pericladium or leaf sheath is very well marked in the fennel plant.

Here and there in orchards and hedges near villages the tall elecampane (*Inula Helenium*, L.), with its large yellow composite flowers looking like a small sunflower, becomes conspicuous by reason of its rigid leaves, which in shape and size resemble large leaves of digitalis, for which, however, neither the plant nor the leaves are likely to be mistaken. The dried root is likely to be confounded with undecorticated marshmallow root, which in colour and size it resembles; its internal structure, however, is not white and fibrous, but is hard and has resinous dots, and its surface is not marked with transverse scars like that of the marshmallow root. Inulin, the carbohydrate which replaces starch in the roots of plants belonging to the compositæ, derives its name from this plant. Although formerly used as an aromatic tonic, it is now chiefly used as a cordial in veterinary medicine.

In marsh ditches near the sea, especially in the Eastern counties, the pretty flesh-coloured flowers of the marshmallow (*Althæa officinalis*, L.) are beginning to open. The plant has a more erect and shrubby habit than the common mallow, to which it bears a strong family likeness, and with which it is often confounded. The marshmallow has ovate, soft, velvety leaves, which are irregularly lobed and toothed (crenate) at the margin, and the calyx is furnished with an epicalyx, which has from six to twelve, or even more, teeth. In the common mallow (*Malva sylvestris*, L.) the leaves are reniform in outline, and have five triangular lobes and five principal radiating veins; they are crenately toothed, and the surface is slightly rough. The flowers are of a bluish lilac or mauve colour, and the epicalyx consists of three distinct bracts. In both plants the stamens are monadelphous, and the tube (androphore) formed by the united filaments has all the petals attached to its base, so that at first sight the corolla appears to be monopetalous. By examining the back of the corolla, however, the petals are seen to be quite distinct from each other. The anthers are one-celled, by which character malvaceous plants are distinguished from those of all other families which have monadelphous stamens. The pollen is covered with minute spines, and forms a very pretty microscopic object.

The chicory (*Cichorium Intybus*, L.), with its straggling rigid stems, studded with brilliant blue flowers, may now be met with by the roadside or in cornfields. The flowers, in shape and size, resemble those of the dandelion, but are sessile on the branches, and are often crowded together in twos and threes, only one in each axil being open at one time. The roasted and powdered root when mixed with coffee may be detected by its colouring cold water when dropped into it; or with greater certainty by its microscopical structure, which is described and figured in Dr. Hassall's work on the adulteration of food.

On chalky and limestone banks, the marjoram (*Origanum vulgare*, L.) may now be found abundantly, and is easily recognized by the odour of its leaves and its purplish tinted panicled inflorescence. This colour is due more to the bracts than to the flowers, the latter being sometimes almost white in colour. The inflorescence in most labiate plants is mixed, that is, the flowers in each tuft open from centre to circumference, while the whole floral axis opens from circumference to centre. In this plant, however, this arrangement is by no means obvious, for owing to the non-development of the lateral flowers in each axillary tuft the ultimate branches of the inflorescence appear to consist of small spikes opening in a centripetal manner. The oil of origanum of English commerce is not derived from this plant, but from the common thyme (*Thymus vulgaris*, L.). The cheaper kind, used in veterinary medicine, etc., is too often a mixture of oil of turpentine, oil of spike, oil of rosemary, and oil of thyme, the mixture being coloured with alkanet root.

Other labiate plants in blossom this month are the thyme, spearmint, and white horehound. Spearmint is easily distinguished from peppermint by its sessile leaves and tapering inflorescence, as well as by its odour. Peppermint has stalked leaves, and an obtuse spike-like inflorescence. Both of these mints, as well as pennyroyal (*Mentha Pulegium*, L.), will be in flower during the coming month. Pennyroyal has small leaves and slender prostrate stems, and the inflorescence consists of axillary verticillasters which are never clustered together at the top of the stems as in the peppermint and spearmint. It is not unfrequent in damp ditches on sandy commons or heaths. White horehound (*Marrubium vulgare*, L.), in this country is nowhere a common wild plant, but may occasionally be met with, especially on calcareous soil near the sea. It bears some resemblance to catmint (*Nepeta cataria*, L.) in general aspect, but is easily distinguished by its dense whorl-like axillary inflorescence of small white flowers and the ovate leaves tapering below, which as well as the whole plant have a whitish-green hue. In catmint the leaves are cordate at the base, and the flowers are arranged in terminal clusters, which is never the case with the white horehound.

Lactuca virosa, L., may also be found in flower during this month. It is, however, rather local, and is rarely found in the west beyond Somersetshire, or in Scotland beyond the north-eastern highlands. In general appearance it bears a strong resemblance to the common sowthistle (*Sonchus oleraceus*, L.), but is at once known by the very narrow, almost linear flowerheads (capitula), which any one who has seen the garden lettuce in flower would at once recognize as characteristic of the lettuce genus. The leaves abound in milky juice and turn blackish when bruised.

The vervain (*Verbena officinalis*, L.), although by no means so pretty a flower as its garden relatives, yet sometimes occurs in such profusion as to give a bluish tint to the meadow in which it grows. Its usual position is, however, amongst grass by the dusty roadside, or in stony places, and on this account it was formerly used as a remedy for stone. It appears to have been valued from the earliest times as a charm and to have been used in religious ceremonies. At the present day it is largely sold by herbalists as a tonic, and occasionally as a remedy for epilepsy. The plant is exceedingly bitter. It may easily be recognized by its square stem, opposite pinnatifid leaves, and long slender erect loose spike of small sessile pale blue flowers, and by the ovary not being divided into four distinct pieces, as in the Labiatæ, by which feature the Verbenaceæ are distinguished from that family.

Another very bitter plant, which is much used in domestic medicine in country districts, is the pretty little pink flowered centaury (*Erythræa Centaurium*, Pers.), a gentianaceous plant that may be found abundantly in sandy or calcareous pastures during the present month. The opposite leaves are lanceolate or elliptical, and the delicate pink blossoms are arranged in level topped corymbose cymes. It seems to be very sensitive to light, shutting up its flowers when a cloud obscures the sun for a time. The object of this phenomenon is not clear; it cannot be to protect the honey from being washed away by rain, for no nectar has yet been found in the blossoms. A white flowered variety may occasionally be met with. This plant is sometimes called the lesser centaury to distinguish it from the greater centaury (*Centaurea Centaurium*, L.) a thistle-like composite plant growing in Italy. The American centaury (*Sabbatia angularis*, L.) is very similar in appearance and properties to the lesser centaury, and also belongs to the Gentianaceæ. It is used in America as a tonic and vermifuge.

In the various botanical gardens a large number of plants are now in blossom, although few of them are hothouse plants. At Kew the only plant of medicinal interest in the economic house is the grass known under the singular name of Job's tears (*Coix Lachryma*), the greyish shining tear-shaped fruit of which is about the size of a pea. It is used in the East as a diuretic and tonic. In the open ground *Argemone mexicana*, L., displays its handsome yellow flowers, which are very like those of the yellow seaside poppy (*Glaucium luteum*, Sc.), but the leaves and fruit are very different from those of that plant. The leaves of the Mexican poppy are marked with white veins and bear considerable resemblance to those of the milk thistle (*Carduus marianus*, L.); the fruit is a quadrangular bristly capsule. The seeds are black and spherical and are about the size of turnip seed. The oil obtained from them has been recommended in cholera. The liquorice plants (*Glycyrrhiza glabra*, L., and *G. glandulifera*, W. K.) are now both in blossom at Kew. The former has pinnate leaves with larger leaflets, the terminal leaflet being stalked, and the flowers are of a pale blue colour. In the latter the leaflets are more narrowly lanceolate and the flowers are white and the terminal leaflet is sessile. The chief difference, however, lies in the pod, which is smooth in *G. glabra* and prickly in *G. glandulifera*. The leaves are seen under a lens to be covered with minute sessile glands, which look like tiny particles of clear liquid immersed in depressions of the surface of the leaf. The presence of these gives the leaves a curious sticky appearance that the touch does not confirm. The Russian liquorice of commerce is said to be chiefly derived from *G. glandulifera*. The root has a reddish tint and a scurfy surface which distinguish it from the smoother one of *G. glabra;* both are, however, frequently marked with transverse scars. Sometimes the underground stems are sold with the root; these have no transverse scars, have usually a distinct pith, are in straighter pieces, and have a less sweet taste.

The *Lathyrus sativus*, L., has remarkably pretty blue flowers, exactly the colour and about the size of the small blue butterflies so common in heathy places, and might well have suggested the name papilionaceous for the form of flower so named. The outer surface of the upper petal (standard) is of a pinkish colour. The seeds of this plant are used in India as food, but are worthy of notice here on account of having occasionally poisonous properties attributed to them.

Ecballium officinarum, with its coarse grey heart-shaped leaves, is not easily forgotten when once seen. The plant is monœcious, both male and female flowers being produced on separate stalks from each axil. There is usually only one pistillate flower, but the staminate flowers are often two or three or more in number. The female flower usually opens first, and the male flowers sometimes are not matured, so that unless carefully examined the plant might be supposed to be diœcious.

The scammony plant, *Convolvulus scammonia*, L., is now just coming into flower. The blossom is very similar in size and appearance to the common bindweed (*Convolvulus arvensis*, L.), but the pink stripes are only seen outside the corolla, the inner surface being white. The plant has also a twining rather than a trailing habit. Among the umbelliferæ, the coriander, carrot, hemlock, opopanax and several others will be found in good condition for examination. The coriander has umbels of pinkish flowers and is remarkable for having the lower leaves less finely divided and different in appearance from the upper ones, also for the disgusting odour of the leaves when bruised, which is exactly that of oxalate of amyl, and very different from the fragrant odour of the oil obtained from the fruit. Whether there be any relation between the oil of coriander and oxalate of amyl is a point for future investigators to decide. Those who examine this plant are advised to handle it tenderly, on account of the persistency of its odour. The same remark will apply to another plant now in blossom (*Chenopodium Vulvaria*, L.), whose strong odour of stinking fish, due to trimethylamine, can hardly be removed from the hands without soap and water. *Opopanax chironium*, Koch, has neither the odour nor taste of the gum resin opopanax, and certainly cannot be its botanical source.

Several American medicinal plants are now in blossom: *Apocynum androsæmifolium*, L., or bitter root, used as an alterative in chronic hepatic affections; *Apocynum cannabinum*, L., sometimes called Indian hemp in the United States, a diaphoretic and purgative; *Asclepias Cornuti*, Dec., common silkweed, and *Asclepias incarnata*, L., or swamp milk weed, the former used as an alterative and the latter as a vermifuge. *Asclepias Curassavica*, L., or West Indian ipecacuanha, is also in blossom in the economic house. All these species have the same curious structure of the flower. The five petals are bent backwards, almost hiding the five small sepals. The five stamens have their short filaments united into a pentagonal tube, and the anthers are almost free from each other, but are closely applied to the stigma, so that the only space for an insect to insert its proboscis is a narrow slit between each anther. The pollen is not powdery but agglomerated into two pollen masses, each of which occupies half of the anther and terminates in a small black gland. This gland does not unite the two pollen masses of each anther together, but is united to the gland belonging to the next anther, and these two united glands adhere slightly to the side of the stigma while the pollen remains in the anther cells, so that an insect in visiting the flower would draw out with it a double pollen mass, consisting of half the contents of two contiguous anthers. This may be easily confirmed by inserting the tip of a penknife between the curious boat-shaped processes, one of which is attached to the back of each anther, and drawing it upwards towards the top of the flower. Each of the boat-shaped processes has a short curved horn-like body projecting from its centre, the object of which is not very obvious, unless it be to act as a hook to catch the pollen masses carried by insects from one flower to another. The dull red flowers of the two silkweeds have a sweet honey-like odour. *Heuchera Americana* L., or alum root, so named on account of its astringent properties; *Actæa racemosa*, L. and *Veratrum viride* are also to be seen in blossom. Several abnormal umbelliferous plants are worth examination. *Bupleurum rotundifolium*, L., with perfoliate entire leaves and small umbels almost hidden by the large involucre; *Eryngium maritimum*, L., very like a thistle in appearance, but at once known from the compositæ by its anthers not being united; and *Hydrocotyle asiatica*, L., with its entire peltate leaves and minute umbels of very few almost sessile flowers. *Castanea vesca*, Gærtn, the Spanish chestnut, the leaves of which are useful in hooping cough, is now covered with its drooping catkins.

In the Chelsea Gardens may now be seen in blossom *Delphinium Staphysagria*, L.; *Colutea arborescens*, L., or bladder senna; *Melilotus cœrulea*, L., used in Switzerland to give the characteristic flavour to Schabzieger cheese; *Pimpinella anisum*, L.; *Carthamus tinctorius*, L.; *Lolium temulentum*, L.; *Anchusa tinctoria*, Lam.; *Marrubium vulgare*, L., and many others which want of space forbids us to notice at present. The pretty plumose pappus of the valerian may now be seen in all stages of development, and is well worth examination. At the Botanical Gardens at Regent's Park *Tanghinia venenifera*, Poir, is fully in blossom and *Jatropha Curcas*, L., or purging nut, is just opening its greenish flowers. The oil of the seeds of this plant is the kind which has been supposed to be used in India to adulterate croton oil.

At the drug sales we have seen but few novelties. Egyptian soap root (*Gypsophila Struthium*, L.), which contains a quantity of saponin, and is used by dyers and cleaners for removing grease from silk and other fabrics; oil of cedar wood, "Cuscus"; oil of ginger-grass, the oil which is used in India, etc., to adulterate otto of rose; hog tragacanth, better known to pharmaceutical students under the name of caramania gum, and which is used in Asia Minor for mixing with inferior tragacanth; these are a few of the articles which only occasionally appear in the lists. We have also noticed a peculiar kind of fluid galbanum about the consistence of fresh honey, having a decided taste of galbanum, but an odour which recalls that of turpentine and ammoniacum mixed. It was offered under the name of *Baridche*, and appears to correspond to one of the varieties of Persian galbanum, described by Hirschsohn (see *Pharm. Journal*, vol. vii., p. 371); a new kind of valerian root imported from Yokohama, in Japan, under the name of Kesso, probably the root of a species of a nearly allied genus. It has even a more powerful odour than the common valerian. The drug consists of a very small portion of root, with from six to twelve rather straight rootlets proceeding from it. The rootlets are about the size of those of valerian, but are of a brighter brown colour and have a soft spongy or scurfy surface. By this character and the absence of a well-marked rhizome it is easily distinguished from the English drug, to which, judging only by its odour it may prove to be superior.

Another root strongly resembling valerian in appearance, but nearly odourless, and having a more slender straggling rhizome, has recently been sold for white hellebore. The botanical and commercial sources of this root we have not as yet been able to ascertain. A nearly transparent kind of vermicelli, from Japan, is now also being offered for sale. It is probably made from rice. Dragon's-wood, a substance yielding a bright red colour to alcohol, is another article whose source is at present obscure. Santonin has recently figured in considerable quantity in the lists, but whether of home or foreign manufacture it is difficult to ascertain; remembering the suspected admixtures of strychnine with this principle which have recently been noticed it seems advisable that buyers should test its purity. At the present time it is worth while investigating whether the yellow colour of santonin which has been exposed to light is due to xanthopsin, a body which is supposed to possess poisonous properties.*

From the recent investigations concerning the active principles of calabar bean it would appear that the physostigmine of the English and the eserine of French commerce are identical bodies, and that an ethereal extract of the bean is far superior to an alcoholic one for medicinal purposes, since it will contain neither rubreserine nor the poisonous calabarine, which resembles strychnia in its effects. In other words, the physostigmine of commerce may be purified by treatment with ether which will only dissolve out the pure alkaloid.

In the July number of Bentley and Trimen's Medicinal plants four British species are figured, viz., *Sambucus nigra*, *Anthemis nobilis*, *Mentha Pulegium*, and *Lolium temulentum*. The fruit of *Arachis hypogœa* is probably known by sight to most people, but the curious development of the fruit described in the text will be known to but few beside good botanists. Only one other complete figure of this plant is extant, and that is in the Flora Brasiliensis. The other two plants figured are *Zea Mays*, and an Indian purgative, *Ipomœa Nil*.

Perhaps the most interesting contribution to pharmaceutical knowledge during the past month has been the results of the examination of the distribution of alkaloids in cinchona trees, by Mr. D. Howard. The experiments seem to point to the conclusion that light and oxygen are the two chief factors in the development of quinine and cinchonidine, while cinchonine and quinidine are produced in proportion as these are diminished. We thus get one step nearer to the knowledge of the circumstances under which quinine can be developed to the greatest extent. The relation which climate and soil bear to the successful growth of different species still, however, requires careful investigation.

* See before, p. 25.

The result that has followed the institution in this Journal of a special column for Dispensing Memoranda shows that dispensing difficulties are evidently of daily occurrence. To assist in their solution shall be our earnest endeavour, and we hope that our exertions in this direction will rather stimulate than supersede the efforts of those who are more immediately brought into contact with the difficulties themselves; when their own shoulders are at the wheel, the call for help shall be cheerfully responded to. The memoranda are here referred to in the order in which they appeared.

No. 1 is a prescription containing tinct. guaiaci. The mixture was sent out having the usual appearance of a guaiacum mixture, but it was alleged to have been made up incorrectly, and to have been since dispensed perfectly clear at a West-end establishment. This mixture cannot be other than an opaque mixture, with, as stated, the usual guaiacum appearance. As to its having been sent out perfectly clear by a West-end establishment, this "West-end establishment" is often a bugbear to dispensing houses of a smaller type, and it is recommended that in all cases of this description reference should at once be made to the house in question, that the mistake may be explained or the misrepresentation exposed.

No. 2. An attractive mixture is required from the ingredients contained in the prescription, and information is asked as to the order in which they should be mixed together to obtain the desired result. If the vin. ipecac. and chlorodyne be mixed together, and added to the tinct. tolu and tinct. opii ammon. previously mixed, and finally the glycerine, a homogeneous mixture will be formed that will not readily separate; and a still more satisfactory and permanent result is obtained by the addition of one drachm of mucilage; but whether the mixture be an attractive one or otherwise will mainly depend on the patient's view of a bottle of medicine which has to be taken in repeated doses.

No. 3. An explosive mixture from a prescription containing bismuthi subnit. and sodæ bicarb. That explosions do occur from this combination there has been abundant evidence in the subsequent correspondence, and there can be no doubt that it is immediately due to the evolution of carbonic acid, either through the presence of free nitric acid, resulting from imperfect washing of the bismuthi subnit., or decomposition of the bismuth salt in the presence of bicarbonate of soda. As the change does not take place with all samples of bismuth. subnit. it is very desirable that a sample of that from which the explosive mixture was made should be forwarded for examination; decomposition not being a necessary result of the combination of bismuth. subnit. and sodæ bicarb., most probably the explosion is due to an impure sample of the bismuth salt. It is possible for a mixture to be chemically incompatible, yet not medicinally so, and the *intention* of the prescriber should always guide the dispenser. If it be found that a mixture with these ingredients, now frequently prescribed, cannot be dispensed without the probability of an explosion, it is specially one of those instances where reference should be made to the prescriber, and his attention directed to the circumstance. At the same time, bismuth. carb., which is growing in favour, may very properly be suggested as a not incompatible alternative. Prescriptions, the ingredients of which are so incompatible that the combination results in medicinal destruction, should not be sent out without reference to the writer; the dictum that "there is no alternative but to follow the letter of the chemical incompatibilities as ordered" is a view of a dispenser's duties which his education and intelligence will call in question.

No. 5. Ung. sulph. hypochlor. crass. The formula for ung. sulph. hypochlor. is generally sent out on a printed form on each bottle of sulph. hypochlor., one drachm to the ounce of lard or simple cerate. By "crass." it is evidently intended that it should be of firm consistence. The sulph. hypochlor. is made by passing chlorine gas over sulphur, but it is questionable if a definite compound is formed. When freshly made it is very liable to burst the bottle, filling the atmosphere around it with chlorinetted and sulphurous vapours; on the other hand if it be kept any length of time the contents of the bottle will be found to be little else than sulphur. Formerly this ointment was often prescribed, but of late years it has not so frequently been met with. The hypochloride of sulphur is one of the subjects on the "blue" Conference list, demanding investigation, and it is to be hoped that at no distant period some member of that body may undertake the examination of this substance, although the subject may remain long in abeyance as being too large for small minds and too small for large ones.

No. 6. This chloric ether question is one that presents some difficulties. The spirit of chloroform was introduced into the British Pharmacopœia with the view of supplying an official solution of chloroform miscible with water, and superseding the non-official but very generally used chloric ether (1 in 10). At the present time most dispensing establishments use the official spirit of chloroform when either chloric ether or spirit of chloric ether is ordered in a prescription. A difficulty will sometimes occur in determining whether the prescription was written before the introduction of the British Pharmacopœia. If this be evident, clearly chloric ether (1 in 10) should be used, but if written subsequently to the issue of the B. P., the official spirit of chloroform takes its place. The rule which obtains in most of the leading dispensing establishments of the metropolis is that in prescriptions written since the issue of the B. P., whether æther. chloric. or spt. æther. chlor. be ordered, the one official preparation, spirit of chloroform, is used. It is true that there is an article known as spt. æther. chloric., which has for many years been made by a house in the north, and this is by some houses in London considered the correct thing to use when spt. æther. chlor. is ordered. But this view is exceptional. In retail it is now the practice to send out chloric æther when this article is asked for. Uniformity with regard to the use of spirit of chloroform when either æther. chlor. or spt. æther. chlor. is ordered in a mixture is most desirable, and dispensers should take every opportunity of bringing the subject under the notice of medical men, with the view of educating them to the uniform employment of the official spirit of chloroform of the British Pharmacopœia.

No. 8. This question is how to combine one ounce of carbolic acid (Calvert's No. 5), two drachms of bichloride of mercury, and eight ounces of water so that no separation should take place when further diluted. In this mixture a dark coloured, oily matter separates, but the addition of a little mucilage will emulsify it and no further separation will take place on the addition of water.

No. 9. Here mist. febrifuga is ordered in a prescription. It would, therefore, be proper to refer the prescription to the writer for particulars. If that be not feasible the dispenser must be guided by his own judgment, and he would do well to adhere to a simple saline composed of bicarbonate of potash and citric acid, in the proper proportions to form citrate of potash. This would be safe, and he could justify the course he had taken.

With regard to some of these questions it is desirable that leading houses should state their practice, and give their reasons for it, so that smaller establishments in their sense of duty and conscientious regard in carrying out the intentions of the prescriber may find that they are on "all fours" with those "West-end houses" so often referred to by correspondents, who are supposed to have the ear of the leading men in the medical profession.

Before closing, mention may be made of a substance that promises to be of interest to the pharmacist. Unguentum Petrolei is the name of a preparation very similar to vaseline, which is prepared by Messrs. Houghton and Co., of Philadelphia, and supplied in this country by Messrs. Allen and Hanbury. Like vaseline it consists of a mixture of heavy petroleum oils and contains a large amount of the paraffins and olefines of the formulæ $C_{16}H_{34}$ and $C_{16}H_{32}$. It melts at 38° C., and being non-oxidizable it forms a valuable lubricant for surgical instruments, etc. It is further recommended as a surgical dressing.

Also, Messrs. Mawson and Swan, of Newcastle, have recently brought out a new form of water-jet aspirator, which admits of use by attaching it to any pipe supplied by ordinary town water. In exhausting effect it is certainly better than most forms of aspirators hitherto employed, and it may be used with great advantage for the purposes of quick filtering, drying and evaporating *in vacuo*.

FORMULÆ FOR NEW MEDICAMENTS ADOPTED BY THE PARIS PHARMACEUTICAL SOCIETY.

(*Continued from page* 47.)

NARCEINE.—$C_{23}H_{29}NO_9$.

To obtain narceine, solution of ammonia is added to the uncrystallizable mother liquors left in the preparation of morphine and codeine by Gregory's process. A precipitate is thus formed, consisting of narcotine, thebaine and a resinous matter. To the filtered liquor is added solution of lead acetate, which produces a precipitate. The solution is again filtered, excess of lead removed by sulphuric acid, and the liquor neutralized by ammonia and evaporated at a gentle heat until a pellicle is produced on its surface. Upon cooling, a crystalline deposit is formed, which augments by standing. This mass is thrown upon a cloth, washed with cold water, and then boiled with a rather large quantity of water; upon cooling, silky crystals of narceine are deposited.

These are purified by treatment with animal charcoal, and again crystallizing from water. By a final treatment with ether any meconine the product might contain is removed.

Narceine appears under the form of delicate prismatic needles, slightly soluble in cold water and cold alcohol, more soluble in boiling water, very soluble in boiling alcohol, and nearly insoluble in pure sulphuric ether. It commences to fuse at 145°. Narceine does not reduce iodic acid and is not coloured blue by solutions of ferric salts. A 2 per cent. solution of iodine gives with narceine a fine blue colour.

Syrup of Narceine.—Water containing 6 grams of Hydrochloric Acid (sp. gr. 1·16) per litre, 100 grams; Narceine, 1 gram; Powdered White Sugar, 650 grams; Water, 250 grams. Dissolve the narceine with heat in the acidulated water, add the 250 grams of water and the sugar, and make a syrup by simple solution. The syrup will contain 10 centigrams of narceine per 100 grams, 2 centigrams in a tablespoonful (20 grams) and 5 milligrams in a teaspoonful (5 grams).

Pancreatine.

The pancreas, freed from all the foreign parts accompanying it, is suspended in twice its weight of water containing a small quantity of chloroform to prevent alteration. After digesting for a time, throw upon a filter; press the residue, and after filtering add the liquor obtained to the preceding. Evaporate rapidly in a current of air and in vessels exposing a large surface at a temperature not exceeding 45° C.

0·10 gram of pancreatine added to 5 grams of fibrine and 25 grams of water and heated for twelve hours to 50° C. produces complete solution and transformation. The filtered liquor should give scarcely any turbidity upon the addition of nitric acid. 0·10 gram of pancreatine added to 100 grams of paste containing 5 grams of starch gives a liquor filtering very readily and decolorizing four times its volume of Fehling's liquor.

Zinc Phosphide.—P_2Zn_3.

Fragments of pure distilled zinc are introduced into a tubulated stoneware retort, so as to occupy about one-fourth of its capacity; the retort is placed in an ordinary furnace, and a current of dry carbonic acid is passed into it through the neck. Over the tubulure is placed a crucible cover so as to close the orifice incompletely and allow the carbonic acid after traversing the retort to escape. When the zinc enters into ebullition, small fragments of previously dried phosphorus are successively thrown in through the tubulure, the cover being removed and returned after each addition to prevent loss of phosphorus. From time to time it is necessary to break the crust of phosphorus formed in order to expose a new layer of metal to the action of the phosphorus. The operation is terminated by increasing the heat strongly, a precaution that is indispensable in order to separate as completely as possible the zinc phosphide from the metallic button of nearly pure zinc which collects at the bottom of the retort. Further, the zinc phosphide should be reduced to a very fine powder and the fragments which resist the action of the pestle, however slightly, should be reserved for another operation. The product pulverizes the more readily in proportion as it approaches more closely the formula P_2Zn_3. In this state it resembles iron reduced by hydrygen, and only thus should it be used by pharmacists. It is completely soluble in hydrochloric acid.

Zinc phosphide crystallizes in right prisms with a rhombic base, and having a metallic lustre. Its sp. gr. is 4·72. It is very friable, the powder being slate-coloured; it keeps without alteration exposed to the air. Treated with dilute hydrochloric, sulphuric or tartaric acid, it is decomposed, giving rise to zinc salts and an evolution of phosphoretted hydrogen.

Zinc phosphide is administered under the form of pills containing 8 milligrams of the compound, representing 1 milligram of active phosphorus.

Picrotoxin.—$C_5H_6O_2$.

Powdered cocculus indicus is exhausted with two successive quantities of boiling alcohol. The liquors are submitted to distillation to remove the alcohol and the residue boiled with water. A little lead acetate is added to the boiling solution to remove colouring matter, and after rapid filtration excess of lead is removed by sulphuretted hydrogen. The cold liquid is again filtered and evaporated, when it deposits the greater part of the picrotoxin. This is purified by crystallization from boiling water.

This substance, which is not an alkaloid, occurs under the form of white prismatic needles, without odour, but having an insupportable bitter taste. It dissolves in 150 parts of cold water, 25 parts of boiling water, 3 parts of strong alcohol, and 2½ parts of ether. Sulphuric acid colours it saffron red. It does not give off ammonia when heated dry with the fixed alkalies, and leaves no residue upon incineration.

Alcoholic Extract of Podophyllum Peltatum.

The *podophyllum peltatum* (leaves and stalks) is employed under the form of a powder in doses of from 25 to 60 centigrams. By means of alcohol (90°) a yellowish green resinoid matter is extracted from it to which the name of "podophyllin" has been improperly given. To obtain it in a state of purity the alcoholic solution is precipitated with water. The dose in which this is employed is from 2 to 6 centigrams, rarely more.

Syrup of Polygala.

Polygala Root, 50 grams; Boiling Water, 350 grams; Sugar, 650 grams. Infuse during six hours, strain and press, filter, add sufficient water to make 350 grams of liquid, and dissolve the sugar in it by the aid of a covered water-bath.

Tincture of Polygala.

Polygala Root, 100 grams; Alcohol (60°), 500 grams. Bruise the polygala root, add the alcohol, macerate during ten days with occasional agitation, strain and press, and filter.

Syrup of Potassium Bromide.

Potassium Bromide, 50 grams; Distilled Water, 50 grams; Simple Syrup, 900 grams. Dissolve the potassium bromide in the distilled water with the aid of a gentle heat, and mix the simple syrup.

Each tablespoonful (20 grams) contains one gram of potassium bromide.

By substituting the syrup of bitter orange peel for simple syrup, the *sirop de bromure de potassium à l'écorce d'oranges amères* will be produced.

(*To be continued.*)

THE MANUFACTURE OF PALM OIL IN WESTERN AFRICA.

A very full and detailed account of the cultivation and produce of the oil palm (*Elaïs guineënsis*) on the West Coast of Africa, has recently been received at Kew, from the Colonial Office. From this report the following extract is quoted in the *Gardeners' Chronicle* for June 30:—

"Referring to cultivation, we are told that the ground is first well raked, and the ripe nuts which have been selected for sowing are scattered broadcast over the prepared ground and lightly covered with earth, or a number of nuts ranging from six to ten is deposited in one spot, at various distances, and covered with earth. The planting must be during the rainy season, as it requires a good quantity of water. When the young shoots have grown to about one foot in height they are carefully removed in the evening and transplanted at distances of at least fifteen feet from each other, and if planted during one season it is better to allow them to remain until the next before they are transplanted.

"The palm grows luxuriantly and bears more abundantly at the height of from ten to twelve feet in a damp semi-marshy soil, but where water does not, however, stand. In arid dry soil it becomes stumpy, and grows very slowly, and sometimes bears at four feet; but to cultivate the plant so as to ensure a proper growth, a development of a good number of spadices, large in size, with nuts or fruits well supplied with flesh, or what is technically called "fat nuts," the trees must be at a distance of at least twenty feet from one another, and well supplied with water. The supply of nuts fit for use is biennial, but the most abundant supply of commercial oil is obtained from nuts gathered during the rainy season.

"For the production of commercial palm oil, that is, oil for exportation, we are told that the spadices are cut down from the trees, and put in a heap outside in the air, where they are allowed to remain for a week or ten days, which causes the joints of the nuts to be weakened by the process of decomposition, and they are easily detached by simply beating them. The nuts or fruits are gathered together, and the husks that adhere to their base are removed either by the hand or by rubbing them together, and separated by throwing them in the air, and allowing a strong breeze to blow them away. A hole about four feet deep is dug in the earth, which is lined with plantain leaves, into which the nuts with the hard unyielding pulp are put and covered over, first with plantain leaves and then with palm leaves and earth. The nuts are allowed to remain for various periods—from three weeks to three months—until more or less decomposition has taken place, so that when removed the pulp is soft, and appears as if it had been thoroughly boiled. They are now put into a trough made by digging a hole four feet deep in the earth, and paving it below and around with rough stones. In some cases a portion of the nuts is boiled in iron or earthenware pots and then mixed with the unboiled portion before putting into the trough. They are now pounded with wooden pestles by several persons standing round the trough until the pulp is quite removed from the surface of the hard nut; the whole is removed from the trough, put into a heap, and the stones taken out, leaving the oily fibrous pulp, which is put into a pot with a small quantity of water under a good fire, and well stirred until the oil begins to melt out. The pulp is then removed and put into a rough net open at both ends, to which are attached two or three short sticks, by turning which in opposite directions the oil is squeezed out from the nets: it runs into a receiver or tub, leaving the fibre behind. The longer the oil-nuts remain underground the thicker the oil will be when made; the quality will also be inferior and the smell bad. On the other hand, the shorter time, within certain limits, the nuts are underground the more superior will be the quality of the oil made from them. This in a great measure will account for the difference in the quality of the oil shipped from different parts of the coast.

"The following is given as the method of manufacture of the oil for internal consumption: The spadices are kept in a hot place for three or four days, and the nuts are then taken out. A small quantity—from 3 lb. to 4 lb.—is made at a time. They are boiled in iron pots, then put into a wooden mortar and pounded with wooden pestles. The pulpy mass is then mixed with tepid water with the hand. The chaff is first removed, and afterwards the stones. The oil remains mixed with the water, which is passed through a sieve to remove the remaining chaff into a pot placed on the fire, and heated up to boiling point, and allowed to continue in that state whilst the oil floats up as a bright red substance. The water at this stage is being continually stirred, and the oil removed as it floats up until the whole is removed. The oil is now put into a pot and heated, to drive out any water that may remain. The nuts which have been subjected to the process already described in making oil are deprived of their external pulp, or old nuts picked up from under the palm trees are put in the sun for days, and even months, until they are perfectly dry. They are then broken between two stones, and the kernels obtained whole or in perfect condition and fit for exportation, and so form the commercial palm kernels. If they have not been perfectly dried the kernels break into pieces. The oil obtained from these kernels by the following process is called white kernel oil: They are put into wooden mortars and pounded very finely, then removed to a grinding-stone and ground into a homogeneous mass, which is put into cold water and stirred with the hand. The oil rises in white lumps on the surface of the water, which is collected and boiled. It is of a very light straw colour, and, when exposed to the sun and dew, becomes, after a time, perfectly white.

"Brown or black oil is thus obtained. The kernels are put into a pan and fried, the oil oozes out and is strained, the fried nuts are put into wooden mortars, pounded, and afterwards finely ground on a grinding-stone. The mass is thrown into a small quantity of boiling water and stirred continually, the oil rises, and is continually removed until it ceases to rise. The pulpy mass is removed from the fire and spread out in a large bowl and allowed to cool, after which it is again ground and put by until the cool of the day, when it is mixed with a little water to soften it. It is now beaten with the hand for some time until the oil comes out in white pellets. As soon as this is observed a large quantity of water is put into it, and the oil in some fatty substance floats on the top, which is skimmed off and boiled, and the pure oil obtained. As pointed out in the report, under the circumstances here detailed the exported kernels could not possibly retain their germinating powers, so that it would be impossible to raise plants from them."

CHEMISTRY OF THE BARKS OF THE OAK, WILLOW, AND ELM.*

BY E. JOHANSEN.

The investigation was undertaken with the view of ascertaining the nature of the different tannin-like substances contained in the barks of the oak, willow, and elm, and it was hoped, by isolating these and carefully examining their properties and the nature of their principal compounds, to ascertain whether they were analogous or even identical. By a long and elaborate process, the different tannins were separated from the three barks in something like a pure state.

Oak Tannin is a red-brown amorphous glistening body, easily soluble in alcohol, slightly soluble in ether, and forms an imperfectly clear solution in water. In its behaviour to litmus paper, metallic salts, and alkaloids, it is completely analogous to gallotannic acid. Dried at 110°, it lost 8·48 per cent. of water. On analysis, it gave 54·61 per cent. of carbon, 5·32 per cent. of hydrogen, and 40·07 per cent. of oxygen, agreeing approximately with Wagner's formula, $C_{14}H_{16}O_8$, which requires 53·85 per cent. of carbon, and 5·13 per cent. of hydrogen. It contains also 0·77 per cent. of nitrogen and 0·13 per cent. of ash.

Willow Tannin consists of a brown-red amorphous body, with a slightly astringent taste; easily soluble in alcohol, slightly soluble in ether, and forming a thick solution with water. With ferric salts it gives a deep black colour, turned violet-red by alkalies. It precipitates mercuric nitrate and chloride, and zinc and copper sulphates, as well as albumin, starch, and alkaloids. At

* From *Arch. Pharm.* [3], ix., 210–248. Reprinted from the *Journal of the Chemical Society*, June, 1877.

120° the willow tannin lost 10·10 per cent. of water, and on analysis gave 51·13 per cent. of carbon, 4·78 per cent. of hydrogen, and 44·09 per cent. of oxygen. It contains also 1·88 per cent. of nitrogen, and 1·63 per cent. of ash. Another specimen, prepared in a different manner, though possessing the same reactions as the last, contained 51·26 per cent. of carbon and 5·99 per cent. of hydrogen, besides having independently 0·44 per cent. of nitrogen, and 1·42 per cent. of ash.

Elm Tannin.—In appearance and solubility this variety resembles oak tannin. With ferric chloride, it gives a dirty-green precipitate, turned violet-red by sodium hydrate. With ferrous sulphate, it gives a pure-green precipitate. It precipitates lead and copper acetates, and zinc sulphate after some time. With zinc chloride, mercuric nitrate, calcium acetate, etc., it gave the usual reactions. At 110° elm tannin loses 3·32 per cent. of water, and, on analysis, gives 44·54 per cent. of carbon, 4·72 per cent. of hydrogen, and 50·71 per cent. of oxygen, besides containing 1·21 per cent. of ash.

The salts of these three tannin acids (quercitannic, salitannic, and ulmotannic) were next examined.

Lead Salts.—Quercitannate of lead is a chocolate-brown, amorphous mass, slightly soluble in water, insoluble in alcohol or ether. On heating it to 110°, it lost 9·66 per cent. of water; and on analysis it gave 22·85 per cent. of carbon, 1·47 per cent. of hydrogen, 9·14 per cent. of oxygen, and 36·54 per cent. of lead oxide. The salitannate of lead resembled the last body, and on drying at 120° lost 4·50 per cent. of water, and on analysis gave 22·53 per cent. of carbon, 1·35 per cent. of hydrogen, and 53·28 per cent. of lead oxide. By fractionally precipitating with a lead salt, both these acids gave salts of varying constitution. Ulmotannate of lead was greyer than the last body; and on analysis gave 21·36 per cent. of carbon, 1·51 per cent. of hydrogen, 10·32 per cent. of oxygen, and 66·81 per cent. of lead oxide.

Copper Salts.—Quercitannate of copper is a brown substance, insoluble in alcohol and ether, and sparingly soluble in water. At 110° it lost 12·23 per cent. of moisture, and on analysis gave 39·99 per cent. of carbon, 2·38 per cent. of hydrogen, 28·14 per cent. of oxygen, and 29·49 per cent. of copper oxide. Salitannate of copper forms a dark reddish-brown salt, which lost at 120° 12·4 per cent. of moisture; and on analysis gave 39·36 per cent. of carbon, 2·35 per cent. of hydrogen, 27·83 per cent. of oxygen, and 30·46 per cent. of copper oxide. Ulmotannate of copper is chocolate-brown, and after drying at 110° gave 39·68 per cent. of carbon, 1·93 per cent. of hydrogen, 17·98 per cent. of oxygen acid, and 40·41 per cent. of copper oxide.

Tin Salts.—Quercitannate of tin is a greenish-brown substance, insoluble in alcohol and ether, and only sparingly soluble in water. At 110° it loses 5·98 per cent. of moisture, and on analysis gave 36·32 per cent. of carbon, 2·56 per cent. of hydrogen, 20·69 per cent. of oxygen, and 40·43 per cent. of stannous oxide. The formula $C_{30}H_{26}O_{13}.3\,SnO$ agrees fairly with these numbers. Salitannate of tin is a chocolate-coloured body, which loses 7·18 per cent. of moisture at 120°, and on analysis gives 35·17 per cent. of carbon, 2·79 per cent. of hydrogen, 15·05 per cent. of oxygen, and 46·50 per cent. of stannous oxide. Ulmotannate of tin on drying at 110° gave 38·99 per cent. of carbon, 2·40 per cent. of hydrogen, 13·66 per cent. of oxygen, and 44·95 per cent. of stannous oxide.

When these different tannins were acted on by dilute acids in the usual manner, as Grabowski has already shown, the oak tannin yields an easily decomposed saccharide and a crystalline body. The amount of these bodies obtained varies with the strength of acid employed. On purification the saccharide is obtained as a brown substance, forming a dark-brown bitter syrup. Similar bodies were obtained from the willow tannin. On analysis the saccharide obtained from the willow tannin gave 36·94 per cent. of carbon, 5·19 per cent. of hydrogen, and 57·87 per cent. of oxygen. Elm tannin, on the contrary, yields no crystalline body, but only a saccharide resembling in every respect the last.

On fusing with potassium hydrate, the oak tannin yields, amongst other products, butyric acid amongst the volatile products, and protocatechuic acid from the residue. Willow tannin, similarly treated, yielded acetic and butyric acid amongst the volatile products, whilst the residue in the retort contained a body whose identity could not be satisfactorily made out. Elm tannin, treated in the same manner, yielded acetic and butyric acids among the volatile products, and oxyphenic acid in the residue.

SATURATION-TABLE OF SALICYLIC ACID.*

BY DR. H. HAGER.

Saturated or neutral solutions of solium salicylate may be prepared by the following table :—

5·0	of salicylic acid	require	3·25	sodium bicarbonate.
6·0	„	„	3·90	„ „
7·0	„	„	4·55	„ „
8·0	„	„	5·20	„ „
9·0	„	„	5·80	„ „
10·0	„	„	6·50	„ „

Or, to state it more correctly, the weight of salicylic acid, multiplied by 0·65, gives the weight of sodium bicarbonate necessary for saturation.

If it is desired to use crystallized sodium monocarbonate, or sal soda, the proportions will be as follows :—

5·0	of salicylic acid	require	5·2	of sodium carbonate.
6·0	„	„	6·3	„ „
7·0	„	„	7·3	„ „
8·0	„	„	8·3	„ „
9·0	„	„	9·4	„ „
10·0	„	„	10·4	„ „

Or, to state it more exactly, the weight of salicylic acid, multiplied with 1·04, gives the weight of sodium carbonate necessary for saturation.

NOTE ON GINGER.†

BY JOHN STENHOUSE, LL.D., F.R.S., AND CHARLES E. GROVES.

As the nature of the resinous substance contained in ginger, and to which its pungent character is due, has not as yet been investigated, it seemed possible that a careful examination of it might lead to interesting results. The few preliminary experiments we made, however, did not appear very promising.

The ground ginger, *Zingiber officinale*, from Cochin China, was extracted by boiling with alcohol and the solution evaporated after filtration. The viscid residue had a strong odour of ginger, and when heated in a current of steam yielded a small quantity of essential oil lighter than water. A portion of the extract was fused with three times it weight of soda, and the product neutralized with sulphuric acid, and extracted with ether in the usual way. The ethereal solution, on evaporation, left a mass of crystals impregnated with a dark coloured liquid ; these, after purification by pressure and two or three recrystallizations from water, were examined and proved to be protocatechuic acid. They gave the ordinary well-known reactions of protocatechuic acid, and fused at the same temperature. On heating them with excess of bromine in a sealed tube, carbonic anhydride and tetrabromopyrocatechin were formed.

SUGAR IN THE BLOOD AND GLYCOSURIA.

DR. PAVY has recently communicated to the Royal Society two papers which have commanded a deal of space in medical literature, on a subject in relation to which he has been working for many years past. In our opinion, the results of this work seem to bear a very poor relation to the toil. That this is so may be gathered from what follows. Many years ago BERNARD and HENSEN discovered in the liver a kind of dextrin ($C_6H_{10}O_5$), elaborated as they concluded through a decomposition of albumin exerted by that organ, and eventually a theory called "the glycogenetic function of the liver" was developed. On this theory the liver first of all produces dextrin or glycogen, and this becomes sugar which, passing into the blood by way of the hepatic vein, there becomes oxidized in the circulation. The disease known as diabetes mellitus was therefore conjectured to consist in a lack of oxidizing power, so that the sugar is voided in the urine.

At first Dr. PAVY was one of the chief admirers of the theory to which we have alluded, but without entering further into the history of the matter it may be said that in course of time he changed his opinions, and from his later experiments (which were until quite recently of a purely physiological order), he was led to different conclusions. In these studies Dr. PAVY has investigated the causes of glycosuria, or artifical diabetes, and he explains its production when brought about through influences on the nervous system, as due to a vasomotor paralysis affecting the vessels of the chylo-poietic viscera, by which means the blood reaches the portal system without having been dearterialized.* Dr. PAVY was thus led to believe that glycosuria is the result of the presence in the arterial blood of a particular ferment capable of transforming the liver dextrine into sugar. He found that inspiration of carbonic oxide or oxygen gave rise to comparable results, but while by elaborate methods of research he thus attempted to lend weight to his conclusions, he virtually destroyed them, for if glycosuria be the result of the presence of a particular ferment to which oxygen gives rise in the blood, then carbonic oxide cannot give a like result; if it does, then Dr. PAVY's conclusions are wrong, and he himself has shown that the two gases behave similarly. Moreover, many years ago Dr. PAVY claimed to have demonstrated that temporary glycosuria could be induced by impeding respiration. Now unless he can show that under these conditions blood also reaches the liver in an arterial condition, what becomes of his conclusions which regard glycosuria as the particular resultant of an action brought about by arterial blood?

* *Proc. Roy. Soc.*, vol. xxiii., p. 539, and vol. xxiv., p. 51. Also criticism of these researches by C. T. Kingzett (*Chemical News*, vol. xxxii., p. 183).

To be brief, these researches have thrown but very little new light either upon the function of the liver or the disease known as diabetes. We are without a knowledge of its causes, and are not possessed of a rational treatment of the disease. The last two papers read by Dr. PAVY before the Royal Society, on the 14th and 21st ults., relate however to a method of determining sugar when present in the blood, and the application of this method in various cases.

The method virtually consists in properly preparing the blood by coagulation, filtration, and otherwise, and then boiling the solution with excess of potassio-tartrate of copper. The suboxide of copper thus obtained is oxidized by a few drops of peroxide of hydrogen, and the resulting cupric oxide dissolved in nitric acid. From the solution the copper is electrolytically deposited on a platinum spiral, and weighed. In all this we may say at once, there is nothing new. With every particular of the method chemists have long been acquainted, and all that Dr. PAVY can claim is the application of the method to his special objects, but even here he has been anticipated in some measure. However, the results he has obtained are as follows:—In parts per 1000, dogs' blood proved to contain, on an average, 0·787; sheep's blood gave 0·521 part; bullocks' blood an average of 0·543 part sugar per 1000.

Dr. PAVY contrasts these figures with some obtained by BERNARD, who has stated* that the lowest limit of sugar in the blood is 1 per 1000, and that normally it varies from 1 to 3 per 1000. But Dr. PAVY in criticizing BERNARD's results does not tell us whether these figures refer to human blood or not; and other physiological chemists have found sometimes as much as 2 per cent. of sugar in blood. He continues to show that between arterial and venous blood there is virtually no difference in the amount of sugar, whereas BERNARD has arrived at totally distinct conclusions. Both PAVY and BERNARD agree in the spontaneous change occurring in blood after death, which results in the disappearance of sugar; but as regards the other matters to which we have alluded, and wherein these physiologists disagree it is not easy to decide how far each is right or wrong, and further work of a strictly chemico-mathematical nature is required before this can be done.

* *Comptes Rendus*, June 19, 1876, p. 1409.

THE CONFERENCE MEETING.

The Local Secretary of the Conference is apprehensive that our remarks last week on the subject of lodging accommodation for those who attend the forthcoming meeting at Plymouth, may mislead intending visitors. We think this is scarcely possible, but in order to avoid any such result, we may state that though Mr. Clark has found the publication of a tariff of lodgings to be entirely out of the question, he is prepared to secure accommodation for those who apply to him at once with that object. At the same time he adds that there should not be any delay in doing so, and therefore we take this opportunity of impressing upon our readers the desirability of giving prompt attention to the advice of the Local Secretary, and not leaving their applications to the last few days before the meeting if they desire to avoid being awkwardly situated.

BILL TO AMEND THE SALE OF FOOD AND DRUGS ACT.

Quite at the fag end of the Parliamentary Session just as it has become an interesting question, which of the Bills before the legislature will meet the untoward fate of being included in the "slaughter of the innocents," a Bill to amend the Sale of Food and Drugs Act (1875) has been brought forward in the House of Commons. Leave to bring the Bill in was given to Mr. Isaac on Monday, and on Wednesday it was read a first time and ordered to be printed. At the hour of going to press, however, copies could not be obtained.

THE UTILITY OF LOCAL ASSOCIATIONS OF PHARMACISTS.

We are pleased to find that the chemists in country towns are becoming alive to the fact that it is greatly to their interest to form associations. We have received from the Lancaster and District Chemists' Association a List of Dispensing Prices which it appears to have adopted. We have no doubt the Hon. Secretary to this Association, Mr. Bagnall, would gladly forward a list and other information to gentlemen who are desirous of forming societies in other country towns.

DEATH OF DR. A. HUSEMANN.

We regret to announce the death, on the 17th inst., of Dr. August Husemann, of Coire, at the early age of 44 years. Dr. Husemann is perhaps best known in this country as the author, in conjuncture with his brother, of the valuable work, 'Die Pflanzenstoffe in chemischer, physiologischer, pharmacologischer und toxicologischer Hinsicht.'

We observe that Messrs. T. and H. Smith and Co., of Edinburgh and London, have received a diploma of honour and gold medal—the highest award bestowed—for chemical products, and a gold medal for essence of coffee and aërated waters, at the South African International Exhibition. In connection with the same exhibition, a gold medal has also been awarded to Mr. Hickisson, the proprietor of the Crystal Palace Marking Ink.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

July 12th, 1877.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Haselden, Linford, Martindale, Moss, Southall, Taylor, and Umney.

MAJOR EXAMINATION.

Twelve candidates were examined. *Three* failed. The following *nine* passed and were declared qualified to be registered as Pharmaceutical Chemists:—

Avison, David ....Wakefield.
Fletcher, Redfern.............. Newcastle-upon-Tyne.
Hardwick, Stewart ....Sleaford.
Holmes, Alfred John ....Preston.
Jones, Thomas ....Tenby.
Longman, John Ham ....Exeter.
Simpson, John ....Lewes.
Tuck, Walter Barber ....Eastbourne.
Wallis, Owen ....Hastings.

MINOR EXAMINATION.

Nineteen candidates were examined. *Seven* failed. The following *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Atkins, William Ralph ....Salisbury.
Balcombe, Charles ....Ticehurst.
Bartlett, Hubert ....London.
Cliff, James ....Wakefield.
Gosney, Charles Frederick ......Crewkerne.
Harding, Christmas ....Denbigh.
Kent, Edward ....London.
Lister, Charles Edward ....Manchester.
Middleton, Ambrose ....Nottingham.
Milton, Harry ....Exeter.
Wilkerson, Wallace .... Weymouth.
Williams, Alfred Joseph ....London.

July 13th, 1877.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Haselden, Linford, Martindale, Moss, Southall, Taylor, and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MAJOR EXAMINATION.

Eleven candidates were examined. *Nine* failed. The following *two* passed and were declared qualified to be registered as Pharmaceutical Chemists:—

Reece, Thomas ....Llandilo.
Snell, Charles Henry ....York.

MINOR EXAMINATION.

Sixteen candidates were examined. *Nine* failed. The following *seven* passed and were declared qualified to be registered as Chemists and Druggists:—

Foster, James Edward...........Bridgwater.
Jackson, Barnet Edward.........Heywood.
Newbery, Frank ....Lambeth.
Revell, John ....Plymouth.
Roe, Robert ....Lancaster.
Shone, Owen Ellis ....Lambeth.
Todd, Matthew James...........Sunderland.

MODIFIED EXAMINATION.

One candidate was examined and declared qualified to be registered as a Chemist—

Hickman, William ....Dorking.

July 18th, 1877.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Haselden, Linford, Martindale, Moss, Southall, Taylor, and Umney.

Dr. Greenhow was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

Eight candidates were examined. *Four* failed. The following *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Burden, John Britten ....London.
Chapman, Joseph John ....Chertsey.
Giles, William Egbert ....Penydarran.
Griffiths, John Moore ....Birkenhead.

MINOR EXAMINATION.

Twenty-two candidates were examined. *Seven* failed. The following *fifteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Austin, Josiah ....Nechells, Birmingham.
Clarabut, Frank Stone............Folkestone.
Clarke, Ethelbert..................Maidstone.
Harpham, John ....Newark.
Jones, Thomas Bevan ....Merthyr.
Lacey, James ....Clifton.
Mead, Charles John...............Wimborne.
Moore, John William ....Northampton.
Nichols, Arthur Fitzroy ....Leicester.
Oldershaw, William ....Nottingham.
Ord, Septimus William ....Newcastle-on-Tyne.
Perry, John ....Congleton.
Saunders, James Warnes ......Hackney.
Slinger, Robert Thomas .... Manchester.
Warburton, William ....Haslingden.

July 19th, 1877.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Haselden, Linford, Martindale, Moss, Southall, Taylor, and Umney.

MAJOR EXAMINATION.

Seven candidates were examined. *Four* failed. The following *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Barron. William ....Leamington.
Maggs, Frederick Richard ......Yeovil.
Rickarby, Árthur George ......Bromley.

MINOR EXAMINATION.

Twenty-two candidates were examined. *Eleven* failed. The following *eleven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Abbott, George......................Liverpool.
Bishop, Henry ....Wisbeach.
Cobb, Joseph Septimus ....Doncaster.
Edwards, Charles Richard ......Harrow-on-the-Hill.
Inglis, William Keiller ....Ashton-under-Lyne.
Jenkins, Henry......................Salisbury.
King, William ....Southend.
Mills, William Hamer............Heywood.
Perkin, Thomas ....Stourbridge.
Walker, Charles Joseph ....London.
Wild, John ....Bury.

July 20th, 1877.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Haselden, Linford, Martindale, Moss, Southall, and Umney.

Dr. Greenhow was also present.

MINOR EXAMINATION.

Twenty-six candidates were examined. *Eighteen* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

James, Richard.....................Camborne.
Longbotham, Alonzo ....Ripon.
Riley, John Cowgill...............York.
Roberts, David ....Rhyl.
Singleton, Richard ....Preston.
Taylor, Henry Patrick............London.
Ward, John Septibo...............Stamford.
Wooldridge, Elijah ....Cradley Heath.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's examination:—

Certificates of the University of Cambridge.

Lewis, Albert Sturt ....London.
Littlewood, Harry ....Hempstead.

Certificate of the University of Oxford.

Watkins, William Richards ...Llanelly.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The competitions for the two sets of prizes announced by the Council of the Bristol Pharmaceutical Association took place on June 22nd and 29th. Messrs Stoddart, Schacht and White kindly undertook the conduct of the examinations, and the report of these gentlemen was as follows:—

CHEMISTRY.

Seven candidates presented themselves. The questions were creditably answered by all, the three first returning exceedingly good papers.

1st prize, £3 3*s.* 0*d.*—Mr. Morris.
2nd prize, £2 2*s.* 0*d.*—Mr. R. S. Cuff.
Extra Prize, £1 1*s.* 0*d.*—Mr. W. Stroud.

BOTANY.

Four candidates came forward. The papers in this subject were not so good as the preceding, and only a second prize of £2 2*s.* was awarded to Mr. W. Stroud.

Candidates for the above were obliged to be associates of the Bristol Pharmaceutical Association, and must have attended a systematic course of instruction on the subject in which they competed.

HILLS PRIZES.

This competition was open to all associates of the Bristol Pharmaceutical Association who had not passed either the Minor or Modified examination at Bloomsbury Square. Four gentlemen presented themselves for this examination in materia medica and pharmacy, and the examiners report that very good and careful papers were returned.

1st prize, £3 3*s.* 0*d.*—Mr. T. W. Hall.
2nd prize, £2 2*s.* 0*d.*—Mr. W. Stroud.
3rd prize, £1 1*s.* 0*d.*—Mr. W. Powell.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The annual meeting was held at the Great Western Hotel, on Friday 13th inst., Mr. Arblaster in the chair. The Committee presented their Annual Report and Balance Sheet.

The Chairman congratulated the Association upon its satisfactory financial condition, there being a balance of £30 1*s.* 8*d.* in the hands of the Treasurer.

The report of the Librarian was very satisfactory, the library having been more resorted to than in any previous year. Many additions to the library of useful and valuable works were reported, and several books had been very kindly presented by the authors. The Committee recommended a further grant of money for the purchase of books.

Mr. Stokes Dewson reported that the educational work of the past year showed very gratifying results, just over 30 students had presented themselves during the past year, of these 25 had passed; and in a recent examination in London out of seven candidates from this school six had passed; such results he considered placed the Birmingham school in the foremost rank among provincial schools and compared very favourably with results obtained in the metropolis. One student also obtained Queen's prize for botany. Considerable additions were recommended to the prizes (which are awarded after competitive examination only to those who have passed their pharmaceutical examinations), and a new prize of one guinea was offered by the President, Mr. W. Jones.

The result of the recent prize examinations was as follows:—

First prize (for men holding Minor qualification), 1876 Mr. R. Hollick.

First prize (for men holding Minor qualification), 1877 Mr. C. Arblaster.

Second prize (for men holding Minor qualification), 1877 Mr. S. Russon.

First prize* (for men having passed Preliminary), Mr. Prosser.

Second prize (for men having passed preliminary), Mr. Norman Smith.

The election of officers was then proceeded with. Mr. W. Jones, the President, was unanimously re-elected, Mr. F. S. Morris, the vice-president, Mr. Lucas, the treasurer, were also re-elected. Mr. Stokes Dewson was appointed honorary secretary, *vice* Mr. H. Sanderson, who from pressure of private business had resigned. The following gentlemen were elected to form the Committee:—Messrs. Alldridge, Arblaster, Barclay, Brassington, Brown, Chase, Churchill, Gibson, Green, Grieves, Healy, Holdsworth, Pare, Price, Sanderson, Snape, A. Southall, W. Southall, Wilkes, Wilcox, Whittles.

It was also reported that the soiree had been a success and a good balance of profit had been realized.

On the motion of Mr. Hayden, seconded by Mr. Pare, the meeting was adjourned until August 8th, when Mr. Churchill will read his paper upon the "Position and prospects of the trade." A cordial vote of thanks to the Chairman brought the meeting to a close.

Proceedings of Scientific Societies.

KING AND QUEEN'S COLLEGE OF PHYSICIANS.

THE INFLUENCE OF CHEMICAL CONSTITUTION ON PHYSIOLOGICAL ACTIVITY.†

BY J. EMERSON REYNOLDS, M.D., F.C.S.,

Professor of Chemistry, University of Dublin, etc.

Introduction.

(*Concluded from p. 57.*)

Another view of the matter may be taken, which is in accordance with the results of the experiments hitherto made. If we suppose that both the pyro- and meta-phosphates are attracted to and accumulated within an important organ by means of an essential basic constituent of that organ with which the phosphates form slightly soluble compounds, we are justified in expecting that the interference of the pyro-phosphate with the performance of the functions of the organ would be much greater than that of the meta-phosphate, because a given weight of basic substance is capable of attracting to a particular point precisely twice the weight of phosphorus in the form of pyro-phosphate as in that of meta-phosphate (see diagram); and the interference with the functions of an organ is, at least, likely to bear some simple and direct proportion to the amount of foreign matter accumulated within or around it. This view is evidently consistent with the fact that the pyro-phosphate is the most poisonous of the two compounds; but, I must add, that the explanation which I have just given in outline, is but one of many which might be suggested—my chief reason for having selected it for remark, in preference to others, being that it is the one which seems to be least open to objection on chemical grounds.

I will now refer to some corresponding experiments on vanadates made by Messrs. Priestly and Larmuth.

The admirable researches of Roscoe have recently made us acquainted with the true nature and relations of the compounds of the rare metal vanadium. It has been long known that vanadium yields several acids analogous to the phosphoric acids to which reference has been made. Roscoe has shown that a series of sodic vanadates exist corresponding to the sodic phosphates already referred to. Thus we have ortho-, pyro-, and meta-vanadates, which are the strict analogues of the ortho-, pyro-, and meta-phosphates, and their formulæ may be written in a similar manner, the pentad element phosphorus being replaced by vanadium (=V), which is also a pentad. In a very elaborate memoir Priestly has given the results of his researches on the physiological action of the vanadic salts, and has shown that they exert a strong irritant action on the gastro-intestinal mucous membrane, while they are also remarkably active as poisons of the spinal cord, the medulla oblongata, and the heart. The active vanadium compounds paralyse the vaso-motor centres; they do not affect the vagus as a cardiac inhibitory nerve, but exert some influence upon the intrinsic nervous mechanism of the heart.

Larmuth has compared the action of the three sodic vanadates, and shown that the ortho-vanadate exerts distinct poisonous action, though less than the pyro- and meta-vanadates; he has further proved that the pyro-vanadate is most energetic as a poison, while the meta-vanadate is intermediate in activity between the two extremes. The order of activity is, therefore, the same in the group of vanadates as in that of the phosphates. I may add that the analogous arsenates agree to some extent with the vanadates in being all poisonous, and in exhibiting differences in degree of activity.

In the cases just mentioned the observed differences in extent of action are probably to be explained by the aid of the considerations which guided us in dealing with the group of phosphates, for it is evident that the degree of activity is in the inverse ratio to the degree of satisfaction of the triad nucleus (PO''', VO''', or AsO''') with basic material, and seems to be dependent upon that condition. It will be noted, however, that the ortho-vanadate and the corresponding arsenate differ from the ortho-phosphate in exerting well-marked physiological action. It may be that this marked distinction is to be connected with the facility with which ortho-vanadates and arsenates can be reduced to lower states of oxidation by means which are wholly insufficient to effect the reduction of phosphates. The product of such reduction is necessarily an unsaturated compound, and is, therefore, capable of exerting physiological action. Rabuteau has shown that certain bodies easily suffer reduction or deoxidation during absorption—thus selenious acid (H_2SeO_3) and tellurous acid (H_2TeO_3), or selenites and tellurites, lose oxygen in transit, and are reduced to selenuretted hydrogen (H_2Se) and telluretted hydrogen (H_2Te) respectively.

* Prize value 30 shillings, given by Mr. R. T. Barclay.

† The substance of two lectures delivered before the King and Queen's College of Physicians in Ireland, being the first and second of the Annual Scientific Lectures for 1877. From the *Dublin Journal of Medical Science.*

But this reducing action is not very powerful, as shown by the fact that sulphurous acid (H_2SO_3) and sulphites do not suffer reduction, and in fact are oxidized into sulphuric acid and sulphates; and even the salt commonly called "hyposulphite of sodium" (Na_2SO_3S, or sodic thio-sulphate) resists reduction like the sulphites and the sulphates. Vanadates and arsenates seem to belong to the class of bodies which suffer partial reduction during absorption, or when in contact with insufficiently oxidized blood, while the phosphates do not suffer that change, so far as we know.

In view of these facts we have reason to think that the action of the vanadates and arsenates is complicated by secondary changes, whose effect is quite intelligible in altering physiological activity. It is, then, in the group of phosphates that we recognize most distinctly the influence of the degree of saturation or satisfaction of the grouping element upon the physiological activity of the compound.

If the reduction theory which we have just suggested be true, a saturated vanadium or arsenic compound which happened to be *difficult of reduction* ought, even if easily dissolved and absorbed, to be physiologically inactive. I cannot bring forward evidence affecting vanadium compounds as yet, but the researches of Bunsen have made us acquainted with a very remarkable compound of the much more energetic metal, arsenic, which fulfils our expectations completely. The substance referred to is called kakodylic acid, and is related to one of the arsenious acids in the following way:—

Arsenious Acid.	Kakodylic Acid.
$O{=}As{<}:$ $\vert$ OH	$O{=}As{<}^{CH_3}_{CH_3}$ $\vert$ OH

Arsenious acid we all know to be highly poisonous, but the easily soluble kakodylic acid, containing 54 per cent. of metallic arsenic, is inert.

Passing from this group of bodies, let me now briefly refer to the alcohols. We are acquainted with a large number of chemical compounds which are classed by chemists as alcohols, because they resemble more or less in chemical relations the body to which the term "alcohol" is commonly restricted; thus the syrupy liquid glycerine belongs to one division of the alcohols, and the white crystalline substance mannite, extracted from manna, belongs to another section. The bodies with whose action I now propose to deal differ from those just referred to in being very closely related to the chief member of the group—the common alcohol of wine—as well in their chemical relations as in their action upon the animal organism. Their names and formulæ are as follows:—

Monatomic Alcohols.

Methyl alcohol (wood spirit)	$-H$ $\vert$ CH_2 $\vert$ $-OH$
Ethyl alcohol (spirit of wine)	$-CH_3$ $\vert$ CH_2 $\vert$ $-OH$
Propyl alcohol	$-CH_2CH_3$ $\vert$ CH_2 $\vert$ $-OH$
Butyl alcohol	$-CH_2(CH_3)_2$ $\vert$ CH_2 $\vert$ $-OH$
Amyl alcohol	$-CH_2CH(CH_3)_2$ $\vert$ CH_2 $\vert$ $-OH$

All these alcohols, except the first of the series, are produced during the fermentation of grain spirit; but the three last-named occur in very small quantity, and are found in the poisonous "fusel oil" of new whiskey. The poisonous action of "fusel oil" is chiefly due to the presence of these higher alcohols.

These alcohols, or isomeric modifications of them, have been made the subject of numerous and interesting researches, conducted with a view to the comparison of their physiological action. The experiments which are of most direct interest to us in the present connection are those of Messrs. Dujardin-Beaumetz and Audigé, and of Dr. B. W. Richardson, of London. As the researches of Dr. Richardson on this subject are, no doubt, familiar to my hearers, I shall confine my remarks to the work of the French investigators.

Messrs. Beaumetz and Audigé have shown that the alcohols above named act most energetically when introduced into the stomach of an animal. By means of a series of experiments, which seem to have been conducted with care, they have arrived at the conclusion that the lethal dose of each alcohol per pound weight of animal is approximately—

42	grains of	ethylic	alcohol
33	„	propylic	„
13	„	butylic	„
5	„	amylic	„

It would appear, then, that the alcohols which have the most complex molecules are most energetic. Beaumetz has, however, still more recently shown that methyl alcohol (the lowest term of the series of compounds) is more poisonous than the alcohol of wine. With this important exception, the statement seems to be generally true.

Now, all these bodies are represented in the diagram as saturated compounds, and they are so; but they all contain one atom of hydrogen which is easily displaced by various radicles, so that under favourable conditions they are capable of acting as if they were unsatisfied though saturated. It is probable that the physiological activity exhibited by the lower members of the series—with the exception of methylic alcohol—is due to this cause, but it cannot be the sole cause, else we should expect all the members of the group to act with nearly equal energy; and Beaumetz and Audigé's results, cited above, as well as Richardson's, prove that the alcohols are not equally active. It is probable that the members of the series of more complex constitution not only act as I have just mentioned, but partially break up in the organism under the influence of oxygen or other agents, and afford as products of their decomposition more simple but unsaturated bodies, which then exert the marked effects of compounds of that class. As the number of carbon atoms in the molecule of the alcohol increases, the number of unsaturated bodies which a given weight can yield also increases; and it is, at any rate, a remarkable coincidence that there is a corresponding gain in physiological activity.

It is now necessary to turn for a moment to the first member of the group of alcohols—methylic alcohol—a body which is, according to Beaumetz, more poisonous weight for weight than the more complex alcohol of wine. If we admit the fact, the explanation of it is probably to be found in the circumstance that methyl alcohol can be much more readily broken up by oxidation than ethyl alcohol; and one of its products of oxidation is formic acid—a substance which, though seemingly inactive when directly introduced into the system, appears, according to the researches of Byasson, to be capable of producing very marked effects when formed within the organism, and so presented, as it were, in the nascent state.

Before leaving the group of alcohols, I may add that we are acquainted with isomeric propylic, butylic, and amylic alcohols, whose physiological effects yet require careful study.

If time permitted I might refer to other and highly interesting researches in support of our proposition—notably to those of Cahours and Jolyet on the action of substituted anilines, and of Dewar and M'Kendrick on the action of the pyridine bases, while the study of the action of chloral hydrate and its homologues, of formic and oxalic acids, and of many other bodies, could be shown to afford additional evidence—but I trust enough has been said to show that a strong experimental foundation exists for the statements made.

Before passing to the consideration of our next proposition, I may be permitted to digress so far as to point out that we can alone correctly compare the physiological activity of one element with that of another when we study compounds of similar chemical constitution. Thus sodic nitrate (meta-nitrate), meta-phosphate, meta-vanadate, and probably meta-arsenate, accord in composition with the general formula, $NaRO_3$, and are similarly constituted bodies. If otherwise suitable, their comparative study ought to afford us data for the determination of the relative physiological activity of the elements, nitrogen, phosphorus, vanadium, and arsenic, when in that particular form of combination. So far as experiments of this kind have been made with the four elements just named, it appears that nitrogen is lowest in the scale of activity; then follow phosphorus and vanadium, while the most energetic of all is arsenic. If we now compare the atomic weight of these elements, we find that the physiological activity increases with the atomic weight. Thus, the

Atomic weight of nitrogen is	. . .	14·0
,, ,, phosphorus	. . .	31·0
,, ,, vanadium	. . .	51·2
,, ,, arsenic	. . .	75·0

Considerations of this order led Rabuteau to state generally that the physiological activity of an element is directly proportional to its atomic weight. I need only to mention here, however, that "Rabuteau's law" is but partially true, even when we compare similarly constituted groups of active bodies, for when we thus compare some corresponding compounds of chlorine, bromine, and iodine, we find that chlorine (at. wt. 35·5) is more active than bromine (at. wt. 80), and bromine than iodine (at. wt. 127). In fact, if we substituted for "Rabuteau's law" the statement that the physiological activity of an element is in the inverse ratio to its attraction for oxygen, we should enunciate a "law" which seems to be, on the whole, open to fewer objections than Rabuteau's, but which is. nevertheless, governed by the question of constitution.

In this connection I might also refer to the interesting experiments of Blake, who sought to connect the physiological action with physical structure, and who asserts that isomorphous salts produce similar effects on the animal organism; and to the experiments of Dr. B. Wills Richardson on the comparative effects of the ordinary urea and the sulpho-urea which I discovered some years ago; but I must leave the detailed consideration of these cross-comparisons for another and more convenient time.

THIRD PROPOSITION.

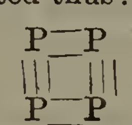
Our third proposition asserts "*that bodies which are unlike in composition, but which agree in being either actually or constructively unsaturated, and are alike in certain marked chemical relations, often agree in physiological action.*"

Few bodies differ from each other more than the element phosphorus from the well-known compound called pyrogallic acid, or pyrogallol; yet Personne asserts that they act in the same way in the animal organism, because they agree in one strongly-marked chemical character—namely, intense avidity for oxygen.

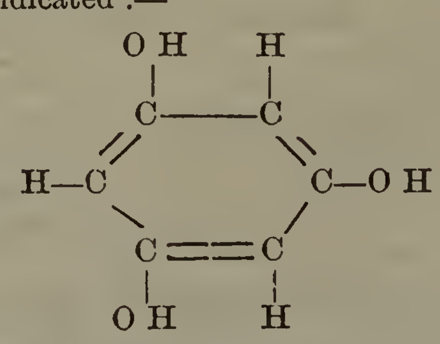
Personne believes that absorbed phorphorus poisons by abstracting oxygen from the blood, and that the death of an animal poisoned by phosphorus is really due to asphyxia. If this be a true explanation, argued M. Personne, any other body capable of absorbing oxygen with equal energy from the blood ought to resemble phosphorus in its action on the animal organism. Pyrogallic acid is such a body, especially when present in a slightly alkaline liquid; consequently Personne injected sixty grains of the pyrogallic acid, dissolved in a large quantity of water, into the stomach of a dog. Symptoms of poisoning were quickly developed, and closely resembled those caused by phosphorus. The animal died, and the morbid changes observed were precisely similar to those well known to be produced by phosphorus. A second dog received a dose of thirty grains of the pyrogallic acid, and the same train of symptoms and morbid appearances were observed.

Ordinary waxy phosphorus is, as is well known, a body which possesses most energetic properties, and is unsaturated, as all elements are. It is, moreover, one of the very few chemical elements which admits of being absorbed to any sensible extent in the elemental condition, owing to its solubility in, or miscibility with, fatty matter. Pyrogallol, or pyrogallic acid, has the composition represented by the formula $C_6H_3(OH)_3$, and the carbon atoms within its molecule are very far from having their "bonds" completely saturated by hydrogen and hydroxyl, as there are at least six "bonds" latent in the group, and some of these appear suddenly to become active when the compound is mixed with an alkali, although in the absence of alkali the pyrogallol does not exhibit any very energetic properties. The extreme avidity with which ordinary gaseous oxygen is absorbed by the alkaline pyrogallic solution seems to be due to the breaking up of the pyrogallol, under the influence of the alkali, into a number of unsaturated groups, which are as energetic in some at least of their chemical relations as phosphorus, for they even more readily combine with free oxygen. Personne's view—that any pyrogallol introduced into the slightly alkaline blood acts in a similar manner—was, therefore, not an unreasonable one.

The molecule of pentad phosphorus is chemically divisible into four parts, or atoms, unlike the free molecules of most other elements, which consist of two atoms only. The probable structure of the phosphorus molecule on this view is represented thus:—



The probable structure of the molecule of pyrogallol may be thus indicated:—



This mode of writing the formula enables us easily to understand how the body can break up symmetrically under the influence of alkali into unsaturated groups. While ready to accept Personne's experiments I am not disposed to follow him to his conclusion that phosphorus poisons by abstraction of oxygen because (1) the symptoms of phosphorus poisoning are not those common to asphyxiants; and (2) Curie and Vigier have shown that the quantity of phosphorus required to poison a rabbit weighing 3 kilogrammes (6·6 lbs.) is only sufficient to absorb one centigramme (·154 grain) of oxygen. The facts only warrant the statement contained in our proposition, as phosphorus and pyrogallol seem to agree in physiological action as well as in power of absorbing oxygen, though they are wholly unlike in composition; and it is highly probable that this resemblance in activity is due to the actually unsaturated condition of phosphorus, and to the constructively unsaturated condition of pyrogallol.

FOURTH PROPOSITION.

I have now to assert that "*the result of chemical addition to unsaturated molecules is either to destroy or to materially modify their physiological action.*"

In all the cases hitherto dealt with we have been able to connect physiological activity with the actual or constructive unsaturation of the molecule of the body considered. We now have to determine the effect of chemical addition to the unsaturated or unsatisfied groups, upon the physiological activity of the body experimented with, and to note how far this is altered. In all such experiments we have to take care that the elements or groups added shall produce a new compound which will not easily decompose in the animal organism.

Carbonic oxide is a good example of an unsaturated compound whose special action is destroyed by the addition of an atom of oxygen, so as to form the familiar carbon dioxide or "carbonic acid." In carbonic oxide the tetrad carbon atom has but two of its four "bonds" satisfied by diad oxygen; in the higher oxide all the bonds are engaged.

Carbonic oxide.	"Carbonic acid."
$:>C<>O$	$O<>C<>O$

The unsaturated carbonic oxide we know readily unites with the hæmoglobin of the blood to form Preyer's carbonic oxide-hæmoglobin—a body which, when once formed, very slowly undergoes change, even in presence of oxygen, and therefore neutralizes, for the time, a certain quantity of the great oxygen carrier of the blood, and interferes to a corresponding extent with the vital processes. If the amount of carbonic oxide compound formed is large, the absorption of oxygen by the blood can take place to a very limited extent, and death ensues. On the other hand, "carbonic acid"—the saturated compound—does not combine with hæmoglobin, and, when inhaled by an animal, prevents oxidation chiefly by excluding air, or by so diluting it as to render the oxygen supply insufficient for the amount of blood pumped through the lungs, and consequently favours the accumulation of effete products in the system.

The poisonous action of carbonic oxide is direct and consequent on the unsaturated condition of its molecule. The poisonous action of "carbonic acid" seems to be, in great part, traceable to a physical cause. The result of the chemical addition in this instance is, at any rate, to materially modify physiological action.

Bunsen's remarkable experiments on the kakodyl compounds, already alluded to, have shown that chemical addition of a certain kind ($2\ CH_3$) to an arsenious acid destroys the power of that well-known poison.

Again, Rabuteau states that cyanates are not poisonous. If we regard potassic cyanide as the analogue of a carbamine, as I have already pointed out, its relation to a cyanate may be thus shown:—

Potassic cyanide.	Potassic cyanate.
$:>\overset{\diagup K}{N}{=}C<:$	$:>\overset{\diagup K}{N}{=}C<O$

Thus by the addition of an atom of oxygen to potassic cyanide the salt loses its extraordinary physiological activity.

I may remind you of the experiments which have been previously dwelt upon, and which prove that sodic ortho-phosphate is inert, though the pyro- and meta-phosphates exhibit considerable physiological activity. I have pointed out that the two latter salts can easily be converted into the inactive ortho-phosphate by the addition of basic oxide; hence chemical addition in these as in the other cases mentioned destroys the physiological activity of the body so treated.

In most of the cases just cited in support of our proposition there is a seemingly total destruction of the physiological activity of each body consequent upon the complete satisfaction of the tendency to accumulate matter within the molecule. I shall now turn to the work of the distinguished pioneers of this branch of inquiry—Drs. Crum-Brown and Frazer, whose results place beyond question the fact that chemical addition to unsaturated compounds—notably to the vegetable alkaloids—can materially modify, but not necessarily destroy their physiological activity; but it must be borne in mind that in all those cases in which a certain residual effect has been observed we are unable to assert that all the "bonds" of the body treated have been fully satisfied. In fact, the argument from analogy rather leads us to the conclusion that the satisfaction is but partial.

The two well-known alkaloids, strychnia and brucia, are unsaturated bodies, for they both easily unite with methyl iodide or sulphate to form seemingly saturated compounds whose relation to the parent base may be thus represented in the cases of the iodides:—

Strychnia.	Iodide of methyl-strychnium.
$C_{21}H_{22}O_2N_2)<:$	$C_{21}H_{22}O_2N_2)\begin{matrix}\diagup CH_3\\ \diagdown I\end{matrix}$
Brucia.	Iodide of methyl-brucium.
$C_{23}H_{26}O_4N_2)<:$	$C_{23}H_{26}O_4N_2)\begin{matrix}\diagup CH_3\\ \diagdown I\end{matrix}$

The methylated derivatives of these and other alkaloids are not only easily prepared, but they possess the great advantage of being difficult of decomposition by the agents they are likely to meet in the animal organism. The comparative physiological experiments made by Drs. Crum-Brown and Frazer with strychnia and its methylated derivatives, conducted as they were, with consummate skill, have afforded the remarkable results which I can best state in the words of the distinguished investigators:—

"These experiments clearly prove that the methyl derivatives of strychnia possess a very different action from strychnia itself. In none of our experiments, not even in the fatal cases, were the symptoms those of strychnia-poisoning; no starts nor spasms occurred, nor did stimulation give evidence of the slightest increase of reflex excitability.

"In fact, a condition exactly the reverse of that produced by strychnia was produced by these compounds. In place of violent spasmodic contractions and muscular rigidity, the appearances were those of paralysis, with a perfectly flaccid condition of the muscles. The limbs of the animal first yielded, its head gradually sank until it rested on the table; by-and-by it lay in a perfectly relaxed condition, and when death occurred it was due to stoppage of the respiratory movements. In the autopsies further evidence was obtained to distinguish the effects of the methyl-strychnium compounds from those of strychnia. The heart was found acting with nearly its normal rapidity; the spinal motor nerves were either paralysed or nearly so; and in place of the almost immediate occurrence of *rigor mortis* that follows the action of strychnia, the muscles continued flaccid, contractile, and alkaline for many hours.

"These symptoms are sufficient to suggest a close resemblance between the action of the methyl derivatives of strychnia and that of curare (*wourali*)—a well known and elaborately studied poison. In a recent publication Professor Schroff, of Vienna, has indicated a resemblance of this kind between the nitrate of methyl-strychnium and curare. Both substances undoubtedly produce a condition of general paralysis; but the special characteristic of curare-poisoning is that this paralysis is the result of an impairment or destruction of the function of the peripheral terminations (end-organs) of the motor nerves. It is impossible to demonstrate such an action without undertaking experiments of a special character. We accordingly extended our research for the purpose of examining this question.

"The sciatic artery and vein were tied at the knee of a frog, and one-tenth of a grain of sulphate of methyl-strychnium, dissolved in distilled water, was injected under the skin of the back. Eight minutes afterwards the frog was lying in a perfectly flaccid state, and in ten minutes irritation of any portion of the skin produced energetic movements of the tied limb *below the points of ligature*, but nowhere else. The sciatic nerve of the untied limb was now exposed, and, on stimulating it with a weak interrupted galvanic current, movements occurred in the tied limb only; not the slightest effect occurred in any part to which the poison had access. At the same time the muscles were everywhere active, and freely contracted when directly stimulated. The sciatic nerve was then exposed in the tied limb *above the points of ligature*, and on stimulating it energetic movements occurred below the knee of that limb, and there only. The heart was at this time acting at the rate of fifty per minute.

"This experiment was repeated with one grain of iodide of methyl-strychnium, and the same general results were obtained. The evidence that was thus acquired in favour of an action on the peripheral terminations of the motor nerves was strengthened by a modification of this method of experiment.

"The right gastrocnemius muscle of a frog was carefully dissected from its connections, excepting that its origin and insertion, and the nerve-fibres entering it, were untouched, and that all its blood-vessels were ligatured. One tenth of a grain of sulphate of methyl-strychnium, dissolved in five minims of distilled water, was then injected under the skin of the back. Twenty minutes afterwards, the animal being in a perfectly relaxed and motionless condition, the two sciatic nerves were exposed. Galvanism of the left produced no movements of the left limb, while galvanism of the right produced energetic movements of the right limb, which were seen to be due solely to contraction of the right gastrocnemius muscle, the other muscle remaining motionless. At the same time direct stimulation by galvanism caused contractions as freely in the poisoned muscles as in the non-poisoned right gastrocnemius.

"In an experiment, in which iodide of methyl-strychnium was substituted for sulphate, the effects were the same. We have, therefore, demonstrated that the methyl-strychnium derivatives produce paralysis and death by destroying the function of the motor nerve end-organs, and that their mode of action is, therefore, identical with that of curare. This conclusion is an extremely curious and interesting one. It is difficult to imagine a more decided modification in the action of any substance than has been produced by the addition of iodide or sulphate of methyl to strychnia. The striking characteristic of strychnia-action is the great and uncontrollable activity of the muscular-system; that of curare, of iodide and sulphate of methyl-strychnium, and, as we shall presently see, of several other similarly modified poisons, is the flaccid and motionless condition caused by the impossibility of exciting muscular action through the nervous system. So opposite are their effects that physiologists look upon curare as a powerful counter agent to strychnia, while physicians have employed it with success in the treatment of strychnia poisoning and of tetanus. It is remarkable that by so simple a chemical process so thorough a change should be produced in physiological action."

The same line of experiment was adopted in the case of brucia, thebaia, codeia, and morphia, and with similar results. The convulsant action of morphia was destroyed by the addition of methyl iodide or sulphate to the group; and, strange to say, the alkaloid so modified did not produce hypnotic effects in man or other warm blooded animals.

The results afforded by atropia, however, possess even greater interest than those which I have just referred to. Atropia, unlike the other alkaloids, not only acts as a convulsant, but also on the peripheral terminations of the motor nerves, though in a minor degree. The new compound produced when the alkaloid is treated with methyl iodide—the iodide of methyl-atropium—does not act as a distinct convulsant on the animal organism; but the action of the alkaloid upon the motor nerves is greatly exalted by the addition, without interfering with the mydriatic action of atropia.

The general conclusions arrived at in the course of this highly important investigation were—

1. That the addition of methyl iodide or sulphate to the alkaloid molecule profoundly alters the physiological action of the body.

2. That the methyl derivatives of all the alkaloids act on the peripheral terminations of the motor nerves.

The first of these results is evidently of chief importance for our present purpose, as my aim in this portion of the lecture has been to show that the result of chemical addition to unsaturated molecules is to materially modify their physiological action.

We know so little of the chemical constitution of these alkaloids that we are unable to assert that the addition of a methyl compound fully saturates the molecule. But even if, strictly speaking, *saturated* by methyl iodide, the attractive powers of the components of the bodies are not necessarily fully *satisfied*—a distinction the value of which I endeavoured to point out in referring to the experiments with the sodic phosphates. The convulsant action of any of the alkaloids experimented with is unquestionably connected with the existence of two unsaturated "bonds" which tend strongly to attach the molecule to other matter. Save in the case of atropia, this power of attachment is so great that the widely different paralysing action scarcely comes into play until the molecule has been saturated with CH_3I. In atropia the paralysing action rises more nearly to the level of the convulsant, so that in that alkaloid we have, as it were, a polar condition.

The train of thought suggested by these considerations is highly attractive, but were we to pursue it we should probably be led beyond the bounds of legitimate scientific speculation. I must, therefore, rest content with having suggested a probable cause for the residual and distinct action of the alkaloidal groups after the saturation by methyl iodide or sulphate.

Conclusion.

The evidence adduced in support of the four propositions which I sought to establish in these lectures could have been largely supplemented, but I preferred to select some well marked cases for comment rather than to attempt to deal with the whole of this wide subject in the necessarily short time allotted to these discourses. I trust, however, that the observations made have sufficiently shown that the study of the chemical constitution of medicinal substances, and of bodies not yet used in therapeutics, should go hand-in-hand with the study of their physiological action, as the latter is evidently dependent to a great extent on the mode of grouping of the components of the molecules.

Having thus connected chemical constitution, rather than mere composition, with physiological activity, it is reasonable to expect that the effect produced by an active body within the organism can be explained on ordinary chemical principles. In dealing with several of the cases of physiologically active bodies I have shown that we can trace out to a certain small extent the probable *rôle* performed by some of the compounds within the organism; but our knowledge of the chemical changes involved in vital processes is as yet too limited to justify us in going far in this direction. I may, however, supplement any observations made under special heads by pointing out here that if we exclude from consideration those bodies which exert a local corrosive action on the gastrointestinal surface, and those which seem (like carbon dioxide) to act *chiefly* by quenching oxidation, the remaining substances which are chemically and physiologically active can directly or indirectly interfere with the production of nerve force in one or more of at least five different ways :—

1. By directly removing oxygen from the blood, and thus interfering with the ordinary processes of oxidation.
2. By uniting with hæmoglobin to form compounds analogous to carbonic-oxide-hæmoglobin, or to Ray Lankester's cyano-hæmoglobin, thus preventing the normal production of oxy-hæmoglobin.
3. By combining with effete material and increasing the difficulty of its removal by oxidation or otherwise.
4. By withdrawing from living tissue material essential to its vitality.
5. By chemically combining with living tissue and interfering with the performance of its proper function.

In concluding this section, and with it these lectures, permit me to express the hope that the outline I have endeavoured to give of some recent work on the borderland between chemistry and physiology, may serve to show that the progress of true therapeutics must, in the future, largely depend on the extension of our knowledge of the chemical changes involved in the so-called vital process.

Parliamentary and Law Proceedings.

Prosecution Under the Apothecaries Act.

At the Redruth County Court, on Tuesday, July 17, 1877, before Mr. M. Bere, Q.C., Judge, the case of the Master, Wardens and Society of the Art and Mystery of Apothecaries *v.* T. J. T. Corfield, of St. Day, was heard. Mr. G. A. Jenkins appeared for the plaintiff, Mr. W. T. Tresidder for the defendant, and Mr. G. T. Bray watched the case on behalf of the Redruth Medical Association.

Mr. Jenkins said the action was brought under the 55th George III., chap. 194, and the plaintiffs brought it against Mr. Corfield to recover a penalty of £20 for practising as an Apothecary, having no right to do so. The 14th section of the Act prohibited persons from practising without being duly examined and certified. The defendant was a chemist, carrying on business at St. Day, and for a long series of years he had been in the habit of visiting persons, taking diagnoses of their diseases, prescribing for them, supplying them with medicine, and practising as a licensed apothecary. It was of great importance that gentlemen who had pursued a course of study for many years and were properly licensed should not have their practice interfered with by persons not qualified to pursue the course which the plaintiffs said Mr. Corfield had pursued. He wished the same course could be taken in the legal profession, as they were poached upon a great deal by many persons who act as attorneys, but who should be prohibited from so doing. He was prepared to call six witnesses, to all of whom the defendant had acted in the capacity of an apothecary.

Mr. Tresidder said it would save time if before any evidence was called, he directed attention to the 30th section of the Act, which laid down that notice of action must be given twenty-one days before the action was brought, whereas he had received no notice of action.

Mr. Jenkins urged that there had been a correspondence with Mr. Tresidder on the subject.

Mr. Tresidder contended that that was insufficient, as no notice of action had been given.

His Honour held that the notice was imperative. The summons was issued on the 5th April, and the plaintiff must show that twenty-one days before that date notice was given.

Mr. Jenkins said that a letter on the subject was written to the defendant from the office in October, 1876. Mr. Upton, the clerk to the society, sent a notice.

Mr. Tresidder disputed that statement.

His Honour adjourned the case, but made no order as to costs in order to see upon what pretext the objection was raised.

Mr. Tresidder, after stating that there was an appeal from the Nottingham County Court shortly to be heard, in which a Mr. Shepperley had been mulct in the penalty, asked his Honour to postpone the case until the appeal had been heard.

His Honour, in assenting, said the cases were not quite analogous, as in the case referred to a policeman went into Mr. Shepperley's shop complaining of a sore throat, when defendant gave him some medicine, telling him to call again ; and that the judge held to be prescribing within the meaning of the Act.

Mr. Tresidder stated that a similar action was, on the 2nd and 3rd July, tried before the judge of the Birmingham County Court, in which His Honour had deferred judgment until after the appeal in Shepperley's case should have been argued.

The case was then further adjourned until the November Court.

Dispensing Memoranda.

We are constantly in receipt of requests for aid in over coming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be conidered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions. *See before, p. 66.*

[10]. Ext. Tarax. Liquid.—In reply to the question of S. I. W.—"Which preparation of taraxacum should be used when ext. tarax. liquid. is prescribed in a mixture—the old-fashioned treacly preparation made by dissolving extract of taraxacum in water, and adding a little spirit, the more elegant liquor tarax., or the succus?"—in my opinion the prescriber intends the liquefied extract, and not either the liquor or succus. If he did not he would certainly write liquor or succus as the case might be.

The rule in practice in one of the largest dispensing establishments, some years ago, was to use a liquefied extract, and I have myself ever since continued the usage. The extract of taraxacum of the present Pharmacopœia does not resemble the old-fashioned treacly preparation met with formerly, and obtained by boiling the crushed root and evaporating the decoction, but is the clarified juice of the roots evaporated, and possessing the characteristic odour and flavour of taraxacum in a vastly more concentrated state.

J. B. Barnes.

[11]. TINCT. FERRI PERCHLORIDI.—I have found a great deal of difficulty in making tinct. ferri perchlor., B. P., with liq. ferri perchlor. ; when made as directed in the B. P. it soon deposited ferri oxyd. I

therefore used one part water, and two parts sp. vini rect. for dilution, instead of sp. vini rect. three parts. This product does not deposit, but soon generates what appears to be chlorine gas, which darkens the tincture, and gives it a very strong smell rendering it unfit for use. Can any reader suggest a way for making it so that it will remain unimpaired?

A prescription was presented to me a few days since, as follows:—

℞. Tinct. Ferri Sesquichlor.
Acid. Nit. Hyd. dil. . . . . āā ℥vj.

and which I dispensed with t. ferri seschlor., P. L. It had been previously dispensed in London aad in a town in a Midland county. That dispensed at the latter had exploded, and burst the bottle. Evidently B. P. t. ferri perchlor. had been used and gas generated, which caused the explosion.

J. S. H.

[12]. PILL COATING.—Can any reader inform me how pills may be coated with a preparation of liquorice, without heat, so as to give them a shiny black appearance?

---

[13]. QUININE MIXTURE.—I shall feel obliged if you will kindly insert the following prescription among the dispensing queries. I want to know if it can be dispensed containing the quinine in solution. A similar one I have been told has been made up at one of the leading dispensing establishments in London, with a satisfactory result, I always find the quinine separate.

℞ Pot. Bicarb . . . . . . ℈ij
Pot. Iodid. . . . . . . ℈j
Quinæ Sulph. . . . . grs. xx
Spt. Ammon. Co. . . . . ʒiij
Aquæ. ad . . . . ℥viij
M. ft. Mist.

D. MORRIS.

---

[14]. DISPENSING QUERY.—Can you inform me how the following prescriptions may be dispensed clear? The first has been sent out so.

℞ Quin. Ferro-Cit. . . . . . ʒj
Acid. Phos. Dil. . . . . . ʒij
Liq. Strychn. . . . . . . ʒj
Sp. Chlorof. . . . . ʒij
Aq. Dest. . . . . ad ℥vj
M.

℞ Sp. Ammon. Co. . . . . . ʒvj
Pot. Brom. . . . . ʒj
Ferri Quin. Cit. . . . . . ʒj
Tr. Aurant . . . . ʒss
Aq. ad . . . . ℥vj
M.

[15]. MIST. AMMONIACI CONC. Will anyone favour me with the formula for the above preparation, 1 to 7? W. H. R.

Obituary.

Notice has been received of the death of the following:—

On the 1st of July, 1877, Mr. Thomas George Rees, Chemist and Druggist, Red Lion Square, Stamford. Aged 43 years.

On the 11th of July, 1877, Mr. Aubrey Lum, Chemist and Druggist, Chesham, Bucks. Aged 73 years.

On the 12th of July, 1877, Mr. John Heaton, Chemist and Druggist, Colne, Lancs. Aged 66 years.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE WORD DISPENSER.

Sir,—I am not quite sure that I can agree with your correspondent, Mr. Langridge, as to the derivation of the word "dispenser." I have always thought that it came directly from the two Latin words "dis," asunder, or apart, and "pendo," to weigh. Penso is sometimes used instead of pendo. The meaning is therefore simply "a weigher apart." A dispenser of medicines is one who "weighs medicines asunder," or into portions, and this precisely expresses what an ordinary dispenser does. I think this is the "top and bottom" of the whole matter.

8, *The Strand, Torquay.* EDWARD SMITH.

ILLEGAL SALE OF POISONS.

Sir,—I am grateful for the energetic manner in which the Committee of the Trade Association is defending the rights and privileges of chemists and druggists, but I must demur to the course they are taking in pressing on the Council of the Pharmaceutical Society the discontinuance of the Secretary's warning letter in cases of infringement of the Pharmacy Act of 1868.

There is nothing very dignified in prosecuting by the dozen sellers of pennyworths of laudanum and red precipitate, and it would, in my judgment, be harsh and unfair, if not impolitic, to take legal proceedings without previous warning. I hope, therefore, the Council will continue to give the Secretary, in all first offences, a discretionary power, which I am sure he will exercise judiciously. I believe the cautionary letter has generally been effective, and I do not speak without some knowledge of the subject. At any rate we should, in the event of ulterior proceedings having to be taken, stand better with the court, by having sent such a letter.

Hull, July 24th, 1877. JAMES BAYNES.

"*Sebe.*"—We agree with you that the practice of prescribing medicines under names that are understood only by certain dispensers is open to serious objections, and we have given expression to this opinion on several occasions. With regard to the other statements in your letter, in their present form they are too indefinite for publication.

"*Pharmacist.*"—We do not think that the instance you quote substantiates your allegation that the questions for the Preliminary examination were too difficult; no less than four other subjects having been given, from which the candidate was at liberty to select one for his theme.

R. Modlen.—*Œnanthe silaifolia.* The Curator would be glad of two or three specimens with both root and fruit.

S. M. Seward.—Yes.

J. C. H.—(1) the answer to your question would depend upon the conditions under which the preparation is sold, especially as to whether or not it is recommended for the relief or cure of disease. (2) Your second question we do not quite understand.

"*Spes.*"—Place some odoriferous substance together with the paper in a closed box.

"*Finance.*"—(1) *Cryptogamme crispa;* (2) Too fragmentary to name; (3) *Polypodium vulgare,* var. *cambricum;* (4) *Lastrea Filix-mas, β Borreri;* (5) *L. Filix-mas, δ abbreviata;* (6) *Lastrea spinulosa;* (7) *Epichloe typhina.* Specimens to be named in the Journal should be addressed to the Editor, not to the Secretary.

F. C.—Your question should be addressed to the Editor of a medical journal.

T. P. B.—*Trifolium arvense.*

J. T. Fox.—(1) *Anthemis Cotula;* (2) May be *Carduus pratensis;* send larger specimens; (3) *Ranunculus flammula;* (4) *Sium angustifolium;* (5) Send larger specimen; (6) *Sparganium ramosum.*

"*Vincere.*"—(1) *Sium angustifolium;* (2) *Torilis Anthriscus;* (5) *Filago germanica;* (6) *Hypericum androsæmum;* (7) *Equisetum arvense.*

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Tresidder, Prof. Dymock, Mr. Rowe, Mr. Heanley, Colorado, J. S. H.

THE TURPENTINES AND RESINOUS PRODUCTS OF THE CONIFERÆ.

BY DR. JULIUS MOREL,

Professor of Chemistry in the Industrial School, Ghent.

(*Continued from page 23.*)

III.—COMMON TURPENTINE.

Synonyms.—E.: Crude Turpentine.—G.: Gemeiner Terpenthin.—F.: Térébenthine commune; Térébenthine de Bordeaux; Térébenthine de Pin maritime; Térébenthine de Boston or d'Amérique.

Botanical Origin.—The plants which yield the common turpentine may be divided into two groups, (1) those yielding the turpentine of Europe and (2) those yielding the turpentine of America.

(1) European turpentine is yielded by the *Pinus sylvestris* of Russia and Finland, by the *P. Laricio* of Austria and Corsica, by *P. maritima*, Poiret, of the Landes Department and the neighbourhood of Bordeaux.

(2) American turpentine is best known in France under the name of "Boston turpentine," because it is sent to Europe by the way of Boston. It comes from the United States, especially from Virginia and the Carolinas, where it is obtained from *Pinus australis*, Mich., and *P. tæda.*

Botanical Synonyms of Pinus maritima.

Pinus Sancta Helenica, Loud. ex Gord. l.c.

Pinus neglecta, Low.

E.: Pinaster; Cluster Pine; Maritime Fir.—G.: Italienische Kiefer; Strandkiefer.—F.: Pin de Bordeaux; Pin des Landes; Pin maritime.

In France the maritime pine forms considerable forests (*pignadas* in Gascony), principally in the Landes department and along the sea coast to Mans; it reaches even to Brittany, but there it proceeds from artificial sowing. It is found on the shores of the Mediterranean, and in the mountainous regions of Corsica it attains an elevation of 1000 metres. It prefers particularly light silicious soils.

Pinus sylvestris squamosa, Bosc., Nouv. Cours. d'Agric., art. Pin.

Pinus sylvestris scariosa, Lodd.

E.: Scotch Pine; Scotch Fir.—G.: Gemeine Föhre; Weissföhre; Gemeine Fichte; Kiefer; Tanne, and 55 other names which are given in Haynes's 'Abbildung.'—F.: Pin d'Ecosse; Pin sauvage; Pin sylvestre; Pin de Horgenau; Pin de Genève; Pin rouge.

The habitat of the *Pinus sylvestre* ranges over a widely extended surface, but is rather restrained in altitude; the tree constitutes vast forests in the North of Europe, as far as Siberia. In France it is met with alone or mixed with the oak, birch or fir, in the plains and upon the lesser ranges of mountains; in the south, as for instance, in the Pyrenees, it does not make its appearance until an altitude of about 1200 metres is reached. The weight of the frost and snow that accumulates upon its long acicular leaves, and the fragility of its branches, exclude it from very elevated regions. Usually it occupies the zone immediately below that of the fir. It prefers silicious and fresh soils, but succeeds in dry ones.

In consequence of the very precocious development of a periderm in the interior of the liber layers, the bark of the *Pinus sylvestris* loses from its earliest years its epiderm, its suberous envelope, its green cellular envelope, and with this its reservoirs of turpentine. This periderm, composed of reddish cells with thin walls that rupture easily, is arranged in numerous laminae, concave outwardly, and separating the liber in flakes of a corresponding form. The cellular tissue of the liber thus divided, is transformed and grows into a brown, dry, and fragile suberous parenchyma, which being quickly driven outwards by the increasing formation of periderm, gives rise to a rhytidoma cracked in every direction, and especially in long scales, becoming with age of a considerable thickness at the foot of the tree. It is reddish-brown or grey-brown, according as the activity of the vegetation provokes a more or less rapid superficial scaling. In an old tree the formation of the bark is modified greatly for a dozen metres above the soil. The periderm is of organized very thin concentric continuous layers, and causes the unmodified liber to fall off in membranous flakes, resembling paper. The bark, therefore, does not thicken, but remains thin, smooth, shining, and of a clear red colour, which is brighter in proportion as the vegetation is more vigorous.

Botanical Synonyms of Pinus Laricio.

Pinaster, Plin., Hist. Nat., xvi. 17.

Pinus sylvestris, ε maritima, Ait., Hort. Kew, ed. 1 iii. 366.

Pinus Laricio, Poir, Dict., v. 339; Loisel, Nouv. Duham,

v. t. 6 and t. 71, f. 2; Lamb., Pinet., ed. 2, i. 9, t. 4; Forb., Pinet. Wob., 23; Loud., Arbor., iv. 2206, f. 2081-2084; Encycl. of Trees, 957, f. 1768-1769; DC., Fl. Fr. iii. 274; Desf., Hist. Vég. Phan., xi. 384: Endl., Syn. Conif., 27; Lindl. and Gord., Journ. Hort. Soc., xi. 384; Knight, Syn. Conif., 27; Carr., Man. des Pl., iv. 357; Tr. Gén. Conif., 384; Gord., Pinet., 168.

Pinus maritima, Ait., Hort. Kew, ed. 2, v. 315 (non Lamk. nec Lamb.).

Pinus Laricio Poiretiana, Hort.

Pinus Laricio Cebenensis, Hort. ex. Gord. l. c.

Pinus Laricio Corsica vel *Corsicana*, Hort.

Pinus Laricio altissima, Hort. alis.

Pinus nigricans, Hort.

E.: Corsican or Larch Pine.—G.: Schwarzfôhre.—F.: Laricis de Corse.

The Corsican larch pine is met with in mountainous regions, where it occupies a zone above that of the *Pinus maritima*. It commences to appear at an altitude of 1000 metres, and rises to 1700 metres, an elevation at which it exists only as a stunted bush. It seeks the argillaceous gravels that result from the disintegration and decomposition of granites, and attains its maximum growth when these are moderately fresh. Its growth is sometimes very rapid.

Botanical Synonyms of Pinus australis.

Pinus americana palustris, Hort. Angl.; Duham., Arbr., ii. 126.

Pinus palustris, Mill., Dict., n. 14; Soland. in Ait. Hort. Kew, ed. 3, 368; Duroi, Harbk., ed. Arbr., ii. 612; Link. in Linnæa, xv. 506.

Pinus australis, Mich. fil., Arbr. For., i. 62, t. 6; Sylv. North Amer., 60, t. 41; Loud., Arbor., iv. 2255, f. 2156-2160; Encyc. of Trees, 987, f. 1842-1845; Loisel, Nouv. Duham., v. 246, t. 75, f. 3; Spach., Hist. Vég. Phan. xi. 392; Endl., Syn. Conif., 165; Lindl. and Gord., Journ. Hort. Soc., v. 217; Knight, Syn. Conif., 30; Carr. Man. des Pl., iv. 353; Gord., Pinet., 187.

Pinus Georgica, Hort. ex Gord. l. c.

Pinus palmiensis, ex Gord. Pinet. Suppl., 63.

Pinus Palmieri, Manetti ex Gord. Suppl. l. c.

E.: In *America*, Long-leaved Pine, Yellow Pine, Pitch Pine and Broom Pine in the Southern States; Southern Pine and Red Pine in the Northern States; and Yellow Pine and Pitch Pine in the Middle States. In *England* and the *West Indies*, by the timber merchants, Georgia Pitch Pine.

This pine is found in Virginia and Florida, on the downs near the sea, and it is very common in certain parts of the Southern States, to which the name of "pine barrens" has therefore been given. In America the tree attains a height of 60 to 70 feet; in England it seldom exceeds 10 or 12 feet.

Botanical Synonyms of Pinus tæda.

Pinus Virginiæ tenuifolia, Plukn., Almag. 297.

Pinus foliis longissimis, Cold., Nov. Fl. in Act. Ups. 1743, No. 230.

Pinus foliis ternis, Gronow, Virgin., 152.

Pinus tæda, L., Spec., 1419; Willd., Baumr., 269; Lamb., Pinet., ed. 2, i. 26, t. 17-18; Loud., Arbor., iv. 2337, f. 2118-2122; Encycl. of Trees, 978, f. 1816-1819; Desf., Hist. Arb., ii. 612; Loisel, Nouv. Duham., v. 249, t. 75, f. 2; Forb., Pinet. Wob., 43, t. 14; Ant. Conif., 25, t. 7, f. 1; Link. in Linnæa, xv. 503; Mich. fil., Arb. For., i. 97, t. 9; Spach., Hist. Vég. Phan., xi. 391; Endl. Syn. Conif. 164; Lindl. and Gord., Journ. Hort. Soc., v. 217; Knight, Syn. Conif., 30; Carr., Man. des Pl., iv. 353; Tr. Gén. Conif., 344; Gord., Pinet., 210; J. E. Nelson, Pinæ., 136.

E.: In America, White Pine (in Virginia); Frankincense Pine; Loblolly Pine; Torch Pine, Oldfield Pine.—F.: Pin de l'Encens.

This pine inhabits the sandy and uncultivated spaces of Florida and Virginia, where it forms vast forests; it is met with also in North Carolina. It attains a height of 70 to 80 feet.

Extraction.—The process of extraction from the maritime pine is described in great detail by Mathieu ('Flore Forestière,' p. 353). In Gascony, and especially in the department of the Landes, the production of turpentine is sacrificed to that of the wood. When the tree has a circumference of about 1·20 metres at the base, the bark is roughly removed from the side which is to be attacked, and then thinned off with the axe, rendering it smooth and even; next with a special instrument the workman makes towards the foot a rectangular cut which lays bare the sap-wood, and which is generally 10 centimetres wide, and 3 centimetres high. Below this cut a small trough is scooped out in some salient part of the foot of the tree to collect the products. If this be not possible, a portable trough is placed there. Every week the incision is renewed by the removal of a thin shaving from its upper part, in such a manner that the height continually increases, whilst the width is preserved constant, or, better still, decreases, and the incision attains in five years an elevation of about 3 metres. It is then abandoned, and a second is commenced, which is managed in the same manner as the first, from which it is separated by a band of bark 5 to 6 centimetres, or more, wide. In this way, the entire circuit of the tree is made, taking care to carry each new cut a little higher than the preceding one. Next, the spaces between the cuts are attacked; these are widened so as to cover more or less the old wounds, and they are always cut after the same fashion. This operation, when well conducted, can extend over 150 years or more, especially if in the earlier period, whilst the pine is yet weak, a year's rest be given to it after each period of seven or eight years' working.

Sometimes, when the strength of the tree will allow of it, two cuts are made at the same time, one higher than the other. Finally, instead of making the cuts one by the side of another, they are also made opposite to each other, the new ones being cut in the centre of the interval between the oldest.

The method of working calculated to preserve the health of the tree, is called "*gemmage à vie.*" If, on the contrary, the pine has to be worked in a short period, no attempt is made to preserve it; it is cut upon all sides at once, and the height of the cuts is tripled in a single year; the pine is said then to be "*gemme à mort,*" or "*à pin perdu.*"

The working is carried on from May to the end of September, the turpentine flowing into the troughs, from which it is removed from time to time. A good workman can cut from two hundred to three hundred trees per day.

A vigorous pine, standing alone, will produce annually 20 to 40 kilograms of crude matter; when the trees are in masses the figure does not exceed 5 or 6 kilograms. The pines of the Gascony downs are in this respect more productive than any others; those of Provence do not give such satisfactory results.

The crude products are of three kinds: (1) soft turpentine, which is collected in the troughs; (2) galipot, the portion which solidifies in the cuttings, from which it is detached in pieces, bark débris being frequently mixed with it; (3) barras, which has to be scraped off, and is only an impure galipot, mixed with chips, fragments of bark, etc.

The best description for the *extraction of American turpentine* is given by Flückiger and Hanbury.* It is in North Carolina that the extraction is principally carried on.

"In the winter, from November to March, the negroes in a *turpentine orchard*, as the district of forest to be worked is called, are occupied in making in the trunks of the trees cavities which are technically known as *boxes*. For this purpose a long narrow axe is used, and some skill is required to wield it properly. The boxes are made from 6 to 12 inches above the ground, and are shaped like a distended waistcoat pocket, the bottom being about 4 inches below the lower lip, and 8 or 10 below the upper. On a tree of medium size, a box should be made to hold a quart. The less the axe approaches the centre of the tree the better, as vitality is the less endangered. An expert workman will make a box in less than ten minutes. From one to four boxes are made in each tree, a few inches of bark being left between them. The greater number of trees from which turpentine is now obtained are from 12 to 18 inches in diameter, and have three boxes each.

"The boxes having been made, the bark and a little of the wood immediately beneath it, which are above the box, are *hacked*, and from this excoriation, the sap begins to flow about the middle of March, gradually filling the box. Each tree requires to be freshly hacked every eight or ten days, a very slight wound above the last being all that is needed. The hacking is carried on year after year, until it reaches 12 to 19 feet or more, ladders being used.

"The turpentine, which is called *dip*, is removed from the boxes by a spoon or ladle of peculiar form, and collected into barrels, which are made on the spot, and are of very rude construction. The first year's flow of a new tree, having but a small surface to traverse before it reaches the box, is of special goodness, and is termed *virgin dip*.

"The turpentine which concretes upon the trunk is occasionally scraped off and barrelled by itself, and is known in the market as *scrape*, or by the English druggists as *common frankincense* or *gum thus*."

The authors justly remark that the collection of turpentine in the Departments of the Landes and the Girond, in the south-west of France, is performed in a more rational manner than in America, inasmuch as the plan of making deep cavities in the tree for the purpose of receiving the resin is avoided by the simple expedient of placing a suitable vessel beneath the lowest incision.

Contrary to that which has been observed in the case of Strassburg turpentine, the resiniferous ducts are met with in this plant more abundantly in the external layer of the wood than in the bark, and this explains why it is that there is seldom any exudation of the resin from the plant, and also why it is necessary to incise both the bark and the wood in the extraction of this turpentine.

Before sending the turpentine into commerce it is purified by melting it in a boiler, and afterwards passing it through filters of straw or metallic gauze, or exposing it to the heat of the sun in a wooden box in which small troughs are cut so as to catch the impurities whilst the liquefied turpentine runs off into a recipient placed underneath. The latter process is preferable, because by it only an insignificant loss of volatile oil takes place.

Characters.—The characters of common turpentine differ according to the variety.

* 'Pharmacographia,' p. 546.

The variety known as *Bordeaux* is, when fresh, liquid and transparent; by contact with air it becomes opaque, whitish and semi-solid. That of commerce has the consistence of honey, is granular, and has a milky turbidity. When allowed to stand it separates into two layers, the upper being semi-fluid, transparent, and more or less coloured, whilst the lower is resinoid and has a crystalline appearance. Its odour is strong, disagreeable and very characteristic; its taste is acrid, bitter and nauseous. It is the most siccative of all the turpentines, a thin layer solidifying in twenty-four hours. This solidification is still more prompt in the presence of calcined magnesia; one twenty-eighth part being sufficient to give it a pilular consistence. Its density is variable, but always inferior to that of water. This turpentine dissolves completely in alcohol, ether, fixed and volatile oils and carbon bisulphide. Distilled with water it gives about 25 per cent. of volatile oil. Upon polarized light its action is lævogyre.

The variety known as *German* is met with in commerce of a thick consistence, dirty white, turbid and granular; its odour and taste are very disagreeable. It dissolves completely in the same solvents as dissolve Bordeaux turpentine.

The *American* or *Boston* turpentine has also the consistence of thin honey, but it is yellowish and slightly opaque, becoming transparent by contact with the air. Its odour is agreeable and its taste is acrid and bitter. When kept for a long time in a flask it separates into two layers, the upper of which is clear and slightly fluorescent, whilst the lower one is slightly turbid and granular. A portion of the latter layer examined under the microscope presents a mass of small elliptical crystals characteristic of abietic acid. If this turpentine be heated the crystals pass into solution. The turpentines of Bordeaux and Germany present the same microscopic characters.

Composition.—The proportion of essential oil contained in the common turpentines varies between 15 and 30 per cent. This is always mixed, as will be afterwards shown, with a certain quantity of another oxygenated volatile body. The turpentine from the *Pinus Laricis* of Austria gives about 30 per cent. of essential oil to 70 per cent. of colophony or resin.

Uses.—The common turpentines are very little employed in pharmacy; their disagreeable odour and taste have compelled their abandonment, although they partake of the same properties as the other turpentines. They are still, however, used in the veterinary art. For industrial purposes they are used in the preparation of artificial resinous products (tar, colophony, pitch) and spirit of turpentine.

(To be continued.)

ADULTERATED SULPHATE OF MORPHIA.

BY D. B. DOTT.

I lately examined a sample of morphia sulphate (offered in the English market), which was adulterated to such a scandalous extent, that, in the interests both of the trade and the general public, I think the results of the examination should be made known.

This compound contained 34·63 per cent. of anhydrous sodium sulphate, leaving only 65·37 per cent. of morphia sulphate. The morphia was also determined directly and found to be equivalent to the above proportion of sulphate.

It is needless for me to enlarge on the necessity of procuring these important preparations in a state of perfect purity; but it is obviously advisable for druggists to be on their guard when buying morphia salts.

NOTE ON DIALYSED IRON.*

BY JOHN M. MAISCH.

Dialysed iron, which will doubtless become one of the most valuable ferruginous medicinal agents, has been recently introduced into the United States, under various names. Some claiming it to be a solution of *oxide of iron* in water, it was, and is still frequently called in Europe, *ferrum oxydatum dialysatum;* but like the very similar preparation, *ferrum oxydatum saccharatum*, which has been made officinal in several European pharmacopœias (*Am. Journ. Pharm.*, 1873, p. 161; 1874, p. 559), it is nothing more nor less than a very basic oxychloride of iron. To prevent erroneous conceptions concerning its composition gaining a foothold, a brief review of the earlier literature on the subject will not be out of place.

The first paper on this subject deserving notice is one by John M. Ordway, entitled "Examination of the Soluble Basic Sesquisalts," which was published in the *Am. Journal of Science and Arts*, 2nd ser., xxvi., p. 197 (1858), and in which the following language is used: "Time is a very important element in the production of the highly basic compounds. One may easily be deceived as to when the hydrate ceases to be dissolved, and may set down as opaque that, which by longer digestion becomes quite transparent. By successive steps we get pretty easily as far as $Fe_2Cl_6,11Fe_2O_3$, and in the course of several weeks I have gone as high as $Fe_2Cl_6, 23Fe_2O_3$."

The next important paper is by Béchamp (1859), published in *Annales de Chimie et de Physique*, 3rd ser., lvii., 296, which in the main corroborates the statements of Ordway, but gives the most basic compound obtained $Fe_2Cl_6,20Fe_2O_3$. In both cases the solutions of the normal salt were digested with ferric hydrate.

Th. Graham's celebrated essay on the diffusion of liquids ('Phil. Trans.,' 1861, 183) announces the following results: "If recently precipitated ferric hydrate or carbonate of ammonium is added to an aqueous solution of ferric chloride, as long as the precipitates are redissolved, and if the dark-red solution thus obtained, containing from 4 to 5 per cent. of solid matter, is subjected to dialysis, mainly muriatic acid will pass through the septum upon which, after 19 days, remains a red liquid containing for 98·5 parts of oxide 1·5 part of muriatic acid. It remains liquid for 20 days and then gelatinizes, separating ferric hydrate. A similar solution of colloidal ferric hydrate may be obtained by dialysis of ferric acetate, and contains 6 parts of acetic acid to 94 parts of erric oxide."

Calculating Graham's results as an oxychloride, the formula Fe_2Cl_6, $95Fe_2O_3$ would be obtained, which seems to be hardly probable. At the same time, it must be remembered, that none of the so-called soluble oxide of iron has as yet been obtained free from acid. Graham's figures, I believe, are the lowest thus far observed, and the solution was not permanent, but gelatinized spontaneously. It must therefore be granted that any permanent solution of so-called soluble oxide of iron must contain notable quantities of acid; and within the past year such has been proven by Hager to be the case for several European preparations sold as oxide of iron.

The behaviour of the solutions is quite curious and apt to mislead, unless care be taken to arrive at correct results. They will retain their clearness on boiling, ary miscible with alcohol, glycerin, syrup, etc., but readil yield precipitates on the addition of acids not in excess, or of saline solutions, the precipitates disappearing again on diluting with distilled water. Tannin added in small quantities darkens the solution somewhat, and on filtering leaves but little matter in the funnel; on using a stronger solution of tannin a well diffused gelatinous precipitate takes place, having a deep brown, but not a black colour, and the filtrate is colourless. Solution of nitrate of silver added in small quantity does not disturb the transparency of the liquid; on adding more of the former a gelatinous *brown* precipitate takes place, and the colourless filtrate is free from iron, but the addition of distilled water causes the precipitate to dissolve again. Apparently, therefore, the solution is free from chloride; but on adding first a slight excess of ammonia, filtering from the ferric hydrate, acidulating with nitric acid and then testing with nitrate of silver, a white precipitate of chloride of silver is formed. All these reactions as well as the slight astringent, not inky taste, and the intense brown-red colour have been observed by the investigators named above, and they characterize also the commercial products. A sample recently handed to us, and said to contain no, or only traces of, chlorine, yielded when treated as above abundant evidence of its presence.

Physicians and pharmacists should, therefore, bear in mind that there is *no soluble oxide of iron*, but what is sold as such, be it imported or made in this country, is *very basic oxychloride of iron.* This being the case, the question naturally presents itself whether such a solution cannot be obtained by saturating a solution of ferric chloride with hydrate of iron. That question is easily answered if the behaviour to saline solutions is taken into consideration and the fact is remembered that, when solutions of ferric salts are precipitated by alkalies, the ferric hydrate will invariably retain small quantities of the precipitant, which cannot be removed by washing with water. These saline impurities, minute as they may be, are sufficient to prevent the formation of the very basic oxychloride, or if formed it becomes insoluble in the liquid and nothing but dialysis or considerable dilution with distilled water can dissolve it again. To obtain it of the maximum strength indicated by Graham (5 per cent.) and also adopted by the Pharmaceutical Society of Paris (see before page 27), dialysis appears to be unavoidable.

As to the advantage of the dialysed over the oxychloride made by saturation with hydrate of iron, that is best ascertained by comparing their taste, which in the former is scarcely astringent, while that of the latter is distinctly ferruginous. A preparation now before me, imported from Germany, called Ferrum oxydatum dialysatum, I do not hesitate to say has been made by saturation alone, or by incomplete dialysis; for its reaction is distinctly acid and its taste quite styptic. Some French preparations, sold by the same name, were found to be superior to the German in both respects; but one yielded only 3·3 per cent. of solid matter, another less than half that quantity. A 5 per cent. solution of dialysed iron should yield 3 grains of dry residue when 60 grains of it are carefully evaporated to complete dryness.

The characteristics of a 5 per cent. solution of dialysed iron may be stated to be—

1. The deep brown-red colour, which in thin layers is perfectly transparent.
2. The freedom from odour and taste, it being merely faintly astringent to the palate.
3. The absence of even slight acid reaction to test-paper; and
4. The behaviour to tannin and to saline solutions (even spring water), as stated above.

It is best given by itself upon sugar, or mixed with some simple syrup which is free from acid. It should be mentioned yet that the same preparation has made its appearance in Austria as *catalytic iron.*

* From the *American Journal of Pharmacy* for July.

THE VALUE OF MUSHROOMS AS FOOD.*

BY THEOD. HUSEMANN.

The popular use of edible mushrooms and the problem how to facilitate their general employment without risk of poisoning, is a theme which deserves the highest attention of public economists. A valuable article of food, which occurs nearly everywhere in colossal proportions, is at present completely neglected, although it is worthy, on account of its chemical composition, to be placed by the side of meat, the most important nitrogenous food of man. In many portions of Germany the vegetation of fungi, in favourable years, is so prolific that a single person is able to collect in ten or fifteen minutes sufficient food for several families—not to speak of such giant mushrooms as *Fistulina hepatica*, a single one of which sometimes attains a weight of thirty pounds, capable of furnishing sustenance for a whole family. *Clavaria Botrytis* and *Clavaria flava*, *Boletus edulis* and other allied species occur in such immense quantities, that the gathering of several hundredweights would be a very easy task. The food value of mushrooms has heretofore been made the subject of exhaustive investigations by Kohlrausch and Siegel, who found in 100 parts of *dried Morchella esculenta* 35·18 per cent. of protein, in *Morchella conica*, 29·64 per cent., and in *Helvella esculenta*, 26·31 per cent., besides about 2·3 per cent. of fatty matters, and a considerable quantity of sugar (mannite): in *Morchella esculenta* (dried), as much as ten per cent. In addition, these mushrooms contain a very high percentage of potassium salts, and of phosphoric acid, amounting to 46—49 per cent. of the ash. The following other fungi have also been examined:

Boletus edulis: in 100 parts of dry substance, 22·82 protein; 5·14 mannite; 1·98 fat. The ash contains 50·95 potash and 20·12 phosphoric acid.

Cantharellus cibarius: 10·68 protein; 23·43 mannite; 1·38 fat. The ash contains 48·75 potash, and 31·32 phosphoric acid.

Clavaria flava: 24·43 protein; 4·81 mannite; 12·13 fat. The ash: 51·47 potash, and 35·07 phosphoric acid.

Tuber cibarium: 36·32 protein; 2·48 fat. The ash: 55·97 potash, and 30·85 phosphoric acid.

Agaricus campestris: 20·63 protein; 1·75 fat; 4·91 mannite; 7·13 fermentable sugar. The ash: 50·71 potash, but only 15·43 phosphoric acid, most of which are replaced by sulphuric acid.

It is highly probable that age and location promote variations even in the same species, not only as regards the percentage of protein, but also the composition of the ash. But these differences are so insignificant that they have no effect whatever upon the high rank which mushrooms occupy among nitrogenous foods. Kohlrausoh compares the most usual of the latter in reference to their percentage of nitrogen, in the following tables:—

Protein-substance calculated for	Beef.	Veal.	Wheat bread.	Oatmeal.	Barley bread.	Leguminous fruits.	Potatoes.	Mushrooms.
100 parts of dry substance.	38·69	44·05	8·03	9·74	6·39	27·05	4·85	33·0

This comparison shows that the statement made above, regarding the neglect of one of the most accessible and valuable articles of food, is well supported. It is considered one of the greatest merits of Liebig, that he made the immense quantities of otherwise almost useless South American beef serviceable to man in the shape of extract. The nutritive and therapeutic value of this depends in a great measure upon its percentage of potash-salts and of phosphoric acid; and a simple comparison will show that an equally valuable food may be prepared, in the form of extract, from mushrooms.

This extract, besides can be prepared so as to retain the peculiar aroma of the mushroom, which is very pleasant for itself, and is even more highly valued as a piquant addition to meats in the form of catsup, while the Fray-Bentos extract possesses a flavour by no means agreeable to all consumers. It is true, that some species of fungi, as *Boletus* (which are by far the most numerous and common), are almost devoid of this aroma, but they are at least free from any disagreeable twang, and, if proper care be exercised to avoid the poisonous ones, the labour of collecting and preparing an extract from them for culinary and therapeutic purposes would richly repay some enterprising pharmacist.

FORMULÆ FOR NEW MEDICAMENTS ADOPTED BY THE PARIS PHARMACEUTICAL SOCIETY.

(*Concluded from page* 68.)

SOLUTION OF POTASSIUM SILICATE (*Silicate de Potasse Chirurgical*).

Purified Potassium Carbonate (indicating 78° alkalimetrical), 36 grams; Fine White Dry Sand, 63 grams. Mix and heat to a white heat in an elliptical reverberatory furnace during four hours. The resulting glass is transparent, very homogeneous and colourless, or presenting a slightly amber tint. To prepare the solution of this salt coarsely powdered fragments are introduced into an iron digester under very high pressure, together with sufficient water to make a solution having a specifi gravity of 1·277 to 1·299. It is important that the water should be as pure as possible and carefully freed from lime salts, which would give rise to the formation of insoluble calcium silicate, rendering the solution of potassium silicate more or less turbid and opalescent. Under these conditions the potassium silicate is entirely dissolved.

POTION DE TODD.

Old Eau-de-vie, 60 grams; Sugar Syrup, 40 grams; Distilled Water, 90 grams; Tincture of Canella, 10 grams. The eau-de-vie is sometimes replaced by rum.

WINE OF QUASSIA.

Lunel Wine, 1000 grams; Quassia Chips, 30 grams. Macerate during ten days with occasional agitation and filter.

QUININE.

QUININE HYDROFERROCYANIDE.

$2\,O_{20}H_{24}N_2O_2 \cdot H_4FeCy_6 + 4\,H_2O.$

Quinine Sulphate, 4 parts; Potassium Ferrocyanide, 1 part. Shake the quinine sulphate in a flask with sufficient distilled water to make a clear solution when boiled; add the potassium ferrocyanide in concentrated solution; raise the temperature of the liquor to boiling for a few moments, and allow it to cool; quinine hydroferrocyanide is then deposited as a resinoid mass. The mother liquor is decanted, and may be concentrated to obtain a further yield of the quinine salt, and the salt is purified by one or two washings with warm water.

This compound may be obtained in small crystals by repeatedly dissolving the amorphous product in boiling alcohol and abandoning the solution to spontaneous evaporation.

Quinine hydroferrocyanide is yellow, amorphous or small acicular masses, and bitter. It is scarcely solubl in water, but very soluble in alcohol, especially when ho It effloresces when exposed to the air. In solution it should not be precipitated by barium chloride. When calcined for some time in the air it should leave a residue of oxide of iron without any soluble potash salt.

Basic Quinine Hydrobromide (*Bromhydrate basique de Quinine*). $C_{20}H_{24}N_2O_2, HBr+H_2O$.

Basic Quinine Sulphate, 10 grams; Dry Barium Bromide, 3·40 grams; Distilled Water, 100 grams. Suspend the quinine sulphate in 80 grams of water, filter, evaporate and leave to crystallize.

Basic quinine hydrobromide crystallizes in needles grouped in silky white tufts. It is very soluble in hot water, soluble in about 60 parts of cold water, and should not be precipitated by soluble sulphates.

One gram of basic quinine hydrobromide is entirely precipitated by 0·401 gram of silver nitrate.

Neutral Quinine Hydrobromide (*Bromhydrate neutre de Quinine*). $C_{20}H_{24}N_2O_2, 2HBr+3H_2O$.

Basic Sulphate of Quinine, 10 grams; Sulphuric Acid (1:10) 11·2 c.c.; Dry Barium Bromide, 6·80 grams; Distilled Water, 75 grams. Dissolve the quinine sulphate in 50 grams of water containing the sulphuric acid, and the barium bromide in 25 grams of water. Mix the two solutions, boil for a few moments, and filter. The liquor, evaporated to 35 grams and cooled, yields beautiful prismatic crystals, very soluble in boiling water, soluble in 7 parts of cold water, and very soluble in alcohol. This salt should not be precipitated by soluble sulphates.

1 gram of crystallized neutral quinine hydrobromide is entirely precipitated by 0·629 gram of silver nitrate.

Quinine Tannate. $C_{20}H_{24}N_2O_2, 2C_{27}H_{22}O_{17}$.

Add to quinine acetate in neutral solution sufficient solution of gallotannic acid (tannin of gall nuts), deprived of resinous matters, to redissolve the white mass of quinine tannate that is at first formed. Neutralize this solution exactly with sodium bicarbonate, which precipitates the whole of the quinine tannate in proportion as the acidity of the liquid diminishes. Collect the product upon a filter, drain off the mother liquor, and leave it to dry in the air; then powder the residue, wash it upon a filter with distilled water, and again dry.

Quinine tannate is amorphous, pulverulent and white. When prepared from the sulphate it always contains a quantity of sulphuric acid. When prepared as above described it contains 20·6 per cent. of quinine and corresponds to ordinary quinine sulphate in the proportion of 3·5 of tannate to 1 of sulphate.

Alkaloidal Soaps (*Savons d'Alcaloides*).

These compounds being nearly insoluble in water are usually obtained by double decomposition. An aqueous solution of quite neutral medicinal soap is made to react upon a concentrated neutral solution of the hydrochlorate of the base it is desired to combine with the fat acids of the soap until turbidity is no longer produced in the soap solution. The precipitate is collected, washed, and dried gently in a stove.

This method of production is preferable to that of uniting the alkaloid directly with the fat acids, because the product resulting from the latter method presents a less constant composition.

Metallic Soaps (*Savons métalliques*).

The metallic soaps (oleomargarates) are obtained by double decomposition. An aqueous solution of a metallic salt is poured into a perfectly neutral solution of medicinal soap until the precipitate ceases to augment. The precipitate is collected upon a cloth and strongly pressed.

The soluble sulphates allow of the preparation of a large number of metallic soaps (oleomargarates of iron, copper, zinc, etc.). For the mercurial soap it is necessary to employ the protonitrate dissolved in a little water acidulated with nitric acid or mercuric acetate.

Sodium Bromide. NaBr.

Soapmakers' Ley (caustic soda), free from chlorine, q. s.; Pure Bromine, q. s. Place the alkaline liquor in a long necked vessel, immerse in it the end of a funnel tube slightly drawn out, and pour the bromine into this gradually, with occasional agitation, until the liquor retains the colour and odour of the metalloid. Evaporate the saline product to dryness in a porcelain capsule. Heat it afterwards in a crucible to a dull redness until it ceases to give off gaseous bubbles of oxygen. Allow it to cool and dissolve the mass in distilled water and afterwards evaporate to dryness or to crystallization.

Sodium bromide is white. It is nearly entirely soluble in its weight of water and is also soluble in alcohol. Its solution should not be precipitated by barium chloride, nor coloured by the addition of a strong acid. When shaken with a little starch paste and nitric acid containing nitrous acid, it should not give a blue or violet colour.

1 gram of pure dry sodium bromide is completely precipitated by 1·650 of silver nitrate.

Sodium Hypophosphite (*Hypophosphite of Soda*). $Na\,Ph\,H_2O_2$.

Calcium Hypophosphite, 10 parts; Crystallized Sodium Carbonate, 16 parts. Dissolve the salts separately in a little lukewarm water, and mix the solution, ascertaining by reagents that neither is in excess. Ammonium oxalate should give no precipitate and hydrochloric acid should cause no effervescence. Filter to separate insoluble calcium carbonate and wash the precipitate to remove any hypophosphite it might contain. Concentrate the united liquors in a water-bath at a temperature of 60° C. to avoid detonations. The dry residue should be preserved in a closed vessel.

Sodium hypophosphite is a white, amorphous or crystalline, deliquescent salt, completely soluble in two parts of water, and 15 parts of 90° alcohol. It possesses the characters of the hypophosphites and of the salts of soda. It ought not to effervesce with acids, nor be precipitated by barium chloride or by the sulphates. Oxalic acid does not give with it any turbidity.

Syrup.—Sodium Hypophosphite, 5 grams; Simple Syrup, 445 grams; Syrup of Orange Flowers, 50 grams. F. S. A. a syrup by simple solution. It will contain in each tablespoonful of 20 grams 0·20 gram of sodium hypophosphite.

Sodium Iodide. NaI.

Sodium iodide is prepared similarly to potassium iodide, substituting sodium carbonate for potassium carbonate (Codex). It is a white deliquescent salt, crystallizing in cubes containing two equivalents of water. It is very soluble in water and soluble in alcohol. Air decomposes it, setting free iodine.

One gram of dry pure sodium iodide is entirely precipitated by 1·13 gram of silver nitrate.

Sodium Lactate. $NaC_3H_5O_3$.

Dilute lactic acid with three parts of water, saturate whilst boiling with sodium bicarbonate, then evaporate and run into flakes.

Sodium lactate is a very deliquescent salt. The solution evaporated to the consistence of a syrup deposits flattened prismatic crystals and stellar groups of needles.

Neutral Sodium Sulphite. $NaSO_3, 7H_2O$.

Prepare a concentrated solution of pure crystallized sodium carbonate (1 part of salt to 2 of water); divide it into two parts and saturate one with sulphurous acid gas; then mix with it the other part, boil to drive off excess of gas, and leave to crystallize. A very neutral sulphite is thus obtained. The crystals should be kept sheltered from the air.

This salt occurs in oblique rhomboidal prisms, containing seven equivalents of water. It is very soluble in water, its maximum solubility being at 33° C., above that temperature it deposits anhydrous crystals of neutral sulphite. Its solution, if slightly alkaline, oxidizes slowly in the air.

100 cubic centimetres of a solution containing 1·26 gram of pure neutral sodium sulphite per litre, with starch paste added, absorbs 10 c.c. of iodine solution containing 12·7 grams per litre before giving a persistent blue colour.

SODIUM SULPHOVINATE. $NaC_2H_5SO_4,H_2O$.

Sulphovinic acid is first prepared by pouring gradually, with great care and unceasing stirring with a glass rod, 1000 grams of 60° sulphuric acid into 1000 grams of rectified 96° alcohol. The mixture is left for some hours in contact, then diluted with 4 litres of distilled water, and afterwards saturated with pure barium carbonate. When the saturation is complete the barium sulphate is allowed to deposit on a filter. The solution of barium sulphovinate is then decomposed with pure carbonate of soda until it ceases to give a precipitate. The liquid evaporated in a water-bath is left to crystallize. If necessary, the crystals are purified by recrystallization. They should be kept in well-closed flasks. The proportions given yield about 1000 grams of sodium sulphovinate.

Sodium sulphovinate crystallizes in hexagonal tables, which are slightly unctuous to the touch and very soluble in water and in alcohol. If heated in a capsule they give off at 120° the alcohol which they contain in combination. They become gradually deprived of bitterness. Sodium sulphovinate ought not to contain sulphuric acid, nor have an acid taste. It should not be precipitated by barium chloride, and especially by soluble sulphates. The possession of either of these properties is a proof of faulty preparation and that a portion of the sulphovinic acid has been decomposed. In such a case it should be rejected.

EXTRACTION OF CAFFEINE FROM GUARANA.*

BY FRANCIS V. GREENE, M.D., U.S.N.

In determining the percentage of caffeine in guarana, Stenhouse (*Pharm. Journ.*, 1st ser., vol. xvi., p. 212; *Amer. Journ. Pharm.*, 1857, p. 68) employed the following process: The finely powdered substance was boiled for some time with distilled water, the insoluble portion removed by filtration, and a slight excess of basic acetate of lead added to the filtrate. The resulting brownish-red precipitate was thoroughly washed with boiling water, and sulphuretted hydrogen gas passed through the filtered liquid. The sulphide of lead was filtered off, the filtrate evaporated to dryness on a water-bath, and the residue dissolved in a small quantity of boiling alcohol and filtered. On evaporating this liquid nearly to dryness, yellowish crystals were obtained, which, after being pressed between folds of bibulous paper, were dissolved in diluted alcohol. By the evaporation of this menstruum, the crystals of caffeine were obtained perfectly free from colour.

In repeating this process for the purpose of estimating the quantity of caffeine contained in a specimen of guarana procured from the Brazilian collection at the Centennial Exhibition, the difficulty of separating the solution from the portion insoluble in boiling water, and the tediousness of the process of washing the mass precipitated by the acetate of lead solution, led me to seek some other method by which these impediments might be avoided, and I therefore determined to attempt the separation by means of litharge, which substance has been highly recommended (*Amer. Journ. Pharm.*, 1875, p. 135) by Professor E. S. Wayne, for the extraction of caffeine from tea and coffee. The result, confirmed by several trials of the process, proves that this compound of lead answers equally well for guarana, and that by its employment the quantitative determination of the caffeine in this substance can be effected with the utmost facility.

The details of the method are as follow: the powdered guarana is intimately mixed with three times its weight of finely divided litharge, and the mixture boiled in distilled water, the ebullition being continued until, on allowing the temperature to fall below the boiling point, the insoluble portion is found to subside rapidly, leaving the supernatant liquid clear, bright, and without colour. The quantity of distilled water required will be found to be about a pint for every fifteen grams of the guarana used in the experiment, and, as the boiling has to be continued for several hours before the desired and all-essential separation mentioned above takes place, water must be added from time to time to supply the place of that lost by evaporation. When cool, the clear liquid is decanted upon a filter, and when it has passed through, which it will be found to do with facility, the precipitate is to be transfered to the filter and washed with boiling water, the washing to be continued as long as yellowish precipitates are produced with either phosphomolybdic acid solution, auric or platinic chloride. A stream of sulphuretted hydrogen gas is now passed through the filtrate to remove the small quantity of lead that has been dissolved, and the sulphide thus formed is separated by filtration. The solution is evaporated on a water-bath to expel the excess of sulphuretted hydrogen, filtered to remove a trace of sulphur, finally evaporated to the crystallizing point, and the caffeine, which crystallizes out on cooling, removed from the mother liquor and pressed between folds of bibulous paper. After being thus treated the crystals will be found to be perfectly white. On diluting the mother liquor with distilled water, filtering and evaporating, a second crop of crystals are obtained, which are also perfectly white, after being pressed as above. The crystals are now dissolved in boiling diluted alcohol, filtered, and the solution set aside to crystallize by spontaneous evaporation. The resulting crystals of caffeine are perfectly pure and colourless.

In order to test the accuracy of the process, fourteen grams of guarana in an impapable powder were treated with the utmost care, as above described. The extracted caffeine, after drying at 100° F. until the weight became constant, was found to weigh ·707 gram, 5·05 per cent., a remarkably close approximation to the results of Stenhouse, who, from 25 grams of guarana, obtained 1·260 gram of caffeine = 5·04 per cent., and from 14 grams 5·1 per cent. Average = 5·07.

As this method of extracting caffeine is entirely devoid of all complicated steps, and requires but a short space of time for its completion, it may be used advantageously in estimating the percentage of caffeine in the fluid extract of guarana, which is prescribed to a certain extent at present, and may possibly be more extensively used in the future.

In regard to the proper accentuation of the name of the substance prepared from the seeds of the *Paullinia sorbilis*, by the Indian tribes on the upper Amazon, I would state that throughout Brazil, and in all parts of South America, where the preparation is used, the word is universally accented on the last syllable, *Guaraná* and never pronounced *Guarána*, the popular method of accenting the term in this country. The placing of the accent on the last syllable in words ending in *a* is not at all unusual in the Guarany language; for instance, as regards localities, Paraná and Ceará, retain their Indian accentuation; and in the vegetable world, the *Caladium esculentum* is always spoken of as the Tajá or Tayá, the *Franciscea uniflora* as the Manacá, and the *Gomphia parviflora*, as the Batiputá.

* From the *American Journal of Pharmacy*, July, 1877.

NOTE ON HYPOPHOSPHITE OF BERBERINA.*

BY J. U. LLOYD.

Take of Sulphate of Berberina, .	1 part
Distilled Water, ...	24 parts
Lead Monoxide, ...	½ part
Hypophosphorous Acid, .	q. s.

Dissolve the sulphate of berberina in the distilled water

* From the *American Journal of Pharmacy*, July, 1877.

at the temperature of 180° F. Add the lead monoxide, and digest at the above temperature until a filtered portion will not produce a precipitate with solution of acetate of lead (or a hot solution of chloride of barium); from 6 to 12 hours will accomplish this. Filter out the excess of lead and sulphate of lead formed, pass sulphuretted hydrogen through the solution to separate any traces of lead which may remain, and filter again. Evaporate the solution of berberina to the measure of 8 fluidounces, add solution of hypophosphorous acid until in slight excess, and allow the mixture to cool. Separate the magma of fine crystals with a filter paper or muslin strainer, and dry.

Hypophosphite of berberina is a beautiful yellow salt, much more soluble than the muriate.

By substituting other acids for the hypophosphorous almost any salt of berberina can be easily formed. When free from foreign substances, I have failed to find any salt of this alkaloid as soluble in cold water as the berberina itself, but the hypophosphite will dissolve readily to a considerable extent, and is the most desirable form I am acquainted with.

COMMERCIAL DRUGS OF THE CHINESE PROVINCE OF KUANG-TUNG (CANTON).*

BY DR. F. HIRTH DU FRENES, OF AMOY, CHINA.

Ginger grows in nearly all parts of the province of Kuang-tung. According to Chinese sources the district Nan'-hai, which belongs to the city of Canton, produces greater quantities and a better quality than the other neighbouring districts. The independent tribe of the Miao-tsu, in the mountains at the north-western border of the same province, are also said to produce large quantities of ginger. In the district of Hsin-hsing—about thirty miles south of the city Chao-ching, on the Western River—three-tenths of the flat land and seven-tenths of the cultivated soil in the hills are planted with ginger. A distinction is made between flat-land ginger (in the Canton dialect tin-keung), which is generally soft and tender, and mountain ginger (shan-keung), which is brittle and very pungent. For home consumption the Chinese pickle it in vinegar; the more expensive syrup-ginger (t'ong-keung) is almost exclusively consumed by foreigners or exported.

A less important, but interesting drug is *galgant* root, which has its original home, and, even now, almost exclusive growth in the province of Kuang-tung. European druggists distinguish two varieties: radix galangæ majoris, the greater galgant; and radix galangæ minoris, the lesser or true galgant. The latter is the Chinese drug. The dried root, which is sold by the grower at the rate of about 1·50 dollar per picul (=133⅓ lbs.), and which may be purchased at present in the new treaty-port Hai-k'on upon Hainan, for 1·60 dollar per picul, is brought by junks to Hongkong and Canton, where its price ranges at about three or four dollars, and whence it is exported to Hamburg or to the United States. Russia also consumes considerable quantities of galgant, which is said to be mostly carried over Hankow; it is there chiefly used to impart a characteristic aroma to a favourite liquor, called Nastoika, and is a favourite spice and medicine among the Livonians and Esthonians.

Another product occurring upon the Canton market is *Curcuma* or turmeric, which is the root of various species of Curcuma growing in the immediate vicinity of Canton, chiefly in the district Tan-yü, to which the eastern half of the city of Canton belongs. A great deal of it reaches the market already in the form of powder.

Much confusion has been caused by the application of the term *China-root* (Radix Chinæ) to various entirely different drugs. In reality this name is applied to two products only, which have only a distant resemblance to each other. The true China-root, which is understood by this name in European pharmacy, grows in the neighbourhood of Canton. In the Chinese herbal, Pên-tsao, it is described under the name tu-fu-ling, while the false China-root, which grows in the province of Sze-chuen, and is brought to market at Hankow on the Yang-tse, is called in the same work by the similarly sounding name fu-ling; and it is not impossible that this resemblance in Chinese names has been the cause of the confusion.* Dr. H. F. Hance, who examined one of the plants from which the true root is derived, declared it to be *Smilax glabra*, Roxb. It is said to be found all over the province Kuang-tung. The description of China-root, which is found in Dr. S. Wells Williams's 'Commercial Guide,' refers only to the China-root of the North (a species of fungus, *Pachyma Cocos*), which forms indeed a considerable article of trade, but is scarcely ever exported further than to the Chinese colonies in Southern China and in the Malay Archipelago. On the other hand, the China-root of the South—which is the only one in demand for the European Market, although it fetches a much lower price—is exported from Canton either direct or by way of Hong-kong to Europe, the United States, or to the East Indies.

Canton is also a chief market for various industrial oils, principally *pea-nut oil* from *Arachis hypogæa.* This plant is of great agricultural importance in Southern China, particularly in the four western departments of the province of Kuang-tung.† The oil obtained from the nuts is carried upon junks belonging to a great commercial native corporation, first to Ch'en-tsun, a river-harbour close by Canton, whence it is distributed to the interior by means of a highly-ramified system of canals. Of the various grades of the oil produced in the neighbourhood of Canton, that from Tsung-hua, about 20 miles north of Canton, is considered the best. The trade in other oils is insignificant in comparison to that just mentioned; nevertheless, a few deserve mention. *Tea-oil*, obtained from the seed-kernels of *Camellia oleifera* (Chin. ch'a-shu, *i.e.*, tea-tree), is mostly produced in the northern districts of the province, namely, in Nan-hsiung, Shao-chou, Lien-chou, and Lien-shan. In Kuang-chou fu, in the department "Kanton," and in Chao-ch'ing fu a sweetish aromatic oil is obtained from various sorts of cabbage, which is known in the market as *cabbage-oil* (tsai-yu). All these oils, when purified, are used by the Chinese for culinary purposes, while the inferior sorts are utilized for burning in lamps. Other oils are produced from *sesame*, from the Chinese *olive* (a species of *Canarium*, the fruit of which has only a slight resemblance to the European olive), and from yellow and white *beans*. *Wood-oil* is obtained from the seeds of the wu-t'ung tree (*Dryandra cordata*, Thunb.,‡ which has its home in the north of the province of Nan-hsiung and Shao-chou fu.

The woods of Hainan are rich in aromatic woods, the botanic origin of some of which is still enveloped in doubt. The most important are *eagle-wood* (lignum aloës and *rose-wood*, the chief depot for export being Ai-chou at the south-coast. The principal commercial articles of Pei-hai (Pak-hoi) are sugar, oil, and indigo, the best quality of which latter is produced near Pei-lin (Pak-loa), about 60 miles north of Pei-hei. Next may be mentioned: China-root, galls, incense, myrrh, wood-oil, assafœtida and *star-anise*. Of the latter between 1000 and 2500 piculs are brought to market annually at Macao and Canton. In 1871, at the latter port alone, 2704 pic. were delivered from Pak-hoi in junks. Our pharmacological text-books usually attribute the production of star-anise to Japan, the Philippine Islands and to the Chinese province Fu-chien, while is now well-known that the border districts of An-nam, Kuang-tung and Kuang-hsi are its real home.

---

* On China-root see 'Pharmacographia,' p. 648.

† These are called the "lower 4 Fu," "hsia-ssu-fu," namely, Chiung-chou (Hainan) Lei-chou (the peninsula), Lien-chou and Kao-chu.

‡ This is different from gurjun or wood-oil, obtained from various species of *Dipterocarpus*.

The Pharmaceutical Journal.

SATURDAY, AUGUST 4, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE DISPUTE BETWEEN M. PASTEUR AND DR. BASTIAN.

THE hope that, for once, a dispute between scientific men on a point of fact might be settled rationally, and that it would be conclusively ascertained whether Dr. BASTIAN was right in affirming, or M. PASTEUR in denying, that bacteria will swarm in previously boiled urine, after being exactly neutralized by pure caustic potash and carefully protected from contamination,* has been rudely dashed to the ground by an announcement just made. It will be remembered that in order to decide between the disputants a commission consisting of Messrs. DUMAS, MILNE-EDWARDS, and BOUSSINGAULT was appointed by the French Academy of Sciences. The miscarriage of the proceedings of this Commission, as described by Dr. BASTIAN, is certainly very ludicrous.

Learning from the *Compte Rendu* of the sitting that the Commission had been appointed, Dr. BASTIAN wrote on the 27th of February to M. DUMAS, offering to go to Paris for three days at a convenient time to perform his experiments before the members. The reply to this letter appears to have miscarried, for on the 5th of May Dr. BASTIAN received a letter,—that had been misdirected,—referring to one that had been sent three weeks earlier but not received, reiterating that the Commission were ready to receive Dr. BASTIAN, and that the laboratory of the Ecole Normale or any other that he chose would be placed at his disposal. To this Dr. BASTIAN replied, asking for the purport of the missing letter, and saying that in consequence of the delay that had occurred he would not be able to visit Paris until the third week in July. Upon receiving a duplicate copy of the missing letter, Dr. BASTIAN considered it not to be sufficiently explicit as to the limits of the inquiry. He therefore wrote back to say that he considered the essential condition of the inquiry to be, "whether previously boiled "urine, protected from contamination, can or cannot "be made to ferment and swarm with certain organ-"isms by the addition of some quantity of liquor "potassæ which has been heated to 110° C. for twenty "minutes at least." An extension of the inquiry to the theoretical bearings of the experiment he refused to entertain on the ground of the brief time at his disposal. No objection was made to these restrictions, but after a month had passed without reply, Dr. BASTIAN wrote asking for the assurance he required, to which M. DUMAS answered that the Commission would be at his disposal on the 15th of July, and that if possible it would only occupy itself with the subject of urine treated with potash. This did not satisfy Dr. BASTIAN, and he again wrote, asking for a more explicit statement. M. DUMAS replied as follows:—"The Commission "desires, like yourself, that the investigation should "be limited to the point in discussion between you "and M. PASTEUR. It would be only in the case of "your desiring to go further that it would have to see "whether the time would permit more being under-"taken, your visit being short."

* See Vol. vii., p. 758.

After this preliminary epistolary skirmishing, Dr. BASTIAN went to Paris. Upon his arrival, he found that one member of the Commission, M. BOUSSINGAULT, could not attend, and that another, M. MILNE-EDWARDS, would not, unless the Commission were allowed to vary the experiments at discretion. Dr. BASTIAN then suggested that at present his experiment should simply be repeated, and that he should visit Paris again, if any variations were considered necessary. A new member of the Commission, M. VAN TIEGHEM was then appointed by the Academy.

The last act of this comedy was equal to anything that went before. It having been arranged that the experiments should be performed in M. PASTEUR'S laboratory, the disputants and M. VAN TIEGHEM were there at the appointed time. Next M. MILNE-EDWARDS arrived, but, learning then for the first time of the compromise, he at once left the laboratory, followed by M. VAN TIEGHEM. These gentleman appear to have waited for M. DUMAS until they were tired, and then the former went away, and the latter returned to the laboratory. When M. DUMAS arrived, he learnt that M. MILNE-EDWARDS had left, so he went away also, declaring the Commission at an end, without communicating with M. VAN TIEGHEM, M. PASTEUR, or Dr. BASTIAN. And then Dr. BASTIAN went home too.

THE BILL TO AMEND THE SALE OF FOOD AND DRUGS ACT.

THE above Bill, which was mentioned as having been introduced into the House of Commons last week, has made extremely rapid progress, notwithstanding the "obstructiveness" that has since been prevalent in that assembly. It has already been read a second time and passed through committee, and probably before these lines appear it will have been read a third time and passed the lower House. On reading the Bill the necessity for such haste is not altogether manifest in the subject matter, and it presents a novelty in legislation that, although the subject is not strictly pharmaceutical, warrants reference to it here.

The Bill consists of a preamble and one clause, which provides that in determining whether an offence has been committed under section 6 of the Sale of Food and Drugs Act, by selling to the prejudice of the purchaser, whether wholesale or retail, spirits reduced by the admixture of water, regard shall be had not only to the extent of such admixture, but also to the price at which the spirits so reduced are sold.

The principle here laid down is, from some points of view, a reasonable one. But, as a matter of fact, it has already been acted upon in reported spirit cases, and, for this and other reasons, special legislation on the subject seems undesirable. Of course, the object of the measure is to prevent a dishonest sale of a diluted article. As the Bill stands, however, it appears that the essence of the offence will lie, not in the dilution but in the charge of a relatively high price for a small percentage of spirit, a test, it may be remarked, that leaves out entirely the quality as indicated by aroma and flavour, and might place a mature whisky below a crude one. Whether the magistrates are supposed to be sufficiently cognizant with the average amount of water present in gin sold at 5*d.* or any other price per quartern in their respective localities, or whether they are to be able to appeal to Somerset House when puzzled by the conflicting evidence of experts, we cannot say; the most objectionable part appears in the novelty of giving a tradesman the liberty of selling an article, but prohibiting him from putting his own price upon it. Moreover, if price is to be so important a factor in deciding what is an adulteration of spirit, to be consistent, the plea of a seller of diluted milk, or even of watered sweet spirit of nitre, that the price charged was in accord with the quality of the article sold, ought also to be allowed.

REBUILDING OF THE PARIS SCHOOL OF PHARMACY.

About eighteen months since, as was stated in this Journal at the time, the French Legislative Assembly voted a large sum of money for the rebuilding of the Ecole Supérieure de Pharmacie at Paris. A correspondent informs us us that rapid progress is now being made with the foundations. The works are the more interesting from the fact that part of the building will be over catacombs and disused quarries. The entire space to be utilized is four and a quarter acres, the larger part of which will be a garden, as in the present school. There will be two amphitheatres of 480 square yards superficies each, and capable of holding conveniently 600 pupils. At the back will be a laboratory of three stories, greenhouses, etc. It is expected that the new buildings will be ready in 1880.

Those who know the stifling little theatre and mean surroundings of the present school in the Rue de l'Arbalète will feel inclined to congratulate French pharmaciens.

BRITISH PHARMACEUTICAL CONFERENCE.

The following Papers, in addition to those previously announced, are to be read at the meeting of the Conference at Plymouth on the 14th inst.:—

23. Further Note on the History of Tea Hair. Thomas Greenish, F.C.S.
24. Copaiba Testing. Louis Siebold, F.C.S.
25. A New Medicinal Solution of Phosphorus. Mr. W. W. Urwick.
26. Blood-Albumen. C. T. Kingzett, F.C.S.
27. Note on Pilocarpine. C. T. Kingzett, F.C.S.
28. Note on Hederic Acid. C. T. Kingzett, F.C.S.
29. Effects of Variations of Temperature on Boiled Putrescible Liquids. Mr. W. Willmott.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, August 1, 1877.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present — Messrs. Atkins, Betty, Bottle, Churchill, Cracknell, Gostling, Greenish, Hampson, Hills, Owen, Rimmington, Robbins, Sandford, Schacht and Shaw.

The minutes of the previous meeting were read and confirmed.

The following being duly registered as Pharmaceutical Chemists were respectively granted a diploma stamped with the seal of the Society.—

Avison, David.
Barron, William.
Burden, John Britten.
Chapman, Joseph John.
Clark, William Inglis.
Dick, Robert Gibson.
Fletcher, Redfern.
Giles, William Egbert.
Griffiths, John Moore.
Hardwick, Stewart.
Holmes, Alfred John.
Jones, Thomas.
Longman, John Ham.
Maggs, Frederick Richard.
Reece, Thomas.
Rickarby, Arthur George.
Simpson, John.
Snell, Charles Henry.
Tuck, Walter Barber.
Wallis, Owen.

Elections.

MEMBERS.

Pharmaceutical Chemists.

The following Pharmaceutical Chemists were elected Members of the Society:—

Avison, David ....London.
Burden, John Britten ....London.
Chapman, Joseph John ....Bramfield.
Clark, William Inglis ....Edinburgh.
Dick, Robert Gibson ....Edinburgh.
Dimmock, Augustus Frederick London.
Francis, Rawson Parke ....London.
Hardwick, Stewart ....Grantham.
Holmes, Alfred John ....London.
Jones, Thomas ....London.
Longman, John Ham ....Weymouth.
Rickarby, Arthur George ......Kirby-le-Soken.
Simpson, John ....London.
Snell, Charles Henry .... Saõ Paulo, Brazil.
Tuck, Walter Barber ....London.

The following registered Chemist and Druggist was elected a Member of the Society:—

Chemist and Druggist.

Hassall, Elijah ... .Stalybridge.

ASSOCIATES IN BUSINESS.

The following having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year were elected "Associates in Businesss" of the Society:—

Minor.

Davidson, William ....Chester.
Hinks, John ....Worcester.
Ogilvie, William Ogilvie ....Arbroath.
Wild, John ....Manchester.

Modified.

Davis, Joseph Burnard ....Lynton.
Hickman, William ....Red Hill.
McAdam, Robert................. Glasgow.
Taylor, John ....Rochdale.
Tocher, George ....Friockheim.

ASSOCIATES.

The following having passed the Minor examination and having tendered (or paid, as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Abbott, George...... ....Liverpool.
Atkins, William Ralph ....Salisbury.
Bartlett, Hubert ....London.
Bishop, Henry ....Wisbeach.
Boa, Peter ....Stranraer.
Clarke, Ethelbert ....Maidstone.
Cliff, James ....Wakefield.
Cobb, Joseph Septimus ....Doncaster.
Foster, James Edward...........Bridgwater.
Gosney, Charles Frederick ......Crewkerne.
Harpham, John ....Newark.
Inglis, William Keiller ....Ashton-under-Lyne.
Jackson, Barnet Edward.........Heywood.
Jones, Thomas Bevan ....Merthyr.
King, William ....Southend.
Mead, Charles John ....Wimborne.
Mills, William Hamer............Heywood.
Milton, Harry ....Exeter.
Moore, John William ....Northampton.
Mortlock, William John ....Peckham.
Nicholson, John Hastie ....Moffat.
Pattinson, William ....Hexham.
Perkin, Thomas ....Stourbridge.
Rheeder, Thomas ....Knaresborough.
Saunders, James Warnes.........Hackney.
Shone, Owen Ellis ....Lambeth.
Slinger, Robert Thomas ....Manchester.
Starkey, George Thomas.........Stratford-on-Avon.
Taylor, Henry Patrick............London.
Walker, James ....Auchmull.
Williams, Alfred Joseph ....London.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination, and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Borkwood, Edward Turner......Boston.
Brown, Alexander ....Motherwell.
Cappell, Robert................. .....Crieff.
Capper, Henry ....Liverpool.
Clarke, Henry R. Stanhope ...Malvern.
Clay, Charles.......................Clay Cross.
Clayton, Christopher ....Market Rasen.
Cleland, Andrew Hutcheson ...Eastwood.
Cole, William ....West Cowes.
Day, Arthur Joseph..... ....Maidstone.
Gowans, John Bruce ....Perth.
Graham, George Leslie............Maidstone.
Greaves, William Thomas ......Nottingham.
Jackson, George Granger ......Buxton.
Kenny, Thomas......................Boston.
Kett. George Robert ....London.
Laing, Alexander ....Kelso.
Mann, Samuel William ....Bristol.
Marsh, Edward......... ....Luton.
Metcalfe, John ....Darlington.
Moody, Lewis ....Lincoln.
Odhams, George Frederick ......Faversham.
Painter, William, junr. ....Broadstairs.
Parker, Charles.....................Lancaster.
Parker, Henry George... ....Kettering.
Porter, Samuel Edward ....Southery.
Powell, Francis Edward ....London.
Pringle, George......................Kirkcaldy.
Rawes, William ....Hulme.
Richards, Benjamin ....St. Dogmells.
Schofield, Frederick Elston......Morpeth.
Sergeant, Furlow Ross ....Goxhill.
Slicer, Walter ....Bingley.
Thompson, Charles Letchford ..London.
Thomson, Ernest Andrew ..... Plymouth.
Watts, George William ....Clapham.
Wheldon, James Alfred ....Darlington.
Wilkins, Walter Sydney ...... .London.
Williams, Evan Wynne ....Dolgelly.

The names of the following persons were restored to the Register of Chemists and Druggists:—

Charles James Merrick, 52, Great Coram Street, London, W.C.

Francis Miles Stickler, 5, The Pavement, Forest Hill, Kent.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts were ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included the recommendation of the following grant:—

£10 to a registered chemist and druggist, who had previously received a grant of £10.

Other cases had been considered, but from various causes it was not deemed desirable to make any recommendation in respect to them.

The report and recommendation of the Committee were received and adopted.

Mr. GREENISH brought forward one of the cases in which the Committee had declined to recommend a grant, and hoped the Council would reconsider the decision, but after a short conversation, the motion meeting with no support, it was not pressed to a division.

Mr. OWEN reported that he had expended the thirty guineas voted last month to assist in securing the election of an orphan into an asylum, and that the child was elected. He might add that no money had been wasted, for the number of votes obtained was only seven above the lowest required. He hoped, therefore, that the Council would be encouraged to take up the cases of orphans in future.

The PRESIDENT said the Council was very much indebted to Mr. Owen for the trouble he had taken in this and many similar cases.

LIBRARY, MUSEUM AND LABORATORY.

The Librarian had reported the average attendance in the library during the previous month to have been, day 21, evening 9. The circulation of books had been, in town 141; in the country, to 21 places, 36. He reported donations from Guy's Hospital, Mons. L. Pasteur, Prof. Dragendorff, and Dr. W. Douglas-Hogg. Letters of thanks were ordered to be sent to the donors. The following was recommended for purchase: Cooke's 'Myxomycetes of Great Britain.'

The Committee recommended that the Library be closed in the evening during August and September.

The Curator had reported the average attendance in the Museum during the month to have been, morning 19, evening 4. Donations had been received from Prof. Attfield, Mr. E. Fielding, Mons. Chantre, Mrs. Reeves, Mr. Bullock, Mr. Walter Hills.

A proof of a portion of the chemical part of the catalogue had been submitted, and at the request of the Committee the President and Mr. Greenish had undertaken to revise the proof before going to press. On the application of Mr. Mackay, the curator had been instructed to send labels to the North British Branch for the museum in Edinburgh.

Professor Bentley had reported a very good attendance in his class at the Botanical Gardens, the average being higher than usual.

Professor Attfield had also reported that the attendance in the laboratory had been better than usual at the end of the session.

The Secretary had submitted the returns respecting the educational department of the Society, as ordered at the last meeting of the Council, but the Committee not considering them sufficiently comprehensive had instructed him to prepare further and more detailed particulars.

The arrangements for the evening meetings had been considered and it had been resolved to recommend that the Professors, the Editor of the Journal, and the Curator be appointed a Committee to examine all papers presented for reading at the evening meetings, and that the arrangements made by the Evening Meetings Committee at its meeting on November 18, 1874, be again adopted, viz., that all papers selected to be read at the evening meetings shall, on the recommendation of the Committee, be paid for at the usual rate when published in the Journal. The Committee also recommended that the above arrangement be carried out for not less than one session, and that the Evening Meetings Committee report to this Committee at the end of the session. It was also recommended that a notice be made public, that papers intended to be read at the evening meetings should be forwarded to the Secretary a week previous to the day of the meeting. It was considered desirable that the Evening Meeting Committee should meet regularly, the time of meeting being left to the Committee itself to determine.

At an adjourned meeting of the Committee a letter asking if the Society intended to exhibit specimens of drugs at the Museum of the British Medical Association during the annual meetings to be held in Manchester, had been directed to be answered in the negative. Donations to the library were announced from the Royal College of Veterinary Surgeons, the Surgeon-General of the United States Army, Mr. Udoy Chand Dutt (of India), and the University of Durham, and letters of thanks were ordered to be sent. The following books were recommended for purchase:—(General Fund)—Roscoe and Schorlemmer's 'Treatise on Chemistry'; (Hanbury Fund)—De Candolle's 'Géographie Botanique.' Some conversation took place with regard to the appointment of the Evening Meetings Committee.

Mr. Churchill asked if it were really desirable to close the library in the evenings during the months of August and September.

The President said that no practical inconvenience was found to arise from so doing.

Mr. Betty remarked that the arrangements recommended by the Evening Meetings Committee would be reconsidered at the end of a year.

Some remarks having been made respecting the publication of the Evening Meeting papers in the Journal.

Mr. Atkins observed, though it did not strictly arise out the report of the Committee, that he had been much gratified by the series of the articles appearing in the Journal, under the heading "The Month." He was quite sure that he was only expressing a general feeling in so speaking.

The President said he quite concurred.

The report of the Committee was then adopted unanimously.

House.

The Report of this Committee included nothing beyond trifling details of house management, cleaning, and minor repairs. It was received and adopted.

Law and Parliamentary.

The report of this Committee was lengthy and important. The first portion stated that a Sub-Committee had considered the form of cautionary letter to be sent to persons accused of infringing the Pharmacy Act, and had submitted an amended form, but the Committee had desired the Sub-Committee to further consider the matter.

The Solicitor had sent in his usual report as to matters which had been placed in his hands, in some of which proceedings are still pending.

In the case of John Jones, 197, Westminster Road, Kirkdale, Liverpool, the penalty of £5 and costs had been paid into Court.

In the case of Edmund Mainprize, of 64, High Street, Bridlington, proceedings had been stayed upon payment of costs, an undertaking having been entered into by the defendant not again to violate the provisions of the Act of Parliament.

Several cases of alleged infringement of the Pharmacy Act had been brought under the notice of the Committee, the details of which were reported.

A case of laudanum being sold by an unregistered person under a patent medicine stamp had been considered by the Committee, and it was recommended that the legality of such sale should be tested.

The Committee also recommended that hydrate of chloral be placed in part 2 of schedule A. to the Pharmacy Act, 1868.

The Chemists and Druggists' Trade Association had forwarded a copy of a resolution passed by the Law Committee of that body to the following effect:—"That this Committee regrets the action which the Council of the Pharmaceutical Society has thought best to adopt in reference to cases of illicit trading, evidence of which has been supplied by this Association, particularly the resolution of the Council by which it decided to give the Registrar power to warn in all cases of infringements without receiving the instructions of the Council in each case."

On the motion that the report be received,

Mr. Bottle moved as an amendment:

"That the report and recommendations of the Law and Parliamentary Committee be received with the exception of the copy of resolution annexed to the letter of July 13th, from the Secretary to the Chemists and Druggists' Trade Association."

It seemed to him that it was not pertinent to the discussion which had previously taken place; and he did not think it quite courteous to the Council.

Mr. Rimmington seconded the amendment.

The President said he should be sorry if the amendment were pressed. The resolution come to by the Association seemed a very natural one, and probably the suggestions now thrown out by the Law and Parliamentary Committee would very much remove the objection which was felt by the Trade Association, which chiefly arose from the fact of the Society not availing itself of information which had been very difficult to obtain. It was thought at the Committee meeting, on the previous evening, that some means might be found for utilizing this information.

Mr. Sandford thought Mr. Bottle was perfectly in order, inasmuch as the resolution was addressed to the Council, and had no business to have been laid before the Committee.

Mr. Betty also thought it would be quite out of order for the Council to receive as a portion of a report from a committee, any matter which had not properly come before that committee.

The Secretary said he should like to know for his future guidance, whether all letters addressed to the Council must be submitted to it in the first place; because if he were not allowed to bring such letters before the Committee first, in some instances inconvenient delays would arise.

The President said it was the usual custom to lay such letters before the Parliamentary Committee.

Mr. Hampson regretted that Mr. Bottle had brought forward this amendment. The Committee of the Trade Association was simply exercising the privilege of commenting on the action of another body, and he was quite sure that in so doing it was only endeavouring to carry out what it thought best, without reflecting in any manner on the Council. He was quite sure there was no *animus* on the other side, and he hoped there would be none shown by the Council. The action of the Trade Association was no doubt a delicate one, but the information which had been furnished in respect to illegal trading had been very useful.

Mr. SANDFORD thought it was a pity to discuss the merits of the question. It seemed to him purely a matter of form, whether the Council would be in order in taking this resolution from a Committee to which it had not been addressed.

Mr. HAMPSON said he thought he was in order in speaking to the amendment which he hoped would be withdrawn.

Mr. CHURCHILL also hoped that Mr. Bottle would see his way to withdraw the amendment. It seemed to him that it was necessary for the Trade Association to pass a resolution of some kind, and a more polite one could scarcely have been passed. When a body went to some expense and trouble in getting up information, it was only natural to regret that it was not made full use of. However he was pleased to think that the debate at the last Council seemed to have paved a way for better regulations as to the treatment of cases of infringement in future.

Mr. SHAW said this seemed a very technical question whether this resolution should be received as embodied in the Committee's report, because if it were omitted there it must come before the Council, when the question of sending a cautionary letter in each case might be discussed.

The PRESIDENT said the letter could not raise the question. It was open to any member of the Council to bring it forward again, but it was hardly desirable to do so, considering how thoroughly it was discussed last month.

Mr. ATKINS said he could not of course tell what had been the practice of the Council, but in similar bodies he knew it was usual to refer letters to a Committee for consideration. The address upon it was purely accidental.

The SECRETARY said that the letter was addressed to him and consisted of two portions. The first portion of the letter requested that a resolution, a copy of which was annexed to the letter, should be submitted to the Council, and the other portion of the letter reported a case of infringement of the Pharmacy Act. The letter had therefore been brought, as was usual with all letters containing such information, before the Committee.

Mr. OWEN thought the Council was really making too much of this point. It did not matter whether the resolution came before the Committee or the Council.

Mr. SCHACHT thought the resolution referred to was a most natural one, but it did not follow that the Council was bound to record it on its own minutes, for which he saw no necessity.

The amendment was then put, when 8 votes were given for it, and 8 against.

Mr. BOTTLE said he would withdraw the amendment rather than place the President in the position of having to give a casting vote.

The Council then went into Committee to consider the details of the various cases referred to in the report of the Committee.

After a long discussion, the report and recommendations of the Committee, with one exception, were received and adopted.

CHLORAL HYDRATE.

It was then resolved, on the motion of Mr. SHAW, seconded by the VICE-PRESIDENT—

"That the proceedings in reference to placing Chloral Hydrate on Schedule A. be postponed until the meeting of Council in October next, to afford an opportunity to add other articles if necessary."

COUNTER PRACTICE.

Mr. HAMPSON moved, and Mr. ATKINS seconded, a resolution to the effect that the Council defend, if necessary, a member of the Society, who had been threatened with prosecution under the Apothecaries Act.

Mr. OWEN said he was on the best possible terms with the medical profession, amongst whom he had moved since he was ten years old, but he must confess that a large part of his business was done over the counter. He considered he was doing what he was entitled to do, and that any other member who was doing the same ought to be supported.

Mr. SHAW also supported the motion.

The VICE-PRESIDENT quite concurred with the proposition, but it occurred to him that some difficulty might arise if both the Trade Association and the Society undertook the defence. He did not know how the two solicitors could act together. He had taken the trouble to go through some of the early numbers of the *Lancet*, and found the editor was strongly in favour of the position which chemists were now assuming; in fact, he went much further. The Vice-President proceeded to read extracts from the *Lancet*, written in 1826, which spoke of the Apothecaries Act as being "projected by avarice, supported by intrigue, and enacted by ignorance," and said it could have no other effect than to "excite unmixed contempt for its authors."

The PRESIDENT doubted if these extracts were relevant at the present time.

The VICE-PRESIDENT thought they were; the Act having been passed in 1815, the writers were quite as likely to understand it in 1826 as fifty years later, during which period no action had been taken to enforce it as it was now sought to do. The *Lancet* defined the position of chemists at that time, saying they were accustomed to prescribe and even to visit patients.

The PRESIDENT said that was not the law.

The VICE-PRESIDENT said it was the opinion of men who ought to know. If the case now under consideration were a good one the Council was bound to defend it.

Mr. ROBBINS agreed that the rights of chemists and druggists ought to be supported. The question had often come before the Council and he had always voted against it being taken up, because it had hitherto been always connected with some doubtful case, and he felt that if the Council undertook to defend a man who had been accustomed to prescribing, in the general sense, it would be doing mischief. But in this case the chemist seemed to be conducting his business properly, according to the practice of the majority of the trade, and he ought to be supported.

Mr. SCHACHT hoped he would be forgiven if he endeavoured to check the enthusiastic career of the Council at the present moment, but he sincerely hoped it would take further time to consider before deciding on such an important step. There was, it was true, on the minutes an abstract resolution that the Council would be prepared to entertain a good case where vexatious proceedings were threatened. He had opposed that at the time, and now it came to a concrete proposition that an individual case should be taken up he must oppose it, because it appeared to him that the Council would be taking up the indefensible position of justifying what could not be justified,—the prescribing for disease by those who were not qualified so to do. He did not say whether men were right or wrong in so doing, but legal authorities agreed that in so doing they were acting against the law, and it seemed to him to be a great mistake to set themselves against the law as interpreted by the best authorities. If one man were defended all ought to be, but though some of his neighbours and friends did the same, as Mr. Owen said he did, they said to him that they knew they were offending against the law, and if they were proceeded against they were prepared to take the consequences. That seemed to him a manly course for those who knew they were legally wrong, though they might consider themselves morally in the right; and he did not see that they had any right to throw the defence on the Society. Those who so acted reaped the benefit, the Society did not, and it ought not to be involved in the question. He admitted it was very hard on gentlemen to be put in the position of having to do things which were illegal, or which many persons deemed illegal, but he considered the proper course was to try and obtain a more favourable definition of their position, and for that purpose he proposed to bring forward a motion in October that the Council communicate with the Apothecaries' Company, and endeavour to arrive at some amicable arrangement as to the limits which should be laid down as being unobjectionable.

Mr. Betty said this matter would not be decided by the personal influence of medical men, or their amicable relations with particular chemists and druggists. He hoped the Council would not take any step without being well advised in the matter. The chemists and druggists' position as prescribers of medicine was ambiguous, especially in the face of Baron Bramwell's opinion, and he hoped the Council would adopt Mr. Schacht's proposal, and at any rate do nothing at present.

Mr. Bottle said he would not occupy many minutes, especially as the Committee had sat until half-past 10 on the previous night in considering this and other matters; but he did think the time was now come when it was the duty of the Council to endeavour to settle on a firm basis what were the rights of chemists and druggists. Whether that was to be done by defending a particular case in the County Court, and if necessary, in a superior court, or by bringing the matter before the House of Commons, he thought it was the duty of the Council to look the matter fairly in the face, and he was therefore prepared to support the motion, but he could suggest a modification in its terms to the following effect—

"That this Council authorizes its Solicitor at his discretion and at the expense of the Society to defend the gentleman referred to in the threatened prosecution by the Apothecaries' Society."

After some conversation, Mr. Hampson and Mr. Atkins agreed to accept this form.

The President said the real question was whether the Council was prepared to defend the case at all. He must remind the Council that it had for many years protested against medical practice by chemists and druggists, and not a single resolution would be found on the minutes which either encouraged or sanctioned it. He could not himself agree that it was right for the Society to protect a practice which he could only look upon as illegitimate. Chemists and druggists had no education, properly speaking, in the practice of medicine, and under these circumstances he did not see how they could defend the system objected to, although he admitted its universality, and its public convenience. He looked rather to the good sense of the medical profession than to any decision in a court of law for protection.

Mr. Hills agreed with the President. It was very easy to run into law but more difficult to get out of it. It was very difficult, if not impossible, to define the proper limits of counter practice, and he should like much more consideration to be given to this particular case before the Council pledged itself to defend it.

Mr. Shaw was glad Mr. Hampson had accepted Mr. Bottle's suggestion, especially, as Mr. Flux had already stated that he had no doubt of the issue of any case that went into court for *bonâ fide* counter practice.

Mr. Cracknell said he had many old customers who would feel highly offended if he refused to prescribe for them; but at the same time he felt that he did so entirely on his own responsibility, and if he were attacked he should not think of applying to the Society for assistance. He did not consider it right for such a body to undertake the defence of a practice which he could not help thinking was somewhat doubtful, and he should, therefore, vote against the motion.

Mr. Churchill said he was surprised that no reference had been made in this discussion to their 3000 or 4000 constituents, whose interests were affected. Personally, they all agreed that the less prescribing and the more dispensing they did the better, but it seemed to him that the course some medical men were now taking would tend to crush out the chemists and druggists altogether, for they would not be allowed to prescribe or to dispense. He did not wish to see any extension of counter practice, but the case under discussion seemed to him as plain and simple a one as could be imagined, and he thought it was the duty of the Council to defend it. He should be quite prepared to support Mr. Schacht's proposal, when he brought it forward, for endeavouring to make an arrangement with the Apothecaries' Society; but it appeared to him that if they gave up entirely the right of counter practice they would have little chance of obtaining from medical men the right of dispensing. The Society must go into Court and defend the case, because the Solicitor of the Society had information which it would be difficult to obtain elsewhere, and if the history of the saving clause with regard to the rights of chemists which was introduced into the Apothecaries Act could be traced it would no doubt be very useful. The opinion of Baron Bramwell would be very likely to influence the county court judges until a decision of the Court of Queen's Bench was obtained. But whatever the opinion of the judges might be it seemed to him pretty clear that if the decision was adverse chemists would soon have no trade at all, and in a hundred years there would be no one left in the trade.

Mr. Hampson, in reply, said the Council must really face the difficulty, and the difficulty was this, that a certain portion of the medical profession were determined to put a stop to what was called counter practice, though for time immemorial up to a recent date, there had been been no attempt to interfere with what they considered their legitimate rights. This was an attack upon the trade and the public as well, and it was the duty of the Council, representing both, to take up the matter.

On the motion being put, the following voted:—

For.—Messrs. Atkins, Betty, Bottle, Churchill, Gostling, Greenish, Hampson, Owen, Rimmington, Robbins, Savage, and Shaw—12.

Against.—Messrs. Cracknell, Hills, Schacht, and Williams—4.

The motion was therefore carried.

Reports of the Council Proceedings.

The President read the following letter which he had received from the Editor:—

"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, London, W.C.,
"July 30, 1877.

"Journal Department.

"To the President of the
"Pharmaceutical Society of Great Britain,

"Sir,

"In the report of the proceedings of the Council published in the *Pharmaceutical Journal*, of the 7th inst., statements are represented to have been made by some members of the Council which appear to require notice, since they are not in accord with the facts of the case; I refer to the observations of Mr. Hampson and Mr. Sandford respecting the official report of the Council proceedings.

"In the first place, Mr. Hampson is represented as urging that it was impossible for the Council reporter to give an absolutely genuine report of the proceedings, and the reason given by Mr. Hampson for this allegation appears to have been expressed in the following words:—

"'After he [the Council's own reporter] had written down what he considered to be important the remarks of each speaker were sent to the Editor, and were put into type, and were then sent to the town members and they had an opportunity—a very pleasant one he might admit —to amend, to improve, or to add to, or possibly to suppress a portion of the report.'

"As regards the procedure systematically followed with the reports of the Council's proceedings, the first part of Mr. Hampton's statement is substantially correct, but the interpretation which he offers of that procedure is erroneous, and I therefore think it necessary to state that though a proof of the reported remarks of each town member is sent out on Friday morning no opportunity is given for any amendment of the report beyond such verbal corrections as will not affect the general tenour and purport of the speaker's remarks. Neither is any opportunity furnished for adding to or suppressing any portion of the report as it is handed to me by the official reporter.

"The assumption that the report of the Council's proceedings is altered, supplemented, and in part suppressed while passing through the Editorial department is one entirely without foundation in fact, and, as regards the performance of my duties as Editor, I think it necessary to point this out, since it appears to be solely upon the basis of that assumption that Mr. Hampson expressed the opinion that the official report now published in the Society's Journal was not such a report as he desired should be published.

"Mr. Sandford's remarks on this subject may also be read as indicating a misapprehension similar to that evinced by Mr. Hampson, for he is reported to have said, 'The reporter took notes and sent them to the Editor, who published just what he liked, and the members of the Council themselves had no authority to interfere.' So far from attempting to exercise any such censorship over the report of the Council proceedings, I have always considered it to be imperative on me to publish whatever is handed to me by the Council's official reporter. I have always acted upon that principle in regard to these reports, and have uniformly assigned that as my reason for declining to adopt alterations which appeared to me to be beyond mere press corrections.

"As regards the advantages enjoyed by some of the members of the Council in having proofs of their remarks submitted to them, it is entirely incorrect to suppose that this proceeding involves anything unfair to others, or that any distinction is made in this respect between town and country members of the Council; as, in fact, both have enjoyed this advantage, and it has always been open to all; the only real difference arising from the inaccessibility of members of the Council who are not on the spot at the time available for the purpose. On numerous occasions country members of the Council have stayed in town for the purpose of seeing proofs of their remarks, but it would be obviously useless to send proofs to them in distant parts of the country.

"In addressing you on this subject I do not desire to raise any further discussion, but have done so because it appeared to me that the remarks I have referred to conveyed some reflection upon me in my position of Editor, and that it was desirable on that account, so far to place on record my individual protest against them. I shall, however, feel obliged if you will exercise your own discretion in deciding whether or not it is desirable to take any official cognizance of my letter.

"Believe me,

"Yours very truly,

"BENJ. H. PAUL."

Mr. SANDFORD said he thought Dr. Paul had unintentionally misrepresented him. What he meant to convey was, as he believed the context would show, that the *Council* exercised no control over the report.

Mr. HAMPSON also referred to the subject, and said he must adhere to what he had before stated; and he must add that in his own case he had made more than verbal corrections, though he had always done so in perfect harmony with the opinions he had expressed at the Council. He also again expressed the opinion that in some cases gentlemen were not reported so fully as those who had heard the proceedings would have expected.

THE PHARMACEUTICAL CONFERENCE.

The President said it had been suggested that the Council should send delegates to the Pharmaceutical Conference to be held at Plymouth, as was done by several other bodies. He would therefore propose that all members of the Council who intended attending the Conference should give their names and be appointed delegates. The duties would be purely honorary, of course.

The President, the Vice-President, and Messrs. Atkins, Betty, Cracknell, Greenish, Owen, Robbins, and Schacht were thereupon elected delegates accordingly.

GENERAL PURPOSES.

The Professors' Reports, etc.

Professor Redwood had presented a very satisfactory report as to the result of the examinations for the prizes, the result of which will be found below.

Professor Bentley reported in very favourable terms of his class, the average number of marks obtained by the first six candidates having on no previous occasion been so high.

For the botanical prize there had been three herbaria sent in, the first of which contained 715 specimens; the other two were also very commendable.

Professor Attfield also had reported in very satisfactory terms as to the attendance in the practical chemistry class, and the good conduct of the students.

The examiners who had been appointed to conduct the examination for the "Council Examination Prizes," had also made their report, and the result of the competition will be found below.

PRIZE AWARDS.

The following awards were made on the recommendation of the General Purposes Committee:—

Chemistry and Pharmacy.

[Five months' course.]

Bronze Medal	Robert Henry Parker.
Certificate of Merit	Robert Brown Betty.

[Ten months' course.]

Silver Medal	George William Bullen.
Certificates of Honour	Robert Henry Parker. Geo. Fredk. Gutheridge. Rawson Parke Francis.
Certificates of Merit	David Avison. Robert Brown Betty.

Botany and Materia Medica.

[Five months' course.]

Bronze Medal	Robert Henry Parker.
Certificates of Merit	Stewart Hardwick. Robert Brown Betty.

[Ten months' course.]

Silver Medal	Robert Henry Parker.
Certificates of Honour	George William Bullen. Geo. Fredk. Gutheridge. Henry Peirson. David Avison. Rawson Parke Francis.

Practical Chemistry.

Silver Medal	Robert Henry Parker.
Bronze Medals	Geo. Fredk. Gutheridge. Rawson Parke Francis.
Certificates of Honour	George William Bullen. William Ralph Atkins. William Bevan.

Certificates of Merit............	David Avison. Walter Barber Tuck. Fredk. Wm. W. Corden.

Botanical Prize.

Silver Medal..........................J. T. Creswick Williams.
Bronze Medal........ ....Thomas Francis Elton.
Certificate of Honour...............John William Ellis.

Council Examination Prizes.

Pereira Medal (silver); and Books value £5, presented by Mr. T. H. Hills.

George William Bullen.

Pharmaceutical Society's Medal (silver); and Books value £3, presented by Mr. T. H. Hills.

Henry George Greenish.

Pharmaceutical Society's Medal (bronze); and Books value £2, presented by Mr. T. H. Hills.

William Inglis Clark.

In reply to questions from Mr. Shaw and Mr. Schacht, The PRESIDENT said there had been thirteen competitors for the Pereira Medal, twelve in London, and one in Edinburgh; the majority of the London men being practically at work in the laboratory, or studying in the school. He then congratulated those members of the Council whose relatives figured so honourably in the prize list.

Mr. GREENISH said he should shortly take an opportunity of again bringing before the Council the question, whether the papers for the prize examinations could not be set by some competent persons other than the Society's professors. He should like, also, to see the subject of the Pereira Medal further considered, for he was satisfied from an inspection of the last paper on practical chemistry, that the questions were more calculated to encourage cramming from text books than to test the real practical abililty of the student.

JACOB BELL MEMORIAL SCHOLARSHIPS.

The Committee appointed to award, subject to the approval of the Council, these Scholarships reported that the Examination was held on July 2nd, when fourteen Candidates competed, viz., London, 5; Birmingham, 1; Boston, 1; Bristol, 1; Colchester, 1; Liverpool, 1; Macclesfield, 1; Manchester, 1; Nottingham, 1; Portsmouth, 1.

The mottoes adopted by the two Candidates who had obtained the highest number of marks, were "*Facta non verba*" and "*Veritas*," and the Committee recommended that the Scholarships should be awarded to the competitors adopting these mottoes.

The Committee had opened the envelopes bearing these mottoes, and the successful candidates were found to be Henry Allen, London, and John Graham Sangster, of Portsmouth.

The report and recommendation of the Committee were adopted.

The following were declared to be the scholars for the Session 1877-78:

Henry Allen.
John Graham Sangster.

The PRESIDENT thought the result of this Examination was very gratifying. Mr. Henry Allen was a pupil of Mr. Owen's, his father being a printer's reader, and the father of Mr. Sangster was, he understood, a stoker or engineer on board H.M.S. *Spitfire*.

Mr. OWEN expressed his gratification at the success of Mr. Allen who had given him the greatest satisfaction in every respect.

SUPERINTENDENTS AND DEPUTY SUPERINTENDENTS OF WRITTEN EXAMINATIONS.

The following Superintendents and Deputy-Superintendents of written examinations at the various local centres were appointed for the ensuing year:—

SUPERINTENDENTS OF EXAMINATIONS.

Aberdeen	Davidson, Charles.
Aberystwith	Wynne, E. P.
Barnstaple	Goss, Samuel.
Berwick-on-Tweed	Carr, William Graham.
Birmingham	Southall, William.
Boston	Fowler, W. R.
Brighton	Gwatkin, James Thomas.
Bristol	Stoddart, W. W.
Cambridge	Deck, Arthur.
Canterbury	Bing, Edwin.
Cardiff	Procter, Samuel J.
Cardigan	Jones, J. E.
Carlisle	Thompson, Andrew.
Carmarthen	Davies, R. M.
Carnarvon	Lloyd, William
Cheltenham	Smith, N.
Chester	Grindley, W.
Colchester	Shenstone, J. B. B.
Darlington	Robinson, A. F.
Doncaster	Dunhill, W. W.
Dorchester	Evans, A. J.
Douglas, I. of Man	Brearey, W. A.
Dumfries	Allan, William.
Dundee	Hardie, James.
Edinburgh	Mackay, John.
Exeter	Delves, George.
Glasgow	Kinninmont, A.
Guernsey	Arnold, A.
Hereford	Jennings, R.
Hull	Bell, C. B.
Inverness	Galloway, G. R.
Jersey	Ereaut, J., jun.
Leamington	Jones, S. U.
Leeds	Reynolds, R.
Leicester	Cooper, Thomas.
Lincoln	Maltby, Joseph.
Liverpool	Abraham, J.
London	Taylor, Geo. Spratt.
Lynn	Atmore, George.
Macclesfield	Bates, W. I.
Manchester	Wilkinson, W.
Newcastle	East, Rev. W. B.
Northampton	Bingley, J.
Norwich	Sutton, Francis.
Nottingham	Atherton, J. H.
Oxford	Prior, G. T.
Peterborough	Heanley, M.
Plymouth	Balkwill, A. P.
Portsmouth	Rastrick, J. L.
Preston	Barnes, J.
Reading	Hayward, W. G.
Salisbury	Atkins, S. R.
Scarborough	Whitfield, J.
Sheffield	Ward, William.
Shrewsbury	Cross, W. G.
Southampton	Dawson, O. R.
Stafford	Averill, J.
Swansea	Brend, Thomas.
Taunton	Prince, Henry.
Truro	Serpell, S.
Worcester	Virgo, Charles.
York	Davison, R.

DEPUTY-SUPERINTENDENTS OF EXAMINATIONS.

Aberdeen	Kay, James Petrie.
Aberystwith	Davies, J. H.
Barnstaple	Symons, Charles.
Berwick-on-Tweed	Carr, Robert.
Birmingham	Churchill, Walter J.
Boston	Thomas, F.
Brighton	Savage, William Wallace.
Bristol	Schacht, G. F.

Cambridge	Church, H. J.
Canterbury	Amos, D.
Cardiff	Bartleet, John.
Cardigan	Evans, E. C.
Carlisle	Hallaway, John.
Carmarthen	Davies, R. M., jun.
Carnarvon	Hughes, Richard.
Cheltenham	Barron, William.
Chester	Williams, Thomas.
Colchester	Cordley, William. B.
Darlington	Hutchinson, E.
Doncaster	Shaw, H. W.
Dorchester	Durden, Henry.
Douglas, I. of Man	Cannell, C.
Dumfries	Carruthers, R. B.
Dundee	Laird, William.
Edinburgh	Ainslie, William.
Exeter	Lake, J. H.
Glasgow	Davison, T.
Guernsey	Collenette, A.
Hereford	Parkin, T.
Hull	Baynes. J.
Inverness	Galloway, G.
Jersey	Ereaut, J.
Leamington	Davies, H.
Leeds	Smeeton, W.
Leicester	Cooper, Henry.
Lincoln	Battle, J. S.
Liverpool	Shaw, John.
London	Bremridge, Richard.
"	Knapman, J. W.
"	Holmes, E. M.
Lynn	Willis, C.
Macclesfield	Wood, R.
Manchester	Wilkinson, G.
Newcastle	Usher, J.
Northampton	Mayger, W. D.
Norwich	Corder, O.
Nottingham	Fitzhugh, R.
Oxford	Thurland, H.
Peterborough	Buckle, F. G.
Plymouth	Hearder, H. P.
Portsmouth	Rastrick, R. J.
Preston	Barnes, L. R.
Reading	Bradley, Charles.
Salisbury	Orchard, E. J.
Scarborough	Fryer, C.
Sheffield	Maleham, H. W.
Shrewsbury	Cross, W. G., jun.
Southampton	Spearing, James.
Stafford	Averill, H. A.
Swansea	Brend, K. B.
Taunton	Gregory, G. H.
Truro	Richards, J. E.
Worcester	Lunn, Thomas.
York	Cooper, Thomas.

Provision for Orphans.

Mr. Robbins next brought forward the following motion, of which he had given notice—

"That the benefits of the Benevolent Fund be further extended by making a provision for the orphan children of deceased Members or Associates of the Society, according to the intention of the Founders as expressed in the Charter of Incorporation.

"That the surplus income derived from subscriptions be appropriated to the benefit and advancement of such children by the purchase of admissions into Orphan Institutions, or in any other way the Council may deem desirable.

"Candidates for admission by purchase to be nominated by the Council. The election to be by voting papers, and to take place at the same time and in the same manner as the Election of Annuitants."

In proposing this resolution he wished to remove the misconception which existed amongst some members with regard to the position and working of the Benevolent Fund. Whenever a proposal was made for extending the benefits of this charity in any way, a great deal of alarm was excited, and they were cautioned against jeopardizing the safety of the annuitants. Now this arose from total misconception, because they were already as safe as it was possible to make them. The funded capital had been accumulated for that very purpose, and an annuitant once elected had a claim on that fund as long as he lived, or as £30 existed to satisfy that claim. This explanation he generally found re-assuring as regarding the annuitants, but then it was said it would never do to jeopardize the safety of the invested capital. But it appeared to him that the invested capital was as difficult to jeopardize as the position of the annuitants. Suppose for instance the subscriptions were to totally fail—a supposition almost too ridiculous to be urged; in that case the interest of the invested capital would not be sufficient for the present moment, and at first would draw somewhat heavily on that capital, but in the course of a very short time, by the natural process of deaths, the number of annuitants would be reduced sufficiently for the interest to pay all charges; and any one who would take the trouble to work out the problem would be astonished to find how little the invested capital would suffer by such a process. Having reached that point, every annuitant who died would afford capital again for re-investment, so that by the time the last had paid the debt of nature the invested capital would be as much or more than it was at the time of starting. All fears therefore as to the safety either of the annuitants or of the invested capital were purely imaginary. The Benevolent Fund had taken thirty-five years to attain its present position, and it was capable, under good management, of doing whatever it was necessary to accomplish in the way of charity. The time had now arrived, therefore, when some provision should be made for the orphan children of deceased members or associates of the Society. This was particularly mentioned, amongst other things, by the founders of the Society; they mentioned members, associates, their widows and orphans; the first three had already been dealt with, but the fourth had not, but the time had now arrived when the Council ought to complete what was intended by the founders. To accomplish that would be to crown the edifice, the foundation stone of which was then laid. To carry out this proposal there were no difficulties to be encountered at present nor any liabilities to be incurred in future. This was a different proposal to the one he had urged some few years ago, viz., to increase the number of annuitants. In creating an annuity they could not say what liability would be incurred; it might last for one year or twenty, at a cost of £30 or £600, but in electing a child to be provided for in an institution there was no liability incurred. There was surplus money derived from subscriptions already in hand, and according to the practice hitherto adopted that surplus would be taken to Threadneedle Street, and in the course of twelve months there would be returned about $7\frac{3}{4}d.$ in the pound to expend in charity. That, no doubt, in the early history of the Society, was quite right, but at the present time it was quite wrong. All the subscriptions sent in should be used if there was need for them; if not, and no reason could be shown why there should be any need for them twenty years hence, he could not see why the Council should try to build up a great fund, so that chemists twenty years hence should have no need to put their hands into their pockets. Again, in spending the whole of the subscriptions, they would not prevent the Fund from increasing. Donations and legacies would have to be invested as heretofore. Only recently, a gentleman gave Mr. Bremridge fifty guineas for the Fund; and such donations must be invested, and would go to increase the invested capital whether advisable or not, and he must say that to such a society a large invested capital was sometimes mischievous. Some four years ago, when making inquiries on this subject, one secretary of a benevolent institution told him the great difficulty he had to contend with was the large amount of their invested capital, because people would not subscribe when there was so much money in hand. He thought, therefore, the time was come when the Council ought to carry out the intentions of the founders. Looking over the obituary in the Journal, one could not but be struck with the large number of deaths amongst chemists and druggists in the very prime of their existence, whilst their career had yet been too short to make proper provision for those dependent upon them for support. The widows of such persons would frequently rather suffer many privations than ask for a casual grant of £10 or £15.

The PRESIDENT here said he believed they were all of one mind on the abstract question, and suggested that Mr. Robbins should confine his remarks to the question of what was the best way of carrying out the idea.

Mr. ROBBINS continued that he was just going to observe that such persons would welcome the privilege of having a child provided for, and ultimately sent out into the world fitted to fight the battle of life successfully.

The PRESIDENT said all were agreed as to that, he believed, but the question was whether it would be advisable to have elections with voting papers.

Mr. ROBBINS said that was a matter of detail which he was quite willing to refer to a Committee.

The PRESIDENT remarked that the Council had over and over again expressed its desire to make provision for orphans.

Mr. ROBBINS said it had not practically done anything, and he thought it was quite time to begin. There was now about £400 or £500 a year surplus, and if such a plan were adopted he believed the subscriptions would soon be doubled. However, he was quite willing to withdraw the last part of the motion.

Mr. BOTTLE, in seconding the resolution, said Mr. Robbins had left but little for him to say. He was willing to admit a certain amount of good service had been done for orphan children, but there was an opening for more to be done. At the end of every year there was a balance of subscriptions, which under the bye-laws had to be invested, and Mr. Robbins' notion was that the Council should take care to expend that balance rather than invest it. Observations sometimes reached them that posterity had done nothing for them, and they did not see why they should do anything for posterity in heaping up a lump of money for benevolent or any other purposes; but the position taken up by Mr. Robbins would meet that, because it gave an opportunity of doing something for posterity, not by heaping up money, but by taking care of orphans and rendering them useful members of society. The Council knew that as a rule the country practice of a chemist was not a money making business, as might be seen by the advertising columns of the Journal, offering businesses for disposal, the returns of which were £200, £300, or £400 a year,—and what could there be in the way of profits from such establishments? It must follow that there was a large number of people, who, if they managed to make a living for themselves, could not leave much behind them, and though the widow might not come and ask for an annuity she would be much relieved by having one of her children provided for.

The VICE-PRESIDENT doubted the advisability of establishing a separate fund for the purpose of providing for orphans, and thought it would answer every purpose to apply the funds at disposal from time to time in this way.

The PRESIDENT said Mr. SANDFORD had been obliged to leave, but he had left the following observations on this subject which he would read:

"It appears to me that these resolutions are unfortunately framed. I do not for a moment object to the granting of such relief as they propose, but the Council already possesses full power to grant it.

"Clause 1 of the regulations, describing the 'objects of the Fund,' states expressly that 'occasional grants' may be afforded to 'orphan children.'

"Clause 10 empowers the Council, after due investigation to 'decide on the amount and character of the relief to be afforded.'

"Clause 33 specially sets forth that 'the Council may, if they think fit, provide a home by purchase in one of the public asylums for orphans.'

"I believe that in the amended regulations, to come into operation in 1878, this 33rd clause is more prominently put in an earlier part of the regulations.

"The allusion to 'the intention of the founders' is altogether superfluous as the whole rules are framed, and the whole money subscribed, to carry out the objects proposed in the Charter and perpetuated by the Acts.

"To speak of 'the surplus income' being applied to this or that special purpose appears to be unreasonable. All relief granted under the regulations must be a legitimate application of the Fund, and there can be no surplus until the end of the year when the Council has relieved such cases as it had the means, and deemed it right to relieve, whether by grants to distressed men, widows, or orphans.

"Mr. Robbins' third proposition is undoubtedly intended to excite a more general interest in the Benevolent Fund, and thereby to obtain for it increased support. Those who are of opinion that the present system of electing pensioners is open to abuse, entailing unnecessary expense on the candidates and often ending in the election of the least needy and deserving, will scarcely deem it wise to adopt this system of relieving orphans.

"For myself, I am not prepared to support this view, I believe the Council, having full particulars of all the cases before them, could select better than the general body of subscribers, but I think the popularity given by the general voting outbalances the occasional mistakes thus arising, and, bringing in a large income, enables the Council to relieve more freely and extensively than it might otherwise be able to do.

"One serious objection to the proposal seems to me to be, that it would render the relief granted only periodical, instead of available when most needed. For instance: a child becomes an orphan, a month after the election proposed by Mr. Robbins; no other election will occur for eleven months, by which time this child may have passed the age at which he could be admitted to any Orphan Asylum.

"It may be assumed that if the power to grant sums for the purpose advocated by the present proposal be once vested in the Society at large, the Council will for ever relinquish its privileges in the matter, beyond the decision as to the number of children who may be thus assisted and the merits of the candidates. I take it that, although not so stated in words, this would be the natural result.

"I presume Mr. Robbins would not advertise for needy orphans, any more than we now advertise for pensioners: such a course would have what is called a pauperizing effect. The Committee studying the applications for aid from month to month could select as many, or perhaps more than as many, cases in which this kind of assistance would be a great boon as the Fund could afford to relieve.

"Knowing it to be the wish of the Council to give such aid more frequently than hitherto, the Committee would naturally do this; but we are not now to begin *de novo*.

"At the very last Council meeting a sum of fifty pounds was granted 'in aid' for the admission of an orphan. Query.—If these resolutions be passed will the Council have the power to make 'grants in aid' hereafter?"

Mr. Owen said as far as he could gather, Mr. Robbins desired an extention of the principle which had been hitherto acted on, not that they should in every case durchase the admission of an orphan into an asylum, which would cost a great deal of money. He should recommend that the principle acted upon last month so successfully, as he had already reported, should be continued, since it stimulated exertion on the part of those who were specially interested; and £50 or £60 in each case would then be found sufficient.

Mr. Betty said this was a very important subject, and with Mr. Robbins' permission, as several members had left, he would move the adjournment of the discussion to October next, when he should be prepared to state his views upon it.

This motion was seconded by the Vice-President and agreed to.

The Secretary suggested that Mr. Robbins should also bring forward a motion for increasing the amount of annuities by £5 annually in the case of those over 60 years of age, and by £10 to those over 70 years, in view of the increased cost of living since the amount of the annuities was fixed.

Mr. Robbins said this matter had occurred to him, but it was quite distinct from the subject of his motion, and he thought it better to deal with one thing at a time.

Mr. Schacht moved, according to notice, that a sum of money be voted for the purpose of obtaining a report of the proceedings at the Conference.

The motion was agreed to.

The consideration of a further motion that the travelling expenses of country members attending Committees should be defrayed by the Society was deferred.

Report of Examinations.

July, 1877.

ENGLAND AND WALES.

Preliminary Examination.

Candidates. Examined.	Passed.	Failed.
251	139	112

Four certificates received in lieu of the Society's examinations:—

2 University of Cambridge.

1 University of Oxford.

1 Royal Colleges of Physicians and Surgeons of Edinburgh.

The Secretary read letters of thanks which had been received from the Bristol Association for specimens for their museum, and from the Chemists' Assistants' Association, London, for the use of the Society's rooms for their meeting.

Provincial Transactions.

BRIGHTON CHEMISTS AND CO-OPERATIVE STORES.

At the latter end of June a meeting of the chemists of Brighton was called at the Town Hall, by Mr. W. D. Savage, President of the Local Association, to consider whether any steps should be taken to meet the existing action on the part of several chemists in the town who are endeavouring to compete with the co-operative stores by selling patent medicines, drugs, etc., at the same prices. This meeting was, after considerable discussion *pro* and *con.*, adjourned for a month in order to give time for further consideration.

On Friday, July 27th, the meeting again assembled, when the following resolution moved by Mr. Vizer, and seconded by Mr. Haffenden was carried *nem. con.*:

"That in the opinion of this meeting any attempt to compete with 'co-operative stores' and 'underselling chemists' by a systematic reduction of prices of patent medicines, drugs, etc., would be injurious to the real interest of the trade, and prejudicial to its position in the eyes of the public. This meeting, therefore, deprecates any such act on the part of the chemists of Brighton."

Review.

Sanitary Engineering (A Series of Lectures given before the School of Military Engineering at Chatham, 1876). By J. Bailey Denton, F.G.S., M. Inst. C.E., etc.

Mr. Bailey Denton's work of more than four hundred pages is far too bulky to receive anything like a detailed review, and moreover, being somewhat of the nature of a compilation of all matter relating to his subject, it does not particularly call for it.

The work is elaborately got up, and is illustrated with numerous and excellent plates; it has also a full chapter of contents, and a good index.

Mr. Bailey Denton treats of his subject in five divisions, and concludes with an appendix containing much valuable information bearing upon what has gone before.

In his preface he expresses the hope that the work will "be regarded not as an attempt at a finished literary production, but as an earnest expression of the views formed during an active professional life;" and as there can only be one opinion of Mr. Bailey Denton's earnestness in all subjects affecting sanitary engineering, so there can be but one opinion of the skill, knowledge, and comprehension with which he has treated of this science in the volume before us.

The first division of the book is concerned with air, and it may not be inappropriate at this time of the year to remind our readers that the air of the Metropolitan Railway between Gower Street and King's Cross contains ·338 per cent. of carbonic anhydride.

Writing of ozone, the author quotes from Dr. Cornelius Fox the opinion that this substance is simultaneously developed with electricity, partly through "the dashing and splashing, the smashing and crashing of the restless waves on the rocky coast." Dr. Fox's expression reminds us forcibly of a famous poem, where 'The Bells,' so far as we remember, behaved somewhat similarly.

After treating of the quantity of air respired by human beings, and of the foreign matters which are regarded in the light of pollution, etc., the author proceeds to consider the danger arising from the inhalation of ground air, associated as it often is with ammonia, carbonic anhydride, sulphuretted hydrogen, and organic matter. There can be but little doubt that malaria and miasma generally arise from the presence in the air of affected districts of certain nitrogenous substances liable to putrefaction. The beneficial influence of the peroxide of hydrogen and other substances generated in the oxidation of volatile oils from pine and eucalyptus trees, in destroying or burning up this malarial matter, is now beyond doubt, and we could have wished that Mr. Bailey Denton had devoted more consideration to this matter in his book.

In some further sections the influence of dry and wet subsoils upon the quality of the superincumbent atmosphere is studied, and it is pointed out that the amount of watery vapour, which in this country is considered most congenial to health, is from 65 to 75 per cent. of saturation.

Water forms the subject to which the second division of the book is devoted, but comprehensive as it is, we can only notice here one point—and one of importance for rural districts, like the country round Hampton Court and Walton-on-Thames, where the question of water supply is a serious one. Although rain water is "often polluted to a dangerous extent by excrementitious matters," and "rarely of sufficiently good quality to be employed for dietetic purposes with safety,"* it is by no means necessarily so, and if properly collected on the roofs, and stored in a manner protecting it from contamination, it compares favourably with deep-well and spring waters in purity and fitness for use. This is the view entertained by Mr. Bailey Denton and Dr. B. H. Paul, whose chemical investigations regarding such waters have lent strong corroboration to this opinion.

The third division of the book includes all sorts of considerations affecting the dwelling. Of the entire death rate of England and Wales, a proportion of one-ninth is due to consumptive diseases alone, and hence nothing can be more important than that proper precautions be taken in regard to the drainage of the site of dwellings. For it has been well established that pulmonary consumption and phthisis often follow the drying of the soil.

In this section, then, drainage and sewerage are well studied, and the modes of treating the sewage of isolated dwellings are described. Beyond this, the subjects of ventilation, water closets, scavenging, etc., receive a detailed account.

The sanitary engineering of towns and villages is a large subject, and commands lengthy treatment in the fourth division, while in the last one the various processes for the treatment and disposal of the sewage of towns and villages are described and discussed.

In conclusion, we heartily recommend Mr. Bailey Denton's work to all who are interested in public health, remembering that Franklin once said "public health is a nation's wealth."

BOOKS, PAMPHLETS, ETC., RECEIVED.

THE MATERIA MEDICA OF THE HINDUS; compiled from Sanskrit Medical Works. By UDOY CHAND DUTT. With a GLOSSARY OF INDIAN PLANTS. By GEORGE KING, M.B., and the Author. Calcutta: Thacker, Spink and Co. 1877. From the Author.

EPITOME OF SKIN DISEASES, WITH FORMULÆ. For Students and Practitioners. By TILBURY FOX, M.D., F.R.C.P., etc., and T. C. FOX, B.A., M.B. Second Edition. London: H. Renshaw. 1877. From the Editor.

Correspondence.

M. Wilks.—Cholera Mixture.—The following extract contains probably what you refer to:—

"The remedy is the cholera mixture consisting of equal parts of laudanum, tinct. rhei., and spt. camphor. Begin with 30 drops taken clear and unmixed, with a little sugar in the mouth afterwards; repeat the dose after every evacuation, increasing it if the case becomes urgent to 60 drops (a tablespoonful), or 90 drops if necessary. If the diarrhœa is not controlled by this means an injection of from 30 to 90 drops of laudanum in a tablespoonful of starch will prove a valuable help. This may be often repeated. If the diarrhœa ceases, do not entirely intermit the medicine, but give in gradually diminished doses every one or two hours for a period of twelve or even twenty-four hours.

"(2) For the vomiting stage the best remedy is—

℞ Laudanum.
Tinct. Capsicum.
Tinct. Ginger.
Tinct. Cardamoms.

Of each equal parts. To be given 40 to 60 drops undiluted, and followed by sugar, after every fit of vomiting, taking care to give it as soon as the fit ceases; when a useful adjunct to the medicine will be a mustard poultice to the abdomen.

"(3) For the stage of malignancy, the only remedy is stimulants, especially brandy, which must be given with great freedom, from two to four teaspoonfuls every half or even quarter of an hour till heat returns, and pulse and sensibility are restored. It is always to be given undiluted. Alcohol would answer if brandy is not to be had. Continue with this artificial heat. Bottles of hot water, fricture of the limbs (which no one need fear apply), and mustard, perhaps, to the feet and hands, stomach and limbs. Be bold rather than cautious."

"Natura."—(1) *Vicia Cracca*; (2) *Plantago lanceolata*; (3) *Rumex crispus*; (4) *Stachys sylvatica*; (5) *Matricaria inodora*; (6) *Sonchus oleraceus*; (7) *Lapsana communis*.

"Herba."—It is against the rules to name specimens for persons contending for the Botanical Prize.

"Eriophorum," in sending plants to be named, must comply with the rule as to all correspondents communicating their names and addresses.

T. D.—(1) *Scrophularia nodosa*; (2) *Agrimonia odorata*; (3) *Galium Mollugo*; (4) *Galium palustre*.

T. A. R.—(1) Hair Oil Scent: Ol. Lavand., and Ol. Rosmarini, of each 8 parts; Ol. Cassiæ, 1 part; Ol. Caryophylli, 2 parts. (2) Apply to the Secretary for a copy of pamphlet entitled, "Hints to Apprentices and Students."

A. Mitchell.—(1) *Trifolium arvense*; (2) *Euphrasia officinale*.

"Finance."—(1 and 4) *Lastrea Filix-mas*; (2) Send a perfect frond with sori; (3) Send a specimen with sori; (5) *Cystopteris fragilis*; (6 to 9) *Athyrium Filix-fœminea*.

G. Sampson.—(1) Genus *Œnanthe*; send specimens with root and fruit for the determination of species. (2) *Obione portulacoides*.

J. T. Thomas.—The formula for Acetum Ipecacuanhæ approved by Dr. Duckworth (See *Pharm. Journ.* [3], vol. ii., p. 723) is as follows:—

"Ipecacuanha Root (bruised) . 1 oz.
Acetic Acid . . . . 1 oz.
Distilled Water, a sufficiency.

Macerate the ipecacuanha and acid for twenty-four hours, pack in a percolator, and pour distilled water gradually over it until one pint of percolate has been obtained."

"Julus."—You are recommended to consult a solicitor.

"Tinctura."—We do not think any agency exists for the sale of such things.

E. B. J.—The plant is an exotic.

"Pharmacist."—See Mr. Vernon Harcourt's Cantor Lectures on the Chemistry of Gas Manufacture, now publishing in the *Journal of the Society of Arts*.

M. Heanley, R. H. T., and *"Colorado."*—The so-called "Paris Green" is an aceto-arsenite of copper.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Fisher, An Apprentice, Associate, M., R. H. T., S.A.R., H. S. F., C., E. M.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 25.)

OCIMUM PILOSUM.—*Local name*, TUKM I RIHAN.

Small, black, oblong, seeds barely, $\frac{1}{16}$ of an inch long, slightly arched on one side and flattened on the other, blunt-pointed. At the base there is a small projection with a white point, where the seed was attached to the ovary. They have no odour. The taste is oily and slightly pungent. When placed in water or in the mouth they immediately become thickly coated with semiopaque mucilage. The plant was obtained by sowing some fresh bazaar seed imported from Persia. It does not grow in this part of India, but is worthy of introduction, as it has a peculiarly delicate verbena odour. Roxburgh describes it as a native of India, and gives the Bengalee name as "Babooi toolsi:" he also notices its use as a medicine. Large quantities of the seed are imported from the Persian Gulf. The Bombay druggists corrupt the name into Takmeria. Medicinally, it is mucilaginous and slightly stimulant.

DALBERGIA SYMPATHETICA.—*Local names*, PETGULI' *and* TITABLI.

The leaves of this plant are used at Goa as an alterative. It is a very remarkable scandent shrub; the stem studded thickly with large blunt thorns, often nine inches long, some of them contorted so as to assist in supporting it upon high trees; the leaves are pinnate and furnished with numerous small delicate oblong, very obtuse, leaflets; the flowers are in short axillary cymes; the legumes generally one seeded, about two inches long. Titabli is the native name at Goa and in the South Concon. In Bombay the plant is not, as far as I know, used medicinally. Cattle eat the leaves.

PLANTAGO PSYLLIUM.—*Local name*, BARTUNG.

Minute, oblong, brown seeds, marked with waved, slightly elevated, longitudinal ridges of a darker colour; one side of the seed arched, the other concave, and marked with a scar showing the attachment to the ovary. They are insipid, and have an oily smell when crushed. Soaked in water they become coated with a transparent mucilage. Bartung, usually pronounced Barhang, is a remedy of great repute in Persia for dysentery. A large quantity is imported into India, through Bombay. We have the evidence of Valentine Baker as to its efficiency when he suffered from the above-mentioned disorder during his travels in Khorasan. When dysentery is supposed by the Hakeems to be due to a heated condition of the humours, Ispaghool (*Plantago Ispaghula*) is preferred. When a cold condition is diagnosed, Bartung is given. The Arabs call it *Lisan ul Hamal* (kid's or fawn's tongue), from a supposed resemblance of the leaves to the tongue of those animals.

PHYLLANTHUS MADRASPATENSIS.—*Local name*, KANOCHA.

Small, polished, heart-shaped seeds of a grey colour, prettily marked with delicate dark brown lines like basket work; length $\frac{1}{10}$ th of an inch; breadth somewhat less. One side of the seed is arched; the other presents two sloping surfaces uniting to form a longitudinal ridge. At the pointed end is a small scar marking its attachment to the ovary. The testa is hard and brittle. When soaked in water it immediately becomes thickly coated with a semiopaque mucilage. The kernel is oily and has a sweet nutty taste. For a description of the plant *vide* Roxburgh's 'Flora Indica,' iii. 654.

HIBISCUS SP.?—*Local name*, ALTI, *or* ULTEE.

The drug consists of several roots branching from a knotted woody stock, the largest being about as thick as the little finger. They are straight, unbranched, and have a thin brown cortex covering a thick white farinaceous parenchyma, in which are seen well-marked yellowish medullary rays spreading from a tough, woody, central column, the diameter of which is less than the semidiameter of the farinaceous portion. Examined under the microscope most of the cells of the farinaceous portion are seen to be filled with starch granules; but some large ones contain mucilage only. The central woody column abounds in large pitted vessels. When soaked in water the root gives out abundance of mucilage having a faintly bitter taste. Alti is used by the Portuguese at Goa as a substitute for Althæa, of which the native name appears to be a corruption. It is a stunted, woody shrub, with cordate, serrated, leaves. I have not seen the flowers or fruit. The roots, when properly scraped and dried, are very white, and apparently an efficient substitute for the imported article.

BIGNONIA XYLOCARPA.—*Local name*, KURSING.

By a rough process of the same nature as that by which tar is obtained from pine wood, a thick fluid of the colour and consistence of Stockholm tar is obtained from the wood of this tree. So much does this substance resemble tar in odour as well as appearance that it may easily be mistaken for it. The wood of *B. xylocarpa* is hard, but easily split. When sawn across it presents a yellow resinous surface. Sections examined microscopially show that the yellow colour is due to a solid resinous deposit in the pitted vascular system.

Heterophragma Roxburghii, Warus, another of the Bignoniaceæ, yields a similar product. It is a large and very common timber tree. These tars have both an established reputation among the natives as remedies in certain cutaneous eruptions of a scaly nature. As oil of cade has lately been recommended in similar diseases, it might be worth while to give them a trial.

PARAMIGNYA MONOPHYLLA.—*Local name*, KARWA WAGUTTY.

This scandent, prickly shrub bears a pulpy four-celled fruit, the size of a small apple. The root is medicinal; it is long and woody. The pieces selected for use are about as thick as the finger, and covered with a somewhat scabrous brown bark, which has a bitter saltish taste. If allowed to remain for some time in the mouth, the salt taste becomes much more decided. Sections of the bark placed under the microscope show from ten to twelve rings, composed of bundles of liber cells closely set and encased in an armour of crystalline cubes, which, from the taste of the bark, are doubtless chloride of sodium. A somewhat similar arrangement of cubes may be seen in several other barks, but in none of those which I have examined is it nearly so marked as in this. *Karwa Wagutty* is considered to have alterative properties. It must not be confounded with Wagutty (*Capparis brevispina*).

CENTAUREA BEHEN.—*Local name*, SUFFED BEHMAN

The dry root is of a whitish brown colour, much shrivelled and twisted; near the crown it is marked by numerous circular lines. It may be either a simple tapering root or more or less branched; sometimes a portion of purplish stem remains attached; the average length is about 2½ inches, diameter ¾ of an inch; the interior is white and spongy; when soaked in water it swells and becomes mucilaginous. The taste is mucilaginous and slightly bitter. Microscopic examination shows that behen contains no starch. The parenchyma appears to consist almost entirely of mucilage cells. There are numerous large bundles of spiral vessels. This drug has been confounded with Ashva-gandha, the root of *Physalis somnifera*, by Ainslie. It is imported into Bombay from the Persian Gulf in considerable quantities, and is always to be found in the shops. The Hakeems prescribe it largely; they consider that it purifies the blood, fattens the body, and greatly increases the virile powers.

SPHÆRANTHUS MOLLIS.—*Local name*, MOONDI.

A very common annual plant, generally about eight inches high; stems winged; leaves thick, sessile, decurrent, obovate; bristle serrate, covered with down consisting of long white hairs; flower heads solitary, mostly terminal, subglobular, the size of a horse bean, purplish when fresh, but lose their colour when dried; roots fibrous. The drug generally consists of the whole plant, but the capitula are sometimes sold separately. The taste is a little bitter; the odour of the capitula terebinthinate. Moondi appears to be well known all over India as an alterative and purifier of the blood; the peculiar odour may be observed in the urine and perspiration of those who take it. It is considered to be hot, and moist in the second degree. Its uses in native medicine are fully described in the 'Makhzan ul Adwiya.' The flower heads of this plant will probably be found to yield an essential oil likely to contain its active principles.

PHYSALIS SOMNIFERA.—*Local name*, ASHVA-GANDHA.

The plant consists of a stout, long, tapering, woody root, an inch or more in diameter, surmounted by a knotted crown, from which spring several shrubby flexuose branches, which are generally round, and from one to two feet long. The leaves are double, ovate, variable in size, but not more than three inches long; flowers axillary, subsessile, crowded at the ends of the branches; corolla campanulate, yellowish green, very small; berry red, smooth, size of a pea, covered by a membranaceous closely fitting calyx, open at the apex; seeds numerous, yellowish white, reniform, laterally compressed, about one sixteenth of an inch long; testa honeycombed. The whole plant is covered with small branched and pointed white hairs, which give it a hoary appearance. The odour is pungent and disagreeable, like the urine of horses; this is expressed in the native name, Ashvagandha. The root consists of a twisted, white, woody column, which is covered by a thickish soft bark, containing a good deal of red colouring matter, visible through the greyish epidermis. The microscopic characters are not in any way remarkable. The fresh root bark has the same odour as the plant; the leaves and fruit are a little bitter and nauseous. This drug must not be confounded with the Asgund of the Bazaars, described in the next article. We have no reliable information regarding the physiological action of *P. somnifera*.

Botanical source uncertain.—*Local name*, ASGUND.

The dry root is from six to eight inches in length, often less, and from one quarter to half an inch in diameter at the thickest portion, a little below the crown; it is plump, smooth, tapering, and of a light yellowish brown colour externally, white internally, brittle, fracture short and starchy. The root is seldom branched. Attached to the crown are the remains of several slender stems. Microscopic examination shows the substance of the root to be principally composed of starch, inclosed in delicate oval cells; the cortical portion is about one twentieth of an inch in thickness. The vascular system consists of a large central bundle of scalariform and dotted vessels; round this several smaller bundles and single vessels are arranged in a radiating manner. Asgund has a mucilaginous and slightly bitter taste. In the 'Makhzan ul Adwiya' it is described as a tonic and alterative, and is said to have much the same properties as *Centaurea Behen*. There is no mention of its being a narcotic. It is uncertain where the drug comes from. The 'Makhzan' describes it as an Indian root.

TIARIDIUM INDICUM.—*Local name*, BOOROONDI.

An annual plant, one to two feet high, common in ditches in Bombay: it seems to like a rich soil. The whole plant is more or less covered with simple hairs; stems several, as thick as the little finger, hollow, branched from the axils of the leaves; leaves generally alternate, cordate-ovate, rugose, long-petioled; petioles margined; spikes terminal, solitary, simple; flowers like those of heliotrope, but smaller; fruit mitre-shaped. The plant has a fetid odour like stramonium; taste a little bitter. It is used as a local application to boils, sores, and the stings of insects.

FERULA ALLIACEA.—*Local name*, HING.

In a former number of the *Pharmaceutical Journal* I briefly noticed the botanical source of this drug, interesting on account of the enormous quantities of it which are used as a condiment by almost every class of vegetarians in India, and for its medicinal properties, which are much more powerful than those of the officinal asafœtida. Early in 1874, the late Mr. Hanbury was kind enough to forward to me the proof sheets of the article upon Asafœtida in the 'Pharmacographia,' with a request that I would obtain further information upon the subject. Unfortunately this could not be done in time for publication in that work, as it involved sending to Persia for specimens of the plant and drug. In August, 1874, through the kindness of Mr. Ardeshir Mehrban, a Parsee merchant, of Yezd, I obtained the first box of specimens collected in the neighbourhood of that city. It contained: 1st. The fresh root, with gum resin adhering to the broken portions, and from which, upon section, a further exudation took place, at first opaque and milky, but drying in the course of a day or two into a light-brown translucent substance. 2nd. The flower stem with flowers and very immature fruit. 3rd. The leaves. The plant arrived in a broken state, and was forwarded to Mr. Hanbury. Upon its receipt, he wrote: "This morning I have devoted to the asafœtida plant, and to a comparison of it with the figures and descriptions published by Borszczow, Balfour, and Hooker; but to decide on its botanical name is at present a difficult, if not impossible task. I suppose it to be either the *Narthex* of the Edinburgh garden, or the *Scorodosma* of Borszczow, admitting for the moment that these are two good species; but the specimen does not furnish all the characters requisite for a strict comparison. I cannot tell whether the plant has the great sheathing petioles that form so striking a feature of the *Narthex*, nor is it possible to say whether the flower stem bore umbels arranged in a tall regular obelisk as *Narthex*, or crowded towards the summit as in *Scorodosma*. The foliage might do for either plant, though in having shorter segments it better agrees with the latter. The inflorescence which I have soaked and dissected consists of fertile female, and abortive flowers, none stameniferous. They are remarkably glabrous, not pubescent, as in Borszczow's plant; but this is of small moment."

Early in 1875 I was able to send another box of specimens, with ripe fruit and a large supply of leaves. In acknowledging it, Mr. Hanbury wrote: "The box containing the asafœtida plant arrived on the 29th January, in excellent order, and its contents have given me great pleasure. The large plant, though it had been rudely broken up and stuffed into a narrow space, proved to be fairly perfect; and by soaking in cold water I was able to restore it to shape, and then to fix it together so as to make a really beautiful specimen, measuring three feet six inches in height. The leaves, also by soaking them and taking some pains, form very decent herbarium specimens, and there are enough of them to supply several collections. But the chief point with me has been to determine the plant. From the foliage, the pink colour of the stem, and the size of the fruit, I judged it might be the *Ferula alliacea* of Boissier; but there being no specimen of this at Kew, I had to transmit a portion of yours to M. Boissier, in Switzerland. His reply was definite. The plant from Yezd agrees in foliage exactly with *F. alliacea*, in stature, size of fruit, and other respects; but the fruit has a broader margin than in M. Boissier's specimen. However, M. Boissier thinks it may be set down as that species, a conclusion in which I entirely agree. *Ferula alliacea* was previously known to me only by description. You will observe that we have named it in the 'Pharmacographia' as a possible source of asafœtida. I have thought it right to make a wide distribution of the fine supply of seeds with which you have favoured me, and I have therefore sent packets to the Botanical Gardens of Kew, Edinburgh, Oxford, Paris, St. Petersburg, Bern, Strassburg, Florence, Pisa, Naples, Palermo, Athens, and to botanical friends on the Mediterranean coast, in South Africa, and a few other places. As the seeds seemed fresh and good, I am in hopes that many plants may be raised."

Soon afterwards I received a sample of the unsophisticated drug, which is obtained by taking thin slices from the crown of the root, together with the gum resin which has collected upon them, until the root is exhausted. In this sample the slices are extremely thin and form only a small portion of the mass. The gum resin is brown and translucent; the odour purely alliaceous. To make the commercial article the exhausted root is collected, cut up, and mixed with the asafœtida, which has been obtained in the manner described above. To do this water is required, which impairs the translucency. Hing comes to Bombay in skins, each package weighing 100 lbs. or more; latterly some boxes have been received. The quality varies greatly, the adulteration consisting in an undue proportion of root. In Bombay it is often still further adulterated by mixing it with gum arabic in different proportions, according to the priced article required. To do this, the package is broken up and moistened, the gum is then added, and the whole trodden together by men with naked feet upon a mat. When sufficiently mixed up, is sewn up in skins to imitate the original packages. Hing must not be confounded with Hingra, the officinal Asafœtida.

NARTHEX ASAFŒTIDA.—*Local name of gum resin*, KANDAHAREE HING.

This substance appears to be quite unknown in Europe; neither Professor Flückiger nor the late Mr. Hanbury had ever seen it until I sent them samples. I have not as yet been able to obtain authentic specimens of the plant from Kandahar, but for the following reasons I consider it likely that it will prove to be the same as that which produces the officinal drug:—

1. Bellew mentions a very high priced asafœtida obtained by wounding the leaf bud of the plant which produces ordinary asafœtida; our article is generally mixed with numerous leaf buds, which have evidently been cut off by a sharp knife; its price is also much higher than that of any other kind.

2. When examining a number of bales of common asafœtida from Kandahar I found some of them to contain particles of the more expensive drug, and a large quantity of what appeared to be gum resin in a transition stage between the transparency of Kandahar Hing and the opacity of the commercial article.

3. A portion of root found in a bale of Kandahar Hing agreed exactly with a piece obtained from a bale of common asafœtida.

Kandaharee Hing comes to Bombay in small quantities; it is sewn up in goat skins, forming small oblong bales, with the hair outside. When it first arrives it is in moist flaky pieces and tears, from which a quantity of reddish-yellow oil separates on pressure; the gum resin also is of a dull reddish-yellow colour, soft, and somewhat elastic, with an odour recalling that of garlic and oil of carraways. By keeping, it gradually hardens and becomes brittle and of a rich red-brown colour; the odour also becomes more purely alliaceous, and approaches to that of the commercial kind. In one instance I have known the drug to arrive in Bombay in a semi-fluid state; this also happens sometimes in the case of common asafœtida, and is probably due to an exceptionally moist season, which makes the juices of the plant unusually liquid. This kind of Hing is, I am informed, used by wealthy people in Central India as a condiment and medicine; it is not generally known in Bombay, and is only to be found in the warehouses of a few wholesale dealers.

NARTHEX ASAFŒTIDA.—*Local name of gum resin,* HINGRA.

This is the asafœtida of European commerce; it arrives in Bombay from Persia and from Affghanistan. The former is produced in the province of Laristan, and is known to Persian merchants as Anghuzeh i Lari; it generally arrives in a moist condition, but soon hardens. The latter comes by the Indus route, and is generally hard and dry. Very fine samples are not uncommon. The stony asafœtida described by Pereira is commonly met with in this market; it is simply a mixture of very fluid common asafœtida with the white sandy soil of the country in which the plant grows; it fetches a very low price, and, as far as I can make out, the mixture is made more for convenience of carriage than for the purpose of deception. Besides, when the juice is unusually fluid it runs out upon the surrounding ground and becomes mixed with the sand. Common asafœtida is only used in India by the poorest classes. The product of *Ferula alliacea* is a much more powerful drug, and is always issued instead of it from the Government stores in Bombay.

BALSAMODENDRON OPOBALSAMUM.—*Local name of fruit,* HAB UL BALESAN.

These berries are imported from Arabia, and are kept by all the native druggists; they have a pleasant terebinthinate odour. I have compared them with the figures and description of the fruit of *B. opobalsamum* in Bentley and Trimen's 'Medicinal Plants,' and consider that there can be no doubt of their identity. If soaked in water they soften and can be easily dissected and the remarkable form of the pulpy layer within the epicarp be seen. Sections of the epicarp show very large ramifying balsam cells, which appear to communicate one with another. The fruit is considered to be a powerful carminative and digestive; it is also praised as a stimulant expectorant, and is usually administered in combination with tragacanth.

PEGANUM HARMALA.—HURMARO AND HURMAL.

The drug, as found in the bazaar, consists of the seeds mixed with a few pedicels surmounted by the five-partite calyx and portions of the three-celled, three-furrowed capsule. The seeds are of a dull greyish-brown colour, irregularly angular, and about one-eighth of an inch long; they have a heavy narcotic odour when crushed, and a bitter taste. Examined under the microscope, the testa, which is rough and squamous, may be seen to consist of two rows of large honeycombed cells, the walls of which contain brown colouring matter. The kernel is greenish, and when a section is placed in glycerine for examination it immediately develops a fine green fluorescence; it consists of two longish cotyledons surrounded by albumen; the cell contents of both appear granular. Some seed crushed and treated with water for a few minutes produced after filtering a pale yellow fluid with a marked green fluorescence; this was destroyed by alkalies and restored by acids.

A further examination of the seeds was made by exhausting them with rectified benzene, spt. rectificatus, and water acidulated with hydrochloric acid. The benzene solution was of a pale yellow colour, and upon evaporation yielded a rich reddish-brown oil having no very marked odour and a nauseous taste.

The tincture made with rectified spirit was of a deep red, like Tinct. lavandulæ comp., very opaque and highly fluorescent. Upon evaporation it yielded a soft extract of the colour of dragon's blood, and the odour of *Cannabis indica.* This, when exhausted, with water, gave a pale red solution with a green fluorescence, which, when treated with a solution of oxalate of ammonia, threw down the red colouring matter and became pale yellow, but retained its fluorescence. The remainder of the spirituous extract after complete exhaustion with water consisted of a soft resin of a deep carmine lake colour, having a heavy narcotic odour like resin of *Cannabis indica.*

The portion treated with acidulated water yielded a pale sherry-coloured fluorescent solution, which upon evaporation gave a soft yellow extract, with an odour like honey; the greater part of this dissolved in rectified spirit, forming a yellow fluorescent solution; this, after filtration, was evaporated to a thin syrup, and upon cooling formed a dark brown crystalline mass, which was not further examined, as the alkaloids contained in the seeds have already been fully investigated. *Vide* Watts' 'Dictionary,' article "Harmaline."

In native works on materia medica Hurmal is described as an alterative and purifying medicine in atrabilis, and also in diseases supposed to arise from cold humours, such as palsy, lumbago, etc.; it is also said to stimulate the sexual system both in the male and female, increasing the flow of milk and menses in the latter. For administration a concentrated decoction is mixed with sweet oil and honey, or the crushed seeds are boiled in wine down to one fourth of the original bulk of the latter, and the mixture strained. *Vide* 'Makhzan ul Adwiya,' article "Hurmal."

Dr. Pandurang Gopal, a medical graduate of the Bombay University, has experimented with this drug. He informs me that the infusion or tincture acts as a stimulant emmenagogue and produces slight intoxication like *Cannabis indica.* He gave the tincture in ½ drachm doses to a female suffering from amenorrhœa, and it had the effect of producing a free menstrual discharge; in five cases of dysmenorhœa he has found it effective in restoring a free discharge; he further says that it is sometimes used by the native midwives to procure abortion. Dr. Pandurang believes that it has properties in common with ergot, savin and rue. The equal activity of watery and spirituous preparations may be explained by the fact that the red resinous colouring matter is a secondary product formed by the oxidation of the alkaloid harmaline; it is only produced after a prolonged digestion of the seeds in spirit.

Hurmal seed is imported from Persia, but the plant has been introduced into India by the Mahometans, and in this presidency is to be found in abundance among the ruins of Beejapur. The Persian name is Sipand. When sprinkled upon burning coals it is supposed to avert the malignant influence of the evil eye. Its medical properties are worthy of further investigation.

(To be continued.)

THE ACTION OF CERTAIN MANIPULATIONS AND REAGENTS ON CALOMEL.*

BY FRED. M. CORWIN, PH.G.

Mercury forms two classes of salts, one containing proportionately twice as much acid radical as the other, and each convertible into the other by certain agents.

The mercurous chloride, or calomel, is mild in its action on the human system, being a safe and much-used remedy.

The mercuric chloride, and mercuric salts in general, are powerful and corrosive agents, often producing serious and fatal results.

The object of the following experiments was to ascertain whether *mercuric* salts were produced from *mercurous* (namely *calomel*) by the agents and methods described.

The agents were either physical or chemical.

The physical agents were trituration, boiling with water, and sublimation.

The chemical agents were certain dilute acids and salts of the U. S. P.

The tests used for the detection and identification of mercuric mercury were metallic copper and hydrosulphuric acid in strongly acidified solutions.

In all cases where a deposit was obtained on copper, the copper, after being thoroughly washed and dried, was placed in a clean dry test-tube and heated to redness.

If mercury was present it sublimed and collected in a cooler part of the tube. A crystal of iodine was then placed in contact with it, and heat again applied, when the yellow iodide of mercury turning red by friction sublimed in another part of the tube.

The hydrosulphuric acid was added in small portions at a time, producing at first a light coloured precipitate, turning yellow, orange, brown, and black as the successive portions were added. This reaction is characteristic of a mercuric salt.

Several attempts to obtain absolutely pure calomel proved unsuccessful. That used, being the purest which was examined, was found to contain a small quantity of ferric iron, probably as ferric chloride.

I. PHYSICAL AGENTS.—a. *Trituration.*—About two drachms of calomel were rubbed in a dry porcelain mortar. On moving the pestle through it with pressure, it produced shining *straw-yellow* streaks, and the whole powder gradually assumed a yellowish tint. After rubbing for half an hour it was macerated with water, filtered, and the filtrate acidified with hydrochloric acid.

Copper: no action. Hydrosulphuric acid: no action.

b. *Boiling.*—1. About two drachms were heated in a flask with water, on a water-bath, for fifteen minutes, the mixture filtered, the filtrate evaporated about one-half on a water-bath, and acidified with hydrochloric acid.

Copper: no action. Hydrosulphuric acid: no action.

2. About two drachms were boiled in a flask with water by direct contact with flame, and under constant agitation, for fifteen minutes, filtered, the filtrate evaporated about one-half on water-bath, and acidified with hydrochloric acid.

Copper: *a deposit.* Hydrosulphuric acid: *characteristic precipitate.*

c. *Sublimation.*—1. About twenty grains were heated in a dry test-tube, the heat being only sufficient to slowly sublime it. It was then macerated with a small quantity of water, filtered, and filtrate acidified with hydrochloric acid.

Copper: no action. Hydrosulphuric acid: no action. The sublimate was perfectly white.

2. About twenty grains were heated so as to sublime rapidly, the glass becoming red hot. It was macerated with water, filtered, and the filtrate acidified with hydrochloric acid.

Copper: *a deposit.* Hydrosulphuric acid: *characteristic precipitate.*

The sublimate had a greyish appearance in places, probably due to metallic mercury.

II. CHEMICAL AGENTS.—a. *Acids.*—The acids used were the dilute acids of the Pharmacopœia. About a drachm of calomel was placed into a five-inch test-tube, the tube was nearly filled with an acid, and allowed to macerate for three days, being agitated occasionally. It was then filtered and the filtrate evaporated about one-half on a water-bath.

With some acids a change was noted in the appearance of the calomel: with others it remained unaltered. The following table exhibits the results:—

Acids.	Copper.	Hydrosulph. Acid.	Appearance.
Hydrochloric . .	Deposit.	Characteristic ppt.	Unchanged.
Nitric	Not used.	,, ,,	,,
Sulphuric . . .	No action.	No action.	,,
Hydrocyanic . .	Deposit.	Characteristic ppt.	Turns dark.*
Nitro-hydrochloric	Not used.	,, ,,	Unchanged.
Phosphoric . . .	No action.	No action.	,,

b. *Salts.*—Of the salts used, sixteen were in solution with water. The solutions were made by dissolving one part of the salt in ten parts of water, with one exception, namely, the potassic chlorate solution, which was made by dissolving one part of the salt in twenty parts of water.

About half a drachm of calomel was placed into a five-inch test-tube, the tube nearly filled with a solution and allowed to macerate three days with occasional agitation. It was then filtered, and the filtrate acidified with hydrochloric, nitric, or sulphuric acid, according to the character of the salt.

With some of the solutions a change was noted in the appearance of the calomel, either immediately or on standing.

Solution of	Copper.	Hydrosulph. Acid.	Appearance.
Potass. Bromide .	Deposit.	Characteristic ppt.	Lead colour.
,, Chlorate .	No action.	No action.	Unchanged.
,, Cyanide .	Deposit.	Characteristic ppt.	Dark, nearly black.
,, Hypophosphite . .	No action.	No action.	Unchanged.
,, Nitrate . .	,,	,,	,,
,, Sulphate .	,,	,,	,,
,, Sulphite .	,,	No ppt. Separation of S.	Green, grey.
Pot. & Sod. Tartrate	Deposit.	Characteristic ppt.	Unchanged.
Ammon. Bromide .	,,	,, ,,	Slate colour.
,, Chloride .	,,	,, ,,	Unchanged.
,, Iodide .	,,	Orange red ppt., which gradually turns dark, same as $HgCl_2$ in NH_4I.	Turns yellow then dark with green tint. Solution is yellow.
,, Nitrate .	,,	Characteristic ppt.	Dark at point of contact. Grey on agitating.
,, Sulphate	,,	,, ,,	Unchanged.
Sodic Chloride . .	,,	,, ,,	,,
Ferric ,, . .	No action.	No action.	,,
,, Pyrophosphate . .	,,	,, ,,	,,

* On the reaction between calomel and hydrocyanic acid, see a paper by T. H. Powell and J. Bayne in *Pharm. Journ.*, April 8, 1876.

Of the two following salts, about a drachm of each was rubbed, with an equal bulk of calomel, in a porcelain mortar for fifteen minutes. They were then macerated with a small quantity of water, filtered, and the filtrates acidified.

Filtrate from	Copper.	Hydrosulphuric Acid.
Bismuth Subnitrate.	No action	Peculiar ppt. Not characteristic of mercury.
Ferric Ferrocyanide.	,,	No action.

SCLEROTIC ACID, THE ACTIVE PRINCIPLE OF ERGOT.

This Journal last year* contained a condensed summary communicated by Professor Dragendorff, of Dorpat, of his important researches in conjunction with Mr. Podwissotzky, on the constituents of ergot, in which they announced the discovery of a proximate principle of an acid character and exerting in a high degree the specific effects of the drug. Since then the authors have published their results in detail.† In the following translated abstract which we borrow from *New Remedies*, is described their method of preparing this principle, to which they gave the name "sclerotic acid."

Referring to the accounts previously given, and leaving aside the recital of various abortive attempts, on the part of the authors, to obtain the substance in a perfectly pure state, we shall at once give the process finally adopted, which yields a nearly pure product.

Very finely powdered ergot is exhausted with distilled water, the solution concentrated *in vacuo*, and the residuary liquid mixed with an equal volume of 95 per cent, alcohol. This causes the precipitation of a peculiar slimy substance, scleromucin, together with a portion of the salts and the greater part of the suspended fatty matter. The mixture having been allowed to stand on ice for twenty-four or forty-eight hours, it is filtered and the filtrate mixed with a further quantity of 95 per cent. alcohol, sufficient to precipitate all the sclerotic acid in combination with the bases (chiefly as calcium sclerotate). The separation of the precipitate is promoted as before by placing the mixture on ice for some days. This causes the deposited mass, which has a brownish colour, to adhere firmly to the walls of the vessel, so as to permit the supernatant liquid to be easily poured off. The precipitate is kneaded with alcohol of 80 per cent., and immediately thereafter dissolved in a sufficient quantity of 40 per cent. alcohol, when the remainder of the scleromucin and another larger portion of the foreign salts are left behind. The filtered liquid is now mixed with absolute alcohol, whereby sclerotic acid is precipitated in conjunction with certain bases and other substances. The impure product, when carefully dried over sulphuric acid, was found on analysis to contain 8·5 per cent. of potassium, about 0·36 per cent. calcium, 4·3 per cent. sodium, 2·74 per cent. phosphoric and 3·4 per cent. silicic acid, or altogether, 12·9 per cent. of ash.

The greater part of these admixtures may be removed and the sclerotic acid obtained free, by adding, before the final precipitation with absolute alcohol, a considerable quantity of hydrochloric acid (for every 100 c.c. of solution, 5–6 gm. of the acid, spec. gr. 1·100), allowing to stand at ordinary temperature for a few hours, and then proceeding to precipitate. In this manner the amount of ash may be brought down to 3 per cent., and by repeated solution, addition of acid, and precipitation, it may further be reduced to less than 2 per cent. or 3 per cent. A more complete purification is difficult and hazardous, because every addition of hydrochloric acid causes the decomposition of a small quantity of the sclerotic acid, while at the same time a portion of the latter is lost by remaining in solution.

The resulting product, although not chemically pure, is nevertheless, so to say, physiologically pure, as it always produces constant and identical results, no matter from what sample of (good) ergot it was obtained.

Sclerotic acid is entirely odourless and tasteless. In aqueous solution it has a faint acid reaction, and decomposes calcium carbonate slowly, even on warming. Boiling nitric acid of 1·200 spec. gr. produces a little picric and oxalic acid, and a new substance, which assumes a bright yellow colour on adding ammonia or other alkalies. More concentrated nitric acid converts it into picric, oxalic, mucic, tartaric, and aposorbic acids. It is not a glucoside; nor does it lose its effectiveness on the addition of dilute sulphuric or hydrochloric acids; on the contrary, the latter appears to intensify its effects. Boiling alcohol, in presence of sulphuric acid, extracts it from ergot in small quantities, cold alcohol not at all. It is therefore possible to abstract by means of cold alcohol and sulphuric acid a portion of the colouring matter from ergot, before extracting the sclerotic acid with water. But, unfortunately, the aqueous solutions (which carry with them a portion of the alcohol and sulphuric acid) spurt or bump so energetically during the distillation, that this modification of the process becomes unadvisable.

It might be supposed that sclerotic acid is not an acid, but an alkaloid, as it yields with phosphomolybdic acid a yellow, and with tannin an almost colourless precipitate. But other alkaloidal precipitants are without action upon it, and only lead acetate with ammonia produces a strong flocculent precipitate.

When properly purified, sclerotic acid is hygroscopic but not deliquescent, which circumstance distinguishes it advantageously from the commercial purified extracts of ergot. It is found in these in greater or lesser quantity according as a weaker or a stronger alcohol was employed in exhausting the ergot. A few commercial extracts were found to be very deficient. In Bonjean's and Wernich's preparations and in Wiggers' Osmazom it exists in considerable quantity, while scleromucin is almost entirely absent, as is the case in all alcoholic extracts of ergot. In Zweiffel's preparation the acid occurs in a tolerably pure state, in a less pure condition in Buchheim's. In alcoholic tinctures of ergot, and in Wiggers' ergotin it is only present in traces or is entirely absent.

Good ergot contains about 4 to 4·5 per cent of the acid, although samples are met with which contain scarcely 1·5 to 2 per cent.*

* *Pharm. Journ.*, June 17, 1876.

† *Arch. f. experim. Pathol. und Pharmacol.*, condensed in *Pharm. Zeit. f. Russl.*, 1877, No. 5. etc.

* Sclerotic acid (acidum scleroticum or sclerotinicum) is quoted in the United States prices-current at 20 dols. per ounce. It is administered hypodermically in doses of 0·04 0·05 gm. (one-sixteenth to one-twelfth grain).

THE SPONGES OF COMMERCE.†

From a very elaborate and learned paper in a recent number of the Memoirs of the Boston Society of Natural History on the North American Poriferæ, with remarks upon foreign species, we extract the following new and valuable information on the characteristics and classification of the commercial sponges. The great difficulty which is experienced in any attempt to distinguish species results from the extreme susceptibility of all keratose sponges to any change in external conditions. They appear to require for the production of the forms in abundance, tropical or sub-tropical seas, and attain by far their greatest development in the number of the forms and species in the West Indian Seas. The typical forms, the commercial sponges, are essentially confined to the

† From the *Journal of Applied Science*, August 1, 1877.

waters of the Caribbean Islands, Bahaman Archipelago, and the southern and western coasts of Florida in the western hemisphere, and to the Mediterranean and Red Seas in the other. Australia affords a few forms, and I have heard, though I cannot substantiate the fact, of some species on the Atlantic coast of Brazil. Bermuda also has a few of the commercial kinds, which, according to Mr. Goode's report and his suite of specimens, are much coarser than the Keo West, darker in colour, and, in fact, just about intermediate between these and those of Australia. They are occasionally found in the stores, but as a rule, are used only by the fishermen themselves about their boats, the Bahama sponges being preferred for domestic purposes by the inhabitants. Of course no complete report can be written until Mr. Goode's collection from Bermuda, which is very large, and has been very carefully made, can be examined; but it appears that the finest forms grow only in the protected lagoons at depths varying from five to twenty feet on a sandy bottom. The temperature was not stated. They are cured in a very careless manner by exposure to the weather, a process which doubtless does not increase their value. The true spongiæ are all shallow water forms. In the Mediterranean, according to Eckhel, they are not found below thirty fathoms, and in American seas about the same probably, though not fished to greater depths than five fathoms. The fishery is principally carried on in the West Indies by the aid of a sort of hooked fork, like two shepherds' crooked hooks on a long pole. The fishermen cannot so successfully work at considerable depths with this instrument as by diving, or with the diving apparatus or armour, and various forms of drags, etc., employed in the Mediterranean. The greater part of the fishery is accomplished between the depth of three and twenty feet, according to the report of Dr. Palmer, from which these remarks are principally derived. The finest qualities of American sponges are obtained in the Bahamas, the principal depot being at Nassau.

The process of preparation is not so careful as in Europe, probably owing to the greater coarseness and cheapness of the specimens. The actual fishing is done from boats, generally belonging to some schooner or larger craft. The boats are sent out from the vessel manned by two men. One sculls slowly along, while the other watches the bottom with a water glass. This is a tube about a foot square, closed by a pane of glass at the lower end, which prevents the reflection of light from the surface, and enables a keen observer to detect objects on the bottom at a considerable depth. When sponges are sighted, a signal causes the sculler to stop the boat, the water glass is laid aside, and the sponges are dragged up by means of the hooks. When the fishing is at an end, or the vessel loaded, the cargo is taken to land and "killed," as it is called, by exposure for a few days to the air. After this, the now highly offensive mass is moved into the "crawls." These are pens made by driving stakes into the sand where the water is from six to ten feet deep. They are thrown into these cribs and left to be washed clean by the action of the surf. This takes about one week, at the end of which time the skeletons are examined, and if found to be entirely cleansed of animal matter, dried, sorted according to quality, and strung on cords a fathom in length. They are generally sold by the cargo. The bases are clipped off, and the sponge trimmed with shears and packed in pressed bales for transportation to New York or England, where they are largely used for the manufacture of pilot cloth, hats, etc. The coarser kinds and clippings are also used quite extensively for stuffing mattresses, carriage cushions, etc., in place of hair. They are not of sufficiently good quality to compete with Mediterranean sponges, and are therefore rarely employed for domestic purposes, except in Great Britain(?) and the countries of North and South America. The fisheries near shore are abandoned in the winter on account of the turbid state of the water, which becomes "milky" with suspended coral sand during the more tempestuous months. A more limited fishery, however, is still carried on at Anchor Keys, some thirty-five miles outside of Cedar Keys, and in other places where the water is stiller, clearer, and warmer than nearer shore.

The commercial grades coincide very closely in America and in Europe, but it is quite easy to show that each of them may be considered a distinct species if one has an inclination to multiply in this direction. The grades are Glove Sponge (*Spongia officinalis*), sub-species *tubulifera;* Wool Sponge (*Spongia equina*), sub-species *gossypina*, and Yellow and Hard Head (both under the name of *Spongia agaricina*), sub-species *corlosia*. These correspond with remarkable accuracy to the three principal grades of commercial sponges in Europe. These are the Bath Sponge (*Spongia officinalis*), the Horse Sponge (*Spongia equina*), and the Zimocca Sponge (*Spongia agaricina*). This result, in which three species appear on both sides of the Atlantic as representing alone the marketable qualities of the genus Spongia, becomes of double interest when these varieties, or local species as they might be called, are compared one with another. It is then found that the aspect of the surface is closely similar in each of the three; that sub-species *tubulifera* represents *Spongia officinalis*, sub-species *gossypina* offsets *Spongia equina* in the same way, and lastly, sub-species *corlosia* has the same relation to *Spongia agaricina*. In order to make it still more convincing that such a relationship is not the result of an artificial arrangement, it becomes necessary to describe some of the facts more at length. First, their similarities of surface and aspect are precisely the same as those which experience has led me to adopt in the designation of species in this group. Thus, if they had occurred in different parts of the same sea, I should not have hesitated to unite them. Secondly, their differences can be accounted for by the difference in habitat, and are of varietal and not of specific value, according to the accepted use of the term species. For establishing the first proposition, it is only necessary, as previously remarked, to consult the descriptions of the genus Spongia and the figures. The second proposition, however, requires more attention.

The whole group of Keratosa is confined to seas in which the differences observable between the winter and summer isotherms are not excessive. None are found north of Cape Hatteras and the Islands of Bermuda, and doubtless a similar limit occurs to the southward of the equator: at least it is a noticeable fact that the only specimens in the Museum of Comparative Zoology are from the Island of Fenndo Noronha. On the Pacific shore, Southern California and Chili are the extreme points so far known. On the opposite coast of the Atlantic they are recorded from England to the Cape of Good Hope, and also at the Island of Teneriffe. In the Indian Ocean they are found all along the east coast of Africa, at the Mauritius, and on the shores of India. They have been described from the southern part of the sea of Ochotsk, on the Asiatic continent, and specimens are not uncommon on the coast of Australia and New Zealand. In the Pacific they have been found at the Kingmills Island and Hawaiian Islands. The extreme outlying form to the north, on both sides of the Atlantic, is the excessively coarse *Dysidea fragilis*, with its fibres loaded with debris. Those from the Cape of Good Hope and Southern Australia also belong to the coarser genera. The species cited by Miklucho Maclay from the sea of Ochotsk seems to be one of the Phyllospongidæ, but there is no analysis of the characteristics of the skeleton, only the external form being described and figured in his article on the sponges of the North Pacific (Mémoires de l'Acad. Imp. de St. Petersburg, Vol. 75, No. 3). It would seem, therefore, that the finer skeletons of the Keratosa, those of the genus Spongia, were only to be sought in the intermediate zone, where the waters are of equable and high temperature. Again, in examining the species of this genus with relation to each other, it becomes equally evident that they are finest and most numerous in archipelagoes, or off coasts which are bordered by large numbers of islands, or long reefs, or in sheltered seas.

I am informed by Mr. Gurdon Saltonstall that the sponges near Nassau lie on reefs very much exposed to the action of the waves, often thirty miles from land, and always in currents, sometimes running three or four knots an hour. Such currents are usual wherever groups of islands confine the tide water within certain definite channels, and they have also the effect of concentrating the floating food in the channels, or whenever tides meet. Both of these conditions are essential to successful sponge growth, namely, a continuous renewal of aërated water and a plentiful supply of food, and are probably partly the cause of their abundance in such places. This entirely agrees with my own observations upon many species on our own coast of Chalininæ and Halichondrida. Constant reference to physical influences is also noticeable in the map prepared by Von Eckhel, and in the method of classification adopted by him. The marketable qualities are described as "sorts," and the different "sorts" designated by letters, as "sort A," "sort B," and so on. These sorts he has found it most convenient to arrange according to localities, and thus under some "sorts" we have all the three species represented; all, however, from the same place, and all having some local peculiarity which makes them either of superior or inferior quality. The author also frequently refers to the slimy character of the bottom as a reason for inferiority or dark colour. On the American side of the Atlantic this is also shown by the great difference in point of colour and fineness between the Nassau and Key West sponges. The former are lighter coloured, finer, more elastic and more durable than the same species at Key West, where the colour is so dark that it designates at once the locality from which the specimen came. Again the shallow water sponges are coarser than the deep water forms. This is probably due, in part, as in other species, to the quantity of sediment, which is of course less in deep than in shallow water, as for example, at Key West in the winter time. I am informed, in this connection, by Mr. Saltonstall, who made inquiries for me among the spongers, that no fine qualities of any sponges are found within the limits of the milky water, but all the finer qualities of the marketable kinds in the deepest water in which the species occur, except, perhaps, in the case of the Reef sponge. Glove, Reef and Hard-head are fished in shallow waters, greatest depth two fathoms, and the other and generally finer marketable varieties, from two to five fathoms. This fact also explains, in a measure, but not wholly, the greater coarseness of American sponges as compared with the European; for though it may be assumed from the examination of the skeletons that Mediterranean sponges are much less exposed to turbid waters, and though it may be shown by the microscope that the primary fibres contain less débris, this does not wholly explain their greater fineness and elasticity. I think that we may attribute this either wholly or partly to climatic conditions.

If either the temperature or density of the water had been exceptional, we might have gained some additional information, but as it is, we cannot assume that either cause would have been sufficient to account for the absence of the Spongiæ from the Euxine. According to Carpenter in his articles on the Mediterranean and Black Sea, there is a strong current continually flowing at the depth of twenty fathoms from the Mediterranean into the Black Sea, and a return surface current from the Black Sea into the Mediterranean. The sponges occur necessarily in the shallower waters of the Sea of Marmora, since they are said by Von Eckhel to be fished for mostly with the harpoon, and are probably exposed more or less to the influence of the surface current. Under these circumstances they must very often be able to endure a degree of cold during the winter, and an amount of change in the density of the water, for which it becomes difficult to account, even taking into consideration the inferior quality of their skeletons. It is possible, however, that the water of the northern part of the Black Sea may not affect the temperature of the southern part to such an extent as would at first sight appear probable, and that, notwithstanding the lower temperature of the northern shores, the general temperature of the surface water during the winter immediately east and west of the Bosphorus may not fall below 55° as a minimum.

The northern shore of the Ægean Sea and the eastern shore of the Adriatic Sea are populous with sponges, and yet the former throughout its whole extent, and the latter from Ragusa to Istria, have nearly the same average winter temperature, and possess a colder climate in winter than the coasts of southern Italy or Spain, where no Spongiæ exist. Again, upon consulting the invaluable little Eckhelian pamphlet, we find that the sponges correspond in quality to this climatic change. The sort found at the head of the Ægean is said to be the *Spongia officinalis* alone, and to have a "heavy, hard, close, very hairy skeleton, often containing slime," and it is further added that it is not much liked, and is usually fished with the harpoon. The same species exist also alone at corresponding localities along the shore of the Adriatic, and at the extreme locality, the Island of Istria, upon the limit of its distribution, it is said to be very rare, the form to be ugly, the skeleton hard, the colour dark. Farther south, along the Dalmatian coast, it becomes abundant, finer in texture and of a lighter colour, but it is still inferior to the more southern or Levantine variety. In considering such classes of facts, it must also be borne in mind that the habitat of a certain sort or variety may largely determine the quality of the skeleton, even where the temperature may be very favourable. Thus, to the south of Quarnero, among the islands, a much better quality of *Spongia officinalis* occurs than in the milder sea about the Ionian Islands, which, as Eckhel remarks, is probably attributable to the slimy character of the bottom.

The finest sponges in the Mediterranean, those of the Levant and off the Syrian and Tripoli coasts, are found between the average aerial winter temperatures of 63° and 70°, and the isochrymals of 50°-57°, and at no time of the year are these, which, as stated by Von Eckhel, occur in the deeper water at a distance from the coast, probably exposed to a lower temperature than 60°.

In describing the species of this genus I have made comparisons between three principal Mediterranean, and three of the American commercial sponges, in order to show the very evident relationship of these forms. Schmidt describes five Mediterranean species in all, and may be right; but so far as I can understand his descriptions, with the aid of a fine collection of specimens purchased by Prof. Baird for the National Museum from Mr. Isaacs, of New York, I cannot make more than three out of the ordinary commercial varieties, which were fully represented and appeared to include the entire range of his five species. Von Eckhel's work upon the 'Badeschwämme,' although a purely commercial treatise, has the same view of the affinities of the sponges, based upon the observations of the fishermen and dealers, and the distribution of the species; the latter is quite remarkable. Only one species, the *Spongia officinalis*, Linn., *Adriatica*, Schm., is found on the eastern shore of the Adriatic and coast of Greece, from Trieste to the Bay of Nauplia. From Nauplia and the island of Candia to Eritra, on the coast of Asia Minor, two occur, *Spongia officinalis* and *Spongia agaricina*, Pall., *Zimocca*, Schm. From Eritra, opposite the island of Chios, to Tripoli, all three, *Spongia officinalis*, *agaricina* and *equina*, are fished, except at the island of Cyprus, where the *Zimocca* sponge does not live. From Tripoli to Tunis two only occur, *Spongia officinalis* and *equina* and from thence to Ceuta, at the Straits of Gibraltar, a very peculiar dark-coloured and coarse variety of the *Spongia equina* is obtained, called the Gerbis sponge.

(*To be continued*).

The Pharmaceutical Journal.

THE BRITISH PHARMACEUTICAL CONFERENCE.

Now that the time has so nearly arrived when the British Pharmaceutical Conference will hold its Fourteenth Annual Meeting in the town of Plymouth, it may be of service to intending visitors, and of interest to many who will have to stay away, to bring together within a small compass what is known of the local arrangements up to the present time.

The meetings of the Conference will be held on Tuesday and Wednesday next, in the Athenæum, George Street, Plymouth, the chair to be taken at 10 a.m. each day. After the usual business of the reception of delegates from pharmaceutical associations, the Report of the Executive Committee and that of the Treasurer will be submitted, and then the Inaugural Address will be delivered by the President for the year, Professor THEOPHILUS REDWOOD, Ph.D., F.C.S. The reading of papers will follow, and, as will be seen from the list published below, these appear to be already numerous enough to test the Chairman's skill in confining the proceedings within such limits as will allow of them being read and discussed in the allotted time. Amongst the papers may be noted five reports on the results of investigations towards the expenses of which grants have been made from the Conference funds.

An adjournment will take place each day from 12.30 until 2 p.m. Luncheon will be provided at the Mechanic's Institute, Princess Square, and Luncheon Tickets will be issued by the Local Secretaries to all who attend the meetings.

The business portion of the Conference will terminate on Wednesday afternoon, giving such members as wish so to do the opportunity of hearing the President of the British Association deliver his Address. Next morning, Thursday, the 16th, the Local Committee, acting on behalf of the pharmacists of Devon and Cornwall, invite the visitors to the Conference to accompany them on a steam-boat excursion over the course we were enabled to sketch a short time since. The "Eleanor" will leave the Millbay pier punctually at 9 p.m., and after calling at North Corner, Devonport, proceed through the harbour to the Hamoaze, and up the river Tamar. Stoppages will be made at Pentillie, Cotehele, and Calstock, and it is intended to return in time to reach Mount Edgcumbe about 4 p.m. Here those who wish it will land, whilst the steamer proceeds for a further cruise to Cattewater and Bovisand, and thence to the Breakwater and Cawsand Bay, returning to Mount Edgcumbe about 5 p.m. Luncheon and refreshments will be provided on board by the Committee, and a "High Tea" will be served in the Orangery or private gardens at Mount Edgcumbe on the return of the boat from her trip across the Sound. Visitors desirous of taking part in this excursion should intimate their wishes as soon as possible to the Local Secretary, Mr. ROBERT CLARKE, 77, Old Town Street, Plymouth, who will supply them with tickets. A separate ticket will be required for admission to Mount Edgcumbe Park.

The following is a list of the Papers expected to be read at the meetings on Tuesday and Wednesday, corrected up to the present time:—

1. The Supply of Cinchona Bark as connected with the Price of Quinine. John Eliot Howard, F.R.S.
2. Report of the Committee on the Extraction and Investigation of the Aconitines of *Aconitum Napellus.* Dr. Wright, F.C.S., J. Williams, F.C.S., and T. B. Groves, F.C.S.
3. Report on the Active Principle of Cayenne Pepper. J. C. Thresh, F.C.S.
4. The Pill Masses of the B.P., which are of Inconvenient Consistence or acquire that Consistence by Keeping. J. C. Thresh, F.C.S.
5. Report of Continued Researches on Essential Oils. Dr. Tilden, F.C.S.
6. On a Product of the Oxidation of Barbaloin and Socaloin. Dr. Tilden, F.C.S.
7. Report on the Proximate Constituents of Ivy Berries. R. H. Davies, F.C.S.
8. Report of a Research (part 2) on Essential Oil of Sage. M. M. P. Muir, F.C.S., and Mr. Siguira.
9. An Impurity in Oxide of Zinc. W. W. Stoddart, F.C.S.
10. The Microscope in Pharmacy. Mr. J. Cooke.
11. Additional Notes on the Assay of Opium. Mr. B. S. Proctor.
12. Tincture of Acetate of Iron. Dr. C. R. C. Tichborne, F.C.S.
13. Sugar in Pharmacy. Dr. C. Symes.
14. A Point in Pharmaceutical Ethics. Mr. S. R. Atkins.
15. Proximate Principles of *Narcissus Pseudo-narcissus.* Mr. A. W. Gerrard.
16. The Alkaloids of Japanese Aconite. Dr. Paul, F.C.S, and C. T. Kingzett, F.C.S.
17. Preserved Foods and Copper. Dr. Paul, F.C.S., and C. T. Kingzett, F.C.S.
18. Analyses of Preserved Carrots, Potatoes, Cabbage, and Mixed Vegetables. Professor Attfield.
19. Scammony Root. C. T. Kingzett, F.C.S.
20. Further Note on the History of Tea Hair. Thomas Greenish, F.C.S.
21. Copaiba Testing. Louis Siebold, F.C.S.
22. A New Medicinal Solution of Phosphorus. Mr. W. W. Urwick.
23. Blood Albumen. C. T. Kingzett, F.C.S.
24. Note on Pilocarpine. C. T. Kingzett, F.C.S.
25. Note on Hederic Acid. C. T. Kingzett, F.C.S.
26. Effects of Variations of Temperature on Boiled Putrescible Liquids. Mr. W. Willmott.
27. Suggestions for a Small Practical Laboratory. G. F. Schacht, F.C.S.
28. A Glance at the Materia Medica of Devon. E. Smith, F.C.S.

THE BRITISH MEDICAL ASSOCIATION.

On Tuesday last the British Medical Association commenced its forty-fifth annual meeting in Manchester. As usual the members first attended Divine Service, which was held in the Cathedral, the sermon being preached by the Bishop of Manchester, from 1 John, iii. 2. In the afternoon the first General Meeting was held in the Concert Hall, when the retiring President, Dr. Bartolomé, made way for Dr. M. A. Eason Wilkinson, of Manchester, the new President. Dr. Bartolomé, in some valedictory sentences, remarked that during his year of office the colliers of Pontypridd had been rewarded for their heroism, but the medical men had not. It had therefore been decided by the Council of the Association to have a medal struck for presentation in recognition of the noble behaviour of those gentlemen, and it had been further recommended to adopt the medal as the medal of the British Medical Association. The programme included the reading of papers, etc., on the three succeeding days; also a *soirée* given by the Mayor and Corporation at the Town Hall, on Wednesday, and a public dinner on Thursday. The attendance was very good.

THE POISON SCHEDULE TO THE PHARMACY ACT.

We have been favoured by the Registrar of the Pharmaceutical Society of Ireland with a Copy of a Chart that has been issued by the Council of that Society. It contains a list of the "Dangerous Medicines," with their doses, as contained in the British Pharmacopœia, and a List of the Poisons contained in the Poison Schedule to the Irish Pharmacy Act. We are not prepared to say how far it is necessary in the sister island to reproduce in this form the posology contained in the British Pharmacopœia, but we think it very probable that the attempt to diffuse correct information as to the law in respect to the sale of poisons will be very useful. In our law reports this week, for instance, a coroner is represented as gravely talking about the provisions for the sale of laudanum laid down in the Pharmacy Act, 1868, being overridden by those of the Pharmacy Act, 1877.

A relative of Mr. Sangster who was one of the Successful Candidates for the Bell Scholarship writes to correct the incidental statement of the President that he understood his father was a stoker or engineer on board H.M.S. *Spitfire*. This remark was not intended in any way to disparage either Mr. Sangster or his father, but had simply reference to the principle upon which the Bell Scholarship was established of furnishing assistance "for young men less favoured by fortune than by industry."

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The half-yearly meeting of the members of the Association was held at the rooms, Halford Street, on Thursday, the 26th July last. The report, which was very favourable, having been read, was unanimously adopted. It stated that two prizes had been offered for competition by the Association, and two others by Messrs. Lloyd and Hammond, the successful candidates being Messrs. Lewitt, Crane, Garrett, and Mason. The average attendance at the classes had been nine, which though a slight decrease on that of previous sessions, was regarded as satisfactory, considering the counter attractions during the summer months. Forty-one meetings of classes had been held, conducted respectively by Messrs. Hammond, Clark, Raynor, and Garrett; also four special and interesting lectures had been delivered by W. Johnston, Esq., M.D., F.G.S., W. J. Harrison, Esq., F.G.S., Mr. W. B. Clark, and Mr. E. Jones; also an exhibition of microscopic slides has been given by Mr. J. J. Edwards; and to each of these gentlemen the Committee desired to tender their sincere thanks, as well as to the honorary members, for their constant kindness and liberality. After the transaction of routine business the members proceeded to elect the Committee for the ensuing session, with the following result:—Mr. T. C. Raynor, president; C. B. Lomas, vice-president; W. Hammond, hon. secretary; W. B. Clark, treasurer; E. H. Butler, J. Garrett, Chas. Hodgson. The Treasurer's report showed that the receipts during the half-year had amounted to £4 14*s.* 11*d.*, and the payments to £13 6*s.* 6*d.*, leaving a balance of £1 8*s.* 8*d.* A programme of lectures, classes, etc., extending to the 31st of January next, was also announced.

On Tuesday, August 7, a tea was held at the Association Rooms, Halford Street, after which the President, Mr. T. C. Raynor, read his inaugural address; songs and readings were also given by various members of the Association.

In the course of his remarks, after giving a brief sketch of the past history of the Association, the President said that during its earlier years it was found that many of the students had not passed the Preliminary examination, and classes had to be formed on their behalf. These classes were discontinued afterwards, owing to the old members having passed, and the apprentices being able to pass upon entering the trade. This made a great improvement in the social aspect of the Association, it placed all the students upon the same footing, and caused them to work with a will towards passing the other examinations. Soon after the Association had started, it was found desirable that the shops should close earlier, so that the assistants and apprentices might have a better opportunity for study; this object was supported, and is still kept up by nearly all the chemists in the town. The Association had steadily increased from the first, and it had now a good museum, a library, a microscope, and laboratory. Thanks were due to many members, both past and present, for the interest they had taken in the welfare of the Association, to the members and the Pharmaceutical Society for the pecuniary aid they had given, and to the wholesale firms who so kindly presented the specimens and bottles. After some remarks on the best method of conducting classes, and the advantages students might obtain through attending them, the President directed attention, in conclusion, to the *Pharmaceutical Journal*, as containing many articles in it worth reading. The mention of new medicines there, if noticed and understood when they appeared, would save a deal of trouble in referring for or inquiring about them, when they come into general use. The article appearing at the end of the month, entitled "The Month," should have special notice; it being a condensed report of articles brought under the notice of the trade during the month. The botanical portion was very interesting, giving an account of plants in flower during the month, and where to be found; also some very good botanical notes upon some of the plants mentioned.

NEWCASTLE-ON-TYNE CHEMICAL SOCIETY.

The Estimation of Nitrous and Nitric Acids.

BY G. LUNGE, PH.D.

Professor of Technical Chemistry, Polytechnicum, Zurich.

Some time ago I proposed to myself to study the action of sulphur dioxide on the solution of chamber crystals, or, more scientifically speaking, of nitrosulfonic acid, $SO_2(OH)(NO_2)$, in sulphuric acid, which constitutes the acid flowing from the "absorbing columns" of sulphuric acid works, and which is commonly called "nitrous vitriol." Although this action is utilized every day on a very large scale in most sulphuric acid works, viz., in all those employing the denitrating columns invented by Mr. Glover, and bearing his name, there are great varieties of opinions existing as to its nature. Some of the contradictions arising out of these controversies, which have been more particularly carried on in German periodicals, appeared to me to arise from imperfect modes of testing for nitrous, and perhaps even for nitric, acid, and it thus became the first portion of my task to thoroughly examine at least those methods of estimating the acids of nitrogen which have been proposed or used for testing "nitrous vitriol."

1.—*Estimation of Nitric Acid.*

One of the oldest and probably the most widely used methods of estimating nitric acid is that first proposed by Pelouze, but considerably modified afterwards by Fresenius, viz., dissolving metallic iron in hydrochloric or sulphuric acid, adding the compound containing nitric acid, or one of its salts, heating till the action of NO_3H on the ferrous salt is complete, and all NO is given off, and estimating the unoxidized portion of the ferrous salt by means of potassium bichromate or permanganate. In the latter case sulphuric acid must be employed for dissolving the iron. If the air has access to the liquids during these operations, there may be some oxidation of ferrous to ferric sulphate, at the expense of atmospheric oxygen; but a more serious source of error is the regeneration of nitrogen acids from the evolved NO, which act again upon ferrous sulphate, and thus too high a proportion of nitric acid is indicated by the process. The process, as originally proposed by Pelouze, is certainly altogether faulty; but it became most accurate when Fresenius proposed to conduct the operation with a number of precautions the most important of which is the carrying on of the whole process in an atmosphere of carbon dioxide. The process of Fresenius is, however, somewhat lengthy and complicated, and entails the use of cumbrous apparatus, and this would militate against its use in many, especially in all works', laboratories. A modification is therefore adopted by very many chemists, consisting in dispensing with the current of CO_2, but conducting the operation of dissolving the metallic iron and partly oxidizing the solution by nitric acid or its salts in a flask, fitted with a Bunsen's india-rubber valve; that is to say, a cork, through which passes a short glass tube open at both ends, but closed at the outer end by means of a small piece of india-rubber tubing and a bit of glass rod stopping the latter again. The india-rubber tubing is provided with a sharp longitudinal incision of about one centimeter's length, which allows any gas or vapour to pass out, but none to enter into the tube, and thence into the flask. In this apparatus the steam arising from the boiling liquid soon expels the air, and prevents its injurious action upon the accuracy of the process; nor can the air enter again on cooling, as the valve prevents it from doing so, so that a vacuum is formed in the flask, which ought to be of strong glass to resist the atmospheric pressure. This apparatus is so very simple that even the smallest laboratory can use it; but doubts have arisen whether the results obtained by it are really trustworthy. I have, therefore, made with this apparatus a number of experiments (nine), in which I worked with every possible precaution against error, and in which I employed exactly known quantities of nitric acid or potassic nitrate. In order to save the time consumed by cleaning, accurately weighing, and dissolving the iron wire, I employed in this series of experiments, as well as in all those following, a solution of pure ferrous sulphate (100 grams per litre), acidulated with 5 per cent. of sulphuric acid. Of this solution a certain volume, more than sufficient for the nitric acid contained in the test liquid, was employed, and a similar volume was tested at the same time by a standard solution of potassium permanganate; one such standardizing of the iron solution is sufficient for a whole day, as the free acid prevents its too rapid oxidation. The potassium permanganate solution itself was made from pure crystals and standardized once a week with pianoforte wire in the same apparatus (taking 100 wire to contain 99·6 Fe); it was found to be unchanged after a month's standing.

The time consumed by each test till the NO was completely driven off was very inconveniently long, unless a large quantity of free acid was present, say 20 parts of SO_4H_2 to each 100 parts of liquid. If there is less acid present, the reaction, as shown by the colour of NO dissolved in the solution of the ferrous salt, goes on extremely slowly, or, with great dilution, not at all, until by prolonged boiling the above concentration has been reached. It is, therefore, convenient to add a sufficiently large quantity of pure strong sulphuric acid at once, in order to hasten the progress. A pinch of sodium bicarbonate may be thrown in as well to fill the vessel with CO_2, but my results were as accurate without as with this modification.

With proper precautions, especially if the concentration and temperature of the liquids are not such as to cause an instantaneous reaction before the air has been expelled from the apparatus by aqueous vapour, the results obtained in all the nine experiments made by this process are as accurate as it can be expected by any method; and it can be recommended to chemists even in its simplified form, as described above.

I have also made a number of experiments with the process first proposed by F. Schulze, and modified by many subsequent chemists, viz., the reduction of nitrogen acids in an alkaline solution by means of iron or zinc; (aluminium has also been used for this purpose). The total nitrogen is thereby supposed to be converted into ammonia, which is collected in hydrochloric acid of known strength, and estimated by re-titrating the same. Nearly the whole of my experiments were made according to the prescription given by Siewert (*Annalen der Chemie und Pharmacie*, vol. cxxv., p. 293); he employs an alcoholic solution of potash in order to prevent the violent bumping of aqueous solutions of caustic alkali and a mixture of zinc and iron, similar to Harcourt's process, published about the same time. From the latter I adopted the recurved gas-delivery tube and the inclined position of the reduction-flask, as a precaution against spurting over of any fixed alkali. I had, however, to use caustic soda in the place of caustic potash, as I could not procure the latter free from nitre, and it is just possible that the apparently good results obtained by this process may in some cases be due to the employment of impure potash. I for my own part, working with rigid accuracy and, if anything, overdoing all the precautions prescribed for this process (for instance, allowing the mixture to stand some time and distilling very slowly, say three to four hours), never obtained any satisfactory results. The ammonia produced fell short, in six experiments, from 16 to 26 per cent. of that calculated from the pure potassic nitrate, etc., employed. Nor could I better the case by some experiments tried with the original plan of Schulze's, and by a modification proposed by Hager. A number of chemists have come to the same conclusion, viz., that the process of estimating nitrates by reduction in an alkaline solution cannot be depended upon; and although a number of other chemists certainly have obtained accurate results by it, this may be due partly to the fact that in some special circumstances the process does work well, whilst it does not in other cases, and partly to a compensation of the loss of ammonia by the nitre consumed in the potash employed, or by carrying over of fixed alkali. A process which gives such uncertain results in spite of scrupulously carrying out the prescriptions given for it, ought not to be resorted to so long as any other process of undoubted accuracy is available.

2.—*Estimation of Nitrous Acid.*

In this case the discrepancies among the results obtained by different chemists are still greater—probably because the methods have not been controlled in many cases by means of a substance of absolutely certain composition. As such I employed silver nitrate, obtained by mixing a hot solution of silver nitrate and of sodium nitrite; it was recrystallized twice from boiling water, and dried *in vacuo* over sulphuric acid. Its purity was proved by igniting it.

0·4780 grm. yielded 0·3357 Ag.; theory 0·3352.
0·5057 „ „ 0·3532 „ „ 0·3546.

By means of this, several test-liquids of artificial "nitrous vitriol" were made. Each time 5 grams of pure $AgNO_2$ were dissolved in 500 c.c. of pure concentrated sulphuric acid of a density of 1·842 at 15 degrees C. in such a way that the salt only came into contact with the acid at the bottom of the vessel, so that the N_2O_3 evolved was immediately dissolved by the acid, and only one or two bubbles of it escaped. The sulphuric acid employed was absolutely free from nitrogen compounds, as proved by the most delicate of all reagents—diphenylamine. The liquid obtained was perfectly clear, the silver sulphate dissolving in the strong acid.

This liquid was used for testing with potassium permanganate and potassium bichromate with urea, and the silver nitrite was tried directly by reduction in an alkaline solution (Siewert's process). It should be stated from the outset that the only really accurate method for estimating N_2O_3 was proved to be that by means of potassium permanganate (first proposed by Feldhaus); but this plan also is only perfectly accurate when used in the less convenient form of running the nitrous vitriol from a burette into a measured quantity of permanganate, so as to oxodize the N_2O_3 momentarily before it can split up into NO and NO_3H (with the water present) since a certain quantity of NO always escapes if the opposite plan be followed—that of running the permanganate into the nitrous vitriol. Only in one way the latter plan gave approximately good results; perhaps near enough for factory work, but never quite accurate, viz., if either the nitrous vitriol was used undiluted, the bulk of the permanganate necessary for its oxidation was run upon it, the strata were allowed to mix very slowly and ultimately permanganate added, till the pink colour remained; or, if the nitrous vitriol—say 5 or 10 c.c.—was run by means of a pipette down to the bottom of a large quantity of water - say 500 c.c.— without mixing them at first, and then permanganate was run in, so that the reaction takes place more in the lower part of the liquid. The first plan has been proposed by Mr. Crowder, the second one by Professor Winkler (in an unpublished letter to myself). A very large number of tests were made by every one of these modifications, but there was always a certain loss of N_2O_3, and only by the process of running the nitrous vitriol into the permanganate solution, really accurate and wholly constant results were obtained. The permanganate solution was employed as a semi-normal one; that is to say, giving up 0·004 oxygen for each c.c., or indicating 0·0095 N_2O_3. It had to be diluted pretty strongly—say 1·20 water—to avoid too great a heating. When the temperature of the measure rises above 80° C., the results are no more accurate; from 30° to 40° C. is the most convenient temperature, as then there is no danger whatever of any over-heating, and at the same time the reaction takes place much more rapidly than in the cold. When ordinary nitrous vitriol of about 1·7 specific gravity is employed, the rise of temperature caused by its mixing with the test solution is only slight, and it is convenient to dilute the permanganate with tepid instead of cold water, in order to hasten the reaction.

Potassium bichromate has been used for years in the Tyne district for testing nitrous vitriol, and the same has been introduced into many German works by Gerstenhöfer. It is employed precisely in the same way as the permanganate, according to that plan which I have found to be the most accurate one, viz., pouring the nitrous vitriol out of a burette into a measured quantity of potassium bichromate of known strength. Its colour thereby changes soon into brownish green, and at a certain point there is a sudden change into blue green, which shows the end of the reaction. After some practice this point can be hit with great nicety, but there is always an uncertainty to the amount of several drops, whilst with permanganate no experienced eye is required, and it is easy to work to a single drop. Since stable test solutions can be obtained by employing pure crystallized potassium permanganate, there is no reason left for the use of the less convenient bichromate.

Bleaching powder has also been used for the same purpose, and it seems to work tolerably well, to judge from the experiments of Mr. Davis (*Chemical News*, vol. xxv., p. 124), but, as the only recommendation in its favour can be cheapness, and in every other respect it is necessarily inferior to permanganate, I have not even drawn it into the range of my experiments.

I have further tried Siewert's method (reduction by zinc and iron in an alcoholic solution of potash), but on finding no more accurate results with silver nitrite than I had previously found with potassium nitrate, I at once abandoned this tedious and troublesome plan, which has no *locus standi* beside any of the methods mentioned hitherto.

A good deal of time was, however, spent with the urea method, which has been recommended as the most accurate test for nitrous acid—first by Peter Hart (Muspratt's 'Chemistry,' ii., 1040). Mr. Hart does not appear to have tested the method by pure silver nitrite (the only reliable way), but simply to have inverted Millon's urea test, and to have assumed, from theory, that the only reaction taking place is the following:—

$$CON_2H_4 + N_2O_3 = N_4 + CO_2 + 2\,H_2O.$$

Nitrous vitriol is dropped into a boiling solution of nitrate of urea until a drop of the liquid shows an excess of N_2O_3 to be present by staining blue a mixture of starch and potassium iodide in solution. I cannot conceive that this method could ever have come into extended application. Even the costliness of pure nitrate of urea must have deterred most chemists—certainly nearly all factory chemists—from its use, otherwise its utter worthlessness would have been proved more universally before. Working with all precautions, I found that 1·230 grm. of nitrate of urea required in two experiments 18·0 and 17·5 c.c. of my artificial nitrous vitriol (prepared with silver nitrite), instead of 32·5 c.c., which it ought to have taken, and that up to the point when the starch and potassium iodide were stained blue instantaneously. But long before this point the coloration took place after a few seconds' contact, so that it is impossible to say with any degree of accuracy when the end of the reaction had come. Nor can it be expected that Hart's method should give any accurate results since Claus has proved ('Berichte der Deutschen Chemischen Gesellschaft,' iv., 140), that the reaction between urea and nitrous acid is anything but so simple as assumed by Mr. Hart, and that a considerable quantity of ammonium salts is formed thereby.

I also tried the plan proposed by Mr. Crowder (read before our Society in 1871 and further published in the *Chemical News*, vol. xxiv., p. 237), viz., to put a certain quantity of nitrate of urea in a Geissler's apparatus for estimating carbon dioxide; to run the nitrous vitriol into the delivery flask from the stoppered side tube, and to calculate the N_2O_3, present from the loss of weight corresponding to the N and Co_2 formed. The four following results were obtained, viz.:—

1. Employed: 26·8095 nitrous vitriol, containing 0·0359 N_2O_3; found, loss of weight, 0·0463 = 0·0357 N_2O_3.
2. Employed: 25·6670 nitrous vitriol = 0·03421 N_2O_3; found loss of weight = 0·0472 = 0·03587 N_2O_3.
3. Employed: 25·2250 nitrous vitriol = 0·03361 N_2O_3; found loss of weight, 0·0490 = 0·0372 N_2O_3.
4. Employed 26·2163 nitrous vitriol = 0·0347 N_2O_3; found loss of weight, 0·0562 = 0·0427 N_2O_3.

It will be seen that the results obtained by Crowder's process are a great deal nearer the truth than those of Hart's process, but they are still very unequal, and sometimes very inaccurate, and as the process is both costly and tedious, requiring, as it does, three accurate weighings of a heavy apparatus on a delicate balance, it cannot for a moment hold its ground beside the permanganate process, which takes a few minutes for its performance, and even in its less accurate forms, as described above, gives far better results than the urea process. Mr. Davis (*Chemical News*, vol. xxv., p. 124) has had similar unfavourable experience with both Hart's and Crowder's process. He likewise recommends the permanganate process, but without basing his judgment on the examination of a material of certain composition, such as silver nitrite.

III. Estimation of Nitrous and Nitric Acid in the Same Sample.

This can be effected in the most satisfactory way by first oxidizing the nitrous acid by means of standard potassium permanganate, then adding a measured volume of a solution of ferrous sulphate of known relation to the permanganate, and finishing the process as prescribed for the estimation of nitric acid. From the total quantity of nitric acid thus found a deduction is made for that corresponding to the N_2O_3, the difference corresponding to the nitric acid originally present. It is only necessary to deduct one and a half times the number of c.c. first consumed for oxidizing N_2O_3 into N_2O_5, from the number afterwards found (in the shape of ferrous sulphate) consumed for reducing N_2O_5 to N_2O_2; the remainder will show how much N_2O_5 (or rather NO_3H) was present. The whole operation is carried on from beginning to end in the same flask, fitted with a Bunsen's india-rubber valve, as above described. This I proved to be altogether correct by dissolving some pure potassium nitrate in my artificial nitrous acid prepared with silver. On testing, as by the plan just described, I found—

1. Employed 0·2010 KNO_3, found 0·2012.
2. ,, 0·1950 ,, ,, 0·1936.

A third blank experiment was made with the nitrous acid without adding any potassium nitrate. Originally used 12·0 c.c. permanganate; found to require for reduction, ferrous sulphate equal to 15·15 c.c. permanganate instead of 15·3; the 0·15 c.c. of permanganate used in excess of the theoretical quantity in retitrating the iron solution would be required for staining the large volume of liquid obtained at the end, so that the blank experiment may be declared to be quite satisfactory.

IV. Analysis of Nitrous Vitriol from a Sulphuric Acid Works.

It seemed to be desirable to apply the just-described process to the analysis of nitrous acid obtained on a large scale from the absorbing column of a sulphuric acid works. I procured such from a factory on the borders of the Lake of Zürich. It had a specific gravity of 1·691, and was evidently almost saturated with N_2O_3. Eleven experiments proved it to contain 4·13 grams. N_2O_3 in 100 c.c. of acid (= 2·44 per cent. by weight). Now, the published analyses of nitrous vitriol generally mention the presence of NO_3H in the same as well. For instance, Winkler found 0·256 per cent., Kolbe even 0·9 and 1·14 per cent., calculated as N_2O_5. It is not, on the face of it, clear how nitric acid can get into nitrous vitriol, since it cannot very well bodily traverse the chambers without being reduced to lower nitrogen oxides; and since it is not regenerated either from the latter in the presence of sulphuric acid, the oxidation in this case never going beyond N_2O_4, as proved by Winkler himself. Experiment has proved in my special case that the nitrous vitriol really contained no NO_3H whatever. The additional permanganate, over and above that corresponding to N_2O_3, amounted, in two experiments, to 0·05 and 0·1 c.c., which is just sufficient to stain the liquid; and I am inclined to believe that nitrous vitriol really does not contain any nitric acid, except perhaps traces, in any case, for I was able to show by experiment, performed purposely by the faulty method generally in use, that nitric acid was generated during the testing process where it did not exist before. My artificial nitrous acid prepared from pure $AgNO_2$, and thus absolutely free from NO_3H, required, as mentioned above, for its reduction, after oxidation to NO_3H by means of permanganate, as nearly as possible exactly the theoretical quantity of ferrous sulphate, viz., that corresponding to one and a half times the quantity of permanganate first used. But this was only the case when the oxidation had taken place in the way described by me as the only accurate one, viz., by dropping the nitrous acid into the permanganate. When, purposely, the opposite way had been employed, viz., diluting the nitrous vitriol with very much water, then oxidizing by permanganate and reducing again, the following results were obtained:—

1. Real percentage in 100 volumes of acid, 0·235 N_2O_3, 0·000 N_2O_5. Found by the above faulty method, 0·180 N_2O_3, 0·045 N_2O_5; the latter corresponding to 0·027 N_2O_3. leaves 0·028 for absolute loss (probably as NO).
2. Found 0·199 N_2O_3, 0·036 N_2O_5, the latter corresponding to 0·021 N_2O_3, leaving 0·015 for absolute loss.

It was thus positively proved that, by the more usual plan of testing nitrous vitriol, nitric acid is generated in the process of dilution, according to the equation:—

$$3\,NOOH = 2\,NO + NO_2OH + H_2O.$$

Parliamentary and Law Proceedings.

The Personations at the Preliminary Examination.

At the Central Criminal Court on Tuesday last, the 7th of August, 1877, before the Recorder, the cases of Regina (on the prosecution of the Pharmaceutical Society of Great Britain) against Frank Oates, and Andrew Ritchie Hunter; and Regina (on the like prosecution) against George Frederick Webb, and Andrew Ritchie Hunter, were heard.

Mr. Douglas Straight, instructed by Messrs. Flux and Co., appeared on behalf of the prosecution. Mr. Grain appeared on behalf of Frank Oates and George Frederick Webb.

In each case the indictment was for a conspiracy that at preliminary examinations duly held by the Pharmaceutical Society of Great Britain at Brighton and Reading respectively, the defendant, Andrew Ritchie Hunter, with the connivance, and by the procurement of the other accused person, did present himself, and in the name of and for the other accused person did undergo the said examinations as if he, the said Andrew Ritchie Hunter, then was the said other accused person, and did personate the said other accused person at the said examinations respectively.

On the cases being called all the accused pleaded Guilty.

Mr. Douglas Straight, on behalf of the prosecution, brought under the attention of the judge the fact that Hunter had on a former occasion been found guilty of a similar offence.

Counsel for the defendants Oates and Webb called witnesses as to character.

The Recorder sentenced Hunter to six months imprisonment, and in regard to the two other defendants, directed that they should enter into their own recognisances to appear and receive judgment if hereafter called on.

The Sale of "Castor-Oil Pills."

At the Christchurch petty sessions, on Monday, July 30, before the Hon. R. Douglas, Messrs. W. W. Farr, G. T. Lowth, W. C. Dean, Stuart, R. Stevens, and Entwisle, and Dr. Gream,

Mr. Alexander Duncan, chemist and druggist, of the Commercial Road, and Lansdowne Crescent, Bournemouth, was summoned for having on the 22nd of June, at the parish of Holdenhurst, unlawfully sold to William White, a certain drug which was not of the nature, substance, and quality of the article, to wit castor-oil pills, then and there demanded by the said William White, to the prejudice of the purchaser.

The defendant pleaded not guilty.

Superintendent White deposed: On the 22nd of June, I went to Mr. Duncan's branch shop at Lansdowne, Bournemouth, and asked for a shilling's worth of castor-oil pills. I was served with a box containing a number of pills, for which I paid a shilling. I then told the person in the shop, Mr. Duncan's assistant, that I was going to send them to the public analyst to be analysed, and offered to divide them in three parts. The assistant said that it was not necessary. The same day I sent them to Mr. Arthur Angel, the county analyst, Southampton, in a registered letter. On the 1st of July, I received a certificate from the analyst and a box containing a part of the samples.

In cross-examination Mr. White said he had heard since he made the purchase that it was the common practice to call such pills castor-oil pills, but he did not know before then that ordinary purgative pills were universally sold as castor-oil pills in this part of the country. He was not aware that castor-oil pills would be useless.

The certificate, which was put in, stated that in the analyst's opinion, the sample of pills contained rhubarb, aloes, peppermint, oil, and soap, and that the application of the term castor-oil to these pills was a dangerous practice and might be attended with injurious results by leading the purchaser to understand that the active ingredient of the pills was castor-oil.

Mr. Lacey objected to the latter statement being taken as part of the certificate. All the analyst had to do was to analyse the sample and state the particulars of the analysis. Extraneous matter ought not, he urged, to be brought into the certificate.

The Chairman: Where is that laid down?

Mr. Lacey: Nowhere, but it is clear to everyone that it is no part of the certificate.

The Bench overruled the objection.

Mr. Lacey then proceeded to address the bench on behalf of the defendant. The very gist of the offence, he observed, was that it should be "to the prejudice of the purchaser," which words were inserted in the bill when it was passing through committee, and it could not be said that the purchaser had been prejudiced in this case. These pills had been known to the public and to the medical and chemical profession for several years as castor-oil pills, and it had been universally the custom to call them so. The pills in question were very much more valuable than pills made of castor-oil would be; for only one grain of castor-oil could be contained in one pill, so that it would take from 200 to 400 pills for one dose. Therefore it had been the custom for 25 or 30 years to sell such pills as those in question as "castor-oil pills;" the custom, he believed, originated at Bournemouth, through people who desired a mild aperient asking for castor-oil pills, and being supplied with something very much better. This could not be to the prejudice of the purchaser.

The Chairman said he believed it had been decided in a tea case that the purchaser was entitled to have what he asked for, and that if the vendor could not supply him, he had a right to be told so.

Mr. Lacey quoted from Stone's 'Justices' Manual' the opinion of the editor that the words "to the prejudice of the purchaser" were intended to prevent injury to the person or pocket of the purchaser, and not to stop the production and sale of articles of various qualities and prices. The words were very ambiguous, and it might be contended that they would include the case of a mere mistake of selling one thing for another, if the purchaser could not use the thing bought for the purpose or to the extent which might have been possible if he had obtained exactly what he asked for, but Mr. Stone considered that they must be limited to the case of a seller knowing what it was that the purchaser actually demanded, and knowing what was the description he handed over. He (Mr. Lacey) contended that the statute was not aimed at such a case as this. The sale was clearly not "to the prejudice of the purchaser."

The Chairman said it was argued in the gin case that the purchaser was not prejudiced by having 27 per cent. of water mixed with the gin, as the weaker the dilution the less harm it would do him, but the bench ruled that the purchaser was entitled to have what he asked for.

Mr. Lacey said this case was different. There was no castor-oil at all in the pills.

The Chairman: This is the case of a purchaser asking for one thing and getting another.

Mr. Lacey: Which was better than the thing he asked for. He might state that his own opinion was fortified by that of a very eminent counsel, Mr. Charles, who went this circuit.

The Chairman said they had a great respect for Mr. Charles's opinion, but Mr. Lacey knew very well that the value of an opinion depended very much on the case submitted.

Mr. Lacey said he was perfectly willing for the bench to read his case. He intended to call before them several chemists who held a high position in their profession to prove the custom with reference to castor-oil pills. There were many articles sold by chemists which were called by names not properly applicable to them, and if the bench convicted in this case—

The Chairman: You would have to call a spade a spade.

Mr. Lacey was about to show that chemists sold many articles popularly called by names which were not properly applicable to them, when

The Chairman humorously suggested that Mr. Lacey should not go into this question, as he did not think chemists would thank him to disclose all the secrets of the trade.

Mr. Lacey, however, went on to say that there was, for instance, "sweet spirits of nitre," which contained no nitre. There were several other articles known by certain names not strictly applicable to them, and it was clearly not an offence to sell them under such names. Mr. Lacey then called

The defendant, Mr. Duncan, who was examined as a witness on his own behalf. He deposed:—Some little time ago I opened a branch establishment in Lansdowne Crescent. My assistant there is Michael Mason, who is registered by examination. The two shops are nearly a mile apart, and I am very seldom at the one in Lansdowne Crescent. The pills in question are a compound of rhubarb, aloes, myrrh, soap, peppermint, and treacle, and are the mildest aperient mentioned in the pharmacopœia, and safe for the most delicate constitution. I have heard of these pills being sold as castor-oil pills, and I believe that people know them as such. I myself have never sold them under that name, but I know that it is the custom to do so. Pills made of castor-oil would be dangerous if relied upon for the ordinary action of castor-oil, as an ordinary dose would have no effect. A serviceable dose would be two tablespoonsful or 600 pills.

The Chairman: Under what name were you in the habit of selling these particular pills?

Mr. Duncan: As compound rhubarb pills. I believe it has been the custom for many years to sell them as castor-oil pills.

Mr. Lacey: Do you know of any other misnomers in the drug business?

The Chairman: You are asking your witness to incriminate his own profession, which is hardly fair.

Mr. Lacey: Sweet spirits of nitre, for instance. Is there any nitre in that?

Mr. Duncan: No.

The Chairman: Now, you see, Mr. Lacey, I shall buy no more spirits of nitre.

Mr Lacey: Spirits of hartshorn?

Mr. Duncan: There is no hartshorn in that.

The Chairman: If you make these disclosures, I shall lose my faith in the entire Pharmacopœia.

Mr. Lacey: Cold cream. Is there any cream in that?

Mr. Duncan: None.

Mr. Lacey: You see, your worships, these names are given first by the people themselves, and then by the chemists, because they fancy there is some resemblance.

The Chairman: Because they draw.

Mr. Lacey: All these names are well understood to be misnomers?

Mr. Duncan: Yes.

The Chairman: Shall I take down that the public well understand that they do not get what they ask for?

The next witness was Mr. Green, chemist, of Christchurch, who said he had been in the habit for 25 or 30 years of selling a mild aperient—generally compound rhubarb pills—as castor-oil pills, by which name people asked for them. He had done this in four or five counties in which he had lived. The action of compound rhubarb pills was similar to that of castor-oil pills, but not quite so quick.

The Chairman: Do they not act on a different part?

Witness: Yes. They act on the rectum and bladder. They do not affect the same intestine. Two tablespoonfuls of castor-oil would act more quickly.

Mr. Lacey: How came these pills to be so named?

Witness: I believe it was in consequence of some proprietor of patent medicine bringing out pills under the name of castor-oil pills. Gradually the public came to ask for them in small quantities, and it has been the custom in all parts of England to sell under that name such pills as those supplied in this case.

Mr. Lacey: You have heard the description of the pills in the certificate. Are those more expensive than pills made of castor-oil would be?

Witness: Decidedly so. It might be possible to get one drop of castor-oil into a pill, but such pills would not be of the slightest use unless one took at least 200 or 300.

Mr. Lacey: I believe there are similar instances of misnomers in the trade. Vinegar-with-four-thieves, for instance, does not really contain thieves?

Witness: It does not.

Mr. Lacey: Epsom salts. Are those made at Epsom?

Witness: No; in the North of England.

Mr. Lacey: Violet powder. Are there any violets in that?

Witness: Not the least.

Mr. Lacey: I apprehend that no one seriously thinks he is buying these things when he asks for them?

The Chairman: Possibly not, but it is difficult to limit woman's faith.

Mr. Lacey: And from a pecuniary point of view, these compound rhubarb pills would be very much more expensive than castor-oil pills. My client has not acted from any mercenary motive. It is simply the case of the public having asked for one thing which has practically no existence and being supplied with the nearest we can give them.

The Chairman: They think they have what they ask for, and they go away with a contented mind.

Mr. Lacey: Yes, when it is impossible for them to get what they ask for—devil's dung, for instance.

Mr. Lacey: Dragon's blood. Is that procured from the dragon?

Witness: No.

Mr. Robert Chipperfield, chemist and druggist, o Southampton, deposed: I am a member of the Pharmaceutical Society, and have practised for some years. I have been in business for thirty years in London and Southampton. I have heard of castor-oil pills. A very mild aperient is sold under that name, but I scarcely apprehend that anyone out of a lunatic asylum really supposes that they are made of castor-oil. Such pills as those described in this case have been known as castor-oil pills for a quarter of a century to my knowledge. The action is that of a very mild aperient, and I can state positively from my own knowledge than those who purchase them know that they are not made from castor-oil, but are compounded in order to save the necessity of taking castor-oil. We sell butter of antimony, but there is no butter in it. There are many other instances of misleading names given to articles by the public, and I do not know that we are bound, even if we had the time, to educate everyone who comes to our shops and tell him the composition of these articles.

The Chairman: You had better leave the argument to the solicitor and tell us the fact.

Witness: That is the fact.

Mr. Lacey: Which would cost the most, these castor-oil pills or compound rhubarb pills?

Witness explained that if a person required sufficient pills really made of castor-oil for a dose, he would have to take 438, as only one drop can be got in a pill. There was no harm in these pills. The active ingredient was rhubarb. Spirits of nitre, he might observe, had just been mentioned. It had been known for 200 years by that name, but the proper name was spirits of nitrous ether. In this case no blame could be attached to the vendor, even if the public did not know the composition of the pills.

The Chairman: How should the public know if you do not tell them?

In delivering the decision of the Bench, the Chairman said the evidence which had been given for the defence did not touch the fact that Mr. White had asked for one thing and been served with another, but the evidence adduced had shown the existence of a custom in the trade which they admitted as evidence in mitigation. It was a singular custom, however, and the sooner it was left off the better. It would be much better when the public asked for castor-oil pills to tell them, "There are no such pills in the trade, but we can give you something which will answer the purpose as well." At all events the intention of the Act was perfectly clear—to give the public a right to have what they ask for or be told that they could not get it. The penalty they should inflict was a very light one, because they thought it quite probable that the chemist in this case acted in good faith and was not aware of the law as it existed. They fined the defendant 1*s.* and 19*s.* 6*d.* costs. — *Bournemouth Observer.*

Poisoning by Corrosive Sublimate.

An inquiry has been held at Woodford, Wilts, into the circumstances attending the death of Florence Thorn, one year and seven months old, the daughter of a shepherd. The evidence of Professor Redwood, who had made an examination of the stomach and its contents, proved the presence of corrosive sublimate.

John Thorn said he was brother of the deceased; he was thirteen years of age, and was a shepherd boy. About a month before the child died, his father gave him some stone mercury for the purpose of destroying maggots in the sheep. The piece given him was about the size of a small marble. Witness only used it once before he lost it. He believed he lost it at home before he went on the down. He looked about for it, but could not find it, and told his father he had lost it. He did not find it till his sister Elizabeth picked it up and gave it to him on the same Sunday his sister Floe died. He came home about six o'clock, and when his sister gave it to him and told him it was picked up in the garden, she asked him what it was, and he told her it was stone mercury. It appeared to be the same quantity that he had lost. He kept one piece and gave the two other pieces to Mr. Long's boy. He did not tell the latter that it was sweets, but that it was "stone mercury." No one said it was sweets, and no one tasted it at all.

A sister of the deceased deposed that she remembered one of the children bringing into the house something like a piece of soda, about the size of a small marble, which she dropped down in the house. It was of a light colour, and in falling it broke into several pieces. She (the witness) had never seen such stuff before till the previous day, when she found it near the gate in front of the house, and picked it up, thinking it was a marble, but put it down again. Her sister brought it into the house and let it drop out of her hand on to the floor and broke it. Witness picked up all the pieces she could see, and rolling them up in a piece of rag, kept them till her brother John came home, when she gave them to him. She did not see Florence pick up any. She did not sweep the house afterwards. She thought her brother John had told her some time before that he had lost some "stone mercury." On giving him the pieces she asked him what it was, and he told her it was "stone mercury." She believed when she gave the pieces to him that he put them into his pocket.

The jury, at the inquest, returned an open verdict. Subsequently the father of the deceased and a sister were charged with administering the poison, but the magistrates after hearing the above evidence discharged them, saying their was nothing to inculpate them.—From the *Salisbury and Winchester Journal.*

Suicide by Laudanum—A Coroner's Ignorance of the Law.

On Thursday August 2, an inquest was held at Walsall, before A. A. Fletcher, Esq., Coroner for the Borough, touching the death of a man named Baldwin, who had died after taking a quantity of laudanum. In the course of the proceedings:—

Mr. George Elliott, 50, Park Street, Walsall, was examined, and said: I am a member of the Pharmaceutical Society and a registered druggist. I remember the deceased calling at my shop on Tuesday, about twenty minutes to 9 p.m. He asked for one ounce of laudanum. I supplied him myself. I did not know him. He was a stranger to me. I did not ask his name. It was not necessary for me to do so. He was not introduced to me by any one. I did not ask him for what purpose he wanted it, but I asked him if he knew it was poison, and he replied "Yes." I then asked him if it was for someone who was used to taking it. He said it was for a woman who was in the habit of taking it to make her sleep. I did not inquire his address. I did not know where he lived. The laudanum was put into a one-ounce phial, and labelled in large letters, "Laudanum—Poison," and my name and address were upon the label. I sold deceased one ounce. The witness added that he was not required to ask a customer his name and address.

The Coroner: I think the law requires the name and address of the purchaser to be ascertained.

Witness: I think not. I have the Act here.

The Coroner: What Act is that?

Witness: It is the Act of 1868. [Here Mr. Elliott produced an extract from the Act].

The Coroner said the Act of 1877 was very different.

By Mr. Power (foreman of the jury): Deceased had no appearance of insanity when in my shop.

By the Coroner: I had not seen the deceased in my shop before.

The Coroner: I think it would be the wiser plan to question strangers, and ascertain the name and address of the purchaser. In fact, you cannot sell the poison without someone introducing the purchaser in cases where the purchaser is a stranger.

After hearing other evidence, the jury returned a verdict of *felo de se.*—From the *Walsall Observer.*

Obituary.

We regret to announce the death of Mr. John Huskisson, of Swinton Street, Gray's Inn Road. In a future number we hope to be able to give some account of his labours in connection with manufacturing chemistry.

Notice has also been received of the death of the following:—

On the 21st of July, 1877, Mr. William Agnew Martel, Chemist and Druggist, Great Yarmouth. Aged 37 years.

On the 26th of July, 1877, Mr. Walter Clarke, Chemist and Druggist, Commercial Road, E. Aged 42 years. Mr. Clarke had been a Member of the Pharmaceutical Society since 1870.

AUGUST HUSEMANN.

In a recent number of this Journal the death of this well-known pharmacologist was announced. We are indebted for the following information respecting his life and work to the *Pharmaceutische Zeitung.*

Professor August Husemann, Ph.D., was born on the 5th of September, 1833, at Stolzenau on the Weser. During the years 1848 to 1852 he learned pharmacy in the *Hofapotheke* at Detmold. He studied at Göttingen, whither he returned after brilliantly passing the Hanoverian state examination, in order to devote himself entirely to chemistry. In 1860, in consideration of an investigation of carotin and hydrocarotin, the degree of Doctor of Philosophy was conferred upon him. For some time afterwards he acted as assistant in the physiological chemistry laboratory, and in 1862 he became Private Teacher of Chemistry. To this period of his residence at Göttingen, besides his studies upon glycol compounds, which led him to the discovery of several new bodies, belongs his first considerable literary work, which made him known to a wider circle; this was the elaboration of the judicial information in the 'Handbook of Toxicology' which he issued in association with his relative, Dr. T. Husemann. During this time he also discovered various vegetable principles, as for instance, lycin in *Lycium barbarum* (the identity of which with betain he subsequently demonstrated), cytisin and helleborine. Delicate from his youth, and subject to frequent attacks of asthma, a severer illness than usual compelled him in August, 1863, to seek health through a winter residence in Italy. Even there, however, he was not inactive, as a large portion of his share in the supplementary volume to Gmelin's great work owed its origin to his residence in Pisa. Invigorated, though not cured, he returned from Italy, accepted an invitation to fill the post of Professor of Chemistry and Physics in the Cantonal School at Coire, and remained in that position until the year 1876, notwithstanding repeated offers from other educational establishments. Last year, however, in consequence of continually increasing sufferings that frequently laid him on a sick bed, he resigned his office, the faithful and zealous performance of the duties of which had been repeatedly acknowledged by the Academy authorities. The more important works composed during this period of his stay at Coire are his well-known 'Die Pflanzenstoffe—again in conjunction with Dr. T. Husemann—and a Manual of Chemistry that has been introduced into many upper schools, and reached a second edition in 1876. A small work on Agricultural Chemistry also belongs to this period. During many years, too, he contributed to Wigger's 'Jahresbericht für Pharmacie.' Amongst his smaller memoirs may be mentioned a number of careful analyses of the more important mineral springs of the Canton. After the resignation of his office, Dr. Husemann spent last winter in Meeran, from whence he returned to Switzerland, so far improved in health as to meditate undertaking another extensive literary work. A violent cold however, which he caught whilst travelling, again laid him upon the bed of sickness and ended his active and useful life on the 17th of last month.

Review.

ANTHRACENE, ITS CONSTITUTION, PROPERTIES, MANUFACTURE, AND DERIVATIVES, including Artificial Alizarin, Anthrapurpurin, etc., with their applications in dyeing and printing. By G. AUERBACH. Translated and Edited by WILLIAM CROOKES, F.R.S., etc. London: Longmans and Co. 1877.

Mr. G. Auerbach's monograph, according to the editor of the English edition, is generally recognized by "manufacturers and by scientific theorists as the authority on this interesting and important section of organic chemistry;" and in justice to the work it may be said to be well entitled to this praise.

The book, which numbers 245 pages, is not illustrated, otherwise it is as complete as can well be, except that its index is somewhat brief; the chapter of contents is however more complete; as for the translation, in our opinion, it might be better.

Mr. Auerbach commences with the history of anthracene, and in connection with this subject the researches of Dumas, Laurent, Fritzsche, Berthelot, Anderson, Limpricht, Graebe and Liebermann are summarized. Then follows a digest of researches bearing upon the constitution of anthracene and its derivatives, and this quasi-philosophical part of the book appears to us as the weakest section, and more particularly illustrates the fact that chemical science is, properly speaking, without a theory. Chemical constitution as at present understood, is the non-entity of an entity; we can scarcely appreciate its meaning, but if it has a meaning at all, that meaning must be relative in so far that the constitution of a chemical individual stands in relation to that of other bodies, influenced in its production and by its reactions. Thus it is seen that all the views of the constitution of anthracene explained by Mr. Auerbach are based upon Kekulé's theory of aromatic compounds—a theory which is entirely gratuitous, and one which, although it has led to much good work and this to some brilliant results, yet remains without an actual proof.

Graebe and Liebermann first expressed the opinion that anthracene was formed of three benzene rings like as naphthalin is supposed to be formed of two rings.

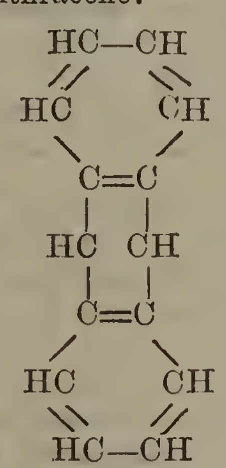
Anthracene and dibenzyl resulting as the main products of the action of water upon benzylchloride (C_6H_5 (CH_2Cl)) in sealed tubes at 180° it might be inferred that anthracene is diphenylacetylen. Thus

$$2\,C_6H_5(CH_2Cl) = (C_6H_5)C{\equiv}C(C_6H_5) + 2\,HCl + 2\,H.$$

But the derivation of alizarin from anthracene was regarded by Graebe and Liebermann as antagonistic to the above view, because alizarin yields phthalic acid on oxidation, while derivatives of dephenylacetylen must yield benzoic or substituted benzoic acids.

This judgment received corroboration from the almost simultaneous production of tolen or true dephenylacetylen by Limpricht and Schwanert, and since then anthraquinone has been regarded not as a true quinone but as a double ketone, inasmuch as anthracene yields it with soda lime.

Nevertheless, any one formula for anthracene is associated with so much assumption that we are left without any exact knowledge as to its true constitution. Thus the formula given below and adopted by most chemists, assumes that each methyl group is united by one bond with the benzene ring of the other benzylchloride, while Berthelot's synthesis of anthracene from styrol and benzol may be equally well explained by several other views of the constitution of anthracene.



It is both interesting and perhaps profitable that some chemists should devote themselves to such considerations, but it is seen that these never result in much real knowledge, and in our opinion they lead to views which are tenable only so long as they are used first to explain facts and to help to lead to new results; in themselves they are without meaning.

Kekulé's theory becomes still more unmeaning when it is seen that between the so-called aromatic series, and the fatty series of bodies there is no virtual diagnosis to be effected, and at the best it can be exercised only in an extremely narrow sphere of chemical science. Take for instance the partial transformation of acetylene (C_2H_2) into benzene (C_6H_6) by passage through a red-hot tube. It is seen that this is to some extent a reaction not unlike to the condensation of oxygen into ozone, and the fact of the condensation is quite as instructive as any hypothetical reasonings in connection with the specific manner and position in which the particular atoms of carbon and hydrogen are united. All that we understand of the reaction is expressed by the fact, and although chemists may derive some help in their personal labours from such hypothetical reasonings as are here alluded to, they cannot be said to increase our real knowledge. In these days, however, it might be deemed a mistake on the part of Mr. Auerbach or any other writer to omit such considerations in their writings.

From the constitution of anthracene, our author proceeds to describe the physical properties and preparation of this substance. The manufacture from coal tar is well described and betrays an intimate acquaintance on the part of the author with the various details of the process employed.

The several methods of valuation of crude anthracene are then discussed; Luck's process being the one of course, which receives the greatest recommendation. The multitudinous derivatives and compounds of anthracene are afterwards described one by one, and in time, alizarin and the many discoveries made of late years in regard to this tinctorial principle, its artificial synthesis and commercial fabrication, receive full attention. In relation to this part of the subject, the madder plant and its chemistry, and the most important derivatives of alizarin are also studied.

In short, as stated in the editor's preface, the work presents us with a summary of all important researches regarding anthracene and alizarin, and the industries which exist in connection with them and more or less allied substances.

To review such a work in detail would be interesting, but would occupy more time and space than can be devoted to it.

At the end of the book Mr. Auerbach gives a very complete bibliographical appendix, which must prove of great value to chemists who are occupied with work treated of in this volume. In recommending the book very strongly, it may be pointed out that chemical literature of the future will be probably far more special than it has been in the past. This is not only probable but recommendable in view of the vast ground covered by the various branches of chemical science, and as the science will become more and more special in certain directions, so also must its followers become more and more specialists, if they would materially extend the boundary lines of their science or profession.

Fownes' Manual of Chemistry, Theoretical and Practical. Vol I. Physical and Inorganic Chemistry. Twelfth edition. Revised and corrected by Henry Watts, B.A., F.R.S. London: J. and A. Churchill. 1877.

Fownes' 'Manual of Chemistry' is now so well known to the English scientific public that the appearance so lately of a twelfth edition cannot but elicit a renewed congratulation of its able editor and publishers. Perhaps the student is most to be congratulated on the possession of a valuable treatise. There are indeed few manuals of its class that can compete with it in its completeness of matter or its perspicuity of explanation.

But although the book is one of the best of its kind it does not represent the *ne plus ultra* of introductory works. That perfection has not yet been attained. Where indeed is the manual of chemistry which alone is sufficient to lead the student step by step from absolute ignorance to a clear perception of his science, not imparting too much nor too little, connecting dry facts by an interesting chain of generalizations, a book which shall take a place in scientific literature comparable to that of Herschel's 'Elements of Astronomy,' or Lyell's 'Elements of Geology'?

A special feature of this new edition of Fownes' manual is that it is in two volumes in place of the single bulky volume of former editions. The volume to which we draw special attention includes 'Chemical Physics' and 'Inorganic Chemistry.' The second part of the work, which is to include the latest advances of organic chemistry, is yet in course of publication.

It is somewhat puzzling to find that out of eighty pages devoted to chemical physics only half a page is deemed sufficient to instruct the student in thermo-electricity. On the other hand it must be allowed that what is taught in this section of the book is taught well, and it is difficult enough to draw the line in elementary works between diffuseness and completeness. We find, for instance, gallium occupying a place of honour on p. 434, although this metal has only been discovered two years, and its atomic weight is still in some obscurity. The chapters on so-called chemical philosophy are well done. It is curious to note here how chemists cling to the ancient term of chemical affinity with a persistency best illustrated, perhaps, by the term itself. Thus we find on p. 278, "The term chemical affinity or chemical attraction is used to describe that force," etc. Yet it might be pointed out that the term affinity is altogether a misleading and ill-applied term, for the student has to learn that those substances which have the least affinity or relation one to the other as regards their properties have on the contrary the greatest attraction for one another chemically.

But these and other shortcomings are not fatal ones, for by manuals alone the student cannot enter the domain of chemical science. Before any larger chemical treatise can be any good to him, or before he can select from the mass of original publications which inundate our libraries, he must by practical observation and judicious reflection choose his own path and make his individual compromise with the opportunities of instruction which are afforded to him. It has been well said by a great chemist that the study of chemistry may be compared to a journey of exploration; we must, like the traveller, never lose sight of the main track, though we may by choice wander away from it to return again, and thus, at times proceeding straight ahead, at others selecting a circuitous route, we obtain a comprehensive idea of the general features of the country through which we have passed. In the same metaphorical sense we may compare a manual like Fownes' 'Manual of Chemistry' to the trusty guide-book which, while neglecting no important information, leaves much to the individual powers of observation of its numerous readers.

Dispensing Memoranda.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be conidered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.

---

[10]. Ext. Tarax. Liquid.—Respecting this question I see Mr. J. B. Barnes advocates the use of a preparation made by adding water to solid extract of taraxacum, and adds that that preparation was used on such occasions in a large dispensing establishment. I think this question, before being allowed to drop, would be better for a little

more ventilation. In one large house of business, I am informed, succus taraxaci is generally used. In the business in which I have myself been engaged (including two large West-end establishments) the liquor has always been used. Which can be considered correct? The liquefied extract, spoken of by Mr. Barnes, had its origin in an obsolete Prussian Pharmacopœia, and, from what he says, seems still in use in some businesses. I myself have not met with it, and did not know such a preparation was in use until I saw it in this Journal. The liquor, prepared, in common with many other liquors (or liquid extracts), from the dry roots, either by infusion or percolation with water, evaporating the solution *in vacuo* or otherwise, and preserving by the addition of spirit, is generally of such a strength that one part by measure represents one part by weight of the root. This "liquor" seems established as a pharmaceutical preparation and is much preferred by many prescribers. If then a "liquor" be admitted in dispensing, why not use it when liquid extract (in vegetable preparations of this class, I believe "liquor" and "liquid extract" are synonymous terms) is ordered? It is a rule observed with many other preparations of a similar nature, and I also think it is carried out in this particular instance in the majority of businesses where dispensing is a reality. There is this objection to its absolute correctness, viz., that there is no pharmacopœial authority for its preparation; it thus becomes by no means certain but that those who argue in favour of the succus may be the most correct, for a liquid preparation being intended, and the succus being the nearest approximation in the present Pharmacopœia, it would be preferable to use that rather than other preparations, having no such authority, and sometimes varying in strength. If the fact of what is most commonly used determines that which is right, my own experience and what I can ascertain, shows that liquor is generally used when ext. tarax. liq. is prescribed.

[18]. A PILL QUERY.—Can any reader inform me of the best mode of preserving Pure Ox-Gall Pills from falling after being made a day or two? I have tried the tolu process, silvering and putting into stoppered bottles, also packing in cotton wool, all of which gave unsatisfactory results.—X.Y.Z.

Notes and Queries.

[552]. COLOURING FOR MIXTURES.—Can any reader give an idea of the composition of an article which is supplied by a London house, chiefly to surgeons, for colouring mixtures. It is labelled "Liq. Rosæ Comp," and is compatable with acids and alkalies? C.

Correspondence.

COUNTER PRACTICE.

Sir,—Those members of the Council, who on the 1st inst. constituted a minority of four, when voting on the question of "counter practice," apparently feel little sympathy for those whose interests the said question vitally affects. If the want of sympathy be real, I am quite sure that it can only be accounted for by those gentlemen being in utter ignorance of the ruinous effect the prohibition of counter-prescribing would have on *a very large majority* of druggists throughout the kingdom, and of the extreme injury it would inflict on a large portion of the poorer part of the population. I would ask those gentlemen to consider what their position would be if they were suddenly to be deprived of the right of dispensing medical prescriptions. Their several businesses would simply be wiped out or washed away. It would be ruin to the "upper ten" of the trade (many of whom, by the way, would doubtless be able to survive the cataclysm), but the greater bulk of their brethren would be quite unaffected by such deprivation, inasmuch as they have not the pleasure to dispense a prescription once in a week. The equivalent that would affect them, would be to deprive them of their right of dispensing—deprive them of it, and *their* "occupation would be gone;" and *they*, in a pecuniary sense, would *not* "be able to survive it." A speaker at the meeting in question said "those who so acted (*i.e.* prescribed) reaped the benefit, the Society did not." I contend that the Society "does (indirectly) reap the benefit." The guineas of those who subscribe to the Society's funds, and are enabled to do so, by prescribing, far outnumber the guineas of those, who subscribing are enabled to do so by dispensing.

In reply to the President's observation that "chemists and druggists had no (medical) education, properly so called." I would like to ask him "if he would be surprised to hear" that applications to druggists in country places by the poorer classes to prescribe for them, after having derived no benefit from the customary *two pills* of their club doctor are very numerous? They certainly would not be so numerous did not experience teach the applicants that the febrifuge or quinine mixture (for club-patients, quinine is like angels' visits in its infrequency), or what not, was worth the 1*s*. or 1*s*. 6*d*. they invested in it. Is the President unaware, that great numbers of druggists in business have gained a considerable amount of experience with surgeons in private practice, and at dispensaries, infirmaries, and hospitals? And does he not think that they must be dunderheads indeed, if under such circumstances they have obtained "no education properly so called" to fit them to prescribe across the counter for cases of simple ailments? And now a word for the public, for it is a question that affects a large portion of them quite as much as it affects the major portion of the druggists.

With regard to medical advice, the public may be said to be divided into three classes. The first class constitute Society's upper crust, who, when ailing send for their physician, pay him his guinea, and get a prescription made up by one of the "upper ten" of the trade (who are well represented on the Council) at a cost perhaps of from 1*s*. 6*d*. to 3*s*. 6*d*. or more. The second class, unable to indulge in (to them) so great a luxury, in place of the guinea physician, call in a general practitioner, who, in nine cases out of ten supplies medicine as well as advice at a price *per diem*, varying possibly from 7*s*. 6*d*. to 2*s*. 6*d*., the charge depending partly on the "standing" of the general practitioner and his opinion of the depth of his patient's purse; his diagnosis in this respect—whatever it may be in others—not always being infallible. But half-a-crown may be taken as the *minimum* charge entailed by seeking his advice. The third class, quite unable to indulge in any of these (to them) luxuries, having perhaps 6*d*. or possibly at most 1*s*. to invest, seek relief for their every day ailments of some intelligent druggist, and to tens of thousands of the poorer classes such men are an almost invaluable boon. The poor cannot, as I have said, when *thus* ailing afford to pay the charges of a medical man, it is almost more than they can compass in cases of serious sickness. What would "the minority of four" recommend such to do in place of applying to a druggist? Anything like "Wade's Act," which met with such scathing sarcasm in your Journal of 31st June, at the hands of "Yecapnhoj" (which being richly merited, was pleasant to peruse), would be an unmitigated curse to them.

ROBT. CHIPPERFIELD.

Southampton, 6th August, 1877.

The Verb "Dispense."

Sir,—In the Apothecaries' Act, the right of chemists and Druggists to dispense medicines is unlimited by any restriction, such as the preparing of physicians' prescriptions. Dispense ought therefore to carry the same force that it has in ecclesiastical law, or even in ordinary conversation.

Thus we say that the sun dispenses heat and light—a most apt use of the term analogous in its application to our own position and rights; being at once stationary, dative, and distributive.

This verb invests its nominative either with power, or with authoritative volition, according as that nominative is personal or impersonal; moreover, it is used to denote that supremacy, which gives or suspends law.

For my own part, I believe the verb dispense implies that our position is a stationary one; viz., that we should *stay* in our shops and not visit; but whether this be so or not, I do not think we are called upon to draw boundary lines, because the Act does not.

If the Act is imperfect, or inconsistent with itself, that is no reason why the meaning of words which reserve and secure our rights should be pared and whittled and twisted to suit the fancied interests of the Apothecaries' Company.

And further, considering the knowledge which our constant familiarity with drugs and medicines gives, and the multiplication of books on all branches of medical science, it is, in the public interest, most desirable that Chemists and Druggists should not be interfered with; otherwise people will "doctor" their small ailments themselves. The instinct of self preservation is quite sufficient to send sufferers to highly trained practitioners, when their ailments are serious enough to warrant the expense; and the few exceptions which occur to the contrary, may safely be considered to confirm the soundness of this view.

York, August 6, 1877. J. W.

Pharmacy in the Isle of Man.

Sir,—Nine years ago, the British Parliament deemed it "expedient for the safety of the public" to pass a law requiring "persons known as chemists and druggists" to demonstrate their competence by passing two examinations before opening "a shop for the retailing, dispensing, or compounding of poisons." That Act has been found to work very satisfactorily; so satisfactorily indeed that it would be difficult to find a hundred intelligent, uninterested persons in the kingdom who would vote for its repeal.

Since the passing of the Pharmacy Act in 1868, laws of a similar character have been introduced into some parts of the United States, the Canadian Dominion, and our distant Australian Colonies. Yet, while countries thousands of miles away have been following Great Britain in the path of progress, the Isle of Man—within five hours' sail from England, Ireland, or Scotland—has earned the rather doubtful credit of having maintained a stationary position. The Isle of Man, abreast of England as regards education and civil and religious liberty, remains behind Turkey in pharmaceutical legislature, since she possesses no pharmacy law whatever. Nay, what makes this legal omission most astonishing is the fact that, in some other respects, the Manx are in advance of their fellow-subjects, being free from both Income Tax and Poor Law, and having enjoyed—I believe, upwards of a quarter of a century—that which Ireland has, so far, asked in vain—Sunday closing.

The rising generation of Manx pharmacists, although not required to pass any examination, invariably present themselves before the London Board of Examiners; but should they commence business in the island—after spending time and money to qualify *pro bono publico*—they are liable to be opposed by any unexamined man who chooses to settle there. This is their grievance; and those who know the island will bear me out in saying that it is not an imaginary one.

If, however, the people of the Isle of Man have stood still while others have been moving in the right direction, it is mainly owing to an incomprehensible want of energy on the part of the Manx chemists themselves. One would naturally expect them to be seeking the requisite protection; but, like the Orientals, they have a decided weakness for taking things easy. They neither speak nor act. They view the situation with an "opiated indifference" that would fill the soul of a Turkish Pasha with envy and admiration.

It does not require an immense amount of exertion, however, to raise the Isle of Man, in this respect, to the level of other civilized communities. All that is needed is the extension of the English Pharmacy Act to the Island. The absence of such an Act from the insular Statute Book concerns visitors as well as inhabitants; and it is my firm conviction that if the matter were represented to the Lieutenant Governor—who has already conferred untold benefits on the island—the present anomalous state of things would be brought to a speedy termination. Further, I believe the House of Keys, instead of opposing, would facilitate the introduction of the Act, for the following reasons:

1st. Because they would be merely introducing a system which has been adopted by nearly every State in Europe.

2nd. Because the local press—representing the people—has more than once pointed out the necessity for immediate action.

3rd. Because the Pharmacy Act guarantees that none but educated and trained men shall dispense medicines for the sick.

4th. Because it does this without imposing an additional burden on the ratepayers.

Douglas, July 28, 1877. H. S. F.

Castor-Oil Pills.

Sir,—Last week at Christchurch Petty Sessions, a case was tried of selling Compound Rhubarb Pills, when "Castor-Oil Pills" were asked for. Mr. Angel—the public analyst—appended to his certificate of their composition, the following:—"The application of the term 'Castor-Oil' to their pills was a dangerous practice, and might be attended with injurious results by leading the purchaser to understand that the active ingredient was castor-oil." The chairman delivered the opinion of the bench in these words—viz. "The evidence which had been given for the defence did not touch the fact that Mr. White (the policeman) had asked for one thing and been served with another, but the evidence adduced had shown the existence of a custom in the trade which they admitted as evidence in mitigation. It was a singular custom, however, and the sooner it was left off the better. It would be much better when the public asked for castor-oil pills to tell them "there are no such pills in the trade, but we can give you something that will answer the purpose as well." At all events, the intention of the Act was perfectly clear—to give the public a right to have what they ask for, or be told that they could not get it. The penalty they should inflict was a very light one, because they thought it quite probable that the chemist in this case acted in good faith, and was not aware of the law as it existed, the defendant is fined 1*s*. and 19*s*. 6*d*. costs."

I do not venture to question the correctness of the decision—no doubt the letter of the Act was infringed, but there is as little doubt that the framers of the Act never intended its provisions to be thus used. But the question is where is this sort of thing to end—where the line of demarcation to be drawn. Will druggists be "liable to a penalty of £20" for selling "*Crabs Eyes*," "*Milk of Roses*," "*Cold Cream*," "*Blue Butter*," "*Violet Powder*," the popular names of which—with many other articles of every day sale—are as great misnomers as "Castor-Oil Pills." The provisions of the Act apply equally to preparations intended for external as for internal use.

Southampton. Robert Chipperfield.

C. E. Stuart.—(1) Linnæus; (2) We believe the fact is as you state, but think the important "feat" too far removed from the domain of pharmacy to need special record in these columns.

"*Bromo Paper*" and *W*. are referred to the rule respecting anonymous communications.

Mr. E. Jerrett is thanked for his communication.

J. Gildert.—The Act does not appear to be very definite on the point. You are recommended to put the question to the Inland Revenue authorities.

Communications, Letters, etc., have been received from Messrs. Fox, Watson, Large, White, Cock, Welborn, Fletcher, Stuart, Natura.

NOTE ON COSTUS.

BY PROFESSOR FLÜCKIGER.

Mr. Cooke's article on the above named root (*Pharm. Journ.*, July 21st. 1877, p. 41) gives a full and I think correct idea of this drug, which played so important a part from the remotest antiquity down to the end of the last or even the beginning of the present century. When we were at work for the 'Pharmacographia,' my late friend Daniel Hanbury and myself, in examining the costus-root, resolved to exclude it from our work, the drug not being used by English practitioners in India, nor having a place even in the Pharmacopœia of India, except among the non-officinal drugs.

Mr. Cooke mentioning but very briefly the microscopic structure of the root, I beg to say in addition to his statement, that the specimens before me agree well with Guibourt's figures in his 'Histoire naturelle des Drogues simples,' III. (1869), p. 33. I have already stated in my pamphlet 'Die Frankfurter Liste,' Halle, 1873, p. 25, that the tissue of the root abounds in *inulin* and shows, especially in the bark of the branches of the root, large *balsam-ducts.* In both these respects costus root agrees well with elecampane and other aromatic roots of Compositæ. The microscope, therefore, affords further evidence of the correctness of Falconer's suggestion, that costus is derived from *Aplotaxis*, at least in as much as inulin is not to be met with in any other natural orders than in Compositæ and a few allied orders, viz., Campanulaceæ, Goodeniaceæ and Stylideæ. Starch is usually wanting in these plants, and so I found none to occur in costus.

Externally costus-root likewise reminds of elecampane, although it is much more woody; curiously enough, Dioscorides already alluded to this fact, pointing out that elecampane from Northern Syria (Kommagene) might be substituted for costus. Long before the period of Dioscorides, costus was already mentioned as a spice by Theophrastus, about the end of the fourth or the beginning of the third century B.C. It also occurs in the offering made B.C. 243 by Seleucus II., king of Syria, and his brother Antiochus Hierax, to the temple of Apollo at Miletus (see 'Pharmacographia' 467). The royal gifts consisted chiefly of vessels of gold and silver, the weight of each being mentioned in the inscription on the walls of the temple; but it included besides ten talents of **λιβανωτον** (olibanum), one talent of **σμυρνη** (myrrh), two pounds of **κασια** (cassia), two pounds of **κινναμωμον** (cinnamon) and two pounds of **κοστος** (costus).

Costus again occurs among the commodities coming in the first century of our era from India by way of the Erythrean Sea, that is to say the gulf of Aden and the Red Sea, for it is mentioned, together with the spices just alluded to, in the famous Periplus of the Erythrean Sea, as published by Dr. Vincent, Dean of Westminster (see 'Pharmacographia,' 467).

There is also further evidence that costus was well known at an early period in continental Europe. In the diploma granted, A.D. 716, by Chilperic II., king of the Franks, to the monastery of Corbie (monasterio Corbeiensi), near Amiens ('Pharmacographia,' 488), mention is made of piper, cuminum, cariofili, amandoli, pasticiæ, olivæ, cinnamomum, spica (spikenard), *costus*, dactyli, and karigæ (figs).

A.D. 745 Gemmulus, diaconus at Rome, announced to St. Bonifacius, the German apostle, that he was to receive from the Roman synodus the following gifts "cum magna reverentia," viz., cinnamon four ounces, *costus* four ounces, pepper two pounds, cozumber one pound (Taffé, 'Bibl. rerum germanicarum' 1866, III., p. 156, 199, 218). This list evidently proves that costus was much valued then.

Costus is also met with in a curious receipt of the ninth century (Dümmler, 'Mittheilungen der antiquarischen Gesellschaft in Zürich,' xii., 1859, p. 139) showing what ingredients the monks of St. Gall in Switzerland then used for seasoning fish. The document says: "Capiantur pisces natura pingues, ut sunt salmones, anguillæ, alese, sardine vel haringe, et fit ex eis atque ex herbis odoratis aridis talis compositio. . . ." Among the spices *costus* is enumerated along with pepper, cinnamon, cloves.

In the 'Antiqua Statuta Abbatiæ S. Petri Corbeiensis,' the above mentioned monastery of Corbie, of the year 1322 ('Polyptique de l'abbé Irmino II.' 1844, p. 336 (see 'Pharmacographia,' 496), *costus* is met with together with galanga, rhubarb, and mastix.

Mr. Cooke has already pointed out that costus continues still in the East to form an important article of trade. It was so from time immemorial; the "*Sommario*" di tutte le regni, città e populi orientali, in Ramutio's Collection: 'Delle navigationi et viaggi,' Venezia, 1554, fol. 372, states costus to be largely imported, probably from Cashmir, in the Malayan Peninsula. Similar remarks may be found in Milburn, 'Oriental Commerce II.' (1813), 463, 482, and I., 290, and again in Aitchison's recent book 'On the Trade Products of Leh,' Calcutta, 1874. Aitchison notices the strong violet-like odour given off by the root and retained for a very long time by the sacks in which it is packed. In the fresh state the odour may be different from what it is in the dried drug, for the sample before me in this respect reminds rather of German chamomiles.

The chemistry of elecampane is far from having been satisfactorily investigated, but it has already afforded quite interesting information; it would be well worth while to submit likewise to chemical examination the costus-root—the elecampane of the East.

THE SPONGES OF COMMERCE.*

(*Concluded from page* 108.)

This distribution indicates the naturalness of the three species, and shows also that the dealers have to do with a vast variety of forms. They can, however, pick out the three species and their varieties without hesitation, and I was amused and interested at finding that the method pursued was precisely similar to that which I had been obliged to adopt in distinguishing empirically the various sub-species and species of Spongia. They are led mainly by the general aspect of the surface. This has a distinct appearance in every species, and though much altered by the greater or less development of superficial tufts, is much more constant than any other character. It is due to the fact that the surface takes its aspect largely from the number, distribution, and size of the pores, cloacal orifices, superficial canals and primary fibres. These characteristics, of course, are directly correllated with all that is important in the internal anatomy of the animal, and should therefore be more constant than the length, form, or composition of the tufts of fibres, or the shape of the whole, which are capable of great modification, according to the locality in

* From the *Journal of Applied Science*, August 1, 1877.

which the specimen may be found. The forms of *Spongia officinalis* may vary from cup-shape to fistular, and to irregular or lump-like. The latter are usually coarser and looser in texture, the superficial tufts are longer and more numerous, and they approximate more closely to the coarser varieties of sub-species *tubulifera* of the Caribbean Sea in the external aspect of the surface and the apertion of the interior than the finer varieties.

The texture of the poorest variety of the Mediterranean sponges is, however, always better for domestic purposes than the best of the corresponding American varieties, being firmer and more elastic; and it is also to be remarked that the last never have the cup-shape, which is so common in the sub-species *Mediterranea*, and that the fistular form takes its place. The forms of *Spongia agaricina*, sub species *Zimocca*, vary from saucer-shape to irregular, lump-like growth. As in the *Spongia officinalis*, it may be shown that these aberrant forms are quite similar to the aberrant or formless varieties of the sub-species *punctata* of Florida, as regards the aspect of the surface; but these also are nevertheless much finer than the finest varieties of the latter. Here, again, the platter or saucer-shape, which is a modification of the cup-shape, is absent. *Spongia equina* exhibits similar degrees of variation in the texture of the surface and the form. There are no proper cup-shaped specimens among the American varieties of sub-species *gossypina*, but in place of these the fistular form. These occur generally associated in clumps, more or less densely filled up into heads, and solid, but sometimes the tubes are almost isolated. The younger specimens of this species have a very loose and open texture, due to the approximation and large size of the openings, and to a less degree this is also to be remarked in the Gerbis sponge. The former approximate in aspect to the coarser qualities of the American species, and so also does the latter, which has very nearly the same colour and aspect as the dark-coloured Key West specimens, but is not so coarse or dark. It seems, then, that there are three sub-species of commercial value in the Mediterranean, and although there are more than three in the list of the American forms which follows, there are really only three, or at most four, sub-species which find their way into the New York and European markets. The coarsest varieties of the European sponges are finer, firmer, and more elastic than the finest of the corresponding American sub-species. This is directly traceable to the larger amount of foreign matter included in the primary threads, the looser mesh of the tissue; the fibres are also comparatively coarser and the large cloacal channels more numerous throughout the mass.

Thus the different varieties of sub-species *gossypina* differ in an exactly similar way from each other, and from the third form, sub-species *cerebriformis*; they differ in texture, in surface, and also in habitat, the finer kinds, as stated prevously, being found in the deeper water, equally removed from excessive heat and excessive sediment. These three sub-species run together by means of specimens of the coarser varieties, which cannot be distinguished from each other with any certainty, in the same manner as the corresponding sub-species in the Mediterranean and Caribbean Seas were connected, through the coarser, and not by the aid of the finer varieties. It is evident, however, that besides the general differences previously noted, that the cup-shape form is not found in the American sub-species, whereas it is the prevalent form of the Mediterranean sub-species. A cursory examination of a large collection will, however, satisfy any one that the shape does not necessarily correllate with a finer or a coarser skeleton, but probably with a more or less extended base of attachment and local peculiarities, such as currents, and the kind of bottom, etc., which have not been investigated in this connection.

THE MOTIONS OF THE LEAVES IN OXALIS.*

Of all the remarkable phenomena in the life of plants, perhaps the most singular is the so-called "Sleep of Plants." The object of these investigations was to discover the source of motion *in the leaves*, and for this purpose a species of oxalis was taken, when it was found that the source of the motions originates in the petioles or leaf-stalks, and not in the leaves. The plant chosen for these experiments was the *Oxalis acetosella*, or wood sorrel, the true shamrock of the Irish. This plant has trifoliate leaves, the separate folioles of which, at the approach of night, a storm, or during a high wind drop down until they lie parallel with the leafstalk; but under the influence of the sun's light and heat are again raised until the surfaces of the separate leaflets are even with one another, and at right angles with the petiole. It was found by means of paper caps, tubes, and similar apparatus placed over the leaflets, that they are not affected so long as the petiole remains uncovered; but, on the contrary, if the petioles are covered, the edges of the leaflets are deflected in a short time. These experiments may be imitated in a simple manner by placing a strong, healthy, growing plant in a window exposed to the sun and behind a common roller window blind, when by alternately raising and lowering the blind (allowing it to stop for a short time at the same spot) the effect of the sunlight on the leaves and petioles will be well seen; in this case, however, the effect was produced by blowing on the leaves with a pair of bellows; at three minutes before nine o'clock the leaflets were all closed; the plant was then shaded in some parts and exposed to the sun. The following is the time when fully open:—9.25, sunlight on petioles, but not leaflets; 9.30, sunlight on leaflets and petioles; so that it would seem almost as if the leaflets themselves, by their weight, rather retarded than accelerated their being open to full extent. This power of raising and deflecting the leaflets seems to rest in the liber cells of the petiole, and would almost seem to point out the presence in plants of fibres analogous to the muscles which move the legs and arms in animals; but is more probably due to the effects of moisture and elasticity. Nitric acid, liquid potash, and the ordinary reagents, when applied to the sutures of the leaflets, had no effect in deflecting the leaves other than by destroying the entire tissue in a short time.

REMOVAL OF STRONG ODOURS FROM THE HANDS AND FROM UTENSILS.

The *Schweizerische Wochenschrift für Pharmacie* (1877, 84) has a communication from F. Schneider, in which he states that ground mustard, mixed with a little water, is an excellent agent for cleansing the hands after handling disagreeably or strongly odorous substances, such as cod-liver oil, musk, valerianic acid and its salts. Scale-pans and vessels may also be readily freed from odour by the same method.

In a succeeding number of the some journal (p. 104), A. Huber states that all oily seeds, when powdered, answer for this purpose. Flax-seed meal, for instance, removes odours as well as mustard. The use of ground almond-cake as a detergent is well known. The explanation of this action is somewhat doubtful, but it is not improbable that the odorous bodies are dissolved by the fatty oil of the seed, and emulsionized by the contact with water. In the case of bitter almonds and mustard, the development of ethereal oil, under the influence of water, may perhaps be an additional help to destroy foreign odours. The author also mentions that the smell of carbolic acid may be removed by rubbing the hands with damp flax-seed meal, and that cod-liver oil bottles may be cleansed with a little hot sesame or olive oil.

THE BRITISH PHARMACEUTICAL CONFERENCE OF 1877.

ON Sunday, August 12th, a hundred men in perhaps a hundred places, were preparing for their visit to Plymouth, and during the whole of Monday the trains which arrived at that town brought thither numbers of visitors, some for the Conference, some for the British Association, and others for both. If anything were wanted to prove the general interest taken in pharmacy, both by pharmacists and some scientific chemists, it might perhaps have been found in the abandonment of pleasure by many who formed part of Tuesday and Wednesday meetings. There were present gentlemen from the far North, East, West and South, and even those who had been rambling during their annual holiday amid the wilds of Dartmoor and roving along the yet wilder and craggy coasts of Cornwall forsook those charming resorts for the sake of science.

By midnight on Monday small gatherings of visitors had assembled at all the chief hotels, and were to be seen seriously discussing the virtues of their tobacco and their glasses. And punctually at ten the next morning did the Conference summon its members to consider the report of the executive, and listen to the interesting address of the President, Professor REDWOOD.

This address, which will be found on another page, consisted of a timely *résumé* of the history of the steps by which "the druggist of to-day has been transformed into the apothecary of the seventeenth century." Recognizing the existence of circumstances liable to induce fears that in the attempt to raise the *status* of the practice of pharmacy substantial advantages may be lost, and only barren honour gained, the President sought in the history of the past a demonstration that the profit as well as the honour from such an occupation will mainly depend upon the qualifications of those following it to render valuable and efficient service to the public. In doing so he traced the rise of the barber surgeons and physicians, the origin of the apothecaries in the need of the physicians, and their subsequent antagonism to them, how a sense of the public requirements was too strong to allow of the restriction of the apothecaries to the mere dispensing of medicines, and how the apothecaries in their turn, having attained a higher position by virtue of their recognized utility to the public, became the assailants instead of the assailed. This led to the opposition of the chemists and druggists, organized in 1813, which left a mark upon the Apothecaries Act passed two years later, not without interest at the present time. Professor REDWOOD'S address was listened to with deep attention, and will no doubt be read with much interest by many who were not present to hear it.

The first paper was a Report read by Dr. WRIGHT, in the names of Mr. GROVES, Mr. WILLIAMS, and himself, who constituted a committee, appointed at the last meeting to continue investigations upon the aconite alkaloids. It was pointed out that in past reports the existence of two well defined alkaloids in *A. Napellus* had been established, viz., aconitine, $C_{33}H_{43}NO_{12}$, and picraconitine, $C_{31}H_{45}NO_{10}$, while from *Aconitum ferox* a third alkaloid had been isolated, expressed by the formula $C_{36}H_{49}NO_{11}$. The results which formed the chief features of the present communication illustrated the decompositions undergone by aconitine and pseudaconitine under influences resulting in the assimilation of water, for instance, treatment with dilute acids and alkalies. These decompositions Dr. WRIGHT expressed as follows:—

$$(1)\quad \underset{\text{Aconitine.}}{C_{33}H_{43}NO_{12}} + H_2O = \underset{\text{Benzoic Acid.}}{C_7H_6O_2} + \underset{\text{Aconine.}}{C_{26}H_{39}NO_{11}}$$

$$(2)\quad \underset{\text{Pseudaconitine.}}{C_{36}H_{49}NO_{11}} + H_2O = \underset{\text{Dimethylprotocatechuic acid.}}{C_9H_{10}O_4} + \underset{\text{Pseudaconine.}}{C_{27}H_{41}NO_8}$$

Among other matters treated of in this paper Dr. WRIGHT detailed a method for assaying the commercial aconite alkaloids, which he claimed to yield approximately accurate results.

In the next paper, Dr. PAUL and Mr. C. T. KINGZETT described the alkaloid of Japanese aconite, which was shown to be different from anything described by WRIGHT or other observers. A sample of the crystalline base was exhibited, the formula attributed to it being $C_{29}H_{43}NO_9$. The authors gave their reasons for believing that the various alkaloids which had been universally described and analysed as alkaloids of aconite were probably salts of the bases in combination with an acid perhaps aconitic. In the course of the discussion following the reading of these two papers Mr. KINGZETT criticized the analytical data submitted by Dr. WRIGHT in his various reports on this subject.

"The Active Principle of Cayenne Pepper" was the title of the third paper, by Mr. J. C. THRESH. The author reported that he had found free palmitic acid to be a natural and predominating constituent of cayenne pepper fat, and further described capsaicin or the active principle which is obtained in small amount from cayenne pepper, and which has a formula near to $C_6H_{14}O_2$. In the discussion which followed the imperfectly known physiological action of capsaicin formed the chief topic.

The next communication was by Dr. TILDEN "On the Essential Oils with special reference to the

Hydrocarbons contained in them." In it were described the results of a further study by the author of the action of nitrosyl (NOCl) upon various terpenes of the formula $C_{10}H_{16}$, and upon other substances of the composition $C_{15}H_{24}$. The terpenes give compounds which yield on suitable treatment substitution products expressed by the formula $C_{10}H_{15}$ (NO), while the hydrocarbons $C_{15}H_{24}$ fail to show this character.

These results agree with those of KINGZETT and WRIGHT, who each by pursuing different lines of research have arrived at similar conclusions regarding these classes of bodies. Whereas however these chemists believe that only one cymene, $C_{10}H_{14}$, exists, and may be got from all the terpenes, TILDEN believes that a number of isomeric cymenes exist, the only ground for this belief brought forward, being the differences exhibited by different specimens in their rotatory power over light.

In the next paper, by Messrs. M. M. P. MUIR and S. SUGIURA, essential oil of sage was further described; also the terpenes which they have obtained from it and their action upon light, and the composition of certain camphor-like bodies contained in the essential oil.

Following this paper was one by Mr. R. H. DAVIES upon "The Constituents of the Ivy," although virtually the only one treated of by the author was hederic acid, a substance isolated originally by POSSELT, and further described by HARTSENS. In analyses made of this substance Mr. DAVIES had experienced a difficulty in combustion, although as a matter of fact, it may be remarked that when heated on platinum foil alone, it burns away quite easily and entirely, leaving not a trace of charcoal. Mr. DAVIES arrived at a higher percentage of carbon for the substance than did POSSELT, whose analyses led to the formula $C_{15}H_{24}O_4$ while those of Mr. DAVIES give $C_{16}H_{26}O_4$. A nitro compound $C_{16}H_{25}(NO_2)O_4$ was also described, but attempts to prepare certain salts proved futile. This might have been expected of a substance having the character of a glucoside as predicted last year by Mr. KINGZETT, who now followed Mr. DAVIES with a note on Hederic Acid.

In this communication Mr. KINGZETT described the means whereby, following up his own suggestion as to the nature of this substance, he had isolated glucose from hederic acid, and had obtained a barium salt of the same, the analysis of which was described. Mr. KINGZETT explained that this research formed part of a broader investigation, the first part of which had been communicated to the Chemical Society recently by Dr. HAKE and himself, and he regarded the production of sugar from hederic acid as one proof of the correctness of his theory described in that paper.

Mr. J. ELIOT HOWARD was the author of the next paper "On the Supply of Cinchona Bark, as connected with the present price of Quinine." The discussion which ensued was perhaps as interesting as the paper itself, the points which were elicited being as follows:—Although it would be attended with some advantages to use other cinchona alkaloids than quinine for at least some purposes, yet the medical evidence available is far from satisfactory as regards the specific action of any of the other alkaloids except quinine. More satisfactory evidence of the kind must therefore be obtained before the commercial development of cinchonidine, etc., can be attempted on a large scale.

In his "Supplementary Note on the Assay of Opium," Mr. B. S. PROCTOR described certain improvements he had introduced into the method described at the last Conference meeting. In reference to this method it is questionable whether the extraction of opium by percolation satisfies the requirements of commercial analysis. It may also be pointed out that in washing morphia when separated from the other alkaloids, no fixed standard of the amount thus dissolved can be depended upon, varying as it does not only with other conditions but notably according to the influence of certain very soluble bodies in causing other bodies by themselves insoluble to pass into solution.

Mr. W. W. STODDART'S "Notes on an Impurity in Oxide of Zinc," were directed to the presence of sulphite of zinc, and in the discussion which followed various explanations were offered, the most plausible one being that the sample in question had been made by ignition of the sulphate which constitutes to some extent a waste product of the autogenous soldering process.

Dr. SYMES then read a paper on "Sugar in Pharmacy," in which he described the various sugars to be found in commerce, their degree of purity and impurity, their inversion by acids, and their general uses in pharmacy. In particular he showed that the syrups of saffron and roses could be readily prepared by making concentrated infusions and filtering upon granulated sugar contained in a hot water bath, with frequent stirrings till dry.

The meeting on Tuesday concluded with a paper by Mr. A. W. GERRARD, in which he described experiments leading him to the conclusion that *Narcissus Pseudo-Narcissus* contained an alkaloid and certain other principles of interest. He had not obtained any product in a state of purity, nor were any analyses forthcoming or other evidences of identity.

The Conference meeting of Wednesday opened with an interesting paper by Mr. E. SMITH, on the "Materia Medica of Devon." This, of course, included a sketch of the botany of the county, and an account of the large copper, iron, manganese, arsenic and other mining industries which are so actively prosecuted. Mr. SMITH, however, did not allude to the diminution of pyrites and manganese mining brought about since the large importation of these minerals first commenced.

The second paper on Wednesday's list was by

Mr. G. F. SCHACHT, who related "Some Experiences in the Equipment and Working of a small Pharmaceutical Laboratory." The paper was illustrated by some excellent drawings by Mr. J. T. THOMPSON, and gave rise to a conversation in which many gentlemen took part, and gave other personal experiences as to the best form of several pieces of laboratory apparatus and appliances.

Mr. W. H. MARTIN'S "Note on Diphenylamine as a Test for Nitric and Nitrous Acids" was illustrative of the observations made previously by Professor LUNGE, and recently published in this Journal. The test appears to be an exceedingly delicate one. In applying it a small granule of diphenylamine is placed in a test tube, and a drop or two of sulphuric acid added, then water so as to increase the temperature in order to effect a perfect solution of the diphenylamine. If to such a prepared test solution sulphuric acid be added containing only a trace of nitric or nitrous acid a beautiful permanent blue colour is immediately produced at the junction of the liquids.

A paper by Mr. J. C. THRESH on "The Pill Masses of the B.P.", contained a report on those which in his opinion are of inconvenient consistence or become so by keeping, and suggestions for their improvement.

After this, a paper by Dr. TILDEN was read upon "A Product of the Oxidation of Barbaloin and Socaloin," which he has named alloxanthin, constituting a yellow colouring matter closely related to chrysammic acid and to emodin.

It had been determined at the meeting of the previous day that Mr. S. R. ATKINS' paper "On a Point in Pharmaceutical Ethics" should be read without being subjected to discussion. This course was, however, protested against by Mr. GUYER, as forming an undesirable precedent, but the protest was overruled. In the paper Mr. ATKINS defined the specific positions occupied by pharmacists and medical men, and showed that it was quite feasible to decide the hotly disputed matter of counter practice without evincing bad spirit and acrimony. He contended that pharmacists had a public justification for counter practice in simple complaints, but warned them against carrying it to an unjustifiable degree.

This paper was followed by one relating to a question which not only affects a large trading interest, but is also one of importance as regards the public health. The paper in question was intended to elucidate the influence exercised by the presence of metallic compounds in alimentary substances. It was chiefly occupied with the results of an investigation by Dr. PAUL and Mr. KINGZETT into the physiological action of the copper known to be contained in preserved peas, particularly those of French manufacture, and it was shown by the authors that the copper as it exists in the peas is not only in an insoluble state and in actual combination with the albuminous constituents of the peas, but is not removed by the water used in the process of cooking. During digestion this copper passes entirely into solution if sufficient time be allowed; nevertheless it is for the most part excreted in the fæces, being probably reprecipitated through the agency of biliary fluid as phosphate. Only a very minute trace, therefore, is absorbed into the system, thus proving the non-injurious nature of such peas as an article of food. It was also shown that many compounds used largely in colouring confectionary contain from 6 to 70 per cent. of stannic oxide; besides which other articles of food containing metallic compounds were described. In the discussion which followed Dr. WRIGHT called attention to some instances of poisoning through the agency of lead, tin, and zinc, which had been reported in the daily papers. Dr. REDWOOD stated that, in his opinion, the vendors of preserved peas containing copper should be prosecuted on the ground that they were selling an article of food containing something not natural to the peas, but intentionally introduced. To this it was replied that persons who consumed such peas would not suffer the slightest injury to health, a conclusion which received considerable support from evidence given in the discussion by various speakers. It was particularly insisted upon by the authors that medical opinion, no matter how unanimous, was worthless, so long as that opinion was based upon an imperfect knowledge of the facts necessary for its formation.

The "Analyses of Preserved Carrots, Potatoes, "Cabbage, and Mixed Vegetables," detailed by Professor ATTFIELD in the next paper, have been for the most part previously published in the report of the Commission appointed to inquire into the causes of the outbreak of scurvy on the Arctic Expedition.

Mr. KINGZETT next read a paper on "Scammony Root," by Mr. FARRIES and himself, in which it was shown that the roots of *Convolvulus scammonia* contain no alkaloid, although it has been asserted by MARQUART that an alkaloid does exist in the root. Resin of scammony yields glucose on decomposition with dilute sulphuric acid and by various other processes given in the paper, an analysis of barium glucinate being brought forward in support. Mention was also made of the volatile oil produced below 90° C. by dry distillation of the resin; its examination is not completed.

In a "Further Note on the History of Tea Hair," Mr. T. GREENISH showed that the hairs contain no theine and gave a general description of their occurrence and properties.

Mr. L. SIEBOLD'S paper on "Copaiba Testing" showed that beyond fatty oils, such as linseed, turpentine oil was the only other probable adulterant. He also pointed out that the methods of testing still given in many books are valueless. He had found that Dr. MUTER'S process for testing copaiba also was unreliable, while the simple process of evaporation to dryness was sufficient to yield indications of purity or impurity, according to the stickiness or dry nature of the product. Turpentine could be easily detected when present, in the first portions obtained on the distillation of copaiba oil, and recognized by its lower boiling point and odour.

Mr. Moss stated in the discussion that as regards Fluckiger's test for the purity of copaiba oil, he had never experienced any difficulty in the use of it. Mr. W. W. Urwick's "new medicinal solution of phosphorus" consists of a preparation in which egg albumen is employed, and Dr. Redwood pointed out that he had already given a formula in which that substance was used for the purpose stated.

Mr. Kingzett's paper on "Blood Albumen" contained a detailed account of the process patented by Mr. Zingler and himself for bleaching and preserving blood albumen, and the various uses of the product. The process consists in passing a current of air through albumen solution admixed with a certain small percentage of turpentine, and maintained at about 40° C. The oil oxidizes, forming peroxide of hydrogen, which effects the bleaching, while the camphoric acid and other substances simultaneously produced preserve the solutions of albumen almost permanently from any putrescible or other change.

In his next paper on "Pilocarpine," Mr. Kingzett gave the analysis of a platinum salt made from a sample of the nitrate given to him by Professor Attfield, which proved the identity of the alkaloid with that to which he had previously assigned the formula $C_{23}H_{34}N_4O_4$. On distillation of the salt $C_{23}H_{34}N_4O_4$, 2HCl, $PtCl_4$ to dryness with strong caustic soda solution, trimethylamine appears to be produced.

The last paper read was by Mr. Willmott on the "Effects of Variations of Temperature on Boiled Putrescible Liquids."

It was then determined to hold the next annual meeting of the Conference at Dublin, and after the usual business matters had been concluded, including the appointment of a new President in the person of Mr. G. Schacht, the Conference dissolved.

On Thursday, notwithstanding a smart shower just before the time fixed for embarkation, a considerable number of ladies and gentlemen accepted the invitation of the Local Committee to join in an excursion up the River Tamar. The programme, as previously sketched out, was closely followed. The boat proceeded up the river as far as Cotehele, the grounds of which were visited, then returned to Pentillie where an ample lunch was followed by a stroll through grounds, from which a magnificent view including the windings of the river was obtained. The kindness of Colonel Corydon in throwing open the grounds was recognized in three hearty cheers given by the company. After the company had once more returned on board, the "Eleanor" proceeded on her course down the river to Mount Edgcumbe, where some landed whilst others went on for a run to the breakwater. By a little after six o'clock, however, the company had once more reunited in the "orangery," where, within view of numerous splendid specimens of the genus *Citrus*, bearing fruit and flowers in the open air, and within hearing of the musical strains of the capital band of the Royal Marines, "high tea" was served. Then, at the conclusion of a most successful day, the threatening clouds of the morning having soon dispersed, the President, Professor Redwood, speaking on behalf of the visitors, acknowledged the kindness and hospitality of the Local Committee, and also their appreciation of the generosity of the Earl of Mount Edgcumbe, which had allowed them to view his magnificent seat.

In concluding this notice it may be said that from the beginning to the end of the Conference meeting there was ample evidence that no effort had been spared to secure the comfort and enjoyment of the visitors, and there can be no doubt that in the manifest appreciation of this fact Messrs. Clark, Skinner, Turney, Codd, Balkwill, and the other members of the Local Committee will find the most grateful acknowledgment of their labours.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The President of the British Association delivered his Address at the Guildhall, Plymonth, on Wednesday evening, and a considerable portion of it will be found in another portion of this Journal. The topic was a biological one, the development of the forms of animal life, and was chosen by Dr. Thomson as one with which his studies have been particularly associated. The audience was not so numerous as it has been on some previous similar occasions. In fact, general appearances in the Reception Room and elsewhere would lead to the inference that the general attendance of members at Plymouth is not large; neither are the lists of papers to be read in the various sections very long. But it would be premature at present to pronounce a decided opinion in these respects.

A NEW ANTIEPILEPTIC.

Professor Xavier Landerer, of Athens, states that he has been able to recognize in a substance that has locally acquired some reputation as a remedy against epilepsy, the root of the *Clematis cirrhosa* or *sylvestris*. In two cases of epilepsy treated with a decoction of this root, which is strongly diuretic, there has been a cessation of the attacks for more than three months. The bruised fresh leaves of the plant act as a rubefacient, and sometimes even as a vesicant when applied to tender parts of the skin.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

The proceedings of the Fourteenth Annual Meeting of the British Pharmaceutical Conference commenced on Tuesday, the 14th inst., at the Athenæum, Plymouth. Professor Redwood, Ph.D., F.C.S., President, in the chair.

Mr. Codd, on behalf of the local pharmacists, having welcomed the Conference to Plymouth,

The President called on Professor Attfield, General Secretary, to read the names of delegates present

Professor Attfield expressed his pleasure in finding that this year not only every provincial association connected with pharmacy was represented there, but also each of the Pharmaceutical Societies, for there were now more than one; especially the Pharmaceutical Society of Great Britain had sent several delegates. The delegates present were as follows:—

Pharmaceutical Society of Great Britain.—The President (Mr. Williams), Messrs. Atkins, Cracknell, Greenish, Owen, Robbins, Savage, and Schacht.

Pharmaceutical Society of Ireland.—Messrs. J. A. C. Payne and C. R. C. Tichborne.

Midland Counties Chemists' Association.—Mr. Stokes Dewson.

Bristol Pharmaceutical Association.—Mr. Schacht.

Exeter Pharmaceutical Association.—Messrs. G. Delves and G. Pasmore.

Glasgow Chemists' Association.—Messrs. Davison and Frazer.

Leeds Chemists' Association.—Mr. Peter Jefferson.

Liverpool Chemists' Association.—Dr. Symes.

Manchester Chemists' Association.—Messrs. Benger and Siebold.

Wolverhampton and District Chemists and Druggists' Association.—Mr. Fleeming.

Mr. F. B. Benger, F.C.S., General Secretary, read letters from Mr. Brady, Newcastle, and Mr. Reynolds, Leeds, expressive of their regret at not being able to be present.

Mr. Benger then read the report of the Executive Committee as follows:—

Report of the Executive Committee.

In presenting their fourteenth annual report the Executive Committee again avail themselves of the opportunity of congratulating the members of the British Pharmaceutical Conference on the continued prosperity and usefulness of the association.

The work of your Committee during the past year presents no special features. The collection of members' subscriptions, the publication of the Year-Book, and the issue of the usual lists of proposed subjects for research, and of circulars having reference to the present meeting, are the chief items which have occupied their attention.

It will be seen from the balance sheet to be presented by the Treasurer, that practically the whole of the income of the Conference has this year been devoted to the advancement of scientific pharmacy. Your Committee believe that such a disposal of the funds is in strict accordance with the intention of the founders of this association, and with the wishes of present members; and they may be excused for looking with some pride, as well as much satisfaction, to the important services which the Conference is now, year by year, rendering to pharmacy proper, and therefore to the practice of medicine, and to the sanitary interests of the community. These results are being achieved, first, by the character and amount of the original matter directly communicated to the Conference by the authors of papers read at its annual meetings, and evolved during the discussion of such papers by the members present.

Then, secondly, by the substantial grants of money which your Committee have been able to make to gentlemen undertaking special costly researches connected with pharmacy, original work of the highest importance is being promoted, and discoveries are made which will have interest and value wherever medicine and pharmacy are practised; whilst the investigation of difficult and complicated problems, such as that undertaken by Messrs. Groves, Williams, and Wright on the aconite alkaloids are of great scientific and probable practical importance; moreover, they are scarcely likely to be undertaken by individuals at their own expense, and are on that account the more suitable subjects to be investigated at the partial cost of the Conference.

Thirdly, by the production and distribution of the now well-known 'Year-Book of Pharmacy.'

Fourthly, by the pleasant and profitable friendly intercourse brought about amongst the widely scattered pharmacists who assemble at our annual meetings.

The papers sent in to the Secretaries to be read at the present meeting are of great and varied interest, and sufficiently numerous to fully occupy the two days devoted to their reading and discussion.

A number of applications for grants in aid of research were received and considered during the Glasgow meeting.

The following amounts have been drawn during the year by members to whom such grants were voted, and reports on the various subjects will be presented:—Mr. J. C. Thresh, F.C.S., for the purchase of materials in connection with an extended research on the active principle of capsicum fruit, £7; Dr. Tilden, F.C.S., for the purchase of essential oils required in a research, £20; Mr. T. B. Groves, F.C.S., Mr. J. Williams, F.C.S., and Dr. C. R. A. Wright, F.C.S., for the extraction and investigation of the aconitines of *Aconitum Napellus*, £30; Mr. M. M. P. Muir, F.C.S., for a second research on oil of sage, £3.

The salary of the Editor of the Year-Book has been advanced from £100 to £150 per annum.

It was at the Exeter meeting of the Conference in 1869 that the Sub-Committee appointed to consider the desirability of publishing a 'Year-Book of Pharmacy' presented their report; and on the motion of Messrs. Palk and Cooper that the recommendation was adopted. At that date the Conference numbered less than 700 members. After an absence of eight years the Conference has returned to Devonshire. Its membership roll now contains between 2000 and 3000 names, and the Year-Book occupies a deservedly high position amongst the publications of the year, and is, as it was intended to be, the familiar desk companion of the pharmacist.

It may be remembered that the MS. of the 1876 volume, was laid on the table by the editor at the last annual meeting: its issue was however, unavoidably delayed by circumstances beyond the control of the Committee, mainly, in consequence of the illness of the editor, and the great pressure on his time, caused by accumulated work and engagements. Some loss of members has doubtless been caused to the Conference by this unfortunate circumstance, but your Committee confidently hope that the forthcoming volume will be in the hands of the members before the end of the year. The MS. is now complete, with the exception of the introduction, and the editor, having made arrangements which relieve him of all business engagements, is able to devote his whole time to literary and professional work; your Committee have felt it to be due to the members to make this statement, as much disappointment has been felt by those who were unacquainted, or only partially acquainted with the circumstances of the case.

At a meeting of your Committee held last evening Professor Attfield placed on the table, with the usual eighteen guineas' worth of books from the Bell and Hills Library Fund, copies of Hanbury's 'Pharmacographia' and 'Science Papers,' stating that Mr. Thomas Hanbury desired to present a copy of each of these works in memory of his brother, the late D. Hanbury, F.R.S., to the local associations in towns visited by the Conference.

In conclusion, your Committee would urge members to bring the Conference under the notice of as many of their pharmaceutical friends as possible: the mere mention of the objects aimed at by the Conference, the advantages derived from membership, the intrinsic value of the Year-Book and the smallness of the annual subscription, are generally sufficient to ensure a willingness to be nominated for election. It should be borne in mind that the Conference must of necessity lose yearly many members from various causes, and that merely to maintain its present strength, a considerable number of new names must be added annually.

The Treasurer, Mr. Schacht, read the Financial Statement (see following page).

On the motion of the President, the report and accounts were received and adopted.

The Treasurer then read the statement with regard to the "Bell and Hills" Library Fund (see following page).

The President suggested that the thanks of the Conference be presented to Mr. Thomas Hanbury for the gift of books referred to in the report, which was unanimously agreed to.

Professor Attfield said he had next to announce that Mr. T. H. Hills, in addition to the books already alluded to, had commissioned him to present to the local association two portraits of eminent pharmacists, viz., the first President of the Pharmaceutical Society, Mr. William Allen, and the second that of Mr. Jacob Bell. He hoped these portraits would be placed in the room which would hereafter become the library of the Association.

Mr. R. J. Clark (Local Secretary) moved a vote of thanks to Mr. Hills, and said he hoped the books now presented would form the nucleus of a library which should be extensively used by the young men engaged in the practice of pharmacy.

The motion was seconded and carried unanimously.

The President next delivered the following address:—

The President's Address.

Gentlemen,—As you have done me the honour of placing me again in the President's chair it becomes my duty to address you at this stage of our proceedings, and I think I cannot more appropriately commence my address than by referring to the satisfactory evidences of the continued prosperity of our association, which are afforded us in the reports which have been read relating to the past year, in the prospect we have of much good matter for the present meeting, and in the indications we receive from various quarters of a desire to co-operate with us in furthering the objects for which we have met here in conference.

One of the objects we desire to promote by these meetings is that of effecting a union of pharmacists for scientific purposes on the broadest basis, and of bringing into close and friendly intercourse not only the scattered members of the body we represent, but those of other associations and of every nationality, who have a common interest with us in the advancement of the art of pharmacy. We are endeavouring to effect such advancement by an extension of pharmacological studies and researches among those with whom we are associated, and by encouraging the cultivation of the knowledge which will best enable the druggist to fulfil the duties which the requirements of the public and the medical profession impose upon him. The means which are adopted by this and other kindred associations for effecting these important objects, if they be pursued in unison with each other, as I believe they are being, and are likely to be, cannot fail to produce results that will tend to place the practice of pharmacy in the honourable position it deserves to occupy. If at times any of our friends should be ready to falter in their progress, and to fear that we are pursuing a course which may lead them away from the few substantial advantages they possess into the utopian regions of empty honour, it behoves us to hold out the hand of encouragement, and to endeavour to demonstrate to them that the profit and the honour resulting from our professional occupations will mainly depend on the value of the services we are enabled to render to those who have pressing need of them, and the completeness of the qualifications we possess for the efficient performance of all we undertake to do. The position in which we as pharmacists are placed in the present day is very different from that which our predecessors, the druggists of a century and a half ago, occupied. The druggist of the 17th century has become an extinct species, while the druggist of to-day has been transformed into the apothecary of the 17th century. In the transitions which have thus taken place we may find matter from which to derive profitable instruction. We may also learn from a restrospect of our past history, that there has always been in this country an indisposition to legislate in reference to the practice of medicine until the public wants have developed the means of providing what is required and best suited to supply them.

The early history of the practice of medicine in this country is involved in some obscurity, but it appears that both medicine and pharmacy were formerly often associated with the ecclesiastical profession, and that surgery, being of too sanguinary a character to admit of such an association, formed a more natural alliance with the occupation of the barbers.

Medicine, but not surgery, was studied at our universities, but there was no law to define the qualifications of a physician or to regulate the practice of medicine.

Before legislation commenced on these subjects, the surgeons took the lead of the physicians in obtaining recognition from the Government.

About the middle of the 15th century a charter of incorporation was granted by Edward IV. to the company of barber-surgeons, who were invested with authority to examine the instruments and remedies employed, and to bring actions against those who practised illegally and ignorantly, none being allowed to practise who had not been previously admitted and judged competent by the master of the company.

An attempt to legislate for the purpose of regulating the practice of medicine had been made as far back as the year 1422, at the instigation of the universities of Oxford and Cambridge, where degrees in physic were granted to those who had studied for the profession; but although an Act passed through Parliament in that year to the effect that "no one shall use the mystery of physic unless he hath studied it in some university, and is at least a bachelor in that science," this Act appears not to have come into operation, for having been referred to the Privy Council for confirmation, it was there allowed to drop.

The first successful attempt at legislation was made in 1511, when a law was passed which imposed upon physicians and surgeons practising as such in and around London, and also in the provinces, the necessity of passing an examination, and being approved and admitted, by a body of examiners consisting of the bishop or some other dignitary of the church, with four members of the faculty of medicine.

The College of Physicians was established by Royal Charter in 1518, and four years afterwards, in 1522, a law was passed by which the examination of those allowed to practise as physicians was transferred to the college from the body previously entrusted with the performance of this duty.

Independently of the barber-surgeons, there was but one class of recognized medical men, namely, the physicians, who prepared and dispensed the medicines they prescribed. The only class of men who at that time could be properly called apothecaries were the assistants employed by the physicians to prepare their medicines.

FINANCIAL STATEMENT, 1876-77.

THE GENERAL FUND.

THE SENIOR HON. SECRETARY IN ACCOUNT WITH THE BRITISH PHARMACEUTICAL CONFERENCE.

FOR THE YEAR ENDING JUNE 30, 1877.

Examined and found correct, { T. DAVISON, Glasgow, S. B. TURNEY, Plymouth, } *Auditors.*

Some of these assistants from time to time, no doubt, started on their own account, and probably occupied an equivocal position either as doctors or dealers in medicines, for until the year 1511 there had been no law to define the qualifications of a physician, and at that period, and for many years afterwards, there is no evidence of the existence in this country of a body of men engaged on their own account as dispensers of medicines. This indeed would necessarily have resulted from the fact that physicians were not then in the habit of writing prescriptions for their patients. The first notice we find of apothecaries engaged in business as such, and probably these were only dealers in compounded medicines, is in the middle of the 16th century, when the College of Physicians acquired the power of searching apothecaries' shops, examining their medicines, and destroying such as were found to be unfit for use.

It appears that about this time the surgeons were considered to have exercised the power that had been given them of restricting the practice of their profession to members admitted by their Company, too strictly, and without sufficient regard to the requirements of the poor. An Act of toleration was therefore passed in 1542, which set forth that "the Company and Fellowship of Surgeons of London, minding onely their oune lucres, and nothing the profit or ease of the diseased or patient, have sued, troubled, and vexed divers honest persons, as well men as women, whom God hath endued with the knowledge of the nature, kind, and operation of certain herbs, roots, and waters, and the using and ministering of them, to such as have been pained with customable diseases, as women's breasts being sore, a pin and the web in the eye, uncomes of the hands, scaldings, burnings, sore mouths, the stone, stranguery, saucelin and morphem, and such other like diseases. . . . And yet the said persons have not taken any thing for their pains and cunning. . . . In consideration whereof, and for the ease, comfort, succour, help, relief, and health of the King's poor subjects, inhabitants of this his realm, now pained or diseased, be it ordained, etc., that at all time from henceforth it shall be lawful to every person, being the King's subject, having knowledge and experience of the nature of herbs, roots, and waters, etc., to use and minister them according to their cunning, experience, and knowledge . . . the aforesaid statute (the Act of 1511) or any other Act notwithstanding."

This Act was intended for the relief and toleration of those who, although not legally qualified medical men, yet possessing some knowledge of medicines, administered them gratuitously. The previously existing law was still allowed to take its course against notorious quacks and ignorant pretenders, many of whom were punished by fine and sometimes by exposure in the pillory.

As yet we have no knowledge of druggists as a recognized class of traders. Crude drugs were mostly supplied by grocers, who dealt in foreign drugs as well as grocery, and by herbalists and simplers who collected indigenous medicinal plants. Those grocers who gave most attention to, and were best acquainted with, drugs, became drug-grocers, and these assuming the title of druggists, confined themselves to this class of merchandise. The physicians purchasing the crude drugs from such sources, not only dispensed, but also prepared and compounded such medicines as they administered to their patients. But this practice was felt to be irksome and unsuited for members of a learned profession, therefore, in the early part of the seventeenth century, physicians were getting into the habit of issuing prescriptions or "bills" as they were then called, which necessarily caused the establishment of dispensing apothecaries, the number of whom must have increased as this new practice extended.

Until the year 1618 there had been no authorized pharmacopœia, and indeed such a work could not have been required while physicians were their own apothecaries, but when prescribing and dispensing became distinct and independent occupations it was necessary to have a recognized and authoritative standard by which to determine the meaning and value of the terms employed in extemporaneous prescriptions. Hitherto the medicines used belonged principally to the class called galenical, for which complicated formulæ had been handed down from generation to generation for centuries, without any attempt having been made to improve or alter them. But with the sixteenth century a new class of remedies was introduced which, in spite of much opposition, acquired and maintained a position which was daily increasing in importance, and to the more extended use of this class of chemical agents in medicine may in part be ascribed the necessity which arose for a class of men trained and exclusively devoted to the practice of pharmacy, including the preparation of chemical and galenical medicines.

Pharmacy was now for the first time assuming an independent position in this country, but circumstances which followed this result contributed more to the production of a new form of medical practice than to the maintenance and improvement of pharmacy as an independent art. In 1606 the apothecaries, then few in number, formed an alliance and became incorporated with the grocers, but this alliance was shortly afterwards dissolved, and in 1617 the Apothecaries' Company was formed, for which a charter was obtained giving them some exclusive privileges. They established a dispensary near Blackfriars Bridge in 1623, for the preparation of some of the more important medicines then in use, and to this was subsequently added a chemical laboratory in 1671. The medicines prepared or manufactured at this establishment were only supplied to members of the company for use in their practice. The establishment still exists under the title of Apothecaries' Hall, but important changes have been made in the character of the institution and the purposes to which it is applied.

At the time of the formation of the Apothecaries' Company, the number of its members was 114, and that this number included all the then established apothecaries may be inferred from the fact that a few druggists or drug-grocers were included in the Company to make up the number to that of the physicians practising in London.

The apothecaries were a prosperous body, and probably this was to no inconsiderable extent due to the incidence of their advent at a time when wealth and luxury, pestilence and poverty were providing a rich harvest for doctors of all degrees, while the law had only provided doctors of one, and that the highest degree. Oxford and Cambridge had furnished London with 114 physicians, learned in all the science and mystery of physic as then taught at the Universities, but London with its densely packed and increasing population, with its undrained streets and festering cesspools, seemed to require something more than this to stay the ravages of plague and other forms of pestilence. The apothecaries had been trained in a school in which medicine and pharmacy, dispensing and prescribing, went hand in hand, and it need not be matter of surprise that with so many demands for medical advice for the poor, and for those who could ill-afford to pay a physician, they were easily induced to apply such knowledge as they possessed in ministering to the relief of the sick, without too nicely considering the extent of their qualifications for doing so. It is a significant fact, that although prosecutions were frequently instituted against ignorant quacks, and although the College of Physicians took proceedings against members of the College of Surgeons for prescribing in other than surgical cases, and successfully prevented such practice, yet for a century or more the apothecaries were permitted to pursue an illegal practice which commenced with the treatment of trifling ailments, but grew by degrees and was supported by public opinion, until it not only rivalled, but surpassed in extent, the practice of legally qualified physicians. The result of this was that in less than a hundred years the number of apothecaries increased from 114 to nearly 1000, and notwithstanding the many and strong protests which were made by some of the physicians against the encroachments of apothecaries upon their legitimate functions, this was of no avail, so long as there was a great public want that was not otherwise provided for than by allowing the members of a lower grade of the profession to overstep the strict limit of their duties.

It was in the seventeenth century that druggists, as distinguished from grocers, came into existence and assumed a recognized position among traders. To the title of druggist they afterwards added that of 'chemist when chemical medicines came into more general use, but the chemist and druggist was at first and for some time, with perhaps a few exceptions, a mere dealer in drugs and chemicals, without possessing or pretending to possess the knowledge required for their preparation or production, and as yet they had nothing to do with the dispensing of medicines prescribed by the physicians.

It was not until the middle of the last century that chemists and druggists undertook the duty of dispensing medicines, and they were called to the performance of this duty in consequence of the apothecaries having relinquished the position they had originally occupied and usurped the functions of medical men.

The transference of the dispensing of physicians' prescriptions, however, was not made directly from the apothecary to the chemist and druggist. There was an intermediate period during which much of the dispensing in London was done at institutions, called dispensaries, which had been established by the physicians, ostensibly to enable the poorer classes to get prescribed and other medicines at a moderate cost. These dispensaries, of which there were three, were established in 1697, by subscriptions from the fellows and members of the College of Physicians. The principal establishment was in Warwick Lane, Newgate Street, at the Hall of the College of Physicians, where medicines were not only dispensed but prepared for use in dispensing at the other establishments in St. Martin's Lane, Westminster, and St. Peter's Alley, Cornhill.

The physicians justified the establishment of these dispensaries, on the ground that while they were in the habit of prescribing gratuitously for the poor, their patients had no means of getting the prescriptions prepared without taking them to an apothecary, who was often in such cases not only ready to replace the prescriber, but accustomed to make unnecessarily high charges for the medicines supplied.

A very acrimonious controversy took place between the physicians and apothecaries respecting these dispensaries, and they were at length given up when druggists undertook the duty of dispensing for which they had been preparing themselves.

There is reason to believe that the physicians' dispensaries, while they existed, were the schools at which instruction was principally acquired by those who were intending to establish themselves as dispensing chemists and druggists. By the middle of the last century, the dispensaries had disappeared, and soon afterwards chemists and druggists began to display the notice, "Physicians' prescriptions carefully prepared."

We thus arrive at the distribution of medical and pharmaceutical duties, such as exists at the present time, and it will be seen that the arrangements adopted when druggists took the position previously occupied by the apothecaries, resulted from the growing wants of the public, which were not otherwise provided for. Legislation has followed our medical and pharmaceutical institutions with slow and reluctant steps, and has been chiefly directed to the remedy or prevention of evils when these have appeared and have grown into serious abuses. At the time when druggists became dispensers of medicines, no adequate provision had been made by the legislature for the medical treatment of all classes of the population. Colleges of physicians and surgeons had been established with powers, which, if they had been exercised to their fullest extent, would have left a large proportion of the people without even the consolation of having their ailments ministered to by those who, although not possessing the highest medical knowledge, were the only medical advisers their means enabled them to consult. The apothecary, without any specified or required qualifications for such a duty, had become the poor man's doctor, and public opinion and the liberality and good sense of the heads of the medical profession enabled him to maintain that position until better arrangements were made.

The regulations adopted in other countries present a marked contrast with such as have existed here. From early periods, dating back to the twelfth and thirteenth centuries, we may trace the recognition of pharmacy as a distinct and separate branch of the medical profession in continental countries. In France and Germany apothecaries' shops existed in most of the large cities in the thirteenth, fourteenth, and fifteenth centuries, and these were sometimes kept up at the public expense, with botanic gardens attached to them. The number of these establishments greatly increased in the fifteenth and sixteenth centuries, when they were placed under strict regulations. Laws were passed for regulating the practice of pharmacy in France in the early part of the sixteenth century, and on several occasions throughout that century. The tendency of legislation in France, Germany, and Italy was to effect and maintain a complete separation between the treatment of disease and the preparation and dispensing of medicines. The law defined and limited the nature of the occupations, in the critical direction, which practitioners of pharmacy were allowed to engage in, and a sense of emulation stimulated the members of the body thus circumscribed in their pursuits to the attainment of the qualifications required for the discharge of the duties assigned to them. It was never a question with them whether they should become general practitioners of medicine; if it had been, pharmacy and the shop would have gradually sunk in their estimation while they were seeking to attain to a higher grade in the profession of medicine. But tied as they were to the plain and legitimate duties connected with the preparation and dispensing of medicines the only direction in which they could hope to elevate their social and professional position was that of increasing their professional qualifications. Long before pharmacy had emerged in this country from the condition in which it was represented by the physicians' assistants, there was a class of independent apothecaries or pharmaciens in Paris who were supporting a school for the special instruction of those who were intending to devote themselves to this occupation. In the year 1576 this school was founded by a public-spirited pharmacist, Nicholas Houel, who deserves to be canonized among pharmaceutical worthies. The Paris School of Pharmacy afterwards received the support of the corporation of apothecaries, and ultimately became the College of Pharmacy, in which so many distinguished pharmaciens have been trained.

By these and similar means, adopted not only in France, but also in most other continental countries, the practice of pharmacy being strictly defined and limited to the exercise of functions for which its followers were especially and well qualified, has assumed the character of a profession, the members of which fill an important position in the social scale.

If we now return to our own country and to the middle of the eighteenth century, we find laws existing for regulating the qualifications of physicians and surgeons and for restricting medical and surgical practice to examined and approved members of those branches of the profession. We also find a Society of Apothecaries with a charter authorizing them to prepare, dispense, sell, and administer medicines. These apothecaries, having been originally the servants, were now the attendants of the physicians, whose duty it was, if called in with a physician to carry his instructions into effect, not only preparing and sometimes administering the prescribed medicines, but performing operations that are now left to the nurse. To a certain extent, the apothecary was supposed to be, and generally was, an educated man, that is to say, he had served an apprenticeship to one of the same class, and being intimately associated with the physicians, he had frequent opportunities of observing how they treated their patients, especially as the prescriptions or "bills" as they were called, all passed through his hands. Pope in his 'Essay on Criticism,' which was written in the early part of last century, says:

"So modern 'potecaries,' taught the art
By doctors' bills to play the doctors' part;
Bold in the practice of mistaken rules,
Prescribe, apply, and call their masters fools."

But not unfrequently the apothecary was called in without the physician, and then he usurped the functions of both, for which, however, his education had not properly qualified him, for he had not necessarily received a systematic and scientific education, nor had he passed any examination. This was a subject of complaint between the physician and apothecary, which for a century or more had been growing stronger and louder. As a natural consequence physicians ceased to advocate the calling in of an apothecary and transferred their patronage to the rising and rapidly increasing class of chemists and druggists. We find this class of recently introduced compounders and dispensers of medicines taking zealously to their new occupation, and apparently thriving, as the apothecaries had done when they first started on their career. They were good men of business, but had no pretensions to much education of any sort, and they were not even required, as the apothecaries were by their charter, to have served an apprenticeship to one who practised the same art.

The rise and progress of dispensing chemists and druggists caused, as might have been expected, a falling off in the prosperity of the apothecaries, and complaints soon began to be made on this account.

In 1748, an Act was passed which extended the powers given to the Society of Apothecaries by their charter and enabled them to examine and grant licenses to those who were authorized to act as apothecaries in and within seven miles of London. It was through the power supposed to have been given to them by this Act that they endeavoured some years afterwards to prevent druggists, not only from dispensing the medicines prescribed by physicians, but also from selling any compounded medicines. It is probable that, strictly speaking, they had legally acquired a monopoly in these respects, but when it was known how they intended to apply the power they had acquired, it soon became evident that the public and the higher branches of the medical profession would not support them in maintaining such a position.

It was not until the end of last century, that any active steps were taken with the view of contesting the right of chemists and druggists to prepare, compound, dispense and sell medicines. In 1793 an association of apothecaries was formed, for the purpose of investigating the causes of the diminished prosperity which was complained of among their fraternity, and which was ascribed to two principal causes.

"First, the encroachment which chemists and druggists have, of late years, made on the profession of the apothecary, by vending pharmaceutic preparations, and compounding the prescriptions of physicians."

"Secondly, the want of a competent jurisdiction in the profession itself, to regulate its practice and to restrain ignorant and unqualified persons from practising at all."

A committee of twenty members was appointed who met once a month at the Buffalo Tavern, in Bloomsbury Square, and by means of an extensive correspondence with apothecaries throughout the kingdom they obtained a vast amount of statistical and other information which was published in their reports, and a detailed account of which is given by Mr. Bell, in his 'Historical Sketch of Pharmacy.' It was ascertained as the result of the inquiry that druggists were springing up in every part of the country, and in some places with a four-fold increase in ten or twelve years, that they undertook the dispensing of prescriptions and the sale of medicines of all sorts, and were in the frequent habit of prescribing for those who applied to them for advice. Evidence was adduced to show that many of these druggists were ignorant of the meaning of terms used in prescriptions, and of the qualities and effects of the drugs they were dealing in, but the evidence went also to show that not a few of those who practised as apothecaries were equally ignorant, and that even the power given to the Society of Apothecaries by the Act of 1748 to grant licences on examination was only partially and very imperfectly applied. The final result of the committee's labour was that addresses embodying these facts and suggesting a system of reform were presented to the Colleges of Physicians and Surgeons and the Society of Apothecaries, after which a petition was presented to the House of Commons, and there the matter ended.

The physicians and surgeons had taken no part in this contest between the apothecaries and chemists and druggists. Even the Society of Apothecaries in their corporate capacity appear to have held themselves aloof. All the parties interested, and still more those who were disinterested, must have seen that the contention had reference to private gain more than the public good. Yet there can be no doubt that great advantage resulted from the searching inquiry that was made into the merits and demerits of the opposing candidates for public favour. Public opinion had given to the apothecaries, or at least had called them into, a position which was by no means an unimportant one, but it obviously involved the relinquishment of that which they had previously held, and which was now being handed over to the chemists and druggists. Neither party were as yet fully qualified for the duties they were undertaking, and of this, if they were not themselves previously sensible, they must have been rendered so by the discussions which took place on the subject. The contest was comparatively a short and harmless one, and being over, each party no doubt retired with the wise determination to set his own house in order before he again complained of his neighbour's. Such a resolution, if carried into effect, must have tended to strengthen the chemists in their position, for the better qualified their adversaries became for medical practice, at which they were aiming, the less fitted they must necessarily have become for the duties of dispensing. On the other hand, a large number of chemists and druggists, including the founders of many pharmaceutical establishments in London, and various parts of the country, which have acquired and sustained high reputations, devoted themselves to the carrying out of the most approved methods of preparing and dispensing medicines, which secured to them extensive patronage, and enabled them effectually to silence any further attempts at an outcry, such as was previously raised by the apothecaries on account of the assumed encroachment of chemists on their privileges.

A period of eighteen years now elapsed before any further steps were taken to legislate on medical affairs; but in 1813, an association of apothecaries, not the Society of Apothecaries, again appeared in the field, and introduced a bill into parliament, which proposed to create a licensing board consisting principally of apothecaries with a few physicians and surgeons, who were to have the power of licensing not only apothecaries, but chemists and druggists also, although the latter were not to be represented in, and were to have no voice in the election of, the board. This bill was immediately opposed by the chemists, and as it met with little favour either in or out of the profession, it was soon withdrawn.

Two years afterwards the Society of Apothecaries took up the subject of legislation and carried the Apothecaries Act of 1815, by which the practice of apothecaries has been since regulated. If we may judge from the statements of the authors of that bill and their representatives, the measure was not intended to interfere in any way with the then established and admitted practices of chemists and druggists, in preparing, dispensing, and selling medicines. The Committee of chemists and druggists, however, who were appointed to watch the progress of the measure, influenced perhaps by the attempt which had previously been made, on the strength of the then existing law, to prevent any but apothecaries from dispensing prescriptions, insisted on having a clause introduced into the bill, which should not only in general terms exempt chemists and druggists from its operation, but should specify the acts for which such exemption was granted. In the clause as it stands in the Act, the words, "in the buying, preparing, compounding, dispensing, and vending drugs and medicinal compounds, wholesale and retail," were introduced at the suggestion, and by the desire of the Committee acting under the advice of counsel. In fact, everything that was asked for by the Committee was granted, and the bill passed without further opposition.

By this Act the original charter granted to the Society of Apothecaries by King James the First in 1617 was confirmed, except that the jurisdiction of the Society, which by the charter had been limited to London and its environs was now extended to England and Wales, and fresh powers were given them to examine candidates and grant certificates to such as were qualified to practise as apothecaries or to act as assistants to apothecaries. The Act having recited, that "whereas it is the duty of every person using or exercising the art and mystery of an apothecary, to prepare with exactness, and to dispense such medicines as may be directed for the sick by any physician lawfully licensed by the president and commonalty of the Faculty of Physic of London, or by either of the Universities of Oxford or Cambridge," proceeds to enact that every apothecary shall be subject to a penalty if he refuse to make, mix, dispense, apply, or sell any medicines so prescribed by a physician, or if he negligently, falsely, or fraudulently prepare and sell such medicines. These, however, were mere confirmations of what had previously been considered to be the duties of an apothecary as defined in their Charter and in the Act of 1748. The important feature of the Act of 1815 is contained in the fourteenth clause, which specifies that no person thereafter, except those previously practising, shall be authorized to practise as an apothecary in England or Wales, unless he has been examined and has proved his skill and abilities *in the science and practice of medicine*, and his fitness and qualifications to practise as an apothecary. This gave to the apothecaries, by legal enactment, what they had previously assumed in opposition to many protests from physicians, namely, the right to practise medicine. The clause in the Act which exempts chemists and druggists from its operation as far as relates to "the buying, preparing, compounding, dispensing, and vending drugs, medicines, and medicinable compounds," established the right which chemists had also previously assumed in opposition to many protests from apothecaries, but it had become more important to have this right clearly defined, as now for the first time there were heavy penalties imposed on those who infringed the privileges of the apothecaries.

Under this Act the apothecaries entered upon a new career, and although it was some time before any marked change was observed in the general character of this part of the profession, yet gradually they have become more highly qualified for their professional duties, and being now merged in the great body of medical practitioners they occupy an important and honourable position among those to whom all medical and sanitary affairs are entrusted. Their weak point, no doubt, is materia medica and pharmacy, which might be advantageously relinquished by those who practise medicine if the habits and requirements, not to say the necessities, of the public would admit of it.

A long interval was allowed to elapse after the passing of the Apothecaries Act before any measures having a similar object were adopted for regulating the qualifications of chemists and druggists. What has since been done by the Pharmaceutical Society is too well known and appreciated by those I am addressing to require comment here. A distribution of medical and pharmaceutical duties has been gradually effected to meet the exigencies of a great mixed population, and to the extent to which these have been established by law the public are provided with the means of having their medical wants supplied by men well qualified in their several departments.

We represent one of these departments, in connection with which we are endeavouring to raise the standard of professional proficiency by promoting scientific research in those branches of knowledge which relate to the preparation of medicines. This is our special object, and although, for the purpose of meeting what has been represented as a present want among our members, I have referred to some historical details, it has been my desire to deal with them simply as matters of fact which are not intended for general discussion here. Our tendencies lie in another direction and I feel assured that the matter which will be submitted for our consideration, and the discussions relating to it, will show that we are following out our own proper subjects and advancing their scientific and practical study in a way best calculated to make the practice of pharmacy at once honourable and useful to those who are engaged or interested in its pursuit.

Mr. Balkwill (Plymouth) proposed a vote of thanks to the President for his opening address. Last year, at Glasgow, he had delivered an address which he characterized as an outspoken and eminently useful one, and that of this year seemed to be no less so. The future could only be judged by the past, and if there had been times of difficulty heretofore which had been safely passed through by those now occupying honourable positions in the community, it was highly encouraging to those who could not help seeing that the present time was one of transition in relation to pharmacy. The distinguishing mark of the present day was division of labour, and for his own part he accepted most thankfully the fact that their field of labour was entirely distinct from that of the medical man. At the same time their field lay side by side with that of the physician, and their duties could not be properly carried on without a knowledge of some of those matters which properly belonged to medicine, especially physiology and therapeutics. In nothing probably was there greater ignorance than in therapeutics, and he believed that most light was to be thrown upon it from the side of pure chemistry, and he wished therefore that those who were studying chemistry in the laboratory could have opportunities of studying it in the human body, because he believed that in this way more useful results might probably be derived than even from the ordinary practice of medicine. He just threw out this idea, but he must add that he was quite aware of the temptation to which such studies might give rise, and that some might be tempted to dabble in prescribing, and to become bad medical practitioners instead of good chemists. Still it must be remembered that no position in life was free from temptation, and this seemed to him to hold out a most promising field for research.

Mr. E. Smith (Torquay) seconded the motion which was put by Mr. Groves, as Senior Vice-President, and carried by acclamation.

The President having briefly thanked the meeting, the reading of papers was commenced.

(*To be continued.*)

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The meeting of the British Association for the Advancement of Science commenced on Wednesday, August 15, at Plymouth, under the presidency of Allen Thomson, M.D., L.L.D., F.R.S., F.R.S.E., who, according to usual custom, delivered the opening address:—

The President's Address.

After the long interval of six and thirty years the British Association for the Advancement of Science holds its annual meeting, the forty-seventh since its foundation, in this beautiful and interesting locality; and, strangely enough, on this occasion as on the former, it passes from Glasgow to Plymouth. We are delighted to be assembled here, and are even surprised that the Association has been able so long to resist the power of attraction by which it has been gravitating towards this place. While we are prepared to be charmed with the surpassing beauty of its scenery, and know the deep interest of its prehistoric vestiges, its historic memories, and its artistic associations, we have been frequently reminded of its scientific vigilance by the records of its active scientific work; and we are now ready and anxious to witness all we can behold of its energy and success in the application of scientific discovery to the practical arts. Should we, as might be expected in a place hitherto so famous in its relations to our naval and military history, find most prominent those relating to the mechanism of war, we shall still hope that the effect of greater perfection in the engines of destruction may only be the means of rendering peace more permanent and secure.

It is a source of regret to myself, and may be, I fear, a cause of detriment to this meeting, that the choice of a President should have fallen upon one whose constant occupation with very special branches of science has fitted him so inadequately for the distinguished position to which he has been called. I can only derive comfort from knowing that, wherever it may be necessary, there are many others present most able to supply what may be wanting on my part; and I must therefore at once bespeak their assistance and your indulgence.

I have selected for the subject of the remarks which I am about to offer for your acceptance a biological topic, namely, the "Development of the Forms of Animal Life," with which my studies have been occupied, and which has important bearings on some of the more interesting biological questions now agitating the scientific world. But before proceeding with the discussion of my special subject, it is my desire to call your attention shortly to the remarkable change in the manner of viewing biological questions which has taken place in this country during the last half century—a change so great, indeed, that it can scarcely be fully appreciated except by those who have lived through the period of its occurrence.

In the three earlier decades of this century it was the common belief, in this country at least, shared by men of science as well as by the larger body of persons who had given no special attention to the subject, that the various forms of plants and animals recognized by naturalists in their systematic arrangements of genera and species were permanently fixed and unalterable, that they were not subject to greater changes than might occur as occasional variations, and that such was the tendency to the maintenance of uniformity in their specific characters that, when varieties did arise, there was a natural disposition to the return, in the course of succeeding generations, to the fixed form and nature supposed to belong to the parental stock; and it was also a necessary part of this view of the permanency of species that each was considered to have been originally produced from an individual having the exact form which its descendants ever afterwards retained. To this scientific dogma was further added the quasi-religious view that in the exercise of infinite wisdom and goodness, the Creator, when He called the successive species of plants and animals into existence, conferred upon each precisely the organization and the properties adapting it best for the kind of life for which it was designed in the general scheme of creation. This was the older doctrine of "Direct Creation," of "Teleological Relation," and of "Final Causes;" and those only who have known the firm hold which such views had over the public mind in past times can understand the almost unqualified approbation with which the reasoning on these questions in writings like the 'Bridgewater Treatises' (not to mention older books on natural theology) were received in their time, as well as the very opposite feelings excited by every work which presented a different view of the plan of creation.

On the Continent of Europe, it is true, some bold speculators, such as Goethe, Oken, Lamarck, and Geoffroy St.-Hilaire, had, in the end of the last and commencement of this century, broached the doctrine that there is in living beings a continuous series of gradations as well as a consistent and general plan of organization, and that the creation, therefore, or origin of the different forms of plants and animals must have been the result of a gradual process of development or of derivation one from another, the whole standing connected together in certain causal relations. But in Britain such views, though known and not altogether repulsive to a few, obtained little favour, and, by some strange process of reasoning, were looked upon by the great majority as little short of impious questionings of the supreme power of the Almighty.

How different is the position of matters in this respect in our day!—when the cautious naturalist receives and adopts with the greatest reserve the statement of fixed and permanent specific characters as belonging to the different forms of organized beings, and is fully persuaded of the constant tendency to variation which all species show even in the present condition of the earth, and of the still greater liability to change which must have existed in the earlier periods of its formation—when the belief prevails that, so far from being the direct product of distinct acts of creation, the various forms of plants and animals have been gradually evolved in a slow gradation of increasing complexity—and when it is recognized by a large majority of naturalists that the explanation of this wonderful relation of connection between previously existing and later forms is to be found in the constant tendency to variation during development and growth, and the perpetuation of such variations by hereditary transmission through successive generations in the long but incalculable lapse of the earth's natural mutations. These, as you must all be aware, are in their essential features the views now known as Darwinism, which were first simultaneously brought forward by Wallace and Darwin in 1858, and which, after being more fully elaborated in the works of the latter and ably supported by the former, secured, in the incredibly short space of ten or twelve years, the general approval of a large portion of the scientific world. The change of opinion is, in fact, now such that there are few scientific works on natural history, whether of a special or more general character, in which the relation which the facts of science bear to the newer doctrines is not carefully pointed out; that, with the general public too, the words "evolution" and "development" have ceased to excite the feelings, amounting almost to horror, which they at first produced in the minds of those to whom they were equally unfamiliar and suspicious; and that, even in popular literature and ephemeral effusions, direct or metaphorical illustrations are drawn in such terms of Darwinian theory as "struggle for existence," "natural selection," "survival of the fittest," "heredity," "atavism," and the like.

It cannot be doubted that in this country, as on the Continent, the influence of authority had much to do with the persistence of the older teleological views; and, as has been well remarked by Haeckel, one of the ablest and keenest supporters of the modern doctrine, the combined influence more especially of the opinions held by three of the greatest naturalists and biologists who have ever lived, viz., Linnæus, Haller, and Cuvier (men unsurpassed in the learning of their time, and the authors of important discoveries in a wide range of biological science), was decidedly adverse to the free current of speculative thought upon the more general doctrines of biology. And if it were warrantable to attribute so great a change of opinion as that to which I have adverted as occurring in my own time, to the influence of any single intellect, it must be admitted that it is justly due to the vast range and accuracy of his knowledge of scientific facts, the quick appreciation of their mutual interdependence, and, above all, the unexampled clearness and candour in statement of Charles Darwin.

But while we readily acknowledge the large share which Darwin has had in guiding scientific thought into the newer tracks of biological doctrine, we shall also be disposed to allow that the slow and difficult process of emancipation from the thraldom of dogmatic opinion in regard to a system of creation, and the adoption of large and independent views more consistent with observation, reason, philosophy, and religion, has only been possible under the effect of the general progress of scientific knowledge and the acquisition of sounder methods of applying its principles to the explanation of natural phenomena.

I have already referred to Goethe, Oken, Lamarck, and Geoffroy St.-Hilaire as among the most prominent of the earlier pioneers in the modern or reformed conceptions of biological laws. But were it desirable to mark the progress of opinion by quoting other authors and labourers whose contributions have mainly supplied the materials out of which the new fabric has been constructed, I should have to produce a long catalogue of distinguished names, among which would be found those of Lyell and Owen, as earliest shaping the doctrines and guiding opinion in this country, Johannes Müller and Von Baer, as taking the places of Haller and Cuvier on the Continent, and a host of other faithful workers in biology belonging to the earlier part of this century, such as those of G. Treviranus, J. F. Meckel, Carus, and many more.* To Huxley more especially and Herbert Spencer the greatest influence on British thought in the same direction is to be ascribed.

Let us hope that in these times, when it has been found necessary to modify the older teleological views to so great an extent, although there may still be much that is unknown, and wide differences of opinion in regard to the nature and sequence of natural phenomena and the mode of their interpretation, all naturalists will now concur in one important principle, viz., that truthful observation and candid judgment must alone be our guides in the interpretation of nature, and that that theory of creation is most deserving of our adoption which is most consistent with the whole body of facts carefully observed and compared.

To attempt to trace, within the limits to which my remarks must be confined, the influence which the progress of knowledge has exercised upon the scientific and general conception of biological doctrines would be impossible, for the modification of opinion on these subjects has proceeded not less from the rapid advance which our age has witnessed in the progress of general science, especially of physics and chemistry, than from hat of departments belonging to biology itself.

Thus, to go no further than the most general laws of nature, the whole doctrine of the conservation and transmutation of force in physics, so ably expounded to this Association by Mr. Justice Grove, the theory of compound radicals and substitution, with the discovery of organic synthesis, in chemistry, and the more recent advance in speculation with regard to the molecular constitution and properties of matter, with which we must associate the names of our last President and of Clerk Maxwell, in completely changing the aspect of physical and chemical sciences within the last thirty-five years, have paved the way for views of the constitution and action of organized bodies very different from those which could be formed at the time of the first Meeting of the Association in this place. And if, confining ourselves to the department of Biology, we add the discovery by microscopical observation of the minuter elementary forms of organization, more especially as flowing from the comprehensive views of organized structure promulgated by Schleiden and Schwann nearly forty years ago, the later discovery and investigation of living protoplasmic substances, the accumulated evidence of progressive types of animal and vegetable forms in the succession of superimposed strata composing the crust of the earth, the recent discoveries as to the conditions of life at great depths in the ocean, the vast body of knowledge brought together by the labours of anatomists and physiologists as to the structure and functions of almost every plant and animal, and (still more, perhaps, than any other single branch of biological inquiry) if we note the rapid and immense progress which has been made during the last fifty years in the study of the entirely modern science of the development of living beings, we shall be able to form some conception of the enormous extension in our time of the basis of observation and fact from which biological phenomena may now be surveyed, and from which just views may be formed as to their mutual relations and general nature.

It is now familiarly known that almost all (if not, indeed, all) the plants and animals existing on the earth's surface derive their origin from parents or previously existing beings whose form and nature they closely reproduce in their life's history. By far the greater number spring from germs in the form of visible and known spores, seeds, or eggs; a few may be traced to germs, or to vestiges of the parental body, the exact nature of which may be doubtful; and some, including even a certain number of those also produced from known germs, are either constantly or occasionally multiplied by budding, or by a process of cleavage or direct and visible division of the parent body.

The germ constituting the basis of new formation, whether it have the form of spore, seed, or ovum, is of the simplest kind of organization, and the process by which a new plant or animal is produced is necessarily one of gradual change and of advance from a simpler to a more complex form and structure: it is one of 'evolution' or, as I would rather name it, 'development.' But before proceeding to discuss the subject of development in the higher animals, it is right to advert to the preliminary and often debated question, which naturally presents itself, viz.:—Do all living or organized beings, without exception, spring from germs, or from any kind of organized matter that has belonged to parents? or may there not be some, especially among the simpler forms (with regard, indeed, to which alone there has of late been any question), which are produced by the direct combination of their component elements, in the way of the so-called spontaneous or equivocal generation, heterogenesis or abiogenesis?

The importance of the right solution of this problem is not confined merely to the discovery of the mode of origin of the lowly organisms which have been the more immediate object of investigation by naturalists in recent times, but is one of much wider significance, seeing that, if it shall be satisfactorily proved or even rendered probable that in the course of cosmical development all the various kinds of plants and animals have been gradually produced by evolution out of preexisting simpler forms,

* It would also be unjust to omit to mention here one of the earliest attempts to bring British opinion into a new channel, by the remarkable work entitled 'Vestiges of Creation,' which appeared in 1844, nor to conceal from ourselves the unmerited ridicule and obloquy attempted to be thrown upon the author, not perhaps so much on account of the many inaccuracies unavoidable in an attempt at the time to overtake so large a field, as directed against the dangerous tendencies supposed to lurk in its reasoning.

and thus the whole series of organized beings in nature has been shown to be one of hereditary connection and derivation, then it would follow that the history of the origin of the simplest organisms may be the key to that of the first commencement of life upon the earth's surface, and the explanation of the relation in which the whole succeeding progenies stand to their parental stocks.

From the very lucid and masterly view of this subject given by Professor Huxley in his Address to the Association at Liverpool, so recently as in 1870, in which the conclusion he formed was based very much on the exhaustive and admirable researches of Pasteur, I might also have dispensed with making further reference to it now, but for the very confident statements since made by the supporters of the doctrine of abiogenesis, among whom Dr. Bastian stands most prominent in this country, and for the circumstance that the life-history of many of the lower organisms was still imperfectly known.

During the last seven or eight years, however, renewed investigations by most competent inquirers have followed one another in quick succession, from a review of which we cannot but arrive at a conclusion adverse to the theory of heterogenesis, viz., that no development of organisms, even of the most simple kind, has been satisfactorily observed to occur in circumstances which entirely excluded the possibility of their being descended from germs, or equivalent formative particles, belonging to preexisting bodies of a similar kind. I can do no more now than name the authors of the most conclusive experiments on this subject, which I do nearly in the order of the publication of their researches, as those of Mr. W. N. Hartley in 1872, Messrs. Pode and Ray Lankester in 1873, Dr. Burdon Sanderson in that and the following years, Dr. W. Roberts in 1874, Professor Lister in 1875, and most recently of Professor Tyndall, Professor Cohn, and of Messrs. Dallinger and Drysdale.*

But, admitting that the evidence from direct experiment is such as entirely to shut us out from entertaining the view that spontaneous generation occurs in the present condition of the earth, we are not relieved from the difficulty of explaining how living organisms or their germs first made their appearance, nor are we debarred from attempting to form hypotheses as to how this may have taken place. First, upon the theory of evolution, which, strictly carried out, supposes the more complex organisms to be derived from the more simple, it might be held that the conditions affecting the combination of the primary elements of matter into organic forms may at one time have been different from those which now prevail, and that, under those different conditions, abiogenesis may have been possible, and may have operated to lay the foundations of organic life in the simpler forms in which it at first appeared—a state of things which can only be vaguely surmised, but in regard to which no exact information can be obtained. Or, secondly, evading the difficulty of strict cosmical evolution, we might suppose that vital conditions may have been coeval with the first existence of physical and chemical properties in the rest of natural bodies. But this hypothesis would be exposed to the objection that, according to the cosmical view generally held by physicists, the whole materials composing the earth have originally been subjected to incandescent heat. Nor is the difficulty abolished, but only removed to a more remote period, by the supposition of the transport of germs from another planet or their introduction by means of meteorites or meteoric dust; for, besides the objection arising from the circumstance that these bodies must have been subjected to a very high temperature, we should still have everything to learn as to the way in which the germs arose in the far distant regions of space from which they have been conveyed.

The incompleteness of the geological record leaves us in the dark as to the time at which the first dawnings of life appeared in the lower strata of the earth's surface. The most recent researches tend to carry the origin of life back to a much earlier period than was at one time believed, and (if the famous *Eozoon* be admitted as evidence) even into that of the Laurentian strata. But even if doubts should prevail with regard to the presence of definite organized forms in the older sedimentary strata, the occurrence in them of carbon in the form of graphite in large quantities makes the previous existence of living organisms at least possible, and it may be that the complete metamorphosis which these rocks have undergone has entirely removed all definite traces of organization.

Nor have we the means from geological data of determining whether the beings of the vegetable or of the animal kingdom first made their appearance. If we adopt the view which has for some time been entertained by physiologists that animals are entirely dependent, directly or indirectly, on plants for the material which constitutes their living substance, and that plants, as constructive agents, alone have the power to bring together the elements of lifeless matter, from such states as carbonic acid, water, and ammonia, into the condition of the living solid, the inference would be inevitable, at least for the great majority of the animal creation, that they must have been preceded by plants. But palæontology is as yet silent on this interesting question; and, if we consider the remarkable approach which is made in structure and properties between the lowest and simplest members of the two kingdoms of organic nature, so that at last all distinction between them seems entirely to vanish, and a set of organisms is found which partake equally of animal and vegetable characters, or, rather, exhibit properties which are common to them both, we shall hesitate to postulate confidently for the primitive antecedence of vegetable life, although, perhaps, in later epochs the preexistence of vegetables may be looked upon as necessary to the life of more developed animal organisms.

The reflection forces itself upon us that we are just as ignorant of the mode of first origin of all the compounds of the inorganic elements as we are of that of living matter; and we may therefore be excused if we suspend all theory and conjecture until we shall be guided to more reliable hypotheses through the plain track of observation and experiment.

The practical applications of the increased knowledge of the origin of minute animal and vegetable organisms are so numerous that it would occupy a much longer

---

* I may refer to Dr. Bastian's paper in *Nature*, of June 30, 1870, and to his two works, 'The Origin of the Lowest Organisms,' and 'The Beginnings of Life,' and papers to Roy. Soc. 1873. Mr. Hartley's researches, which were commenced in 1865, are described in a paper printed in the 'Proceedings of the Royal Society,' for 1872, and in his 'Lectures on Air,' 2nd edition, 1876, where an interesting account of the whole subject will be found. The experiments of Mr. Pode, of Oxford, and Professor Ray Lankester are described in a paper on the 'Development of *Bacteria* in Organic Infusions,' in the 'Roy. Soc. Proc.', 1873, vol. xxi., p. 349. Dr. Burdon Sanderson's researches are contained in the Reports of the Medical Officer of the Privy Council, and in various papers in *Nature*; Dr. W. Roberts's paper is printed in the 'Transactions of the Royal Society.' for 1874, vol. clxiv., p. 457. Professor Lister's 'Contribution to the Germ Theory of Putrefaction and other Fermentative Changes,' etc., is contained in the 'Transactions of the Royal Society of Edinburgh,' for 1875, p. 313, and is also given in *Nature*. Professor Tyndall's researches are described in his papers in the 'Proceedings of the Royal Society' during the last two years. The work of Professor Cohn, of Breslau, entitled 'Beiträge zur Biologie der Pflanzen,' 1873-76, contains many memoirs bearing upon this subject, which have been partly published in abstract in the *Microscopical Journal*, in which also will be found, in a series of contributions extending from 1873 to the present time, the interesting observations of Mr. W. H. Dallinger and Dr. J. Drysdale.

time than is at my disposal to give any detailed account of them; but they are of such immense importance in their commercial, social, and sanitary relations that they ought never to be lost sight of.

It is now proved beyond doubt that the origin of putrefaction and fermentation is dependent on the presence in the substances which are the seat of change in these processes, or in the surrounding air, of the germs of minute organisms of an animal or vegetable nature, and that the maintenance of the chemical changes in which these processes mainly consist is coincident with and casually (if not essentially) dependent upon the growth and multiplication of these organisms.

Professor Lister had the merit of being the first to apply the germ theory of putrefaction to explain the formation of putrid matters in the living body; and he has founded on this theory the now well-known antiseptic treatment of wounds, the importance of which it would be difficult to overestimate.

The success or failure of plans for the preservation of meat and other articles of food without question depends on the possibility of the complete exclusion of the germs which are the cause of putrefaction and fermentation; and their management must therefore be founded on the most accurate knowledge of these organisms, and the circumstances influencing the persistance of their vitality and the vigour of their growth.

The theory of biogenesis has also lately been the guide in the investigation of the causes of various forms of disease, both in the lower animals and in man, with the result of showing that in many of them the infective substance consists, in all probability, of germs of minute animal or vegetable organisms.

There is very great probability, indeed, that all the zymotic diseases (by which we understand the various forms of fevers) have a similar origin. As has been well remarked by Baxter in an able paper on 'The Action of Disinfectants,' the analogies of action of contagia are similar to those of septic organisms, not to processes simply of oxidation or deoxidation. These organisms, studied in suitable fluids, multiply indefinitely when introduced in all but infinitesimal proportions. Thus they are, as near as we can perceive, the very essence of contagia.*

Leaving, however, these and many other general questions regarding the origin of the lowest forms of animal and vegetable life, let us now turn our attention to the mode of development of a new being in those belonging to the higher groups. The general nature of the formative process, in all instances where fertilized germs are produced, will be best understood by a short sketch of the phenomena ascertained to occur in different kinds of plants.

In the higher or phanerogamic plants it is generally well known that the combination of two parts of the flower is necessary to the production of a seed containing the embryo or young plant. Beginning with the discovery of the pollen-tubes by Amici in 1823, the careful and minute investigations of a long line of illustrious vegetable physiologists have brought to light the details of the process by which fertilization is effected, and have shown, in fact, how the minute tube developed from the inner membrane of the pollen-granule, as soon as it falls upon the stigmatic tissue of the seed-bearing plant, insinuates itself by a rapid process of development between the cells of the style, and reaches at last the ovule, in the interior of which is the embryo-sac; how, having passed into the micropyle or orifice of the ovule, it makes its way to the embryo-sac; how a minute portion of the fertilizing substance of the fovilla transudes from the pollen-tube into the cavity of the embryo-sac, in which by this time a certain portion of the protoplasm has become differentiated into the germinal vesicle—thereby stimulating it to further growth and development, the earliest phenomena of which manifest themselves by the formation of an investing cell-wall, and by the occurrence of cell-division which results in the formation of the embryo or plantule of the seed.

Thus it appears that the essential part of the process of production in phanerogamic plants is the formation in the parent plant of cells of two different kinds, which by themselves have little or no independent power of further growth, but which, by their union, give rise to a product in which the power of development is raised to the highest degree.

By further researches it is now known that the same law prevails in all the remaining members of the vegetable kingdom, with the exception only of the very simplest forms.*

In viewing the reproductive process in the series of cryptogamic plants, two facts at once strike us as remarkable in the modifications which are observed to accompany the formation of a productive germ, viz. :—first, that the difference between the two productive elements becomes as it were more prominent, or more highly specialized, in the cryptogamic than in the phanerogamic plants; and second, that in the simpler and lower forms this difference gradually disappears till it is lost in complete uniformity of the productive elements.

Thus in the whole tribe of the Ferns and Cryptogams, in the higher Algæ and Fungi, in the Characeæ and in the Mosses, the differentiation of the productive elements is carried to a very high degree; for while that belonging to the embryo or germ presents the structure of a simple cell which remains at rest, or in a comparatively passive state, and, absorbing into itself the substance of the other, becomes the seat of subsequent development, the other, corresponding to the pollen of the staminiferous phanerogam, is usually separated from the place of its formation, and, having undergone a peculiar modification of structure by which it acquires active moving cilia, it changes place and is directed towards the germinal structure, and, coming in contact with its elementary cell, is more or less absorbed or lost in the fertilizing process. The protoplasm of the germinal cell thus acted on and fertilized then proceeds to undergo the changes of development by which the foundation is laid for the new plant.

In the Algæ and Fungi, however, there are gradations of the differentiation of the two reproductive cells which are of the greatest interest in leading to a comprehension of the general nature of the formative process. For in the lower and simpler forms of these plants, such as the Desmidieæ, Mesocarpeæ, and other Conjugatæ, we find that there is no distinction in structure or form to be perceived between the two cells which unite or undergo conjugation; and a complete fusion or intermixture of the two masses of protoplasm results in the production of a single, usually spherical, mass holding the place of an embryo. And that there is an absence of specialization between the two uniting cells is clearly shown, in both *Desmidium* and *Mesocarpus*, by the fact that the embryo or zygospore is formed in the mass resulting from the union of the protuded portions of the two cells; and in more ordinary cases, as in *Spirogyra*, where the embryo is formed in one of the two cells, it seems to be indifferent in which of them it is formed.

From this, which may be regarded as the most elementary type of new production by the union of the two cells, the transition is not a great one to the development of a progeny without any such union. We might conjecture, then, that the capacity for separate or individual existence extends in the lowest organisms to the

* For the most interesting information on this subject, I cannot do better than refer to the very able Reports by Dr. Burdon Sanderson in the 'Reports of the Medical Officer of the Privy Council,' 1873, 1874, and 1875.

* It will be observed that I leave entirely out of view the whole subject of the multiplication of plants by budding or simple division.

whole or to each structural element of their organization, while as we rise in the scale of vegetable life (and the same view might apply to the animal kingdom) this capacity is more and more divided between the two productive elements, or at least, is only called into full action by their combination.

The germinal element consists of a simple primordial cell, varying in different kinds of plants, but in all of them probably containing the essential substance protoplasm; and the most immediate result or effect of fertilization is the multiplication by repeated fissiparous division of the previously existing cells. The new individual resulting from this cellular growth usually remains within the parent body, without, however, direct union or continuity of tissue, till the embryo has attained some advancement, as in the well-known case of the seeds of a phanerogam; but there are many varieties in the mode of its disposal among the lower plants.

A remarkable exception to the more direct relation of the process of fertilization to the formation of the new individual or embryo occurs in some plants, simulating in some respects that kind of variation in animal reproduction which has been named alternate generation. A well-known instance of this belongs to the Vascular Cryptogams. The prothallium of the Ferns, for example, results from the development of so-called spores or unicellular buds, which are familiar as being formed in small capsules on the lower leaf-surface; and in this prothallium, when it has reached a certain stage of vegetation, there are formed the archegonia, containing the oospheres or germ-cells, which are fertilized by the moving ciliated particles developed in the cells of the antheridia, leading to the production of a new spore-bearing plant.

Recent researches have also called attention to the remarkable arrangements in phaneroganic plants for the prevention of fertilization of the pistils by pollen from the same flower, or even from the same plant. In the latter case this is effected by the separation of stamens and pistils in different flowers on the same or on different plants. In the former case, where both organs occur in the same flower, the adaptations, whether of a mechanical or of a physiological character, by which self-fertilization is prevented, as ascertained by numerous recent investigations (among which those of Darwin are most conspicuous), are of the most varied and often the most complicated kind.

Let us now turn to the consideration of the Development of Animals; and let me say in the outset that it will be necessary for me to confine my remarks chiefly to the higher or vertebrated animals, and to certain parts only of the history of their development—more particularly the structure and formation of the ovum or egg, its earlier developmental changes, and the relation of these to the formation of the new animal.

I cannot enter upon the consideration of this topic without adverting to the very recent acquisition of some of the most important facts upon which this branch of knowledge is founded; and I feel it to be peculiarly appropriate, in the year of his death, to refer to a biologist whose labours contributed more powerfully than those of any other person to give to animal embryology the character of a systematic branch of science, and to whom we owe some most important original discoveries—I mean Karl Ernest von Baer, of Königsberg, St. Petersburg, and Dorpat.

Of observers who, previous to Von Baer, were mainly instrumental in preparing the way for the creation of a more exact modern science of embryology only two can be mentioned, viz., Caspar Frederick Wolf, of St. Petersburg, well know as the author of a work entitled 'Theoria Generationis,' published in 1759, by which the *epigenesis* or actual formation of the organs in a new being was first demonstrated, and Christian Pander, who, by his researches made at Würzburg, explained, in a work published in 1817, the principal changes by which the embryo arises and is formed.

Von Baer was born in the Russian province of Esthonia on the 29th of February, 1792. After having been fifteen years professor in the Prussian University of Königsberg, he was called to St. Petersburg, and having some years later been appointed to a newly established professorship of comparative anatomy and physiology, he remained in that city for nearly thirty years as the most zealous and able promoter of scientific education and research, stimulating and guiding all around him by his unexampled activity, comprehensive and original views, sound judgment, and cordial cooperation. In 1868, at the age of 76, he retired to Dorpat, from the university of which he had received his degree in 1814, and continued still to occupy himself with working and writing in his favourite subjects, as well as interesting himself in every thing that was related to educational and scientific progress, to very near the time of his death, which occurred on the 28th of November, 1876, in his 85th year.

Although Von Baer's researches, according to the light in which we may now view them, contributed in no small degree to the introduction of the newer views of the morphological relations of organic structure which have culminated in the theory of descent, yet he was unwilling to adopt the views of Darwin; and one of his latest writings, completed in the last year of his life, was in vigorous opposition to that doctrine.

It would have been most interesting and instructive to trace the history of the progress of discovery in embryology from the period of Von Baer down to the present time; but such a history would not be suitable to the purpose of this address; and I can only venture here, in addition to Rathke, the colleague of Baer in Königsberg, to select two names out of the long list of distinguished workers in this field during the last forty years, viz.:—Thomas Bischoff, of Giessen and Munich, to whom we owe the greatest progress in the knowledge of the development of mammals, by his several memoirs, appearing from 1842 to 1854; and Robert Remak, of Berlin, whose researches on the development of birds and batrachia, appearing from 1850 to 1855, gave greatly increased exactness and extension to the general study of development.

The germinal element from which, when fertilized, the new animal is derived is contained within the animal ovum or egg—a compact and definite mass of organic matter, in which, notwithstanding great apparent variations, there is maintained throughout all the members of the animal kingdom, excepting the protozoa, which are destitute of true ova, a greater uniformity in some respects than belongs to the germinal product of plants.

Usually more or less spherical in form, the animal ovum presents the essential characters of a "complete cell," in the signification given by Schwann to that term. The germinal substance is enclosed by an external vesicular membrane or *cell-wall.* Within this covering the *cell-substance* (generally named yolk or vitellus, from the analogy of the fowl's egg) consists, to a greater or less extent, of a mass of protoplasm; and imbedded in this mass, in a determinate situation, there is found a smaller internal vesicular body, the *germinal vesicle* or nucleus, with its more or less constant or variable *macula* or nucleolus.

Now the first thing which strikes us as remarkable connected with the ovum is the very great variation in size as compared with the entire animal, while in all of them the same simple or elementary structure is maintained. The ovum of mammals is, for example, a comparatively small body, of which the average diameter is about $\frac{1}{150}$ of an inch, and which consequently scarcely weighs more than a very minute fraction of a grain, which may be calculated perhaps only at the $\frac{1}{12000}$ part. And further, in two animals differing so widely in size as the elephant and the mouse, the weights of which may be held to stand towards each other in the proportion of 150,000 to 1, there is scarcely any difference in the size of the mature ovum.

On the other hand, if we compare this small ovum of the mammal with the yolk of the egg in the common fowl the part to which it most nearly corresponds, it may be estimated that the latter body would contain above three millions of the smaller ova of a mammal.

The attribute of size, however, in natural objects ceases to excite feelings of wonder or surprise as our knowledge of them increases, whether that be by familiar observation or by more scientific research. We need not, at all events, on account of the apparent minuteness of the ovum of the mammifer or of any other animal, have any doubts as to the presence of a sufficient amount of germinal substance for explaining in the most materialistic fashion the transmission of the organic and other properties and resemblances between the parent and offspring. For we are led to believe, by those who have recently given their attention to the size of molecules composing both living and dead matter, that in such a body as this minute ovum of the mammal there may be as many as five thousand billions of molecules; and even if we restrict ourselves to the smaller germinal vesicle, and, indeed. to the smallest germinal particle which might be made visible by the highest microscopic enlargement, there are still sufficient molecules for all the requirements of the most exacting material biologist.*

This great disparity of size, however, is connected with an important difference in the disposition of the yolk-substance, according to which ova may be distinguished as of two kinds—the large- and the small-yolked ova, between which there are also many intermediate gradations. The larger-yolked ova belong to the whole tribe of birds, scaly reptiles, osseous and cartilaginous fishes, and the Cephalopods among the Invertebrates; and are distinguished by the strictly germinal part or protoplasm being collected into a small disk, known familiarly as the cicatricula of the fowl's egg, and to be seen as a whitish spot on that side of the yolk which naturally floats uppermost, while the rest of the yolk, of a deeper yellow colour, contains a large quantity of vitelline granules or globules of a different chemical nature from the protoplasm.

The phenomena of embryonic development are, in the first instance at least, confined to the germinal disk, and the rest of the yolk serves in a secondary or more remote manner to furnish materials for nourishment of the embryo and its accessory parts. Thus we distinguish the germinal from the nutritive or food-yolk, or, as the younger Van Beneden has named them, the *protoplasm* and the *deutoplasm*.

In the smaller ovum of the mammal, on the other hand, it seems as if the whole, or nearly the whole, of the yolk were protoplasmic or germinal. There may be some admixture of yolk-granules; but there is not the marked separation or limitation of the protoplasmic substance which is so distinct in birds, and the earliest changes of development extend to the whole component substance of the yolk, or, in other words, the yolk is entirely germinal. Hence some have given the names of *meroblastic* and *holoblastic* (meaning partially and entirely germinal) to these two contrasting forms of ova. There are many of the invertebrate animals of which the ova present the same entirely germinal arrangement as in those of mammals, and the *Amphioxus* may be included in the same group.

The Amphibia stand in some measure between the two extremes—the purely protoplasmic or germinal part occupying one side, and the nutritive or vitelline the other. But among the Invertebrates the gradations are often such as to make it difficult to determine under which group the ova should be placed.

The genesis or formation of the ovum itself, if it be considered with reference to its first origin, carries us back to a very early period of the formation of the parent in which it is produced; and it is one of the most interesting problems to determine what is the source of the cells in the parent from which the ova originally spring. All that I can venture to say at present in regard to this point is, that the primordial ova or germs appear in the parental body, while still embryonic, at a very early period of its development, and clearly derive their origin from a deeply-seated part of the formative cells which are undergoing transformation into the primitive organs; but the exact seat of the origin of the reproductive cells is still a matter of doubt.

When the ovum attains its full maturity in the ovary, the seat of its formation within the parent, it is separated from that organ, and when perfected proceeds to undergo embryonic development, a marked difference in this respect existing between the germinal product of the higher plants and animals.

The period of maturation of the ovum is marked in the greater number of animals by a series of phenomena which have generally been interpreted as the extrusion or absorption of the germinal vesicle; and various observers have actually traced the steps of the process by which that vesicle appears to leave the yolk and is lost to sight, or has passed into the space between the yolk and its membrane in the shape of the peculiar hyaline bodies named the *polar* or *directing* globules. But recent researches, afterwards to be referred to, tend to show that some part at least of the substance of the germinal vesicle remains to form, when combined with the fertilizing element, the newly endowed basis of future development.

(*To be continued*).

* According to a calculation made by Mr. Sorby, the number of molecules in the germinal vesicle of the mammalian ovum is such that if one molecule were to be lost in every second of time, the whole would not be exhausted in seventeen years. Obituary.

JOHN HUSKISSON.

John Huskisson, the late father of the chemical trade, was born on Christmas Day, 1789, at the Old Bath House, Cold Bath Fields, his father's residence. In the adjoining neighbourhood his father, Samuel Huskisson, in conjunction with his brother, Thomas Huskisson, and uncle, George Towers, were carrying on the business of manufacturing chemists, being a continuation of that first founded in the latter half of the seventeenth century by Dr. Samuel Towers, their direct lineal ancestor, in Oxford Street, or Oxford Road, as it was then called. Previous to this the apothecaries of that day, the precursors of the present race of chemists and druggists, were accustomed to prepare their chemicals on the leads of their houses, and it was Dr. Towers who was the first to carry out the idea of establishing a laboratory to manufacture chemicals for them.

John Huskisson was educated at Enfield, at the school of

Dr. Clarke, whose son, Charles Cowden Clarke, the writer, afterwards became his relative by marriage. John Keats, the poet, was his schoolfellow, and when Keats came to London to study medicine at St. Thomas's Hospital, he spent many pleasant evenings in the laboratory in Little Warner Street. Upon leaving school his father, anxious that before he entered the chemical trade he should have a good commercial education, placed him for a few years with Messrs. Green, the eminent merchants of the City of London, and it was there that he acquired those strict habits of business, which always distinguished him. His father separated from his partners, and went into business by himself in Swinton Street, at the commencement of the present century, where in 1811 his son joined him, the firm being then Samuel Huskisson and Son, from which time until January 1861 (when he retired) he was actively engaged in the business, which he then left to his brother and his nephews, one of whom still carries it on. He died at his residence, Colonnade House, Upper Holloway, on the 24th July last, in his 88th year.

He was a member of the Pharmaceutical Society from the commencement, and though never taking any office otherwise than once being auditor, in the troubled times of the Society many disputed points were settled by him when surrounded by his friends of both sides under the old cedar tree in his garden.

Counter Practice.

Sir,—The burning question of "Chemists' Prescribing," has derived an accession of heat from the recent systematic enforcement of a statute supposed to be levelled against the practice. Whether this be persecution or not matters little, but it is of absorbing interest that a question which concerns the peace of pharmaceutists and the convenience of the public should be removed from the realms of hazy legislation, and that it should be clearly established, whether the liberty of the subject is to be subordinated to the jealousies of the two departments of medicine.

It is not a question which may be left to look after itself in an unequal contest between a powerful organization and individual offenders (?). The Pharmaceutical Society owes it to its members to take up the cudgels in their behalf, and to propound the general aspect of the case in a manner unattainable by an individual tainted with the imputation of breaking the law. It is satisfactory to see that the Council have thrown off their usual (and commendable) reserve, and have "authorized their solicitor, at his discretion, and at the expense of the Society to defend the gentlemen referred to, in the threatened prosecution by the Apothecaries' Company." Further, it appears likely that in October next, the Council may be invited to consider a more important proposition in the form of a motion, "that the Council communicate with the Apothecaries' Company, and endeavour to arrive at some amicable arrangement as to the limits which should be laid down as unobjectionable." Let the Council beware of the fundamental error which lurks in such an "arrangement," and let them avoid action which acknowledges the dependence of the pharmaceutical body upon any other corporation, medical or non-medical.

Pharmacy holds and must maintain an equal position under the laws of the country with any of those bodies.

The onslaught upon certain pharmaceutists, who in all probability are not more criminal than their neighbours, is obviously dictated by anxiety on the part of its promoters for the extension of their fees. It must be acknowledged that the attack has been resented in a similar spirit, and that troubled pharmaceutists have exclaimed with Demetrius of old, "Our craft is in danger." We may discuss both considerations as outside the record, but we must not forget that a third party is involved whose liberty and convenience is directly assailed, and whose power is omnipotent.

Is there any doubt of the utter inability of the medical profession to grapple with the innumerable demands made by the public upon the ever accessible pharmaceutist?* Is there any doubt that the pharmaceutist supplies a real want with considerable success? Or does any one believe that the public would tolerate the withdrawal of this accommodation if there was any possibility of putting the proposed prohibition into actual operation?

The real grievance is that while chemists are compelled, often unwillingly, to give advice in minor ailments; while the public will have it or be "highly offended" (even in such grades as resort to the pharmacy of a respected member of the Council in the West End of London) they do so with a halter round their necks, giving their best services and making no charge. I wonder if there is a single Judge upon the Bench, Baron Bramwell included, who has not provoked the act which he rules to be contrary to law!

I will raise no false issues; the whole purpose of my letter is to remove this question to its rightful position as one of public necessity, for which if the law does not now provide it must be made to provide. I will not dwell as I easily might upon the qualifications of those "assistants accustomed to prescribing but not duly qualified," for whom medical practitioners advertize, and whom they presumably employ—nor will I enlarge upon the character of the advice and remedies meted out to the Working Men's Clubs contracted for at 2*d* per head. It is not upon the platform of trades-unionism that the real issue must be decided. Rather let me indicate in a few words the course which in my judgment should be taken.

I have already said that no attempt should be made to settle by compromise the interests of two parties in a question in which *three* are concerned, the third more materially than the other two; but an arrangement might be made to test the present state of the law by a typical case, fairly representing the every day experience of an average pharmacist—and let it be understood that if this goes against us, we shall agitate for the repeal of the law as antagonistic to public necessity.

Let some *bonâ fide* customer, who is determined not to spend a series of half guineas which perhaps he can ill afford, apply to his accustomed chemist for medicine for his children suffering from a prevailing epidemic; let the chemist fill up the measure of his iniquity by actually inspecting the child, and diagnosing "Whooping Cough," and let him furnish one of those remedies with which every experienced *nurse* is familiar. Let such a case be tried upon even terms, that is to say, with the authority of the Pharmaceutical Society upon the one side, against the Society of Apothecaries upon the other. And let our Society stand to its guns without flinching, instead of damning their case from the outset with faint encouragement. Then shall we know either that such a transaction as any man, woman, or midwife might perform with impunity, is in the eye of the law innocent when done with the greater experience of a pharmaceutist, or, that the laws of England condemn the perpetrator of this enormity to a fine of £...(I don't know whether the judge has the power to send a hardened offender to goal), and by consequence that it condemns paterfamilias to a fine of indefinite amount in fees which middle class families do not now think it necessary to incur.

In the latter event it would be the duty of the Society to take action for obtaining the repeal of a law which cannot possibly be enforced, because it is antagonistic to the habits, instincts, and convenience of the people; and we should be thankful to those whose ill-advised zeal to sketch the limits of an oppressive statute has led to its abrogation.

One who has fallen out of the Ranks.

W. Bradshaw, F. C. Clayton, T. Fore, and Spes.—Your communications should have been sent to the publishers.

Communications, Letters, etc., have been received from Messrs. Hoddinott, Barry, Whitelaw, Baildon, J. B. L. Mackay, Welborn, Gardner, Dr. A. S. Taylor, Ph. Chemist, An Associate, Devonian, Juvenis, Young Associate in Business, A Jersey Chemist, H. P., G. W., M. B., W. T., G., J. B., W., J. G., T. T. B.

We are compelled from want of space to defer publication of several communications.

* Are they not at the present moment rebelling vehemently against the alleged abuse of the medical charities, although these constitute their chief means of meeting that class of cases which resort to the chemist for advice?

"THE MONTH."

August is preeminently the harvest time of the year, and it is not less so for the dealer in medicinal plants than for the agriculturist. Many of the plants which have been in blossom during the past two months are now in their full maturity and will soon fall beneath the sickle and find their way into the insatiable evaporating pan or gigantic still. In various districts around London the air is already scented with the perfume of the lavender, marjoram, savory, thyme, balm and mint, and many other sweet herbs. Even in the great metropolis the passer by is every now and then saluted by a whiff of delicate odour from the stock in trade of some itinerant lavender seller. Soon, too, the undulating hills of Kent and Surrey will present a scene of intense activity and bustle and the air will be redolent of the powerful aroma of the hop, whose elegant festoons of fruit will grace many a cottage parlour for months to come.

Scarcely more than four hundred years ago the hop was called an unwholesome and wicked weed, and parliament was petitioned against its use as an ingredient in beer. But times and tastes have altered, and the immense warehouses in the neighbourhood of Southwark Street bear witness to the favour with which the hop is now universally received and to the enormous quantity which is consumed every year.

The plant itself is interesting from a botanical point of view. The pistillate or female plant is alone propagated by hop growers, and as the plant is diœcious it would, at first sight, appear impossible that the plant should produce fruit without the proximity of male plants. Singularly enough, under these circumstances the plants become to a certain extent monœcious and produce sufficient staminate flowers to fertilize the pistillate ones. The former are arranged in loose panicled cymes arising from the axils of the upper leaves. Each flower has five linear obtuse sepals and five stamens scarcely exceeding the calyx, the anthers are rather long, and the filaments very short and slender. The pistillate flowers consist of small dense catkins arranged either simply or in a panicled manner in the axils of the upper leaves. Each catkin consists of concave membranous bracts (which afterwards enlarge and form the strobile), each of which has a single ovary enclosed in a sepal at its base. The sepal is covered with minute glands, which when separated from the hops by sifting form the lupulin of commerce. For the sake of uniformity it would be better that this name should be kept for the bitter principle of the hop, and lupulite (a term which is sometimes given to the bitter principle) reserved for the glands. This arrangement has been followed in Sowerby's 'Botany,' and is worthy of being followed in works on materia medica.

The chamomile (*Anthemis nobilis*, L.), which was briefly alluded to in June, is now in full maturity, and may be found abundantly on grassy commons; even so near London as Clapham Common it may be found in plenty. The creeping habit and strong odour of the plant at once distinguishes it from the many other plants which have flowers similar in appearance. Only the flowering stalks are erect, and these usually bear only one blossom, although the flowering axis is sometimes branched below, and then bears two or even three flowers. The flower, or more properly flower-head (capitulum), consists of an outer ring of bracts (phyllaries) surrounding a number of florets. If these florets are pulled off there will be found other membranous bracts (paleæ) between each of the florets. When the paleæ are removed the solid conical receptacle will come into view. It will be remembered that the shape and consistence of the receptacle and the presence of paleæ distinguish this plant from the *Matricaria Chamomilla*, L. Upon careful examination with a lens, it will be found that the outer white ligulate florets (florets of the ray) have only a pistil and forked stigma, while the yellow tubular florets in the centre (florets of the disk) have a regular corolla with five teeth, and five united (syngenesious) anthers surrounding the pistil. The florets open from the circumference towards the centre (centripetally) of the flower-head. The florets of the ray, having no pollen to produce, are enabled to enlarge the corolla and thus render the flower conspicuous, and thereby attract insects. Under cultivation this property is increased, and many double composite flowers, such as the dahlia and chrysanthemum, are formed by the development of the corollas of the central florets at the expense of the stamens. The same thing happens in the double chamomile. It may be here remarked that the single chamomiles of commerce are almost always more or less "double," and can practically only be distinguished by the presence of a very few yellow florets in the centre and by the florets being narrower than in the flowers which are called double in trade.

The way in which the pollen is discharged from the tube formed by the united anthers is very curious. The style is at first shorter than the anthers, and its two stigmas are folded together so closely that the style does not appear to have any. By the growth of the style the pollen is pushed before it out of the top of the anther tube. The stigmas then protrude beyond the corolla, and separate so as to expose their sticky surface. The florets are therefore incapable of fertilizing their own stigmas. The two stigmas are best seen by examining a floret near the circumference first, and then comparing it with a central unopened one.

The wormwood (*Artemisia Absinthium*, L.) although not now official, is too widely known and used to pass altogether unnoticed. It cannot be called a very common plant in this country, although widely distributed and often very abundant where it occurs. In the neighbourhood of old villages in hilly districts, it may occasionally be found, and is easily recognized by its powerful odour and hoary, finely cut leaves. The small greenish yellow flower heads are arranged in erect rather leafy panicles. The florets are all tubular, and the outer row contains only pistils. The phyllaries are in two rows, the outer linear and silky, the inner rounded and membranous. Like *Matricaria*, *Tanacetum*, and *Anthemis*, the plants of this genus are without pappus. The ash of the plant contains a considerable quantity of carbonate of potassium, hence the origin of the name of salt of wormwood. Another species, very common in hedges, *Artemisia vulgaris*, or mugwort, is often used for fomentations in some parts parts of England. The flowers are very similar in general appearance, but the leaves are white on the under surface only, the upper being dark green.

The golden yellow heads of the tansy (*Tanacetum vulgare*, L.), with its elegant fern-like leaves, may now be seen adorning the hedgerows or damp wayside. The leaves are bipinnatifid and serrate, and the flower-heads have no ligulate florets, although the outer row of florets consists of pistillate flowers only. The odour of the plants is strong and camphoraceous. It is said to possess stomachic and anthelmintic properties.

Several other plants belonging to the compositæ are now in blossom. The burdock (*Arctium majus*, Schk.), of which the seeds were formerly official, and the roots are still highly esteemed in many of the provinces for their alterative properties. The plant owes its name to the burrs or flower-heads armed with hooked phyllaries which cause them to adhere to the passer by. This plant is cultivated in Japan as a vegetable, under the name of Gobo.

Yarrow (*Achillea Millefolium*, L.) was anciently much prized as a vulnerary and astringent, and sometimes called "nosebleed," because its leaves put into the nose caused it to bleed. The flowers are very likely to puzzle the tyro in botany, on account of the flower-heads being very small, and the florets of the ray being only five in number; examination with a lens will, however, at once reveal that what appear to be stamens are perfect flowers.

The Canadian fleabane (*Erigeron Canadense*, L.), is not uncommon in the neighbourhood of London, where it has become to some extent naturalized since 1690. The flower-heads look something like those of the wormwood, but the leaves are linear and green and the plant is much smaller. The volatile oil is used in America for hæmorrhages and the infusion as an astringent and diuretic.

The feverfew (*Matricaria Parthenium*, L.) is chiefly of interest to the pharmaceutist on account of the flower-heads having been once found in commerce intermixed with chamomiles, from which they are distinguished readily by the flattened receptacle. The plant has a disagreeable camphoraceous odour recalling that of tansy, from which it is easily known by having white ligulate florets and by the lighter coloured, less divided leaves. Although occasionally found wild it is probably not truly indigenous, but an escape from cottage gardens, in which it is a great favourite. In the West of England it is known under the name of feather foil, and an infusion is used as a fomentation. The pretty plant with yellowish green pinnatifid leaves now used so extensively in flower borders is a variety of the feverfew.

The annual henbane is now in full blossom and is easily distinguished from the biennial plant by the paler colour of its less deeply divided leaves and by the long straggling branches bearing the flowers. The leafy bracts subtending the flowers are usually placed regularly in a two ranked manner, and the flowering axis has considerable resemblance to the scorpioid cyme of a forget-me-not (*Myosotis*). Practical pharmacists should not forget that the tincture of this plant does not show a milkiness when mixed with water, as that made from the biennial does, nor that the preparation made from the two kinds can be distinguished, as shown by Stoddart, by means of the spectroscope.

The handsome foliage of the tutsan (*Hypericum androsæmum*), with its yellowish flowers and red or blackish berries, may now be seen here and there on shady hedge banks and in bushy places. This plant was formerly much esteemed as a vulnerary, as indicated by its corrupted French name, meaning heal-all The bruised leaves of this and other species of hypericum are still used in country districts with some success in healing ulcerated legs, etc.

In the various botanical gardens most of the plants described in June and July are still in blossom. Among those not before noticed are the following:—

Rue (*Ruta graveolens*, L.), although not much used in this country at the present day, was formerly very highly esteemed. The leaves are tripinnate and the leaflets somewhat obovate in outline and marked with transparent dots (oil glands) like most of the plants of this family. The corolla consists of four serrate yellowish petals, hooded at the end. The stamens are eight in number, four being opposite, and four alternate with the petals. In the bud these petals are folded in a rather curious way, one petal being overlapped by two lateral ones, which are again overlapped by the fourth, so that the æstivation somewhat resembles that of the papilioneæ. In the first or inner petal three stamens are enclosed, in the lateral petals two stamens in each, and in the fourth or outer petal only one stamen. When the flower is expanded, four stamens, alternate with the petals, mature first, and raise themselves one by one until the anther stands over the stigma, afterwards returning to their original position on a level with the petals.

The lavender (*Lavandula vera*, D.C.) is now in full perfection. The fragrant blue flowers are arranged in axillary cymes (verticillasters), most of which are so close together as to form an interrupted spike. The floral leaves or outer bracts are rhomboidal and tapering, of a brown colour; those under each flower much smaller and narrower, but of the same colour. The calyx is nearly cylindrical and ribbed, with many veins, but is only furnished with one small tooth which may be seen at the back of the flower; the corolla is two-lipped and of a deeper tint on its inner surface than on its outer. The lower verticillasters are often somewhat widely separated. In the *Lavandula spica*, L., which yields the oil of spike, there are very few characters by which it can be distinguished from *L. vera*. It has, however, a denser habit and whiter aspect, and the spike is shorter and less interrupted; and it is more susceptible of cold, extending less far north than *L. vera*. As cultivated in botanical gardens in this country, its odour is scarcely to be distinguished from that of *L. vera*, and the inferiority of the oil of spike, or essence d'aspic, is probably caused by the use of the whole plant in distillation. The different varieties of tobacco are now in full flower; the stramonium is showing its prickly capsules, and the belladonna its purplish blackberry like fruits. The bladder senna (*Colutea arborescens*, L.), the leaves of which were at one time found in senna on the continent, is now very conspicuous, by reason of its large inflated pods, looking like miniature pigs' bladders, and the bright yellow blossoms of the margold (*Calendula officinalis*, L.) are abundant everywhere in gardens. The tincture of calendula is much used by homœopaths to form a lotion for cuts and abrasions. The structure of the flower is very interesting. The central florets, not having any ovary, develop only a pistil for the purpose of pushing the pollen out of the tube formed by the united anthers, and have no stigmas.

In the Chelsea Gardens the botanist will be pleased to see fine specimens of the rare Roman nettle (*Urtica pilulifera*, L.) in full blossom; and several fine plants of the plant lately described as yielding a large proportion of Russian rhubarb, viz., *Rheum palmatum*, var. *Tanguticum*, Max. We believe this is the only garden in England where this plant can be seen growing. In the economic house at Kew, the jute plants (*Corchorus capsularis*, L., and *C. olitorius*, L.) have been putting forth their small flowers, and the *Osmanthus fragrans*, Lour., is again perfuming the air with its delicious odour. At Regent's Park, the tea plant, *Thea sinensis*, and the West Indian arrowroot plant, *Maranta arundinacea*, are in blossom sparingly, and the ordeal plant of Madagascar (*Tanghinia venenifera*) still puts forth its handsome white flowers.

In the present number of 'Medicinal Plants' by Bentley and Trimen, the following species are illustrated:—*Cimicifuga racemosa*, a double plate including a figure of the fresh root, but not showing a section of the rootlets; the balsam of tolu plant; the German pellitory root (*Anacyclus officinarum*, Hayne); *Andrographis paniculata*, Nees., one of the chiretta plants of India; the plant yielding the teel or sesame seed and the gingelly oil of commerce (*Sesamum indicum*, L.); *Cannabis sativa*; and the arrowroot plant, including a figure of the rhizome showing the transverse section. The balsam of tolu plant was drawn from specimens in the Hanbury collection now belonging to the Pharmaceutical Society, and the arrowroot rhizomes also from specimens in the Museum of this Society. It is rather singular that the *Anthemis altissima*, D.C., should have occurred in several English herbaria, as stated by the authors, in place of *Anacyclus officinarum*. This is the case, even in the herbarium of so accurate a botanist as the late D. Hanbury. The two plants however have considerable resemblance in habit.

During the past month the counties of Devonshire and Cornwall have been inundated by scientific men; the meetings of the British Association and other societies having attracted representatives of all the sciences from the most distant parts. There is plenty of food for men of science in these two counties; the geologist may explore rocks, caves, and pits to his heart's content; the mining engineer finds more than sufficient to engross his attention; the botanist may execute his walking excursions and return with glorious treasures in the way of ferns, mosses, and lichens; the chemist is attracted by the sources of mineral wealth to be found here and by the processes of extraction employed. But above and beyond all these things is the charming wildness of scenery and beauty of landscape to be witnessed in the counties in question. And it is seriously to be feared that in these features British philosophers have found more charms than in the section rooms of the Association. In consequence, but few hotels in Plymouth, even to the smallest, are unable to boast of the amount of philosophy which has of late been entertained at them severally. British philosophy as understood by the crowd is a curious entity; it is chiefly boasted when some learned and shaggy man of science propounds doctrine whose very tenets prohibit the possibility of its truth; it sinks to its lowest ebb when it assembles, or rather does not assemble, to listen to so many hard and dry matter of fact results sufficient to form the basis of a reasonable hypothesis. British philosophy is much like British virtue—its life is a series of fits and starts, nothing even and continuous in it, but appearing from time to time like the nodes in a wave of light or sound.

Nevertheless English science is very unlike British philosophy; it is true the public, and especially the effeminate public, rejoices in eloquence brought to bear upon subjects far removed from the mental grasp. A lecture on spiritualism or table-rapping, a discourse on life derived from meteoric sources, a paper on the prehensile movement of the upper joint of the big toe, a dissertation on germs: these are the subjects for the public. Therefore it is that the under-current of true and profound science prosecuted in this country fails to attract great public attention; it is too hard, dry, and technical, and even were it otherwise there are but few men who have the power to convey such knowledge in such a way as both to please and instruct a popular audience. Daily newspaper science is, therefore, for the most part popular science, and the more clap-trap there be in it, the more popular is it.

The meeting of the British Association which has just concluded, was not prolific of sensational papers; but though the various contributions to the several departments were not so numerous as on some previous occasions, their merit was quite up to the normal standard. Although Professor Allen Thomson's address has appeared *in extenso* in this Journal, there are yet a few points in it worthy of some observation. Thus, in presenting a summary of information which has been obtained regarding zymotic diseases (or the various forms of fevers), he states that organisms are, as near as can be perceived, the very essence of contagia. The various reports, however, of Dr. Burdon Sanderson to which he refers, and those of Dr. Creighton present another and more plausible view of these fevers. It is true that in these processes of disease, so called organisms, are always present, but that they are present as the acting cause is a proposition absolutely without any foundation in fact, so far as is known at present. On the other hand, it has been shown that in putrid animal infusions capable of producing such fevers, there is present ferment-matter of a particulate nature, which may be removed by a suitable process of filtration, and inasmuch as the filtered extracts are no longer poisonous, the source of the fever-process must reside in the ferment thus separated. Of the nature, quality, and quantity of that ferment matter we know extremely little; it is certain we do not recognize in it an organism, and it is more than probable we never shall do so. That is to say, germs or organisms are the general concomitants of disease; that they constitute the causes is an unproven and improbable doctrine. Strong as these words are, they are not too strong, for this subject is one which calls strongly for further elucidation, and preconceived opinions are but so many stumbling-blocks in the way of the investigation.

While speaking of this subject, a passing reference may be made to the address on Contagium Vivum, recently delivered at the meeting of the British Medical Association, by Dr. Roberts of Manchester. After reviewing the various researches of Pasteur, Cohn, and others, upon the subject of germs and their development, Dr. Roberts concluded with these words, "I believe that the doctrine of a contagium vivum is established on a solid foundation." In arriving at this conclusion, he is guided by the work of Dr. Burdon Sanderson, Dr. Creighton, and others who have carried out similar investigations, and from what has been stated above in allusion to Dr. Thomson's oration, we find it impossible to accept Dr. Roberts' anticipations. Germs are the concomitants of certain diseased processes, their life may influence and modify disease and even produce secondary processes, but it has not been established in any way that they are the first causes of disease.

Professor Abel, in his address to the chemical section of the British Association, which is also printed *in extenso* in this Journal. expatiated on the advantage likely to accrue to industry from the prosecution of researches in abstract science. This he illustrated by references to Mr. Perkins' address of last year, and by the history of iron and steel manufactures. Some observations made also on the relative importance, as regards the advancement of science and its influence upon industrial progress, of researches in analytical and organic chemistry, were particularly to the point in the present day when so many chemists are led away from the pursuit of their science generally, to one particular and indeed subordinate branch of it. The branch referred to, is that of the chemical structure of carbon compounds, and it is one whose pursuit not rarely leads to the building on paper of the most airy structures with no kind of stability. Not that this branch of inquiry is altogether to be condemned, but depending as it does upon what must ever remain hypothetical, its importance can never be paramount.

All research conducted upon reliable materials by sound methods, yields useful and valuable results, but it cannot be denied that these have different values at different times, and it must ever be the object of the scientific and philosophical chemist not alone to learn new facts, but to ascertain principles, make generalizations, and discover laws. In the present day but few men ever attempt generalizations; their work is too much devoted to isolated facts, and Professor Abel's address would have been still more valuable had he laid more particular stress upon this subject.

But comparatively little new matter was presented to the chemical section, most of the papers having appeared to a greater or less extent elsewhere, and having been noticed in this Journal.

On Friday, the 17th August, the Society of Public Analysts held a meeting at Plymouth, Dr. Dupré being in the chair, and in the course of a brief address he referred to the paper read a few days before at the Pharmaceutical Conference. In doing so, however, he entirely ignored the facts established by Dr. Paul and Mr. C. T. Kingzett, and followed the precedent of Professor Redwood, whose remarks regarding the sale of preserved peas containing copper were at least purely speculative if not quite irrelevant to the research in question. The authors of the paper did not deal with the right of shopkeepers to sell such peas, but proved by experiment that if such peas were eaten, no injury whatever to health could result, inasmuch as most of the small quantity of copper present in such peas is excreted in the fæces. The two propositions, therefore, have nothing in common, but what is important to remember is this, that where persons have been fined for selling such peas, the decisions have always been arrived at upon mere sentimental opinions. Now Dr. Paul and Mr. Kingzett showed beyond doubt that these opinions were incorrect, and consequently the decisions in question have been unjust and mischievous to trade. Dr. Dupré has no right to reject such a conclusion, unless he can disprove by experiment its correctness.

On the evening of Monday, August 20th, Professor Odling gave an address at the British Association on the newly discovered metal gallium, so named in honour of France. Among other characters, the lecturer stated those that are here noticed. The metal occurs for the most part in zinc blende, in which M. Lecoq Boisbaudran discovered it by means of spectrum analysis. The richest ores contain about 1 part of gallium in 100,000 parts, while the poorer ones only yield 1 part in 400,000 parts of ore. At a temperature of about 30°C. the metal melts and has a tendency to remain liquid even below that point, until it is touched by some solid substance, when it congeals to a crystalline solid with the specific gravity 5·93. In relation to this specific gravity, it is interesting to note that it is identical with that predicted by Mendeleef for the metal before it was discovered, on the basis of his so-called periodic law among the elements. Dr. Odling gave an interesting account of this law, and stated that Mr. Newlands was the first chemist to arrange the elements in such a seriation that new ones might be predicted to exist where certain gaps are observed in the seriation of atomic weights. It may be noted here, that the Chemical Society refused to publish Mr. Newlands' paper in their journal, although it was read before a meeting of that society, and beyond Mr Newlands' own claim to this theory of the chemical elements, it was stated and admitted for the first time in the *Pharmaceutical Journal.* Gallium is not readily oxidizable, and therefore does not tarnish on exposure to the air; it forms an alum consisting of the double sulphate with ammonium which is beautifully crystalline. This salt is more soluble in cold than in hot water, so that if a saturated neutral solution of it, contained in a tube, be immersed in boiling water, it deposits as a crystalline mass making the liquid opaque. Dr. Odling exhibited specimens of the metal, and some of its salts, and performed several experiments before his audience, illustrative of the distinguishing features of gallium.

In a recently published pamphlet (2nd edition) 'On a plan for Rendering Salted Meat more Nutritious, thereby Preventing Scurvy,' Professor Galloway calls attention to the loss of phosphate of potash, which results by the operation of salting meat. It is to the deficiency of this mineral substance in such meat that the author ascribes the outbreaks of scurvy that from time to time occur among those who partake largely of such food, and he advocates the plan of eating phosphate of potassium with salted meat, just as in like manner common salt is eaten with fresh meat. Whatever value Professor Galloway's method may ultimately be proved to possess, it is so simple and reasonable in its argument that it deserves a thoroughly good trial.

Perhaps there is no department of the business of a pharmacist demanding more care and attention than that of dispensing. In it he is constantly meeting with fresh difficulties, which frequently the teachings of experience alone can solve. Some members of the medical profession write as though incompatibilities had no existence; others throw the most incongruous materials into a mixture and expect the dispenser from those ingredients to develop an elegant and palatable result. Hence the cry for assistance, and the earnest appeal to know what in the presence of certain difficulties would be done by those leading houses that are representatives of high class pharmacy. It is unfortunately the case that many of those who write prescriptions do not take the trouble to make themselves acquainted with changes, the result of progress, necessarily involved in a new pharmacopœia, and it is equally unfortunate that immature preparations are sometimes introduced into the Pharmacopœia, and trifling changes made in some of those preparations which remain, without any apparent object, making a distinction without a difference, by no means indicative of progress but rather of an "advance in the rear." A spirituous solution of chloroform was found useful, and frequently prescribed, hence the spirit of chloroform was introduced into the Pharmacopœia. Taraxacum also was a favourite with some prescribers, but there was no officinal fluid formula, hence succus taraxaci found a place there also; but in both these cases some members of the medical profession ignore the official formulæ for sp. chloroformi and suc. taraxaci, and continue to order proprietary preparations which have no official existence. This may seem a light matter to those who are in a position to know what the prescriber means, but it is no light matter to those less favourably situated who, guided by the Pharmacopœia, entertain a very reasonable belief that every prescriber is acquainted with its contents and will prescribe accordingly. An instance of this kind occurs among the difficulties that have been made known in the Dispensing Memoranda during the past month.

No. 10 relates to ext. taraxaci liq. For this preparation there never has been an official formula. Formerly solutions of the extract, in some cases, supplied its place, and were dispensed of different strengths at different establishments. Even now a preparation of the dried root is considered by some to represent it; but the introduction of the succus taraxaci into the Pharmacopœia was probably intended to supply a formula for the most reliable preparation of a very unreliable remedial agent.

No. 11 describes a difficulty that has been experienced in making tr. ferri perchl., B.P., from the liq. ferri perchl. fort. A reference to the correspondence which has taken place in this Journal on the subject will afford a good deal of valuable information. The change in colour is well described, and its occurrence is not infrequent. It has been shown that a more satisfactory result is obtained by using in the preparation of the liq. ferri perchl. fort, about one-seventh less nitric acid. The addition of water to the spirit in making the tincture from the liquor is not admissible, and is also quite unnecessary. The gas evolved is believed to consist of chlorinated ethereal compounds liberated by the action of the excess of nitric acid on the spirit of wine. The deposition of ferric oxide is unusual and must have resulted from imperfect manipulation.

No. 12 is a question how to coat pills with a preparation of liquorice without heat, so that they shall have a shiny black appearance. This probably refers to such a coating as is given to pipe liquorice, which is done by dipping it into gelatine. Formerly pills were coated in a similar manner, but the process is in practice too tedious. Now the tolu in ether is generally used and with satisfactory results. This subject has been well discussed in the earlier journals, where fuller and more detailed information may be sought.

No. 13 relates to a mixture containing quinæ sulph. with potass. bic. and sp. am. co., and asks how it can be dispensed so that the quinine will remain in solution. Such a mixture is said to have been made up at one of the leading dispensing establishments in London with a satisfactory result. If quinine be ordered in a mixture with sodæ or potassæ bicarb., it should be rubbed to a powder and mixed with the diluent, when it will remain more or less suspended, but the moment that the sp. am. co. is added to this mixture the quinine will be thrown out in a resinous condition. This is one of those cases in which it is the duty of the dispenser to represent the difficulty and the incompatibility of the ingredients to the writer of the prescription, and to suggest an alteration, so that his intention may be carried out, that "each dose should contain a definite quantity of quinine," which cannot be the case when the greater part of the quinine adheres to the sides of the bottle.

No. 14 asks, respecting two prescriptions, how they can be sent out clear, this being reported to have been done with the first. In the first prescription, if all the ingredients be mixed and the acid. phosphoric. dil. added gradually and last, there will result a mixture slightly opaque, but in other respects perfectly satisfactory. In twelve hours a slight deposit will occur. If a ferri et quinæ cit. containing less than the proper quantity of quinine be used, a more satisfactory looking mixture may be made but at the expense of its full medicinal value. This probably explains how it may have been sent out quite clear, but it is better to have a clear conscience and a slightly opaque mixture than an opaque conscience and a clear mixture.

The second mixture referred to in No. 14 is one containing ferri et quinæ cit. and sp. am. co., and the remarks on the mixture in No. 13 will also apply here. If the ferri et quinæ cit. has its full quantity of quinine there will be separation of the quinine in flakes floating for a time on the surface of the mixture, and ultimately adhering to the sides of the bottle. If the sample of ferri et quinæ cit., from which the mixture is made, be deficient in quinine, the resulting mixture will show less separation.

No. 15. A formula is required for mist. ammon. conc., 1 to 7. This is scarcely a dispensing question, but a manufacturer would probably proceed somewhat as follows:—Make a permanent emulsion of 1 part of ammoniacum in 4 parts of water, and when required for use add 1 part to 7 of water.

No. 16. It is not quite clear whether the difficulty in this prescription lies with the quantity of capsicum, which is not given, but only q. s., or in the make of the mass. If the former, it is a case where the dispenser, in the absence of the writer, must use his own judgment. Three grains of capsicum in one dozen pills is quite usual, and to make the ingredients combine well there is no better excipient than the jelly of glycerine and tragacanth so frequently alluded to in this Journal. It may be accepted as a useful and practical fact than when ferri sulph., either dried or otherwise, is prescribed with aloes, there is no better excipient than the glycerine and tragacanth jelly.

No. 17 is a pill query as to how a good mass may be made from which the oil of caraway shall not separate, or the pill mass become crumbly when made into pills.

In making pill masses regard must always be had to the excipient, and as this query is one from an apprentice, he will do well to remember that he cannot pay too much attention to this fact. Here the tragacanth jelly is not the best, but a drop or two of decoct. aloes co. is most satisfactory in its result; the whole of the oil is retained, and the mass is all that can be desired for rolling into pills. But no time should be lost in doing so, or there will result a partial separation of some of the ingredients.

No. 18. Ox gall pills are frequently ordered by some prescribers, and there is always more or less difficulty in making them so as to retain their shape. A very satisfactory, and probably the best, method is to evaporate further the purified ox gall, make up the loss in weight by tragacanth, roll pretty quickly, either varnish with tolu or omit the varnish, and then send out in a bottle; but where any ingredient in a pill is especially liable to absorb moisture from the atmosphere, a coat of the varnish of tolu in a suitable solvent is very valuable.

Information as to the dispensing of empirical formulæ will only be of value so long as the same conditions present themselves. It is preferable that in these columns the principles mainly should be indicated, and the cultivated intelligence of the dispenser required to assist in their application. In this way only can the dispensing memoranda while rendering present assistance be of any practical and permanent value.

ASBESTOS.*

It is only quite recently that this substance has risen from being simply a mineral curiosity to a quasi-important article of commerce, on account of its peculiar qualities, being indestructible in fire or by acids, fibrous, and capable of being woven into cloth or made into paper, often as fine as the finest flax or silk, or like spun glass, although strictly a mineral product. In early antiquity it was made the subject of curious myths and strange tales bordering on the fabulous. Practically its sole use then seems to have been for winding sheets, in which to burn distinguished dead, or to be spun into napkins, which were used at exceptional feasts, and, to the astonishment of the guests, afterwards thrown into the flames, to come out intact, white and purified. At least Pliny mentions this; and it also would appear that Charles I. had tablecloths made of it, which he also was accustomed to throw into the fire for the same purpose. More recently stockings and a handkerchief were made in Elba of asbestos, as gifts to Napoleon I. while living there in exile. From time immemorial the peasantry where it is found, in various countries, have turned it to economical use as an incombustible lampwick, for which purpose its power of capillary attraction admirably qualifies it.

Common asbestos, more or less fibrous, but of a powdery, brittle quality, is abundant in most countries, and begins to find its way into some of the industrial arts, but largely mixed with other materials. The strong, long, fibrous sorts, varying in colour from pure white to dark brown, thus far are only found in sufficient quantity for commerce in the Italian Alps, at elevations of several thousand feet, and often, for much of the year, buried under the snow. They occur in serpentine rocks, in irregular veins, usually very narrow, and requiring much heavy labour and blasting to open. Sometimes, but very rarely, masses are found in one lump, weighing several hundredweight. More frequently the veins prove very superficial, and give out almost at once. Then again, they can be steadily worked for years, as they extend or penetrate into the mountain. Although some of these have been yielding as much fibre as there was a demand for since they were first opened in 1871-2, recently the increased call has led to the discovery of new productive veins of the very best quality, which will increase the outcome from a few scores of tons per annum to several hundreds. But the price, heretofore varying from £50 to £100 a ton, according to the quality and condition of the fibre, threatens to grow firmer, owing to the new uses now springing up for it, mostly based on patents, whilst Italian capitalists themselves begin to see the importance of a mineral, of which Italy has as yet a virtual monopoly, and are preparing to manufacture it on the spot where it is found into those goods which already find a steady and increasing demand.

These are chiefly, steam-packing in the rope or loose form for piston and pump rods, and stuffing boxes, and millboards for steam-joints, gaskets, man-hole plates, and a species of felting to cover boilers and steam-pipes. The ability of asbestos to resist an elevated temperature, moisture, friction and flame itself, joined to its lubricating quality, specially recommends it for the above purposes. The chief objection to the manufacturer is that, when properly prepared and applied it lasts too long. As a covering for boilers and pipes, it saves 25 per cent. or more of the waste heat; and in domestic uses in cellars, to prevent loss of heat by radiation, it is found to reduce the temperature of the cellar 15°, while raising that of the house above 10°, *i.e.*, it saves the furnace or steam heat, and sends it where it is most wanted.

Asbestos lining or sheathing paper, especially for wooden houses, for ceilings, floors and partitions, to prevent the spread of flames and make each room fireproof, is now attracting attention in America, and must recommend itself to builders generally, as rendering buildings not only safer from fires, but cooler in summer and warmer in winter, and free from insects that harbour in common papers, These papers are made in rolls of any thickness or length, and can be coloured or printed with any desirable pattern. Fireproof boxes for shelves in shops can also be made of this substance, and scenery for theatres, if fabricated of it, would be impervious to flames.

The varieties of asbestos are quite astonishing to those who have not made a study of this mineral. No two localities seem to yield precisely similar fibre. In the cabinet of Mr. C. A. Wilson, Genoa, Italy, there are at least one hundred distinct varieties from the Alps alone; one specimen when taken out of the mine was five feet long, and weighed 700lb., of the most delicate cream colour, and soft, like raw silk, after separating the fibres.

In America the asbestos business is mainly in the hands of a Boston company, protected by fifteen patents on various goods, and begins to assume a prosperous condition, calling for increased supply of the crude article, whilst in Great Britain it is chiefly centred in a flourishing Glasgow company, which was the first to risk the novel enterprise of trying to utilize a well-known mineral that has waited more than 2000 years to become useful to men. In Paris it is begun to be adopted for civil and public registers in the form of a fireproof writing paper. Recently, patents have been taken out in America and England to cover its use as a fuel-bed for petroleum in any sort of stove or engine-furnace. It absorbs and retains the oil, its capillary attraction causing it to burn only on its surface, where it is under perfect control, and gives out an intense heat. By a simple arrangement the hydrocarbons can further be converted into gas-fuel, so it is claimed.

These facts would indicate that there is a business future for this mineral, and that new uses for it are likely to be discovered. The most beautiful varieties of the long, soft, flexible and extremely fine fibres, commonly known as "floss," and which are more abundant than the strong, tenacious fibres, yet await a call in the industrial arts.

The Pharmaceutical Journal.

SATURDAY, AUGUST 25, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

OFFICIAL VERSUS NONOFFICIAL PREPARATIONS.

IT is no part of the pharmacist's duty to attempt to dictate to the medical practitioner as to the forms in which medicine shall be prescribed, whether they shall have the sanction of the Pharmacopœia or simply the seal of the trade mark. He may, and not unnaturally will, have decided opinions as to the advantages or disadvantages of certain preparations, and he is quite justified in taking suitable opportunities for making known such opinions, which, as the result usually of peculiar facilities for forming a judgment, would have their value. But he will be careful not to overstep the mark, and having liberated his soul upon the subject he will hold himself ready scrupulously, and to the best of his ability, to carry out the prescriber's wishes. Even in such a special case as the use of the lower priced cinchona alkaloids during the present abnormally high price of quinine, as was remarked by a speaker at the late meeting of the Conference, the medical man is the sole judge of its propriety, and any pertinacity on the part of the pharmacist in recommending such a course would be officious and out of place.

Nevertheless the subject is not unimportant to the pharmacist, and he will therefore follow with interest a discussion that is occupying the columns of some of our medical contemporaries. This discussion had its origin in a letter to the *Lancet*, in which the writer, calling attention to the growing practice of prescribing special preparations, alleges that the fact of a physician ordering in an ordinary case no less than four advertised preparations is "a great confession of the poverty of the Pharmacopœia." How far this is true, and whether the poverty may not too frequently lie in another quarter, namely, in the prescriber's knowledge of the best ways of using the official materia medica, appears to be fairly open to question.

Everybody must admit the skill and ingenuity in making nauseous medicines palatable displayed in many of the preparations that have been recently introduced; probably what has been termed "elegant pharmacy" has never before been carried to such perfection. Examples need not be cited here; they will be present to the mind of every reader. It is not surprising, therefore, that the physician should avail himself of some of these facilities for administering medicine in a form agreeable to the patient. But we are not sorry to notice in our contemporary, the *Medical Press and Circular*, a timely word of caution against carrying this practice too far, "to the neglect of those standard Pharmacopœia preparations which would be often found more serviceable."

To say nothing of the inconvenience to the pharmacist who finds himself called upon to supply a multiplicity of preparations other than the official ones, and the doubt which not unfrequently occurs as to what compound is meant, there are other obvious disadvantages that would accompany an extension of the practice. It must be confessed, for instance, that there would always be an element of uncertainty as to how far these compounds answered to what they were represented to be. It is no reflection upon preparations now in the market to assume that as the demand developed others might appear that would not always contain the ingredients attributed to them, or to put it euphemistically the active properties of which might be partially lost during the preparation. It will not be forgotten that in the United States, where the practice of prescribing proprietary preparations is carried out more extensively than in this country, a committee not long ago reported meeting with elixirs in which the strychnia they were supposed to contain was not only imperceptible to the palate, but undiscoverable by chemical analysis. Moreover it is at least plausible to suggest that the prescribing of such compounds made up according to a fixed formula, unless there be an infinity of them, must sometimes tend to the accommodation of the dose to the form of the medicine as much as to the necessity of the case. Finally, there is the fact, which, as pointed out by our contemporary, before mentioned, probably explains to some extent the tendency to prescribe the preparations in question, namely, that materia medica is already a comparatively neglected portion of the medical education. But if the acknowledged imperfect acquaintance with the Pharmacopœia and its preparations be still further diminished through disuse, the loss to suffering humanity and the consequent reproach to medicine must increase in proportion.

THE AMERICAN PHARMACEUTICAL ASSOCIATION.

IT will be remembered that at the meeting of this Association last year in Philadelphia it was decided to accept the invitation of the pharmacists of Toronto, and to meet this year, for the first time on British soil, in that city. The gathering will take place in the first week in September, and already the Dominion pharmacists are making preparations to give their United States brethren a hearty reception. Besides the reading and discussion of papers, there will be an exhibition of objects connected with pharmacy to compete for the attention of visitors. There is to be a reception in the Normal School Building, which has been placed at the disposal of the Association by the Minister of Education, and Dr. S. P. May, of the department, has promised to deliver a lecture on some scientific subject. The arrangements for the inevitable sequence to such a meeting, an excursion, are not yet completed, but the formation of camps at some fishing station is shadowed forth, and even the organization of a ladies' camp is to be attempted. On the other hand there is a project for the intending visitors from the United States to form one party, to rendezvous at the Niagara Falls in the previous week, and indulge in some preliminary excursions before proceeding to Toronto.

Whilst speaking of Canada it may be remarked that at present Pharmacy Acts are in operation in three of the provinces of the Dominion, but in the others the practice of pharmacy and the sale of poisons are unrestricted. The inconvenience resulting from this state of affairs has turned attention to the advisibility of having one uniform law for the whole Dominion, and the introduction of such a Bill into the Dominion Parliament is contemplated.

THE BRITISH ASSOCIATION MEETING.

The meeting of the British Association at Plymouth came to an end on Wednesday last, when the Treasurer announced that the total attendance, as indicated by the subscriptions, amounted to 1,244. Mr. William Spottiswoode, F.R.S., has been chosen President-Elect for the meeting in Dublin next year. There is an understanding that in 1879 the Association shall meet in Swansea, whilst its fiftieth anniversary is to be held in 1881 in York, the city in which it was established in 1831. The grants of money that have been voted in aid of research in connection with various subjects amount altogether to £1,081. This is a smaller sum than has been devoted to a similar purpose in previous years, the decrease being attributed to the falling off in the receipts. In replying to a vote of thanks the President alluded to the loss that the Association and science generally had sustained in the recent death of Mr. Gassiott.

DEATH FROM CHLOROFORM AVERTED BY THE INHALATION OF NITRITE OF AMYL.

A correspondent of the *British Medical Journal* communicates the interesting observation, that in a case of syncope during the administration of chloroform, where the usual treatment was without effect and death seemed imminent, the application of some lint saturated with nitrite of amyl to the nostrils was followed almost immediately by restoration of the pulse, and the subsequent recovery of the patient.

The revenue derived from the stamp on patent medicines during the financial year ending March 25, amounted to £112,978 17*s.* 5*d.*, after an allowance of £5,242 15*s.* 2½*d.* in discounts, etc.

Proceedings of Scientific Societies.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The President's Address.

(*Concluded from page* 139.)

Among the earliest changes to which the perfect animal ovum is subject, I have first to refer to the segmentation of the germ, a series of phenomena the observation of which has been productive of most important results in leading to a comprehension of the intimate nature of the formative process, and which is of the deepest interest both in a morphological and histological point of view. This process, which was first distinctly observed by Prevost and Dumas more than fifty years ago, and is now known to occur in all animal ova, consists essentially in the cleavage or splitting up of the protoplasmic substance of the yolk, by which it becomes rapidly subdivided into smaller and more numerous elements, so as at last to give rise to the production of an organized stratum of cells out of which, by subsequent changes, the embryo is formed.

The process of yolk-segmentation may at once be distinguished as of two kinds, according as it affects in the small-yolked ova the whole mass of the yolk simultaneously, or in the large-yolked ova is limited to only one part of it. The cleavage process, in fact, affects the germinal and not the food-yolk; so that to take the two most contrasting instances of the bird and mammal, to which I have before referred, it appears that while the mammal's ovum undergoes entire segmentation, this process is confined to the substance of the cicatricula or germinal disk of the bird's egg. This process is essentially one of cell-division, but it is also in some measure one of cell-formation. The best idea of its nature will be obtained from a short description of the total segmentation occurring in the mammal's ovum.

When, as before mentioned, the germinal vesicle has been in part extruded or lost to sight, the whole yolk-substance of the ovum forms a nearly uniform mass of finely granular protoplasm, enclosed within the external cell-membrane. Within a few hours later a clear nucleus has arisen in this mass. To this more definite form of organization assumed by the germinal substance of the future animal, which is about to be the subject of the segmenting process, the name of the first segment-sphere may be given.

By the process of cleavage which now begins, this first segment-sphere and its nucleus undergo division into two nucleated spheres of smaller size, the whole substance of the yolk, in a holoblastic ovum, such as that of the mammal, being involved in the segmenting process.

The second stage of division follows after the lapse of a few hours, and results in the formation of four nucleated segment-spheres; and the process of division being repeated in a certain definite order, there result in the succeeding stages (that is, the third, fourth, fifth, and up to the tenth) the numbers of 8, 12, 16, 24, 32, 48, 64, and 96 nucleated yolk-spheres, germ-spheres, or formative cells.

In the rabbit's ovum the tenth stage is reached in less than three days; and as during that time the size of the whole ovum has undergone very little increase, it follows that the spheres of each succeeding set, as they become more numerous, have diminished greatly in size. These segment-spheres are all destitute of external membrane, but are distinctly nucleated; and their protoplasmic substance is more or less granular, presenting the usual histological characters of growing cells.

By the time that segmentation has reached the seventh or eighth stage, when 32 or 48 spheres have been formed, the ovum has assumed the appearance of a mulberry, in which the outer smaller spheres, closely massed together, project slightly and uniformly over the whole surface; while the interior of the ball is filled with cells of a somewhat larger size and a more opaque granular aspect, also resulting from the process of segmentation.

Already, however, the mutual compression of the spheres or cells on the surface, by their crowding together, has led to the flattening of their adjacent sides; and by the time the tenth stage is reached, when the whole number of the cells is about 96, the more advanced superficial cells, having ranged themselves closely together, form a nucleated cellular layer or covering of the yolk, enclosing within them the larger and more opaque cells, derived like the first from the segmenting process. In a more advanced stage, the deeper cells now referred to having also taken the form of a layer, there results at last the bilaminar blastoderm or embryonic germinal membrane.

The process of partial segmentation, such as occurs in the bird's egg, though perhaps fundamentally the same as that of the mammal previously described, stands in a different relation to the parts of the whole yolk or egg, and consequently differs in its general phenomena. The segmentation is mainly restricted in the meroblastic ova of birds to the germinal disk of cicatricula, and does not immediately involve any part of the larger remainder of the yolk. This takes place during the time of the descent of the yolk through the oviduct, when the yolk is receiving the covering of the white or albumen, the membrane, and the shell previous to being laid—a progress which, in the common domestic fowl, usually occupies less than twenty-four hours. Corresponding essentially to the more complete segmentation of the mammal's ovum, the process leads to the same result in the production of two layers of nucleated formative cells in the original seat of a protoplasmic disk—a bilaminar blastoderm resulting as in the mammal's ovum, though in a somewhat different relation to the yolk.

I will not fatigue you with a description of the details of these phenomena, interesting as they may be, but only mention generally that they consist in the formation of deep fissures running from the surface into the substance of the germ-disk. The first of these fissures crosses the disk in a determinate direction, dividing it into two nearly equal semicircular parts. In the next stage another fissure, crossing the first nearly at right angles, produces four angular segments. Then come four intervening radial fissures which subdivide the four segments into eight; and next afterwards the central angles of these eight radial segments are cut off from their peripheral portions by a different fissure, which may be compared to one of the parallels of latitude on the globe near the pole where the radial or *longitude* fissures converge. And so thereafter, by the succession and alternation of radial and circular clefts (which, however, as they extend outwards, come soon to lose their regularity), the whole germinal disk is divided into the two layers of nucleated cells, constituting the blastoderma or germinal membrane of Pander and all subsequent embryologists.* If a laid egg be subjected to the heat of incubation for eight or ten hours, the cicatricula, now converted into this segmented blastoderm, is found to be considerably expanded by a rapid multiplication of its constituent cells; and in as many more hours, by further changes in its substance, the first lineaments of the chick begin to make their appearance. Similar changes affect the blastoderm of the mammal; and thus it appears that the result of segmentation, in the bird as well as in the mammal and other animals, is the production of an organized laminar substratum, which is the seat of the subsequent embryonic development.

I must still request your attention to some details connected with the process of segmentation, which bear upon the question of the origin of the new cells, and on which recent research has thrown a new and unexpected light.

With respect to the nature of the first segment-sphere of the ovum and the source of its nucleus, as well as of the other segment-spheres or cells which follow each other in the successive steps of germ-subdivision, it appears probable, from the researches of several independent observers, and more especially of Edward Van Beneden and Oscar Hertwig, that in the course of the extrusion of the germinal vesicle a small portion of it remains behind in the form of a minute mass of hyaline substance, to which Van Beneden has given the name of *pronucleus*, and that, as the result of the fertilizing process, there is formed a second similar hyaline globule or pronucleus, situated near the surface, which gradually travels towards the centre and unites with the first pronucleus, and that these two pronuclei, being fused together, form the true nucleus of the first segment-sphere. According to this view the original germinal vesicle, when it disappears or is lost to sight, as described by so many embryologists, is not dissipated, but only undergoes changes leading to the formation of the new and more highly endowed nucleus of the first embryonic or segmental sphere. It further appears that the subdivision of each segmenting mass is preceded by a change and division of the nucleus, and that this division of the nucleus is accompanied by the peculiar phenomenon of a double conical or spindle-shaped radial lineation of the protoplasm, which, if we were inclined to speculate as to its nature, seemed almost as if it marked out the lines of molecular force acting in the organizing process. These lines, however, it will be understood, if visible with the microscope, even of the highest magnifying power yet attained, belong to much larger particles than those of the supposed molecules of the physicist; but, considered in connection with what we know of the movements which frequently precede the act of division of the yolk-spheres, we seem in this phenomenon to have made some near approach to the observation of the direction in which the molecular forces operating in organization may be supposed to act.*

* The more exact nature of the process of segmentation was first made known by the interesting researches of Bagge in 1841, and more especially of Kölliker in 1843. The phenomena of complete segmentation were first duly described in the mammal's ovum in Bischoff's description of the development of the rabbit, 1842, and followed out in his succeeding memoirs on the dog, guinea-pig, and roedeer. The phenomena of partial segmentation were first made known, in their more exact form, by Kölliker's researches on the development of the Cephalopoda, published in 1844. In birds the process was first described by Bergmann in 1846, and more fully by Coste in 1848.

* The observations referred to above as to the division of the nucleus are so novel and of such deep interest that I am tempted to add here a short abstract of their more important results from a very clear account given of them by Dr. John Priestley, of Owens College, Manchester, in the *Journal of Microscopical Science* for April, 1876.

The researches now referred to are those of Auerbach, Butschli, Strasburger, Hertwig, and Edw. Van Beneden; and the following may be stated as the points in which they mainly agree:—

The nucleus when about to divide elongates into a spindle-shaped body, becomes irregular and indistinct, acquires a granular disk or zone in the plane of its equator; this divides into two, and each half moves towards the pole of the spindle on its own side, there being radiated lines of protoplasm between the poles and the equatorial disk.

The disk segments are the new nuclei, and the subsequent division of the cell takes place in the intermediate space.

Although these observers still differ in opinion upon some of the details of this process, and especially as to the fate of the germinal vesicle, all of them seem to agree that there are two pronuclei or distinct hyaline parts of the yolk-protoplasm, a superficial and a deep one, engaged in the formation of the new nucleus; and both Hertwig and Van Beneden are of opinion that the two proceed from different productive elements.

The radiated structure of the nuclei had been previously recognized by Fol and Flemming, and further observed by Oellacher.

1. Butschli's researches are published in the *Nov. Act. Nat-Cur.*, 1873, and in the *Zeitschr. für wissensch. Zool.* vol. xxv.

2. Auerbach's observations in his 'Organolog. Studien.'

With respect to the nature of the blastoderm, the organized cellular stratum resulting from segmentation, and its relation to the previous condition of the ovum on the one hand, and the future embryo on the other, there is presented to us, by modern research, the interesting view that the blastoderm consists, after completion of the segmenting process, of two layers of cells—an outer or upper (usually composed of smaller, clearer, and more compact nucleated cells), named *ectoderm* or *epiblast*, and an inner or lower (consisting of cells which are somewhat larger, more opaque and granular, but also nucleated), named *endoderm* or *hypoblast*.

In the meroblastic ova, such as those of birds, the bilaminar blastoderm is discoid and circumscribed as it lies on the yolk-surface, and only comes to envelop the whole of the food-yolk in the progress of later development; while in the holoblastic ova, and more especially in mammals, the blastoderm from the first extends over the whole surface of the yolk, and thus forms an entire covering of the yolk known as the "vesicular blastoderm," the space within being occupied by fluid.

Huxley long ago presented the interesting view that these two layers are essentially the same, in their morphological relations and histological structure, as the double wall of the body in the simplest forms of animals above the Protozoa; and Haeckel has more recently followed out in this view, and supported it by his researches in the Calcareous Sponges, and has founded upon it his well-known *Gastræa* theory. According to this view all animals take their origin from a form of *Gastrula*. In the simpler tribes, as in the instance of the common freshwater polype or Hydra, they proceed no further than the Gastrula stage, unless by mere enlargement and slight differentiation of the two primitive layers of cells representing the persistent ectoderm and endoderm.*

If, pursuing this idea, we take a survey of the whole animal kingdom in its long gradation of increasing complexity of form and structure from the simplest animal up to man himself, we find that all the various modifications of organic structure which present themselves are found, in the history of the individual or ontological development of the different members of the series, to spring originally from two cellular laminæ, ectoderm and endoderm, the component elements of which may again be traced back to the first segment-sphere and primitive protoplasmic elements of the ovum.

Time does not admit of my conducting you through the chain of observation and reasoning by which Haeckel seeks to convince us of the universal application of his theory; but I cannot avoid calling your attention to the extremely interesting relation which has been shown to exist between the primary phases of development of the ovum and the foundation of the blastoderm in very different groups of animals, more especially by the researches of Haeckel himself, of Kowalevsky, Edward Van Beneden, and others, and which has received most efficient support from the investigations and writings of E. Ray Lankester in our own country; so that now we may indulge the well-grounded expectation that, notwithstanding the many and great difficulties which doubtless still present themselves in reconciling various forms with the general principle of the theory, we are at least in the track which may lead to a consistent view of the relations subsisting between the ontogenetic, or individual, and the phylogenetic, or race history of the formation of animals and of man.*

In all animals, then, above the Protozoa, the ovum presents, in some form or other, the bilaminar structure of ectoderm and endoderm at a certain stage of its development, this structure resulting from a process of segmentation or cell-cleavage; and there are three principal modes in which the double condition of the layers is brought about. In one of these it is by inward folding or invagination of a part of the single layer of cells immediately resulting from the process of segmentation that the doubling of the layers is produced; in the second, perhaps resolvable into the first, it may be described rather as a process of enclosure of one set of cells within another; while in the third the segmented cells, arranged as a single layer round a central cavity of the ovum, divide themselves later into two layers. But the distinction of ectodermic and endodermic layers of cells is maintained, whether it be primitive and manifested from a very early period, or acquired later by a secondary process of differentiation. Thus in many invertebrates, as also in *Amphioxus* among the vertebrates, a distinct invagination occurs, while in mammals, as recently shown by Van Beneden's most interesting observations in the rabbit's ovum, and probably also in some invertebrates, the cells of the ectoderm gradually spread over those of the endoderm during the progress of segmentation, and thus the endodermic comes to be enclosed by the ectodermic layer of cells.

From the very novel and unexpected observations of Van Beneden it further appears that from the earliest period in the process of segmentation in the mammal's ovum it is possible to perceive a distinction of two kinds of segment-spheres or cells, and that when this process is traced back to its first stage it is found that the whole of the cells belonging to the ectoderm are the progeny of, or result from the division of the upper of the two first formed segments, and that the whole of the endodermic cells are the descendants of the lower of the two first segmented cells. This, however, is not an isolated fact belonging only to mammalian development, but one which very nearly repeats a process ascertained to occur in a considerable number of the lower animals, and it seems to promise the means of greatly advancing the comprehension of the whole process of blastodermic formation. Thus ectoderm and endoderm, or the primordial rudiments of the future animal and vegetative systems of the embryo, are traced back as distinct from each other to the first stage of segmentation of the germ.

Accepting these facts as ascertained, they may be regarded as of the deepest significance in the phylogenetic history of animals; for they appear to open up the prospect of our being able to trace transitions between the earliest embryonic forms occurring in the most different kinds of ova, as between the discoid or meroblastic and the vesicular or holoblastic, through the intermediate series which may be termed amphiblastic ova.

In the lowest animals, the two layers already mentioned, viz., ectoderm and endoderm, are the only ones known to constitute the basis of developmental organization; but as we rise in the scale of animals we find a new feature appearing in their structure, which is repeated also in the history of the formation of the blastoderm in the higher animals up to man. This consists in the

3. Strasburger's observations in his memoir 'Ueber Zellbildung und Zelltheilung,' Jena, 1875.

4. Edward Van Beneden's researches, partly in his memoir 'On the Composition and Significance of the Egg,' etc., presented to the Belgian Academy in 1868, and more particularly in the extremely interesting preliminary account of 'Researches on the Development of Mammalia,' etc., 1875, and in a separate paper in the *Journ. of Microscopical Science* for April, 1876.

5. Oscar Hertwig's memoirs are contained in the 'Morpholog. Jahrbuch,' 1875, and his most interesting and novel observations in the same work, 1877.

* At this place I will only refer to one of the most recent of Haeckel's works, in which the views alluded to above are fully exposed in a series of most interesting memoirs, viz., 'Studien zur Gastræa-Theorie,' Jena, 1877; and to Dr. E. Perceival Wright's translation of the account of Haeckel's views in *Journ. of Microsc. Science*, vol. xiv., 1874.

* I ought here to refer to the elaborate memoirs of Professor Semper on the morphological relations of the vertebrate and invertebrate animals, contained in the 'Arbeiten aus dem Zoolog.-zootom. Institut in Würzburg,' 1875 and 1876, in which the conclusions arrived at do not coincide with the views above stated.

formation of an intermediate layer or layers constituting the *mesoderm*, with which, in by far the greater number, is connected the formation of some of the most important bodily structures, such as the osseous, muscular, and vascular systems.

I will not stop to discuss the very difficult question of the first origin of the mesoderm, upon which embryologists are not yet entirely agreed, but will only remark that a view originally taken of this subject by the acute Von Baer appears more and more to gain ground; and it is this—that the mesoderm, arising as a secondary structure, that is, later than the two primary layers of ectoderm and endoderm (corresponding to the serous and mucous layers of Pander), is probably connected with or derived from both of these primitive layers, a view which it will afterwards appear is equally important ontogenetically and phylogenetically.

But whatever may be the first origin of the mesoblast, we know that in the Vertebrata this layer, separating from between the other two, and acquiring rapidly by its cell-multiplication larger proportions and much greater complexity than belongs to either ectoderm or endoderm, speedily undergoes further subdivision and differentiation in connection with the appearance of the embryonic organs which arise from it, and in this respect contrasts greatly with the simplicity of structure which remains in the developed parts of the ectodermic and endodermic layers. Thus, while the ectoderm supplies the formative materials for the external covering or epidermis, together with the rudiments of the central nervous organs and principal sense-organs, and the endoderm by itself only gives rise to the epithelial lining of the alimentary canal and the cellular part of the glands connected with it, the mesoblast is the source of far more numerous and complex parts, viz., the whole of the true skin or corium, the vertebral column and osseous system, the external voluntary muscles and connective tissue, the muscular walls of the alimentary canal, the heart and blood-vessels, the kidneys, and the reproductive organs, thus forming much the greatest bulk of the body in the higher animals.*

There is, however, a peculiarity in the mode of the earliest development of the mesoblast which is of great importance in connection with the general history of the disposition of parts in the animal body, to which I must now refer. This consists in the division of the mesoblast in all but its central part into two laminæ, an outer or upper and an inner or lower, and the separation of these by an interval or cavity which corresponds to the space existing between the outer wall of our bodies and the deeper viscera, and which, from the point of view of the vertebrate animals is called the pleuro-peritoneal cavity, but, viewed in the more extended series of animals down to the Annuloida, may receive the more general appellation of pleuro-splanchnic or parieto-visceral cavity, or, shortly, the *cœlom*. Thus, from an early period in the vertebrate embryo, and in a considerable number of the invertebrate, a division of the mesoderm takes place into the somatopleural or outer lamina and the splanchnopleural or inner lamina—the outer being the seat of formation of the dermal, muscular, and osseous systems (the voluntomotory of Remak), and the inner of the muscular wall of the alimentary canal, as well as of the contractible substance of the heart and the vascular system generally.

It is interesting to find that there is a correspondence between the later division of the mesoderm of the higher animals derived from the two primitive blastodermic laminæ and the original absence of mesodermic structure in the lowest animals, followed by the gradual appearance, first of one layer (the external muscular in the higher Cœlenterata), and soon afterwards by the two divisions or laminæ with the intermediate cœlom.

In this account of what may be termed the organized foundation of the new being, I have entered into some detail, because I felt that our conception of any relation subsisting between the ontogenetic history of animals and their phylogenetic evolution can only be formed from the careful study of the earliest phenomena of embryonic organization. But, notwithstanding the many difficulties which unquestionably still block the way, I am inclined to think that there is great probability in the view of a common bilaminar origin for the embryo of all animals above the Protoza, and that the vertebrate equally with the invertebrate animals may be shown to possess, in the first stages of their blastodermic or embryonic formation, the two primitive layers of ectoderm and endoderm.

To attempt, however, to pursue the history of the development of animals in detail would be equivalent to inflicting upon you a complete system of human and comparative anatomy. But I cannot leave the subject abruptly without an endeavour to point out in the briefest possible manner the bearing of one or two of the leading facts in embryology upon the general relation of ontogeny and phylogeny.

We are here brought into the contemplation of those remarkable changes, all capable of being observed and demonstrated, by which the complex organization of the body is gradually built up out of the elementary material furnished by the blastodermic layers—a process which has been looked upon by all those who have engaged in its study with the greatest interest and admiration. And if, by comparing these phenomena as observed in individuals belonging to different classes and orders of animals, it is found that not only are they not different, but, on the contrary, that they present features of the most remarkable resemblance and conformity, we shall be led to conclude that there is a general plan of development proved to extend to the members of considerable groups, and possibly capable of being traced from one group to another. But this is clearly nothing else than another way of stating that there is a similar type of structure prevading the animals of each group, and a probability of a common type being ascertained to belong to them all. The main question, therefore, to be answered is whether there is or is not a general correspondence between the phenomena of development and the gradation of type in animal structure upon which anatomists and zoologists are agreed; and my object will now be to bring rapidly before you one or two of the most marked illustrations of the correspondence, drawn from the early history of development in the higher animals.

As one of the examples of the earlier phenomena of development I may refer to the change which is perceptible as early as the 18th or 20th hour of incubation in the chick, and which is reproduced in the course of development of every member of the Vertebrate subkingdom. It consists in the formation of cross clefts on each side of the primitive neural cavity, which divide off from each other a number of segments of this wall in the length of the axis of the embryo. At first there are only one or two such clefts; but they rapidly increase in a backward direction in the body of the embryo, and as development proceeds they extend into the tail itself. These are the *protovertebræ* of embryologists—not corresponding, as might at first be supposed, with the true or actual vertebræ which are formed later, but representing in an interesting manner transverse *vertebral segments* of the body, and containing within each the elements of a great part of the structure belonging to the body-wall afterwards to be developed, including the true cartilaginous or osseous vertebral arches and the muscular plates.

This change, however, belongs to the mesodermic

* If we reserve the words ectoderm and endoderm to designate the two layers of the primary bilaminar blastoderm, we may apply the terms epiblast and hypoblast to their derivatives after the formation of the mesoderm, and indicate the relations of the whole to the secondary or quadrilaminar blastoderm by the following table:—

Primary Blastoderm	Ectoderm	.....Epiblast..........	Secondary Blastoderm.
	Meso-derm	Somatopleure ..	
		Splanchnopleure	
	Endoderm	........Hypoblast......	

lamina, and occurs in an elongated thick portion of it, which makes its appearance on each side of the primitive neural canal between the epiblast and the hypoblast. The transverse cleavage is ascertained to commence near what afterwards forms the first cervical vertebra, but does not extend into the base of the cranium. And it is most interesting to note in this cleavage the formation at so early a period of the succession of *metameres* or series of similar parts, which forms a main characteristic of vertebral organization.

As intimately connected with the formation of the vertebral column, the appearance of the chorda dorsalis or *notochord* presents many points of peculiar interest in embryological inquiries.

The notochord is a continuous median column or thread of cellular structure running nearly the whole length of the rudimentary body of the embryo, and lying immediately below the cerebro-spinal canal. It occupies, in fact, the centre of the future bodies of the vertebræ. It exists as a primordial structure in the embryo of all Vertebrates, including man himself and extending down to the Amphioxus, and, according to the remarkable discovery of Kowalevsky in 1866, it is to be found among the Invertebrates in the larva of the Ascidia.*

In Amphioxus and the Cyclostomatous Fishes the notochord, growing with the rest of the body into a highly developed form, acts as a substitute for the pillar of the bodies of the vertebræ, no vertebral bodies being developed; but in Cartilaginous and Osseous Fishes various gradations of cartilaginous and osseous structures come to surround the notochord and give rise to the simpler forms of vertebral bodies, which undergo more and more distinct development in the higher vertebrates. In all instances the substance forming the vertebral bodies is deposited on the surface of or outside the notochord and its sheath, so that this body remains for a time as a vestigial structure within the vertebral bodies of the higher animals.

The observations of Kowalevsky with respect to the existence of a notochord in the Ascidia, which have been confirmed by Kupfer and others, have produced a change little short of revolutionary in embryological and zoological views, leading as they do to the support of the hypothesis that the Ascidian is an earlier stage in the phylogenetic history of the mammal and other Vertebrates. The analogy between the Amphioxus and Ascidian larva is certainly most curious and striking as regards the relation of the notochord to other parts; and it is not difficult to conceive such a change in the form and position of the organs in their passage from the embryonic to the adult state as is not inconsistent with the supposition that the Vertebrates and the Ascidia may have had a common ancestral form. Kowalevsky's discovery opens up at least an entirely new path of inquiry; and we must be prepared to modify our views as to the entire separation of the Vertebrates from the other groups of animals, if we do not at once adopt the hypothesis that through the Ascidian and other forms the origin of the Vertebrates may be traced downwards in the series to the lower grades of animal organization.

The notochord extends a short way forward into the cranial basis; and an interesting question here presents itself, beginning with the speculations of Goethe and Oken, and still forming a subject of discussion, whether the series of cranial or cephalic bones is comparable to that of the vertebræ. On the whole it appears to me that it is consistent with the most recent views of the development and anatomy of the head to hold the opinion that it is composed of parts which are to some extent homologous with vertebral metameres.†

The history of the formation of the vertebral column presents an interesting example of the correspondence in the development of the individual and the race, in that all the stages which have been referred to as occurring in the gradual evolution of the vertebral column in the series of Vertebrates are repeated in the successive stages of the embryonic development of the higher members of the series.

There is perhaps no part of the history of development in the vertebrates which illustrates in a more striking manner the similarity of plan which runs through the whole of them than that connected with what I may loosely call the region of the face and neck, including the apparatus of the jaws and gills. The embryonic parts I now refer to consist of a series of symmetrical pairs of plates which are developed at an early period below the cranium, and may therefore, in stricter embryological terms, be styled the *subcranial plates*.

Without attempting to follow out the remarkable changes which occur in the development of the nose and mouth in connection with the anterior set of these plates (which, from being placed before the mouth, are sometimes named *preoral*), I may here refer shortly to the plates situated behind the mouth which were discovered by Rathke in 1826, and formed the subject of an elaborate investigation by Reichert in 1837.

These plates consist of a series of symmetrical bars, four in number in mammals and birds, placed immediately behind the mouth, separated by clefts passing through the wall of the throat, and each traversed by a division of the great artery from the heart—thus constituting the type of a branchial apparatus, which in fishes and amphibia becomes converted into the well-known gills of these animals; whilst in reptiles, birds, and mammals they undergo various changes leading to the formation of very different parts, which could not be recognized as having any relation to gill-structure, but for the observation of their earlier embryonic condition. The history of this part of development also possesses great interest on account of the extraordinary degree of general resemblance which it gives to the embryos of the most different animals at a certain stage of advancement (so great, indeed, that it requires a practised eye to distinguish between the embryos of very different orders of mammals, and even between some of them and the embryos of birds or reptiles), as well as in connection with the transformations of the first pair of branchial apertures, which lead to the formation of the passage from the throat to the ear in the higher Vertebrata. There is equal interest attached to the history of the development of the first pair of arches which include the basis of formation of the lower jaw with the so-called *cartilage of Meckel*, and which, while furnishing the bone which suspends the lower jaw in reptiles and birds, is converted in mammals into the hammer-bone of the ear.

The other arches undergo transformations which are hardly less marvellous, and the whole series of changes is such as never fails to impress the embryological inquirer with a forcible idea of the persistence of type and the inexhaustible variety of changes to which simple and fundamental parts may be subject in the process of their development.

It is also of deep significance, in connection with the foregoing phenomena, to observe the increase in the number of the gill-bars and apertures as we descend in the scale to the cartilaginous fishes and lampreys, and the still further multiplication of these metameres or repeated parts in the Amphioxus; and it is, perhaps, also interesting to note that in the Ascidia the arrangement of the gills is exactly similar to that of the Amphioxus.

The study of the comparative anatomy of the heart and its mode of formation in the embryo furnishes also

---

* 'Mém. de l'Acad. de St. Pétersbourg,' vol. x.

† See the interesting and valuable memoirs of W. K. Parker, 'On the Anatomy and Development of the Vertebrate Skull,' in Trans. of Roy. Soc., the researches of Gegenbaur, Mihalkovics, and more particularly the memoir by F. M. Balfour, 'On the Development of the Elasmobranchs,' in the *Journ. de Anat. and Physiol.*, vols. x. and xi.

most striking illustrations of the relation between ontogenetic and phylogenetic development in the Vertebrates, and is not without its applications to some of the invertebrate groups of animals.

I need only recall to your recollection the completely double state of this organ in warm-blooded animals, by which a regular alternation of the systemic and pulmonary circulations is secured, and the series of gradations through the class of Reptiles by which we arrive at the undivided ventricle of the amphibian, and the further transition in the latter animals by which we come at last to the single heart of fishes; and to state that in the embryo of the higher animals the changes by which the double heart is ultimately developed out of an extremely simple tubular form, into which it is at first moulded from the primitive formative cells, are, in the inverse order, entirely analogous to those which I have just now indicated as traceable in the descending series of vertebrate animals; so that at first the embryonic heart of man and other warm-blooded animals is nothing more than a rhythmically contractile vascular tube. By the inflection of this tube, the constriction of its wall at certain parts, and the dilatation at others, the three chambers are formed which represent the single auricle, the single ventricle, and the aortic bulb of the fish. By later changes a septum is formed to divide the auricles, becoming completed in all the air-breathing animals, but remaining incomplete in the higher animals so long as the conditions of fœtal life prevent the return of arterialized blood to the left auricle. The growth of another septum within the ventricular portion gradually divides that cavity into two ventricles, repeating somewhat in its progress the variations observed in different reptiles, and attaining its complete state in the crocodile and warm-blooded animals.

I must not attempt to pursue this interesting subject further; but I cannot avoid making reference to the instructive view presented by the embryological study of the nature of the malformations to which the heart is subject, which, as in many other instances, are due to the persistence of transitory conditions which belong to different stages of progress in the development of the embryo. Nor can I do more than allude to the interesting series of changes by which the aortic bulb, remaining single in fishes and serving as the channel through which the whole stream of blood leaving the heart is passed into the gills, becomes divided in the higher animals into the roots of the two great vessels, the aorta and the pulmonary artery, and the remarkable transformations of the vascular arches which proceed from the aortic bulb along the several branchial arches, and which, in the gills of fishes and aquatic Amphibia, undergo that minute subdivision which belongs to the vascular distribution of gills, but which in the higher non-branchiated animals are the subject of very different and various changes, in the partial obliteration of some and the enlagement of others, by which the permanent vessels are produced.

These changes and transformations have for many years been a subject of much interest to comparative anatomists, and will continue to be so, not only for their presenting to us one of the most remarkable examples of conformity in the plan of development and the type of permanent or completed organization in the whole series of vertebrated animals, but also because of the manifest dependence of the phenomena of their development upon external influences and atmospheric conditions which affect the respiration, nutrition, and modes of life of the animal.

Nor is the correspondence to which I now refer entirely limited to the Vertebrata. For here, again, through the Amphioxus and the Ascidia, we come to see how an affinity may be traced between organs of circulation and respiration which at first appear to belong to very different types. The heart of vertebrates is, as is well known, an essentially concentrated form of vascular development in the ventral aspect of the body, while the heart of the invertebrate, whether in the more concentrated form existing in the Articulata and Mollusca or in a more subdivided shape prevalent in the Annelida, is most frequently dorsal; yet the main aorta of the Vertebrates is also dorsal; and it is not impossible, through the intermediate form of Amphioxus, to understand how the relation between the Vertebrate and the Invertebrate type of the blood-vascular system may be maintained.

But I am warned by the lapse of time that I must not attempt to pursue these illustrations further. In the statement which I have made of some of the more remarkable phenomena of organic production—too long, I fear, for your endurance, but much too brief to do justice to the subject—it has been my object mainly to show that they are all more or less closely related together by a chain of similarity of a very marked and unmistakable character; that in their simplest forms they are indeed, in so far as our powers of observation enable us to know them, identical; that in the lower grades of animal and vegetable life they are so similar as to pass by insensible gradations into each other; and that in the higher forms, while they diverge most widely in some of their aspects in the bodies belonging to the two great kingdoms of organic nature, and in the larger groups distinguishable within each of them, yet it is still possible, from the fundamental similarity of the phenomena, to trace in the transitional forms of all their varieties one great general plan of organization.

In its simplest and earliest form that plan comprises a minute mass of the common nitrogenous hydrocarbon compound to which the name of protoplasm has been given, exhibiting the vital properties of assimilation, reproduction, and irritability. The second stage in this plan is the nucleated and enclosed condition of the protoplasmic mass in the organized cell. We next recognize the differentiation of two productive elements, and their combination for the formation of a more highly endowed organizing element in the embryonic germ-sphere or cell; and the fourth stage of advance in the complexity of the organizing phenomena is in the multiplication of the fertilized embryo-cell and its conversion into continuous organized strata, by further histological changes in which the morphological foundations of the future embryo or new being are laid.

I need not now recur to the further series of complications in the formative process by which the bilaminar blastoderm is developed and becomes trilaminar or quadrilaminar, but only recall to your recollection that while these several states of the primordial condition of the incipient animal pass insensibly into each other, there is a pervading similarity in the nature of the histological changes by which they are reached, and that in the production of the endless variations of form assumed by the organs and systems of different animals in the course of their development, the process of cell-production, multiplication, and differentiation remains identical. The more obvious morphological changes are of so similar a character throughout the whole, and so nearly allied in the different larger groups, that we are led to regard them as placed in some very close and intimate relation to the inherent properties of the organic substance which is their seat, and the ever-present influence of the vital conditions in which alone these properties manifest themselves.

The formative or organizing property therefore resides in the living substance of every organized cell and in each of its component molecules, and is a necessary part of the physical and chemical constitution of the organizing elements in the conditions of life; and it scarcely needs to be said that these conditions may be as varied as the countless numbers of the molecules which compose the smallest particles of their substance. But, setting aside all speculation of a merely pangenetic kind, it appears to me that no one could have engaged in the study of embryological development for any time without becoming convinced that the phenomena which have been ascertained as to the first origin and formation of textures and organs in any individual animal are of so uniform a character as to indicate forcibly a law of connection and continuity between them; nor will his study of the phenomena of development in different animals have gone far before he is equally strongly convinced of the similarity of plan in the development of the larger groups, and, to some extent, of the whole. I consider it impossible therefore for any one to be a faithful student of embryology, in the present state of science, without at the same time becoming an evolutionist. There may still be many difficulties, some inconsistencies, and much to learn, and there may remain beyond much which we shall never know; but I cannot conceive any doctrine professing to bring the phenomena of embryonic development within a general law which is not, like the theory of Darwin, consistent with their fundamental identity, their endless variability, their subjugation to varying external influences and conditions, and with the possibility of the transmission of the vital conditions and properties, with all their variations, from individual to individual, and, in the long lapse of ages, from race to race.

I regard it therefore, as no exaggerated representation of the present state of our knowledge to say that the ontogenetic development of the individual in the higher animals repeats in its more general character, in many of its specific phenomena, the phylogenetic development of the race. If we admit the progressive nature of the changes of development, their similarity in different groups, and their common characters in all animals, nay, even in some respects in both plants and animals, we can scarcely refuse to recognize the possibility of continuous derivation in the history of their origin; and however far we may be, by reason of the imperfection of our knowledge of Palæontology, Comparative Anatomy, and Embryology, from realizing the precise nature of the chain of connection by which the actual descent has taken place, still there can be little doubt remaining in the minds of any unprejudiced student of embryology that it is only by the employment of such an hypothesis as that of Evolution that further investigation in these several departments will be promoted, so as to bring us to a fuller comprehension of the most general law which regulates the adaptation of structure to function in the Universe.

Address to the Chemical Section.

BY PROFESSOR ABEL, F.R.S.

President of the Section.

Section B (Chemical Science) met on Thursday, August 16th, when the proceedings were opened by the following Address from its President:—

The subject which my predecessor, in the honourable position of President of this Section, made the chief topic of his interesting and instructive address, affords excellent illustrations of the operation of purely scientific research in creating and developing important branches of industry. Mr. Perkin, whose name has from the very commencement of the history of coal-tar colours been identified with their discovery and their scientific and technical history, referred to several series of researches, each one of which formed a link in a chain of discoveries in organic chemistry of the highest value as establishing, illustrating, or extending important chemical theories, but at the time, and for long afterwards, of value purely from a scientific point of view. These researches, undertaken and pursued by ardent and philosophical investigators under more or less formidable difficulties, and solely in the interests of science, resulted in the discovery of certain organic bodies which were produced originally only on a very small scale and at great cost, but which, after the lapse of years, have been readily manufactured from abundant sources, and have constituted important elements in the development of the industry of artificial colouring matters. In fact this industry, which owes its origin to the discovery of mauve by Mr. Perkin about twenty years ago, and which is second to no branch of chemical industry in regard to the rapidity of its development and its influence upon other important branches of manufacture, affords more copious illustrations than any other of the immediate influence of pure science upon industrial progress. It therefore affords a topic which the chemist may well be excused for continually recurring to, with an interest bordering on enthusiasm, when illustrating the material advantages which accrue to communities from the promotion of scientific training and the encouragement of chemical research.

The iron-and-steel industry presents a great contrast to that of the artificial colours in regard to the extent of influence which the labours of purely scientific investigators have exerted upon its development. The efforts of scientific men to unravel such problems as, for instance, the true chemical constitution of steel, or the precise differences between the various combinations known as cast iron, and the conditions which determine their individual production or conversion from one to another, have hitherto been attended by results not at all proportionate to the patient experimental investigation of which from time to time they have been made the subject. Thus, the protracted experiments and discussion carried on by Frémy and Caron, some years back, with reference to the dependence of the characteristics of steel upon the existence in it of nitrogen, cannot be said to have led to results of a more conclusive or even definite nature regarding the conditions which regulate the production, composition, and properties of steel than those arrived at by previous distinguished experimenters; and the same must be said, with respect to cast iron, of such experiments as those carried on for several years by Matthiessen (in which I also took some part) under the auspices of the Association, with the view to eliminate many existing points of doubt regarding the chemical constitution of cast iron, by preparing chemically pure iron and studying its combination with carbon and other elements occuring in cast iron.

The prosecution of purely scientific investigation may, therefore, of itself fail to bear *direct* fruit in regard to the development of new metallurgic achievements, or even to the elucidation of the comparatively complicated and numerous reactions which occur in furnaces, either simultaneously or in rapid and difficultly controllable succession, between materials composed of a variety of constituents in variable proportions. There can, however, be no question regarding the important benefits which have accrued from the application of chemical knowledge to the study and the perfection of furnace-operations, by those who happily combine that knowledge with practical experience, and with the power of putting to the test of actual practice the results of reasoning upon an intelligent observation of the phenomena exhibited in such operations, and upon the data which chemical analysis has furnished. In the hands of such men, the scientific results arrived at by Karsten, Berthier, Bunsen, Scheerer, Percy, and other eminent investigators, acquire new value, and by them the fruits of the labours of the patient toiler at analytical processes meets with that appreciation which their solid and permanently valuable work does not always command at the hands of their numerous brother-workers in chemical science who follow the far more attractive paths of organic research.

Naturally, the brilliant results achieved from time to time by investigators in organic chemistry, the rapidity with which, by those results, theories are established or extended, types founded, their offspring multiplied, and their connection with other families traced and developed, impart to organic research a charm peculiarly its own. This, and the general ease with which new results are obtained by the pursuit of methods of research comparatively simple in their nature and few in kind, have for many years not only secured to organic chemistry an overwhelming majority of workers; they also appear to have had a tendency to lead the younger labourers in the field of organic research to under estimate the value and importance, in reference to the advancement of science, of the labours of the plodding investigator of analysis. Yet no higher example can be furnished of the patient pursuit of scientific work, purely for its own sake, than that of the deviser or improver of analytical processes, who, undeterred by failure upon failure, indefatigably pursues his laborious work, probing to its foundation each possible source of error, carefully comparing the results he obtains with those furnished by other methods of analysis, and patiently accumulating experimental data till they suffice fully to establish the value and trustworthiness of the process which he then publishes for the benefit of his fellow-workers in science. Truly the results of such labours do not stand in unfavourable contrast, from whatever light they may be viewed, to those of the investigator of organic chemistry. It is not to be denied that the labourer at organic research may, so far as the analytical work which should fall to his share in the course of his investigations is concerned, be tempted to reduce this, the least attractive portion of his work, to within the smallest possible limits; and having, for example, by a boiling-point determination, or a single analytical operation of the simplest kind, such as the examination of a platinum-salt, obtained a numerical result approximating to that which his theory demands, may hasten on to the further development of his airy structure, possibly not without risk to its stability. Unquestionably there are instances of frequent occurence, in the pursuit of a particular line of organic research, in which more is not required than the identification of a particular product by some such simple means as above indicated. It is certain, moreover, that the labours of the organic investigator also not unfrequently afford bright examples of indomitable perseverance under formidable difficulties, and this alone should constitute a strong bond of union between the worker in organic research and his brother-worker in analytical chemistry, if one did not already exist in the active interest which each, if a true lover of science, must take in the work of the other.

It has been remarked by one of the most distinguished investigators, and at the same time, one of the most brilliant lecturers and successful teachers of our time, that the contrivance of a new and good lecture experiment may rank in importance with the preparation of a new organic compound; and it may certainly be said with equal truth that the elaboration of a new and good method of analyis may rank in importance with a good research in organic chemistry, in reference both to the part it plays in the advancement of science and to its influence upon industrial progress.

An excellent illustration of this is afforded by reference to the Proceedings of the British Association when it met in this town thirty-six years ago. In a letter to Dr. Playfair, Liebig, who took a very active part in the proceeedings of the Association in the earlier years of its existence, reports that Doctors Will and Varrentrapp have devised an excellent method for determining the amount of nitrogen in organic bodies, "very exact and easily performed." He then describes in a few lines the process so well known to chemists, which not only has been, and continues to be, invaluable to those engaged in organic research, but which, as may be testified by such researches as those Lawes and Gilbert, has born a most important and indispensable part in the advancement of agricultural chemistry. It is, I believe, but an expression of the unanimous conviction of chemists to say that the achievements in analytical chemistry of such men as Berzelius, Heinrich Rose, and Fresenius, take equal rank with the brilliant researches and theoretical expositions of such chemists as Liebig, Laurent, Gerhardt, and Berthelot, and that of all the important contributions to the development of organic chemistry which we owe to Liebig, there is none which has exerted so great an influence on the progress of this branch of chemical science as his beautifully simple method of organic elementary analysis.

Reverting to the industry of iron and steel, which, in regard to some of its most important branches, cannot fail to be a subject of special interest in Plymouth and Devonport, it is not difficult to demonstrate that the labours of the analytical chemists have exercised, and continue to exert, an important influence on the very considerable advance which has in recent years been made, and still proceeds, towards securing complete control over the quality and character of the products obtained. The epoch is well within the recollection of chemists of my generation when the British iron-master first awoke to the benefits which might accrue to him from an application of the labours of the analytical chemist in connection with iron-smelting. When the last great stride was made in the manfacture of cast iron, by the introduction of the hot blast, the iron-smelter was naturally led to seek profit, to the fullest extent, with respect both to the great increase in the rate of production of pig iron attainable thereby, and to the economy achievable in regard to the proportions and characters of the materials employed in the production of pig-iron. But after a time, the great falling off in the quality of a large proportion of the products of the blast furnace, and the difficulties experienced in the production of malleable iron of even very moderate quality, aided by the great impetus to competition in respect of quality given by the first International Exhibition in 1851, directed the attention of our more enlightened iron-masters to the likelihood of their deriving important aid from chemical science, and more especially from the investigations of the analytical chemist.

Among the earliest to realize the importance of trustworthy and detailed information regarding the composition of the iron ores of the country was Mr. S. H. Blackwell, who in presenting to the Royal School of Mines a very extensive and interesting series of British ores, which he had collected with great labour and expense for exhibition in 1851, placed at the disposal of Dr. Percy the requisite funds for engaging the services of competent analysts (Messrs J. Spiller and A. H. Dick), who, under his direction, and with subsequent pecuniary aid from himself and from Government funds, carried out a very careful and complete examination of this series, the results of which have been of great value for purposes of reference to those actively interested in the iron industry. It was, however the first connection of Messrs. Nicholson and D. S. Price, and of Mr. E. Riley, with two of the most important iron works of this country about a quarter of a century ago (*i.e.*, at the time when the above investigation was commenced), that marked, I believe, the commencement of systematic endeavours to apply the results of analytical research to the improvement and regulation of the quality of the products of our iron works.

It is, perhaps, but natural that the primary object sought by application of the knowledge of the analytical chemist should have been to eliminate or reduce the existing elements of uncertainty in obtaining the most abundant yield of pig iron capable of conversion into railway bar sufficiently good to meet the minimum standard of quality, and to reduce still further the cost of production of such bar iron, by utilizing material concerning the composition of which (richness in iron, etc.) the iron smelter was completely in the dark. The information accumulated by the analyst respecting the composition of the ores, fuel and fluxes available at the works, and the composition of the pig iron and slags (or cinders) produced under varied conditions, in regard to materials employed and to the proportions of ore, fuel and flux used in the blast furnace, could not, however, exist long without exerting a marked beneficial influence upon the quality of the iron produced, and generally upon the iron industry of the country.

Percy's invaluable work of reference on metallurgy furnishes abundant evidence of the scientifically interesting, as well as practically useful, nature of the results obtained at that time by the chemists above named, and others working under Dr. Percy, with respect both to the elaboration of important analytical processes (in which direction Mr. Riley has continued to the present day to do valuable work), and to the elucidation of the reactions occurring in the processes of reduction and refining of the metal. It is needless to dwell upon the fact that the aid of the analyst has now long since become absolutely indispensable to the iron and steel manufacture, but I may perhaps be allowed briefly to refer to one or two recent illustrations of the indispensable part which analytical research has played and continues to play in the extension of our knowledge of the chemical reactions involved in the production of cast and wrought iron and of steel, and of the influences which the chief associates of iron in its mercantile forms exert upon its physical characters.

Among the many valuable communications made to that most important body, the Iron and Steel Institute of Great Britain, by men who combine great practical knowledge and experience in iron and steel manufacture with high attainments in mechanical science, and such knowledge of chemical science as ensures a full appreciation of its value at their hands, one of the most interesting and suggestive to the chemist is that on the separation of carbon, sulphur, silicon and phosphorus in the refining and puddling furnace, and in the Bessemer converter, contributed to the Transactions of the Institute's recent meeting by Mr. Lowthian Bell, whose valuable investigations in connection with the iron industry are as interesting to the chemist as they are useful to the manufacturer. Mr. Bell has brought together the results of an extensive series of practical experiments on the treatment of different kinds of pig iron of known composition in the finery, in the puddling furnace, and the Bessemer converter, and, by comparing the results of analytical investigation of the products of those experimental operations with each other and with those of the materials operated upon, he has obtained valuable confirmation of the views already held by metallurgic chemists, regarding the succession in which carbon, silicon, sulphur, and phosphorus are attacked when pig metal is submitted to the above purifying processes, and the extent to which these foreign associates of iron are abstracted, or resist removal, by the more or less thorough application of those several modes of treatment. He has also thrown new light on the reason why the most difficultly assailable impurity, phosphorus, obstinately resists all attempts to effect even a slight diminution in its amount, by application of the Bessemer treatment. The earnestness with which Mr. Bell wages war against this enemy of the ironmaster, in one of its most favourite haunts, the Cleveland District, not simply with the old British pluck which acknowledges not defeat, but systematically, on scientific principles, calling to his aid all the resources which the continual advances in applied mechanical and chemical research place within his reach, cannot fail to contribute importantly, if it does not of itself directly lead, to the complete subjection of this most intractable of the associates to which iron becomes linked in the blast furnace. Indications have lately not been wanting that the existence of phosphorus in very notable proportions in iron may not of necessity be inimical to its conversion into steel of good quality, and it may be that this element, which is now turned to useful account to impart particular characteristics to the alloys of copper and tin, is even destined to play a distinctly useful part in connection with the production of steel possessed of particular characters, valuable for some special purposes.

In the great development which steel manufacture has received within the last few years, one most prominent feature has been the production with precision, upon a large scale, of steel of desired characteristics in regard to hardness, etc., by first adding to fluid cast-iron of known composition the requisite proportion of a rich iron-ore (with or without the addition of scrap-iron), to effect a reduction of the carbon to the desired amount, concurrent with a refining of the metal by the oxidizing action of the ore, and then giving to the resulting steel the desired special qualities by the addition of suitable proportions of iron-compounds of known composition, rich in manganese and carbon (spiegeleisen and the similar product called ferro-manganese). The germ of this system of producing steel-varieties of predetermined characteristics, exists in crucible processes like that of Uchatius which have been in more or less extensive use for many years past; but it is to such invaluable arrangments as are most prominently represented in the Siemens-Martin furnace, wherein several tons of metal may be fused and maintained at a very high temperature with as little liability to change from causes not under control as if the operation were conducted in a crucible, that we are indebted for the very great expansion which the direct application of the analytical chemist's labours to the development of the steel industry is now receiving.

The production of steel upon the open hearth, to the elaboration of which Dr. C. W. Siemens has so largely contributed, since he first established the process at Llandore in 1868, has, in fact, become assimilated in simplicity of character and precision of results to a laboratory operation, and may be justly regarded as a triumph of the successful application of chemical principles, and of the power of guidance and control afforded by utilizing analytical research to the attainment of prescribed results upon a stupendous scale, with an accuracy approaching that which the experienced chemical operator secures in the laboratory upon a small scale, under conditions which he can completely control. The production of steel by a large number of small separate operations in pots has now become supplanted with great advantage by the Siemens-Martin system of working at some of our largest establishments at Sheffield; this system has also secured a footing at highly renowned continental works, which are formidable competitors with us in the manufacture of steel, such as those of Essen, Creusot, and Terrenoire. It is specially interesting to notice that, in the hands of those who, on the Continent at least equally with ourselves, have learned to combine the results of practical experience, with the teachings of chemical science, the facilities now existing for dealing in a single receptacle with large masses of fluid steel, have greatly facilitated the application of chemical means to the production of *solid* masses of considerable size, thereby reducing, if not altogether dispensing with, the necessity for submitting large steel castings to costly mechanical operations, with the object of closing up cavities caused by the escape of occluded gas as the liquid metal cools. The success in this direction which appears to have attended the addition of silicon, in combination with iron and manganese, to the steel before casting; in preventing the formation of so-called *blow-holes*, and in contributing at the same time to the production of the particular character of steel required, bids fair to be of special importance in connexion with the application of steel to the production of projectiles for use against armour-plates, as affording ready and comparatively very economical means of ensuring the production of perfectly sound castings, which, in compactness of structure will, it is asserted, compete successfully with carefully forged castings, and even with the magnificent material which Whitworth produces by submitting the fluid metal to powerful pressure.

The part which silicon plays, by its comparatively high susceptibility to oxidations in promoting the production of sound steel-castings, is readily intelligible; but the functions of the manganese compounds, which are an indispensable adjunct to the Bessemer process, and the application of which has become an integral part of steel-manufacture, are still far from being thoroughly understood, and there is ample scope for chemical research, in co-operation with practical experiment, in the further study of the influence, not only of manganese in the production and upon the properties of steel but also of elements such as titanium, tungsten, and boron, and of chromium, which exists, associated in considerable quantites with iron, in a very abundant Tasmanian ore, to which prominent attention has lately been directed. The achievements of the mechanical engineer have so facilitated the handling and perfected the means of production and the mechanical treatment of malleable iron and of steel, that the full advantage may now be reaped of any improvement of a chemical nature which may be effected in the production of these materials, and it must be a source of pride to the chemist to observe with what success the teachings of his science are being applied by practical men of the present day in the construction of furnaces capable of withstanding the high temperatures required for the production and working of iron and steel in large masses, and in combining the perfect consumption and consequent great economy of fuel with the attainment of those high temperatures, and with a thorough control over the character of the gaseous agents to which the fluid metal is exposed in the furnace. I need not quote the names of those men who have already rendered themselves prominent by their services in this particular direction, but may refer, in special illustration of the results achieved by purely practical men, to the success in applying very simple furnace-arrangements to the attainment of the above results which has recently attended the labours of Mr. William Price, a principal foreman in the royal gun factories at Woolwich.

A few of the experiments made in the early days of the application of armouring to ships and forts appeared to demonstrate, on the one hand, that steel was quite incapable of competing with malleable iron, of even very moderate quality, as a material for armour-plates ; and, on the other hand, that the penetrative power of projectiles made of chilled iron, upon the Palliser system, could not be surpassed, or even attained, with any degree of certainty, by projectiles of steel, produced at comparatively very great cost. But some recent results obtained on the Continent, and especially in the course of the important experiments instituted by the Italian Government at Spezzia, have afforded decisive indications that steel, the application of which to the construction of ordnance has since that time been very greatly extended may now be looked to hopefully as capable of affording greater protection against the enormous projectiles of the present day than can be secured by proportionately large additions to the stupendous iron-armouring of the most modern iron-clads, and also as applicable, at a cost very moderate when compared with that of ten years ago, to the production of projectiles of large dimensions superior in point of penetrative power, and of uniformity in this respect, to those of chilled iron, the difficulties in the production of which are very greatly increased by the formidable increase which has lately been made in their size. Promising results have also quite recently been obtained at Shoeburyness, with a new system of applying steel in conjunction with malleable iron, by which a perfect union of masses between the two materials at one of their surfaces is effected by the aid of heat.

The superiority of soft and very homogeneous steel over wrought iron of the best quality in regard to lightness, combined with strength and toughness, are leading to its very advantageous employment in the construction of a particular class of vessels for the navy, and the perfect confidence which can be placed in the uniformity, in structure and strength, of steel of such character as is produced by the Whitworth system of manufacture, has greatly facilitated the production of air chambers of small weight, but capable of being quite safely charged with sufficient air, under a pressure of 1000 lb. on the square inch, to carry the Whitehead torpedo through water to the distance of a thousand yards in little more than a minute and a half.

Thus the results of the recent development of the steel-industry, to which the labours of the chemist have not unimportantly contributed, give promise of exerting a great influence upon the resources of nations for defence and attack. Although the necessity for the continual expansion of such resources cannot but be deeply deplored, there can be no doubt that the problems which it presents, and the special requirements to which it gives rise, must operate, and perhaps as importantly as the demands created by peaceful industries and commercial enterprise, in encouraging the metallurgist, the chemist, and the engineer to continue their combined work in following up the successes, to the achievement of which the results of scientific research have greatly though indirectly contributed.

If it were necessary to add to the illustrations which Mr. Perkin gave in his Address last year of the practical fruits of research in *organic* chemistry, I might be tempted to dilate upon the important results which have, especially during the last ten years, grown out of the discovery and study of the products of the action of nitric acid upon cellulose and glycerine. During the six years which have elapsed since I had the honour of bringing before the members of the British Association the chief points of scientific interest and practical importance presented by the history of those remarkable bodies, their application to technical and war purposes has been greatly developed. Nitroglycerine and gun-cotton may now be justly classed among the most interesting examples of the practical importance frequently attained by the results of chemical research, while the history of the successive steps by which their safe manipulation and efficient application have been developed affords more than one striking illustration of the achievements effected by combined physical and chemical research, in the solution of problems of high scientific interest and practical importance, and in the vanquishment of difficulties so formidable as, for a time, to appear fatal to the attainment of permanently practical success.

It is to a careful study of the influence which the *physical* characters of gunpowder (its density, hardness, &c.) and its *mechanical* condition (*i.e.* form and size of the masses and condition of their surfaces) exert upon the rapidity of the explosion under confinement, that we chiefly owe the very important advance which has been made of late years in controlling its explosive force, in its application as a propelling agent, and the consequent simple and effectual means whereby the violence of action of the enormous charges now used in siege- and ship-guns is effectually reduced to within their limits of endurance, without diminution of the total explosive force developed. But, concurrently with these important practical results, the application of combined chemical and physical research to a very extended and comprehensive investigation of the action of fired gunpowder, has furnished results which possess considerable interest from a purely scientific point of view, as in many respects modifying, in others supplementing, the conclusions based upon earlier experiments and theoretical considerations with respect to the nature and proportions of the products formed, the heat developed by the explosion, the tension of the products of combustion and the conditions which regulate it, both when the explosion is brought about in a close vessel and when it occurs in the bore of a gun. The results of these physico-chemical researches have, moreover, already acquired practical importance in regard to the light they have thrown upon the influence exerted by variable conditions of a mechanical nature upon the action of, and pressure developed by, fired gunpowder in the bore of a gun, and in demonstrating that modifications in the *composition* of gunpowder, not unimportant from an economical point of view in dealing with the very large charges now employed, may importantly contribute to render the storing of the maximum of work in the projectile, when propelled from a gun, compatible with a subjection of the gun to comparatively very moderate and uniform strains.

Other interesting illustrations of the intimate manner in which physical and chemical research are linked together, and of the important extent to which some of our most illustrious workers in chemistry have contributed to demolish the semblance of a barrier which existed in past times between the two branches of science, are furnished and suggested by the recently published list of grants of money which the Government has made to scientific men on the recommendation of the Royal Society, from the fund, which, for the first time last year, was added to the very modest sum previously accorded from national resources in support of research. The perusal of that list, representing as it does, a most carefully considered selection by the highest representatives of science in the country, from a very large number of applications, affords important evidence, on the one hand, of the active pursuit of science in Great Britain and, on the other, of the very wide range of subjects of interest and importance, the full investigation of which demands the provision of adequate resources. That the necessity for such resources needs but to be thoroughly made known to ensure their provision, even from other than national sources, has been demonstrated by the success which, in a comparatively brief space of time, has attended the efforts of the Chemical Society to establish, upon the foundation patriotically laid by one of its original members, Dr. Longstaff, a special fund, to be administered by the Society, for the advancement of chemical science. An inspection of the list of contributors to this special fund in aid of chemical research which, in about two years, has reached the sum of four thousand pounds, and from the proceeds of which the first applications for grants have recently been met, is suggestive of two observations; one is, that the proportion and amount of contributions hitherto received are comparatively small from the source whence the greatest support of such a fund may naturally be looked for, namely, from those who most directly benefit by the results of chemical research. It is to be hoped that there are many prominent representatives of the chemical and metallurgic industries in this country who still intend to give practical effect to their natural desire to aid in the advancement of chemical science, and to the appreciation which they can hardly fail to entertain of the usefulness of this fund. On the other hand, it is a matter well meriting special notice that a very prominent section of the contributors to the fund is composed of some of the most ancient corporate bodies of the city of London. Most welcome evidence is thereby afforded of the readiness with which the city companies are prepared to respond to appeals for the substantial support of measures well calculated to promote progress in science. This evidence, and the combined action which they are even now contemplating for promoting the application of scientific research to the advancement of industry and commerce, by establishing an institution for technical education upon a scale worthy to serve as a monument of the true usefulness of wealthy confederations, must be cordially hailed as very substantial proofs that these representatives of our national wealth and commercial supremacy are entering upon a new sphere of activity which will more than restore their ancient prestige, by according them a new rank, more elevated than any which their civil importance could, in the past or future, confer upon them,—a rank high among the chief promoters of our national enlightment.

Parliamentary and Law Proceedings.

The Manufacture of Soda Water.

At the Cambridge Police Court, last week, Mr. John Yeomans, chemist and druggist, Petty Cury, was charged with selling as soda water a mixture which was adulterated.—Mr. Apjohn, public analyst, certified that two samples contained ·16 grains of copper in the gallon, and also a minute quantity of lead, but no soda (sodium bicarbonate). In his opinion soda water containing this quantity of copper and lead was injurious to health.—The defendant said he paid great attention to the manufacture, and the vessels were tin lined to prevent contamination. Every care was taken. He made the soda water of different strengths of soda according to the requirements of the public. If he put in sufficient soda to satisfy the analyst with the Cambridge water they would have a soapy compound, and this the public did not like.—The Magistrates' Clerk said it was not a question of degree here, but of total absence.—The Defendant said that if he put in 15 grains of soda he should not please the public.—The Magistrates' Clerk: You should not call it soda water, but Yeoman's popular mixture —Mr. Balls (one of the magistrates) said the serious part of it was that, while being devoid of soda, the liquid contained copper and lead, which were certified to be injurious to health.—Defendant said he did not know how they came there. —The Magistrates inflicted a penalty of £5.—*Standard.*

Poisonings by Carbolic Acid.

An inquest was held on Friday, August 17, by the Liverpool borough coroner, on the body of Rosannah Connolly, aged forty-two, wife of a labourer living in Chaucer Street. It appeared that the deceased's husband had obtained some carbolic acid as a lotion to apply to a sore leg with which he was afflicted. On Wednesday last the deceased, mistaking the carbolic acid for water, drank some of it out of a cup, and died soon afterwards. A verdict of "Accidentally poisoned," was returned.

A similar mistake occurred at the Prescot Workhouse, on the 14th inst., by which an inmate in the smallpox ward, named William Sharkey, of St. Helens, lost his life. The doctor had ordered him the usual course of medicine necessary in smallpox cases, and on the above date, one of the paupers brought a bottle of carbolic acid, out of which a dose was mixed and administered by the nurse, instead of out of the correct medicine bottle. Sharkey at once became insensible, and died in half-an-hour. An inquest was held yesterday, before Mr. Driffield, at the Union Workhouse, and the jury returned the following verdict:—"The deceased died from a dose of carbolic acid, given in mistake by the nurse in his medicine," and accorded censure, by "considering that there was great neglect in the case in not having every bottle labelled, and thereby avoiding such sad mishaps."—*Liverpool Daily Post.*

Poisoning by "Battle's Vermin Killer."

On Thursday, August 16, an inquest was held at Butts, before Mr. T. Dewes, coroner, touching the death of Harriet Maria Jennings.

Dr. Read said he was called to the deceased on the previous day, and found her dead in a sitting position on the sofa. From his own observation and the certificate of the analyst, he had no doubt deceased was poisoned by strychnine, of which Battle's Vermin Killer is principally composed.

Mr. Frederick John Barrett, F.C.S. (from Wyleys and Co.), presented his certificate, which was as follows: "Received from Inspector Elms a jar containing a stomach, a teacup containing a blue powder adhering to its sides, with an opened paper envelope marked 'Battle's Lincoln Vermin Killer, Poison.' I hereby certify that I have examined the contents of the stomach, with the following results:—The coats of the stomach appeared much inflamed and contained about five drachms of a thick grumous liquid, much of which was adhering to the sides. I separated some few particles of a pigment resembling Prussian blue. The contents of the stomach, upon chemical analysis, I found to contain strychnia—in the proportion of nearly one grain. No other poisons were present."

The jury returned a verdict that the deceased died from the effects of strychnine contained in Battle's Vermin Killer, self-administered, but that there was no evidence to show the state of mind in which she was at the time.

Dispensing Memoranda.

*We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be conidered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.—**See p. 144.*

[17]. A Pill Query.—Dry the ox-gall over a steam-bath until it will rub down into powder. Allow for the loss in weight and make into pills with tragacanth mucilage. These will not fall.—H. C. Baildon.

[18]. Heat ox-gall to dryness and powder; add a few grains of Pulv. Tragacanth. and beat up with the smallest quantity of water.—W.

[18]. In answer to X. Y. Z., I have always found that purified ox-gall pills may be made so as to keep their shape for weeks by using Fell. Bovin. evaporated to a hard pill consistence, and adding a fourth its weight of powdered tragacanth. If another extract be ordered in the pill it is necessary to further evaporate the mass, rolling into pills while warm. I have not found it necessary to keep the pills in a bottle, when prepared as above, and the coating of tolu, though desirable for other reasons, is not necessary to the retention of shape.

W. T.

[19]. CINCHONINE PREPARATIONS.—

℞ Sp. Am. Aromat. . . ʒvj
Eth. Chlor. . . . . ʒiv
Syr. Cinchon. . . . . ʒiv
Vin. Ferri . . . . ad ℥viij M.

The above has been dispensed in several places with different results as to taste and appearance; that sent out from the prescriber's own establishment pleasing the patient best, because, though containing a "bulky sediment," it was "by far the sweetest." Will some one oblige with a good formula for "Syr. Cinchon.;" or, if any, that recognized in leading houses?—G. W. W.

[20]. Last week a gentleman presented the following prescription to be dispensed at my establishment. He saw it when finished and asked if everything had been put in it, as he had it dispensed at a well-known house (whose stamp it bore), and it was a thick opaque mixture. Perhaps you or some of your readers can account for this, or say what appearance it ought to have:—

℞ Potassii Bromidi,
Ammon. Bromidi . āā ʒij
Æther Chlorici . . . ʒj
Tinct. Aurantii . . . ʒij
Aqua Caryophylli . ad ℥xij

M. Ft. mist.—A twelfth part twice a day.

Ph. Chemist

[21]. APOTHECARIES' OR AVOIRDUPOIS?—Can any reader inform me if in dispensing a prescription containing a powder of which, say, one ounce is ordered thus—

Bismuth. Subnit. . . . ℥j

the avoirdupois or apothecaries' ounce should be used?—Difficultas.

[22]. KEEPING LEECHES.—Can any correspondent tell me how to preserve leeches alive? I have tried filtered water, spring water, and rain water; kept them in a cool place, in the dark, and in a moderate light. I put pebbles and weeds in the water, and change the water every day, but still they die off at the rate of about four a week.—F. F. Hoddinott, Barnet.

[*⁎* Several methods have already been suggested in the present series of this Journal (see for instance, vol. vi., pp. 260, 460, and 700). Perhaps the insertion of this query may bring out further experience on this subject.—Ed. P. J.]

Counter Practice.

Sir,—There are few, I think, who like myself were unavoidably absent from the Conference just concluded in the beautiful town of Plymouth, but must have felt great pleasure in reading the President's address, touching as it does so gently, and yet so clearly and nicely, on the subject of counter prescribing.

Obviously this subject has been for a long time coming to a head, and it is clearly necessary therefore that an understanding should be arrived at with regard to it.

The time perhaps could not have been more opportune, judging from all things, than the present, when the Pharmaceutical Society and the medical profession are on such amicable terms, each acknowledging the other's special sphere and education.

But then this happy state of things does not meet the case of the majority of our brethren who live far off in distant country towns; nor indeed does it meet the case of many of our friends at the East-end of London and in suburban districts; so that if the calling into power of this obsolete Apothecaries Act is to be allowed to take away the actual existence of some, who although they prescribe for simple ailments, do so simply to meet the public want, and the public demand in these days of free trade, and because in most instances the case is too simple to call in the attendance of a doctor—then it does seem a little hard.

I myself have frequently known the medical attendant when applied to to say, "You might go to your chemist and get a little gargle or cough mixture, as the case may be, and come to me when you are ill." As a rule, the busy practitioner has too much to occupy his attention to leave any room for him to desire to take away from a few who are honoured with the distinctive title of prescribing chemists, their simple recommendations, for which they get about one and sixpence or two shillings, and there, as a rule, the case ends.

I am not myself a prescribing chemist, my lot being cast in a neighbourhood where, generally speaking, medical men are rather more liberal than to want the whole thing, prescribing and dispensing also; and we find the doctrine of division of labour to answer well here; but then I know that in many country towns, medical men not only visit and prescribe but dispense their own medicines also, and not by any means unfrequently do they employ a chemists' assistant to attend all the minor cases for one half the remuneration which it would be necessary to pay a qualified man.

If medical men in the country complain so much of the little encroachment of chemists on their preserves, surely there is much greater cause for pharmacists, who are now thoroughly well up in their business, to make a much louder cry on the subject of doctors doing the whole thing, which includes sending out their own physic into the bargain.

In conclusion, I have only one word to add, and it is this: not unfrequently, when I have conversed with members of the medical profession on this subject, they have given as a reason for dispensing their own medicines, that chemists in many places are not to be depended upon; and they are more sure of their patients getting the right articles.

Now, sir, I do not agree with this explanation, which strikes at the root of the Pharmaceutical Society; because I am convinced that the whole body of chemists and druggists are an exceedingly intelligent class of men, and as a rule, not only do they do their work well, but would certainly carry out all matters pertaining to pharmacy as their special calling, much better than medical men can do themselves.

A. W. Postans.

35, *Baker Street, W.*

Sir,—The resolution of the Council of the Society to defend counter practice of chemists is a step in the right direction. I regret the question had ever been raised, because it is not advisable to permit chemists to treat disease officially as it were, or as a right; it is also impossible for a chemist to carry on his business, viz., the compounding and sale of remedies as a mute; moreover he is morally bound to protect the ignorant customer against injury resulting from the misuse of medicine, and he can often only do so by putting the patient in the right course.

Theology and medicine have by the general progress of mankind ceased to be the special domain of one or two sets of individual priests, or medicine men. They are matters which affect mankind so closely and intimately that occult practice in either branch is viewed with suspicion, and individual common sense is sharpened. One of the outcomes of this general enlightenment is the position the chemist has assigned to him by the public; they bring their little guesses to him in many minor ailments for his sanction or emendation on the one hand, and for his opinion on the choice of a physician or a medical man on the other. The chemist is by his education and employment a professor of remedies; he has little or no pathology to guide him in the use of them, but contact with well trained medical minds with an earnest desire and habit to comprehend the wishes and directions of those minds, with a very little intuition, puts the chemist above the general intelligence of the public in that department; moreover he is very accessible. This open door invites the man with a pain, it is often not a question of doctor or chemist, but of a draught, or brandy. If he goes to the public house the publican although interested in the sale, may decide for him whether it shall be brandy, gin and bitters, aniseed or shrub. Is the chemist who has to decide between soda and ammonia, gentian and potash, castor oil or rhubarb, to be mute because he is interested in the sale of the remedies? Or, notwithstanding his greater power of discrimination, to stop where the publican stops—Well, gentian and potash wont do you any harm. He takes it kindly from the landlord of the inn, would he not rather say to the chemist—That is not the question; will it do me any good? On this hangs the whole matter; everything else in counter practice is subsidiary to this. Yield this point, all else must follow, and the safeguard to the public interest is the petitioner for gratuitous advice well knows his informant does not possess a medical diploma, and the responsibility of the act rests with the customer not with the chemist; he has done like a king of old time—he has made his priests other than of the house of Levi.

A compromise between the two great branches of the faculty of medicine is the solution of the matter. Chemists must not visit patients nor pretend to be other than they are. And medical men must not keep a dozen kinds of whitened pills for every case, nor concentrated mixtures for every ill, for both are mendacious quackery.

To appeal to statute law, reminds one of a holiday reverie on coming to a sign post with three arms—one dilapidated and erased, pointing to a road overgrown with brambles, thistles and wild flowers, the only intelligible letters are To Apot.......... Farmer: Yokel, where does this lead to? Answer. To apothecaries farm, sir, not been used for many years, as you see, sir. This here road, good many serpents in the long grass. You can get along by the foot path by the hedge side and then cross a meadow by a deep rut—there's no regular foot path; the field belongs to the college of physicians, but they wont interfere with you if the dog keeps out of the preserves.

George Mee.

Mushrooms as Food.

Sir,—In Mr. Husemann's paper on this subject, published in your Journal of August 4th, p. 85, there is surely a very important omission. The proportion of water in mushrooms is very large, but it is nowhere stated. The organic principles in 100 parts of dry substance, and the mineral constituents of the ash are given, but the quantity of water and ash per cent. contained in the recent edible mushroom is omitted. The practical question in using the *Boletus edulis* as found is, how much of the recent mushroom is represented by 100 parts of dry substance, containing 22·82 of protein, etc.?

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 105.)

STERCULIA URENS.—*Local names*, KARAI, PANDROOK, KAVALEE.

This tree is abundant in Khandesh, where the gum is collected for sale, and enters commerce as Karai gond. A few trees probably planted in Bombay. They abound in the Concans. The gum exudes most abundantly in the hot weather; it varies a good deal in appearance, some pieces being in thin laminæ, like tragacanth, while others are lumpy or vermiform. Placed in water it forms a firm, colourless, tasteless jelly, but on the addition of a large quantity it dissolves; the solution is precipitated by acetate of lead. Karai gond is used as a substitute for tragacanth, and is issued from the government stores.

PINILIA TUBERIFERA—ZARAWAND I GIRD.

The small roundish bodies which are sold in the shops under this name have been found by Dr. Sakharam Arjun to be the tubers of an Arum and not the root of *Aristolochia rotunda*, as is generally stated. They are light brown externally and vary much in size, the smallest being no larger than a pea, the largest as big as a marble; at the apex is a depression filled by the scales of the bud, at the base another marking the attachment of the roots. The interior is white and farinaceous, the taste insipid. As a medicine they are probably inert.

HYOSCYAMUS NIGER.—*Local name of seed*, KHORASANEE AJWAN.

The seeds are sold under this name in the bazaar. I find on comparison that they are exactly similar to the seeds produced by plants raised from English seed. They are imported from Persia. Henbane is cultivated for medicinal purposes in the government gardens at Hewra near Poonah.

DELPHINIUM, Sp.?—*Local names*, TRAYAMANA *and* ASFRAK.

The drug consists of the flowers, flower-stalks, and a small proportion of the immature fruit, all of a light greenish-yellow colour, and having a somewhat honey-like smell. The flowers are many of them tolerably perfect, and in size and shape are not unlike those of the common single larkspur. The fruit consists of three folicles which are arranged like those of the aconite, and dehisce on the inside; they are marked with very prominent longitudinal ribs, have pointed apices, and are placed upon a stout curved peduncle. The seeds are numerous, angular, as in aconite, and studded with white feather-like hairs all pointing towards the thick end. Trayamana when placed in water immediately tinges it of a bright yellow. It has a bitter taste not unlike gentian; it is described in the 'Makhzan ul Adwiga' under its Arabic name zarir. "The author says that it grows in the Gorjan or Khorjan Hills, and is called arjeekun in Greek. It has a stem about a span high and yellow flowers. It is detergent, anodyne, and diuretic; useful in spleen, jaundice, and dropsy, also as poultice mixed with barley meal in inflammatory swellings. Dose five drachms." In Bombay it is chiefly used as a yellow dye for silk, and is worth about one shilling a pound. It is also an ingredient in some of the diet drinks which the native druggists prescribe for their customers. I can find no notice of it in any English work on Indian drugs or dyes.

POA CYNOSURIOIDES.—*Local name in Goa*, GRAMINA.

This grass has a creeping root which forms at intervals a number of small, very hard knots or bulbs, from each of which rises a stem, and from the under surface of which numerous strong rootlets are given off. The culm is stout and round, clothed at the base with withered sheaths. In the drug it is cut off a few inches from the root. This article has a bitter taste. It is the gramina of the Portuguese at Goa, and is used as a diuretic. I have not seen it used medicinally in Bombay; but under the names of kash, darbh, or dad, it is in constant requisition at the funeral ceremonies of the Hindoos. The chief mourner wears a ring of the grass upon his finger; it is also placed beneath the pinda's. Darbh must not be confounded with doorba (*Cynodon dactylon*) another grass which is sacred to Gunnesh.

APLOTAXIS COSTUS.—*Bombay name*, OUPLATE; *the* KOOT *or* PUTCHAK *of other parts of India*.

The credit of first suggesting the source of this drug is due to Guibourt; his conjectures were afterwards confirmed by Falconer, who, when on a visit to Cashmere, discovered that an aplotaxis growing there produced the commercial costus. The plant itself had been previously described by Jacquemont in 1831; Falconer's description may be found in the *Transactions of the Linnean Society*, 1845, vol. xix., p. 23. There is also a full account of the drug and plant, with woodcuts, in Guibourt's 'History of Drugs,' vol. iii., p. 32, *et seq*. Large quantities of ouplate are imported into Bombay from Cashmere by way of Amritsir. It is extensively used as a perfume, and to protect clothes from moths; also as an aphrodisiac and vermifuge. It occurs in crooked twisted pieces about 3 inches long, and from $\frac{1}{2}$ to $1\frac{1}{2}$ inches in diameter, almost always split. The central portion is generally absent and appears to have been removed by decay before the root was collected. Externally it is brown and marked by longitudinal ridges, internally dirty white and resinous; taste bitter, odour something like orris root. A microscopic examination shows that the root consists of two parts, viz: a thick cortical layer of close texture, pervaded by a few laticiferous vessels, and an inner radiating portion, the parenchyma of which is not so dense. This portion is also provided with laticiferous ducts, and a very abundant scalariform vascular system which appears loaded with resinous matter. No trace of starch is to be seen, nor does the iodine test indicate its presence. The central portion of the root is absent as already noticed.

TEPHROSIA PURPUREA.—*Local name*, SARPANKHA.

This is a common weed in the rains. The whole plant, which is about two feet in height, is pulled up when the flowers begin to appear, and tied in bundles for sale. It is described in the Bombay Flora as "a shrubby, erect, much branched weed, leaves pinnated, leaflets cuneate-oblong, leaf opposed; racemes peduncled, longer than the leaves; legumes slightly compressed, spreading, linear, falcate, obtuse, with a short point. To this may be added that there are from five to eight or nine pairs of leaflets, and generally a single terminal one, the largest an inch long and three-tenths of an inch broad. The plant is a little bitter and is given in dyspepsia and bowel complaints arising from it. Sarpankha is generally to be obtained in the shops.

LODICEA SEYCHELLARUM.—*Local name* DARYAI, NARIL.

The kernel of the sea cocoa nut is in great repute among the Arabs and Indians as a strengthening medicine; it is from three-quarters to one inch thick and very hard, having much the appearance of vegetable ivory; it has no odour or taste; when soaked in water it softens a little and can be split into thin fibrous bundles. Examined under the microscope these are seen to be composed of spindle-shaped cells having a central cavity, from which club-shaped canals extend to the cell wall, where they are opposed to similar canals belonging to a neighbouring cell. The palm which produces this nut grows in the Seychelles, and the nuts are exported to India and Arabia. From the leaves very beautiful work-baskets, hats, bonnets, and many other fancy articles are made. A description of the nut is unnecessary, as it is to be seen in most museums and cannot be mistaken for any other object.

(*To be continued.*)

COMPARATIVE CHEMICAL EXAMINATION OF THAPSIA GARGANICA AND THAPSIA SILPHIUM.*

BY M. YVON.

A short time since, in an exhaustive paper, an abstract of which was published in this Journal,† M. Herincq claimed to have demonstrated that an Algerian plant to which the name *Thapsia Silphium* had been given, and which was alleged to be the source of the silphion of the ancients, was identical with the *Thapsia Garganica* of Europe. Admitting this as proved, M. Yvon thought it would be interesting to examine whether the growth of the same plant in different latitudes affected its ultimate composition.

Exposed to prolonged heat in a stove, the root bark of *Thapsia Garganica* lost 12·93 per cent. of water, that of *Thapsia Silphium* lost 17·35 per cent. The dried substance gave the following results upon analysis:—

	T. Garganica.		T. Silphium.	
Organic Matter	91·24		90·26	
Starch		22·510		26·124
Gum		5·179		5·421
Gum-resin		5·759		4·271
Resin		2·554		3·192
Albumin		1·354		0·624
Inorganic	8·76			
Lime		1·365		1·368
Magnesia		0·677		0·697
Iron		0·370		0·224
Albumin		0·338		0·508
Sulphuric Acid		0·297		0·300
Phosphoric Acid		1·468		1·919
Chlorine		0·219		0·420
Silica		2·715		0·707
	100·00	100·000	100·00	100·000

An examination of this table shows that there is a considerable concordance between the mineral constituents of the plants dried at 100° C., and almost as great in the organic constituents, the quantity of resinous matters being nearly the same. Inquiries directed to ascertain what influence the nature of the soil might have brought out the fact that in Algeria the plant grows equally well in all soils. In consequence of the presence of resinous matters the author does not speak decisively as to the existence of an alkaloid in the plant.

Examined under the microscope the starch of the two kinds appears to be similar except as to size, that of the *T. Silphium* varying in diameter from $0^{m}\cdot004$ to $0^{m}\cdot015$, and that of *T. Garganica* from $0^{m}\cdot006$ to $0^{m}\cdot026$.

Although the amount of resin obtained from the two plants was so nearly the same it differed considerably in activity. During the extraction of the resin from the root bark of the *T. Silphium*, which was done by exhausting it with 99° alcohol after previous treatment with 60° alcohol, there was given off a peculiar not unpleasant aromatic odour that was not observed with the *T. Garganica*. The activity of the silphium resin, however, was found to be excessive. In spite of all precautions a stay in the laboratory during the evaporation of the alcohol produces a rather painful sensation of heat which afterwards became localized in the nostrils, eyelids, and especially in the neck behind the lobes of the ears. After twelve hours of intolerable itching at these points a very intense miliary eruption took place, together with swelling of the eyelids and finally desquamation. The work was therefore dropped for two months, but the same symptoms followed a renewal of it. Even contact of the fingers with resin produced the symptoms notwithstanding immediate washing with alcohol and soda. A curious point is that no inconvenience was experienced in the hands and arms. Nothing of the kind occurred during the manipulation of the garganica resin.

* Abstract of a paper read before the Union Scientifique des Pharmaciens de France, and published in the *Journal de Pharmacie* [4], vol. xxv., p. 588.

† See before, vol., vii., p. 750.

THE DISPENSING OF MONOBROMATED CAMPHOR.*

BY M. PATROUILLARD LEPAGE.

Having had occasion to prepare medicines into the composition of which monobromated camphor entered together with syrups or water, the author, after several experiments, took advantage of the property this substance has of dissolving in fixed oils, especially oil of sweet almonds, which will take up about one-sixth of its weight of monobromated camphor. In this way he obtained homogeneous preparations of monobromated camphor, miscible in aqueous vehicles, easy to administer and acting promptly, it being introduced into the body in a liquid state. The plan adopted was to dissolve the monobromated camphor in six times its weight of almond oil by the aid of a gentle heat, emulsify the oily solution with gum arabic, and then suspend it in syrup or in water according to the indications of the prescription. The emulsions obtained were as perfect as those with almond oil alone.

In consequence of the instability of the oil used as a solvent, the emulsion should be prepared as required; the monobromated camphor, however, appears to keep without undergoing any decomposition, even after an interval of three months.

To emulsify seven grams of the oily solution, containing one gram of the active substance, the author employs three grams of powdered gum arabic suspended in double its weight of water. When the emulsion has been made, the necessary quantity of syrup or water is added in the usual manner.

The author has made some experiments on the dispensing of salicylic acid in a similar way, but these were unsatisfactory in consequence of the slight solubility of this substance in the oil.

* From a paper in the *Journal de Pharmacie* [4], vol. xxv., p. 533.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 1, 1877.

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

COUNTER PRACTICE.

IN the last number of the *Lancet* additional prominence is given to the discussion of this subject by the comments of the Editor upon the proceedings in reference to counter practice at the last meeting of the Council of the Pharmaceutical Society, and the views put forward are throughout characterized by considerable exaggeration. In the first place, it is assumed that by the terms of the resolution passed by the Council the Society has been distinctly pledged to defend medical practice by chemists, and it is also stated that this was done notwithstanding the acknowledgment by most of the speakers who voted for the resolution in question that counter practice is illegal.

We take decided exception to both the assumption and the statement as being wholly at variance with the facts of the case. In the first place the terms of the resolution passed at the last meeting of the Council do not in any degree justify the interpretation put upon it. Even as originally put it was only to the effect that the Council should defend, if necessary, a member of the Society who had been threatened with prosecution under the Apothecaries' Act. In the amended form, in which the resolution was eventually passed, it merely gave authority to the Society's Solicitor to defend the case at his discretion. In the course of the discussion it was stated that there was reason for considering that in the case referred to the chemist had been conducting his business properly, and according to the practice of a majority of the trade, and the provision that the defence of the case should be subject to the discretion of the Society's Solicitor clearly shows that there was no intention to set the law at defiance. It must also be remembered that the resolution had reference to the defence of a case of prosecution under the Apothecaries' Act, the propriety of which is rendered at least doubtful by the comments of Baron BRAMWELL in his summing up of the case tried by him last year. Although this judge pointed out that the Act was so strict in its terms that if a man entered a chemist's shop and asked for something to cure a headache, and the chemist gave him a draught, he would technically infringe the terms of the Act, still he added his opinion that it would be very unreasonable if the Apothecaries' Company were to interfere in such a case. As regards the particular merits of the case tried by Baron BRAMWELL, it is unnecessary to offer any opinion since that is a matter entirely apart from the question now under consideration. It is against the unreasonable application of the Apothecaries' Act that chemists are now protesting, and that the Council of the Pharmaceutical Society has decided to take action.

It is therefore only by an unwarrantable straining of the terms of the Council's resolution that it can be represented as indicating a determination to defend medical practice by chemists. The Society as a body has always sought to develope the opinion that the business of the pharmacist should not comprise the prescribing of medicine; but under existing conditions the general acceptance of this view of the case can only be regarded as a desideratum which may be realized at some future time. It is futile to suppose that the Pharmaceutical Society can put a stop to the practice which has long prevailed amongst chemists, though many of it members abstain from it themselves and would gladly see their example followed.

However the action of the Medical Defence Association in prosecuting chemists under the Apothecaries' Act has contributed very much to awaken a spirit of resistance, and it has led to the assertion of a right on the part of chemists to continue doing what they have long been accustomed to in furnishing remedies for minor ailments. It has always been our practice to deprecate discussion even of the propriety of this proceeding and it is with much regret that we now find the opposition to it conducted in such a manner as to raise the question whether or not chemists have a less right to prescribe medicines than every other individual in the country has.

As regards the statement made by the *Lancet*, that most of the speakers who voted for the resolution acknowledged the illegality of counter practice, we can only give it the most unqualified contradiction, and that we are justified in doing so the report of the discussion will clearly show. The *Lancet* is indeed totally in error on this point, and beyond the remarks of the President and MR. HILLS, there is no ground for the satisfaction it expresses at observing that the large majority of speakers at the Council meeting had a conviction that prescribing over the counter is illegitimate. On the contrary, the majority of the members of the Council and the majority of the trade are decidedly of opinion that counter practice is legitimate, and although many of those who hold this view are also disposed to think that it would be to the advantage of themselves as well as medical men if prescribing and dispensing could be dissociated, we cannot shut our eyes to the fact that if the Apothecaries' Act be oppressively applied to chemists the general feeling will be one of resolute determination to try the question of right.

Here another aspect of this matter requires to be noticed, viz., the convenience of the public; and we apprehend that in the event of a contest between the medical profession and chemists, the decision arrived at would probably be influenced much more by consideration of this point than by any abstract regard for the rights of either contending party. Although we do not endorse all the views of correspondents who have written on the subject of counter practice in this Journal, it cannot be denied that in very many instances the possibility of obtaining simple remedies at a very moderate cost from the chemist is a great boon to a large class of the community who would otherwise be unable to obtain relief. At the same time it may reasonably be assumed that the improved educational advantages which the chemist now enjoys through the efforts of the Pharmaceutical Society will not be inoperative in preventing him from exceeding reasonable limits in the matter of counter practice.

A MYSTERIOUS PLANT.

Although nearly four centuries have elapsed since the island of Hayti was first trodden by European feet, it is at the present time, from political causes, almost a *terra incognita*. But Major Stuart, Her Majesty's Consul-General in that island has just sent home an interesting account of the country, which creates a desire that it should be scientifically explored and especially that its rich tropical flora should be investigated by a competent botanist. Major Stuart makes special reference to one plant —whether a tree, shrub or a herb he does not say— which he has no doubt would prove, as an anæsthetic, a valuable acquisition to medical science. The knowledge of this plant, he says, is confined to a few families, who transmit the secret from generation to generation as a heirloom. The heritage is highly prized as conferring a power of miracle working, and this power, known as "wanga," is used not only to bolster up superstition but to facilitate crime. It is asserted that a skilful "wanga" priest has such a knowledge of the effects of this plant that he can produce with it coma of any intensity or duration and by his knowledge of the moment of returning consciousness can make a show of recalling the patient to life. Major Stuart goes on to say that if a burglary is to be committed the "wanga" man "can "by means of his art cast a deep sleep on all in-"doors, and one may understand how he can attain "other forbidden ends in the same way." Perhaps so, but we confess we do not understand the way.

PROPRIETARY MEDICINES IN JAPAN.

It appears that medical compounds of the nature of those to which in this country the term "quack medicines" is often applied, share the confidence of the Japanese public with charms against every description of disease and misfortune, which are sold at all the temples. The Mikado's Minister of Finance, in his zeal for the welfare of the community—quickened probably by having to provide for one of the luxuries of western civilization, a national debt—has sought to limit this unorthodox medical treatment of the people by the imposition in January last, of a tax on druggists' licences. This tax does not affect the drugs and medicines used and prescribed by the medical profession, but is directed solely against the "quack" compounds referred to. To obtain permission to make or sell these medicines a minute description in writing of the nature and effect of each has to be sent to the Ministry of the Interior, and heavy penalties are attached to their unauthorized sale and manufacture. A licence for the manufacture of such medicines costs eight shillings per medicine, and a druggist pays one shilling per medicine for a licence to sell.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 133.)

After the conclusion of the President's address the reading of papers commenced. The first paper was a—

Report of the Committee appointed in 1876, for the purpose of continuing Investigations on the Aconite Alkaloids (consisting of Mr. T. B. Groves, Mr. J. Williams, and Dr. C. R. Alder Wright): being the "Third Report on the Chemistry of the Aconite Alkaloids."

DRAWN UP BY

C. R. ALDER WRIGHT, D.SC. LOND.,

Lecturer on Chemistry in St. Mary's Hospital Medical School,

AND A. P. LUFF,

Demonstrator of Chemistry in St. Mary's Hospital Medical School.

Since the presentation of the Second Report last year, a large number of experiments have been made in the hope of obtaining information as to the chemical "Structure" of aconitine (the chief crystallizable active alkaloid of *Aconitum Napellus*), and of pseudaconitine (the main crystallizable active base of *A. ferox*). Although the experiments are not yet completed, yet several points of considerable pharmaceutical and chemical interest have been arrived at, and a number of discrepancies in the results obtained by former observers have been reconciled and cleared up; whilst an explanation has been gained of several perplexing circumstances connected with the preparation of alkaloids from the roots of various species of aconites, and in particular of the great differences in physiological potency sometimes exhibited by different specimens of alkaloids derived from these plants. Some valuable information as to the deficiencies and imperfections of the manufacturing processes for the isolation of these alkaloids has also been gained; and a method of assaying elaborated whereby a sufficiently close approximation to the percentage of active alkaloid contained in the manufactured bases can be readily attained.

The experiments made may be most conveniently described in five sections, referring respectively to the decomposition products of aconitine, those of pseudaconitine, the further investigation of the alkaloidal constituents of different species of the aconite family, processes for assaying commercial aconite alkaloids, and the conclusions to be drawn from the work hitherto done on the subject.

§1. *Decomposition Products of Aconitine. Action of Water on Aconitine.*

When aconitine is heated to 140—150 in a sealed tube with water for from 10 to 24 hours it completely dissolves, forming a slightly yellowish liquid of *acid* reaction; this latter circumstance clearly indicates either that one equivalent of acid is produced by the decomposition for one of nitrogenous decomposition-product, or else that the latter substance is deficient in acid-saturating power; the latter appears to be the case from the following results:—

One gram of pure aconitine thus treated yielded an acid liquid to which a known quantity of standard soda solution was added until strongly alkaline; the fluid was then agitated with ether, to remove, as far as possible, bases, and the excess of alkali was then titrated with standard acid. In this way it was found that the acid produced permanently neutralized 14·1 c.c. of decinormal soda solution, equivalent to 0·909 gram of aconitine, or somewhat less than one equivalent of acid for one of aconitine employed, the deficiency being due, as will be subsequently shown, to the imperfect removal from the alkaline fluid of the complementary nitrogenous product.

The reaction is indicated by the equation

$$C_{33}H_{43}NO_{12} + H_2O = C_7H_6O_2 + C_{26}H_{39}NO_{11}$$

the acid produced being *benzoic acid.* To the complementary product $C_{26}H_{39}NO_{11}$, it is proposed to assign the term "*aconine,*" to represent its connection with aconitine, which, in fact, as shown below, is apparently *benzoyl-aconine* $C_{26}H_{38}(C_7H_5O)NO_{11}$. The benzoic acid thus produced was quantitatively determined by adding hydrochloric acid to the product of the action in sealed tubes, agitating with ether, and allowing the ethereal solution to evaporate spontaneously, the residue being finally dried for a night over sulphuric acid; when weighed quantities of benzoic acid were thus treated as a check on the method, almost exactly the amount employed was regained. In hot weather, by exposure to air for some days, however, a considerable volatilization of benzoic acid takes place. In this way—

2·910 grams of aconitine yielded 0·441 of benzoic acid
3·000 " " " 0·479 " "

	Calculated from above equation.	Found.	
Benzoic acid per 100 aconitine used,	18·9	15·2	16·0

The numbers found, are sufficiently near to show (when taken in connection with the subsequent data), that the above equation represents the main change taking place.

After recrystallization from boiling water, the acid melted at 120°·5 and possessed all the physical characters of ordinary benzoic acid, yielding also its qualitative reactions; on combustion

0·2090 gram gave 0·5215 CO_2 and 0·0935 H_2O.

	Calculated.		Found.
C_7	84	68·85	68·05
H_6	6	4·92	4·97
O_2	32	26·23	
$C_7H_6O_2$	122	100·00	

The isolation of the complementary product was a matter of far greater difficulty, on account of its peculiar properties. As above stated it is only imperfectly removed from an aqueous alkaline solution by agitation with ether; the ethereal extract dried up to a wholly non-crystalline varnish, but this did not seem to be the body in a state of purity, being contaminated with traces of unaltered or differently changed aconitine, bye-products, etc., and in particular giving a slight precipitate on solution in a drop of hydrochloric acid and addition of sodium carbonate, which does not occur with pure aconine salts. Attempts were first made to obtain aconine as hydrochloride by adding hydrochloric acid to the product of the action in sealed tubes, removing benzoic acid by agitation with ether, and then evaporating to dryness; but in this way a substance was obtained, which was not only impure from the admixture of the bye-products, etc., capable of solution in ether when the solution was rendered alkaline, but also contained some products formed by the action of the excess of hydrochloric acid on the aconine during the evaporation: the residue refused to crystallize and gave the following numbers.

0·2685 gram, gave 0·5470 CO_2 and 0·1995 H_2O
0·3870 " " 0·1080 AgCl

	Calculated for $C_{26}H_{39}NO_{11}$,HCl.	Found
Carbon	54·03	55·56
Hydrogen	6·93	8·25
Chlorine	6 15	6·91

Attempts to prepare the gold salt were not more successful, as the aurochloride when first precipitated forms yellow flakes, but during drying these clot together, forming a resinous substance which is apparently somewhat decomposed: this gold salt is somewhat soluble in water, and the solution leaves, on standing over sulphuric acid in the dark, a resinous substance containing particles of metallic gold, indicating reduction and decomposition.

0·9500 grains of resinous gold salt formed by the clotting together of the precipitate, gave 0·2250 Au = 23·68 per cent.

The formula $C_{26}H_{39}NO_{11}HCl,AuCl_3$ requires 22·27 per cent.

The following process, however, was found to yield aconine compounds in a state of tolerable purity. The liquid obtained by acting in sealed tubes with water on aconitine was rendered slightly acid by hydrochloric or sulphuric acid, and freed from benzoic acid by agitation with ether; it was rendered slightly alkaline by sodium carbonate, and again agitated with ether to remove bye-products, etc., soluble therein. The alkaline fluid was then evaporated to dryness, and treated with absolute alcohol, or better chloroform. The substance thus dissolved out was found to differ in character according to the amount of sodium carbonate added in the earlier stage of the process; if the carbonate was in quantity insufficient wholly to neutralize the sulphuric or hydrochloric acid originally used to acidify, a basic sulphate or hydrochloride was dissolved out; but if a large excess of sodium carbonate was used, the soluble body was simply aconine itself, contaminated with small quantities of sodium carbonate. The following numbers were obtained, due corrections being made for inorganic substances when small quantities of these were present.

Basic Sulphate of Aconine.

0·3250 gram gave 0·6615 CO_2 and 0·2295 H_2O
0·5405 " " 0·0300 $BaSO_4$

	100·00	100·00

Free Aconine. It was found difficult to obtain aconine perfectly free from all traces of inorganic matters. On treatment with absolute alcohol of the purified aconine salts evaporated to dryness with excess of carbonate of soda, small quantities of sodium carbonate and chloride, etc., are dissolved out; whilst they are not wholly separated by again evaporating to dryness and taking up with chloroform.

0·2335 of substance, purified by absolute alcohol gave 0·500 CO_2, and 0·1830 H_2O.

Another sample further purified by chloroform: 0·2725 gram gave 0·5740 CO_2, and 0·1990 H_2O.

	Calculated		Found

$C_{26}H_{39}NO_{11}$	541	100·00		

Aconine is very readily soluble in alcohol and chloroform, but is almost insoluble in ether; the solutions are bitter and produce no tingling of the skin or lips. Aqueous solutions precipitate, when moderately concentrated, tannin, gold chloride and lead acetate. In all these respects aconine exactly agrees with the "Acolyctine" of Hübschmann (*Jahresbericht*, 1866, 483) and of Von Schroff (*N. Repert. Pharm.*, xx., 641) obtained by the former from the roots of the yellow-flowered aconite by a process with involved heating the alcoholic tincture of the root with lime, and also with sulphuric acid, and finally evaporating to dryness with sodium carbonate, separation of matters soluble in ether, and purification by solution in chloroform. As shown below, these processes must inevitably have decomposed aconitine, if originally present, with formation of aconine; hence there seems to be good reason for supposing that the "acolyctine" of Hübschmann (and consequently the "napelline" of the same chemist, discovered by him in commercial so called "aconitine" (*Jahresbericht*, 1857, 416), and subsequently stated by him to be identical with "acolyctine") is not a natural alkaloid characteristic of a particular species of aconite, but is simply a decomposition product of aconitine formed by the violent treatment to which the roots were subjected; and this is rendered the more probable in that the second base (so-called "lycoctonine") found simultaneously by Hübschmann, is apparently the analogously formed decomposition product of pseudaconitine (*vide* § 2); whilst, on the other hand, both aconitine and pseudaconitine appear to occur both in *A. Napellus* and *A. ferox* roots, the former predominating in the first and the latter in the second species (*vide* § 3).

On adding potassium mercuriodide to a solution of an aconine salt (rendered slightly acid by hydrochloric acid), a floculent white precipitate is thrown down, much resembling the analogously formed precipitates with aconitine and pseudaconitine, but sensibly more soluble in excess of the reagent, and on dilution of the turbid fluid with water. After drying over sulphuric acid, and finally at 100° this compound gave the following numbers:—

0·4155 gram gave 0·2570 Ag I. Iodine 33·43 per cent.
Calculated for

$C_{26}H_{39}NO_{11},HI,HgI_2$ „ 33·93 „

It deserves notice that benzoic acid has been previously obtained by the decomposition of two other alkaloids, viz., atropine (Kraut, *Jahresbericht*, 1865, 448), and cocaine (Lossen, *ibid.*, 451).

The decomposition of aconitine in accordance with the equation

$$C_{33}H_{43}NO_{12}+H_2O=C_7H_6O_2+C_{26}H_{39}NO_{11}$$

seems to indicate that aconitine is *benzoyl-aconine* $C_{26}H_{38}(C_7H_5O)NO_{11}$, analogous to the benzoylated acetylated and butyrylated morphine and codeine prepared by one of us in conjunction with Mr. G. Beckett (*Chem. Soc. Journal*, 1874, 1031, and 1875, 15 and 312). It might be hence supposed that by acting on aconine with benzoic anhydride aconitine might be reproduced in accordance with the equation

$$C_{26}H_{39}NO_{11}+(C_7H_5O)_2O=$$
$$C_{26}H_{38}(C_7H_5O)NO_{11}+C_7H_6O_2.$$

On trying the experiment this seems to be the case; but the action does not stop here, *two* benzoyl groups being appparently introduced so as to give rise to a *benzoyl-aconitine*, or *dibenzoyl-aconine* $C_{26}H_{37}(C_7H_5O)_2NO_{11}$. This substance forms a hydrochloride much less soluble than that of aconitine; its gold salt is a stable body not decomposed at 100°, and the solutions of the salts of the base are precipitated by carbonate of soda. As yet we have not prepared it in sufficient quantity to obtain it perfectly pure, wherefore we leave its description until our experiments are further advanced. It is particularly noteworthy that a substance of exactly the same properties and composition is obtained by the action of benzoic anhydride on aconitine itself by virtue of the reaction.

$$C_{36}H_{38}(C_7H_5O)NO_{11}+(C_7H_5O)_2O=$$
$$C_{36}H_{37}(C_7H_5O)_3NO_{11}+C_7H_6O_2.$$

Hence in the formation of aconine from aconitine there does not seem to be any "molecular rearrangement."

Action of Alkalies on Aconitine.

As might be expected, the saponifying action of water on aconitine is greatly intensified if alkalies be present; thus, if excess of ammonia be added to a solution of an aconitine salt, and the whole be allowed to stand for some hours in the cold, a perceptible amount of action takes place, benzoic acid being obtainable from the solution by simply acidifying and shaking with ether. If the alkaline liquid be boiled, the action is brought about yet more quickly; complete solution speedily takes place, not from the greater solubility of aconitine in the heated fluid, for the reverse seems to be the case, but from the splitting up of the aconitine into the two products aconine and benzoic acid, each of which is readily soluble in ammonia. Fixed alkalies and sodium carbonate act in the same way. It may be noticed that this splitting up is the cause of the peculiar phenomenon observed by Mr. Groves ('Year-Book,' 1873, 508; *Pharm. J.* [3], iv., 295), viz., that an ammoniacal solution of aconitine after standing thirty hours yielded on acidification no precipitate whatever with potassium mercuriodide; the aconine formed giving rise, as above stated, to a double iodide with mercury sensibly more soluble in water than the corresponding salts of aconitine and pseudaconitine. One practical conclusion to be drawn from this is that in the isolation of aconitine, prolonged contact of the free base with alkaline solutions must be avoided as far as possible; very probably the different yields of aconitine obtained by different observers are quite as much due to varying amounts of loss of aconitine through this decomposition as to differences as the amounts originally contained in the roots.

Action of Acids on Aconitine.

The action of acids on aconitine is not so marked as that of alkalies, being scarcely appreciable in the cold, though energetic enough in some cases at 100°. An acid solution of hydrobromide of aconitine was allowed to stand in a covered beaker for eight months; at the end of that time only minute quantities of benzoic acid could be extracted by ether. Again, aconitine was dissolved in a large excess of tartaric acid, and the solution kept boiling (an inverted condenser being attached) for twelve hours: at the end of this time only traces of benzoic acid could be extracted by ether.

Hot inorganic acids, however, act much more rapidly; thus an appreciable formation of benzoic acid is noticeable on boiling for some hours a slightly acid solution of aconitine in very dilute sulphuric acid; when 20 parts of 5 per cent. acid are employed (1 part aconitine, $1H_2SO_4$, and 20 of water) a considerable action ensues, about a third of the aconitine being converted into aconine and benzoic acid at the end of twelve hours. On adding sodium carbonate in excess to the acid liquid (previously freed from benzoic acid by agitation with ether) unchanged aconitine is precipitated and aconine remains in solution; by evaporating the solution to dryness and treating with chloroform or absolute alcohol this is dissolved out from the sodium sulphate and carbonate. The benzoic acid thus produced melted at 121° and gave all the reactions and possessed the physical characters of that acid. The carbonate of soda precipitate was carefully examined to see if it contained any other substance beside aconitine, but without success; on treatment with hydrobromic acid it furnished crystals of aconitine hydrobromide.

0·960 gram lost 0·061 at 100 = 6·35 per cent.
Calculated for $C_{33}H_{43}NO_{12},HBr, 2\frac{1}{2}H_2O = 5·83$.
0·612 gram of dried salt gave 0·1560 AgBr. Br=10·84 per cent.
Calculated Br=11·02 per cent.

The mother liquors of these crystals deposited more of the same crystals on evaporation, and the final mother liquors gave with a little ammonia a precipitate which furnished a gold salt of which

0·5070 gram gave 0·0835 Au = 20·51 per cent.
Calculated for aconitine aurochloride=19·92 per cent.

It may hence be inferred that the use of sulphuric acid for extracting aconitine from aconite roots as usually practised is likely to cause a considerable amount of loss of aconitine by splitting it up into benzoic acid and aconine; whilst the employment of tartaric acid, as suggested by Duquesnel, is comparatively free from this objection.

When hot concentrated mineral acids are in contact with aconitine, the saponifying action takes place very quickly: thus on heating aconitine to 100° in a sealed tube for three hours with about 15 parts of concentrated hydriodic acid solution, 8·3 per cent. of benzoic acid was obtained, or about half as much as was formed by the complete decomposition of the aconitine; the aconine produced is probably further altered by the hydriodic acid, but the nature of the product has not yet been examined. No methyl iodide was formed during the reaction, but that does not prove that aconitine does not contain a methyl group, as the same negative result was also obtained in a companion experiment at 100° with pseudaconitine which contains two methyl groups (*vide* § 2). Similar results were obtained on heating with concentrated hydrobromic acid to 100°, benzoic acid melting at 120—121 being formed in quantity.

§ 2. *Decomposition Products of Pseudaconitine.*

In the First Report ('Year Book' 1875, 514; *Pharm. Journ.* [3], vol. vi., p. 188), the formula $C_{36}H_{49}NO_{11}$ was assigned to pseudaconitine as the most probable one; the experiments since made confirm this formula, although it cannot be regarded as established with the same certainty as that of aconitine. $C_{33}H_{43}NO_{12}$, owing to the difficulty in forming any definite crystallized salt of pseudaconitine.

The amount of pseudaconitine at our disposal not being large, we took advantage of the circumstance that Messrs. Hopkin and Williams had recently worked up a considerable amount of alkaloid from *A. ferox* roots into a commercial preparation. As shown further on, this substance was very far from being pure pseudaconitine; but still it contained a considerable amount of that base, which was easily isolated by the purification process of M. Duquesnel, viz., dissolving in ether, adding light petroleum spirit, pouring off from a little watery and resinous matter thus thrown down, and finally allowing to crystallize by spontaneous evaporation. In this way something like one-third of the weight of material employed was obtained in a crystallized condition after collecting on the pump filter and slightly washing with ether and ether-petroleum mixture. A considerable amount of pseudaconitine was contained in the filtrate from these crystals, being prevented from crystallizing well by other matters also present; the filtrate dried up to a resinous mass in which a few crystals were interspersed; for the examination of this (*vide* § 3). The crude pseudaconitine crystals thus obtained were purified by a repetition of the process and then gave the following numbers

(1). 0·3225 gram gave 0·7465 CO_2 and 0·2135 H_2O.

In order still further to purify the crystals they were dissolved in hot alcohol and water added until the solution became milky; alcohol was then added till the whole was clear, and the liquid then set aside to cool in a covered beaker. Crystals exactly resembling the original ones then separated. These were separated by the pump filter next day and treated in the same way again.

(2). 0·2395 gram of the final crystals gave 0·5540 CO_2 and 0·1610 H_2O.

	Calculated		Found (1)	Found (2)
C_{36} . .	432	64·38	63·13	63·09
H_{49} . .	49	7·30	7·35	7·47
N . .	14	2·09		
O_{11} . .	176	26·23		
$C_{36}H_{49}NO_{11}$	671	100·00		

These numbers do not agree with the formula as sharply as might be desired; on the other hand, the gold salts prepared from these two specimens gave numbers agreeing well with the formula—

(1). 0·3840 gram of gold salt gave 0·0750 Au
0·3215 gram of gold salt gave 0·5025 CO_2 and 0·1545 H_2O.

(2). 0·7045 gram of gold salt gave 0·1385 Au
0·2930 gram of gold salt gave 0·4600 CO_2 and 0·1410 H_2O.

	Calculated for $C_{36}H_{49}NO_{11}$,HCl,$AuCl_3$	Found (1)	Found (2)
Carbon	42·77	42·61	42·82
Hydrogen . . .	4·95	5·34	5·35
Gold	19·40	19·53	19·66

It was subsequently found that these specimens (1) and (2) contained a small quantity of aconitine (*vide* § 3 and 4); but as the amount of this impurity was very small (less than 1 per cent.) it would not appreciably alter the numerical values.

Owing to the ease with which pseudaconitine breaks up in accordance with the equation—

$$C_{36}H_{49}NO_{11} + H_2O = C_9H_{10}O_4 + C_{27}H_{41}NO_3$$

parallel with that undergone by aconitine (§ 1), it is very doubtful whether any of the pseudaconitine yet obtained was perfectly pure, being probably more or less contaminated with the decomposition product $C_{27}H_{41}NO_8$; thus the alcoholic mother-liquor from which specimen No. 2 was obtained contained about two-thirds of the crystals No. 1 originally dissolved up in a form which did not admit of pseudaconitine crystallizing therefrom; they dried up on evaporation to a varnish, and the change was clearly traced, as shown below, to the occurrence of the above reaction to a great extent in presence simply of the hot aqueous alcohol.

Neither the acid $C_9H_{10}O_4$ nor the base $C_{27}H_{41}NO_8$ into which pseudaconitine thus splits is identical with the corresponding aconitine product: the former is found to be *dimethylprotocatechuic acid*, identical with that obtained by methylating protocatechuic acid, and by the oxidation of eugenol; the latter is very different from aconine, but as shown below is in all probability the main constituent of the mixture of bases obtained by Hübschmann from *A. Lycoctonum* and termed by him "lycoctonine:" to indicate this new base it is proposed to use the term *pseudaconine*, which calls to mind that pseudaconine bears to pseudaconitine the same relationship that aconine does to aconitine. It may be here noticed parenthetically, that the former researches of one of us have shown that *narcotine* when heated with water splits up in a parallel fashion forming hydrocotarnine and opianic acid, thus—

$$C_{22}H_{23}NO_7 + H_2O = C_{10}H_{10}O_5 + C_{12}H_{15}NO_3$$

(*Chem. Soc. Journal*, 1875, 573) and that the opianic acid thus produced is chemically closely allied to dimethylprotocatechuic acid, the two bodies being benzene derivatives represented by the formulæ:—

$$C_6H_2\left\{\begin{array}{l}CO.H\\CO.OH\\O.CH_3\\O.CH_3\end{array}\right. \quad \text{and} \quad C_6H_3\left\{\begin{array}{l}CO.OH\\O.CH_3\\O.CH_3\end{array}\right.$$

Hence, there is a certain amount of family connection between narcotine and pseudaconitine; whilst on the other hand, according to T. and H. Smith (*Jahresbericht*, 1864, 448) the juice of fresh aconite roots contains an alkaloid termed by them "aconellin," which appears to be identical with narcotine.

Action of Water on Pseudaconitine.

The dimethylprotocatechuic acid formed by the saponifying action of water, at 140—150°, on pseudaconitine is easily extracted by acidifying the product of the action with hydrochloric acid and shaking with a large bulk of ether. By spontaneous evaporation of the ethereal solution the following numbers were obtained:—

(*a*) 2·650 gram. of the pseudaconitine originally prepared by Mr. Groves and examined in the 1st Report (probably the purest specimen yet obtained, as it gave 63·84 per cent. of carbon on combustion, and its gold salt contained 19·46 per cent. and closely agreeing with the calculated values) gave 0·604 gram of acid.

(*b*) 3·000 gram of pseudaconitine from Messrs. Hopkin and Williams' preparation (crystals No. 1 above) gave 0·6645 gram. of acid.

	Calculated for above equation	Found (*a*)	Found (*b*)
Per cent. of acid	27·12	22·8	22·15

The deficiency is probably due partly to the formation of bye-products and partly to the pseudaconitine employed containing an admixture of pseudaconine and a trace of aconitine as above stated.

The acid thus obtained is less soluble in boiling water than benzoic acid, and very sparingly soluble in cold water; after recrystallization from boiling water, two different samples first completely melted at 176°—177° and 177°—178° (corrected) respectively. The following numbers were obtained on combustion:—

0·2325 gram gave 0·5030 CO_2 and 0·1175 H_2O

		Calculated.	Found.
C_9	108	59·34	59·01
H_{10}	10	5·49	5·62
O_4	64	35·17	
$C_9H_{10}O_4$	182	100·00	

That the acid was really dimethylprotocatechuic acid was shown further by the circumstance that on fusing at about 250° with caustic potash, acidification of the "melt" and treatment with ether, protocatechuic acid is formed readily recognized by its remarkable colour reactions. Moreover, the acid obtained, like synthetically prepared dimethylprotocatechuic acid, formed on exact neutralization with ammonia and addition of a drop of concentrated silver nitrate solution a most characteristic gelatinous silver salt. After crystallization from water the acid gave not the slightest trace of colour with ferric chloride; the crystals deposited from water were anhydrous after exposure to air for a few hours, as also were the crystals after draining on the pump filter, washing first with alcohol, and then with ether, and exposure to the air for a few minutes till the ether had evaporated. According to Kölle (*Annalen der Chemie* 159, 240) dimethylprotocatechuic acid crystallizes anhydrous. Beckett and Alder Wright, however, found (*Chem. Soc. Journ.*, 1876, 304) that the synthetically prepared acid was $C_9H_{10}O_4,H_2O$.

In order to obtain pseudaconine in a state of purity the acid liquid from which the dimethylprotocatechuic acid had been removed by ether was rendered alkaline by sodium carbonate and agitated with ether. Unless the solution was tolerably concentrated, no precipitate was formed on rendering it alkaline, and ether then dissolved out but little, pseudaconine being readily soluble in sodium carbonate and not being readily removed from the solution by ether; concentrated pseudaconine salts, however, precipitate with sodium carbonate, the precipitated base being readily taken up by ether. By evaporating down the alkaline liquid thus freed from traces of bye-product, etc., soluble in ether, pseudaconine was obtained as a resinous mass, separating out as the solution became concentrated; the last portions were readily obtained by evaporating to dryness and treating with ether; small quantities of aconine and colouring matters soluble in chloroform were thus left undissolved. Neither from the alcoholic nor the ethereal solutions could pseudaconine be obtained in the form of crystals, only transparent resinous varnishes being left; but on moistening these with water they become opaque, white, and brittle, readily breaking up into what to the naked eye appeared to be distinctly crystalline particles: under the microscope, some of these appeared indistinctly crystallized, but most were apparently coalesced globules. The formation of this apparently crystalline mass, from the transparent resin left on spontaneous evaporation of the solution of the base in ether (or ether and petroleum spirit) is extremely characteristic, not having been noticed with any of the other aconite alkaloids or their derivatives. It is especially noteworthy that this peculiar behaviour is, according to Flückiger (*Jahresbericht*, 1870, 837), precisely that of the so-called "lycoctonine" of Hübschmann (*loc. cit. supra*), obtained together with "acolyctine" from *A. Lycoctonum*. Inasmuch as the method adopted for the extraction of the alkaloids must inevitably have more or less converted pseudaconitine if originally present into pseudaconine, it is extremely probable that the "lycoctonine" of Hübschmann was simply a mixture of pseudaconine with more or less unaltered pseudaconitine, and possibly a little unaltered aconitine and bye-products, etc. A mixture of about equal quantities of pseudaconitine and pseudaconine does not crystallize from ether alone, but leaves a varnish almost instantly becoming solid and crystalline on touching with water; the crystals thus formed, when dissolved in ether and petroleum spirit, deposit by spontaneous evaporation crystals of impure pseudaconitine. From the marked resemblance between the physical properties of pseudaconine containing pseudaconitine, and those ascribed to "lycoctonine" by Hübschmann, Von Schroff, and Flückiger, together with their exact similarity in deportment with various reagents (*vide infra*), we have but little doubt that "lycoctonine" is really mainly pseudaconine, with more or less pseudaconitine, etc. Taking this into consideration with the apparent identity between aconine and "acolyctine" (§1), it may be fairly inferred that the roots of *A. Lycoctonum* contain both aconitine and pseudaconitine, and hence present no remarkable peculiarity as compared with the other species of aconites.

The following numbers were obtained with the apparently crystalline pseudaconine prepared as above described.

(1). 0·2410 gram gave 0·5000 CO_2 and 0·1815 H_2O.

(2). Another specimen; 0·2410 gram gave 0·5630 CO_2 and 0·1815 H_2O.

		Calculated.	Found (1).	Found (2).
C_{27}	324	63·90	63·36	63·71
H_{41}	41	8·09	8·37	8·37
N	14	2·76		
O_8	128	25·25		
	507	100·00		

The gold salt of pseudaconine, like that of aconine, appears to have a tendency towards spontaneous decomposition whilst drying; the purest specimen obtained gave these numbers:—

0·4840 gram dried over sulphuric acid gave 0·1145 Au = 23·65 per cent.

Calculated for $C_{27}H_{41}NO_8,HCl,AuCl_3 = 23{\cdot}17$ per cent. somewhat higher percentages were given by other specimens.

Pseudaconine does not seem to form salts that crystallize readily; our examination of its compounds, however, is not yet complete. In particular we propose to examine its behaviour with organic anhydrides, *e.g.*, benzoic anhydride, and to reproduce pseudaconitine from it, if possible. Its physiological action seems to be far less marked than that of aconitine or pseudaconitine. Solutions of its salts are bitter, and produce no tingling of the skin or lips.

Action of Alkalies and Acids on Pseudaconitine.

Pseudaconitine is saponified by alkalies quite as readily as aconitine, if not more so. If a little freshly precipitated alkaloid be boiled with ammonia, the action commences very rapidly. In a few minutes, if hydrochloric acid and ether be added, dimethylprotocatechuic acid is dissolved out in quantity. The same result is brought about on heating with sodium carbonate solution. Pseudaconitine itself, however, is sensibly soluble in sodium carbonate solution. On warming a saturated solution of the base in sodium carbonate the alkaloid separates out as a resinous film, containing but little pseudaconine, and capable of yielding crystals by solution in ether, addition of petroleum, and spontaneous evaporation. By continued heating of the sodium carbonate solution the pseudaconitine is almost wholly decomposed, little but resinous pseudaconine being contained in the base which separates as the solution becomes concentrated, and much dimethylprotocatechuic acid being obtained from the aqueous liquors on acidulation and shaking with ether.

As stated above, heating pseudaconitine with dilute alcohol for the purpose of recrystallizing it, saponifies a considerable quantity, so that only a fraction of the alkaloid used crystallizes out on cooling, the mother liquors giving much dimethylprotocatechuic acid on acidification, addition of water, and shaking with ether.

On heating pseudaconitine with inorganic acids, the same result is rapidly brought about; thus on heating with about 15 parts of strong hydriodic acid at 100 for three hours, 10·2 per cent. of dimethylprotocatechuic acid was obtained by treatment with ether; similar results were obtained with hydrobromic acid. (It is noteworthy that no methyl bromide or iodide was obtained in these experiments, indicating that dimethylprotocatechuic acid is not readily demethylized at 100°). Boiling with dilute sulphuric acid rapidly splits up pseudaconitine; on the other hand, the base may be boiled for several hours with tartaric acid without the formation of more than minute quantities of dimethylprotocatechuic acid. Hence, as with aconitine, tartaric acid is far preferable to sulphuric acid, for the purpose of acidifying the alcohol used in the first extraction of the alkaloids from the roots.

The following table exhibits the

Comparative Qualitative Reactions of Aconitine, Aconine, Pseudaconitine, and Pseudaconine

ALKALOID.	Weak bromine water.	Iodine dissolved in potassium iodide.	Mercuric chloride.	Mercuric bromide.	Mercuric iodide dissolved in potassium iodide.	Tannin.	Gold chloride.	Platinum chloride.	Sodium carbonate.	Ammonia.
ACONITINE.	Precipitate much more copious with stronger solution.	Copious precipitate scarcely affected by large dilution.	No precipitate with dilute solution; white precipitate with concentrated solution readily soluble on dilution.	Precipitate with dilute solution readily soluble on large addition of water.	Precipitate in dilute solution, scarcely affected by large addition of water.	No precipitate in dilute solution. Precipitate with concentrated solution readily dissolved on large addition of water.	Flocculent precipitate scarcely affected by large dilution.	No precipitate, save in very concentrated solution* readily soluble in water.	Precipitate sensibly soluble in excess on large dilution, but not very soluble.	Precipitate more soluble in excess on large dilution than with sodium carbonate.
PSEUDACONITINE.	Same as aconitine.	Same as aconitine.	Same as aconitine.	Same as aconitine.	Same as aconitine.	Same as aconitine.	Same as aconitine.	Same as aconitine.	Same as aconitine.	Precipitate almost as soluble in excess on large dilution as with sodium carbonate.
ACONINE.	No precipitate.	Precipitate readily soluble on dilution.	Precipitate only with most concentrated solution; readily soluble on dilution.	Precipitate only with moderately concentrated solution; readily soluble on large dilution.	Precipitate much more soluble on dilution than that given by aconitine.	Precipitate dissolved on dilution.	Precipitate in concentrated solution readily dissolved on adding large bulk of water.	No precipitate in moderately concentrated solution.	No precipitate under any circumstances.	No precipitate under any circumstances.
PSEUDACONINE.	Precipitate somewhat more scanty than with aconitine.	Same as aconitine and pseudaconitine.	Same as aconitine and pseudaconitine.	Same as aconitine and pseudaconitine.	Same as aconitine and pseudaconitine.	Precipitate in dilute solution dissolved on large further dilution.	Precipitate slightly dissolved on dilution, but much less so than that with aconine.	Same as aconine.	No precipitate unless tolerably concentrated solution; readily dissolved on dilution.	Same as with sodium carbonate.

The tests were made with solutions as nearly as possible of the same strength in each case, and consisting of the alkaloids dissolved in the least possible excess of hydrochloric acid, so as to give a slight acid reaction.

§ 3. *Alkaloids contained in various Aconite Species.*

The experiments described above (§§ 1, 2) seem to leave little room for doubt that the "acolyctine" and "lycoctonine" obtained by Hübschmann from *A. Lycoctonum* were really essentially decomposition products of aconitine and pseudaconitine respectively, and hence lead to the presumption that both these parent alkaloids exist in *A. Lycoctonum* roots. This appears also to be the case with both *A. Napellus* and *A. ferox*; the former of the two species, however, appears usually to contain aconitine in far the largest proportion, whilst in the latter species pseudaconitine greatly predominates. That *A. ferox* roots, as met with in commerce, contain aconitine, is indicated by the circumstance alluded to in § 2, that the product of the action in sealed tubes of water on pseudaconitine derived from *A. ferox* yielded on evaporation to dryness with sodium carbonate, a residue from which much pseudaconine was dissolved out by ether, leaving behind a small residuum of an alkaloid which, like aconine, was readily soluble in water, alcohol, and chloroform. Further, the crude dimethylprotocatechuic acid extracted from the product of the action by acidulation and treatment with ether contained notable quantities of benzoic acid; these were separated by long continued distillation with water, the dimethylprotocatechuic acid being not volatile under these conditions; the distillate yielded sensible quantities of benzoic acid on neutralizing with sodium carbonate, evaporation to a small bulk, acidification, and treatment with ether. The benzoic acid thus extracted from the pseudaconitine derived from Messrs. Hopkin and Williams's batch of alkaloid represented a content of something under 1 per cent. of aconitine. Similarly benzoic acid was extracted from the pseudaconitine worked up by Mr. Groves, in 1873 ('Year-Book,' 1873, 500), from Nepaul aconite, the quantity representing a little more than 1 per cent. of aconitine (*vide* § 4).

On the other hand, *A. Napellus* roots appear to contain pseudaconitine in some quantity, the evidence of the presence of this base being as follows:—During the working up of the *A. Napellus* extract as described to the Conference last year (Report No. 2), two batches of mother liquors were obtained, the one (A) from the successive crystallizations from ether and petroleum of the crude aconitine precipitated by potassium carbonate from the condensed extract prepared by M. Duquesnel's process; the other (B) being the potassium carbonate filtrate from this crude aconitine. From this filtrate a batch of alkaloids was extracted, as mentioned in Report 2, by precipitating with potassium mercuriodide, decomposing the precipitate by sulphuretted hydrogen, and finally treatment with sodium carbonate and ether. These two batches of alkaloid appeared to be much the same in general character, each being a mixture of at least five substances, viz., *aconitine*, prevented from crystallizing out by the others; *aconine*, formed by the partial decomposition of aconitine; *pseudaconitine; pseudaconine*, formed by the decomposition of pseudaconitine; and *a fifth base* containing a higher carbon percentage than any of these; this last has as yet not been isolated in a pure state. On dissolving these two mixtures in hydrobromic acid and allowing to stand some months, a very scanty crop of crystals of aconitine hydrobromide was obtained in each case; the mother liquors of these dried up to varnishes. On solution of these varnishes in water and pouring into excess of sodium carbonate solution, a separation was effected in each case of some of the constituents; precipitates were thrown down containing aconitine, pseudaconitine, some pseudaconine, and the fifth base; whilst filtrates were obtained containing the rest of the pseudaconine and the aconine. On cautious evaporation of these filtrates pseudaconine separated as resinous masses; whilst the final mother liquors evaporated to dryness and treated with ether yielded more pseudaconine in solution. On treating the portion insoluble in ether with chloroform, aconine and colouring matters were dissolved out. The pseudaconine thus obtained from the ethereal solutions corresponded exactly in all its characters with that above described (§ 2), and in particular in the apparent crystallization of the resinous alkaloids left on evaporation of the ethereal solutions on bringing them into contact with water; the following numbers were obtained:—

From (A) 0·2280 gram gave 0·5360 CO_2 and 0·1670 H_2O.

From (B) 0·3250 gram gave 0·7555 CO_2 and 0·2330 H_2O.

	Calculated.		Found. A.	Found. B.
C_{27}	324	63·90	64·12	63·38
H_{41}	41	8·09	8·14	8·03
N	14	2·76	—	—
O_8	128	25·25	—	—
$C_{27}H_{41}NO_8$	507	100.00		

The two precipitates thus obtained with sodium carbonate were dissolved in acid and reprecipitated by sodium carbonate for the purpose of removing pseudaconine. The residual alkaloids were then collected, washed, and dried; white amorphous brittle masses were thus obtained, not unlike starch in appearance. In acids these white masses dissolved readily but the solutions would not crystallize. On combustion these masses gave the following numbers; at 100° they did not melt, but slightly fritted together:—

From (A) 0·2950 gram gave 0·7120 CO_2 and 0·2065 H_2O.

From (B) 0·2975 gram gave 0·7140 CO_2 and 0·2030 H_2O.

	A	B
Carbon	65·83	65·46
Hydrogen	7·78	7·58

It is hence evident that a large quantity of some base was present containing more carbon than any of the bases yet examined, the highest percentage being found in pseudaconitine (C = 64·38 hydrogen = 7·30 per cent.); these two precipitates consisted mainly of this substance, with a little unaltered aconitine and a minute amount of pseudaconitine; for they produced a slight amount of liptingling, very far inferior to that produced by either aconitine or pseudaconitine in a pure condition; and on treating with water in sealed tubes for twenty-four hours, each partially dissolved, giving rise to a small quantity of a mixture of benzoic and dimethylprotocatechuic acids, the former largely predominating, so that the mixture of acids melted at close upon 120°, whilst it formed protocatechuic acid on fusion with caustic potash at 250°. It hence seems very probable that the more highly carburized base is comparatively physiologically inert, the little activity exhibited by these two precipitates being presumably due to the small quantity of aconitine and pseudaconitine therein contained.

Is is hence manifest that the *A. Napellus* roots examined last year (Report No. 2) contained the following alkaloids:—

Aconitine $C_{33}H_{43}NO_{12}$ in considerable quantity: about one half of the total alkaloids present.

Pseudaconitine $C_{36}H_{49}NO_{11}$ in less quantity: estimated at about 10 per cent.

Another base of higher carbon percentage in considerable quantity; estimated at about 40 per cent.

Whilst the extract worked up from these roots contained in addition:—

Aconine $C_{26}H_{39}NO_{11}$ in small quantity.

Pseudaconine $C_{27}H_{41}NO_8$ to a somewhat larger extent.

These two bases being probably simply derived from the decomposition during extraction of aconitine and pseudaconitine.

In order to see if the base containing the higher percentage of carbon was also present in the alkaloid obtained from Messrs. Hopkin and Williams, the mother liquors of the ether-petroleum crystallization of the alkaloid as purchased were dissolved in acid and added to excess of sodium carbonate. A copious precipitate was then thrown down which was drained on the pump-filter, dissolved in ether and allowed to crystallize spontaneously after addition of petroleum. A crop of crystals of imperfectly pure pseudaconitine was then obtained; the mother liquors left finally were dissolved in hydrochloric acid, precipitated by sodium carbonate, and submitted to combustion after washing and drying; the substance fused completely at 100°.

0·2640 gram gave 0·6470 CO_2 and 0·1990 H_2O

Carbon 66·83.

Hydrogen 8·37.

It is hence evident that a base containing more carbon than pseudaconitine was present; but the difference in behaviour of this substance and the analogous product from *A. Napellus* at 100°, and the higher hydrogen percentage, would seem to indicate that the *A. Ferox* more highly carbonized base is not identical with that from *A. Napellus*. It is noteworthy that the above numbers are very close to those obtained by Von Planta, on analysis of a specimen of commercial "aconitine" (*Annalen der Chemie*, 74, 257), viz.:—

	One sample.			Another sample.	
Carbon	67·81	68·34	67·75	64·83	66·95
Hydrogen	8·82	8·90	8·64	8·14	8·59
Nitrogen	—	3·59	3·31	—	—

From these numbers, Von Planta deduced the formula $C_{30}H_{47}NO_7$, which was for long attributed to "aconitine."

Inasmuch, however, as the process of Geiger and Hesse in use at that time for the extraction of the aconite alkaloids involved heating successively in contact with sulphuric acid and with lime, it is evident that pseudaconitine and aconitine must have been largely decomposed; and hence it is very probable that the bodies examined by Von Planta consisted largely or wholly of this unnamed alkaloid.

The sodium carbonate filtrates from the two precipitations just described yielded on evaporation an alkaloid or mixture of alkaloids, in which pseudaconine appeared to predominate, as the ethereal solution dried up to a varnish, which became apparently crystalline on moistening with water. Of this—

0·3345 gram gave 0·7955 CO_2 and 0·2550 H_2O.

	Calculated for Pseudaconine.	Found.
Carbon . . .	63·90	64·87
Hydrogen . . .	8·09	8·47

From the somewhat high percentage of carbon it is probable that some of the amorphous unnamed base was also present; a little unaltered pseudaconitine was present, as a small quantity of dimethylprotocatechuic acid was obtained from the mixture on saponification.

It hence results that the alkaloidal substance manufactured by Messrs. Hopkins and Williams contained the following constituents.—

Pseudaconitine $C_{36}H_{49}NO_{11}$ in largest quantity.
Aconitine $C_{33}H_{43}NO_{12}$,, small ,,

Pseudaconine and amorphous unnamed base each in some quantity. The amounts of each of these substances have been approximately determined quantitatively (*vide* § 4).

§ 4. *Processes for Assaying Specimens of Commercial Aconite Alkaloids.*

In order to determine with approximate accuracy the relative amounts of pseudaconitine and other bases present in the substance obtained from Messrs. Hopkin and Williams the following method of analysis was adopted: it is evident that the process can be utilized as a means of assaying the comparative value of commercial specimens of alkaloid—

0·7895 gram lost at 100° 0·0335	=	4·2 per cent.
2·3040 gram dissolved in hydrochloric acid and treated with ether, furnished 0·010 gram of residue left on spontaneous evaporation of ether, consisting of resinous matter with a little dimethylprotocatechuic acid (probably formed by decomposition of pseudaconitine whilst the preparation was drying in Messrs. H. and W.'s factory) - -	=	0·4 ,,
2·0230 gram, heated to 240-250 in a sealed tube for 24 hours with water yielded with hydrochloric acid and ether 0·3660 gram of mixed benzoic and dimethylprotocatechuic acids, with traces of resin	=	18·1 ,,
On distillation with water 0·002 grams of benzoic acid was obtained melting at 119° - - - - -	=	0·1 ,,

Admitting, as seems most probable from the above described experiments, that this benzoic acid was derived from aconitine present, 0·1 per cent. of benzoic acid would correspond to 0·6 per cent. of aconitine, since pure aconitine has been found experimentally to yield about one-sixth of its weight of benzoic acid (§ 1). On the other hand, it may be fairly assumed that *pure* pseudaconitine would yield 25 per cent. or one-fourth of its weight of dimethylprotocatechuic acid, since close upon 23 per cent. was actually obtained from specimens known to be not wholly pure (§ 2), whilst the theoretical value is 27·1 per cent.; hence the percentage of pseudaconitine will be 70·4 as shown by the calculation below.

Total dimethylprotocatechuic and benzoic acids and resin obtained	=	18·1 per cent.
Resin and pre-existing dimethyl protocatechuic acid - - - -	=	0·4 ,,
Acids due to pseudaconitine and aconitine present - - - -	=	17·7 ,,
Benzoic acid due to aconitine -	=	0·1 ,,
Dimethylprotocatechuic acid due to pseudaconitine - - -	=	17·6 ,,

Percentage of pseudaconitine = 17·6 × 4 =	70·4
Ditto of aconitine . . . = 0·1 × 6 =	0·6
Water . . . . =	4·2
Pseudaconine and amorphous unnamed base, etc. (by difference) . =	24·8
	100·0

That is, the percentage of pseudaconitine is practically four times the percentage of dimethylprotocatechuic acid obtained (after making correction for resin, pre-existing acid, and benzoic acid); whilst the aconitine is practically six times the benzoic acid obtained.

Similarly, a sample of impure pseudaconitine was assayed. This had been obtained by Mr. Groves in 1873, and was described by him ('Year-Book,' 1873, p. 504) under the name of "amorphous pseudaconitine," being the substance referred to as "Specimen F," in first report ('Year-Book,' 1875, p. 515); this was found, by treatment with acid and sodium carbonate, solution of precipitate in ether, addition of benzoline, and spontaneous evaporation, to contain much crystallizable pseudaconitine, the crystallization of the original substance being impeded by other products, notably pseudaconine and dimethylprotocatechuate of pseudaconitine, which were to a large extent removed in the sodium carbonate filtrate by this treatment.

Percentages found.		Calculated Composition.	
Total acid and resin	=17·7	Pseudaconitine . . 16·2 × 4 =	64·8
Resin and pre-existing acid . . .	= 1·3	Aconitine . 0·2 × 6 =	1·2
	16·4	Water . . . . =	4·2
Benzoic acid .	= 0·2	Pseudaconine, etc. (by difference) .	=29·8
Acid due to pseudaconitine . . .	=16·2		100·0
Loss at 100 .	= 4·2		

Probably the water present in this, and the preceding specimen, existed as a hydrate of pseudaconitine, the substance having been precipitated from aqueous solution by alkalies. The formula $C_{36}H_{49}NO_{11},2H_2O$ requires 5·09 per cent. of water, so that substances containing 70·4 and 64·8 per cent. of pseudaconitine as this hydrate should also contain respectively 3·58 and 3·30 per cent. of water.

This process for the quantitative examination of aconite alkaloids can, of course, only give correct results in the event of no other substances being present that will yield on saponification with water either benzoic or dimethylprotocatechuic acid. Experiments now in progress, however, seem to indicate that the amorphous comparatively inert base capable of yielding well crystallized salts obtained by Mr. Groves from one batch of *A. Napellus* roots (Base "A" of 'Year-Book,' 1875, p. 514) is capable of also yielding benzoic acid on similar treatment. Should this prove to be the case, the determination of the amount of aconitine present by the above process will be incorrect, and the method must be modified in cases where the amount of benzoic acid yielding alkaloid present is at all considerable; a modification which appears to give results sufficiently satisfactory for practical purposes, consists in dissolving the alkaloid to be tested in dilute hydrochloric acid, and pouring the solution into sodium carbonate solution. By suitably regulating the strength of the solution, it is possible to get a tolerable separation of aconitine, and the other base (to which it is proposed to apply the term *Picraconitine*, on account of its bitter taste), the latter being readily soluble in excess of the reagent, the former but sparingly soluble. By then saponifing the precipitate and determining the benzoic acid thus produced, an estimate of the amount of aconitine present can be obtained; whilst the picraconitine can be deduced from the difference between the total benzoic acid formed and that thus obtained from the precipitated aconitine.

In the case of a crystallized salt of aconitine (more or less mixed with picraconitine) this method of separation has been found to answer fairly, and with a correction for the solubility of aconitine in sodium carbonate solution, still nearer approximations can be obtained. On these points experiments are in progress.

§ 5. *Conclusions.*

From the experiments just described, together with those detailed in the previous reports, and the results obtained previously by Groves, Duquesnel, Hübschmann and others, the following conclusions may be drawn:—

(1.) *A. Napellus* roots as met with in commerce contain a highly active crystallizable alkaloid, furnishing readily crystallizable salts. This is distinguished as *Aconitine*, and is represented by the formula $C_{33}H_{43}NO_{12}$. In addition they contain more or less of another active alkaloid, crystallizable, but not readily yielding crystallized salts. This is distinguished as *Pseudaconitine*, and is represented by the formula $C_{36}H_{49}NO_{11}$. Moreover they contain (or at least the extract of the roots does) more or less of the decomposition products, produced by the saponification of these bases in accordance with the reactions.

$$\underset{\text{Aconitine.}}{C_{32}H_{43}NO_{12}}+H_2O=\underset{\text{Benzoic Acid.}}{C_7H_6O_2}+\underset{\text{Aconine.}}{C_{26}H_{39}NO_{11}}$$

$$\underset{\text{Pseudaconitine.}}{C_{36}H_{49}NO_{11}}+H_2O=\underset{\text{Dimethyl-protocatechuic Acid.}}{C_9H_{10}O_4}+\underset{\text{Pseudaconine.}}{C_{27}H_{41}NO_8}$$

And further, an alkaloid apparently non-crystalline, and yielding non-crystalline salts, and containing a higher carbon per centage than any of these other bases is also present. This seems to be of little physiological potency.

One batch of roots worked up by Mr. Groves contained besides aconitine an entirely different base, not crystallizing itself, but giving well crystallized salts. This base is comparatively inactive, and its salts are bitter and produce no lip-tingling, whence the name *Picraconitine* is assigned to this base, its formula being $C_{31}H_{45}NO_{10}$.

(2.) *A. ferox* roots contain comparatively large quantities of *Pseudaconitine* with a little *Aconitine*, and an alkaloid apparently non-crystalline and yielding non-crystalline salts, and containing a higher carbon percentage than any of the other bases. Apparently this is not identical with the analogous body from *A. Napellus*. The substance from which Von Planta deduced the formula $C_{30}H_{47}NO_7$ probably mainly consisted of this base.

(3.) *A. Lycoctonum* roots appear to contain both aconitine and pseudaconitine, the substances thence extracted by Hübschmann, and termed by him "Acolyctine" and "Lycoctonine," being apparently simply alteration and decomposition products of aconitine and pseudaconitine in a more or less pure state.

(4.) So called "Aconitine" of commerce is a mixture of true aconitine and pseudaconitine, with variable quantities of their alteration products, aconine and pseudaconine, and of the amorphous unnamed alkaloids above alluded to. The "Napelline" found by Hübschmann in commercial "aconitine" having been found by that chemist to be identical with his "Acolytine," is doubtless simply one of these decomposition products, viz. aconine, in a more or less pure condition.

(5.) The processes in ordinary use for the isolation of commercial "aconitine," are such as must inevitably bring about a large loss of active alkaloids through the saponifying actions above alluded to. The products of these actions are apparently far less physiologically active than the parent bases. In order to diminish this loss, the process of M. Duquesnel (use of tartaric acid) is far preferable to the ordinary methods (employment of hydrochloric or sulphuric acid). The crude alkaloids can be readily purified by crystallization from ether and petroleum spirit. True aconitine, $C_{33}H_{43}NO_{12}$, should further be converted into a crystallized salt if perfect purity is required. Unless crystallization of the alkaloids be employed the products obtained will contain (besides other impurities) more or less of the unnamed amorphous alkaloids of higher carbon percentage.

(6.) A method of assay applicable both to *A. Napellus* and *A. ferox* alkaloids has been arrived at, by which the amount of each physiologically active alkaloid present can be obtained with sufficient accuracy for practical purposes. It is probable, that if manufacturers would supply an article at a constant strength (say 30 per cent., 50, 70, or the like), as determined by this process, complaints as to irregularity in the efficacy of commercial "aconitine" would cease, whilst so doing would in many cases render it unnecessary to purify by crystallization the crude alkaloid. If attempts are made to prepare only pure or approximately pure alkaloids, much waste will occur in the form of mother-liquors, uncrystallizable masses retaining much of the active bases, etc. These, however, might readily be utilized for diluting to a fixed standard batches of the commercial article, which happen to be above the standard in the first instance.

(7.) From the ease with which both aconitine and pseudaconitine decompose by saponification, it seems extremely probable that *liquid* preparations, such as tinctures, will gradually lose activity on keeping. This must inevitably occur where the liquids are neutral or alkaline, and will probably occur to some extent when the alkaloids are kept in solution, as salts of organic acids, for lengthened periods.

(8.) Aconitine and pseudaconitine, although allied in physiological action and to some extent in chemical characters, do not seem, as far as experiments have as yet gone, to have a common nucleus or radical. They are allied, as regards their principal decompositions, to the opium alkaloids, narcotine, oxynarcotine, and narceine, which again are akin to the products obtained from the alkaloids morphine and codeine by treating them with the anhydrides of organic acids. From experiments now in progress, they appear also to be allied to veratrine; whilst the results of Kraut and of Lossen indicate a certain amount of analogy between aconitine, atropine, and cocaine, benzoic acid having been obtained by these chemists by the splitting up of the latter two bases.

The President suggested that the next paper, being on a similar subject, should be read, in order that both might be discussed together.

Preliminary Account of the Alkaloids from Japanese Aconite.

BY B. H. PAUL, PH.D., F.C.S., AND CHARLES T. KINGZETT, F.C.S.

This preliminary investigation was undertaken at the request of Mr. E. M. Holmes, who had been examining the structure of the particular roots which formed the subject of our studies.

The roots were known to be genuine, having been imported direct from Japan.

In our experiments 3940 grms. (or 8·6 lbs.) were subjected to the process of M. Duquesnel.

The ground material was first extracted with cold benzoline. This extract on distillation left a dark liquid behind, from which ether in the presence of tartaric acid removed no alkaloid.

The root was then thoroughly extracted with cold alcohol containing 1 per cent. tartaric acid, and the extract distilled to a low bulk. Water was now added and the mixture filtered from the fat-like precipitate and subjected to further treatment according to Duquesnel's method,* that is to say, it was extracted with ether in the presence of bicarbonate of sodium, and the alkaloid obtained in a crude state by distillation of the ether.

In this way, 7·17 grms. of crude mixed alkaloids were obtained; a quantity equivalent to about 0·18 per cent. or 13 grains to the pound. Duquesnel obtained 0·06 to 0·4 per cent., and Wright from 0·03 to 0·07 per cent. in operating upon roots of *A Napellus*.

The crude alkaloid obtained as described was somewhat coloured: from its ethereal solution needle-like crystals formed on standing. This crystalline substance presented the following characters:—

Very sparingly soluble in water.

Soluble in cold alcohol (65 per cent.).

Extremely soluble in dilute acids or water faintly acidified.

Not precipitable from aqueous solution by platinic chloride.

When converted into hydrochloride, however, platinic chloride gave a bulky precipitate soluble in cold spirit. When the platinum precipitate thus obtained was boiled in water, a part became viscid and fused, while another part dissolved and was reprecipitated on cooling.

On boiling for an hour with a very dilute solution of sulphuric acid a solution was obtained which reduced Fehling's test.

The whole quantity was now several times recrystallized from ether, and then from warm dilute alcohol several times also, the later recrystallizations being effected upon solutions which had been rendered practically colourless by animal charcoal. In the earlier recrystallizations a varnish-like substance was deposited upon the sides of the dish along with the crystals. From its greater solubility in the alcohol the crystals were ultimately obtained in a white state and free from this uncrystallized substance. As thus seen, no definite shape could be distinguished in the crystals; they were chiefly crystalline plates and needles, and less than 2 grms. were ultimately obtained in a fit state for analysis. A part of this was finally recrystallized, washed with water, dried at 100° C. (without change of any sort) and analysed.

(a) 0·270 grm. gave 0·623 grm. CO_2 and 0·192 grm. H_2O.

(b) 0·3135 grm. gave 0·218 grm. H_2O.

(c) 0·3230 grm. gave 6·63 c.c. N normal, which required no correction:—

Theory of $\underbrace{C_{29}H_{43}NO_9}$		Found. Per cents.	÷ At. Wgts.	÷N=1.
63·38	C.	62·926	5·2439	28·6
7·83	H.	(a) 7·900 (b) 7·726	7·900	43·1
2·55	N.	2·567	·183	1·0
26·23	O.	26·607	1·662	9·0

Having now obtained the base, we desired to compare it with other substances which have been described and which may be obtained commercially under the name of aconitine.

It is as unnecessary as it would be laborious to attempt a complete *résumé* of all that has been done and written about the aconite bases. The real knowledge possessed regarding them is very limited, and may be expressed very briefly. Doubtless, many of the substances which have formed the subjects of study by chemists have been mixtures or impure, hence it results that nearly every experimenter has arrived at a different formula for the base constituting in his opinion the primary one. Others have concluded that aconite yields two bases, while yet others believe that a whole series of closely related alkaloids are to be obtained from the various roots.

MM. Gréhant and Duquesnel* describe aconitine as a substance which crystallizes in rhombic or hexagonal plates, having a composition represented by the formula $C_{27}H_{40}NO_{10}$. It is said to be very soluble in alcohol, ether, benzene and chloroform, while the acetate is described as highly crystallizable. In another communication† Duquesnel has expressed the opinion that aconitine is a glucoside, but he does not give grounds for this belief. He further says that both glacial phosphoric acid and sulphuric acid give with the base a violet colour, and that the auric and platinic chloride combinations of the alkaloid are soluble in alcohol.

Groves has worked extensively with the alkaloids of aconite, and more recently Wright has subjected his products to ultimate analysis.

In one of his many papers,‡ Mr. Groves says the aconitines of commerce are partly crystalline. Aconitine is described as giving a precipitate with platinic chloride, and a nitrate whose crystals consist of rhombic prisms with dihedral summits; the alkaloid is precipitated from the nitrate by means of ammonia.

In Germany§ a difference was recognized between the English and German preparations, and the existence of two alkaloids was assumed. The name aconitine was applied to the German alkaloid, while the names napelline, nepaline, acraconitine, pseudaconitine were given to the English preparation.

The German substance was said to be coloured violet by phosphoric acid when applied in the hot concentrated state. It was described as yielding no platinum salt (insoluble in water), while the English substance was said to give no colour reaction either with sulphuric acid or phosphoric acid. The English alkaloid was further described as being not very soluble in ether or alcohol, although its alcoholic solution was said to crystallize readily.

Flückiger, on the contrary, came to the conclusion that the English and German alkaloids were identical.

Stahlschmidt and von Planta both give to aconitine the formula $C_{30}H_{47}NO_7$.

Wright,|| in conjunction with Mr. Beckett, and subsequently alone, has submitted the subject of aconite alkaloids to a fresh investigation. Groves had obtained from *Aconitum ferox* a base regarded by him as peculiar to that species of root. It crystallized from ether, but yielded salts which would not crystallize. Wright analysed this, and gave to it the formula $C_{36}H_{49}NO_{11}$, and to the gold salt $C_{36}H_{49}NO_{11}$,HCl, $AuCl_3$. This alkaloid had been extracted by means of alcohol acidulated with hydrochloric acid and the extract had been evaporated down. Now were any of the alkaloids thus extracted of the nature of glucosides, this process would be a most effectual one for their decomposition into glucose and other bodies. How far therefore the body analysed by Wright is to be regarded as a primary consitutent of *Aconitum ferox* it is difficult to decide.

A second product also isolated by Mr. Groves, and obtained from *A. Napellus*, was converted from the nitrate by means of ammonia into the free base which crystallized from ether. This body contained 62·7 to 62·9 per cent. C. and 7·2 to 7·3 per cent. hydrogen; the nitrogen was not determined, but Wright first gave to it a formula $C_{32}H_{43}NO_{10}$, and then afterwards regarded it as an impure or altered body; not from a further examination of it but from distinct results.

Wright rejects Duquesnel's formula $C_{27}H_{40}NO_{10}$ as

* See *Pharm. Journ.* [3], ii., p. 226; vii., p. 1040.

|| *Journal of the Chemical Society*, Feb., 1877.

incorrect, and arising from an imperfect separation of the bases obtained from *A. Napellus*. He says repeated crystallizations do not suffice to separate the two, viz., aconitine which is crystalline and picraconitine which dries up as a varnish.

Two bases are therefore recognized by Wright as existing in *A. Napellus*, viz., picraconitine—an uncrystallizable alkaloid, comparatively inert, yielding crystallizable salts (this often preponderates); and aconitine which is crystalline, and whose salts are crystalline.

To picraconitine Wright assigns the formula $C_{31}H_{45}NO_{10}$ and he gives to its crystallizable hydrochloride that of $C_{31}H_{45}NO_{10}HCl,1\frac{1}{2}H_2O$; a formula which is in our opinion inadmissible. In the analysis of the hydrochloride, Wright obtained more carbon than this theory requires, but less nitrogen, and with the exception of this one instance Wright has not given nitrogen determinations. These are circumstances entirely opposed to general experience, and they suggest the suspicion that Wright's formula is incorrect. At the same time the free base appears to have yielded the theoretical percentage of carbon.

To get aconitine pure, Wright says it is necessary after recrystallizing it from ether to make a crystalline salt, preferably the hydrobromide, and to regenerate the base from this by sodic carbonate in the presence of ether. To pure crystallized aconitine Wright gives the formula $C_{33}H_{43}NO_{12}$, but no nitrogen determinations are given, and several features are presented which raise doubt as to the correctness of this view. Thus in an analysis of the "pure base" he obtained 61·71 per cent. carbon against 61·39 required by theory.

In a further investigation Wright followed Duquesnel's process and confirmed the results of examination of his own preparations by comparison with those obtained with Mr. Groves' products; but, here again nitrogen determinations are entirely neglected, and this is really a serious consideration from the fact that very different substances, capable alike of forming gold salts or hydrochlorides may present similar percentages of carbon and hydrogen; and to reason that because the chlorine or the gold bears a certain atomic ratio to the carbon, therefore nitrogen bears a like atomic ratio to the carbon, is a most dangerous assumption. Above all things in importance is the relation of nitrogen to carbon in such compounds.

The numbers we obtained by analysis of the alkaloid from Japanese aconite agree best with the formula $C_{29}H_{43}NO_9$, and they are not comparable with those obtained by Wright for his crystallizable alkaloid (aconitine). Moreover, unlike the alkaloid he describes, the one we obtained gives no crystallizable salts, or, at least, none have been obtained, although many and various attempts were made to get them. The alkaloid was intensely bitter and it gave, on boiling with dilute sulphuric acid, a solution which readily reduced Fehling's test. By way of comparison, German aconitine, French aconitine, and Morson's aconitine were similarly treated. The French and Morson's preparations behaved, in this respect, like ours, but the German preparation gave an absolutely negative result. These preparations also refused to yield crystalline salts; it is true the acetates, especially that of Morson's, showed signs of crystallization, but practically the hydrochlorides, nitrates, and acetates dried up to varnishes.

The free alkaloid prepared as described did not fuse or change colour at 100° C, nor did it fuse or agglomerate in any measure in the way presented by the other three preparations alluded to, when boiled in water.

The varnish like substance which accompanied the crystalline substance has not been examined particularly, except that it has not been possible to obtain crystallizable salts from it. An interesting and important result however was obtained from an examination of the watery-alcoholic mother liquors left after the crystallization of the pure alkaloid, and containing this uncrystallizable substance. It was found that on addition of ammonia to the solution, a very bulky white precipitate was thrown down, having all the characters of the crystallizable alkaloid. From the very sparing solubility of that alkaloid in water it appeared that it must have existed in combination as a salt, and to test this the ammoniacal filtrate was evaporated to dryness. In this way there was obtained a gum-like mass, which dissolved in water and gave a bulky precipitate with lead acetate, containing when dried at 100° C., 50·82 per cent. lead. As aconitine is supposed to exist in aconite roots, etc., in combination with aconitic acid ($C_6H_6O_6$), and since aconitic acid, as well as the alkaloid, is soluble in ether, it is conceivable that the compound would be extracted, at least partly, by Duquesnel's process, for it is not probable that tartaric acid would effect its decomposition. In such case some process like that of Sonnenschein's, employing phosphomolybdic acid, would have to be employed in order to obtain absolutely satisfactory evidence of the composition of the aconite alkaloid.

The question, therefore, arises whether many of the substances which have been analysed as aconitine were not really aconitate of aconitine. Pure aconitate of lead represented by the formula $3\,Pb\,2(C_6H_3O_6),3\,H_2O$ requires 61 per cent. lead. A further quantity of the lead salt alluded to above was obtained, washed, and decomposed with sulphuretted hydrogen. The filtrate had an acid reaction, and on evaporation to dryness left an acid gummy residue not unlike aconitic acid. On treating the French, German and Morson's preparations by heating them to about 90° C. with water, a quantity was dissolved in each case. This was continued until ammonia no longer gave any precipitate with the filtrates, and on evaporation of the ammoniacal solutions, a substance was obtained in each case resembling the ammonium salt of aconitic acid.

To revert to the method of obtaining the alkaloids, it will be seen that the solution of acid tartrate was decomposed by sodic bicarbonate and the mixture extracted by ether. The alkaline solution remaining after this was rendered acid by nitric acid and the solution fully precipitated by phosphomolybdic acid. A somewhat bulky precipitate was thus obtained; it was decomposed after washing with water acidulated with sulphuric acid, by means of baryta water, and the excess of this reagent removed by carbonic anhydride, the last traces being taken out exactly by very dilute sulphuric acid, which was added to neutrality. The dark coloured fluid thus obtained deposited only a viscid brownish mass on evaporation over sulphuric acid.

The solution had the following characters:—

It gave with ammonia no precipitate.

It gave with potash a bulky precipitate.

It gave with a solution of mercuric chloride in excess of potassic iodide, a bulky precipitate.

It gave with a watery solution of iodine, a precipitate.

When acidified slightly with hydrochloric acid, platinic chloride gave a small precipitate, soluble in alcohol, and containing about 28 per cent. platinum.

Although these characters are not distinctive, they at least indicate the presence of an alkaloid capable of isolation in the manner described. After the precipitation by platinum, the bulk of the substance was left in solution.

In recapitulation of the results above described it may be said that the Japanese aconite examined by us has yielded a crystallizable alkaloid of the formula $C_{29}H_{43}NO_9$, which does not give crystallizable salts; a further substance which behaves as a salt of the crystalline alkaloid but is itself uncrystallizable; from which it appears that a certain part at least of the alkaloid is in combination (as extracted by Duquesnel's process) with an acid, perhaps aconitic; moreover, Duquesnel's process does not extract all the alkaloidal matters from aconite root.

The President said these were two papers on a very important subject, by gentlemen who could hardly be surpassed either in their knowledge of the subject or power of working it out, and one or two points presented themselves in connection with it. They had been accustomed for many years to look to the extraction of the active principles, the alkaloids especially, which were found in the vegetable kingdom, which possessed, as a rule, very powerful and often valuable medicinal properties, and to their use either in an isolated state or in a subsequently artificially combined state, as affording the best if not the only security for anything like uniformity in the preparations administered. The results now brought forward, however, rather tended to weaken the feeling of confidence hitherto reposed in the use of these active principles in their isolated condition. It appeared with reference to aconitine that in the very process of isolation it was subject to very material changes; that a body which was one of the most powerful poisons known to the medical profession, a small fraction of a grain of which would produce death under the most painful circumstances, was liable even by the mere action of heated water to split up, yielding a product which was inert; and that by various chemical actions, to which the body was necessarily subjected in its production, a variety of products more or less inactive were produced. It certainly appeared that the aconitine which had been used in medicine hitherto had never been the pure aconitine in an unmixed condition; and many medical men were perfectly aware of this fact. He recollected hearing the late Mr. Morson—who was a manufacturer of aconitine and who made it, he believed, for the physician who first introduced it in medicine in this country—say, that he had known that gentleman come into his establishment and when shown a specimen of foreign made aconitine, fearlessly taste it, so convinced was he of its want of energy. Fortunately, this substance was rarely if ever used internally, but only externally; still it was a serious consideration that they were constantly using a body of this description, so powerfully poisonous, but which so readily underwent change that there was great difficulty in obtaining it in a state of purity. He would now invite discussion on these valuable papers.

Mr. Holmes said there were only three species of aconite at present known to occur in Japan: *A. Lycoctonum*, L., *A. Fischeri*, Reich., and *A. uncinatum*, L. The root received in commerce appeared to consist in large measure of one kind only, which Mr. Greenish had lately examined for him, and it appeared to possess a very different structure from the ordinary *A. Napellus*, and the root itself certainly was much stronger in taste. Dr. Paul had called attention to some of the specimens having a horny or resinous appearance, while the majority were starchy; but the same feature appeared in *A. ferox* and was probably due to the drying or some other cause with which they were not acquainted, rather than to any difference in species. One source of difficulty in dealing with this subject was that it was almost impossible in commerce to get specimens of one kind of root only, and therefore it was necessary to be very careful in speaking of results. The German aconite consisted chiefly of two species: the *A. Napellus* and *A. Stoerckanum*. In the case of the Japanese aconite of commerce they had no certain knowledge that more than one species did not occur, and the varying results obtained by analysis might therefore be owing to the presence of different species of root; and until one species exclusively was cultivated in this country, so that it might be thoroughly examined, it was impossible to come to any definite conclusion with regard to the alkaloids of any one species.

Mr. J. F. Walker asked whether the compound in which the benzoic radical replaced hydrogen in pseudaconine had been obtained.

Dr. Wright replied not yet. This was only a preparatory report.

Mr. Greenish said that having been for some time engaged in the microscopic examination of aconite roots, he had found that those imported were always more or less mixed, no matter whether they came from Germany or elsewhere. With regard to the Japan aconite there were certainly two roots; he could not say of two different species, but one was a very tuberous root, evidently a young one, and another was longer and shrivelled, being older. Dr. Paul had made a remark that the root was very starchy; and a transverse section of the tuberous root showed this; and when the starch was removed there was nothing left but a clean, clear, cellular tissue, with the fibrovascular bundles. In the case of the shrivelled root the cellular tissue had upon it a deposit of a resinous character, and having been accustomed now and then to put a section into his mouth when cutting, he had arrived at the conclusion that the tuberous root, which formed by far the largest proportion of the Japan aconite, did not contain so much of the pungent principle as the older and longer root. The Japan species was certainly not, in his opinion, *A. Napellus* the histological character being quite different. It had generally a much larger number of fibrovascular bundles in a transverse section than *A. Napellus*. It seemed to him clear that pharmacists could never make preparations of a definite strength until they knew in the first place the relative proportions of young roots as compared with old ones, and whether they were all of one species; and secondly whether the root in Japan was cultivated or not, because the cultivation of the aconite certainly diminished its active properties.

Mr. Umney said it would be very useful if it could be elicited which of the aconites was most powerful. In commerce, large parcels of Japan aconite were occasionally to be met with; sometimes parcels of the large root known as Nepaul aconite (*Aconitum ferox*) were offered for sale, while German aconite root was generally obtainable. All these were used in the manufacture of preparations which were used internally, as well as for liniments. His own impression was that the Nepaul aconite was the strongest. The men employed in crushing the roots in drug mills complained very much of the Japan root as causing a very powerful tingling sensation.

Mr. Greenish did not think this effect was so much due to the greater intrinsic strength as to the starchy character of the root which would cause it to be diffused in the atmosphere. The starchy matter of *A. ferox* was converted probably by the heat in the process of drying into dextrine, and, therefore, when this root was crushed it did not diffuse in the atmosphere.

Mr. Gerrard said he agreed with what was stated in Dr. Paul's paper that the amount of the alkaloid contained in the Japanese aconite was far beyond that given by Duquesnel and Dr. Wright, and that he himself had also obtained another substance with the nature of which he was not acquainted. On the addition of caustic lime and the removal of the precipitated alkaloid by ether, and the addition of carbonate of potash, an alkaline precipitate was obtained which did not crystallize from its solution in ether. With reference to the different strength of preparations of aconite, the liniment made from the Japanese variety was certainly not admissible, by the side of that made from the ordinary aconite root of commerce, for it was double the strength and caused intense irritation when applied externally. In fact, when working with it, it was necessary to envelop the face with some kind of gauze in order to prevent ill effects, and severe numbness of the hands had been caused by contact with the powdered root mixed with spirit.

Professor Attfield agreed with the President that the present condition of pharmacists in relation to aconite had been shown by recent investigations to be a very foggy one, but if so, their previous condition was one of mere chaos, and it might be expected that when more light was thrown on the matter by the very luminous constellation forming the Committee, they might so clearly see their way as not only to be able to prepare aconitine most usefully, but also how best to make the different galenical preparations of aconite. He should therefore be glad to hear from Dr. Wright whether he considered the investigation was one to which the Conference might usefully make a further grant.

Mr. KINGZETT said Dr. Wright, in his researches on the aconitines, seemed to have arrived at the conclusion that there were three distinct alkaloids, the first in importance being aconitine, $C_{33}H_{43}NO_{12}$, which is crystalline and gives crystallizable salts; the second alkaloid being picraconitine, $C_{31}H_{45}NO_{10}$, itself noncrystalline, but furnishing crystalline salts; and pseudaconitine, $C_{36}H_{49}NO_{11}$, said to be crystalline, but yielding salts which dry up to varnishes. In contrast with these results, the alkaloid obtained by Dr. Paul and the speaker was crystallizable; its salts however were uncrystallizable and its formula $C_{29}H_{43}NO_9$. Now, among other extraordinary matters Dr. Wright had assigned * to the hydrochloride of picraconitine the formula $C_{31}H_{45}NO_{10},HCl,1\frac{1}{2}H_2O$. He (Mr. Kingzett) contested that such a formula was incompatible with our present ideas of chemistry; the molecule of an organic body could not be associated with one and a half molecules of water. On the other hand Dr. Wright had stated that a similar molecule of picraconitine combined with one of auric chloride. Taking these two points into consideration, Mr. Kingzett could not accept the formula given to picraconitine by Dr. Wright, and he was equally suspicious of those assigned to aconitine and pseudaconitine. To take Dr. Wright's own analytical numbers it would be seen that the carbon estimations were for the most part too high, while in as many instances the hydrogen figures were too low for the theories against which Dr. Wright compared them, and as these experiences in organic analysis were the reverse of those usually obtained, either the analytical numbers or Dr. Wright's theories must be rejected. Further, Dr. Wright did not give nitrogen determinations except in one case, while the number of carbon atoms in the molecule had been determined by a consideration either of the number of chlorine atoms, or of gold salts, which were not safe to deal with, as the gold might be either too high or too low. The chlorines could not be trusted because there might be half a dozen bodies in mixture, each of which might have the power of combining with one HCl. The only reliable factor, therefore, in determining the molecule of the base, was the relation of the nitrogen to the carbon, and this method Dr. Wright had not adopted, except in one instance. This had been done, however, by Dr. Paul and the speaker in the case of the base from Japanese aconite having the formula $C_{29}H_{43}NO_9$, and therefore there could be no doubt that it differed in its properties from anything described by Dr. Wright. As had been mentioned, in the mother liquor was found a substance that gave a precipitate on adding ammonia, and from this it was onjectured that it was a saline compound with an acid which formed an ammonium salt when the base was thus set free, and they had no doubt at all that this precipitated base was identical with the crystalline alkaloid already alluded to. With regard to Mr. Gerrard's view as to the extraction of the bicarbonate of sodium solution by ether, he remarked that by applying Sonnenschein's process to that solution, a third quantity of base was obtained, a platinum salt of which had been analysed, but the analysis was not completed, nor was the examination of the base generally completed, so that they had reserved further mention of it to a future opportunity.

Dr. WRIGHT was very glad to find that the Japanese alkaloids had been examined. The Committee appointed by the Conference to investigate this subject made several endeavours to obtain specimens of this root, but failed to do so; and he regretted that the authors of the second paper had not thought fit to mention what they were doing to the Committee, or perhaps they might have been saved from falling into one or two trifling errors. In the first place the description given of the alkaloid to which the C_{29} formula was given was quite sufficient to convince him that the body in question was simply the same as he had had in his hands dozens of times, viz., a mixture of pseudaconitine and the decomposition products thereof. The analytical numbers exactly agreed, and so did the physical characters; and he had on doubt that when Dr. Paul and Mr. Kingzett tried the experiment of fusing up some of the acid or resinous mother liquor with caustic potash at a temperature of about 250°, and then acidified, and extracted with ether, they would obtain protocatechuic acid formed from the dimethylprotocatechuic acid. If you started with perfectly pure pseudaconitine and crystallized it from alcohol you would get a mother liquor which only required acidifying and shaking up with ether to yield this body. The alkaloid which crystallized out was the pseudaconitine in a tolerable state of purity, although it partially decomposed even while drying. The gummy mother liquor that dried up to a resin was a mixture of the alkaloids themselves, viz., pseudaconitine and pseudaconine, and the dimethylprotocatechuates of each of these two bases, and, therefore, it was no wonder that on regenerating the akaloid from this resinous mass it was found to possess exactly the same properties as the substance which did crystallize from alcohol, namely, the same mixture of the same two bases. From the short time at his disposal he had not described a considerable number of experiments which really showed that exactly the same bodies were obtained as those described by Dr. Paul and Mr. Kingzett. The body which Mr. Gerrard described as being obtained from the mother liquor he had no doubt was pseudaconine, which was retained in solution much more readily in alkalies than pseudaconitine or aconitine. He should also mention that the aconine, the decomposition product of aconitine, was soluble in water and precipitated lead acetate so that it might be quite possible that the body experimented on by Dr. Paul might have contained aconitine itself in addition to the dimethylprotocatechuates. Mr. Kingzett had referred to the improbability of a body containing one and a half molecules of water of crystallization, but, as a matter of fact, a large number of such instances were known, and if that was the only difficulty it was very easy to double the formulæ as he had advocated in the case of other alkaloids. As regards the question why the nitrogen was not determined in order to get at the ratio between the carbon and the nitrogen, except in one or two instances, he regarded this determination as eminently more fallacious than any you could make in organic chemistry. You could get a fair approximation to the nitrogen, and an almost exact one of the carbon, but whichever method of determining the nitrogen you employed, there was a liability to so many errors that the question whether the ratio was one of nitrogen to thirty of carbon or one to thirty-one was impossible to decide by the soda lime or any other method. That was the result of many observations on the subject. In reply to Dr. Attfield's question, whether he thought a further grant might be usefully expended in solving some part of the pharmaceutical aspect of the question, he must say that in his opinion if the balance which remained in hand of the former grant were regranted, some results might accrue which might be sufficiently interesting to warrant the expenditure. At any rate he should like to complete the investigation in which he was associated with Mr. Groves and Mr. Williams, and even if no further grant were made, he proposed carrying it out as far as the materials he had in hand would permit. A question had been asked whether any observations had been made on the comparative activities of the different aconite roots and the alkaloids thence derived. If his memory served him some specimens of pseudaconitine and nearly pure aconitine, isolated some years ago by Mr. Groves, were examined by Dr. Fraser of Edinburgh, but he did not remember the precise character of the results, nor was he sure whether he was not confusing them with those obtained by a German chemist from the same two alkaloids; but it was found that whilst aconitine was consider-

* *Journal of the Chemical Society*, February, 1877.

ably more active than pseudaconitine with certain animals, such as rabbits, it was less energetic with others such as Guinea pigs, so that the physiological ratio of activity would be different according to the kind of animal experimented on, and very possibly might be different with different individuals of the human species. He had not been able hitherto to carry out any physiological experiments on these substances because he was waiting to get one or two other bodies in a state of perfect purity, and moreover he did not possess a vivisection licence. He hoped however that before the next Conference the physiological activity of all the specimens yet obtained would be carefully examined side by side, by Professor Michael Foster, of Cambridge, who was willing, he believed, to undertake this examination. With regard to the pharmaceutical aspect of the question, he did not think the preparations made direct from the root without the isolation of the alkaloids could be at all relied on. In the first place, in an alcoholic solution even the organic salts of the aconite alkaloids would undergo decomposition slowly on keeping, and therefore a preparation of a certain potency now would be weaker next year; and again, the roots met with in commerce were probably derived from different species grown in different climates and soils, and probably therefore contained different amounts of active alkaloids, so that a preparation made in one case with a certain weight of one class of root would differ from one made from the same weight of another class. If, however, the alkaloids were extracted to a certain degree of purity, say fifty per cent., you could always depend on having an agent of the same physiological potency.

Mr. Kingzett said the discussion of course could not go on indefinitely, but he should like to make one or two remarks on what had fallen from Dr. Wright. In the first place it was generally accepted by chemists that the method of Dumas was an exact method for determining nitrogen; the error being generally on the side of excess to a slight degree, but when corrected in the ordinary way the error was reduced practically to nothing; whilst by the soda lime method you were liable to get a very large error indeed, and it was by this method that Dr. Wright had made his solitary nitrogen estimation It had been shown by Dr. Thudichum and Mr. Wanklyn, and more recently by Dr. Thudichum and himself, that the methods he had mentioned were exact; he (Mr. Kingzett) had made more than 500 analyses, in which correct nitrogens determinations had been so effected. Dr. Wright imagined that the alkaloid they had obtained was his pseudaconitine mixed with what he supposed to be the aconitine decomposition product, but there was not the least evidence for such a statement, as he should now show. There might be in different species of aconite root, different alkaloids, but that the alkaloid obtained from Japanese aconite was identical with any of the alkaloids described by Dr. Wright was perfectly inadmissible. Dr. Wright had stated that while hydrochloric acid and certain other reagents split up these alkaloids into certain decomposition products, tartaric acid was free from this objection, yet, nevertheless it was by a method employing hydrochloric acid that Dr. Wright had obtained his pseudaconitine! On the other hand, Dr. Paul and he had used tartaric acid and therefore on Dr. Wright's own showing, the Japanese alkaloid could not have been at least a mixture of pseudaconitine with aconitine decomposition products. Not only so, but their alkaloid with the formula $C_{29}H_{43}NO_9$ did not split up as stated by Dr. Wright to be true of his substances either into benzoic or dimethylprotocatechuic acid and secondary bases, so that all this theory as applied to their alkaloid was the merest imagination. They had noticed that both the French and English commercial aconitines as well as that which they had prepared from Japanese aconite, when boiled with dilute sulphuric acid (a 2 per cent. solution), yielded a solution which would reduce Fehling's copper test, and in that respect it resembled sugar, but he was not prepared to accept that circumstance as a proof that it was dimethylprotocatechuic acid, especially on the evidence contained in Dr. Wright's paper. He should also remark that the alkaloid from the German aconite failed to give this reaction when boiled with dilute acid. Lastly he should like to ask Dr. Wright what were the physical characters of the acid obtained by splitting up in the way he described, of aconitine by dilute acids, alcohol, and so on.

Dr. Wright said the physical characters of benzoic acid were pretty well known; the melting point was 120·5; it was slightly volatile, and it yielded various characteristic reactions. The other acid was somewhat analogous in its properties; it was extracted from an aqueous solution by ether, almost entirely by one extraction—perfectly by three; the ethereal solution left by evaporation a residue which could be crystallized from boiling water, the substance being nearly insoluble in cold water. He had tested it side by side with synthetically prepared dimethylprotocatechuic acid, and found they were identical. The neutral salts of each of these acids gave with a moderately strong solution of nitrate of silver, a peculiar gelatinous precipitate, and there were several other qualitative tests in which the two bodies absolutely agreed.

Dr. Paul said it would be unreasonable to detain the meeting with the discussion of a subject which was unfortunately in a very incomplete and inchoate condition, but he should like to say just a word or two. The fact that the examination of the alkaloid from the Japanese aconite had been undertaken by himself and Mr. Kingzett had incidentally brought them in contact with the subject on which the report had been read. Having obtained the alkaloid and examined the substance to some extent, they supposed, after the amount of elaborate investigation and reporting which had gone forward for some time—they had merely to do as a botanist did with some questionable plant—compare it with one in his herbarium—and that then they would be able to say whether it was picraconitine, pseudaconitine, or something else described in those reports. But when they came to apply this procedure to the substance in question they found themselves in such a fog that they were unable to say whether it was this, that, or the other, and in pursuing their way through this misty region they found only statements unsupported by any adequate evidence, and chemical formulæ that had no legs to stand upon; they had therefore to try and find some light for themselves. Just at the end of their journey they lit upon a fact which seemed to throw some light on the muddle and diversity of opinion which had prevailed with regard to the chemistry of aconitine. There was this much certain, that there had been a great variety and antagonism of opinion on the subject, and they all knew that aconitine varied very much. Makers would recommend their preparation as being more active than some one else's, and it was also agreed on all hands that the alkaloid obtained from aconite contained a crystallizable substance mixed with a gummy uncrystallizable substance. This agreed with the result of their examination of Japanese aconitine, and the samples of aconitine they had dealt with also contained an uncrystallizable substance, which together with the crystallizable portion was soluble in ether. A further examination showed that this gummy substance when treated with ammonia—not with strong alkalies, which they had avoided, having respect to the tradition that aconitine was a very evanescent substance—yielded an alkaloid identical with the crystallizable body in all its characters which they were able to test it by. The conclusion, therefore, at which they arrived was, that they doubted whether the alkaloid to which the active properties of aconite root are ascribed had ever yet been obtained in a separate state. In fact, it seemed probable that the substance extracted from aconite was to a great extent a salt of an acid like aconitic acid. In regard to the formulæ of the decomposition products which had been spoken of, he thought before they could say much about them they must determine clearly the nature of the substance from which they are supposed to be derived, whether it was really an alkaloid or whether it was a mixture of several accidental combinations of an alkaloid with some acid which might probably be aconitic acid, for that acid was certainly present in aconite, and since it was soluble in ether it would, therefore, certainly be got out by Duquesnel's process together with the alkaloid. With regard to the strength of the pharmaceutical preparations made from aconites he would also remark that in the absence of more definite chemical knowledge of the active principle in aconites it was quite an accident what amount of potency these preparations would possess. The statements given as to the percentage of aconitine in aconite varied from ·03 to ·07, but they had obtained from Japanese aconite as much as ·20. Considering the powerful action of aconite it seemed desirable to have some means of determining the amount of active principle.

A vote of thanks having been passed to the authors of the papers the Conference adjourned for luncheon which was provided by the Local Committee in the Mechanics' Institute.

(*To be continued.*)

Dispensing Memoranda.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be conidered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.

[20]. In answer to "Ph. Chemist," aq. caryophylli, and aq. cinnamomi as well, when recently distilled, make an opaque mixture, more or less dense, according to age of water.

PRACTICE.

[21]. AVOIRDUPOIS OR APOTHECARIES?—According to the British Pharmacopœia "Difficultas" should use avoirdupois weight. It would make matters perfectly distinct if prescribers wrote ℥j troy, or gr. 480.

PRACTICE.

[22]. KEEPING LEECHES.—I have kept leeches about sixteen years and usually have from thirty to eighty in stock, and do not think my loss has averaged three a month during the time. My plan is to keep them in a two-gallon round glass aquarium with a perforated zinc top, to have about two quarts of water in it and a few pebbles, sometimes a piece of valisneria, but not always, as I have not found it to be absolutely necessary. I use water supplied from our waterworks, such as we have for drinking purposes, and have it changed say in warm weather once in ten days, and in colder weather once in three weeks, which is often enough.

This aquarium is kept in a store room, on a shelf which is neither very dark nor very light. I prefer *larger* spotted leeches and do not find any difficulty in keeping them healthy. I have often read of the losses others have had, and perhaps twice during the sixteen years I have had in a stock of fifty and lost a third of them in a week, but with a little extra care I have saved the remainder and had no further difficulty.

I have known them to breed in a glass aquarium and also in a fountain basin in my garden, and there they thrived with fish and water plants uncommonly well; they will, however, not do with fish in a *small* space, because the leeches fasten on the fish and exercise their peculiar function of blood-suckers, but where there is plenty of room the fish are not so much attacked by them.

I think Mr. Hoddinott will find the following hints useful, and I shall be happy to give him any further information that I am able by post:—

1. Have healthy leeches and a clean glass aquarium to start with.
2. Use drinking water as pure as can be obtained.
3. Keep the aquarium where it can easily be seen when the water is cloudy.
4. Be careful that clean hands are always used when touching or changing the stock.
5. Do not change the water too frequently.

ALFRED WILLIAM SMITH.

[22]. KEEPING LEECHES.—In keeping leeches healthy I have found the following plan invariably to succeed:—Keep the stock as low as possible; *never change the water unless it is absolutely necessary*, and, in cleaning, avoid as much as possible touching, or disturbing them with the hands. If the water is discoloured (providing it is not with blood), there is not the slightest necessity for a change as, often enough, such discoloration occurs immediately after cleaning. When the water begins to get turbid and to smell slightly, which happens in from four or five days to a month according to the season, it should be changed as gradually as possible, always remembering that the temperature of the water in your jar differs from that in the cistern or reservoir, and that a direct change from one to the other is prejudicial to the health of your stock. Put the jar under the tap and let a small stream run, after a while it will become clean, often without the slightest disturbance to its inmates. In large aquariums it would be a source of constant fatality to introduce an instant change of water, at a different temperature and, as a matter of fact, it is never attempted—the same body of water being used over and over again—oxygen being supplied by means of air forced in at different stages of its transit from tank to tank. The same broad rule is, I believe, applicable even to a leech jar.

CHARLES B. ALLEN.

[22]. KEEPING LEECHES.—I see from the *Pharmaceutical Journal* a correspondent wishes to know the best way to preserve leeches; the undermentioned I have found a first-class way, viz., keep in common tap water with pebbles in the glass, also put a piece of metallic iron in, say the size of a walnut. I have had to do with leeches for years, and since I tried the above, that will be over twelve months since, I have not had one dead.

A REGISTERED STUDENT OF THE SOCIETY.

P.S.—The water only to be changed weekly.

[22]. KEEPING LEECHES.—F. F. Hoddinott should try *river* water for his leeches, it must not be changed too often—about once in six weeks is quite enough. The water at first undergoes a kind of fermentation, but afterwards becomes quite clear and the leeches thrive in it.

FREDERICK W. E. SHRIVELL.

[22]. KEEPING LEECHES.—If leeches die rapidly and

constantly the best plan is to obtain a fresh supply from a different house to the one previously used; place them in a separate vessel from those already in stock. If an aquarium and gravel be employed with which diseased leeches have been in contact, the aquarium should be well washed with hot water, and the gravel, etc., with boiling water. Ordinary water, changed once a fortnight, and plenty of light keep leeches healthy.

PRACTICE.

[22]. KEEPING LEECHES.—Some year or two ago I drew attention to a method of keeping leeches, which in my hands far surpassed any plan I had seen or practised. I have little or no mortality and a minimum of trouble; I put the leeches into strained rain water, in a glass receptacle, with some bits of iron (a chain is a very good thing), and stand it in a moderately lighted place with a good circulation of air. Frequently it is not moved for six weeks or more, and once the water had so diminished by evaporation that it was only one-fourth the proper quantity, nevertheless the leeches were vigorous and healthy.

HIRUDO.

Obituary.

H. A. WEDDELL, M.D.

A paragraph from a letter, quoted in the *Pharmaceutische Zeitung* conveys the intelligence of the death of the distinguished quinologist, Dr. H. A. Weddell, which took place at Poitiers, on the 22nd of July.

Dr. Weddell was born in 1819, and therefore at the time of his death he was in his fifty-eighth year. He was the author of numerous memoirs on botanical subjects, including papers on ipecacuanha, caoutchouc, etc. But his best known and most valued work has been done in connection with the Cinchonas. In 1843, with M. de Castelnau, he was commissioned by the French Government to travel through the inland provinces of Brazil and Peru. Up to that time Bolivia had not been explored for cinchonas, the search for the officinal species having been confined to New Granada, Ecuador, and Peru, so that nothing had been done in a country known to produce a bark extremely rich in quinine. But after about two years Dr. Weddell separated from his companion and, traversing this region, penetrated into the Peruvian province of Caravaya, and reascending the Andes to Cuzco reached the limit of former explorations, reaping on the way a rich quinological harvest. As one result of this journey he published, after his return to Europe in 1848, his '*Histoire Naturelle des Quinquinas*' (Paris, 1849). In this fine folio work, illustrated by thirty-four plates, eight new species of Cinchonæ were described, and a systematic arrangement of all the known species was given. It exercised considerable influence on the classification of the Cinchonas, and was an important contribution to quinological science, in fact the only one based on original observation published for a long interval.

The gradual accumulation of numerous data respecting the botanical and chemical characteristics of the Cinchonas, induced Dr. Weddell in 1870 to publish his '*Notes sur les Quinquinas*,' which first appeared in the *Annales des Sciences Naturelles*. Agreeing with Mutis that the large number of forms composing the genus *Cinchona*, which are so closely interlinked with each other and show a constant tendency to increase, are possibly the result of the development and variation of a small number of primitive forms, Dr. Weddell in this work distributed them all into five groups, at the head of each of which is a typical form or "*stirps*." The types adopted are *C. officinalis*, *C. rugosa*, *C. micrantha*, *C. Calisaya*, and *C. ovata*. The value of this work was immediately recognized, and the Indian Government at once had it translated into English for circulation in India. It was also translated into German by Professor Flückiger. Only recently Dr. Weddell took a leading part in a Cinchona Congress and Exhibition held at Amsterdam.

Notice has been received of the deaths of the following:—

On the 24th of July, 1877, Mr. William Clark, Pharmaceutical Chemist, Landport. Aged 69 years. Mr. Clark had been a member of the Pharmaceutical Society since 1870.

On the 31st of July, 1877, Mr. William Chenhalls Hemmings, Chemist and Druggist, Penzance. Aged 62 years.

On the 10th of August, 1877, Mr. Thomas Lundie, Chemist and Druggist, Great Grimsby. Aged 40 years.

On the 13th of August, 1877, Mr. William Hope, Chemist and Druggist, Uppingham. Aged 77 years.

On the 14th of August, 1877, Mr. Henry Hunter, Chemist and Druggist, Alnwick. Aged 65 years.

On the 18th of August, 1877, Mr. John Colby, Pharmaceutical Chemist, Weston Road, Brighton. Aged 35 years. Mr. Colby had been a member of the Pharmaceutical Society since 1865.

On the 20th of August, 1877, Mr. Edwin Foy, Chemist and Druggist, York Town, Farnborough Station. Aged 40 years.

Correspondence.

"CASTOR OIL PILLS."

Sir,—I have perused with much interest the account of the "castor oil pill" case, reported in a recent issue. In my capacity of assistant it has frequently fallen to my lot to be pestered for these pills. My impression is that most of the persons using "castor oil pills," so far as they give the matter thought, are firmly convinced of their identity with castor oil, and if an assistant were so unwise as to attempt to upset their belief, the would-be buyers of "castor oil pills" would leave the shop either without purchasing at all or thoroughly dissatisfied with what was supplied them, resolved in future to patronize an establishment where less ignorance (for such they would designate it) and certainly more business tact was displayed. The proprietor of a business might take a turn at playing the schoolmaster if it so pleased him, but I fancy the luxurious delights of an educator would cease to charm the most scrupulous of men, when he discovered that even this amusement had to be paid for by loss of business. Practised by an assistant the educational process would generally involve censure from the master for unbusiness-like behaviour, and a few repetitions of the offence would very like mean the loss of the situation, leaving the assistant to regret that he made not friends of the mammon of unrighteousness. I presume a man's object in selling drugs is to make money, and as druggists are not subsidized by the State it seems no part of their duty to fill gratuitously the office of teachers to their customers, especially in matters which for their complete apprehension require the smallest possible exercise of common sense. The most practicable method of surmounting this difficulty would be to use a label for "castor oil pill" conceived something after this manner, "Mild aperient, hitherto known as castor oil pills." But I gather from the report of the trial that this method would require to be carried to an absurd extent, in fact throughout the complete catalogue of misnomers, if one would satisfy the stern inflexibity of the law; besides, such labels are practically useless, as the public seldom or never trouble to read them, or if they do are no wiser, not even in their own conceit. I imagine that those engaged in the drug trade do not pretend to be more scrupulously honourable than other tradesmen, but when so much dirt is thrown, some will stick, and it behoves us to avoid even the appearance of evil, by adopting such precautions as will keep us out of the meshes of the law, lest we earn, like the proverbial dog, a bad name, to the detriment of the best interests of an honourable occupation.

JUVENIS.

Sir,—The prosecution for the sale of "castor oil pills," I have no doubt, will seem quite as absurd to the intelligent public as it is to chemists, it being well known that "castor oil pills" are merely pills that may be taken with safety, instead of castor oil, at a time when strong purgative medicines would be injurious. However, as it is a fact that a chemist has been fined for selling them, it behoves anyone who can suggest a remedy for this and other like cases, to give others the benefit of it. I therefore enclose you a label which I have used for the last few years, and I think should "castor oil pills" be asked for, they might safely be sent out with a label of this description. The label reads as follows:—"Mild Aperient Vegetable Pills, 1 or 2 at bed-time occasionally. As these Pills are often taken instead of Castor Oil, they are sometimes called Castor Oil Pills."

A. W. GARDNER.

Canterbury August, 13, 1877.

PHARMACY IN THE CHANNEL ISLANDS.

Sir,—Your correspondent from the Isle of Man, in his letter of August 11th, appears to be ignorant of the fact that the Channel Islands still suffer from the same want of pharmaceutical legislation, and that the public remain unprotected from the consequences of the business being thrown open to ignorant and unscrupulous men, and the chemists find themselves exposed to ruinous competition from the same class. Looking at the long and intimate legal relations existing between the Islands and France, one would have expected to have found a system of pharmaceutical laws somewhat similar here, or that measures had been taken for the extension of the English Pharmacy Act. Evidently the oriental apathy complained of by your Manx correspondent is not confined to his Island, as it exists in the same degree here. In this case it is extraordinary, as the Members of the Society are in majority here, and one would imagine that they would be only too anxious to free themselves from unqualified competition which they have had to contend with, not only from England, but France as well. I believe that if steps were taken in a proper manner to bring this under the notice of the States of the Island, that they would at once sanction the adoption of the Pharmacy Act, and thus remove a state of things which is not in accordance with the present age of progress. Perhaps the Manx initiative in ventilating this question may produce some effect here, and induce the chemists to unite together for the purpose of furthering so desirable an object.

Jersey, August 13. A JERSEY CHEMIST.

PHARMACY IN THE ISLE OF MAN.

Sir,—I heartily agree with "H. S. F." with regard to the necessity for a decided improvement in the *status* of pharmacy as it effects the interests of the Manx people. It is indeed a wonder that no one has broached the subject before, but now that the urgency of the case has been so well set forth, and the remedy indicated by your correspondent, I hope prompt action will be taken by the proper authorities to introduce such measures as will benefit the community immediately concerned without detracting from the liberties of other British subjects, or depriving them of rightful privileges.

Whilst the chemists of Great Britain and its sister isle "Hibernia" have got legislative enactments to protect them from the inroad of strangers—however great their pretensions—the populous little island in question has been left out in the cold; yet I trust it may soon be on the same footing as its neighbours, and show the truism of its crest, so that if it cannot share the immunities or restrictions of the shielded parties, it may claim its independence in this matter and prove a successful rival; nay, more! far outvie us in its endeavours to advance pharmacy to that honourable position we so strive to maintain.

The Irish Act was a great mistake, in so far as the title of "Ph. C." is obtainable under its cloak by passing an examination, which, in comparison with the severe test put upon candidates for the "Major" by the Board of Examiners in this country, is a complete farce.

If there is any cause for the repeal of the Pharmacy Act of 1868, it might be well to consider the desirability of amalgamating the whole body of pharmaceutists in the United Kingdom under the general name of "The Pharmaceutical Society of the British Isles," or perhaps the more elegant one of the "British Pharmaceutical Society," which might easily become the younger sister of the "British Medical Association;" just as the British Association and the British Pharmaceutical Conference now work in harmony and their hold meetings together. In the event of such an alliance, of course the compulsory examinations conducted in the respective centres would need to be on a par as regards requirements and stringency—not making "fish of one, and flesh of another," as is the case at present, while two distinct acts exist.

In the meantime, steps should be taken to prevent the pleasant spot and resort of tourists in the Irish Sea from being overrun by ambitious invaders who can display their "colours."

I think there certainly ought to be reciprocity of feeling between the various boards in the Queen's dominions whereby the same qualification would hold good at home or in the colonies, and freedom given to any one holding a diploma of registration to start where he chooses on payment of the requisite fee without being subject to a second ordeal, in the same way as certificates from College of Surgeons or University classical examinations are accepted now in lieu of the pharmaceutical Preliminary.

JAMES B. L. MACKAY.

Newcastle-on-Tyne, August 13, 1877.

"*Devonian.*"—(1) The right of a person who has passed the Minor examination to registration as a "chemist and druggist" is not forfeited by his becoming subsequently registered under the Medical Act. (2) Yes.

A. P. A.—According to section 3 of the Act to Amend the Pharmacy Act, 1868, passed in 1869, nothing contained in section 17 of the first mentioned Act (relating to the labelling and registration of scheduled poisons) is to "apply to any medicine supplied by a legally qualified medical practitioner to his patient or dispensed by any person registered under the said Act, provided such medicine be distinctly labelled with the name and address of the seller, and the ingredients thereof be entered, with the name of the person to whom it is sold or delivered, in a book to be kept by the seller for that purpose."

J. D. Adcock.—We do not quite understand your communication.

J. Brend.—We do not think it could be done legally without a licence. Write to the Solicitor to the Inland Revenue Commissioners, Somerset House.

F. J. Fox.—(1) *Linaria minor*; (2) *Matricaria inodora*; (3) *Amaranthus reflexus*; (4) *Galium Mollugo*; (5) Too fragmentary to determine; (6) *Orchis maculata.*

"*Syrupus.*"—(1) *Tortula muralis*; (2) *Tortula fallax*, mixed with *T. muralis.*

"*Student.*"—The first fifteen sections of the Pharmacy Act, 1868, relating to the registration of chemists and druggists, do not extend to "the business of wholesale dealers in supplying poisons in the ordinary course of wholesale dealing."

T. H. Fletcher.—Yellow prussiate of potash is not a poison; but bichromate of potash is. Although the latter is not included in the schedule of poisons it would be safer to label it "poison."

J. B.—Apply to the Secretary for a copy of the pamphlet 'Hints to Apprentices and Students.'

G. S.—(1) *Senecio aquaticus*; (2) *Lysimachia nummularia*; (3) *Lythrum Salicaria*; (4) *Circæa lutetiana*; (5) *Galium uliginosum.*

J. W. Wood.—*Hyoscyamus niger*.

J. G.—Yes.

THE TINCTORIAL POWER OF SOME PHARMACOPŒIA PREPARATIONS.

BY W. GILMOUR.

Is colour as a rule to be depended upon as indicative of the strength and quality of pharmaceutical preparations? If we were to answer this question in the light of universal custom we should undoubtedly answer in the affirmative, but if we were to judge solely by the absence of all rule and standard we should as unhesitatingly answer in the negative. Nothing is more common, or seems more natural, than to examine the degree of whiteness, say, of a powder, or the depth of colour of a tincture or an infusion. Indeed, this generally forms in common with taste and smell a very important part of the preliminary examination to which all drugs are admittedly subjected, and the absence of any rule or standard, it need scarcely be pointed out, neither invalidates the custom nor the conclusion arrived at.

Still in view of the very deceptive nature of colour (and especially half tones) to different eyesight, as also the artificial manner in which many drugs are manipulated so as to be in many cases in this respect beyond the power of detection by ordinary examination, the following experiments in colorimetry may not be uninteresting. The plan pursued was to estimate the amount of light transmitted through a known strength of solution and reduce it to degrees for purposes of comparison, etc. This is most readily accomplished by a simple adaptation of the spectroscope in which the spider web micrometer is brought to the exact point of complete absorption of the light when the amount transmitted can easily be calculated. Take for example ordinary tincture of iodine, which contains about 10·9 grains iodine to the ounce, place it in a graduated burette, and estimating the total amount of light transmitted at 20°, we find that for each single degree of light passing through beyond that amount there will require to be a reduction of iodine in the solution to the extent of a grain and a fraction to the ounce in uniform proportion, thus—

10·9 grains iodine in 1 oz.	= 20° transmitted light.			
9·5	,,	,,	= 21°	,, ,,
8·2	,,	,,	= 22°	,, ,,
6·8	,,	,,	= 23°	,, ,,

The ratio here is nearly uniform, but if instead of the tincture we take an aqueous solution, say the volumetric solution which contains about 5·5 grains to the ounce, we shall find that instead of continuing uniform as above, and which would indicate about 24°, it immediately leaps to 31°, whilst the reduction of iodine in the aqueous solution by a grain and a fraction as in the previous instance raises it to 36°. Thus—

5·5 grains iodine in 1 oz. aqueous solution = 31°
4·1 ,, ,, ,, ,, = 36°

From which, as well as from other experiments not thought necessary to note, we have brought out the interesting facts, namely, that an aqueous solution has not the same tinctorial power as an alcoholic of the same strength, and that very dilute solutions raise the amount of transmitted light in unequal increments.

Not less interesting was the experiment with two different samples of tincture of opium, the one tincture made from a good sample of opium, the other from what is known as a good second. In bulk, the appearance of the two tinctures was not unlike, although on closer examination in smaller volume, that made from the second opium was not quite so deep in colour. Still, from a general examination, it might have passed for ordinary tincture of opium, B. P., and certainly no one could have been prepared for the extraordinary difference in the amount of transmitted light on comparing the two. Thus—

Tincture opium 1st . = 48° transmitted light.
,, ,, 2nd . = 60° ,, ,,

The difference was fully explained on further examination by the first yielding on evaporation 5·0 per cent. dry extract, whilst the second only yielded 3·1 per cent.

Taking the first tincture again and diluting it gradually the same uniform results were obtained as in the case of the iodine, with this difference, namely, that the amount of light transmitted increased in greater ratio than the dilution, thus—

Tincture opium	full strength	= 48°	transmitted light.
,, ,,	diluted 12·5 p. c.	= 51°	,, ,,
,, ,,	,, 25·0 p. c.	= 56°	,, ,,
,, ,,	,, 37·5 p. c.	= 62°	,, ,,

This last dilution, it will be noticed, corresponds very closely not only with the amount of transmitted light but in strength also with the second tincture, and the coincidence here is more than singular and points to conclusions which further experiments seem amply to confirm. We may take another opportunity of referring to these, but in the meantime we would point out that these preparations were chosen for a preliminary investigation, not from any thought that a better plan of determining their absolute strength could be substituted for those already known, but simply because they were of such a nature that their strength could otherwise be correctly determined and thus compared colorimetrically. But apart from this, both preparations and especially tincture of iodine, admit of considerable variation of strength without being apparent to the eye, and therefore they afford a good indication of the delicacy of the test. If any one doubt this let him take tincture of iodine and dilute in various proportions even to a considerable extent, and then compare the different degrees of strength. He will probably be astonished to find how very gross the adulteration requires to be ere it can be detected by the unaided eye.

NOTE ON RHEUM OFFICINALE (BAILL.).

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

In some remarks made upon *Rheum officinale* a few weeks ago (vol. viii., p. 1017), the hope was expressed that a further opportunity of examining the root might clear up the doubts as to the identity in structure of the true Russian rhubarb and the root of *Rheum officinale*. During the past week Mr. Usher, of Banbury, has kindly afforded me this opportunity.

A plant three years old was dug up, and presented the following features:—

The sympodium or cluster of rootstocks differs from that of *Rheum rhaponticum* in its great size, and in the root forming a tuft at the base of the rootstocks, and not springing from their sides. When the rootstocks were trimmed by depriving them of the roots and small lateral shoots, they weighed on the average about 8¾lbs., the central one being about 10lbs. The rootstocks were nearly cylindrical in shape, tapering very slightly to either end, and about 6 inches in diameter in the middle, and from 15 to 18 inches long. The roots on the average were 1½ to 2 inches in diameter near their attachment to the rootstock, and tapering downwards. The rootstocks of some *Rheum rhaponticum* of eleven years' growth, which was lying near, were not more than a quarter the size.

When the outer portion was carefully sliced off in different parts of the rootstock and root, it *nowhere* presented the appearance characteristic of the true Russian rhubarb. The cortical portion was then removed in several places (this being always absent in Russian rhubarb), and the meditullium or central portion sliced in like manner, but no trace of the network which so markedly distinguishes the Russian rhubarb could be seen. These marks are well represented in *Goebel and Kunze*, pt. II., tab. 1, fig. 2 *b*.

The transverse section of the rootstock also is not so finely grained, and although it is marked with many stellate spots, the markings are much larger and bolder than those of Russian rhubarb, and, in fact, approach more nearly to the markings on English rhubarb. The sections of the true roots present only a radiate structure without any stellate markings. In my opinion, the Russian root is produced by a plant which has a much less rapid growth than the noble *Rheum officinale*, Baill.

From the English rhubarb the rootstock differs chiefly in its paler colour, much larger size, and in the abundance of large stellate markings. As regards its medicinal properties there is reason to believe that it is much stronger than the English kind, and probably equal to the East Indian. It will most likely be soon tried at two of the London Hospitals, and a report upon its action will doubtless follow in due course and awaken considerable interest.

PHYSIOLOGICAL ACTION OF PAO-PEREIRA.*

Geissospermum læve, Baillon.

BY MM. BOCHEFONTAINE AND DE FREITAS.

The pao-pereira tree is a nature of Brazil, and its bark has been much used by the physicians of that country since Professor Silva, about the year 1830, made known its febrifuge and antiperiodic properties. It belongs to the Apocynaceæ, and has been variously designated as *Picramnia ciliata*, *Vallesia punctata*, *Tabernæmontana lævis*, and *Geissospermum Vellosii*. Professor Baillon is, however, of opinion, after a recent examination of leaves and stems received from Brazil, that it should bear the name of *Geissospermum læve*.

The bark of this plant contains an alkaloid in great abundance; this was first extracted in 1838 by Santos, and called by him "pereirine," but the authors propose to change this name to "geissospermine," after the generic name of the plant.

The dried leaves at the disposal of the authors had an extremely bitter taste, analogous to that of *Quassia amara*, which became manifest after chewing them for a few seconds. This taste being similar to that of the stem bark suggested the presence of a certain proportion of alkaloid in the leaves. Some leaves were therefore macerated in dilute alcohol and from the liquor thus obtained an alkaloidal precipitate was obtained, as was a similar one also from an aqueous maceration of bruised leaves. It seems therefore that the leaves contain the alkaloid, though in less quantity than the bark, and this is confirmed by the physiological action of the aqueous extract of the leaves on frogs.

The alkaloid of *Geissospermum*, as employed in Brazil is not a chemically pure product; it occurs under the form of a brownish-yellow amorphous powder, the bitterness of which resembles that of the leaves and the bark. Although daily employed in Brazil for many years past the physiological action of neither the alkaloid nor the bark appears to have been studied experimentally. The authors therefore took up the investigation, using geissospermine dissolved in water or alcohol, and alcoholic and aqueous extracts of the powdered bark.

The experiments showed that geissospermine is a toxic substance, exercising no local irritant action when administered subcutaneously. Two milligrams introduced under the skin caused the death of a frog; paralysis was produced by half a milligram. A full-grown guinea-pig was killed by one centigram, and fourteen centigrams completely paralysed a small dog. The symptoms were a slackening of the cardiac beats, and of the respiratory movements. The voluntary movements were first paralysed, the reflex movements gradually ceasing subsequently. The sensitive nerves appeared to preserve their functions as long as the motor nerves. The muscular contractility was not affected. The authors therefore consider geissospermine to be a poison which acts by destroying the physiological properties of the central nervous grey matter.

* Abstract of paper in *Comptes Rendus*, vol. lxxxv., p. 412.

THE PRESENCE OF TANNIN IN GENTIAN ROOT.

Is will be remembered that in a paper read before the Philadelphia College of Pharmacy in the early part of last year,* Professor Maisch vigorously combatted an assertion just previously made by Mr. Patch, that tannin is present in gentian root, and alleged that in commenting upon an incompatibility between tincture of chloride of iron and compound tincture of gentian Mr. Patch had overlooked the presence of orange peel in the latter tincture. The dispute led Mr. Ville, of the Montpellier School of Pharmacy, to undertake a series of experiments under the advice of Professor Leon Soubeiran.

The experiments were made with *Gentiana Burseri*, which, with *G. lutea*, is found in great abundance in the Pyrenees. The author states that cold macerations of these gentians gave positive indications of the presence of tannin with perchloride of iron, albumen, and gelatine. A small piece of fresh calf's-skin, placed in a concentrated infusion, also presented very apparent indications of tanning in a month after the commencement of the experiment.

In seeking to ascertain to which of the constituents of gentian this property was due the author found that in decolorizing a maceration of gentian with animal charcoal the bitterness was removed at the same time, and also that the colourless liquid then became indifferent towards the above-mentioned reagents. This seemed to warrant the supposition that the tanning principle was constituted either by the colouring principle (gentianin) or by the bitter principle (gentiopicrin). These principles were therefore isolated and tested with the reagents when it was found that the bitter principle, gentiopicrin, gave negative results, but that the colouring principle, gentianin, gave reactions of considerable intensity. The author therefore considers the tanning nature of gentianin to be demonstrated. He considers that there exists considerable analogy in their chemical functions between this colouring matter of gentian and the colouring matters of rhatany and yellow wood. It is proposed that in consideration of these properties "gentianin" should henceforth be called "gentianotannic acid."

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 8, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ILLEGAL SALE OF POISONS AS PATENT MEDICINES.

SINCE the Pharmacy Act was passed in 1868, neither it nor those who have been entrusted with the carrying of it out have at any time lacked criticism, and this has too frequently been uttered in entire forgetfulness of the circumstances under which that Act became the law of the country. It needs but to consult the reports of the debates whilst the Bill was passing through Parliament to find that it was only out of regard to the safety of the public that the limited restriction at present existing in regard to the sale and dispensing of medicines was established. At the same time consideration of what was supposed to be requisite for the public convenience had even then an important modifying influence upon the regulations which operated as a protection to qualified chemists and druggists. One very fertile source of complaint has been that portion of the sixteenth section of the Act which excludes the making or dealing in so-called patent medicines from the operation of the previous sections providing that only registered chemists and druggists shall deal in preparations containing any of the scheduled poisons. Whilst on the one hand it has been complained by chemists and druggists that the government stamp has been used to cover an extensive evasion of the spirit of the Act; on the other hand the medical press has not hesitated to blame the Council of the Pharmaceutical Society for not exercising powers in respect to the sale of proprietary preparations containing poison that have yet to be conferred upon it by Parliament.

It will therefore be noticed with satisfaction that the short report of the proceedings of the Council on Wednesday last mentions a salutary check that has been given to a growing tendency to overstep the encroachments which the exception as to "patent medicines" has hitherto favoured. The case relates to the sale by a Mr. THOMAS P. ALLATT, of Hacconby, Bourne, who is not a registered chemist and druggist, of an article bearing a patent medicine stamp, and labelled, "Smith's Black Sedative Drops, commonly known as Laudanum (Poison)," together with the name of Messrs. STURTON of Peterborough as the wholesale agents. The sale of laudanum by grocers and village hucksters, under such fancy names as "sedative drops," "infants' mixture," and the like, is unfortunately no novelty, though probably the recent development of public opinion on this question will soon allow of a more vigorous policy being adopted towards this class of offenders against the spirit of the Act. But the subterfuge of simply giving the second place to the real name of the drug was too transparent and audacious to be tolerated, and the Society's Solicitor was instructed to take proceedings against Mr. ALLATT for a breach of the Pharmacy Act.

We understand that the proceedings at once drew from Mr. ALLATT a disclaimer of any intention of breaking the law, of which he professed ignorance, and a statement that he had trusted in the matter to the judgment of the wholesale agents who supplied him with the "sedative drops." Messrs. STURTON also on their part accepted this position, but alleged that they were unaware until then that the course adopted by them was illegal. Of course these gentlemen are entitled to the full value of such a reclamation, but, nevertheless, we think that the action of the Solicitor, in accordance with the maxim *ignorantia juris neminem excusat*, will react beneficially, and that possibly the enforcement of the penalty in this case will help materially to dispel fortuitous oblivion still existing in some quarters, and quicken the perception of other dealers in these questionable articles as to their position in respect to the law of the land.

But notwithstanding that this result will be acknowledged generally to be satisfactory as far as it goes, it must be admitted that the entire law relating to the sale of so-called patent medicines is in an anomalous condition. We will not now do more than allude to the want of a clear definition of what constitutes a patent medicine, a want that has led the Inland Revenue authorities themselves into conflicting decisions, and is at the present time the source of expensive litigation in the Appeal Court. Neither will we raise the question as to the factitious value which the use of a government stamp may or may not give these preparations in the eyes of the credulous. Probably the Chancellor of the Exchequer would find many people to agree with him that this is not an unmitigated evil, and that it is not unusual to make the foibles of the people contribute towards the increase of the national revenue. But we apprehend that there would be few disinterested persons found to defend the consistency—or inconsistency— of a law which, for the safety of the public, provides that under their proper names even the smallest quantities of certain poisons shall be sold only by specially trained persons and in accordance with strictly specified conditions, whilst it allows any quantity of them, if under fancy names and covered by a stamp, to be sold unrestrictedly by any person able to pay five shillings annually for a licence.

At the time of the passing of the Pharmacy Act, 1868, this question was hardly ripe for dealing with, but there has been during the last two or three years a considerable expression of public opinion that the dealing in all preparations containing poisons should be restricted to properly qualified persons. Whether this can be brought about without interfering too much with the convenience of the public, or with the vested interests of the patent medicine proprietors, is a problem well worth study, and certainly it does not lie beyond the domain of the pharmacist.

POISONOUS HONEY.

An accident which a short time since befell the war correspondent of the *Daily News* in Armenia, recalls the fact, long known but generally forgotten, that honey sometimes possesses virulently poisonous properties. In this case the correspondent having drunk some water sweetened with honey was shortly afterwards seized with headache, vomiting, coldness of the extremities, temporary blindness, followed by a cataleptic state that appeared to bring him to the verge of death. Suspicion of an intention to poison fell upon an innkeeper and he was arrested, but an examination of his honey, which was from the Batoum valley, where hemlock and henbane grow abundantly, revealed the source of the injury.

It is interesting to note that this incident occurred within a few miles of the spot where more than two thousand years ago a similar accident, but on a larger scale, happened to the "ten thousand" during their celebrated retreat. Xenophon says that two marches from Trebizonde the Greeks encamped in some villages that had been abandoned, where there were a great number of beehives. All the soldiers who ate of the honey suffered from delirium, vomiting, purging, and inability to stand. Those who ate but little appeared intoxicated, whilst of those who ate more some were raving and others seemed to be dying. The soldiers lay on the ground as after a defeat, and a similar consternation reigned. None died, however, the principal effects passing off the next day, though three or four days afterwards the sufferers had the appearance of sick people who had used a violent remedy.

Dioscorides, Pliny, and other authors also mention poisonous honey. Pliny attributes the poisonous properties of one honey from this district to the bees frequenting a plant fatal to the beasts of burden and to goats in particular, which he calls *aegolethron*, or goat's-death, a plant that has been identified with the *Azalea pontica*. He says that when the blossoms of this plant become steeped in the rains of a late spring they contract noxious properties, and in this way the intermittent appearance of poisonous honey was explained. Persons eating this honey are said to throw themselves on the ground and call for cooling drinks. One remedy that Pliny mentions smacks of the *similia similibus curantur* principle: it is a mixture of old honied wine, honey and rue. Another is salt meat, repeated in small quantities and as often brought up again. The peculiar characters of this honey mentioned are that it never thickened, had a peculiar smell that provoked sneezing, and was redder and heavier than good honey. Notwithstanding its bad qualities it was not without a redeeming feature, for Pliny adds that mixed with costus it was the best means for making the skin of females soft and removing pimples from their faces; and that mixed with aloes it disperses the discolorations arising from bruises. Another livid honey from the same district possessed maddening properties; but the poisonous properties of both kinds are said to be dispelled by boiling.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, September 5, 1877.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT, IN THE CHAIR.

Present—Messsrs. Betty, Churchill, Greenish, Hampson, Hanbury and Owen.

The minutes of the previous meeting were read and confirmed.

Elections.

MEMBERS.

Pharmaceutical Chemists.

The following Pharmaceutical Chemists were elected Members of the Society:—

Fletcher, Redfern..................London.
Reece, Thomas......................London.
Wallis, Owen ....London.

Chemists and Druggists.

The following registered Chemists and Druggists were elected Members of the Society:—

Beckett, Thomas Sharpe ....London.
Booth, George ....Chesterfield.
Hughes, Herbert ....Bridgnorth.

ASSOCIATES IN BUSINESS.

The following having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year were elected "Associates in Business" of the Society:—

Allan, William ....Edinburgh.
Ashburner, Isaac ....Broughton-in-Furness.
Palmer, George Smith........... London.
Singleton, Richard ....Preston.
Turtle, William Gillingham ...Chatham.

ASSOCIATES.

The following having passed the Minor examination and having tendered or (paid as apprentices or students) their subscriptions for the current year, were elected "Associates" of the Society:—

Minor.

Blacklock, Philip Walter ......Brighton.
Clarabut, Frank Stone............Folkestone.
Lewin, Arthur Clayton ....Plymouth.
Ord, Septimus William ....Newcastle-on-Tyne.
Roe, Robert ....Lancaster.
Wilkerson, Wallis ....Weymouth.

Modified.

Allman, John Dowling ....London.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination and tendered their subscriptions for the current year were elected "Apprentices or Students" of the Society:—

Dodds, Benjamin Bellamy ......London.
Goodchild, Alfred Clarke ......London.
Hutchins, Edward Coxhead ...Bath.
Keys, William Hall...............Birmingham.
Kittle, Ernest J. ....Lower Edmonton.
Lawrence, Matthew Scott ......Stapleton.
Mowat, John Watt ....Coatbridge.
Parry, Robert Henry ....Rhyl.
Pidduck, William Joseph . ....Southport.
Robertson, George ....Portsoy.
Shephard, William Arthur......Spalding.

The names of the following persons were restored to the Register of Chemists and Druggists:—

Henderson, Robert Hood ......Chirnside, Berwick.
Williams, Thomas John ......George St., Godalming.

Two persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Reports of Committees.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts ordered to be paid.

BENEVOLENT FUND.

The report of this Committee recommended that a grant of £15 be made to the widow of a late member of the Society who had received assistance on three previous occasions. The consideration of another application for aid in securing the election of a child to a school was deferred until the next meeting of the Committee.

The report and recommendations were received and adopted.

LAW AND PARLIAMENTARY.

Prosecution under the Pharmacy Act, 1868.

The report of this Committee stated that the Solicitors had reported that Mr. Thomas P. Allatt, of Hacconby, Bourne, an unregistered person against whom they had been instructed to take proceedings for a breach of the Pharmacy Act, had paid the penalty of £5. The offence for which the proceedings were taken in this case was that of selling an article that had been supplied him by Messrs. Sturton and Sons, of Peterborough, which was labelled as follows and bore a patent medicine stamp:—"Smith's Black Sedative Drops, commonly known as Laudanum (Poison). Wholesale Agents, Sturton and Sons, Peterborough. Sold in $7\frac{1}{2}d.$ and $1s.\ 1\frac{1}{2}d.$ bottles."

The particulars of other cases in which proceedings or inquiries had been commenced had also been furnished by the Solicitor.

Personation at the Preliminary Examination.

The Committee had also recommended that the names of the following persons be erased from the Register of Apprentices or Students, they having fraudulently obtained registration:—

Frank Oates,
George Frederick Webb.

Threatened Prosecution under the Apothecaries Act.

The Secretary had brought before the Committee the case of a member of the Society resident in Blue Anchor Road, Bermondsey, against whom proceedings were threatened by the Medical Defence Association. On receipt of the first communication from this member the Secretary had written asking for particulars, and in reply had received a long narrative which had been laid before the Committee, in which the member stated that although he had received a writ suing for a £40 penalty, no particulars of the offence charged had been furnished. The Committee did not recommend that any action should be taken by the Council until further information was obtainable.

Mr. Churchill said it would be placing members of the trade at a great disadvantage if this practice were followed by the Medical Defence Association of issuing writs without stating particulars. The consequence was that the party sued was obliged to enter an appearance without knowing what he was charged with.

Mr. Greenish said the resolution come to by the Council at a former meeting was that each case should be considered on its merits, and this could not be done until the particulars were furnished. He thought it would be well to appoint a small Sub-Committee, of the nature of a vigilance committee, to consider these cases of prosecution as they arose.

Mr. Churchill said the Chemists' Defence Association had already entered an appearance in the present case, but the same course might be followed by the Medical Defence Association in many others.

The Vice-President did not think the Council need anticipate further cases; it could only deal with what was before it.

After some further conversation the report and recommendations were received and adopted.

A resolution was also passed recommending the appointment by the Law and Parliamentary Committee of a Sub-Committee to watch the cases of threatened prosecutions under the Apothecaries Act.

A letter was read from Mr. Sydney Plowman, apothecary to St. Thomas's Hospital, saying that the Materia Medica Museum at that Hospital was being rearranged, and asking if the Society could favour the Hospital with a set of labels, such as were used in its own Museum.

It was resolved that the request be complied with, so far as the stock of labels in hand would allow.

BENEVOLENT FUND.

List of subscriptions received during the months of July and August, 1877.

Provincial Transactions.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

Meeting of Law Committee.

A meeting of the Law Committee was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on September 3, 1877, at 1 p.m.

Mr. S. U. Jones (Leamington), President, in the chair.

Present :—Messrs. Barclay (Birmingham), Churchill (Birmingham), Hampson (London), Holdsworth (Birmingham), Jervis (Sheffield), and the Solicitor of the Association.

The minutes of the previous meeting of the Committee were read and approved.

The Secretary read communications from Messrs. Flux and Co., the Solicitors of the Pharmaceutical Society, and from the Registrar of that Society, respecting cases of infringements of the Pharmacy Act.

The Secretary stated that a writ issued out of the Exchequer Division of the High Court of Justice for the sum of forty pounds had been served upon Mr. Henry Wiggins, 236, Blue Anchor Road, Bermondsey, London, S.E., a registered chemist and druggist, a member of the Association and of the Pharmaceutical Society. The plaintiffs were the Apothecaries' Company, and the amount claimed was for penalties incurred by the defendant for alleged infringements of the Apothecaries Act, 1815.

The President inquired if Mr. Wiggins, being a member of the Pharmaceutical Society, had informed the Secretary of that Society that proceedings had been taken against him.

The Secretary said immediately he received the information from Mr. Wiggins he requested him by letter to at once communicate with the Pharmaceutical Society and solicit their assistance, as the last day for entering an appearance to the writ would be the 5th instant; he did not know the nature of the reply Mr. Wiggins had received from the Society, but he had thought it best for him to have a personal interview with the members of the Committee, and he had requested him to attend that meeting.

Mr. Wiggins then waited on the Committee when his case was fully discussed. In reply to a question from the President he said he had informed the Secretary of the Pharmaceutical Society that a writ had been served on him by the Apothecaries' Company, but up to that date he had received no acknowledgment to his letter. Mr. Wiggins then withdrew.

Some further discussion then took place when it was moved by the President, seconded by Mr. Jervis, and unanimously resolved:—"That the Solicitor be instructed to appear to the writ issued by the Apothecaries' Company out of the Exchequer Division of the High Court of Justice against Mr. Henry Wiggins, 236, Blue Anchor Road, Bermondsey, London, S.E."

The Secretary said he had received communications from members residing in London, Sheffield, Manchester, Blackburn, Chesterfield, Kegworth, Denton, Kirkby Stephen, Halifax, Bury, Heywood, Rochdale, Attleborough, Sherbourne, Kidsgrove, Middlesborough, Stockton-on-Tees, Chester, etc., etc., reporting cases of illegal trading under the Pharmacy Act, 1868, in some instances strongly protesting against the seeming inactivity of the Association in taking prompt steps to suppress such infringements of the Act. He (the Secretary) thought the time had arrived for the Association to distinctly inform its members that where scheduled poisons were being sold by unregistered persons, labelled in accordance with the provisions of the Act, the Association was totally unable to take proceedings against the vendors, as the power to sue in such cases was, by the Act, vested in the Registrar of the Pharmaceutical Society.

Mr. Barclay said proceedings could be taken by the Association against unregistered persons selling scheduled poisons not properly labelled, and he would move:—"That evidence having been brought before this Committee that scheduled poisons are still being largely sold by unregistered persons, this Committee considers it desirable that proceedings should be instituted, and it empowers the Solicitor to take action under Section 17 of the Pharmacy Act, 1868, in such cases as he thinks expedient."

Mr. Hampson seconded this resolution, which was carried unanimously.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 178.)

The PRESIDENT took the chair again at two o'clock, when the first paper read was "Report on the Active Principles of Cayenne Pepper," by J. C. Thresh, F.C.S.

THE ACTIVE PRINCIPLE OF CAYENNE PEPPER.

BY J. C. THRESH.

In November last I received from Messrs. Hopkin and Williams, 8½lbs. of alcoholic extract of cayenne, obtained from 30lbs. of the fruit. This extract had separated into an upper fatty layer and a lower one containing but little fat.

By treating the whole with benzine and evaporating, 2¼lbs. of a deep red fat was obtained. This was dissolved in warm petroleum and left for a few days, at the end of which time it was found to have deposited a large quantity of a crystalline fat. This was removed and pressed, and after repeated crystallizations first from petroleum, and afterwards from spirit, a colourless, solid fatty acid was obtained, soluble in ether, alcohol, etc. Melting point 62° C. When burnt no acrid vapours were evolved. These and other reactions show that this substance is palmitic acid, and it probably constitutes the greater part of the cayenne fat.

The petroleum solution from which the palmitic acid had been removed was treated repeatedly with dilute alcohol to remove the capsaicin. This process proved on the large scale extremely tedious and unsatisfactory, since I only succeeded in obtaining from three to four drachms of the active principle. This, however, is probably partly due to the comparatively small amount of capsaicin in the original fats. I have examined the fat obtained from various peppers, and find that by the same process very varying amounts of capsaicin is obtainable. The capsaicin thus obtained retained obstinately a trace of colouring matter, but by crystallization from ether I obtained about one drachm of what I believe to be the absolutely pure principle.

·356 grams burnt with lead chromate gave ·9105 CO_2, and ·2995 H_2O.

·381 grams gave ·9745 CO_2, and ·318 H_2O, from these the calculated percentages are :—

	I.	II
C	69·74	70·26
H	9·3	9·28
O	20·96	20·46

These results agree fairly well with the formula $C_6H_{14}O_2$ obtained by Dr. Buri from a small portion of the capsaicin which had been obtained from Natal pepper. As a microscopical examination of this pepper led me to infer that it was yielded by a different species of capsicum, I was anxious to discover whether the principles of both were identical. So far as I have observed this is the case. The disappointingly small quantity of capsaicin obtained has not enabled me to advance much further in my investigation. In fact, it is almost useless to attempt this until some process is devised whereby it may be obtained more readily and in larger proportions.

Oxidized with nitric acid, at least four products are obtainable; oxalic and succinic acids, an almost insoluble crystalline acid, and an oily body. Neither of the latter were obtainable in sufficient quantity for further examination.

Treated with dry chlorine, the crystals of capsaicin assume a deliquescent appearance, then gradually darken in colour, a tenacious dark brown resinous substitution product being ultimately obtained. During the reaction hydrochloric acid is evolved. It is probable that more than one product is formed. I have not succeeded in obtaining a crystalline chlorine compound.

Capsaicin forms crystalline compounds with barium, calcium, and mercury, but the difficulty lies in getting them free from uncombined capsaicin. The combustion of the barium and calcium compounds gave discordant results.

The colouring matter of cayenne fat, traces of which sometimes adhere obstinately to the active principle, is easily obtained from the marc left when the pepper has been thoroughly exhausted by spirit. This marc percolated with benzine yields an orange red solution, and upon evaporation a deep orange red oil. It is insoluble in proof spirit, slightly tints rectified spirit, and is only slightly soluble in boiling alcohol. An alcoholic solution of palmitic acid, capsaicin, or castor oil, takes up a considerable portion. It dissolves readily in oils, sulphide of carbon, petroleum, ether, amyl alcohol, and chloroform; from solution in the latter fluids it is precipitated by dilution with alcohol. Strong sulphuric acid turns it first indigo blue, then black.

Nitric acid strikes a blue colour, changing first to green and becoming ultimately brown.

Hydrochloric acid does not affect it.

All oxidizing agents convert it into a brown fatty matter.

Exposed to the air the colour slowly fades, and an indistinctly crystalline fat is deposited.

Mr. Williams said the extract forwarded to Mr. Thresh was not made by his firm, but by Messrs. Wright, Layman, and Umney.

Mr. Umney said he had experienced great difficulty in getting the oleoresin of capsicum in a uniform condition, there being generally a separation of the fatty matter, and it seemed to him Mr. Thresh had fairly elucidated the cause of its separation. The oleoresin was not of the same kind as was found in ginger, which was perfectly uniform and fairly homogeneous. The yield of crude capsicin from capsicums was enormous, as much as 20 or 25 per cent., whilst the oleoresin obtained from ginger was only about 10 per cent.

Mr. Greenish asked if Mr. Umney could tell what capsicum this was obtained from, as there were several kinds known. One, which was very much sold in this country ground for giving to canary birds, came from Natal, but on examination he found it agreed with the Nepaul capsicum.

Mr. Umney said the official chillies (*Capsicum fastigiatum*) only were used, and not those of *Capsicum annurum*, nor the Nepaul cayenne pepper of commerce.

Mr. Gerrard said he had at the request of Mr. Thresh asked Professor Ringer of University College to make some experiments on the physiological action of capsaicin, but when given internally it produced such violent griping pain and purgative effect that he was obliged to discontinue its use.

Professor Attfield remarked that it was interesting to find that free palmitic acid was obtained from the capsicum. Of course there were other substances that yielded free fatty acids and acid glycerides, such as cocculus and cantharides, but the number was not great.

Mr. Benger asked in what doses the capsicin was given as described by Mr. Gerrard.

Mr. Gerrard replied in $\frac{1}{25}$ of a grain.

The President said it was necessary to distinguish carefully between two terms which had been used, namely, capsicin, used by Mr. Umney, which was the oleoresin yielded in abundance from the capsicum, and the capsaicin described by Mr. Thresh which appeared to be a powerful body only obtainable in very small quantities. This latter body he presumed was almost too powerful for advantageous use in medicine, and indeed there seemed little object in seeking for a concentrated active principle, seeing that the capsicum itself yielded its active matter readily in a sufficiently concentrated state to admit of any medical application that might be required. He did not see that any very practical results were likely to follow this investigation although it was of course desirable that they should know as much as possible of all the proximate constituents of substances used in medicine. He had himself for many years had experience of what Mr. Umney described as capsicin, which had been used to some extent in making what was known as soluble cayenne pepper, which was common salt mixed with the oleoresin and coloured if necessary with anatto.

Mr. Groves asked if the experiments alluded to by Mr. Gerrard included the application of capsaicin to the skin as a vesicant.

Mr. Gerrard said a solution of it in glycerine and weak alcohol was applied externally, and produced the same local effect as tincture of capsicum; there was more redness and severe heat, but no blistering.

Mr. Atkins said it would be a matter of practical interest to know if there was any improvement suggested in the menstruum which could be adopted for the use of this article as an external application. It was pretty well known to chemists that some vesicating papers were prepared with an extractive principle of capsicum.

Mr. Gerrard remarked, that as far as he knew, no vesicating paper was made from capsicum or any of its preparations. Cooper's sinapine tissue was he believed made from capsicin, but it was not a vesicant.

Mr. Manby (Southampton) said he had had considerable experience, both with mustard leaves and with Cooper's sinapine tissue, and he understood that the latter produced a more satisfactory result than the former, but without so much irritation.

Mr. Greenish confirmed what had been stated by Mr. Gerrard, that the mustard paper did not contain any vesicating principle except that of mustard.

A vote of thanks having been passed to Mr. Thresh, the next paper read was—

Essential Oils with Special Reference to the Hydrocarbons contained in them.

BY WILLIAM A. TILDEN, D.SC. LOND., ETC.

For some time past I have been engaged in experiments upon certain essential oils, in the hope of being able to throw some light upon the chemical constitution of the hydrocarbons of the terpene family, which, as is well known, exist in a great many of the volatile oils obtained from plants.* In the course of these researches, however, I have naturally been led to examine, more or less closely, some of the other hydrocarbons and oxidized bodies which accompany the terpenes, and which in many cases contribute very materially to the peculiar characteristics of the essential oil.

The process I have chiefly employed for the identification and classification of the terpenes is based upon a reaction discovered by myself, and of which the first account was published in the Journal of the Chemical Society for June 1875. It consists in passing nitrosyl chloride gas (NOCl) into the terpene, either pure or diluted with chloroform or alcohol according to circumstances, and cooled to about —10° C. by a freezing mixture. A white crystalline body is deposited which always has the formula

$$C_{10}H_{16}NOCl$$

and is therefore made up of a molecule of the terpene with a molecule of nitrosyl chloride. From this compound by treatment with alcoholic potash, or by cautious heating, the elements of hydrochloric acid may be removed and the substitution product

$$C_{10}H_{15}(NO)$$

obtained. These nitroso-compounds are easily obtainable in large crystals, and, by their crystalline form, melting point and optical characters, they serve to determine the character of the terpenes from which they have been derived.

It is necessary here to remark that the name terpene must be carefully restricted to compounds of formula $C_{10}H_{16}$, and must not be extended to the polymeric hydrocarbons $C_{15}H_{24}$ and $C_{20}H_{32}$ into which the terpenes are easily converted by heat or by the action of energetic chemical agents such as sulphuric acid. I find that the reaction to which I have referred occurs only with the true terpenes ($C_{10}H_{16}$) and not with their polymerides. As further indicating difference of structure in these two

* I cannot allow the present opportunity to pass without expressing my sense of the obligation I am under to Messrs. Schacht and Towerzey, of Clifton, for their liberality in supplying to me at cost price all the essential oils used in the latter part of the work. The grant of money that was entrusted to me by the Conference last year has thus been rendered more fully serviceable than would otherwise have been possible.—W. A. T.

classes of bodies, it may be remembered that Mr. Kingzett in his interesting experiments on the atmospheric oxidation of essential oils found that the C_{10} compounds gave peroxide of hydrogen, whilst C_{15} hydrocarbons did not.

Turpentine Oils.—At present I have examined closely only two of the different varieties of turpentine oil met with in European commerce, namely the American and the French.

American turpentine oil is obtained chiefly from *Pinus australis* and *P. Tæda*, and is the kind which is principally employed in this country.

The commercial samples I have examined gave generally about 80 per cent. of nearly pure terpene (australene) boiling at 156° to 159°. The distilled hydrocarbon varies slightly in its action upon a ray of polarized light. 100 mm. gave me in one case a rotation of 15°, in another 13° 18′ to the right.*

French or Bordeaux turpentine oil is the product chiefly of *Pinus maritima*, and is distinguished from American oil by its optical characters. It consists principally of a hydrocarbon (terebenthene) which boils at the same temperature as australene, but rotates the polarized ray to the left. 100 mm. gave me a rotation of − 33° 49′.

The nitroso-derivatives of these two hydrocarbons agree in composition, in solubility and in melting point, also in forming crystals which not only belong to the same (monoclinic) system, but have the same crystallographic elements. The appearance is, however, quite different in the two crystals, so that once seen they are readily distinguished from each other and recognized even when quite small. The measurement of these crystals is in the able hands of Professor N. S. Maskelyne, and his observations will shortly be published.

Both American and French turpentine oils, when mixed with spirit and nitric acid according to Wiggers' process, yield crystals of hydrated terpin, $C_{10}H_{20}O_2H_2O$. These crystals are rhombic and are generally four sided prisms terminated by pyramids.

Whether obtained from right or left-handed turpentine oil their corresponding angles are equal.

I am indebted to Dr. Armstrong for a specimen of Russian turpentine oil, which distils chiefly between 168° and 180°. According to Hanbury and Flückiger, Russian turpentine is the produce of *Pinus sylvestris*. Now if this is the case, it is probably identical with Swedish turpentine oil, and this substance has quite recently been examined by A. Atterberg (*Deut. Chem. Ges. Ber.*, x., 1202). According to this chemist there are two terpenes in this turpentine, one boiling at 156·5° to 157·5°, and dextro-rotatory, but to a greater degree than Berthelot's Australene. The other terpene, which Atterberg calls sylvestrene, boils at 173°—175°, and does not agree with any already known terpene. Its specific rotatory power is +19·5°. I am sorry to say I have not yet prepared the nitroso-compounds from my Russian turpentine, so that I cannot say in what way the terpenes contained in it are related to others that I have examined.

Juniper Oil.—English oil of juniper (*Juniperus communis*) gave about one-third of its bulk below 160°. This liquid is almost inactive upon the polarized ray. 100 mm. gave a rotation of about 1° to the left. The nitroso-compound crystallizes in precisely the same manner as the corresponding compound from French turpentine, and in all other respects agrees with it completely. The other constituents of oil of juniper seem to be similar to those of turpentine oil, that is to say, they consist chiefly of hydrocarbons which are polymeric with the terpene and boil at 180° and upwards.

Sage Oil.—Mr. M. M. Pattison Muir placed at my disposal small quantities of two liquids obtained by fractional distillation from this oil. As he will himself give an account of this essential oil it is only necessary to mention here that one of these liquids has the same boiling point as terebenthene and very nearly the same optical characters. It also yields a nitroso-derivative, $C_{10}H_{15}NO$, which is identical with that obtained from French turpentine oil.

These terpenes from turpentine, juniper and sage oils, I regard as allotropic modifications of the same substance, since they agree in all respects except in the optical properties of the liquid hydrocarbon, and in the slight peculiarity of the crystals of the nitroso-derivative.

Oil of Savin—Juniperus Sabina.—The English oil was used, and the sample operated upon was believed to be perfectly genuine. According to the books, including 'Pharmacographia,' this oil is represented as having the same composition as oil of turpentine. Considering that savin is a coniferous plant, closely allied with the juniper, and most of the coniferæ yield volatile oils of the same general character, it is not unnatural to expect that this would be the case. So far as my experiments at present go, this is, however, a mistake. It certainly does not contain a terpene of the same formula as the turpentine terpenes. The sample which I have examined had the well-known repulsive odour of the plant and a yellowish green colour. Its specific gravity was ·9159. A column of the liquid, 100 mm. long, gave a rotation of +55°. Hanbury found 50 mm. rotate to the extent of +27°, an observation which is, practically speaking, the same as mine. By repeated fractional distillation a small quantity, not more than about 5 per cent. of the whole, was obtained, which boiled at 159°—160°. This had a dextrorotatory power, 100 mm. deviating the polarized ray = 46° 18′. This fraction, however, is not a hydrocarbon at all.

The first indication that it was not a terpene was the impossibility of obtaining from it a crystallized nitroso-compound by the usual process. When analysed by combustion with oxide of copper, supplemented by a stream of oxygen, ·3975 gram gave 1·1415 gram of CO_2 and ·388 gram of H_2O. These results calculated into percentages of carbon and hydrogen give the following numbers from which it will be seen that the liquid contains oxygen and is isomeric with ordinary camphor.

	Exp.	Calc. for $C_{10}H_{16}O$.
C_{10}	78·56	78·94
H_{16}	10·84	10·53
O	—.—	10·53

This liquid possesses an odour which is much less disagreeable than that of the original oil though to a certain extent reminding of it.

The greater part of the savin oil consists of liquids which boil at temperatures above 200°. They are probably hydrocarbons that are very easily polymerized by heat, for a portion that has once been distilled over cannot be redistilled without leaving a very considerable residue of yellow colour and high boiling point, and which on cooling becomes so viscid as to be semisolid. The examination of these higher fractions is not yet completed. It may, however, be said that savin oil is certainly not a true turpentine, for it does not contain a terpene.

Lavender.—English oil of lavender when submitted to distillation began to boil at 135° to 140°, but the ebullition was probably chiefly due to the escape of a little vapour of water, which came over first. The temperature rapidly mounted to 190° and between 190° and 195°, about one third of the oil passed over. The residue in the flask was rather darker in colour than the original oil. A portion of the first distillate dried by calcium chloride gave no crystalline nitroso-compound by the action of nitrosyl chloride, neither did it answer to this reaction after it had been carefully fractioned and treated with sodium. A small quantity of liquid thus prepared boiled at 171°—172°. Lavender oil seems to be a mixture of liquid camphors. Mr. Shenstone has under-

* All determinations of rotatory power made in the course of this work were performed with a Wild's polaristrobometer, using monochromatic light from a Bunsen flame, coloured by common salt and borax.

taken its further examination, and I, therefore, leave the matter in his hands.

Oil of Caraway.—Two and quarter pounds of English oil of caraway submitted to distillation gave about seven fluid ounces of a terpene boiling below 178°, and of which 100 mm. rotate the polarized ray 11° to the right. The residue contained a further quantity of the hydrocarbon, but it consists chiefly of carvol ($C_{10}H_{14}O$ – B.P. 225°), a compound which is also dextrogyrate in its action upon polarized light. 25 mm. give +15·6°. It is characterized by forming a peculiar crystallizable compound with sulphuretted hydrogen $(C_{10}H_{14}O)_2SH_2$.

Carvol is converted into an optically inactive isomeride, carvacrol, by treatment with phosphoric acid.

As to the terpene contained in caraway oil, it gave me a nitroso-compound, which is identical in melting point, solubility and crystalline form with that obtained from the terpenes of the sweet orange and other plants of the orange tribe.

Oil of Sweet Orange Peel. Essence de Portugal.

This oil, like most other essential oils, varies in composition. This is especially true of those which, like lemon, orange, and bergamot, are obtained by expression or by the sponge process.

Thus, with reference to oil of sweet orange peel, Wright ('Year-Book of Pharmacy,' 1871) states that he obtained from this oil no less than 97·2 per cent. of hydrocarbon boiling below 179° and 2·8 per cent. of yellow resinous substance not volatile without decomposition. The material used in my experiments was the contents of an original tin of Ess. Portugal, obtained from Messrs. Piesse and Lubin, and when submitted to distillation it yielded about three-fifths of its bulk at 174°—175°. The residue boils at a much higher temperature. It is greenish-yellow, very fragrant, smelling much more strongly of the fruit than the distilled portion. After standing some weeks it began to deposit a colourless crystalline substance, and this after some months has increased considerably in quantity. A similar deposit is obtained both from bergamot and lemon oils, and all three probably consist of the substance which has been called "bergaptene," and which is perhaps identical with hesperidine. This is a question which I propose to investigate as soon as time will permit. The terpene of the orange oil is a liquid which has an odour by no means so powerful as that of the original oil. It boils at 174°—175° and 100 mm. rotate a polarized ray 85·9° to the right. It yields by appropriate treatment a nitroso-compound which melts at 71° and crystallizes very beautifully in large flat prisms. The alcoholic solution of this compound is lævorotatory.

Oil of Bergamot.—The best commercial oil of bergamot was submitted to distillation. About three-fifths, containing a little water and acetic acid, came over below 190°. This gave about one-fourth of its bulk below 180°, and this, after treatment with sodium for some hours, came over almost entirely below 176°, so that the oil readily yielded 15 per cent. of its bulk of terpene. Probably more might have been obtained. 100 mm. of this hydrocarbon rotate the polarized ray 75·6° to the right. This hydrocarbon gives the same nitroso-compound as hesperidene, the terpene from sweet orange. They are, therefore, chemically identical. They are also very near together in regard to physical properties. With boiling point 174°—175° and optical characters not greatly different, I think it probable that if completely purified they would be found to consist of the same substance.

The higher boiling portions of the bergamot oil are green, and consist of oxidized compounds which have not yet been properly examined. After standing some time a considerable quantity of colourless crystalline matter (bergaptene) is deposited.

Oil of Lemon.—I have reserved to the last the description of lemon oil, because the investigation of the hydrocarbons it contains has been somewhat troublesome. It yields by distillation a large quantity of a colourless liquid boiling between 173° and 176°, and 100 mm. of which were found to rotate the polarized ray 61·5° to the right. When treated with nitrosyl chloride it yields only a very small quantity of a nitroso-chloride which, however, contains 17·13 per cent. of chlorine, and therefore has the general formula, $C_{10}H_{16}NOCl$. This precipitate was, however, found to be a mixture of two substances, for when heated as described at the beginning of the paper, it gives two nitroso-substitution compounds: one recognizable by its crystalline form as nitroso-terebenthene, the other *probably* identical with nitroso-hesperidene.

Further, when some of the hydrocarbon was mixed with nitric acid and alcohol according to the process of Wiggers, it gave, on standing, crystals of a terpin hydrate in quantity very much smaller than was obtained from a similar quantity of turpentine oil. But though the quantity of crystals was very much smaller than is given by either right or left-handed turpentine oil, their form is identical with that of ordinary terpin hydrate, and quite undistinguishable from it. This was shown by actual measurement of the crystals, which, after recrystallization from spirit, are large and well formed.

Again, Dr. Gladstone, who examined in 1864 a perfectly genuine lemon oil gave +67·7° as the rotation of 100 mm. of the hydrocarbon. I only found +61·5°.

These considerations lead to the conclusion that the sample I had to examine contained a quantity of a hydrocarbon which is lævogyre and yields the same chemical derivatives as terebenthene. Since oil of lemon is so well known to be commonly adulterated, I think it by no means improbable that French turpentine, which is lævogyrate, may really have been added to this sample. The admixture of 8 or 10 per cent. of ordinary French turpentine oil would be sufficient to reduce the rotatory power to the extent mentioned. But notwithstanding the undoubted existence of this hydrocarbon in the sample examined, it is by no means proved that its presence is adventitious. It may be a normal constituent of the oil. Further inquiries only can settle this question.

But there are other facts to be accounted for. Some of the liquid distilled from the oil of lemon was oxidized by boiling with acidified bichromate solution. It gave a considerable quantity of paratoluic and terephthalic acids. This could not have been entirely due to the presence of a turpentine oil, for the turpentines give by oxidation mere traces of these acids. Moreover, when the terpin hydrate crystals, referred to above as having been obtained from the oil, were oxidized in the same manner, they gave a very minute quantity of the same acids. The distilled lemon oil, therefore, contains something else which, by oxidation, yields terephthalic acid. The hydrocarbons of the orange group do not furnish this compound. I can, therefore, only suppose that this other constituent is cymene, $C_{10}H_{14}$, which boils at 176°, that is at nearly the same temperature as the lemon hydrocarbon. Its presence would not be discernible by the odour which resembles to some extent that of lemon, and would account for the difficulty experienced in preparing the nitroso-chloride of the terpene. I have made some attempt to isolate the cymene which I suppose may be present in the following way. The distilled oil (173°—176°) was boiled for about ten days in a flask with an upright condenser, in the hope of polymerizing the terpenes. The liquid then distilled off between the same limits of temperature left a considerable quantity of liquid of higher boiling point, slightly yellow colour and strong lemon odour. The distillate, however, was not much changed in optical rotatory power. It was then sealed in tubes and heated to about 240° for about twelve hours. On distilling off again at about 176°, a further residue of high boiling polymerized hydrocarbon was left, but the distillate still rotates +55° 9′ for 100 mm.

There are probably several varieties of cymene, of which one is, I believe, dextrogyrate, but at the most to the extent of 12° or 13° for 100 mm.*

A specimen prepared by myself from turpentine by the action of sulphuric acid was found to be quite inactive, and another separated from oil of cummin, and kindly lent to me by Dr. C. R. A. Wright, is also destitute of rotatory power. I am, therefore, still in doubt as to whether cymene is a natural constituent of oil of lemon or not.

General Observations.

Of the various constituents of volatile oils, the terpenes ($C_{10}H_{16}$) which are present in so many of them, contribute less than any other to the peculiar odour of the oil. The natural terpenes are colourless limpid liquids which vary in specific gravity from about ·84 to about ·86. They are divisible into two groups as follows:—

1. Turpentine Group.
   Boiling point 156° to 160°.
   Melting point of nitroso-derivatives 129°.
   Form solid crystalline hydrated terpin $C_{10}H_{20}O_2 \cdot H_2O$

2. Orange Group.
   Boiling point 174° to 176°.
   Melting point of nitroso-derivative 71°.
   Form (by Wiggers' process) no solid crystalline terpin hydrate.

The liquids included in each group are allotropic modifications of the same hydrocarbon distinguished one from another by their various rotatory action on the polarized ray. It will, however, be found, I believe, that the terpenes from several different plants will on further examination be conclusively proved to be really identical and not simply isomeric. This, I believe, to be the case with the terpenes from French turpentine and sage, also with the terpenes from orange peel, bergamot and lemon. The differences of odour which they usually exhibit are undoubtedly due to the presence of small quantities of the heavier constituents of the oil, which it is almost impossible to separate completely by simple distillation.

P.S.—I am aware that it is sometimes stated that oil of lemon in course of time is transformed into turpentine, and I suppose there can be no doubt that old samples gradually acquire a terebinthinate flavour and odour. I should be glad if members of the Conference would communicate details regarding any instance of this supposed conversion that may have come under their own personal observation. I should also be grateful for specimens if they can be accompanied by a reliable statement of the history of each sample.

Mr. Kingzett said he was glad to find that Dr. Tilden's examination of various essential oils had yielded results comparable with, and confirmative of, his own investigations referred to by Dr. Tilden. Both methods served to classify the numerous hydrocarbons, generally termed terpenes, into groups of distinctive constitution. He might remark, *en passant*, that in an early paper, he (Mr. Kingzett) had demonstrated the existence of a terpene of the formula $C_{10}H_{16}$ in the oils of caraway, bergamot, lemon, etc. From his researches, as also those of Dr. Wright, it followed that all terpenes represented by the formula $C_{10}H_{16}$ yielded cymene $C_{10}H_{14}$ by suitable treatment, and it further appeared that cymene from all sources was identical; he failed to perceive the grounds upon which Dr. Tilden believed in the existence of more than one cymene.

Dr. Wright asked if there was any distinct evidence offered by Dr. Tilden as to the dissimilarity of the various cymenes obtained. Some few weeks ago, Dr. Tilden applied to him for samples of cymene for the purpose of ascertaining whether they possessed dissimilar rotating power on polarized light, but he had not heard whether he had found any difference in that respect. As regards other physical properties, specific gravity, refractive power, etc., the cymenes from eighteen or twenty essential oils were prepared by himself and his coadjutors; but no difference whatever could be discovered in any particular. As far as he remembered, the rotary power had not been examined by Dr. Gladstone, and he should like to know if any other addition to their knowledge on that particular had been made.

Professor Attfield, in reply, said Dr. Tilden did not seem to have examined the cymenes alluded to by Dr. Wright.

Mr. Umney thought no fixed rule could be laid down as to the rotating power of the essential oil of caraway of trade; for instance, sometimes the whole plant was put into the still, sometimes distillers used Dutch caraways and sometimes Mogador caraways, and it could not be, supposed that the rotating power of the oils derived from such different materials could be identically the same.

Mr. Schacht said he thought that the physical properties, of which Dr. Tilden had taken cognizance referred to the hydrocarbons distilled from the oils, not to those of the essential oils themselves. In some of these he believed there were great differences in the rotating power, some turning one way and some the other.

Professor Attfield said this matter was not actually mentioned in the paper, but Mr. Schacht was quite right in supposing that he had experimented on the hydrocarbons obtained from the fractional distillation of these oils.

Mr. Groves observed that it would be very useful if Dr. Tilden or any one else who studied this matter could tell them how to prevent that disagreeable change of flavour which took place in oil of lemons left for a time in contact with air.

Dr. Wright said there was a practical way of preventing this change in flavour in some essential oils which was adopted by perfumers, and consisted in keeping the oil in a tightly stoppered bottle and filling the bottle up with water whenever the stopper was taken out. When prevented in this way from access to the atmospheric air the oil retained its flavour much longer than in a half empty bottle.

Mr. Schacht said it was rather curious that while Dr. Tilden considered the odorous principles of these oils to be due to the oxygenated body associated with the hydrocarbons, this beautiful smell of the freshly prepared essence should be spoiled by further oxidation.

Mr. Atkins said he was struck some time ago with the tendency in certain essential oils to show a terebinthine result, but he found by comparative experiments that if the stock were kept in a cellar away from light and heat this process of decomposition was almost entirely prevented. It was probable also that the action of gas in the shop had a deleterious effect on these bodies.

A vote of thanks was passed to Dr. Tilden for his paper.

The next paper read was—

On Essential Oil of Sage. Part II.

BY M. M. PATTISON MUIR, F.R.S.E.,
Assistant Lecturer on Chemistry,
AND S. SUGIURA,
Chemical Student in The Owens College, Manchester.

1. In a paper communicated to the Conference at the Glasgow meeting, one of us gave an account of preliminary experiments upon the oil obtained by distilling sage with water. We have continued these experiments, and beg now to lay the results before the Conference.

2. The oil was separated into four main constituents; one of these boiled between 156° and 158°, and another between 166° and 168°. Reasons were given for believing that each of these liquids consisted of a terpene of the formula $C_{10}H_{16}$. A third portion boiled from 198° to

* Guareschi, *Gazetta Chimica Italiana*, iii., 545—550.

203°, and was regarded as the oxidized liquid constituent of the oil. The higher fractions deposited solid matter when cooled; this solid matter possessed some of the properties of ordinary camphor.*

3. The liquid boiling from 156° to 158° has not been subjected to analysis, but the results of a determination of its vapour density, and a consideration of its general properties leave no doubt that it really consists of a terpene, $C_{10}H_{16}$.

The vapour density was determined by a slight modification of Hofmann's method which we have described in a paper communicated to the Chemical Society.† The method is easily and quickly carried out, and yields results sufficiently accurate for general purposes.

The following numbers were obtained:—

Height of barometer = 755 mm.
Temp. of air = 17°.
Height of Mercury column in barometer tube = 561 mm.
Temp. of vapour = 185°
Tension of Mercury vapour at 185° = 12 mm.
Weight of Mercury required to occupy space formerly occupied by vapour = 1018·4 grams.
Temp. of Mercury = 20°.
Hence volume of vapour = 73·28 c.c.
Weight of liquid = 0·0682 gram.
Weight of volume of Hydrogen equal to volume of vapour under same conditions of temperature and pressure = 0·00101 gram.

$$\text{Hence } \frac{M}{2} = \frac{\cdot 0682}{\cdot 00101} = 67\cdot 46. \quad \text{Calculated} = 68.$$

4. Dr. Tilden has kindly examined the action of nitrosyl chloride upon this terpene. The action is in every respect similar to that observed between nitrosyl chloride and the terpene from French turpentine oil.‡ The nitroso-derivative, $C_{10}H_{15}NO$, forms monoclinic prisms of the same form as those described by Story-Maskelyne in an appendix to the paper of Tilden referred to. "The plane ends are replaced by a sort of pyramid which makes them look more pointed. In general appearence the crystals are not unlike dog-tooth spar."§

The melting point of the nitroso-derivative is 129°, the alcoholic solution of this substance is optically inactive.

A column of the terpene 100 mm. in length gave a rotation of 32·2° to the left for the soda flame.‖

5. Dr. Gladstone has been so very good as to make determinations of the refractive indices of this and of the higher boiling terpene. His results for the terpene boiling at 157° are as follows:—

$\mu A = 1\cdot 4611$. $\mu D = 1\cdot 4667$. $\mu H = 1\cdot 4855$ at 24·5° C.

Hence specific refractive energy = 0·0534, and
Refraction equivalent = 72·6.

6. These determinations of optical properties agree very closely with those which have been made for the terpene from French turpentine oil (terebenthene). Moreover, the specific gravity of the sage terpene is practically identical with that of terebenthene. Riban¶ gives the formula 0·8767—0·0008377*t*, as expressing the specific gravity of terebenthene at any temperature, *t*, below 80°. At 15° the specific gravity would be 0·8643. The specific gravity of the sage oil terpene is 0·8635 at 15°. The boiling points of the two terpenes are also almost identical—probably really identical. The small quantity of cymene which is almost certainly contained in this terpene (see par. 11) would tend slightly to decrease the specific gravity, and slightly to increase the boiling point of the liquid.

¶ *Compt. Rend.*, lxxviii., 288.

In the following table we have noted some of the physical properties of terebenthene and of the terpene from sage oil boiling at 157°.

B.P.	Sage Terpene. 157°.	Terebenthene. 156°25.
Sp. grav. at 15°	0·8635	0·8643*
Refractive indices at 24°:		
for A.	1·4611	1·4596†
„ D.	1·4667	1·4653†
„ H.	1·4855	1·4845†
Refractive energy	0·0534	0·0532†
Refraction equivalent	72·6	72·5†
Spec. rotatory power [α]	−37·3	−32·4‡ (for transition tint.)

7. The vapour density of the liquid boiling at 166° to 168° was determined.

Height of barometer = 758 mm.
Temperature of air = 18°.
Height of mercury column in barometer tube = 511 mm.
Temperature of vapour = 185°.
Tension of mercury vapour at 185° = 12 mm.
Weight of mercury required to occupy space formerly occupied by vapour = 874·7 grams.
Temperature of mercury = 20°
Hence, volume of vapour = 64·61 c.c.
Weight of liquid = 0·0804 gram.
Weight of volume of hydrogen equal to volume of vapour under same conditions of temperature and pressure = 0·001129 gram.

$$\text{Hence } \frac{M}{2} = \frac{\cdot 0804}{\cdot 001129} = 71\cdot 2. \quad \text{Calculated} = 68.$$

Two experiments, in addition to that the results of which are detailed, were carried out, but in each a small quantity of air found its way into the barometer tube; the results therefore were too low. In every case a small quantity of brown resinous matter remained in the little bottle unvolatilized; hence, it appears, either that the terpene contained a small quantity of a substance boiling very considerably above 185°, or that the action of such an amount of heat as is represented by this temperature exerted a decomposing (polymerizing?) action upon the terpene. The presence of 4 per cent. of a terpene of the formula $C_{15}H_{24}$,—supposing this to remain completely unvolatilized,—would bring the observed vapour density to 68·3, which is almost identical with the calculated number.

8. We are again indebted to the kindness of Dr. Tilden for experiments upon the action of nitrosyl chloride upon this terpene. Dr. Tilden says, "I could get no solid products from this liquid. The action of the gas caused effervescence immediately, and this is always a bad sign. I suspect this to be a mixture containing a hydrocarbon of the $C_{15}H_{24}$ type. I have never got any solid compounds from these."

A column of the terpene 100 mm. in length was found by Dr. Tilden to rotate the plane of polarization 17·7° to the left.

9. Dr. Gladstone has kindly made determinations of the refractive indices of this terpene for the lines A, D, and H.

$\mu A = 1\cdot 4588$. $\mu D = 1\cdot 4646$. $\mu H = 1\cdot 4830$.

Hence, specific refractive energy = 0·0522, and refraction equivalent = 71.

10. The specific gravity of this terpene was 0·8866 at 15°.§

A mixture of 96 per cent of the terpene boiling at 157° with 4 per cent of a terpene of the type $C_{15}H_{24}$—assuming the latter to have a specific gravity of 0·915, which is

* Riban, *Compt. Rend.*, lxxviii.; 288.
† Gladstone, *Phil. Trans.* for 1863.
‡ Berthelot, *Ann. Chem. Pharm.*, lxxxviii., 343.
§ 'Year-Book and Tr. Brit. Pharm. Conf.,' 1876, p. 566.

about the mean of the densities of terpenes of this formula as determined by Gladstone, and assuming that no condensation of volume occurred through mixing the two liquids—would have a specific gravity of about 0·865 at 15°. The assumption that the liquid boiling at 167° is really such a mixture is not therefore borne out by the actual specific gravity of the liquid. We are rather inclined to believe that sage oil contains two terpenes of the formula $C_{10}H_{16}$, differing in physical properties, and perhaps a small quantity of a terpene of a higher molecular weight.

11. It has been already shown by one of us that the lower terpene of sage oil, boiling at 157°, very probably contains cymene. The experiment described in Part I. of these investigations * was repeated, and with a result identical with that formerly obtained. The liquid, which gave all the qualitative reactions of cymene, was analysed. It boiled at 176°–178°.

0·1885 gram gave 0·6125 gram CO_2 and 0·181 gram H_2O.

	Calculated for $C_{10}H_{14}$.	Found.
Carbon . . .	89·55	88·61
Hydrogen . .	10·45	10·72

A small quantity of this cymene was oxidized by chromic liquor; it yielded terephthalic and acetic acids. The residue, after polymerizing the terpene with sulphuric acid, and distilling in steam, was boiled for some days with chromic liquor, no solid oxidation product was obtained.

Wright† has shown that the terpene from orange-peel oil, boiling at 178°, yields no cymene when treated with strong sulphuric acid and distilled in steam; nor does it yield a trace of terephthalic acid on oxidation. The same chemist‡ has also shown that oil of turpentine yields cymene by treatment with sulphuric acid, etc. According to some chemists, terephthalic acid is one of the products of the oxidation of oil of turpentine; according to others this acid is not produced by oxidizing that oil. The fact that when cymene had been removed from the liquid portion of sage oil, boiling at 157°, the residue yielded no terephthalic acid on oxidation, but that the original liquid, before treatment with sulphuric acid, etc., did yield this acid,§ seems to point to the cymene which was present as the source whence the terephthalic acid was derived.

The varying results obtained in the oxidation of oil of turpentine are probably due to the varying composition of the specimens employed. When free from cymene this oil appears to yield no trace of terephthalic acid on oxidation.||

12. The liquid boiling at 166°–168° was treated with strong sulphuric acid, etc., as described in a previous paper. Cymene was again obtained. The polymerized residue yielded no solid oxidation product on treatment with chromic liquor.

13. Each terpene was treated with bromine in the manner previously described. A small quantity of a liquid, boiling from 174° to 177°, and yielding terephthalic acid on oxidation, was, in each instance, obtained.

14. The physical as also the chemical properties of the terpene boiling at 157° leave little doubt of the identity of this compound with terebenthene, the terpene obtained from French oil of turpentine. The terpene boiling at 167°–168° we believe to contain small quantities of a body of higher boiling point. We have already given reasons for this belief.

In a letter to one of us, Dr. Gladstone says, "The lighter terpene is practically identical with that from turpentine in refraction and dispersion, as well as in boiling point and specific gravity. The heavier one with the higher boiling point has a lower refractive energy than any terpene I have examined. Is it pure $C_{10}H_{16}$?"

Investigations carried out on larger quantities of oil can alone enable us to make positive statements regarding the composition of the higher terpene.

15. When that portion of the original oil which boiled above 190° was submitted to fractionation, a considerable proportion of it was found to boil between 198° and 203°.* For this liquid the name of salviol was proposed. We have analysed this liquid, and have also made a determination of its vapour density.

(1) 0·1664 gram gave 0·48 gram CO_2 and 0·162 gram H_2O.
(2) 0·130 „ „ 0·374 „ CO_2 „ 0·124 „ H_2O.

	Calculated for $C_{10}H_{16}O$.	Found. I.	II.	Mean.
Carbon . . .	78·94	78·69	78·46	78·57
Hydrogen . .	10·53	10·81	10·59	10·70
Oxygen . . .	10·53 (by diff.)	10·50	10·95	10·73

Vapour density determination.

Height of Barometer = 755 mm.
Temperature of air = 17°.
Height of mercury column in barometer tube = 492 mm.
Temperature of vapour = 185°.
Tension of mercury vapour at 185° = 12 mm.
Weight of mercury required to occupy space formerly occupied by vapour = 788·1 grams.
Temperature of mercury = 17°.
Hence, volume of vapour = 58·16 c.c.
Weight of liquid = 0·0786 gram.
Weight of volume of hydrogen equal to volume of vapour under same conditions of temperature and pressure = 0·00107 gram.

$$\text{Hence } \frac{M}{2} = \frac{\cdot 0786}{\cdot 00107} = 73{\cdot}46. \quad \text{Calculated} = 76.$$

A small quantity of resinous matter remained in the little bottle at the conclusion of the experiment. The weight of this non-volatile residue was found to be 0·0014 gram. The number given above as representing the weight of liquid taken is the difference between the actual amount weighed out and the weight of the non-volatile residue.

It would appear that the salviol examined was not perfectly pure, or that this substance is decomposed in someway at the temperature to which it was raised, with production of resinous matter. There can, however, be little doubt that the formula $C_{10}H_{16}O$ really represents, not only the quantitative composition, but also the molecular weight of salviol.

From the smallness of the quantity of salviol at our disposal we have not been able to carry out further experiments upon this substance.

16. The solid which separated from the higher boiling portions of sage oil has been examined by us. After several sublimations it melted at 184° to 186°. In Part I. the number 187° was given—this number we believe to be rather too high. The boiling point of sage camphor is 210°. We have attempted to determine the specific gravity of sage camphor; but as the result cannot as yet be looked upon as trustworthy, we do not give it, contenting ourselves with stating that the specific gravity appears to be greater than that of common camphor, and less than that of borneol. Sage camphor crystallizes in monoclinic prisms, ∞ P. m.P: the crystals are generally rounded off on the prism edges. An alcoholic solution of sage camphor is without action upon the polarized ray.

§ 'Year-Book, etc.,' 1876, p. 565.
|| W. Carleton Williams (*Ber. deut. Chem. Ges.*, v., 1024).

* 'Year-Book, etc.,' 1876, p. 563.

(1) 0·112 gram gave 0·324 gram CO_2 and 0·104 gram H_2O.
(2) 0·129 „ „ 0·375 „ CO_2 „ 0·124 „ H_2O.

	Calculated for $C_{10}H_{16}O$	Found. I.	II.	Mean.
Carbon	78·94	78·83	78·86	78·84
Hydrogen	10·53	10·31	10·67	10·49
Oxygen	10·53 (by diff.)	10·86	10·47	10.67

We have not made a vapour density determination, inasmuch as the results of analysis leave little doubt as to the correctness of the formula $C_{10}H_{16}O$, and the boiling point prevents the supposition that the molecular weight is represented by a multiple of this formula.

17. A quantity of sage camphor was dissolved in chloroform, and an equal quantity of bromine was gradually added, the vessel being kept well cooled. Reddish coloured crystals were almost immediately deposited. The whole was allowed to stand over sulphuric acid in vacuo, for 12 hours. When the vessel was brought into the ordinary atmosphere the crystals very quickly melted, and hydrobromic acid was evolved in considerable quantities. On standing for several days over sulphuric acid in vacuo crystals were again formed.

On distilling the red liquid very large quantities of hydrobromic acid were evolved, a camphor-like solid was deposited, and a considerable portion of the liquid was resinized. The solid camphor-like substance, after several sublimations, melted at 160° to 163°. A similar substance having the same melting point was prepared by treating sage camphor directly with bromine, washing with caustic soda, and subliming. In Part I, the melting point of the crystals obtained by treating a solution of sage camphor in chloroform with bromine is stated to be 132° to 133°. We believe that these crystals were most probably impure, containing either uncombined bromine or, it may be, portions of an addition product of bromine and camphor. We find that the melting point of the crystals, produced as described above, increases after each sublimation until the maximum 160° to 163° is attained. During the earlier sublimations hydrobromic acid is evolved.

18. When sage camphor was distilled in contact with phosphorus pentasulphide the greater part of the material underwent resination, but a small quantity of liquid was obtained which after washing with soda, drying, and fractionating, gave the reactions of cymene: on oxidation with chromic liquor terephthalic acid was produced.

19. A few grams of sage camphor were dissolved in about ten parts of concentrated nitric acid, the liquid was boiled for thirty hours or so, the acid was distilled off, the residual semi-resinous matter was dissolved in hot water, and the solution was boiled down and set aside. A small quantity of a colourless indistinctly crystalline body was obtained. This substance melted at 172° to 176°. The quantity at our disposal was too small and not sufficiently pure to allow of an accurate analysis being made. The numbers which we did obtain agreed as closely as could be expected with those required by the formula for camphoric acid, $C_{10}H_{16}O_4$.

20. Sage camphor is almost certainly an isomer of common camphor: its melting point, boiling point and other physical properties, as also the difference of its behaviour towards bromine, prevent us, however, from believing that it is identical with common camphor.

21. In the first part of these investigations the action of hydrochloric acid gas upon sage oil was said to result in the formation of one, or perhaps two, chlorhydrates stable at 200° or so. On making a determination of the amount of chlorine in the liquid boiling from 195° to 200°, 1·85 per cent. only was found to be present. Determinations of carbon and hydrogen gave no constant results, thus we obtained 70·53, 67·34, and 73·2 per cent. of carbon, and from 9 to 10·5 per cent. of hydrogen. These results show that the liquid under examination was not really a chlorhydrate at all, but was evidently a mixed substance. If a chlorhydrate be in the first instance produced by the action of hydrochloric acid upon sage oil, it is evidently very readily decomposed by washing with water. The statement in par. 7 of Part I,* that the chlorhydrate of sage terpene is with great difficulty decomposed by water is therefore erroneous.

22. When sage oil is distilled a very large quantity of resinous and semi-resinous matter is produced. That portion which remained after the thermometer had risen to 240° in the first distillation of the oil was a thick, viscid, very dark coloured liquid. In the hope of procuring a further quantity of salviol we subjected this liquid to distillation in a current of superheated steam. About ⅛th of the total liquid was obtained in the distillate, the remainder having become almost solid. The distillate after drying and fractionation was found to consist almost completely of camphor, held in solution by terpene. No salviol was obtained. We did not consider that an analysis of the residual resin would yield any trustworthy results.

23. Our investigations are not sufficiently complete to allow us to enter into theoretical discussions concerning the structural formulæ of camphor and the substances related to it, nor can we venture to make any generalization concerning the members of the terpene group. Both of these subjects are however of so much interest, that we propose, if the Conference will make us a further grant, to endeavour to prepare much larger quantities of the terpenes, the salviol, and the camphor from sage oil, and to determine the physical and chemical properties of these bodies, combining this investigation with a research into the constitution of the camphors in general.

We take this opportunity of again returning our best thanks to Drs. Gladstone and Tilden for their kindness in examining the optical and other properties of the two sage terpenes.

Professor ATTFIELD said this paper was very interesting. Of course it was rather chemical than pharmaceutical, and seeing that the Chemical and Royal Societies had now followed the plan which the British Association had initiated and the Conference practised of making grants in aid of such researches, he thought the Conference might now discontinue, at any rate for the present, further grants for such purely chemical investigations. The sum annually at the disposal of the Conference was not large, still it was formed by the contributions of pharmacists, hence workers at pharmaceutical research had first claim upon it. He feared, however, that such claimants would be only too few.

The PRESIDENT remarked that this was hardly a paper which would admit of much discussion, but he was sure they would agree in thanking the authors for it.

(*To be continued.*)

Parliamentary and Law Proceedings.

THE SALE OF CASTOR OIL PILLS.

At the Cannock Petty Sessions, on Monday last, before B. Gilpin, Esq., and Colonel Harrison, George Ridding, grocer, of Walsall Road, Cannock, was charged by Mr. J. G. Horder, Inspector under the Food and Drugs Act, for the southern division of the county, with having sold a certain drug, to wit, "castor oil" pills, the same not being of the nature, substance, and quality demanded by the purchaser; also with selling a compound drug not composed of the ingredients in accordance with the demand of the purchaser. Mr. Hutchinson (from the Clerk of the Peace's office, Stafford) prosecuted, and Mr. James E. Underhill represented the defendant, instructed by Messrs. Reade Brothers, wholesale drug-

* 'Year-Book' etc., 1876, p. 562.

gists, of Wolverhampton, the original manufacturers of the pills in question.

George Toy, assistant to Mr. Horder, proved purchasing the pills. The boxes were labelled, "Castor Oil Pills—one or two to be taken occasionally, and at bedtime," and Mr. Horder said he received a sealed packet of the pills which he delivered to the public analyst for examination.

Mr. E. W. T. Jones, F.C.S., of Wolverhampton, and public analyst for the southern division of the county, said he had analysed the sample of pills delivered to him by Mr. Horder, on the 25th of May last. The six pills sent weighed 18·8 grains, which was equal to about three grains per pill. He examined four of the pills for mercury, with the result that he detected the presence of about 9·98 per cent. of calomel in the whole mass. Besides this, there was aloes, jalap, rhubarb, ginger, and a trace of colocynth, with one or two other substances which he was unable to identify in the sample. He did not discover the slightest trace of castor oil in the pills. He considered that the compound would be injurious to health, as it contained calomel under the disguise of so innocent a name as "castor oil."—By Mr. Underhill: It was not possible to make castor oil pills, and it did not necessarily follow that persons would know this, and understand that the pill was another compound. It would not be possible to put more than a grain of castor oil in a pill, at which rate two hundred pills would be necessary for a dose. He knew that it was common to substitute compound pills, all over the country, and sell them as "castor oil pills." He could not say that the castor oil pill had been understood by the public for twenty-five years to be an aperient pill merely. He was certain that castor oil pills would not produce the same effect as castor oil itself; in fact, he should not take a "castor oil pill" to be an aperient at all. He knew that the "pill" in its present form cost the manufacturer a great deal more than if castor oil were used, and, therefore, it would be no saving to use the present ingredients. There was about the third of a grain of calomel in each pill, and an ordinary dose of calomel was generally more than this. He knew that the Sanitary Committee of the Wolverhampton Town Council had had these pills under their consideration, and had sent a caution to the chairman of the local pharmaceutical association respecting them. Since that time Messrs. Reade had issued small circulars to be given away with each box of pills, stating that the pills contained no castor oil, but were simply aperient.—Re-examined: There had been convictions for the sale of similar pills, where the contents of the pill were not so strong as in the present case.

Dr. Day, F.R.C.P., Stafford, said he had made a rough examination of the pill and found the substances in it mentioned by Mr. Jones. He thought that if ignorant persons bought these pills, under the impression that they contained castor oil, and knowing that castor oil was so innocent a laxative that it could be given to any sex at any age, the use of the pills as such would be very objectionable, because they contained calomel, aloes, and colocynth. Even admitting that there were persons and conditions in which these pills might be taken with impunity, and in some cases with advantage, still there were other persons and conditions where in his judgment, they would be very objectionable, and often injurious. Witness described different diseases and conditions of health in which the use of the pills would be inappropriate, under the impression that a simple laxative was being taken. To the ordinary average of cases the quantity of mercury contained in two of the pills would not be injurious, but there were also certain conditions in which it would produce salivation, and, if continued, even death. He had himself salivated a lady with half a grain of calomel. In his opinion he did not think it was the metallic mercury which salivated, but the chlorine or oxygen combined with the metal, and given up in a nascent form.—Cross-examined: He admitted that the cases he had mentioned would be exceptional ones. He was not aware that there was a difference of medical opinion on the action of calomel in kidney disease. He was unaware until he was consulted on the subject that there were any such things as "castor oil pills."

Mr. Underhill, in the course of his remarks for the defence, said the Act under which the offence was brought was useful in cases where articles were adulterated, and not of proper quality, but it did not apply in the present case. This was a "test" case, as the solicitor for the prosecution had stated. The Act stated, "Any person who shall sell to the prejudice of the purchaser, any article, food, or drug, which is not of the quality, substance, and nature demanded by the purchaser, is liable to a penalty not exceeding £20," but to which there were certain exceptions. He argued that the prosecution had shown no infringement of this clause. They had proved that "castor oil pills" had been sold for many years all over the country, and that it was physically impossible to admix any quantity of castor oil with the pills. So it was quite plain that it was impossible to comply in the latter respect. He contended that they had sold the article which they had contracted for. They did not sell the public what they did not demand, for the public asked for "Reade's Castor Oil Pills" and they obtained them. It was understood that the pills were an aperient medicine, and it was not necessary, because they were called by the name of "castor oil," that they should contain any of that substance. Again, it was only possible that they could believe the present pills injurious if they took for granted what Dr. Day had said, viz., that it might do some persons injury, if they thought they were taking castor oil and were not, but with the common average of people it would be beneficial. He should call a medical gentleman from Wolverhampton who would tell them on the contrary that the pills were not objectionable. He concluded by stating that the Act gave an exception in the case of "proprietary" or patent medicines. Now this was a "proprietary" medicine, as Mr. Reade would tell them. The component parts of the pills were from a private recipe which belonged to the firm, and the case therefore failed in this way. He called

Mr. T. Reade, manufacturing chemist, of Wolverhampton, who said he had been connected with the trade seventeen years. The pill sold as "castor-oil pills" were a proprietary medicine. He had never had any complaints as to the effect of the pills during the twenty-five years they had been manufactured.—Cross-examined: The same pills could be made by any person in the kingdom if the component parts were discovered. He was not aware that it was the universal custom to name proprietary medicines as Reade's, Cockle's, or Jones' pills.

Mr. James Mason, chemist, Stafford, said he had been in practice for forty years. Castor oil pills had been sold for about twenty years as an article of commerce. They did not contain castor oil, but were supposed to act in a similar manner.—Cross-examined: As a respectable tradesman he should not sell the pills labelled "castor oil" without informing the public that they were a substitute. He agreed with Dr. Day, that if taken habitually the pills might be injurious to some persons.

Mr. F. A. Manby, surgeon, Wolverhampton, was next called. He stated that the cases mentioned by Dr. Day were very exceptional ones. He considered the pills harmless in the great majority of cases, and of a mild character.—Cross-examined: He did not think, speaking morally, they should be labelled "castor oil pills."

The Bench, after some consideration, said, it had been decided to convict on the ground that the pills were not composed of ingredients in accordance with the purchaser's demand. Defendant would be fined £2 and costs—£14 9*s*. As regarded the proprietary character of the medicine, the bench had nothing to say.—*Wolverhampton Evening Express.*

INQUEST UPON A CHILD AT DEVONPORT.

On Wednesday, August 29th, an inquest was held in Devonport before the Borough Coroner, Mr. J. Vaughan, respecting the death of an infant, six months old, named Vogwell. The mother stated that as the child was suffering from diarrhœa she went without the child to Mr. Codd, a chemist, from whom she received on a first occasion some castor oil, and on the previous Tuesday week a mixture, a teaspoonful of which was to be given every four hours. The administration of the medicine was usually followed by sickness and sleep. On the following Saturday she went to Mr. Codd and told him the child had been very sick, and he then gave her a powder, telling her to give one half to the child at once and the other in six hours. The child vomited after taking the first half, and shortly afterwards the mother, thinking she saw signs of an approaching fit, called in Dr. Row. Dr. Row asked what she had been giving to the child, and upon her telling him, he asked for the remainder of the mixture and powder and took them away saying that he was going to Mr. Codd. Upon his return he prescribed for the child, but eventually it died on the Saturday.

Dr. F. Row then said: On Saturday last a little before midday I visited a child in Duke Street. The child appeared to be about six months old. It was lying in its mother's lap, and had the feeding bottle in its lips. Immediately afterwards it vomited a considerable quantity of milk, and I was told by the mother that this had occurred frequently during the last previous few hours. The surface of the child was very pale and cold, the eyes sunken and glazed, and the pupils of the eyes contracted. On trying to get the history of the case, I was told that the child had been dressed that morning, that it had had diarrhœa previously, and that it had taken two doses of medicine since the previous evening from a bottle that was shown to me. Up to this stage I had made no observation. I was also told that a portion of the powder had been given that morning. On looking at the mixture and smelling it I concluded that it contained opium. I looked at the portion of the powder, but formed no conclusion as to its composition. I concluded that the child was then under the influence of opium; and I might have said so, but I am not certain whether I did or not. In order to be quite sure what the contents of the mixtures were, I suggested seeing Mr. Codd, who I was told had given the medicines. I went to the shop of Mr. Codd with the nurse, who carried the medicines.

The Foreman: Did you give any opinion before going to Mr. Codd's of what was the matter with the child?—I have already said that I possibly stated that the child was suffering from opium.

Did you give any opinion of the disease the child was suffering from?—No.

Then you had no idea up to this time of what disease the child had?—I knew that it had been suffering from diarrhœa.

Dr. Row continued: I saw Mr. Codd behind the counter of his shop, and told him that Mrs. Vogwell's child was in a dangerous or dying state, and that I had been told that the medicines that the nurse had had been prescribed by him. Before we had entered, I casually saw Inspector Matters—who was within a few yards of Mr. Codd's side door—and I asked the nurse to call him. He came, and stood outside, while the nurse and I went into the shop. While we were in the shop I said to Mr. Codd, "I presume the medicine contains opium." He said "Yes, but not to any amount to do injury. I presume there could not originally have been more than ten minims in the bottle."

The Foreman: It is very important to know which word Mr. Codd used—minims or drops.

Dr. Row: He may have said drops; I give him the benefit of it. I asked him to seal the bottle; that was done, and it was immediately given into the hands of the police. I returned to see the child, went home directly, and gave medicine for it. From that time up to eleven at night I saw it five or six times. During that time the sickness ceased, and the child appeared to rally; but throughout the day the surface was cold as a stone. Besides the medicine I administered, I ordered the child to be enveloped in warm flannels, frequently repeated; and this was done carefully, I believe. The next morning I was told the child had died during the night.

The Foreman: Now I wish to ask you, Dr. Row, whether if the medicine had been supplied by a medical man, instead of a chemist, you would have sent for a policeman, and taken him and the medicine to the surgeon's residence, as you did to Mr. Codd's?

The Coroner: I don't think that that has anything to do with the matter.

Mr. Williams: I should like an opinion on the matter.

Dr. Row: I didn't send for a policeman; I saw Inspector Matters near the door of Mr. Codd's shop.

Mr. Williams: All very convenient, I dare say.

Dr. Row: Excuse me, Mr. Coroner, I must call that gentleman to order when he implies animus on my part in this matter. I totally, distinctly, and emphatically deny any animus or arrangement of any kind, and it is too bad to cast such an imputation on me.

Mr. Williams thought it would be better if Dr. Row answered the question.

Dr. Row: I have already said that I made no arrangement of any kind, and I will tell you now that if one of my most intimate friends, being a medical man, had been concerned, I should have had exactly the same feeling towards him as I had to Mr. Codd, and should have acted in the same way.

Mr. Williams: And should have taken the medicine to his house?

Dr. Row: Certainly, I should have done so.

Mr. Williams said he was satisfied with the answer.

The Coroner: You had no further object in calling the Inspector than to give him charge of the medicine if necessary?

Dr. Row: It did not even amount to that. My feeling, and the only feeling I had was that I desired some one to hear what took place in the shop. Afterwards I found it desirable to hand him the medicine.

A Juror: Is it right to administer opium to a child of that age?

Dr. Row: Well, it is, I believe, frequently done; but if you ask me to give an opinion about it, I may say that it is unsafe, and is generally regarded as an unwise proceeding with infants of a very tender age.

A Juror: It is done though, is it not?

Dr. Row: It is.

The Coroner: It is a fact, is it not, that a very small drop of opium on some constitutions will kill?

Dr. Row: It is so far regarded as a dangerous thing that at the examination of students for entry into the profession, a question is sometimes put,—"How much opium would you give a child six months old?" If the person said he would give any he would be at once plucked; the answer should be "none."

A Juror: What did you treat the child for when you gave the medicine?

Dr. Row: It was undoubtedly suffering from the effects of opium—I am certain of it.

A Juror: And you treated the child for that?

Dr. Row: Yes; it was certainly under the influence of opium.

The Coroner: You have made a *post mortem* examination of the body?

Dr. Row: In company with Mr. Cutliffe I have to-day examined the body of the child.

The Foreman to the Coroner: Did you authorize the *post mortem* examination?

The Coroner: I did.

The Foreman: And ordered Dr. Row to make it.

The Coroner: Yes, and I may explain that the rule is to order the medical man who treated the deceased to make the examination, if any be necessary, after death, and I think it is a very proper one.

Mr. Williams thought it might have been better if an independent surgeon had been called in.

The Coroner: Dr. Row wisely took care to be accompanied by another of the most respectable medical men in the town—Mr. Cutliffe, and you can have his evidence also if you please. I desire Dr. Row to be examined and I shall take his evidence. Besides, the jury can order another *post mortem* examination if they think it necessary.

Mr. Shillabeer (on the jury): It seems to me that that is very much like locking the stable door after the horse is gone.

Mr. Williams: I wish to point out that Dr. Row had been called in on the case only a few hours, and he takes the nurse and an inspector of police to Mr. Codd's house. I think a gentleman entirely independent of Dr. Row should have been engaged.

The Coroner: You can do so now if you think it necessary, and if there are any reasons for it; but under any circumstances I should desire Dr. Row to be present at the examination, for it would be due to him.

Mr. Williams: As Dr. Row appears to be the prosecutor—

Dr. Row: I protest against such a remark, sir.

The Coroner sharply to the Foreman: I beg, sir,—nay I insist, that you will not use such a word as that again, and that *you* will not show any animus or feeling in this matter, or take any side. We have no sides here; we have only to discharge a public duty.

Mr. Williams: I have not the slightest animus at all sir; I am only asking a question that, as the Foreman of this jury, I am entitled to do, and a question that I expect to be answered. I came here for the purpose of fully inquiring into a certain case brought before us, and inasmuch as Dr. Row has taken on himself, perhaps very properly—

The Coroner: Dr. Row was appointed to do what he has done; he has not taken anything on himself.

Mr. Williams: Dr. Row has stated that if the medicine had been supplied by a medical man he should have taken it to him as he did to Mr. Codd.

Dr. Row: Certainly.

Mr. Williams: Then would it not have been more satisfactory to have engaged a gentleman independent of Dr. Row?

The Coroner: The usual course has been followed, sir. We must go on with the evidence.

Mr. Williams: I hope you will not think there is any animus on my part; I only wish to see fair play.

The Coroner: Go on with the evidence.

Mr. Williams: I trust, sir, you will withdraw the remark you made just now.

The Coroner: Will you proceed, Dr. Row?

Dr. Row then proceeded: The body was that of a full-grown, well-nourished, fine child. There were no marks specially noticeable about the body, except those of decomposition. The organs were healthy with one exception. The stomach and intestines were quite empty, but in the middle part of the small intestines, extending over three or four feet of their length, portions of the gut were run into one another in the form of intussusception. Considerable portions were thus sheathed, or telescoped, into one another. I never met such a case before, nor ever heard of it in a child. It was most remarkable, and it is proof positive that it existed before the child's death and was the cause of the death; it was undoubtedly the natural result of disease.

A Juror: From sickness or vomiting?

The Doctor: There it is. It could not have been the result of any medicine rightly or wrongly given.

A Juror: Then was the sickness caused by this?

Dr. Row: Or was it caused by sickness? There is the difficulty I cannot decide. Doubtless sickness would have been one of the symptons of this state of things.

A Juror: What is the greatest amount of opium you give to a child six months old?

Dr. Row: I can only repeat what I have already said.

The Coroner: But you say that opium is still given to children?

Dr. Row: Always with more or less of danger. I could not have given a certificate of the death of the child without some inquiry.

The Coroner: Certainly not. It was impossible consistently with your duty; and the *post-mortem* examination has discovered a fact that could never have been known without it.

The Foreman: Do you think now that the state in which you found the intestines of the child originated from sickness?

Dr. Row: I cannot say how it originated. Constant purging, with vomiting, would be the most likely means of causing it; but whether it was due to one or the other I cannot tell.

Mr. Codd, who had been most ready to afford every information in the case was sworn, and said—The mixture that I prescribed for the deceased child consisted of 40 minims of tincture of catechu, 25 minims of tincture of cardamons, 10 minims of tincture of kino, 10 minims of essence of ginger, 10 minims of chloric ether, 6 of aromatic spirit of ammonia, 5 minims of tincture of opium, half an ounce of syrup, and chalk mixture to make $1\frac{1}{2}$ ounces—*i.e.*, 12 drachms or teaspoonsful, or doses.

The Coroner: On your oath, was there anything in that which you would not have given your child under similar circumstances?

Mr. Codd: Certainly not; and I may say that one of my own children at the age of two months has taken as much opium in one dose—and taken it under medical treatment, bear in mind—as is contained in the whole of that bottle of medicine. Further, she has taken it repeatedly.

The Coroner, to Dr. Row: Now having heard that prescription and what Mr. Codd has said, I put it to you whether you think there is anything really harmful in the mixture?

Dr. Row: I do not think I ought to be called upon to pronounce an opinion on such a point as that. The statement now made by Mr. Codd does not agree with what he told me himself in his shop. He distinctly told me that there were ten minims of tincture of opium in the mixture —I was not certain just now whether the word used was minims or drops, but the inspector has decided that it was "minims." As to the merits or demerits of giving such a mixture I will not express an opinion.

A Juror: Can you safely say that the child did not die from taking it?

Dr. Row: Whether such a mixture was rightly or wrongly given to a child so young, it had nothing to do with the state of the intestines of the child as I found them.

Mr. Codd: I may say, sir, for your information and that of the jury, that minims are generally understood, technically speaking, to be more than drops. A minim is a measured drop, and, generally speaking, one minim would represent two ordinary drops. So that in this case five minims would represent ten ordinary drops, although in this particular case, I may say, the quantity given was measured.

The Coroner: Was there any opium in the powder?

Mr. Codd: Yes; one-tenth of a grain, to be divided into two doses.

In the course of several other questions, Mr. Codd stated that the administering of opium to children was largely adopted by the medical profession, and in fact was positively recommended by some of the ablest authorities of the profession. Any disapproval of such administration was therefore only a matter of opinion.

This concluded the evidence, and the Coroner, in summing up, quoted a standard medical authority showing that a judicious administration of opium to infants in certain cases was sanctioned, approved, and even recommended.

The Jury retired for a few moments, and on returning to the Court the foreman said: "The jury are unanimously of opinion that the child died from natural causes; and at the same time they are unanimous in expressing the opinion that Mr. Codd is relieved from the slightest blame in this matter."—*Devonport Independent.*

THE SALE OF "SOOTHING POWDERS."

On Tuesday, September 4, the Coroner for Liverpool held an inquest at the Police Buildings, touching the death of Ann O'Neill, five months old. The child was taken ill on the night of the 23rd of August, and vomited. On the following morning the mother took her to a chemist, in Brownlow Hill, who expressed the opinion that she was teething, and gave the mother one of Steedman's soothing powders, with instructions to administer half of it at a time. The mother gave the child one half of the powder. The child afterwards became worse, and the mother took her to the Children's Infirmary, where she died the same evening.

Mr. Henry Gorst, surgeon, who attended the deceased at the infirmary, stated that when the child was received by him she was in a very drowsy state; the colour of the skin was blue, and the pupils of her eyes were contracted. The child was dying. In company with Dr. Londes and Dr. Chalmers he had made a *post-mortem* examination of the remains. The immediate cause of death was congestion of the brain, which might have been from natural causes, though the appearances were rather the other way. He did not think the administration of half the powder was in any way responsible for the death of the deceased. It was not calculated to lead to congestion of the brain; its effect would rather be in the opposite direction. He could not say with certainty how the congestion was set up.

Dr. Campbell Brown stated that he had analysed the stomach of the deceased, and the portion of the powder which was not given to her. The powder contained when entire from 1 to 1·2 grains of calomel, together with a little sugar and a few minute particles of some organic substance which was not morphia. He did not know what these particles were, but they were not injurious so far as he knew; the quantity was too small to be so. The stomach was nearly empty, vomiting having taken place. It contained only about a teaspoonful of digested thick liquid, and in that he did not find any poison. Opium he did not expect to discover, and the mercury, which he did expect to find, had evidently been removed by vomiting. An ordinarily healthy child would not be injured by the half powder administered to the deceased; but if the child was in a dying state it might have had an effect it would not ordinarily have. He did not think the administration of the half powder had any relation to the congestion. It was possible under some circumstances it might cause blueness of the body. He could not associate the child's sleepiness with the taking of the powder. He looked for opiates, and found no trace in the powder or the stomach; but opiates soon passed away.

The Coroner asked Dr. Brown what his opinion was as to the sale of these powders.

Dr. Brown said it was an improper thing to sell poisons without declaring that they were poisons.

The Coroner: But do the people in the profession never do it?

Dr. Brown: They are prescribed by medical men, but this powder, which contains poison, is sold by an unskilled person simply as "Steedman's Powder." I do not blame the chemist; but I think it is an improper thing that chemists should be induced to prescribe what they know nothing about simply because it is sold under a Government stamp. This powder is sold under a three-halfpenny stamp as a secret nostrum. If it was a patent we should know what it contained. It is simply a poison sold without the poison label upon it. If it was sold by a druggist without the stamp it would have to be sold with a poison label upon it.

A verdict was returned to the effect that the deceased died from congestion of the brain, but how it was caused there was not sufficient evidence to show.

Review.

JAHRESBERICHT ÜBER DIE FORTSCHRITTE DER PHARMACOGNOSIE, PHARMACIE UND TOXICOLOGIE. Herausgegeben von DR. G. DRAGENDORFF. 10 Jahrgang. 1875. Gottingen: Vandenhoeck and Ruprecht. 1876.

The English-speaking pharmacists of Great Britain and of the United States are both now provided, by associated effort, with annual reports on the progress of pharmacy, in the shape of the well-known 'Year-Book' issued by the British Pharmaceutical Conference in the one country, and the report issued in connection with the proceedings of the American Pharmaceutical Association in the other. The corresponding French and German reports are still, however, the work of private enterprise, and so far as can be judged by appearances in the case of France this has not conduced to its vitality. But the Yearly Report upon the Progress of Pharmacognosy, Pharmacy, and Toxicology, in the German language, edited by Dr. Dragendorff, of Dorpat, may fairly claim to very high, if not the highest, rank amongst its competitors.

The 'Jahresbericht' is a volume of 500 large octavo pages, and in its compilation the editor has had the assistance of several gentlemen in the collation of the pharmaceutical literature not only of Germany, France, England, and the United States, but also of Poland, Hungary, Belgium, etc. With this help very little worthy of notice has been overlooked, and the number of articles quoted is very large. It may be mentioned, as an instance of the thoroughness of the work, that the first section, which is devoted to "Literature," contains a list of no less than 324 books and pamphlets on subjects connected with pharmacy and the allied sciences published in different countries during the year. It will be surprising to many to learn that a book on a subject connected with pharmacy is published on the average on every working day of the year.

The method adopted with the quotations is almost without exception to give more or less condensed abstracts from the original articles, but always sufficiently full and clear to indicate their scope. These are arranged upon a definite system that is closely followed throughout, so that all that is to be said on a particular subject is as a rule brought close together. Of course difficulties must have been met with in carrying out the plan but they have been admirably overcome. It may be of interest to sketch briefly the order of arrangement followed.

Part I., as above mentioned, contains a list of works published during the year, to which are appended a few editorial remarks upon the most noteworthy.

Part II. deals with papers having general relations to pharmacy, such as sketches of the condition of pharmacy in, and the materia medica of particular countries.

Part III., Pharmacognosy, is subdivided into (*a*) Pharmacognosy of the Vegetable Kingdom, in which the vegetable materia medica is classed under the natural orders; and (*b*) Pharmacognosy of the Animal Kingdom, similarly arranged. The articles in this section are limited to those referring to the unmanufactured drug. Thus under Rubiaceæ are given notices on the cultivation of cinchona, the testing of cinchona bark, etc., and similar information with respect to opium is given under Papaveraceæ, but papers on quinine, morphia, etc., are referred to a subdivision, "Alkaloids," of the next section.

Part IV., Pharmaceutical Chemistry, is divided into (*a*) General Matters; (*b*) Apparatus and Manipulations; (*c*) Special Pharmaceutical Chemistry. This last division is again subdivided into the Metalloids, Metals, and Carbon and its Compounds (including alcohols, ethers, sugars, acids, alkaloids, etc.).

Part V. is devoted to Practical Pharmacy, one subdivision of which contains information respecting advertised nostrums, some of which, however, is more curious than correct, as, for instance, the statement that Steedman's powders consist only of rice starch.

Part VI. relates to Toxicology and Judicial Chemistry.

A copious index of authors and another of subjects are supplied. Those who are conversant with foreign literature of this kind must have noticed the havoc frequently played with the orthography of authors' names. From this failing the present work is remarkably free, but it does afford one amusing instance. In quoting the name of a contributor to this Journal, Tichborne is transformed into Titchborne; in the Corrigenda this name undergoes further mutilation and is "corrected" to Tischborne.

From what has been said it will be seen that Professor Dragendorff's book will be an acquisition to the bookshelf of any pharmacist who can read German.

Dispensing Memoranda.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be conidered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.

[16]. Pulv. Capsici.—Referring to your remarks on and W.'s reply to above, the difficulty, of course, lay with the quantity of capsicum, and the history is as follows:—The prescription was presented to the writer's firm to be dispensed on the evening of Saturday, 30th June last, when we arrived at the conclusion that it was the intention of the prescriber to define the quantity of *pulv. capsici*, and order *q. s.* of some other ingredient. There was a lotion on the same prescription which we dispensed that evening; the pills, under the plea of taking some time to prepare, we held back till the Monday in order to obtain time to communicate per post with the prescriber—whose handwriting was quite familiar to us—a lecturer on a special subject in connection with a university of a neighbouring city. In our communication to him we called attention to the pulv. capsici; in his reply he says, "the prescription is quite correct, of course you will require to use some medium as an excipient." We then dispensed the pills with pulv. capsici gr. vj., and made the mass with jelly of glycerine and tragacanth. They have been repeated. I may add we hold the original prescription and prescriber's reply.

M.

[21]. Apothecaries' or Avoirdupois?—The sign ℥j is simply an abbreviation for one ounce old apothecaries' weight, viz., 480 grs., and must of course be dispensed accordingly. The writer of the prescription has ignored the B.P. in this particular, perhaps intentionally, wishing to give an even number of grains in each dose.

E. Samson.

[22]. Keeping Leeches.—I have read with interest the letters on the above subject in your Journal of last week. Permit me to state my own plan, for many years acted on with success. 1st, The leeches are placed in a glass receptacle; a very wide-mouthed bottle such as used by confectioners will suffice. 2nd, Pebbles are put therein. 3rd, The bottle about two-thirds filled with our reservoir water is kept near the shop window where there is light and sun. 4th, The water is very rarely changed, only when appearing somewhat turbid or for the sake of cleaning the bottle. 5th, The top of the bottle is covered over with common bunting. I would observe from my own experience the chief care should be *not* to change the water, as generally recommended, *often*, and light and pebbles should never be forgotten.

Samuel Thornton.

[22]. Keeping Leeches.—Never change the water, unless obliged to do so, and always put the fresh arrivals into a jar of well-seasoned water; I always keep a second vessel in hand and find the longer it has been standing the healthier the leeches are. By putting them into fresh, spring, or other water you simply starve them; the same holds good of changing the water. I, of course, at one time followed the beaten track and killed my leeches by the score; now I rarely lose one.

J. Slade.

[22]. Keeping Leeches.—In answer to query 22 I have kept leeches for several years in large and small quantities and have always noticed that the more elaborate the aquarium the shorter lived were its contents. I have found this to be the case with regard to gold and other fish, as well as with leeches. I keep my leeches in a tin can, such as is used for carrying live fish, bait, etc., and may be bought for one shilling; I place a piece of muslin under the cover to prevent them injuring themselves against the perforations of the lid, and keep the whole arrangement in the open air. I seldom lose one by death, and whilst reading through the letters in volume vi. (to which you directed attention), it struck me that my success was perhaps due to the fact that the tin in which I keep them is more or less rusty.

[22]. Keeping Leeches.—In reply to Mr. Hoddinott, I should like to give the method which I have followed for nearly two years and in which time I have lost only five leeches. I have a twelve inch leech aquarium, which holds, when two-thirds full, about two and a-half gallons of water (river). I keep in it twenty-five leeches, three trumpet snails, and five small gold fishes. During very warm weather the water is changed twice a week, at the present time once, and during winter once in three weeks. The leeches are gently rubbed with a sponge kept for the purpose every time the water is changed. They are kept in full light near the window. I would add that the less they are interfered with the better.

Hirudines.

[23]. How should the two following prescriptions be made up so that there shall be no deposit of resin on sides of bottle?:—

℞ Tinct. Myrrh		℥ss.
Alum		gr. cxx.
Aq. Rosm.	ad	℥8.
Misce. Ft. garg.		

℞ Tinct. Guaiaci Ammon.		℥ss.
Potsss. Chlor.		ʒj.
Aquæ	ad	℥8.

Merens.

[24]. PILL COATINGS.—Can any one inform me of a method for sugar coating (or white coating) pills that will bear comparison with that adopted by manufacturers? I have tried those already recommended in the Journal, but do not find them at all satisfactory.

AGENDA.

[25]. EMP. CANTHARIDES.—When emp. canth. is ordered to be spread, is it correct to paint the surface with a vesicating liquid?

W.

[26]. UNG. HYOSCYAMI.—I should be much obliged if some one would kindly tell me how the above is made. I have met with it this week for the first time.

E. BEVAN.

Correction.—In the answer of W. to No. 17, on p. 159, read scruples instead of drachms for the first two ingredients.

Correspondence.

"CASTOR OIL PILLS."

Sir,—The recent absurd prosecutions have given rise to several suggestions for a label so worded as to meet the case and have as yet failed. The explanatory one suggested last week would take too much space, especially if a small label were required, and of course it would have to be on all alike. For some time past I have had my labels printed thus, "Compound Castor Oil Pills," the addition has never been questioned or remarked on by the public, and at the same time it implies that castor oil is not the only ingredient. A small quantity will substantiate the name.

B. T. KIMBER.

London, September 4, 1877.

Sir,—On the vexed question of castor oil pills I have found that customers do not as a rule imagine that the pills are made of castor oil, but that they can be taken instead of castor oil. I have found that in exceptional cases I have had to explain that the name arises from the above custom. My rule now is to say, "These pills are not castor oil, but taken instead of castor oil." I think Mr. Gardner's label too long for a penny box of pills. I annex a few popular names for pills here—

Wake-me-ups.	Castor oil pills.
Rattlers.	Five o'clockers.
Eye openers.	Fly-away-jacks.
Scavengers.	Imperial pills, and
Early risers.	Excavators.

All meaning a common purgative pill.

G. H. WRIGHT.

103, *Boro' High Street.*

COUNTER PRACTICE.

Sir,—I cordially agree with the remarks contained in Mr. Postans' letter in reference to counter practice.

Very many young men after the completion of their apprenticeship take situations as dispensers with medical men until they are able to commence business as chemists for themselves; manifestly they must acquire a certain amount of medical knowledge, and should their business be in a country town where a medical practitioner may not be always accessible, surely for such trifling ailments as a slight cold, sore throat, or disarrangement of the system from diarrhœa, induced by partaking of unripe or overripe fruit, a duly qualified chemist who has passed the examinations of the Pharmaceutical Society is fully competent to prescribe such simple remedies as will at once and effectually give relief.

Medical men are obliged to leave their practice occasionally for needful rest and relaxation; many cases then often come under the notice of a chemist and druggist, requiring simple treatment, which he is fully qualified to deal with by some simple common-sense prescription, and how often does he in his practice dispense many high-class prescriptions of some of our most eminent physicians. I think, then, that where a chemist does not trench upon the practice of a medical man by presuming to treat a serious and complicated case, he may be safely trusted to prescribe over the counter for such slight ailments for which he is often asked to give a remedy.

A CHEMIST OF THIRTY-TWO YEARS' STANDING,
WESTERN DISTRICT.

MEDICINAL USES OF COSTUS.

In addition to the native uses of this drug in China, already quoted from my 'Contributions' by Mr. Cooke, I may add that the root, when cut up in that fine state of "rasps" so admirably done by the Chinese druggists, is a capital remedy for the opium smokers anxious to give up the drug (a watery extract of opium mixed with the ash of the opium pipe). The rasped root should be mixed with the ash just alluded to, or with weak tobacco, and smoked when the "craving" comes on. This, combined with the use of ammoniated tincture of valerian, tincture of nux vomica, tincture of capsicum, and tincture of sumbul, will often effect a cure. The tincture of henbane with bromide of potassium or bromide of ammonium (better still), at night only, should be given in bad cases. I am led to make these remarks as there are several "opium dens" in London.

A NEW METHOD OF DETECTING ALCOHOL, WHEN USED AS AN ADULTERANT OF THE ESSENTIAL OILS.

BY EDMUND W. DAVY, A.M., M.D., M.R.I.A.,

Professor of Forensic Medicine in the Royal College of Surgeons, Ireland.

It is well known that one of the most frequent of the adulterants of the essential or volatile oils, at least of those that are the more expensive, is alcohol; this being the case, at the suggestion of my friend Mr. Charles Tichborne, I made some experiments on the application of my molybdenum test for alcohol to the detection of that substance when used for such adulteration, and finding that it might be usefully employed for this purpose, I brought the matter under the notice of the Pharmaceutical Society of Ireland, at its meeting in last April. A number of circumstances, however, prevented me from publishing before this my communication on that subject.

Having briefly described the molybdenum test for alcohol, which was published last year in the *Pharmaceutical Journal, Chemical News*, and in other scientific periodicals, I pointed out how it afforded a very ready means for the detection of alcohol in the essential or volatile oils, it being only necessary to agitate a little of the oil under examination with a small quantity of distilled water, and having allowed the mixture to stand for a short time till the oil and water have again separated, to take a drop or two of the watery portion and add to it three or four drops of a solution of molybdic acid in strong sulphuric acid, when the characteristic blue reaction will appear if alcohol be present. The following very simple way I adopted in applying this test to the essential oils:—A glass tube of about four inches in length and of about a quarter of an inch in diameter in its internal bore was taken, one end of which being heated was drawn out to a point, and closed so as still to leave a very small hole, whilst the edges of the other end were merely rounded by fusion,* and to this latter was adapted a sound well fitting cork or better still, an India rubber stopper capable of closing the aperture perfectly air tight. The small hole being closed by one of the fingers placed firmly against it, the tube is filled to about one third† of its contents with distilled water, and then about an equal volume of the essential oil added. The larger end of the tube is now to be tightly closed with the cork or stopper, the finger being still kept on the small hole, and the contents of the tube is then strongly agitated for a few moments; after which the pointed end is turned upwards and the finger removed, to allow the air condensed by the closing of the larger end to escape so as to avoid unnecessary loss of the mixture; and finally the tube being again reversed, it is supported on a stand with its pointed end downwards, but not resting on it. In this upright position it is left till the oil has separated from the water and risen to its surface, which in most cases takes place in a comparatively short time, leaving the aqueous portion below quite clear or very nearly so. When such is the case a drop or two of this portion is allowed to escape, which is easily effected, either by pressure on the cork or stopper, by holding the upper part of the tube in the hand so that its warmth may expand the contained air, or by slightly drawing out the cork (which will cause some air to enter at the pointed end) and then pressing it in again; by one or other of those simple means, the necessary quantity of the aqueous portion will be easily forced out of the tube. This on being brought into contact with three or four drops of the molybdic solution placed in a little porcelain capsule or on any white porcelain or delf surface, will, if the oil has been adulterated with alcohol, develop after a few moments the characteristic intense blue reaction of that substance.

The molybdic solution I have employed for this purpose was the same as that which I have already recommended to be used in the adoption of my test for the detection of alcohol generally, which is readily prepared by dissolving, with the aid of a gentle heat, one part of molybdic acid in ten parts by weight of pure and concentrated sulphuric acid. This solution should be kept in a well-stoppered glass bottle, as it quickly absorbs moisture, becoming too dilute, and is otherwise injured if it is left exposed to the air.

As regards the little testing tube I have suggested for the examination of the essential oils, I may observe that if it is properly constructed and corked perfectly air-tight, it will hold its contents without allowing it to drop out when not required; and if the pointed end of the tube is not left touching any object, which would withdraw the fluid by capillary attraction, there will only be a very trifling loss of the watery portion from evaporation through the small aperture, even after keeping for a considerable time.

The experiments I have made on a number of the essential oils,* which were apparently pure, or at least were unadulterated with alcohol, show that if they are agitated with distilled water, and after they have again separated from it a drop or two of the watery portion be taken and tested in the manner already described, there will either be no change of colour observable, or, what is more frequently the case, there will be a faint light-brown or yellowish-brown tint produced, or lastly, in some few instances a light olive or grey is developed, quickly changing to the former tints, all of which soon fade away leaving the mixtures colourless or very nearly so. But if the oil is adulterated with alcohol, the water dissolving out that substance, a drop or two of the aqueous portion develops with the test solution, after a few moments, the deep azure-blue coloration which is so characteristic of that substance, and this is much more permanent, generally speaking, than

* Several tubes suitable for this purpose may be easily made by selecting a tube of rather soft glass, not too thin in its substance and of about the bore stated, and having with a spirit lamp or by means of gas drawn it out to a fine bore at intervals of about eight or nine inches apart, the tube is cut with a file, both at the centres of contraction and of the intervals between them, and finally the edges of the larger end of each tube rounded and of the smaller one closed to a fine point by fusion.

† In cases where the degree of adulteration may be small, it will be well to diminish the proportion of the water employed so as not to dilute the adulterant too much; and where the very expensive oils are the subject of examination, smaller sized tubes than those recommended may be employed.

* The following were the essential oils experimented on: otto of roses, rose geranium, neroli, neroli petit grain, santal wood, rhodium, patchouly, bergamot, verbena, lavender, rosemary, cinnamon, bitter almonds, lemon, bitter orange, cloves, caraway, peppermint, nutmeg, mustard, anise, fennel, cajuput, cubebs, juniper, turpentine.

the shades of colour caused by the essential oils alone when so treated, though even this, as in their case, will fade away leaving the mixture colourless, or very nearly so, after a shorter or longer exposure to the air. If the amount of alcohol present be considerable the blue effect will be produced after a few moments, even at the ordinary temperature, but where the quantity is very small I have found that the application of a very gentle heat renders the test far more sensitive.

As, however, I have ascertained that a heat of 212° Fahrenheit, and in some cases a temperature even considerably below that point, especially if continued for some time, will develop a more or less blue coloration with the water which has been agitated along with essential oils apparently pure, when it reacts on the molybdic solution, some caution must be observed in the application of heat.

It appears, however, from my experiments with the essential oils I have operated on, that the water so treated and then allowed to separate from them, as in this method of testing, might be heated with the molybdic solution to 120° Fahr. on a water-bath, without developing a blue coloration, at least, unless that heat is continued for a considerable time, though such a comparatively low degree of heat is quite sufficient to develop, almost immediately, the blue reaction if alcohol be present. But owing to heat acting in the manner described, I would recommend the test to be at first applied at the ordinary temperature, and if it fails to indicate the presence of alcohol it shows that either the oil is free from that substance, or if any is present the quantity must be extremely minute, and if the latter is the case it may be readily detected by slightly warming the mixture, taking care, however, that the heat should not rise much beyond 120° Fahr., which, if it occurred, would create some uncertainty as to the cause of the blue reaction.

By means of this test I have ascertained that several samples of otto of roses sold to me as genuine were adulterated with more or less alcohol, and that a sample of rose geranium oil lately in the market, which was assured to Mr. Tichborne as being a genuine article and one of superior quality, was very largely adulterated with alcohol. From several experiments I have made with the more expensive essential oils, mixing them with different proportions of alcohol, I found that where they were mixed with one twenty-fifth, one fiftieth, or even with one hundredth part of their volume of rectified spirit of wine, that its presence could readily be detected by this test, and I have no doubt but that it is capable of detecting much smaller proportions of that substance should it be present as an adulterant in different essential oils.

I should observe, that where the oil from its density will not rise readily to the surface of the water after agitation, as occurs with a few of the volatile oils, this difficulty I have found may be readily overcome by adding to the contents of the tube a little sulphate of magnesia, which, dissolving in the water and increasing its density, will if employed in sufficient quantity, cause the oil to rise to the surface, leaving the watery portion below clear and suitable for testing with the molybdic solution.

Before concluding I should also remark that the oils themselves must not be added directly to the test solution, for I find that many of them when so treated after passing rapidly through various shades develop a deep blue even though they are apparently pure, and those that do not produce that colour give rise to such dark shades of brown, olive, or black, as to mask more or less completely any blue coloration which might be caused by admixture with alcohol.

The same I found to be the case to a great extent, though acting more slowly, when the test solution in a capsule was placed under a small bell glass and exposed for some time to the vapour of different essential oils emanating from cotton wadding on which they had been dropped, or from a little vessel containing them. In some few instances, however, by using the test in this way, it enabled me to distinguish very quickly the pure oil from the same kind which had been mixed with a minute quantity of alcohol, and it may, therefore, in some cases be of use in detecting such adulteration, or at least in distinguishing differences in various samples of the same description of oil; but I found that this way of employing the test, though much simpler, was not so generally applicable, nor so trustworthy in its indications, as the method already described.

FRENCH LACTUCARIUM.

The principal if not the sole producer of lactucarium in France is Mr. Aubergier, of Clermond-Ferrand in Auvergne, Department Puy-de-Dôme, whose researches on the chemistry and therapeutics of this drug are well known to pharmacists. His first experiments, which were made previous to 1841, were chiefly directed to the selection of the proper variety of lettuce, so as to obtain the largest possible yield of lactucarium. As a result of his investigations he began the cultivation of *Lactuca altissima*, Bieb., a native of the Caucasus, which is a gigantic herb (hence called *laitue gigantesque*), having, when cultivated, a height of 9 feet, and a stem $1\frac{1}{2}$ inches in diameter.* The manner of collecting the juice differs from that pursued in Germany or Scotland; instead of cutting off the stem near the top, and removing successive slices every day, transverse incisions are daily made at the time of flowering, into the stem from above downward, and the juice which flows from them is collected in a glass vessel. By the time this is full, the juice has coagulated and is removed, after which it is shaped into circular cakes of $1\frac{1}{2}$ inches in diameter, which are dried by exposure to the air upon sieves.

While it was found, in the commencement of the enterprise, that one person could collect at most 60 grammes of the juice per day, Mr. Aubergier has succeeded in training his employés—and he employs only women for this purpose—so well, that the mean daily quantity collected by one person now amounts to about 600 grammes (about 1 lb. 5 oz.), while some very active workers occasionally gather as much as one kilogramme. This activity and skill is stimulated by premiums, which are given for any quantity returned above 300 grammes, and further by a sort of co-operative partnership, the most expert workers receiving at the end of the season some extra gratuities proportionate with the total yield. Dry seasons are very unfavourable to a large yield; and in order to be able to supply the demand, Mr. Auberger, takes advantage of moist seasons to lay in a large supply, sufficient to last for several years ahead.—*New Remedies from La Ruche Pharm.*, 1877, 21.

---

* Prof. G. Planchon believes it to be a mere variety of *Lactuca Scariola*, L. See 'Pharmacographia,' p. 354.

ORGANIZATION OF PROFESSIONAL CHEMISTS.

A TIME ago, in course of some observations upon the Institute of Chemistry, a sort of opposition exhibited by a contemporary, and a few of the public analysts represented by it, was characterized in this Journal as being probably "a pitiful wail against inner consciousness and outward circumstance." These oppositionists appear to suspect that they will be refused admission as members of the Institute, and manifest their fear in a manner which irresistibly reminds one of the famous French proverb, "Qui s'excuse s'accuse." Leaving out of consideration any reasons which may justify such an apprehension—for, apart from the despairing gentlemen who make the complaint, they are unknown—we yet felt justified in describing the opposition as being as spiritless as it would probably prove futile.

More recently the *Analyst* has given some explanation of its conduct, but the explanation is as incomprehensible and unmeaning as the opposition to which it refers.

It is not worth while perhaps to follow the *Analyst* throughout its latest protest; were it so it would be easy to refute everything in it that partakes of the nature of an argument based upon reasonable grounds. The fact is, that journal has acquired, somehow or another, a partial knowledge of the transactions relative to the formation of the professional institute, while it jumps at conclusions regarding its function and future. The *Analyst* grants that the committee of fifty, which had the care of the child institute, was an able body—the "most clever, most competent, and most successful chemists in the country," but, at the same time, it asserts, and has indeed "asserted from the first," that these promoters of organization among chemists are unable to discriminate between competent and incompetent ones. This may be true, but such a discrimination forms no part of the duty of any council or committee attached to the Institute of Chemistry. What has to be determined when the time comes will be this: Are the qualifications presented by candidates for membership such as entitle them to election? The *Analyst* is apparently unacquainted with the just and proper means which will be adopted in order to ensure a just appreciation of merits and qualifications, but that this will be done is as certain as that the promoters are the "most clever, most competent, and most successful chemists in the country." If the *Analyst* would but be candid and speak out, it would, in our opinion, say of the Institute, "Everything would be quite right, and no mistake would be possible in the future, if we had only been chosen to assist in the labours of promoting the organization of chemists; you have made a mistake in the past by ignoring us; please take us in and we will say no more about it!"

Nevertheless, the funny article in the *Analyst* is not without merit. It incidentally raises the question, What is a professional chemist? We remember hearing a solicitor answer this question on one occasion with the reply, "A professional chemist is a man who will swear to anything you like for a five pound note." It is towards the removal of this definition and the substitution of a better and more honourable one that the efforts of the new Institute must be directed.

The *Analyst* defines a professional chemist as a man who earns an income "purely by the practice of professional chemistry as distinguished from pharmacy." Why distinguished from pharmacy more than anything else which is outside the pale of professional chemistry, we do not know. The term professional chemistry is used to distinguish it from chemical investigation, and even this diagnosis is almost unnecessary, because no one earns an income by the prosecution of research in the domain of pure science, and very often professional practice involves research though the results may be published in the usual way. The *Analyst's* definition is moreover unsatisfactory, because there is scarcely a man in all England who earns an income purely by the practice of professional chemistry.

The profession of chemistry when properly administered has a purpose as useful and noble as any comprehended by medicine, the law or the church. This purpose will increase and intensify with the progress of the age. Science—and chemical science in particular—already influences and penetrates the minds of nations, and as it must inevitably become more and more an essential part of the machinery of the times, the machinery by which nations progress, so its administration and fulfilment must be adequately performed and carried out.

Those who in the present day consider themselves professional chemists, or rather those who will advance claims to be admitted as members of the new Institute, present a motley group. First of all there are those gentlemen who pursue science as a profession, and who exercise it in a manner comparable to that in which solicitors do their business—eminently well and eminently respectably. Then there are teachers of chemistry, including men who hold professorships, lectureships, and so forth, many of whom eke out an income by taking professional work, when and where they can get it. Again, there are public analysts, of whom of course some are included in the first group already described, but of whom others are —well—only public analysts. Finally, there are a host of unknown nobodies, assistants, men who have bought degrees, and nonentities of all sorts, all of whom will accept analytical and other work as often as they can obtain it.

Among these classes of practitioners are men who can do their duties properly; others who can do them imperfectly; and, yet again, others who cannot do them at all, and therefore get them done by proxy, or what is still more disgraceful, "arrive at results."

Therefore organization is required. At first it must and will be, wide, liberal, and comprehensive; it cannot be otherwise at starting if it is to succeed. Even doubtful men must be admitted to the Institute, and will be admitted. To time and development must be left the processes of weeding out and survival of the fittest, and in the meantime a proper training for the coming generation of professional chemists may be devised, and a standard of competency and honour adopted, which shall be to every aspirant the goal at which he aims—the object he seeks to attain.

The *Analyst* may dry its eyes; its wound is poignant, but it is not beyond the power of healing.

CRUEL INDIFFERENCE.

According to the journal which boasts of having the largest circulation in the world an incident occurred at a recent meeting of a suburban board of works which manifested either a cruel indifference to the safety of the constituents of the Board, or an almost equally cruel contempt for the opinion of one of its officers. It appears that the public analyst reported that a large quantity of treacle containing arsenic had found its way into the market and was being extensively sold. Already, so the analyst had read or heard, two families had been poisoned by the stuff, and he advised the board to obtain samples from every seller of treacle in the district. This reasonable suggestion was objected to on the ground of the expense that would be involved in the purchase of one hundred samples, and eventually it was decided that only two samples from each parish in the district should be purchased. Probably these will not represent ten per cent. of the treacle sellers in the district, and what an amount of arsenical treacle might not be dealt out by the remainder. Can it be that the board would not spend one hundred pence to avoid so fearful a risk? Did the board think the analyst had found a mare's-nest? Or was there any other reason that limited the inflow of "golden syrup" into the laboratory? We shall look forward with interest to the report on the samples purchased, as an arsenical treacle scare, although it might affect the treacle trade adversely, would be a real "god-send" to a certain class of public analysts, now that castor oil pills devoid of castor oil and soda water without soda have lost their novelty.

By the way, one of the few surprises we have met with during the dead season has been in connection with this "soda water" question. Our contemporary the *Medical Press and Circular*, which has hitherto been more consistent than sensible in its denunciations of the selling of articles under popular names that do not represent their true composition, evidently feels it must draw the line somewhere, and the journal that could not see with equanimity the application of the name "citrate of magnesia" to an article popularly known as such would tolerate the sale of soda water without soda. The reason given is that "soda water" is evidently a misnomer, but can hardly be said to be a deception, for most people know that the beverage so called contains usually no soda, and that it is not the worse for the omission and would be bought as readily under any other name (and, we may add, would probably "smell as sweet"). Our contemporary continues, alluding to a recent indictment for such a sale, that "if analysts aim at disgusting the public with the law they can do so no more effectually than by *prosecuting inoffensive traders for technical offences.*" We are not disposed to quarrel with this opinion, but it is curious that this sudden development of common sense is coincident with what is generally known as the "silly season." What can be the explanation?

ANOTHER MYSTERIOUS TREE.

In a recent number we quoted from a report made by one of Her Majesty's Consuls respecting a marvellous tree, suggestive of the saying, "*Omne ignotum pro mirifico est.*" This account can now be paralleled with another from a consul of the Columbian Government, who reports that in the woods near Moyobamba, in northern Peru, there grows a tree which has the property of absorbing an immense amount of humidity from the atmosphere and subsequently pouring it forth from its leaves and branches in such an abundant shower as to convert the ground in its neighbourhood into a bog. The tree is appropriately called "*tamia-caspi*," or "rain tree," by the natives, and is said, when mature, to attain a height of fifty feet, and a diameter of three feet at the base. It is only what might be expected to learn that this curious property is manifested in its greatest degree in summer time, when rivers are low and water is scarce. It cannot be said that these consular reports contribute much to our scientific knowledge of these vegetable wonders.

FATAL MISTAKE IN A FRENCH PHARMACY.

A Toulouse pharmacien has recently been sentenced to one month's imprisonment, and his wife to three days' imprisonment, for having prepared a draught with arsenious acid instead of phosphate of lime. The mistake cost the life of the patient.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 194.)

The next paper read was a report on the Proximate Constituents of Ivy Berries, by R. H. Davies.

THE CONSTITUENTS OF THE IVY—"HEDERIC ACID."

BY ROBT. H. DAVIES, F.C.S.

At last year's Conference in Glasgow, I had the honour, in conjunction with Mr. C. H. Hutchinson, of reading a paper in which some of the leading characters of so-called hederic acid were mentioned. Some little additional work having been done upon this substance during the past year, I proceed to report upon it. As already stated, so-called hederic acid consists solely of carbon, hydrogen and oxygen. Three analyses have already been published of this body—two in 1849 by Professor Posselt, to whom we owe its discovery, and one in April, 1875, in Dr. Hartsen's paper on "A New Substance in Ivy Leaves." This new substance I last year showed to be identical with Posselt's hederic acid.

I have found it exceedingly difficult to burn "hederic acid" completely by the ordinary combustion process. When oxide of copper is employed I have never succeeded in converting the whole of the carbon into CO_2. With chromate of lead better results have been obtained, but the method finally adopted was to mix the substance with a mixture of chromate of lead and bichromate of potassium in a tube, the fore part of which for 6 or 7 inches was filled with dry copper oxide. By this means I have obtained results which compare favourably with those obtained by burning the weighed substance mixed with granular oxide of copper in a stream of oxygen. The substance lost Exp. *a* 4·87 per cent., Exp. *b* 4·77 per cent. of water at 100° C.; mean of the two 4·82 per cent.

Exp. 1. 0·1729 gram of the dry substance taken yielded 0·4304 gram CO_2, and 0·1452 gram H_2O.

Exp. 2. 0·1546 gram yielded 0·3818 gram CO_2 and 0·1287 gram H_2O.

Exp. 3. 0·309 gram yielded 0·7712 gram CO_2 and 0·2548 gram H_2O.

In these three experiments the substance was burned, mixed with granular copper oxide in oxygen.

Exp. 4. 0·1532 gram "hederic acid" yielded 0·3787 gram CO_2, and 0·1268 gram H_2O.

Exp. 5. 0·1628 gram yielded 0·4037 gram CO_2 and 0·1382 gram H_2O.

In these two experiments the mixture of chromates was resorted to for the combustion.

The formula $C_{16}H_{26}O_4$ would require 68·08 per cent. carbon and 9·22 per cent. hydrogen.

The foregoing experiments indicate the following percentages:

	I	II	III	IV	V	Average	Theory for $C_{16}H_{26}O_4$
Carbon	67·88	67·37	68·03	67·41	67·63	67·66	68·08
Hydrogen	9·33	9·24	9·16	9·19	9·43	9·27	9·22
Oxygen (by difference	22·79	23·39	22·81	23·40	22·94	23·07	22·70
	100·00	100·00	100·00	100·00	100·00	100·00	100·00

The percentage of carbon is greater in every case than was obtained by either of the experimenters before alluded to,* an error on their part which I think due to the difficulty of completely burning the substance. Neither of them attempted to deduce a formula from the percentages he obtained.

Attempts to produce salts of barium, calcium, potassium, sodium, aluminum, copper, and silver, have been attended with uniformly negative results; and I have no reason to doubt that my former statement that this substance is not an acid is correct. An ammonium compound has been produced, but the amount of ammonia contained is so small as to preclude the probability of its being an ordinary salt. It is now under investigation.

A lead compound of "hederic acid" may be formed by mixing alcoholic solutions of "hederic acid" and lead acetate, but the difficulty of purifying it has hitherto prevented my making an analysis. It is noteworthy that the mother liquor in this case is *not* acid, as would be the case if the ordinary double decomposition took place, hederate of lead and acetic acid being formed.

With substitution products I have been more successful. It was stated last year that a probable nitro substitution product had been formed; this has since been prepared and analysed.

It is easily soluble in chloroform, in which "hederic acid" is insoluble, so that it may be purified by making use of this fact. 0·5586 gram of the nitro product dried in air over sulphuric acid yielded 0·0225 gram H_2O at 100° = 4·03 per cent.

Exp. 1. 0·0950 gram of the dry substance yielded 0·2045 gram CO_2 and 0·0691 gram H_2O.

Exp. 2. 0·1916 gram of the dry substance yielded 0·4098 gram CO_2 and 0·1221 gram H_2O.

Exp. 3. 0·2995 gram of the dry substance examined for nitrogen by Dumas' method.

Temperature 21·5° C. Height of barom., 745 mm. Difference in level of mercury, 140 mm. Tension of water vapour, 19·7 mm.

Vol. of nitrogen 15·6 cub. centim. reduced to temp. 0° C. and B. P. 760 mm. = 11·13 c.c. Weight of nitrogen = ·01396.

These numbers in percentages are as follows:—

The formula $C_{16}H_{25}(NO_2)O_4$ requires—

C 58·71 H 7·64 N 4·28 per cent.

	I.	II.	III.	Average.	$C_{16}H_{25}(NO_2)O_4$ requires
Carbon	58·69	58·33		58·51	58·71
Hydrogen	8·08	7·08		7·58	7·64
Nitrogen			4·66	4·66	4·28
Oxygen (by difference).				29·25	29·37
				100·00	100·00

There can, I think, be little doubt that the formula $C_{16}H_{25}(NO_2)O_4$ expresses the composition of this substance, and thus the formula $C_{16}H_{26}O_4$ assigned to the original substance is confirmed.

It seems probable that I shall have another nitro product to report upon, as a substance differing in some particulars from this one is yielded by acting upon "hederic acid" with nitrous anhydride, evolved from a mixture of nitric acid and arsenic; this may turn out to be a nitrosyl derivative.

A bromo derivative has also been obtained, but is not yet analysed.

The results of the destructive distillation of "hederic acid" promise to be interesting. When heated alone, the heat being carefully regulated, charring soon takes place, without any preliminary volatilization, and then the black liquid which is produced gives off dense vapours, which condense to produce what I think is a mixture of two or more fat-like substances, soluble in alcohol and ether, and having a peculiar tarry odour. A small quantity of permanent inflammable gas is also produced. The fatty substances do not react with ordinary reagents in any marked way, but with nitric acid a nitro substance is formed, and precipitated on dilution with water, so

* In Hartsen's paper the numbers are C. 63·44 per cent. H. 10·4 per cent. Posselt gave 66·49 and 66·43 per cent. carbon 9·5 and 9·41 per cent. hydrogen.

that I trust to effect some separation by this mode of operating.

I have retained the name "hederic acid" for convenience, but trust, after some further investigations, to find a name which will more correctly express the constitution of this substance.

I am greatly indebted to Messrs. C. H. Hutchinson and R. H. Parker for the help they have kindly afforded me; to Messrs. Corbyn for preparing the crude hederic acid; and to Professor Attfield for freely permitting the use of the laboratory of the Pharmaceutical Society in this research.

This was followed by a Note on—

Hederic Acid from Ivy Leaves.

BY CHARLES T. KINGZETT, F.C.S.

At the 1876 meeting of the British Pharmaceutical Conference, Messrs. R. H. Davies and C. H. Hutchinson read a communication on the "Chemical Constituents of the Ivy." In that paper certain references were made to former researches upon this subject, but little new matter was brought forward, beyond a further description of the properties of so-called hederic acid, a name given to the substance by Posselt.*

Hederic acid, when pure, is a snow-white powder, insoluble in ether, but soluble in hot alcohol. That specimen which formed the subject of the present paper, was kindly given to the author by Mr. R. H. Davies, and amounted to several grams only. When Mr. Davies read his paper, I then suggested that hederic acid was a body constructed on the type of a saccharide, inasmuch as I had found many bodies of this constitution to give, with strong sulphuric acid, a purple colour, like to that given, as Posselt found, by hederic acid, and because this substance gives on boiling with dilute sulphuric acid, a solution which reduces Fehling's copper test.

Since the time mentioned, I have, in conjunction with my friend, Dr. H. W. Hake, published an account† of a number of new reactions in organic chemistry, similar to the one above described, due to hederic acid, and in the continued prosecution of this study, I have subjected this last-named body to a closer examination.

When heated on platinum foil, hederic acid melts to a colourless oily-like substance, which emits a dense white aromatic and inflammable vapour, and on continuing the heat, the whole of the substance boils away in this manner, leaving no ash and no charcoal.

As already stated, it strikes with strong sulphuric acid a purple colour, which does not form immediately; but this colour is not nearly so intense or so beautiful as that which is immediately formed when a trace of sugar is present, or more faintly when a drop of water is added; further addition of water causes the destruction of this colour.

With the object of finding an explanation of this reaction some further experiments were made.

Posselt gave no formula to hederic acid, but in one analysis found it to contain 66·5 per cent. carbon, and 9·5 per cent. hydrogen. He also found that the substance lost 5·42 per cent. water at 100° C., and chars without melting at a higher temperature.

From Posselt's figures, the simplest formula that results is C_4H_6O; the true formula would be a multiple of this.

An attempt was made by the writer to isolate sugar from the molecule of hederic acid by boiling it for a long time (twenty hours) in contact with a two per cent. solution of sulphuric acid. No visible change occurred, but the solution contained a substance much resembling sugar in its properties. The sulphuric acid was removed by baryta water, and the excess of this by carbonic anhydride, and on evaporation of the filtrate to dryness it left a sticky transparent barley sugar-like mass, possessed of the following characters:—

It contained barium.

It gave with camphor and sulphuric acid the purple colour which Hake and I have shown sugar to produce.

It aqueous solution reduced Fehling's test readily, and also nitrate of silver.

Strong sulphuric acid charred it in a manner resembling the action of the acid upon sugar.

After drying at 100° it admitted of pulverization.

On analysis it afforded the following results:—

(1) 0·290 grm. gave on combustion with plumbic chromate 0·110 grm. H_2O; an accident ruined the carbon estimation.

(2) 0·190 grm. gave 0·103 grm. $BaSO_4$. These figures give 4·42 per cent. H and 31·84 per cent. Ba, the two elements standing in the relation of 1 Ba to 19 H. This is identical with the relationship exhibited between the same constituents of a similar substance obtained in a like manner from scammony-resin. Assuming gluconic acid $C_{12}H_{18}O_9$ to be dibasic its barium salt $C_{12}H_{16}BaO_9$ would contain 31·06 per cent. Ba and 3·62 per cent. H. On the other hand, glucosate of barium 2 $(C_6H_{11}O_6)$ Ba contains 27·8 per cent. Ba and 4·44 per cent. H.

I have no doubt that the body derived from hederic acid whose analysis is given above represents an intermediate state occurring in the spontaneous change of glucosate into glucinate of barium. Of its sugar-like character, however, there can be no doubt.

Mr. Davies said Dr. Hartsen had stated that the substance he had discovered in ivy leaves yielded sugar when boiled with dilute sulphuric acid. He went so far indeed as to give the exact amount of sugar, 33·38 per cent. He (Mr. Davies) had shown the substance to be identical with hederic acid, and in consequence of a remark made by Mr. Kingzett at the Glasgow meeting had performed the same experiment, taking the same means to get rid of the sulphuric acid employed. Although he had not analysed the barium compound, he had shown the presence of sugar by the fermentation method. Mixed with a little yeast the syrupy liquid yielded carbonic acid, so that as the result of the investigation of three observers there could be no doubt that this body was a glucoside, though what the nature of the other substance was remained to be determined. He hoped to have the opportunity of showing this, perhaps at the next meeting.

Mr. Kingzett said, in justice to himself, he must remark that he had not seen Hartsen's paper at the time of the last meeting of the Conference, and had never previously heard of hederic acid, but had made the suggestion on hearing of the colour reaction quoted by Mr. Davies from Posselt. It was true Posselt made the solution and found it reduced Fehling's test; but that did not prove that it contained sugar, as there were other substances that effected a similar reaction.

Mr. Davies did not think he had mentioned Posselt, if so it was in mistake for Dr. Hartsen, who stated that he had found a new substance in ivy leaves. Dr. Hartsen appeared to be manufacturing chlorophyll when he found this new substance in ivy leaves—he described it in the *Archiv der Pharmacie* for April, 1875. On seeing this paper Mr. Davies concluded that this substance was identical with Posselt's hederic acid, and experiments showed this to be so.

Mr. Kingzett explained that for a long time he had been occupied with studies of bodies some of which give, with strong sulphuric acid alone, a violet colour and others which give this reaction on the further addition of cane sugar. It was in virtue of special knowledge, therefore, he had suggested that hederic acid was a glucoside. He had put his own suggestion to experimental test and had substantiated its truth, and Mr. Davies had in this respect imitated him and confirmed the result. As Mr. Davies seemed acquainted with

* *Ann. Chem. Pharm.*, lxix, 62. See also paper by Dr. F. A. Hartsen, in *Archiv der Pharmacie*, April, 1875.

† "On Some New Reactions in Organic Chemistry and their Ultimate Bearings." *Pharm. Journ.*, May 12, 1876.

Hartsen's paper he could probably tell the meeting whether Hartsen had really effected any analyses of the sugar or had contented himself with the reduction test.

Mr. Davies could not tell.

The President in proposing a vote of thanks to Mr. Davies and Mr. Kingzett, said he hoped this subject would lead to some further communications.

The next paper read was on—

The Supply of Cinchona Bark as Connected with the Present Price of Quinine.

BY JOHN ELIOT HOWARD, F.R.S.

The price of quinine is at the present moment abnormally high; and a medicament which, in many portions of the world, has become a prime requisite for healthy life, is thus placed almost out of reach of the masses of mankind.

The cause of this undesirable state of things is to be found, not in any natural failure of the supply of the material from which it is derived, but entirely from the cruel and desolating effects of war in those portions of South America which have till quite recently furnished the largest importations of cinchona bark. I have described, in my 'Quinology of the East Indian Plantations,' the gradual exhaustion of some of the Andean districts, such as the Bolivian forests, which were first depended upon; and the increasing importance of the Columbian districts, on which the war above alluded to has since told with fearful effect. It has, I understand, deranged the whole traffic. The interruption of the import trade during the war, and the failure of many houses, destroyed the means to pay for the bark. Many of the bark collectors have perished; and the small passes and paths to bring the bark from the forests, have more or less been destroyed by the tropical vegetation, and must be opened again. It will take some time to remedy all this, and even yet the disturbances have not entirely ceased.

The dearth of supply of quinine-producing material thus produced, has been to some extent alleviated by the importations of cultivated cinchona bark from the East Indies, both from the British and Dutch possessions. Without this help the dearth would have amounted to an absolute famine. It is very satisfactory to think that the naturalization of the cinchona in these regions should already have produced such good results; so that the value of the importations from the Government plantations of Ootacamund alone have realized, it is said, some £35,000. I have no means of computing the amount cleared by private owners of plantations, but there can be little doubt that the recompense for their venture has been of a satisfactory nature, thus far; and perseverance in a right course will lead to permanent good results.

In order to this end, they must guard against being deceived by present prosperity. I am inclined to believe that plantations will be undertaken without sufficient foresight, and specially without taking sufficient pains to select really good quinine-producing sorts of cinchona. It is quite true, that all the leading species seem to improve by cultivation. So that the bark of the *C. officinalis*, *C. Calisaya* (in its best forms), and also of *C. succirubra*, are much richer in alkaloid, than when grown in their native forests; but I must reiterate the opinion that nothing but first-class cultivation and wise and discriminating management will in the end be successful.

The present price of quinine cannot be maintained, and will in all probability be followed, not *speedily* but *eventually*, by a reaction, which will place it at a lower level than it has been for a considerable time. The causes that must produce this result are obvious. Not only are the plantations increasing in India,* but even in South America, in certain districts, wealthy landed proprietors are beginning to be aroused, intending to avail themselves of the great natural advantages they possess for cultivation. I have recently been consulted by some of these, who have been led to the consideration of the subject.

* I have recently seen fine succirubra bark from Borneo.

Of course any supply of cultivated bark from America might easily be interrupted; and present experience shows how important it is to have a source of supply independent of the political troubles which afflict the new world; but with moderate care and success, it must be presumed that cinchona bark might be cultivated in South America under conditions very favourable to cheap production, by those who can command a sufficient amount of capital and can secure labour of the requisite stamp.

I think that well conducted cinchona plantations whether in the Old or the New World, must always be profitable, but that the inferior will be eventually a failure, as unable to stand the competition when all is at a low price. I have thus far only looked at the production of quinine. I cannot foresee what will happen as to the other alkaloids, but it is reasonable to suppose that *surely*, though it may be *slowly*, they will take their proper place in medical practice; as regards cinchonidine at any rate the supply is so very abundant (the most so perhaps of all the alkaloids) that the price will always be *low* in proportion to quinine. This must be considered by those who grow plantations of *C. succirubra* in which this alkaloid abounds. My own impression is that cinchonidine is in no sense inferior to quinine, but somewhat different in its operation, and in some cases (specially in children) to be preferred to the favourite medicine. A similar remark may be made in reference to quinidine, which is coming much into favour in some quarters, but can never be so cheap as cinchonidine, as it is a comparatively rare product. Cinchonine is, in my opinion, as powerful as quinine. At all events I use no other alkaloid in gratuitous administration. and never fail to arrest with it the intermittent fevers, of which we meet with examples in this country. I do not know whether the quantity required to effect the result is relatively greater than with quinine.* Cheapness and facility of administration are my inducements to employ the "muriate of cinchonine," though I am inclined to think that the concomitant effects are rather more unpleasant than with quinine; and as regards the other and rougher alkaloidal products, I am satisfied that such is the case. I have some reason to suspect emetic effects as attending one of these. All these medical questions ought to be settled by competent authority.

I would encourage the cultivators to believe that they have nothing to fear from the possibility of the artificial production of quinine. The results of examination by polarized light lead to the inference that the molecule of quinine (for instance), is built up in such a manner that it cannot be imitated by processess which we can employ, although these may produce useful antifebrile substance. Such at all events is my opinion, and has been that of other labourers in this field. There is indeed very much more to be learned in reference to the influence of various agencies on the plants themselves, bearing on the interchange chiefly between quinine and cinchonidine and cinchonine and quinidine, according to the place of growth and the degree of exposure.

Otto Kuntze, a writer in the 'Botanische Zeitung' of 13th and 20th April, 1877, gives us information both on these and other subjects connected with quinology, which would be remarkable if correct; but being unsustained by any proofs other than the infallibility of the writer, will not, I suppose, be received, except by the worshippers of *Einsicht*.

He sets aside the labours of all previous botanical observers, adopting only my one species of *C. Pahudiana*, and includes all the rest (for if I understand him aright, he finds all the South American species in Java and

* Following the best medical authorities, I have often cured agues which had been unsuccessfully treated by too small doses of quinine.

India) under the new heads *C. Weddelliana*, *C. Pavoniana* and *C. Howardiana*.

Now I must protest that I have not the slightest claim to have this species named after me, for this plain reason, that it was discovered and described, and well named *C. succirubra*, long before my acquaintance with the genus began. That which I was enabled to do was to resuscitate the somewhat buried and forgotten knowledge of this now widely spread and specially important species. In my examination of Pavon's collection of Peruvian barks, published in the *Pharmaceutical Journal* for 1852, I said, after describing the bark No. 45, the *Cinchona succirubra*, "red juice," whatever its botanical origin, is, I think, commercial "red bark." At a later period (1855-6) I was in possession of authentic specimens from South America, which I described in the same Journal of October, 1856, with a plate of the leaves. I also stated that I had found in the preceding year Ruiz and Pavon's botanical specimen of this plant.

Later on in 1858, I received from South America more abundant and more instructive specimens from Quito, which I have described in my illustrations of the Nueva Quinologia (1862) of Pavon, together with Pavon's diagnosis written in 1826. In 1866 I gave more particulars in reference to the varied forms under which this species appears, which will be found in the report of the Botanical Congress published in 1867. I have now from all quarters beautiful and typical specimens and flourishing plants of this *C. succirubra*, and of its hybrids, which assume indeed such a polymorphous shape that I think out of 800 young plants, which I reared at one time, a person ignorant of their hybridity would have had no difficulty in discovering more than the supposed seventy species to which our author refers.

It is quite otherwise with the unhybridized seed, and with the plant in its original habitat. It is a notably distinct series of forms, markedly distinguished by the chemical composition as well as by botanical characteristics. The word succirubra points to this, for although not generally understood, the juice is wholly different in its chemical reactions, and the tannin strikingly contrasted with that of other cinchona.

It is known from the observations of many observers that spontaneous hybridizations take place almost always between types relatively markedly distinct, rather than between species offering much affinity.

It is perhaps from this cause that the *C. succirubra* tends so much to form hybrids in the Indian plantation. M. Alexis Jordan remarks that "one only species may fecundate many others, and throw disorder into a whole collection. For practical florists there is here sometimes a precious advantage, but for the botanist who seeks to assign limits to species it is a veritable plague; for hybridity introduces confusion, and *chaos reigns wherever it plays a part and gives fertile products*. That which is best to be done in this case is to destroy the hybrid subjects and to throw away their seeds. In order to recommence the study, it is necessary to have new seeds and new subjects."

It is difficult to get seed that may be depended upon from the mixed plantations in India. As an illustration of this, I will describe the results of a sowing of seed professedly of *C. officinalis*, *C. succirubra*, and *C. calisaya*, obtained from Kew, and said to be from Java.

The young plants developing will give me seventeen of *officinalis*, of which one appears hybrid—the rest sorts but not the truest form—ten of *C. succirubra*, of which not one even approaches to the true form, and forty-six *calisaya*, more or less hybridized, but a fair number promising pretty well, and amongst these forty-six, two or three of a curious *sport* with parti-coloured leaves. It is impossible to say what the value of such a sowing would be when grown up into a plantation.

On the other hand, it is an undeniable fact, that the best results have been obtained from plants of which the genealogy is known, and the succession kept perfectly pure. There is not in British India any *plantation** yielding so good bark, as the 60,000 trees which McIver reared from the one tree which I gave the Indian Government. This I have abundantly described as the *C. uritusinga* of Pavon, and the seed was sent me together with botanical specimens from the mountains of Uritusinga. The bark sent me by McIvor exactly reproduces in appearance that from Uritusinga. I have given the analysis of the different generations, and now the bark has yielded me equal to 7.50 per cent. of beautiful sulphate of quinine†—the alkaloid existing in this bark in a state particularly easy to separate and purify. It appears to have the advantage over the other forms of *officinalis*, except the *angustifolia*.

For another striking illustration of the above statement, I should refer to the *C. Calisaya* var. *Ledgeriana* in Java. Of course the genealogy of this tree is perfectly known, and has been described in my 'Quinology.' There is not the smallest reason for supposing it a hybrid, and the exceedingly rich production of pure quinine alike in the three forms I have given, stamp it as a peculiar species, for as I have shown in my analysis of the *Calisaya Anglica*, a real hybrid partakes of the qualities of *both* parents, and here the constitution is *unique*, as under:—

A form.

'Quinology,' page 59	Quinine	9·06	
	Amorphous	1·40	
			10·46
	Cinchonine		0·10
			10·56

B form.

Ditto, page 60.	Quinine	9·91	
	Amorphous	2·09	
			12·00

C form.

Ditto, page 60.	Quinine	9·97	
	Amorphous	1·70	
			11·67

The small *white* flowers, bearing no resemblance to any but those of *C. micrantha*, are also highly characteristic. M. Moens writes me on receiving my 'Quinology,' "the plates are very beautiful and the plants well represented; as your artist had to make them after dried specimens,‡ the colour of the leaves and of the flowers is sometimes a little different from that of the living plants. So in plate IV. the colour of the under side of the leaves is too blue, and the flowers have a reddish or brown hue, whilst those of the tree (now dead) were white with a very light yellow tint. Plates V. and VI. are excellent, as also VII. and VIII."

All this is exactly the opposite to what Kuntze says, p. 239, "ferner steigert sich überhaupt der Chiningehalt mit der hybridität," of which assertion as usual he gives no proof. He also says, "the darker the colour of the flowers, the richer in quinine is the bark." But it would occupy too much time to point out all the errors into which he has fallen.

It seems to me that what we need is not so much fresh classification, as the observation of actual facts, on which true classification may be founded. The genus cinchona does not differ as to its polymorphous character from various other families, and in these it has been well shown that constant hybridism produces a perfect chaos of forms—unstable and liable to revert to the original species. This is not an ordinary condition of things in the native places of growth of the cinchona, as the different

* I take no notice of small importations of good *Calisaya* from British India, nor of the *renewed* Red Bark, which is a complete success.

† 'Quinology, E. I. Plantations,' page 83.

‡ This does not apply to plates IX., X., XI., XII., which were from living plants.

forms are ordinarily very much localized and very distinct. It is possible that in the Yungas of Bolivia where several typical forms are found together, and bees are said to abound, the case may be different. On the whole this family of plants appear to me to exist in a great number of *nearly allied but permanently differentiated forms*, ranging themselves around central groups, having strongly marked physical specialities which can be appreciated even more fully by chemical analysis than by botanical distinctions. These do not appear to have been produced by hybridization, neither do they correspond with the commonly received notion of species and varieties. The careful French botanist, M. Alexis Jordan, has, in the course of some thirty years of observation and of experimental cultivation, arrived at similar views in reference to other genera of plants.

Those who would cultivate successfully must be guided rather by carefully conducted experiments than by unsubstantial theories.

The PRESIDENT said this was a paper from a gentleman who had devoted perhaps more attention to this subject, and had more successfully studied it than any other living man; he had published very largely upon it, and his suggestions were entitled to the very greatest respect. Mr. Howard, with many others, was impressed with the importance of preventing the extermination of these valuable trees which were the only sources from which the cinchona alkaloids could at present be obtained. In South America no special attention had been given to the keeping up of the plantations, and destruction appeared to have been going on for a length of time; and although means had been resorted to by the English Government in India and by other governments elsewhere to develop the cultivation of these trees, Mr. Howard seemed to think that something of the same sort ought to be adopted in South America.

A vote of thanks having been voted to Mr. Howard,

Professor ATTFIELD said it seemed quite astonishing, considering what had been published with regard to the therapeutical value of the cinchona alkaloids other than quinine, that they should not have come into more general use. Experiments had been conducted on a large scale in India, and from the reports put forward by medical men there seemed to be no question of the value of these other alkaloids, but though they were used to some extent it was remarkable that they were not employed more generally. It appeared to him that the pharmacists present might perhaps suggest some means by which this desirable result could be secured. Substances with fanciful names which did not indicate their composition in any way had got widely known by means of advertising, and it occurred to him that if Messrs. Howard would condescend to push these preparations as other men pushed their wares they might be brought more generally under the attention of medical men.

Mr. WILLMOTT said the difficulty of introducing any other alkaloid in place of quinine was very great. This no doubt arose partly from the fact that there was a certainty about quinine which the other alkaloids did not appear to possess. Messrs. Howard not long ago kindly sent him a large bottle of citrate of cinchonidine and iron which he endeavoured to introduce into King's College Hospital in the place of quinine and iron, but found it was quite hopeless and the bottle remained unopened. He regretted this because if cinchonidine was really of the same value as quinine the saving of expense would be of great importance in the case of hospitals and similar public institutions. He had no doubt, however, that such exceedingly able papers as they had just heard would go far to remove the prejudice which existed.

Dr. SYMES stated that Messrs. Howard had published a pamphlet on the subject of these alkaloids and would willingly supply them to any pharmacists who could make use of them. He was glad to say that at least two hospitals in Liverpool were now using citrate of iron and cinchonidine.

Dr. PAUL thought it was not altogether a matter of commercial enterprise to bring these alkaloids into use. Messrs Howard had laboured actively for some years to introduce especially the sulphate of cinchonidine, but their efforts had been to a great extent fruitless. It was not because these alkaloids were unknown or inaccessible, for both Messrs. Howard and Mr. Whiffen made sulphate of cinchonidine almost perfectly pure at 2*s.* an ounce, and several German makers also turned it out in large quantities, but still it was hardly ever prescribed. It was not open to the same objection as the amorphous alkaloid in the making of the scale preparations, where the disagreeable taste of that body was a bar to its use, for citrate of iron and cinchonidine was quite as pleasant to the taste as the preparation of quinine. It appeared to him that before the use of cinchonidine instead of quinine could be looked for, some authority required to be furnished for its use as a medicine; if for instance, the College of Physicians would authorize its use, medical men would be more disposed to prescribe it. The result of the commission appointed in India showed that sulphate of cinchonidine was scarcely inferior to quinine in the class of fevers for which it was principally used. He might mention as a practical result of the introduction of the barks now being used, that they might not improbably look for the introduction of cinchonidine in a rather objectionable form, namely as an admixture, perhaps 10 or 20 per cent., with the sulphate of quinine of commerce. This already existed to some extent, he was sorry to say.

Mr. BENGER said he had been supplied by Messrs. Howard on two occasions with a large number of samples of cinchonidine which he had distributed amongst the medical men of Manchester, but with very small result in the shape of prescriptions. Some gentlemen to whom he introduced it prescribed it for a short time, but then discontinued it, probably from forgetfulness. Several professional gentlemen told him they believed it answered as well as quinine, but no better, and they preferred quinine as they had always been used to it.

Mr. E. SMITH as the result of his experience found there was great difficulty in inducing medical men to use anything which came from bark other than quinine. He struggled very hard at one time to introduce muriate of cinchonine and sulphate of cinchonidine, but to no purpose, and he did not see how the difficulty could be got over except by making cinchonidine fashionable, and the best way to do that probably would be to put a high price and a fancy name upon it.

Mr. PAYNE (Belfast) suggested that these alkaloids should be introduced into the next edition of the Pharmacopœia and so made official preparations. He had had medical men apply to him for some substitute which would do as well as quinine, and on suggesting to them sulphate of cinchonidine they had reported that they could not see any difference in its action.

Mr. GROVES remarked that it was very unpleasant to them all to have to put their hands so deeply into their pockets on account of the present price of quinine, but he derived some consolation from feeling that this high price must compel doctors to give a fair trial to the cheaper alkaloids. It occurred to him that as an enormous quantity of cinchonine and cinchonidine must be made as bye-products in the manufacture of quinine, these bodies must be accumulated to an enormous extent unless indeed they were introduced into practice surreptitiously.

Mr. W. D. SAVAGE said he had recently induced a large public institution with which he was connected to introduce cinchonidine owing to the present high price of quinine although he had failed to do so before.

Mr. EKIN remarked that Mr. Howard had referred to the great increase in the yield of alkaloid from the cultivation of the plants; and notwithstanding this was still rather a moot point, he believed that cultivation properly carried out had that effect and he was therefore surprised to hear a gentlemen state that morning that, in the case of aconite, cultivation distinctly lessened the amount of alkaloid formed in the plant.

The PRESIDENT remarked that that was probably because the proper mode of cultivation was not understood.

Mr. GERRARD said amorphous alkaloid of the cinchona bark was extensively used at University College Hospital amongst the out-patients, for one year entirely, and it was found to be a valuable tonic, but it was also an emetic, and therefore it had to be discontinued.

Mr. PLOWMAN said that the sulphate of cinchonidine had been used in St. Thomas's Hospital for a considerable time. It was decided some time ago to substitute it for sulphate of quinine in all ordinary tonic mixtures, but not where it was given as a specific in fevers. It was also used with citrate of iron; and its consumption was now ten times that of quinine. Whenever quinine was intended to be used it was the custom now to underline the word.

Mr. MANBY was quite certain, from considerable personal experience, that the alkaloids of quinine had not the same effect in a multiplicity of diseases as the original cinchona bark. Whether this was because certain properties were destroyed in obtaining the alkaloids he could not say, but he was quite satisfied that in the case of the agues prevalent in some counties a decoction of the bark had a much more beneficial effect than quinine.

Mr. MAITLAND said he had often had occasion to take sulphate of quinine, compound tincture of bark, and so forth, but had received most benefit from aromatic sulphuric acid combined with well made compound tincture of bark. He might also mention that he did not find headache or constipation arise from taking cinchonidine to so great an extent as from quinine.

Mr. GREENISH said he had quoted from the ablest writer on the subject, Professor Schroff, in his remarks on the effect of cultivation of the aconite plant.

Mr. UMNEY said there could be no question that India was the great field in which quinine and other cinchona alkaloids were tried. In the *Lancet*, about twelve months since, a report was published from a leading surgeon (he believed in Bengal), which stated that cinchonidine was almost valueless as compared with quinine. When there were such contradictory statements as to the value of these bodies they could not expect medical men at home to take them up, except for further experiment. He had no doubt the time would soon come when East Indian cinchona barks and their alkaloids would be introduced into the Pharmacopœia, for they were already largely used in manufacture. Very little fluid extract was now made from calisaya bark, which of late years had much deteriorated, some specimens of which would not contain more than two or three per cent. of total alkaloids, whereas the bark of *Cinchona officinalis* (East Indian) contained as much as six per cent. of quinia and yielded a fluid extract far superior to any made from the finest calisaya bark. The same remark applied to the East Indian *Cinchona succirubra* bark, which was now largely used.

Mr. SIEBOLD thought the nonsuccess of pharmacists in their attempt to introduce these alkaloids to the medical profession was due to their efforts being isolated; if they would all agree to use their influence with those medical men whom they knew they might be more successful.

Mr. SCHACHT ventured to utter one word of protest against what was now proposed, for he thought it hardly becoming on their part to urge any particular article on the medical profession, if such article were not the best; and with all the laudation which they had heard of cinchonidine and the other alkaloids, no one had ventured to say they were better than quinine. In that fact lay, he believed, the whole explanation of the phenomena on which they had been commenting. A medical man should use the best thing he could get, and the mere difference of a fraction of a penny or a farthing in the cost per dose ought not to influence him. Whether quinine, cinchonine, or cinchonidine, or all the alkaloids in combination, represented the whole medical qualities of the bark was another question, but he thought it better not to discuss that now.

Mr. LAWSON TAIT (Birmingham), as a medical man, was bound to say that the difficulties which had been referred to existed in the minds of those who used as well as of those who prepared these alkaloids. In the cinchona bark there were a great many different properties, and from a long hospital experience he was quite satisfied that results were to be obtained from a decoction of bark which were not to be derived from either of the alkaloids. He had had no experience in hot countries, but within a few days he had been called upon to treat a case of ague in the person of a friend who had been long practising in Bengal. He gave him 10 grains of quinine, and the result was the disease was cut short and did not return, which it would have done, being quotidian ague, if the quinine had not been efficacious. At the same time he did not believe quinine alone was a tonic, for he did not find it to act as such in the case of many patients who come under his care.

Mr. BURTON said the result of long observation on his part showed that a decoction of bark was often more effectual than quinine. He had known cases in which persons suffering from ague had been cured by the bark when quinine had produced little or no effect.

Dr. PAUL remarked that a distinction should be drawn between the specific virtues of different constituents in the bark. The value of the astringent principle as a tonic had been long recognized and by some physicians was considered far superior to quinine; but, on the other hand, quinine had a specific value for certain purposes, and if the result of the medical commission appointed in India was to be accepted, the value of cinchonidine was about 80 per cent. of that of quinine. As an immense quantity of bark was now produced which contained only about 1 per cent. of quinine, with 3 per cent. of cinchonidine, it was a very practical question whether the value of that 3 per cent. was to be abandoned because this bark could not be used for making quinine.

The PRESIDENT said they could not anticipate that anything they could say there would tend to deprive quinine of its preeminence. There had, however, been a great deal of testimony from medical men that effects were produced by the preparations of cinchona bark which neither of the alkaloids separately was capable of producing. He thought possibly medical men would be more likely to try these other alkaloids if the whole of them were converted into a soluble salt and recommended for use. The effects he referred to might be due to something beyond the alkaloids but at any rate a preparation containing the whole of the alkaloids seemed to be a desideratum, and might be more readily introduced than they could separately.

Mr. WILLIAMS remarked that such a preparation as the President had referred to already existed under the name of quinetum, manufactured by Mr. Whiffen.

Mr. MARTIN did not find there was any great difficulty in introducing cinchonine or cinchonidine to the notice of medical men and getting them to try them, but the next time they prescribed they went back to quinine, no matter what the price was. Whether this was for want of an authoritative voice to speak in its favour, or from any defect in the alkaloids themselves he could not say, but in the North of England quinetum was considered to be merely a diluent of quinine.

Mr. SILSON (Bradford) observed that one great channel of consumption of quinine seemed to have been overlooked, viz., the purchase of the public themselves. It was astonishing the number of people who had an idea that quinine cured everything, and who came for it whatever ailed them.

The title of the next paper read was—

NOTES ON AN IMPURITY IN OXIDE OF ZINC.

BY W. W. STODDART, F.C.S., ETC.

A few weeks ago I had a sample of oxide of zinc sent to me for analysis. It was bought for mixing with white lead as a paint, but on being ground was found to be nearly useless. It would not readily combine and form a homogeneous mass, as usual, nor would it give the "body" required. In fact it was so unsatisfactory an article that it was laid aside and another used in its stead. Some objection was raised to its being returned and caused the firm to have it examined, and the cause of failure ascertained.

I have brought the subject before your notice, not on account of the peculiar impurity, but because it has a pharmaceutical interest, for it answers well to all the pharmacopœial tests for pure oxide of zinc, and yet it is impure to the extent of nearly ten per cent.

The sample was nearly white with a very slight buff tint. Like the pure oxide it became a strong yellow when heated, regaining its former whiteness when cold. It was perfectly and easily dissolved in an excess of carbonate of ammonia, and the alkaline hydrates. From the alkaline solution a white precipitate was produced by sulphide of ammonium. It dissolved without effervescence in dilute nitric acid, and was so little affected by chloride of barium that after standing for several minutes, the milkiness was so slight as to require a close scrutiny for its recognition.

If, however, the solution in nitric or hydrochloric acid be made in a flask, a strong odour and copious evolution of sulphurous acid gas becomes very evident.

A few grains were placed in dilute hydrochloric acid with a small piece of pure zinc when sulphuretted hydrogen was evolved, and speedily became evident with the help of a bit of lead paper.

The addition of chlorine water produced a distinct precipitate of sulphate with chloride of barium.

The use of nitroprusside gave a red colour with a little of the solution to which a little soda and acetic acid had been added.

An analysis showed that the sample was composed of oxide and sulphite of zinc in the following proportions:—

Oxide of zinc	90·87
Sulphite of zinc . . .	9·13
Sulphate of zinc, a very slight trace.	
	100·00

The trace of sulphate was so small that it was probably due to oxidation of the sulphite. The cause of the presence of sulphite of zinc is not quite apparent, but the sample came from a continental house, and was very likely manufactured from a sulphide of zinc in some rapid and imperfect manner, which had partially oxidized some of the sulphide, and produced the impure product of which complaint had been made. The appearance of the sample suggested a process by heat rather than by precipitation.

The PRESIDENT said it was new to him that oxide of zinc was ever met with contaminated with the sulphite, and he could not see what the source of such oxide could be.

Mr. WILLIAMS though it must be accidental.

Professor ATTFIELD said he had heard it stated that so-called oxide of zinc was made on a large scale by roasting the native sulphide; now every worker at quantitative analysis who had endeavoured to convert his two or three grains of sulphide of zinc into oxide by roasting must know that it was difficult to do so entirely without a trace of sulphide remaining.

The PRESIDENT asked what sulphide of zinc could be used for the purpose. He knew of no native sulphide of zinc that would yield anything approaching to the kind of compound alluded to, as it was always contaminated with iron, and also largely with manganese. If there were an artificial sulphide of zinc produced in any quantity this might account for it.

Mr. WILLIAMS said sulphide of zinc was produced for the purpose of vulcanizing india rubber, but it was rather an expensive thing compared to oxide of zinc, and he therefore could not suppose that that was the source of the impurity in question.

Dr. R. OXLAND suggested that the sample examined by Mr. Stoddart might possibly have been the result of an attempt to decompose sulphate of zinc by some hydrocarbon combined with exposure to heat. He could imagine that passing carburetted hydrogen over sulphate of zinc at a certain temperature would produce oxide of zinc and a sulphide.

The PRESIDENT said the oxide of zinc used for making paint was made by the old method of burning.

Dr. OXLAND said a large quantity of sulphate of zinc was produced in the process of autogenous soldering, in making lead chambers; perhaps an attempt had been made to utlilize the sulphate thus obtained, and convert it into oxide.

A vote of thanks to the author was passed.

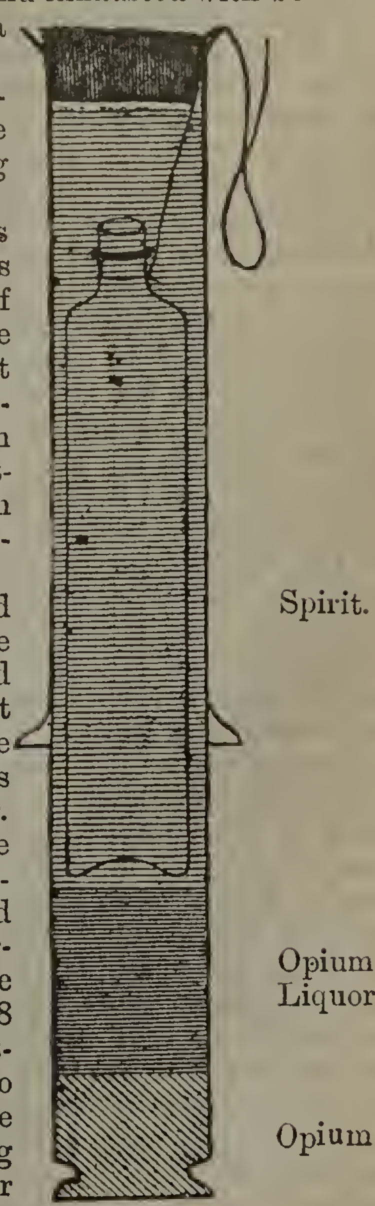
The next paper read was a—

SUPPLEMENTARY NOTE ON THE ASSAY OF OPIUM.

BY B. S. PROCTOR.

Since the publication of my former note on this subject, I have recorded two or three small matters which I now offer for your consideration.

The process as described at our last meeting was devised with the object of being at once accurate and speedy. One ground upon which I advocated its preference to other modes being that a sample of opium from a chest could be assayed and its value determined in the course of a couple of days—most other processes making any pretentions to accuracy requiring considerably more time—such for example is the case with the process described by Mr. Cleaver at the same meeting, the opium having to be dried, powdered, and exhausted with benzine before the extraction of morphia is commenced.



With the view of further expediting the extraction, I have modified the mode of operating thus:—

Rub the lump opium with its own weight of water, to as smooth a pulp as possible, if necessary with the aid of a gentle heat; add spirit equal to about three times its weight and transfer to a percolator tube which is furnished with a loosely fitting inner tube closed at both ends for increasing the hydrostatic pressure.

A phial filled with water and corked answers well for the inner tube, a string being tied round the neck, by which it may be let down gently till the bottom of the phial just touches the surface of the opium liquor. Its position may then be fixed by pressing the string between the side of the tube and a cork wedge. When thus arranged, more spirit may be added till a column of 6 or 8 inches is obtained without disturbing the marc or mixing to any appreciable degree with the opium liquor, and without using more spirit than is required for the exhaustion of the opium.

To quote one experiment in illustration, 200 grains of a soft sample of Turkey opium treated thus, a head of 8 inches pressure was obtained. In four hours, four ounces of percolate had passed through, which contained 98 per cent. of the morphia present; another ounce was considered to have effected practically a perfect exhaustion. Other trials gave similar results.

In assaying sundry samples of opium by the method I have recommended, I have occasionally met with specimens which deposited, along with the morphia, a white amorphous substance which could be washed out only by long continued washing with spirit, strong or dilute.

These specimens I have assayed by the lime process and by the acetate of lead process (in conjunction with the above mode of extracting), but without quite satisfactory results.

Upon the whole, I find it most advantageous to cut the washing short when I find such impurity present, dry the precipitate, wash out the narcotine with benzine as usual, and then redissolve with hydrochloric acid and spirit, and reprecipitate with ammonia, which treatment I have never found fail to give me well crystallized and nearly white morphia of almost absolute purity. If the quantity of spirit and water used for solution be limited to two drachms of each (the quantity I find desirable for an operation upon 100 grains of opium), and the washing be not unnecessarily prolonged, one quarter grain may be allowed for the loss in purification. I find the solution by spirit and acid followed by reprecipitation is both more convenient and less wasteful than crystallization from boiling alcohol, which has been recommended by some analysts; and I find the loss of time is not necessarily great, for the morphia goes down with more promptness and certainty from this approximately pure solution than when deposited from a liquor containing the soluble extractive matters of the opium. Three to four hours are sufficient in the former case, while eighteen to twenty are desirable in the latter.

I have found in sundry cases that the precipitation of the morphia from solution in *strong* spirit and acid is advantageous, inasmuch as the crystals are whiter, larger, and sooner washed clean, but my experience is too limited yet to say whether the strong spirit is generally preferable. When rectified spirit is used, without water, for the solution from which the morphia is to be precipitated, a larger correction must be made for the quantity of morphia retained in the mother liquor.

Mr. Cleaver, at the Glasgow Conference, regarded his washings as saturated solutions of morphia, and pointed to the defectiveness of my process in not making a similar estimate of the loss of morphia in my washings. I thought it more reliable to make a total correction for the loss of morphia in the mother liquor and washings founded upon sundry experiments where the actual loss of a known quantity of pure morphia similarly treated was ascertained. He regarded the washing water as a saturated solution of morphia, and quoted evidence in support of the supposition. It appeared to me theoretically improbable that the washings should be saturated, and I have not been able experimentally to determine their degree of saturation as he did with fusel oil. Of course my failure is my fault and not his, but I have varied the experiment and washed 8·6 grains of pure morphia with a pint of water and found it had lost only 1·4 grains, instead of being entirely washed away as it should have been if Mr. Cleaver's estimate (that the washing waters contain $\frac{1}{1000}$ of morphia) had been correct. I would not be so bold as to assume that the proportion of morphia in the washing waters generally was in the ratio of 1·4 grains to a pint, but I think it is safe after sundry experiments to assume that the loss of morphia in the mother liquor and washings when the process is performed as I have described, amounts to 0·2 to 0·25 grain.

Some analysts recommend the washing of the precipitated morphia with a small quantity of chloroform as well as with ether, benzine, or spirit. In sundry experiments I have found the loss involved by its use to be very trifling, but I have limited its quantity to a fluid drachm or two, and in those cases where the washing with spirit and benzine did not readily remove the impurities the chloroform also failed to do so unless used freely, and as its solvent action upon morphia is much greater than that of ether or benzine, the estimation of the morphia washed away by its use becomes more important, at the same time that it is more troublesome.

It is unnecessary for me to quote in detail the percentage of morphia I have found in the samples I have met with in the ordinary course of trade and analysis, but I may mention briefly that my experience corresponds closely with that of Mr. Dott, published in last year's transactions, except that my results are in general a little lower, and conspicuously so in one or two cases. Thus his lowest percentage of morphia in Turkey opium is 6·9, calculated upon the drug in its moist state, while I have met with one good looking sample offered me as of best quality which contained only 3·5. I also find that 11·2 is the highest percentage of morphia I have found in Turkey opium in its fresh moist condition.

The requirement of the Pharmacopœia that opium in its moist condition should yield 6 to 8 per cent. of a crude precipitate of morphia by a given process has frequently been criticized as being too low. I scarcely think that 8 per cent. should be considered too low if a *pure* morphia be obtained and the sample contains a usual quantity of water, but it would be more satisfactory to say definitely that the opium for pharmaceutical use should contain within a fraction of a grain, more or less, of 10 per cent. of morphia calculated upon the drug in its dry condition. According to present rule a poor sample of opium may be brought up to "Pharmacopœia standard" by partial drying, while the same standard would not exclude another sample of double strength tested in its moist condition.

Basing the calculation upon the dry opium has the further advantage that it is its morphia value in this state which determines its medicinal activity when administered as powder, compound powder, tincture, etc.

The percentage of water in moist opium I have found to vary from 19 per cent. to 27 per cent. Mr. Dott's table agrees closely with my observations in this particular, if we omit one anomalous sample which he found to contain 31·2 per cent. of water and only 20·1 per cent. of aqueous extract.

In conclusion, I may note that the degree of dryness to which an analyst reduces his sample considerably exceeds that to which the bulk is reduced by the drug grinder. Powdered opium, fresh from the mills loses 5 to 6 per cent. of its weight by further drying.

Dr. Paul said he had frequently made attempts to extract opium within a reasonable time by the method of percolation, but had never succeeded in getting a result worth anything, in the time required; for this he had tried all kinds of devices, he could never get the extraction quickly enough. With regard to the correction for morphia remaining in solution, or washed out in the process, he thought great care should be exercised in laying down any specific co-efficient for so much morphia dissolved in so much mother liquor, or removed by washing, because the extent to which alkaloids dissolved in different solvents varied very much according as they were going into solution on passing out. This was very marked in the case of some of the quinine alkaloids; for instance, sulphate of cinchonine could be evaporated until it was quite syrupy without crystallizing; but when it was in hard crystals, like sulphate of potash, it was equally difficult to dissolve it in five or six times the qnantity of water absolutely necessary for holding it in solution.

The thanks of the Committee having been accorded to Mr. Proctor, the following paper was read:

Sugar in Pharmacy.

BY CHARLES SYMES, PH.D.

Of the many thousand tons of sugar refined weekly in this country, in addition to that so imported, but a small portion enters into the domain of pharmacy, and hence whilst volumes have been written on the various processes and treatment which it undergoes from the source of its production till it reaches the table of the consumer, but little of this literature has dealt with the subject from a pharmaceutical point of view. Perhaps pharmacists feel it to be too insignificant a substance, void of medicinal value, and therefore not meriting attention. Yet sugar is an article of the Pharmacopœia, and as an adjunct, excipient and preservative plays an important part. It does more than this; by entering into chemical combination with certain other substances it increases their potency, a familiar example of which we have in saccharated lime water, and perhaps less familiar, its compounds with iron etc., some interesting experiments on which are described by Dr. Gladstone (*Journ. Chem. Soc.* vol. vii, p. 195). When used mechanically to divide the particles of other bodies, it also tends to increase their medicinal activity. Triturated with calomel we have this result most markedly; in other cases it is merely protective, saccharated carbonate of iron affording us an example in which it retards, and in a great measure prevents peroxidation. In solution it forms the best vehicle for the administration of nauseous medicines, is a solvent of certain active principles such as those of Peruvian bark, also a preservative of certain flavouring agents, and of some chemical substances, notably the protosalts of iron.

But it performs these offices in a satisfactory manner only when certain conditions are observed, and only so long as itself remains unchanged, for if fermentation once sets in destruction of the syrup, together with the substance it was intended to preserve, is almost sure to result.

It is perhaps scarcely necessary to remark that in the selection of sugar for syrups, purity is of the first importance; this object fortunately it is not difficult to attain. Good lump sugar such as Say's, crystals such as were formerly produced by Finzel, now by Tate and Son, or granulated such as is sent out from the Eastern Sugar Refinery, Boston, and imported into this country in casks of about 2 cwt. each, are all practically pure sucrose; the ash yielded by either is not more than from three to six parts in 10,000 (representing about double that quantity of mixed potash and lime salts), and a mere trace of glucose. There appears to be a decided prejudice against sugar produced from the beet for use in pharmacy, which arises probably from the fact that the crude article is much more impure than that derived from the cane, but this is not necessarily so in the refined product; a more elaborate process and greater care in the refining are necessary, but we have really nothing to do with this and should look only at the results. Now Say's lump which is largely and for months in the year exclusively prepared from beet, is regarded in the sugar trade as a standard of purity. The prejudice, however, is not altogether unfounded, for unless beet sugar be thus perfectly refined a trace of volatile oil is liable to remain, also a trace of nitrate of potasium, which is probably the source of a minute quantity of nitric acid when in solution. Sugar thus impure is rejected by the confectioner, as it is found to decolorize some of his goods, and of course would be unsuitable for pharmaceutical purposes. Solubility stands next in importance to purity, for it is a well known fact that under the prolonged action of a large bulk of water it becomes inverted and this is accelerated by heat. Some pharmacists always use sugar in large crystals under an impression that it is the purest; it is, however, only equally pure with the other kinds I have mentioned, and possesses the one disadvantage of being the least readily soluble, whilst the granulated is superior in this particular to both it and the lump; indeed, in my opinion, it is the best and most convenient for preparing pharmaceutical syrups, especially as an important point we have to avoid in the preparation of these is invertion, *i.e.*, the breaking up of the sucrose molecule $C_{12}H_{22}O_{11}$, with the appropriation of a molecule of water H_2O into two molecules of glucose $2C_6H_{12}O_6$, which is the first stage in fermentation, and although this is not a necessary sequence it is much more likely to occur when the first stage of the process is already accomplished.

If we have a very soluble sugar to deal with, agitation with cold distilled water will soon produce a syrup of full density and good quality; with a less soluble one the application of heat becomes necessary. But it is better to add the sugar to the water already at the boiling point than to slowly heat the two up to that temperature, as is the usual method; we thus quickly obtain a concentrated solution and avoid the prejudicial influence of continued heat on a weak one.

Syrups containing acids are affected in the cold, but still more readily as the temperature increases. Some acids act more prejudically than others, but inversion to a greater or less extent always takes place. In 1874 Arno Behr published a table of the inverting power of acids on sucrose at various atmospheric temperatures, which being of considerable interest to pharmacists, I will here reproduce. The action of hydrochloric acid is taken as the standard at 100.

INVERTING POWER OF ACIDS ON SUCROSE.
(Arno Behr).

Acid.	211 hours 13°–17°C.	115 hours 19°–27°C.	78 hours 25°–27°C.
Acetic Acid . . .	1·2	1·3	1·6
Butyric "	...	1·9	2·5
Isobutyric "	...	2·2	2·5
Succinic "	...	3·5	4·0
Malic "	...	8·1	8·8
Citric "	8·2	9·2	10·2
Formic "	...	9·2	9·6
Lactic "	10·2	10·4	9·9
Tartaric "	11·4	13·4	13·8
Phosphoric "	24·2	25·8	26·9
Oxalic "	49·6	53·1	54·5
Sulphuric "	83·9	83·1	84·2
Hydrochloric "	100·0	100·0	100·0
Nitric "	100·1	100·4	100·1

It will be seen that acetic acid has the least, nitric acid the greatest, inverting power, and that phosphoric acid stands high in the scale.

The bottles from which syrups are dispensed should be well washed each time before they are refilled; or, to follow the example of some of our continental brethren, syrups, such as those of orange, lemon, etc., should when prepared be put into half pint or one pint bottles (quite full), and stored in a cool dry place with little if any light, one bottle being kept in the pharmacy for use and *replaced* not refilled, by another when empty, thus avoiding the admixture of the fresh supply with a small quantity of that which has been exposed to air and warmth for some time and which has usually undergone a partial change, otherwise the proverb that "a little leaven leaveneth the whole mass" is fully illustrated by the result. There are certain syrups which from being rarely used are sometimes found to be spoilt when required, such for example as syrups of saffron and roses. This difficulty can readily be overcome by making concentrated liquors from the saffron, roses, etc., respectively, filtering on to granulated sugar contained in a water-bath, and drying with frequent stirring at a gentle heat. These products keep well in closed bottles, and the syrups can readily be extemporized from them as required. There are doubtless several others which could with advantage thus be prepared, but the above are the only ones with which I have had any length of experience.

Sugar is not only useful in preserving the protosalts of iron as syrups, but added to the water in which they are precipitated and with which they are washed, it exercises a protective influence; this possibly arises from the fact that saccharated water holds less air in solution than pure distilled water, and although sugar, as I have mentioned, acts readily on iron in the presence of oxygen, it does not combine with its oxide or salts.

I wish these remarks to be regarded not as an attempt to exhaust the subject, but rather as giving some of the results of my experience, with a view of eliciting further information and stimulating inquiry into a subject which to my mind merits a larger share of attention than it has hitherto received.

———

Dr. Oxland said he spoke as an old sugar refiner, though he had been out of the trade for many years. It was quite as possible to obtain pure sugar in this country, and even in that particular town, as in any part of the world. On examining the sample of Say's sugar now exhibited, he had reason to believe that it was decidedly inferior to the best English sugars. English refiners considered it *infra dig.* to use ultramarine for producing a good colour, but this was constantly done on the continent, in order to disguise imperfections in the liquoring operation, which was the final washing in the centrifugal machine or otherwise, by which the last trace of impurities ought to be carried off. The fact of potash, silica and lime, having been found in the minute proportion referred to, would rather tend to show that ultramarine had been used. With regard to beetroot sugar, the very finest lump could be produced from it, and he had been the first to use it exclusively for that purpose in England. Before the employment of superphosphate of alumina as a refining agent in place of blood, only fifty per cent. of beetroot sugar, with an equal proportion of cane sugar could be used, but now the finest loaf sugar could be made from beet alone, and he did not believe it would be possible to detect any difference chemically between it and cane sugar; the crystals however were a different shape being about double as long as broad instead of being nearly square, and having one or two lines down the middle.

A vote of thanks to the author was passed. The next paper read was on—

The Proximate Principles of the Narcissus Pseudonarcissus.

BY A. W. GERRARD, F.C.S.

The natural order Amaryllidaceæ, to which the plant forming the subject of this notice belongs, has a reputation for producing many plants possessed of poisonous or active physiological properties; some are reported narcotic, others emetic and diuretic whilst *Hæmanthus toxicarius*, a native of Cape Colony, is stated to be used by the Hottentots for the purpose of poisoning their arrow-heads. As several of the Amaryllids are readily obtainable in this country, and our knowledge of their composition and physiological action being of a most meagre and unsatisfactory kind, I deemed them a matter worthy of investigation, more especially as Professor Sydney Ringer engaged to undertake physiological experiments with the substances I might obtain.

Narcissus Pseudonarcissus, or daffodil, is an early spring flower, well known by its funnel-shaped perianth and golden corona, growing uncultivated in many parts of England. All parts of the plant are reputed poisonous, especially the flowers. At the time I undertook its examination, bulbs only were obtainable; to these, therefore, my observations were confined.

My first experiments were made upon a few bulbs, and gave indications of the presence of a substance possessing the characters of an alkaloid, and likewise therapeutic properties of an interesting order. A supply of twenty-six pounds of daffodil bulbs were furnished me, and at once reduced to a pulp, then exhausted with 84 per cent. alcohol. From the tincture obtained the spirit was removed by distillation, and the residual extract having some oily looking substance floating on its surface was washed with ether; the ether removed and evaporated gave a residue of oil and resin, odorous, acid, and partly volatile.

The mother extract was now made alkaline with potassic hydrate, and again treated with ether. The ether layer decanted and allowed to spontaneously evaporate, yielded a yellowish brown viscous substance, the surface of which displayed several masses of crystals; these masses were half an inch in diameter and composed of extremely delicate needles radiating from a common nucleus; the reaction of the mass was alkaline. I was much pleased with its appearance and expected to find the crystalline matter an alkaloid, but in this I was disappointed, as the following experiments will explain.

A small quantity of water was added to the partly crystalline mass, and sufficient nitric acid to render it neutral; the crystalline matter remained undissolved, but imbedded in a blackish oily substance; and the separation of the crystals from the oily matter has defied my best efforts. Benzole, carbon disulphide, chloroform, and alcohol, each dissolved the oil, likewise the crystalline body; when the matter was shaken with water a few crystals disentangled themselves, but not in sufficient quantity for a proper examination. A few of the crystals obtained were placed upon a watch glass and treated with solution of caustic potash, which only dissolved them when warmed. A few crystals placed in the mouth appeared tasteless. The yield of this crystalline substance which I am inclined to regard as a neutral principle I should imagine was not more than five grains from the whole of the bulbs employed, and as I had now consumed it all in my experiments, I was compelled to discontinue its examination.

My attention was now directed to the nitric acid solution of the alkaline matter; it possessed a decided bitter taste, and gave, from moderately strong solutions, precipitates with phosphomolybdate of soda and nitric acid, tannic acid, iodohydrargyrate of potassium, perchloride of platinum, sulphocyanide of potassium, and solutions of potash, soda, and ammonia; with the latter it dissolved in excess. By these characters, therefore, I am able to establish the identity of an alkaloid, which, provisionally, may, I think, be termed pseudnarcissia. I have found it soluble in water, ether, alcohol, chloroform, and benzole, from none of which solutions has it crystallized, but formed a transparent yellowish brittle substance. The yield of this alkaloid is very small, about six grains from the pound of bulbs, but it must be borne in mind that fresh bulbs consist very largely of water, and that alkaloids very soluble in water are never completely extracted from their mother liquors by ether or like solvents.

The whole of the nitrate of pseudnarcissia being required for Professor Ringer's experiments, I was unable to carry its purification to a state of completeness, neither could I prepare its compounds with acids as I would wish to have done; a few drops of the nitrate solution placed upon a watch glass gave in about fourteen days some indifferent granular looking crystals.

After exhausting the parent liquor of its alkaloid soluble in ether it was further shaken with chloroform, which solvent extracted some resinous colouring-matter and a minute portion of alkaloid, which latter was soluble in ether, and therefore I concluded to be pseudnarcissia. The same experiment as this latter was repeated with benzole and carbon bisulphide as the solvents, but they gave no residues worthy of notice; these experiments were undertaken as a search for other principles, which ether might not have abstracted, and which the different physiological actions of the daffodil extract and alkaloid point out as being present.

After exhaustion of the bulbs with spirit they yield to water a sweetish viscous extractive, not reducing alkaline cupric tartrate in the cold, but doing so immediately on boiling. Spontaneous evaporation of a solution gave no crystals. Various reagents were applied to this substance but with no apparent effect except the following, which is especially worthy of notice. The extract made semi-fluid, with water and caustic soda added, formed a yellowish mass, no longer fluid but semi-solid, and on agitation a most powerful odour of acetous ether was evolved mingled with that of ammonia. The nature of this substance I cannot conjecture; I have plenty at my disposal and should be glad to hand it to any gentleman who would undertake its further examination.

Professor Ringer's experiment upon the physiological actions of the alkaloid and spirituous extract—which will be published in detail elsewhere—show, that on warm-blooded animals the alkaloid given hypodermically in doses of three or four grains causes profuse salivation, with running at the eyes and nose, also free vomiting and slight diarrhœa, the motions sometimes being slimy. On man it was administered by the mouth and found to act as on animals; sometimes the effects on the salivary glands are most marked, at other times it produces vomiting or diarrhœa, or both without salivation; dropped into the eye it first slightly contracts and then dilates the pupil.

The extract in some respects is far more powerful than the alkaloid; thus eight to ten grains excite nausea and vomiting but produce no salivation. Hence it is very probable that the principle producing the salivation and that producing the emetic and purgative action are distinct. These latter points will be, if possible, determined, and my efforts will also be further directed to preparing the alkaloid in a pure and crystalline form.

A vote of thanks was awarded to Mr. Gerrard for his paper.

Professor Attfield said that Mr. Atkins had sent in a paper on Pharmaceutical Ethics, which he would suggest should be read the following day, without being discussed lest they should get into questions of politics, which would be beyond the scope of the Conference. He would therefore take the opinion of the meeting whether this course should be adopted.

On the motion being put it was carried *nem. dis.*, and the Conference then adjourned.

Wednesday, August 15th, 1877.

The Conference reassembled at 10 o'clock, when the first paper read was, "A Glance at the Materia Medica of Devon," by E. Smith, F.C.S.

A Glance at the Materia Medica of Devon.

BY EDWARD SMITH, F.C.S.

I trust the title of my paper will not be misunderstood. It is not, of course, my intention, even were it possible within the limits of a short paper, to enter minutely into all the details connected with the various products of the county. Neither do I pretend to anything but a very incomplete knowledge of the subject. In this respect I must claim your indulgence, trusting that, as there must be many members present who have probably both a wider range of experience and more intimate knowledge of the county than I can lay claim to, some of you will fill up the gaps necessarily left open by giving us the results of your own observation and experience. I thought even a cursory glance at a subject of this nature might not altogether prove uninteresting to the many members attending the Conference from distant counties.

The pharmaceutical productions derived from the fauna of Devon are of the usual character. Taking the pharmacopœia chiefly as a guide we find mentioned in that work eggs, suet, milk, lard, cod liver oil, ox-gall, honey, etc. In eggs, suet, and lard, we have nothing special to offer. Our oxen are well known as "facile princeps" amongst their species, although our fel bovis is much as other ox-gall. Our milk does not differ materially from the general character of that secretion. It appears to have that singular affinity for water that seems almost to amount to a function. Our clotted cream perhaps deserves a special word. Devonians say you can't get cream out of Devon. But then the Cornish and Somersetshire folks say the same of their respective counties. It is, I believe, on record that a couple of weary travellers, having unwittingly crossed the border of Devon into Cornwall, and asking amongst other good things for a bowl of Devonshire cream, were supplied by the buxom hostess, much to the surprise of her visitors, with a mug of very attenuated milk. A vehement remonstrance brought out the truth, "Oh, you waants *Carnish* crame, I wandered at your askin for that puer Denshire stuff!" I am bound to say, however, that this Devonshire "stuff" is rather a toothsome tidbit, and especially so when strawberries are ripe. Although the cod-fish abounds on the Devonshire coast, I do not know of any important maker of cod liver oil. With regard to honey, the amount produced in Devonshire is not nearly so great as might have been anticipated. Many of the smaller farmers and cottagers possess hives, but only to a very limited extent. Considering the great and special advantages offered by the moorlands, it is, I think, much to be regretted that a production, capable of being readily developed into a profitable business, is not more cared for and cultivated. Some few years ago I made an attempt to collect the honey in the Chagford district, but I found the amount procurable was too small to enable me to enter into any satisfactory business arrangements.

Passing now to the flora of Devon, we find here more material to work upon.

Of the Ranunculaceæ, *Aconitum Napellus* is found in patches in various parts of the county, though not to such an extent as formerly. Some few years ago it flourished luxuriantly in Dartington Park, near Totnes, but it has now disappeared from thence, owing, I imagine, to the poisonous character of the plant having been discovered. It is still to be found on the banks of the Dart, especially near Stoke Gabriel and near Staverton.

Of the Papaveraceæ, *P. rhœas* is common in the cornfields and roadsides. *P. somniferum* is not found, so far as I know.

The Cruciferous plants are represented by *Cochlearia armoracia*, common in the gardens, and sometimes in waste places amongst garden refuse. The three mustards are fairly common. *Sinapis alba* grows luxuriantly on the limestone soils; *S. arvensis* is common in cornfields, and *S. nigra* in the fields and roadsides.

Viola odorata, of the Violaceæ, is found plentifully; a white flowered variety is fairly common.

Of the Linaceæ, *L. usitatissimum* is found pretty abundantly. It grew luxuriantly during the summer about a mile from Torquay on the Paignton Road, also on the "New Cut," Torquay, and is found also near Totnes and Exmouth.

L. catharticum has been gathered near Torquay, and is also met with near Brixham and Paignton.

Rhamnaceæ.—*Rhamnus frangula* is found forming a part of the shrubs of the hedgerows, near Paignton and Torquay. It is not uncommon in the Moreton and Tavistock districts.

Rh. catharticus is not, so far as I am aware, found in Devon.

Sarothamnus scoparius, of the Leguminosæ, abounds nearly everywhere throughout the county.

Of the Rosaceæ, *Rosa canina* is pretty ubiquitous in the county. *Potentilla tormentilla* is found frequently in heathy places about Dartmoor. *Prunus laurocerasus* grows luxuriantly in the gardens. In some parts of the county the fruit is collected by the poor people and eaten as a delicacy, notwithstanding that Bentley says "the fruit is poisonous." It is also made into a most delicious jam or conserve.

The most important Umbelliferous plants are *Fœniculum vulgare*, found plentifully on the railway banks between Paignton and Torquay, and on the roadside between

Teignmouth and Newton, and *Conium maculatum*, which grows abundantly in the lanes around Torquay, and many other places in the county. It may be gathered to an almost unlimited extent.

Caprifoliaceæ.—*Sambucus nigra* is the only medicinal plant of this order, and is common throughout the county.

Valeriana officinalis, of the Valerianaceæ, grows on the swampy ground near Watcombe, also in the neighbourhood of Newton, Tavistock, Plymouth, and other places.

The Compositæ are represented by *Anthemis nobilis*, a somewhat plentiful plant, being common near Torquay, Paignton, Milber Down, Bovey, and Tavistock.

Leontodon taraxacum is common everywhere. The roots of plants growing on limestone soils are not unfrequently dwarfed, and forked into several smaller rootlets, very unlike the strong robust roots I have often gathered in the midland counties and elsewhere.

Of the Solanaceæ, *Solanum dulcamara* grows in the hedgerows almost universally. *Atropa belladonna* is a very rare plant. It has been found, I believe, near Combe Martin, North Devon. I have not met with it in Eastern Devon. *Hyoscyamus niger*, on the contrary, grows most luxuriantly in many parts of the county. Near Torquay, at Paignton, Dartmouth, Slapton Sands, and other places, an almost unlimited quantity could have been gathered during the season just passed. The Pharmacopœia directs the leaves of this plant to be gathered "when about two-thirds of the flowers are expanded." Speaking now of the wild plant, I do not agree with this. My experience points to an earlier gathering. If the collection be left until the plant has partly flowered, by far the largest and best leaves have, to a great extent, withered and become yellow and unfit for use. An earlier collection saves all these. The resulting dried herb is, in my opinion, better in colour and in efficiency than if gathered later. Dr. Christison remarks, with respect to the activity of the leaves, "I have found them sufficiently active even in the spring *before* the appearance of the flowering stem."

Datura stramonium is but rarely met with. Last year it flourished in a field between Paignton and Totnes, but has not this summer appeared in the same place. Several years ago, a luxuriant patch grew near Stoke Gabriel on the Dart. This has since disappeared.

Scrophulariaceæ.—*Digitalis purpurea*, locally known as flap-dock, grows abundantly in every part of the county. In the woods near Moreton Hampstead it may be seen in most luxuriant masses, and when in bloom forms a charming addition to the landscape. The leaves of this plant should, I think, be collected before the plant begins to flower.

The three mints, *Mentha piperita, M. viridis, M. pulegium* represent the Labiates. *M. piperita* is found at Cockington, near Torquay, also at Ashburton, Chudleigh, and other places.

M. viridis is somewhat rare, found in marshy places around Exmouth. *M. pulegium* is found in swampy places, as Forde Bog, near Newton. This herb is called in the Devonshire dialect "organs" or "argans." The origin of this word I do not know. In a poem in the Devonshire dialect, published in 1867, these lines occur :—

"Jist put her tooties in hot watter,
An' gi'er a few strang *argans* arter,
Or else some featherfoul."

That is, "put her toes in hot water and give her a little strong pennyroyal tea after, or else some feverfew."

Daphne laureola alone represents the Thymelaceæ. It is found in the woods between Paignton and Totnes, and several other localities.

Cannabinaceæ.—*Humulus lupulus* is occasionally found, apparently wild, in the Cockington lanes near Torquay; it flourishes also at Goodington, Paignton, Brixham, etc.

Ulmaceæ.—*Ulmus campestris* and *Ulmus montana* are common throughout Devon.

Salicaceæ.—The various willows flourish abundantly throughout the county.

Cupuliferæ.—*Quercus robur* is very abundant in our woods.

Moraceæ.—*Morus nigra* is found cultivated in sheltered gardens in Torquay and neighbourhood.

Coniferæ.—*Juniperus sabina* also flourishes in many gardens and shrubberies as a cultivated plant.

Colchicaceæ.—*Colchicum autumnale* is a rare plant, at least in Eastern Devon. At one time it flourished near Torquay, but has now disappeared.

Filices. — *Lastrea filix-mas* flourishes luxuriantly throughout the county, and is a very common plant.

With regard to the Inorganic Materia Medica, I propose to restrict this paper to a notice of the *minerals* of Devonshire ; which are both numerous and important. For our purpose (and including in this those of more strictly chemical interest), they may be divided into two classes.

α. The rarer minerals, consisting of ores containing antimony, bismuth, cobalt, gold, tungsten, uranium, and mercury (?)

β The commonly occurring minerals, consisting of ores containing arsenic, sulphur, copper, iron, lead, silver, manganese, tin, zinc, barium, and the mineral kaolin.

α. Of the rarer minerals, antimony occurs in several parts of Devon, but only to a very limited extent. Antimonite is found near Bovey Tracey. It was worked for a short time, but the venture was not financially successful. Bismuth ores are occasionally met with, not in sufficient quantity, however, to become marketable.

Cobalt occurs sparingly in several localities. The largest yield on record from one mine occurred in 1820, when, according to Worth, "1700lbs. of ore of inferior quality were raised and sold from Wheal Huckworthy, near Sampford Spiney."

Native gold occurs, too, but in small quantities. It has been found in the beds of the Dartmoor streams, and also by Mr. Flaxman in the hæmatite of North Molton. The working of this hæmatite for gold turned out a financial failure.

Tungsten, in the form of wolfram or tungstate of iron and manganese, is occasionally met with in tin mines, accompanying the tin oxide, and owing to its high sp. gr. greatly impedes the operations connected with ordinary tin dressing. Uranium as pitchblende has been found near Tavistock in very small quantities only, not sufficient to become a marketable production.

I do not think mercury can rightly be considered as a Devonshire metal. A few years ago, some excitement was caused by the announcement in the local papers that mercury had been discovered in the rocks near Exeter. I was sufficiently fortunate to obtain a sample, which was undoubtedly metallic mercury. It seems, however, to have been thrown there, and I am afraid the whole thing was a hoax.

β. Of the commonly occuring minerals. Arsenic is found abundantly in many parts of the county, as arsenical pyrites, or arsenical mundic, or mispickel—arsenio-sulphide of iron. Until a comparatively recent period, arsenical pyrites was considered valueless, or nearly so, but the great demand for arsenic of late years has vastly stimulated its production. At the present moment something like 3000 tons of arsenious acid per annum are produced in Devonshire, the Devon Consols Mine alone producing from 150 to 200 tons a month, enough to destroy the lives of perhaps 500 or 600 millions of men. Almost any day there may be seen at this one mine, packed ready for sale, sufficient arsenious acid to destroy every living creature on the face of the earth—a somewhat startling reflection ! Of course comparatively little of this arsenious acid is used in medicine. As far as I can make out, large quantities are shipped to the continent, Germany chiefly, where I believe it is employed in the aniline colour manufactories. The arsenious acid is obtained from the mispickel by roasting the pulverized ore in a reverberatory furnace, with free access of air. The vapours are conducted into long, nearly horizontal zigzag chimneys, in which the arsenious acid is deposited as a grey or black powder. It is removed from time to time, and refined by resublimation. The sulphur which is evolved as sulphurous anhydride, at the same time, is generally allowed to escape into the atmosphere.

Sulphur occurs very abundantly in combination with iron, as iron pyrites or mundic, FeS_2. Mundic is not accounted of much value by the miner, and although it contains about 53 per cent. of sulphur, it is not, so far as I am aware, utilized to any great extent. The little used is employed for the manufacture of sulphuric acid and ferrous sulphate.

Copper.—This metal is found chiefly as sulphide and sometimes as oxide. It occurs very abundantly in some parts of the county. It is worked in the neighbourhood of Tavistock, Buckfastleigh, and North Molton. The ores of copper have, in all probability, been mined from the earliest times, yet it is only during the present century that copper mines have become a really important branch of national industry. Devon Great Consols Mine was, at one time, the most productive and profitable copper mine in Great Britain. On an original outlay of about £1000, the mine is said to have realized in twenty-one years over £1,000,000 sterling in net profits, the Duke of Bedford, as mineral lord, receiving in that period the princely sum of £200,000 in dues. This mine is still working, and although not yielding such profits, is making large returns, especially in arsenious acid. The total production of copper ores varies almost yearly, being greatly influenced by the market value of copper. None of the ores are smelted in Devonshire. They are simply "spalled" or dressed, that is the gangue or matrix partly removed, and then shipped, chiefly to Swansea, to be smelted.

Iron ores abound in many parts of Devon; the chief are hæmatite, chalybite, limonite, spathic or carbonate, magnetic oxide, and micaceous iron. Hæmatites are worked near Brixham, Sharkham, and Smallacombe, also at Hennock, and Chudleigh. A brilliant micaceous hæmatite raised at Brixham is ground with linseed oil into a paint and is largely used for covering iron work; it is commercially known as "Torbay paint," and is used by gas and water companies, and in several government departments. Spathic iron ore is found in the Teign valley. Micaceous ore occurs near Lustleigh; it was formerly, under the name of Devonshire sand, used as a pounce; its chief use now seems to be for mixing with graphite and as a lubricant. Magnetic oxide was worked years ago at Haytor, near Ilsington, but of late years it has been discontinued. Although Devonshire is comparatively rich in iron, the working of the mines seems to have lacked spirit and enterprise, or in some way to have been discouraged, for the total yield of all the Devon mines in 1874 was but 21,313 tons. Succeeding years have shown a falling off, even from this small yield.

Lead occurs chiefly as sulphide or galena. The Devonshire lead mines have been famous from the most remote times. They are said to have been worked by the Romans. There is a record of their having been worked, more particularly for the silver contained in the lead, in the reign of Edward I., and at that time were accounted profitable. The ancient silver lead mines of Combe Martin were re-opened in the time of Elizabeth, and after yielding enormous profits were again closed, to be within the last few years again re-opened with, it is said, satisfactory results. The Lord Mayor's cup is made of silver extracted from these mines.

Silver.—Native silver is found occasionally, but in small quantities only. The chief source is the argentiferous galena, some of which carries as much as 120 to 140 ounces of silver to the ton. In 1857, 50,000 ounces of silver were produced in the county, since which time the amount seems to have gradually decreased. Very recently a silver lode has been opened up at Wheal Newton, which promises to be exceptionally valuable, some parts of the lode are said to yield as much as 2495 ounces to the ton. A not inconsiderable amount of silver has, of late years, been obtained from a cupreous iron pyrites found in several places in the county. This ore carries from 2 to 4 or even 6 ounces of silver to the ton, as well as from 2 to 3 per cent. of copper. At New Consols Mine ranges of furnaces, lixiviating and precipitating tanks have been erected, and for some time worked to obtain the silver and copper. The process followed is an old and simple one. The ore is roasted with about 10 per cent. of salt to convert the metals into chlorides; it is next boiled with solution of salt, in which the silver and other chlorides dissolve. This solution after filtration is passed, whilst hot, into tanks containing scrap iron, which causes a deposition of the copper and silver in a metallic state, known as cement copper or silver. The silver is afterwards separated from the copper at the refineries in the usual way. Other processes have been devised whereby the silver and copper are deposited, separately, by galvanic agency.

Manganese is mined very largely in Devon. The grey and black oxide are the two ores worked, the latter—the binoxide—is by far the most abundant. It is found chiefly in the district around Milton Abbott. At times the ore is found in very grotesque forms, frequently having the appearance as though it had been fused. The ore undergoes a process of dressing, and is then shipped—chiefly to Glasgow—where it is in pretty constant demand. Devonshire yields by far the greater part of the native manganese of Great Britain.

Tin.—Although there are evidences of very ancient works indicating that tin has been mined from the remotest times, almost in every part of Dartmoor—the only part of the county where tin is found—yet the amount raised is very small as compared with Cornwall. The old stannary towns were Chagford, Ashburton, Tavistock, and Plympton. The three first are noted in a charter, dating about 1305, and the last was constituted in 1328. Up to this period, Devonshire appears to have been the principal tin yielding county, but shortly after this Cornwall took the lead, and still retains it. The only ore of tin raised is the binoxide, or cassiterite.

Zinc occurs as blende or black-jack in small quantities, in many mines, but the amount produced in Devon is exceedingly limited, and certainly not of commercial importance.

Barytes occurs as sulphate in several parts of the county. In the Teign valley it has been worked. Its use appears chiefly to be as an adulterant of white lead. The amount raised is comparatively limited.

Kaolin, the last of the minerals I have to notice, is derived from granite, is in fact the insoluble residue of the feldspar of the granite. Kaolin may perhaps not seem to have any very prominent pharmaceutical interest, still there can be no doubt that, as chemists, we are greatly indebted to this material in the matter of crucibles, evaporating dishes, and such like. But over and above this there is one paramount reason which induces me, in the midst of this gathering of eminent pharmacists, to especially emphasize this simple mineral kaolin, and yet not the kaolin, but the man who, in a generation gone by, discovered in this mineral and the moorstone commonly accompanying it, the material which forms the basis of all true porcelains, and that man was a chemist and druggist, a native of Devon, and a citizen of this very town of Plymouth in which we are now assembled. I cannot do better than give you Worth's * account of this worthy Devonshire pharmacist, by name William Cookworthy. Cookworthy "was born at Kingsbridge, April 12, 1705, and his father, who was a weaver, died when he was a lad, leaving his family in straitened circumstances. Young Cookworthy was apprenticed to a firm

* 'Transaction of the Devonshire Association,' 1876, vol. viii., page 481.

of druggists in London named Bevans; and it is stated that, in consequence of want of means, he had to walk to London to enter upon his duties under that firm. He won the esteem of his employers, becoming not only an able man of business, but an accomplished chemist, and by the aid of the firm established a wholesale drug business in Notte Street, Plymouth, at first under the style of Bevans and Cookworthy. With this firm, which, subsequently, on the admission of his brother Phillip as partner, became that of William Cookworthy and Co., Cookworthy remained connected until his death in October, 1780. He was in many respects a remarkable man, and his life is one of the most illustrious examples of men who have risen, of which even England can boast. Emphatically self-made, he had none of the foibles which frequently mark the characters of those who have been the architects of their own fortunes. An industrious man of business, a shrewd and painstaking inventor, deeply versed in the science of the day, valued in society for his geniality and power of conversation, he was at the same time, one of the simplest and devoutest of Quakers, and an enthusiastic believer in the views of Swedenborg. He was withal most absent-minded, and on one occasion, while on his way to a meeting at Exeter, was so engaged by a novel which he found on an inn table, that he never reached his destination. Yet he was, in the words of Sarah Champion, an 'eminent minister' in the Society. His benevolence was as abundant as his charity was extensive, and he had 'originality of character,' and 'a lively entertaining manner.' He was a firm believer in the divining rod, and left a treatise on its uses. In short, Cookworthy was a man of many sides, but always genial, courageous and persevering; a man who won the respect and esteem alike of high and low by his strict integrity, wide sympathies, and varied powers; one who, having set his hand to the plough, was not ready to turn back. And this was the man who, not by accident, but by patient, well-directed research, prosecuted during his business journeys, first discovered in this kingdom the existence of the china-clay and china-stone—the kaolin and petunste—which are the necessary ingredients of true porcelain; and then, not having, like Wedgwood, been bred a potter, taught himself the potter's art, and by careful study and long protracted experiments, extending over many years, reproduced in England the hard porcelain of the East, the secrets of whose manufacture he had thus attained, and gave to his country new forms of industry and new sources of wealth."

Since Worth wrote this, a stained-glass window has been placed in the new Plymouth Guildhall, to commemorate not the least one of Devon's worthy sons, and one, who in a sense is connected with ourselves, in that, like us, he was a working pharmacist, but of a generation gone to its rest.

May we, especially those amongst us who claim to be of his county, stimulated by his noble example, seek to emulate the earnestness of spirit, which seems to have pervaded his innermost nature, and prove ourselves the worthy successors of this persevering, genial, sympathizing, and illustrious Devonshire pharmacist.

The PRESIDENT in proposing a vote of thanks to Mr. Smith, said this paper was a very interesting one, and it was very important in visiting the different parts of the country that the Conference should have such information brought before it as to the materia medica of the different districts.

Mr. GROVES asked if the use of the fruit of the *Prunus laurocerasus* as a preserve was at all common in Devon.

Mr. SMITH did not think it was general except in one district. He had had jam made from it from the neighbourhood of Bridford and enjoyed it immensely.

Mr. EKIN said there was a market for any amount of willow bark containing salicin, and he should like to know if any species containing it was found in Devon. Many willows did not contain any, and the one containing most was the *Salix pentandra* which was properly a northern willow; he did not know whether it had wandered down to the Devonshire moors.

Mr. COTTRELL (Shepton Mallett) thought the term "organs," did not come from any of the mints but from the wild thyme or origanum. The oil of pennyroyal was very much used in Somersetshire amongst the working classes.

Mr. SMITH said he had not much experience in willows, but he believed they nearly all grew in Devon. With regard to the word organs, it had been suggested to him before that it was a corruption of origanum.

(*To be continued.*)

Parliamentary and Law Proceedings.

ALLEGED POISONING BY TOBACCO OIL.

Dr. Thomas, deputy coroner for Central Middlesex, held an inquiry on Tuesday at the Dartmouth Arms, Dartmouth Park, as to the death of Arthur George Stevens, aged three, of 4, Spenser Road, Highgate Rise.—The father said that on Saturday week deceased was playing in the yard with other children, who were blowing soap bubbles in the air. He gave deceased a new clay pipe, which he soon broke, and returned for another. He then took down from a shelf, where it had been more than a year, the old wooden pipe now produced, which he washed, and handed to the deceased. In an hour's time deceased became sick and vomited very much, afterwards becoming very drowsy, and deadly pale. On Sunday he was worse, when castor oil was administered, and he was put to bed. After a very bad night he was much worse, and on Monday evening witness went to Dr. Rawlins's surgery, and after stating the symptoms received medicine and a powder. The deceased was seen by Dr. Rawlins on Tuesday afternoon, and twice on Wednesday, when the symptoms were much aggravated. The child continued to grow worse, and died at ten on Wednesday evening.

Dr. Rawlins, of Highgate Road, said deceased was suffering from narcotic poison when he first saw him, and the death was undoubtedly from imbibing nicotine contained in the old wooden pipe which the deceased had sucked whilst blowing soap bubbles. Two drops of pure nicotine—the concentrated essence of tobacco—would kill a man, one drop would kill a large dog, and a very small quantity would be sufficient to kill a child.

A verdict in accordance with the medical evidence was returned.—*Standard.*

Obituary.

Notice has been received of the death of the following:—

On the 9th of February, 1877, Mr. William Knowles, Chemist and Druggist, Thorne, Yorkshire. Aged 81 years.

On the 14th of August, 1877, Mr. Joseph Roake, Chemist and Druggist, Shillington, Bedfordshire. Aged 61 years.

On the 3rd of September, 1877, Mr. John Badcock, Pharmaceutical Chemist, Barnard Castle, Durham. Aged 54 years. Mr. Badcock was one of the earlier Members of the Pharmaceutical Society, having joined in 1844. He was a native of Launceston, and succeeded to the business of Messrs. Monkhouse and Sons, of Barnard Castle, in 1845. An ardent politician, he was chairman of the local liberal association, and in that capacity presented an address to Mr. Gladstone on the occasion of his visit to Raby Castle last year. Mr. Badcock was a member of the Local Board of Health, and also served his fellow townsmen with acceptance in various other ways.

BOOKS, PAMPHLETS, ETC., RECEIVED.

CHEMICAL HANDICRAFT. A Classified and Descriptive Catalogue of Chemical Apparatus, suitable for the Performance of Class Experiments for every Process of Chemical Research and for Chemical Testing in the Arts. Accompanied by Copious Notes. By JOHN JOSEPH GRIFFIN, F.C.S. Illustrated. London: Griffin and Sons. 1877. From the Publishers.

SELECT PRACTICAL NOTES AND FORMULÆ relating to Pharmacy, Materia Medica, Chemistry, Therapeutics, etc., with Hints on Dispensing. By W. CANNING. London: J. Davis. 1877. From the Author.

Dispensing Memoranda.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be conidered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.

[23]. GARGLE.—Rub the alum with ℈ij of gum acacia, then add the tincture of myrrh and triturate; lastly, add the water gradually. After standing three days the only separation is a slight brown sediment which does not adhere to the glass.

W.

[23]. No 2. First pour into the right sized bottle half an ounce of distilled water, and shake so as to wet all the inner surface of the glass; immediately thereafter add the tincture (previously measured), and agitate thoroughly, then gradually dilute the mixture with more water (shaking on each addition), until the proper quantity be reached. Lastly, add the potassic chlorate and dissolve.

No. 1. The same *modus operandi* as the above would produce a tolerable mixture in this case, but only temporarily, for soon a flocculent precipitate appears (both floating and sedimental), which cannot be diffused through the liquid by any amount of agitation; hence a slight modification is desirable in order to yield a satisfactory result. An elegant mixture may be made by using a small quantity of mucilage—ʒij mucil. acaciæ will suffice for this formula—triturating in a mortar, adding the aromatic water in successive portions, and, finally, dissolving the salt in the full proportion of fluid. Such a simple addition cannot interfere with the intentions of the prescriber, but is almost requisite to effect a presentable mixture, although it seems strange that myrrh should require a mucilaginous vehicle to suspend it more than guaiacum, considering the former contains in its composition much more gummy matter than the latter.

J. B. L. MACKAY.

[24]. PILL COATINGS.—First varnish with a solution of some resin in ether, then moisten with a very weak syrup, and roll in finely powdered French chalk.

FELIX STEVENS.

51, *Judd Street, W.C.*

[25] EMP. CANTHARIDIS.—It is not correct to paint the surface with a vesicating liquid unless ordered by the prescriber.

F. S.

[25]. EMP. CANTHARIDIS.—The manner of spreading a blister is merely a matter of taste or usage. There are various ways of leaving the surface, each of which can boast of some superiority over the others, according to the opinions of those who practise a special course; *e. g.*, some apply it to the skin smooth, others cover it with tissue paper and rub a little camphorated oil over the top. Another prevalent custom is to sprinkle pulv. cantharidis on the surface, whilst many recommend a few drops of liquor epispasticus to be poured on, and a few advocate the use of both the latter adjuncts. In my opinion the second way is the best. I prefer it because it possesses the following advantages:—1. The blister produced is clean. 2. It is less painful and more easily healed than in the case of the others. 3. The preparation is sufficiently active, even through the paper, if applied long enough. The addition of the loose powder often causes much needless irritation, owing to the minute particles of flies getting under the cuticle should the pustules break, and then the skin remains long abraded.

J. B. L. MACKAY.

[26]. UNG. HYOSCYAMI.—In answer to E. Bevan's inquiry respecting ung. hyoscyami, I beg to refer him to Beasley's 'Pocket Formulary,' where the following recipe is given:—

Fresh Henbane Leaves, bruised . . .	℔ij.
Olive Oil	℔iv ℥ix.
Wax	℔j ℥iij.

Digest for some hours, boil for a quarter of hour and strain.

F. J. BROOKES.

[26]. UNG. HYOSCYAMI is ordered in the Pharmacopœia of the Bristol Royal Infirmary as under:—

℞ Hyoscyami Foliorum Contusorum . .	℔j.
Adipis Præparatæ	℔iss.

Boil till the leaves become soft, and squeeze the product through linen.

W. GARDNER.

Bank, Barnard Castle.

Mr. Botwood and Mr. Stevens also send the above formula. Mr. Stevens remarks:—"There is also a compound ointment containing opium, acetate of lead, and powdered galls added to the above."

[26]. There is a receipt for this ointment in Beasley's 'Pocket Formulary' (1872), but it would be rather troublesome to make it on the small scale after that fashion. It might, however, be extemporized thus—

℞ Extracti Hyoscyami	gr. vss.
Unguenti Simplicis	℥i.

Misce secundum artem.

This gives a nearly equivalent strength, and would doubtless prove equally efficacious.

J. B. L. MACKAY.

[27]. AQ. CAMPH. CONC.—Please oblige by giving me a formula for preparing "Aqua Camphoræ Conc." 1 to 7 or 1 to 15. I believe such a preparation is supplied by the wholesale houses, and observe one person makes Aqua Camph. Conc. 1 to 40. I have been looking in some back numbers of the Journal, but cannot find it.

T

[28]. I should be obliged by some one informing me whether it is possible to make a lotion containing plumbi acet. and sulph. precip. (say about 1 of each in 50 or 60 parts of lotion) so that the precipitate shall lie in a compact mass at the bottom of the bottle, and when shaken up form a smooth looking mixture. All my attempts to form such a compound have resulted in the precipitate forming in a light pulverulent form, which on being shaken up floats in fragments in the water, and has a very ugly appearance.

J. Brookes.

Notes and Queries.

[553]. NON-CORROSIVE BLACK WRITING INK.—Would some subscriber favour me with a really good formula for above, inexpensive, permanent, non-corrosive, that will dry readily and flow freely? I have tried many published formulæ, and found none satisfactory in all particulars.

Quercus.

[554]. FLEXIBLE COATING FOR WOUNDS.—I am also anxious to obtain a formula for a flexible wound protecting fluid containing benzoin and, if possible, no ether.

Negator.

The Composition of Essential Oils.
The Conference Grants.

Sir,—I was unable to be present at the late meeting of the Conference, I should like, therefore, to clear up certain misunderstandings which, from the report I have just read, seem to have existed at the meeting upon the subject of my paper.

My experiments throughout have been intended to assist in the elucidation of the question, as to the chemical constitution of the various natural terpenes, as well as to ascertain what ground there is for assuming, as hitherto, the existence of so large a number of physical isomerides or varieties of the hydrocarbon, $C_{10}H_{16}$. For the moment, at least, I am not concerned with the other constituents of essential oils or only in so far as these present themselves incidentally.

It is explained in the paper itself that I have prepared from many of the terpenes certain substitution compounds by the study of which I hope to obtain evidence bearing upon the question.

Almost from the time when Liebig invented organic analysis the composition of turpentine, lemon, and similar oils has been known, and more than forty years ago the vapour density of these hydrocarbons was determined by Dumas. Mr. Kingzett's announcement that he had "demonstrated the existence of a terpene of the formula $C_{10}H_{16}$ in the oils of caraway, bergamot, lemon, etc.," is therefore superfluous. It ought not to be forgotten, moreover, that it was Oppenheim who first showed in 1871, that the terpenes in turpentine and lemon oils are converted, by removal of H_2, into one and the same cymene. Since then cymene has been prepared from various other terpenes by Dr. Wright, and has been shown by him, in conjunction with Dr. Gladstone, to have invariably the same boiling point and refractive index.

For reading my paper, or a portion of it, I presume I am indebted to my friend Professor Attfield. It is strange that he should have overlooked the express statement that I had examined the cymene from cummin oil sent to me by Dr. Wright, and that I found it destitute of rotatory power. As to the existence of several varieties of cymene I have not myself encountered any but the ordinary kind which is inactive upon the polarized ray. But it is stated by Guareschi, also by Pisati and Paterno, that cymene from oil of cumin is dextro-rotatory.

One word in conclusion about the grants of money made by the Conference. For myself I can say that it was only after repeated invitation to do so that I consented to make an application which certainly never would have been made had I supposed the vote would have met with any sign of disapproval from the general body of members. I refer to this matter not with the view of defending Mr. Muir, but because I feel myself in the same position as that gentleman, and the representations made by Professor Attfield at the meeting apply to my case equally with his.

The Conference it seems to me is stultifying itself if, by awarding a grant of money it first stamps a particular question as one worthy of investigation and then manifests dissatisfaction when the answer is presented.

William A. Tilden.

Clifton, September 10, 1877.

Castor Oil Pills.

Sir,—Is it not time that this piece of deception was done away? Its advocates say that the public are not deceived. I know better—they are. There can be no question that the originator of these pills intended the public to believe the pills were actually what they were called. I have set my face against them from the first, and when applied to for them have assured my customers that the efficacy of the so-called pills was not produced by any castor oil they contained; that it was as impossible to put me into a pint pot, as to put sufficient castor oil into two or three pills to purge. On such occasions I have seen my customers with a contemptuous glance—as much as to say, "you are not up to your business"—turn round and walk off, I suppose, to another druggist more willing to lend himself to the deception.

There is not another business which can be so entirely carried on in an honest and honourable way as ours; why should we lend ourselves to barefaced fraud, when there is really no temptation to do so?

A Druggist for nearly
Half a Century.

H. P.—The books which are the subject of your inquiry were published thirty years since and are now out of print.

"*Negator.*"—*Depilatory.* A strong solution of sulphuret of barium made into a paste with starch, applied to the hair and allowed to remain five or ten minutes and then scraped off with a knife.

R. S. T.—The quantity of citric acid obtainable from lemon juice varies with the quality of the juice. First class juice contains about 12 ounces per gallon. See Mr. Warrington's paper on the Manufacture of Citric Acid, *Pharm. Journ.* [3], vol. vi., p. 768.

J. Wearing.—(1) Phosphorus is not a poison within the meaning of the Pharmacy Act, 1868. (2) Communicate with the Registrar upon the subject.

T.—Your communication shall be forwarded to "Subscriber."

W. Greig.—*Salicin.*—Erdmann's process is as follows:—Sixteen ounces of the bark are macerated twenty-four hours in four quarts of water, mixed with two ounces of lime, and the whole is then boiled for half an hour. The process is repeated with the residue. The decoctions having been mixed and allowed to clear by subsidence, the clear liquor is decanted, concentrated to a quart, digested with eight ounces of bone black, filtered and evaporated to dryness. The residue is exhausted with spirit containing 28 per cent. of alcohol, and the tincture evaporated to crystallization. The impure salicin is again dissolved, treated with animal black and recrystallized. Erdmann in this way obtained 300 grains of salicin from 16 ounces of *Salix pentandra* bark.

Communications, Letters, etc., have been received from Mr. Smith, Mr. Siebold, Mr. Edden, Mr. Crook, G., T., Verity, Syrupus, Country Dispenser.

THE ACID OF WILLOW BARK.

BY D. B. DOTT.

The chemistry of the willow seems to have been little studied, and what attention it has received has been almost entirely devoted to its active principle, salicin. All the information I have been able to obtain regarding the constituents of the bark is very meagre, the majority of works on chemistry and materia medica merely mentioning that salicin is extracted therefrom; while, curiously enough, the 'Pharmacographia' of Flückiger and Hanbury omits all notice of the subject. Neligan states (authority not given) that the bark contains resinous matter, gum, chlorophyll, tannin, an organic salt of magnesia, and salicin; and that is as complete an account as I have found in any of the other books.

When an infusion of willow bark is made the liquor is distinctly acid to litmus. In the preparation of salicin by Erdmann's process this acid is neutralized by the excess of lime, and the salt thereby formed passes into solution. On evaporating to dryness and exhausting the residue with spirit the salt is redissolved and remains in the spirituous solution after the salicin has crystallized out. The salt may be obtained by distilling off the spirit and allowing the residue to crystallize. These crystals are then purified by recrystallization from water. Thus prepared the lime-salt separates in the form of a cauliflower-like mass composed of radiate groups of prismatic crystals.

A portion of these crystals when heated fused, and inflamed, left a residue of calcic carbonate, indicating an organic salt of lime. It was found that the substance lost weight but slowly in the exsiccator, and likewise in the water-bath. A portion of the air-dried salt was therefore dried in the air-bath at 130° C. 9·140 grs. lost 2·745 grs.=30·03 per cent. In another determination with a different crop of crystals 7·85 grs. lost 2·275 grs.=28·98 per cent. A quantity of the salt was then incinerated in a platinum crucible, the residue being treated with excess of sulphuric acid and the crucible again ignited. 6·41 grs. gave 4·00 grs. $CaSO_4$=1·176 grs. Ca=18·34 per cent. In the second determination 6·12 grs. gave 3·82 grs. $CaSO_4$=1·12 grs. Ca=18·35 per cent.

One or two methods for preparing the acid were tried, the following being the process finally adopted:—To a solution of the lime-salt in water solution of oxalic acid is added—not in excess. The precipitate is then separated by filtration, the filtrate concentrated and extracted with ether, which dissolves the acid. The ether being now driven off, a syrupy solution of the acid is left. A few ounces were prepared by this method and placed over sulphuric acid under a bell-glass for two days. The acid then remained in the form of a syrup, almost odourless, with an intensely sour taste. As in these respects it exactly resembled lactic acid, and seeing that the calcium salt in its crystalline form and in its percentages of H_2O and Ca corresponded with calcic di-lactate, there could be little doubt that the acid under examination was lactic acid. To make more certain, however, some further tests were applied. A little was heated in a test-tube, when water and carbonic anhydride were given off, and a residue left which shortly solidified. A portion was then boiled with sulphuric acid, which liberated an inflammable gas burning with a blue flame—no doubt, carbon monoxide. When a small quantity was heated with sulphuric acid and manganese dioxide, a vapour smelling like aldehyde was evolved. A portion of the acid was distilled and the fraction coming over above 130° C. was evaporated and treated with cold alcohol, which separated small white crystals having the form of rhomboidal plates, and in other respects resembling lactide.

From the acid as above obtained the zinc-salt was prepared by warming with excess of zinc carbonate, filtering, and allowing to crystallize. The crystals were pressed between blotting paper and exposed for a short time to the air. In these air-dried crystals the H_2O was determined by drying in the water-bath; 6·065 grs. lost 1·125 grs.=18·46 per cent. In a second determination with another crop of crystals 9·275 grs. lost 1·695 grs.=18·27 per cent. The zinc was determined in the dry salt by ignition in the blow-pipe flame; 6·33 grs. gave 2·12 grs. ZnO=33·49 per cent. In another determination 7·58 grs. gave 2·55 grs. ZnO=33·64 per cent.

The above numbers are here compared with those calculated for the normal calcium and zinc salts of lactic acid respectively—

$Ca(C_3H_5O_3)_2,5\,H_2O$.

	per cent	Found. I.	II.	mean.
H_2O . .	29·22	30·03	28·98	29·505
Ca . .	18·34	18·34	18·35	18·345

$Zn(C_3H_5O_3)_2,3\,H_2O$.

	per cent.	Found. I.	II.	mean.
H_2O . .	18·33	18·46	18·27	18·36
ZnO . .	33·38	33·49	33·64	33·56

The ZnO is too high, owing either to an impurity in the salt or to a fault in the analysis; but I had not time to examine into the matter. The zinc-salt crystallized in four-sided truncated prisms, which were insoluble in alcohol.

I am unable to state from what species of *salix* the acid was prepared but as all the samples of bark I have examined give acid infusions, it is not improbable that lactic acid exists in all the members of the Salicaceæ.

SOME EXPERIMENTS ON THE PHYSIOLOGICAL EFFECTS OF COCA.*

BY E. B. SHUTTLEWORTH.

In introducing this subject it will not be necessary to enter into any account of the effects of coca as observed by residents and travellers in South America. Detailed statements are to be met with in many well-known books of travel, and of late, have been frequently collected together and published. It may be noticed that all authorities agree that coca is a most powerful drug, and that, for ages, it has proved to the native Indian tribes an incalculable blessing. At the present time, in South America, the annual consumption of the leaves cannot fall short of 100,000,000 pounds—a fact in itself sufficiently suggestive and conclusive.

Of the effect of coca on English-speaking people, in Europe and America, the evidence is not so satisfactory. Some experiments have been made, and reported, in which the drug has apparently fulfilled the expectations which were entertained regarding it; while, on the other hand, it has as often been condemned as useless, and, perhaps,

* From the *Canadian Pharmaceutical Journal*, August, 1877.

inert. The statements of Sir Robert Christison, as given in his address before the Botanical Society of Edinburgh, may be taken as representing one side of the case; those of Weston, the pedestrian, the other. In both the evidence is strong but contradictory.

During the past year, and part of the present season, an opportunity has been afforded of testing the merits of coca on a somewhat extensive scale. In the spring of 1876, a number of gentlemen connected with the Toronto Lacrosse Club commenced using coca with a view to the prevention of the fatigue incident to a game of which violent bodily exertion forms so large a part. The result was so satisfactory that fifteen o sixteen players, nearly all connected with the "first twelve," used the leaves at all the important matches played during the season. These were some ten in number, and sometimes lasted for many hours. As this club held the championship of the world, and maintained it throughout, against all comers, Indians and white men, it may well be imagined that the play was of no light character, and that the games were very hardly contested. At one of these, which took place in the middle of summer, the effects of the drug were very strongly marked. The day was exceedingly hot, the thermometer marking 110° F. in the sun. The antagonists of the club were men of sturdy build, of good physique, well trained in the game and, in general, connected with the mechanical trades, or with out-door avocations. In the latter particular they were in strong and apparently unfavourable contrast with the players of the Toronto club, whose occupations were all of a sedentary character. However, at the close of the day, during a short interval of rest between the games, I remarked that the men of the rival club were so thoroughly exhausted that it was with the utmost difficulty they could be roused by their field captain to take part in the concluding game, while the coca-chewers were as elastic and apparently as free from fatigue as at the commencement of play.

Before referring to the statements of the players themselves, I may explain that such evidence may be accepted with confidence, as emanating from gentlemen capable of forming correct conclusions. Without individualizing or making personal references, I may say that all the experimenters belong to the most respectable class of society, are educated and intelligent, and several of them occupy high professional positions.

At the commencement of every match, about a drachm to a drachm and a half of the leaves was served out to each man. This was chewed, in small portions, during the game, the saliva being, of course, swallowed. On first taking the leaves a sensation of heat and dryness was produced in the throat. This was relieved by washing out the mouth, or gargling with water, after which the desire for water was no greater than usual. Soon after, a sensible augmentation of muscular force, and a general feeling of invigoration were realized, and continued to be felt throughout the game, so that fatigue was wholly, or in great part, resisted. The pulse was observed to increase in frequency, perspiration was augmented, but no mental effect was noticed, save the exhilaration of spirits always attendant on the exercise of well-strung muscles, and on the excitement of play. No disagreeable after effects were realized. The leaves were chewed without the addition of lime or other alkaline matter.

As a summing up of the trial, extending over nearly a year and a half, I may say that the majority of the experimenters are strongly in favour of coca—some most enthusiastically so—while two or three out of the number remain indifferent, having derived no direct or apparent advantage from its use.

An athlete connected with the gymnasium in this city is in the habit of taking coca occasionally, and with great benefit. At a recent exhibition he administered to a companion a quantity of the leaves. These were chewed carelessly, and without much thought or faith as to the effect. The invigorating qualities of the dose were such as to wake the curiosity of the patient, who afterwards declared that not only was he free from fatigue, but that during the exhibition he felt unusually elastic and strong.

During the last seven or eight years I have often tried the effects of coca, both on myself and other persons, and I am inclined to think that the drug may be classed in the same category with tea and coffee, but that its effects are more strongly marked. This view has also been advanced by Dr. Pigeaux, of Paris, who made many experiments with fresh leaves submitted to him by the Society of Acclimatization. He, however, observes that he found it less exciting to the nerves than either tea or coffee, but its action over the heart is twice that of the latter and four times that of the former. Mons. Colpaert says that the brain is also affected. Persons using coca for a great length of time, and in excess, are ultimately reduced to a complete state of mental imbecility or idiotcy.

In South America, particular care is taken to procure the leaves in as fresh a state as possible, and many writers have ascribed the want of effect to the use of old leaves. I have no doubt but coca deteriorates by age, as will also tea and most medicinal leaves; but I am certain that it does not become wholly inert, if preserved with care. I have now in my possession a quantity of coca which I know to be at least eight years old, and it will still produce its characteristic effect. The leaves used by the lacrosse players were as fresh as they could be obtained in New York, where the price is about two dollars a pound.

Coca may be substituted for tobacco by those who chew the latter, and the habit may be thus conquered without great discomfort. I much question, however, whether such a change would be advisable, and know not which would be least injurious. I am, however, confident that coca has uses to which it may with advantage be put; and though I do not for one moment encourage or countenance any idea in favour of the continued use of the drug, and I should be very sorry to be instrumental in furthering its introduction for such a purpose, yet, I think that on certain occasions, as those indicated, it will undoubtedly prove useful.

COMPOUND OF THYMOL AND QUININE.*

BY C. PAVESI.

The author reports that he has obtained a crystalline compound which he calls citro-thymolate of quinine, by treating quinine with thymol and a small quantity of citric acid. Four parts of quinine are placed in a matrass or flask with 6 parts of oil of thyme and a sufficient quantity of alcohol to effect complete solution. The mixture is heated in a water-bath for a few minutes, afterwards allowed to stand during twelve hours, and then 2 parts of citric acid in powder added. The whole is again heated, filtered, and the liquid evaporated to a syrupy consistence. Upon cooling, a yellow matter is deposited in confused crystals. This substance is treated with boiling water and animal charcoal, filtered and evaporated at a low temperature; after twenty-four hours the salt is obtained well crystallized.

This crystalline compound of quinine, thymol and citric acid, is very white, moderately soluble in cold water, more soluble in boiling water, and very soluble in alcohol. It has a very bitter taste recalling that of oil of thyme. The presence of the three constituents in the crystals can be demonstrated by the use of suitable reagents; but the exact composition has not been determined by the author.

THE BRITISH PHARMACEUTICAL CONFERENCE.

AT the Bristol meeting of the British Association Mr. VERNON HARCOURT complimented the British Pharmaceutical Conference on the position it had then attained, and spoke of its 'Blue List' in terms of praise. The Conference had earned this reputation not entirely nor even mainly by reason of its purely pharmaceutical contributions, but chiefly through the reading and publication of papers upon chemical subjects possessing much valued interest to the pharmacist. Scientific chemists were invited to become members of the Conference, and to accept grants to assist them in undertaking investigations stated to be required in the 'Blue List.' Heartily was the response made to the invitation, and a goodly amount of honest scientific work has been presented annually and in an increasing amount to the Conference. Murmurings of discontent have of late been floating in the pharmaceutical atmosphere; it is stated that the papers read at the Conference are too scientific, and more fit to be read at Burlington House than elsewhere; the active workers have accepted grants, and have contributed papers having, it is said, no interest for pharmacists. These signs of discontent made their first official appearance in some remarks made by the senior Secretary at the last meeting of the Conference. He thought that as the Chemical and Royal Societies were now making grants of money in aid of research, the Conference might discontinue to do so for purely chemical investigations. Hardly consistent with this, however, was the partially revealed request of the same gentleman that the "luminous constellation forming the committee" would continue their researches on aconitines at the expense of the Conference. Surely this subject has as little meaning or pharmacy as any of those embraced in the list at the Plymouth meeting. We say "as little" advisedly, because we contend that with few exceptions the whole of the papers were on subjects of an importance to pharmacists not to be slightly regarded. Let us go through them briefly and make this observation clear.

Mr. HOWARD'S paper possessed no practical interest to the pharmacist; it only dealt with a subject of an educational aspect, viz., the possible substitution of cinchonidine for quinine in medicine.

The papers on aconite by the "luminous constellation," and Dr. PAUL and Mr. KINGZETT concerned a subject of at least vital importance to the pharmacist, if a knowledge of drugs and their properties have any meaning at all to druggists.

Cayenne pepper is a substance both used and sold by pharmacists, and it cannot be otherwise imagined than that a knowledge of its proximate principles is acceptable to them.

The papers on essential oils by Dr. TILDEN and Mr. MUIR at least find their justification in the fact that the subjects were proposed by the Conference itself. The chemistry of essential oils must be well known before methods of detecting adulteration can be elaborated. We confess, however, that Mr. MUIR might have condensed the details of his vapour density determinations.

Pharmacists lay claim to some knowledge of botany and the chemical constitution of plants, and therefore the contributions on ivy leaves and products derived from them must have been welcome to the members of the Conference.

The "Assay of Opium" is a matter more affecting the professional chemist than the pharmacist; nevertheless, facts are always brought forward in such papers which have some value even to pharmacists.

The impurity which was described as found present in a sample of oxide of zinc is one against which too much guard cannot be taken.

Dr. SYMES' contribution of "Sugar in Pharmacy" was purely of pharmaceutical interest, while the paper on Narcissus Pseudo-Narcissus might have been valuable if it had not been premature.

Again, Mr. SMITH'S paper on the Devonshire materia medica, Mr. SCHACHT'S "Experiences of a Pharmaceutical Laboratory," and Mr. THRESH'S report on the "Pill Masses of the B. P." were eminently pharmaceutical in kind.

The note on diphenylamine as a test for nitric and nitrous acid was illustrative of facts well worth knowing, while Dr. TILDEN'S paper on "A Product of the Oxidation of Barbaloin and Socaloin," completed the study of a subject previously brought before the Conference. The research embracing the "Physiological Action of Copper present in Preserved Peas," brought forward by Dr. PAUL and Mr. KINGZETT, affected the public health and the teaching of pharmacists, and hence its fitness for the Conference could not be disputed.

Professor ATTFIELD'S paper, although previously published, had an interest, but—he will pardon us for saying it—one as remote as any of the papers read, for pharmacists.

One of the questions on the 'Blue List' of the Conference deals with the stated presence of an alkaloid in scammony root. The paper on this subject read at the Conference, negatived this assertion, and brought new light to bear upon the chemistry of scammony root generally.

Mr. GREENISH's note on "Tea Hair" contained some interesting facts, while Mr. SIEBOLD's paper on "Copaiba Testing," embraced a subject which has often been discussed by pharmacists.

Albumen is used by pharmacists for clarifying many decoctions, and hence a new process for bleaching and preserving blood albumen in a fluid state had a decided value for the meeting.

Pilocarpine has found its way into the dispensary, and hence its chemistry should not be unknown to the dispenser.

Mr. WILLMOTT's contribution was claimed to shed a new light upon the "germ theory" controversy.

It cannot be denied that from all these papers—an enviable list—the pharmacists present at Plymouth must have gathered much valuable knowledge, and if from the total number of contributions were deducted those not purely pharmaceutical, the residue would be such as would not entice a meeting together. Not only so, but the kind of information supplied by chemists and other scientific gentlemen to the Conference is such, that were it published elsewhere the Conference would sink in *status* and its members would have to seek the information in another place less easy of access; for all pharmacists who desire to keep pace with scientific progress must make themselves acquainted with all research concerning their business.

It is to be admitted as desirable that papers read at a Pharmaceutical Conference should as much as possible possess some sort of connection with pharmacy, and in that sense the observations of Professor ATTFIELD may serve as a useful hint to future intending contributors. But pharmacy is an art so largely dependent upon chemical science, that it is impossible to abstain from keeping pace with the development of that science, and it is equally impossible to say that the abstract science of to-day may not be, in some particular or other, the basis of the practical pharmacy of to-morrow.

At the same time it must not be forgotten that the contributors of the chemical and other papers are in no wise dependent upon the Conference, but *vice versâ*; the same papers, or the greater part of them, would be very acceptable at Burlington House at times, and if they had all been sent there in the past, the Conference would not hold to-day the position it boasts, with pride, to fill.

In our opinion, insufficient attention is paid to the scientific contributors at the Conference meetings, and we have long thought that some more formal vote of thanks should be passed to them than is done. For the sake of pleasing all, we would suggest that henceforth the authors of papers should summarize all facts of pharmaceutical interest in one final paragraph, so that if the papers be too scientific or too technical, a refuge and a home may be found for those who cannot or do not care to follow authors—sometimes prosy enough—through their writings *in extenso*. GIL BLAS got into trouble for reminding the Archbishop when his sermons fell off in eloquence and reasoning; the Conference should guard itself against committing the more unpardonable mistake of blaming authors for contributing requested papers which are too valuable.

SERIOUS ACCIDENT TO A PHARMACEUTICAL CHEMIST AT RICHMOND, SURREY.

Mr. HARRY LLOYD having undertaken to prepare an explosive mixture consisting of chlorate of potash, sulphur, and sulphuret of antimony, for use at the theatre, the compound spontaneously ignited with terrific effect. Mr. LLOYD lies at the Richmond Infirmary suffering intense agony from the severe burning of his face and hands; the eyes are closed and the features sadly distorted. It appears a mortar was used instead of mixing the ingredients upon a sheet of paper, the usual method.

PROPRIETARY MEDICINE LICENCES IN JAPAN.

IN a recently issued report on the Finances of Japan we are told that a new licence for druggists was imposed last January. It is described as not affecting the drugs and medicines used and prescribed by the medical profession, its object being to restrict the sale of medical compounds partaking of the character of quack medicines, in which, as well as in the charms against every description of disease and misfortune sold at every temple, the Japanese seems to have great confidence. To obtain permission to make and sell these medicines, a minute description in writing of the nature and effect of each must be sent to the ministry of the interior and heavy penalties are attached to their unauthorized sale and manufacture. A licence for the manufacture of one such medicine costs eight shillings per annum. A druggists' licence for their sale costs one shilling per medicine. Those of itinerant and other vendors cost one shilling for all sorts of these medicines. The latter licences are valid for five years.

AN Ordinary Meeting of the QUEKETT Microscopical Club will be held at University College, Gower Street, on Friday, September 28, at 8 o'clock, p.m.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 218.)

The next paper read was entitled:—

Some Experiences in the Equipment and Working of a Small Pharmaceutical Laboratory.

BY G. F. SCHACHT.

The contrasts that exist between English and continental pharmacy have been a favourite topic with many of our travelled brethren; the lines of comparison have been many and various, and the conclusions arrived at have naturally not always commanded universal consent. But upon one point many of us have agreed in thinking that English pharmacists (taken as a body) were open to a charge that did not so generally lie against their continental neighbours, namely, that they bought too many and made too few of the preparations they consumed.

Critics of the severe order have sometimes followed this charge with the assertion that want of knowledge and want of skill are the true reasons for the phenomenon, and, on the other hand, the defence has not unfrequently been heard, that the question is solely one of economics, and that if premises and profit could but be put out of consideration, a very different order of things would prevail.

The defence, no doubt, sounds mean, and perhaps in an assembly like this ought scarcely to have been whispered; but my own experience (known only to myself) teaches me rather to sympathize with than to criticize the difficulties of those who, out of the workings of a small business, are trying, as a first duty, to pay twenty shillings in the pound; and consequently I am disposed to even applaud the defence.

Nevertheless I urge two points—1stly, an expenditure is not in every case an extravagance; and 2ndly, a very hopeful economy for pharmacists to practise is the economy of their overtaxed energies. And from these follows the deduction, that it cannot be otherwise than wise to sustain and refresh those energies by all available methods, and especially by such as will enable them in the fulfilment of daily duties, to labour with the best and therefore most profitable result.

Upon such a subject one must be careful not to dogmatize; nevertheless every man's experience ought to be of some value, and I therefore beg to offer such as I can give.

I long since came to the conclusion that it was best to make as many of the preparations we consumed as possible; and also that it was best to conduct operations of manufacture away from the interruptions of the shop. Several attempts to adapt one's premises to these ideas have been made at various times, and with certain measures of success; the latest I shall try and explain to you. Perfection is not for one moment thought to have been reached, still I find myself working with more satisfaction than hitherto. And here it is my duty and pleasure to remind you of a communication forwarded to the Journal, by Mr. Corder, of Norwich, and published in October of last year. It is thoroughly worth attention, and would perhaps have been of still greater practical value had fuller references been made to the cost of the several portions of apparatus there figured, the spaces they actually occupy in his laboratory, and the expense of some of the more frequent operations they assist to perform. But I feel personally grateful to Mr. Corder for his paper, and willingly acknowledge that, as far as this communication is concerned, I am following his lead.

The size of our firm's laboratory is 10½ feet by 13 feet, and it is 10 feet high. Its erection absorbed the last available bit of our back yard. We would gladly have extended its area a few feet had that been possible, but, space being peremptorily limited, our only course was to try and turn such as we had to the best account.

Light being fortunately obtainable from the roof, the whole of the wall space, with the exception of 2½ feet by 7 for the door, became available for fittings.

These four drawings, executed by the clever and willing hand of my pupil, Mr. John Tatham Thompson, represent the aspect of the four walls.

No. 1 represents the west wall, through which we enter by the door on the left. It is almost entirely occupied by a stove and drying closet. The former is 16 inches wide, 20 long, and 12 deep, and is enclosed by a portion of the square hood of zinc, the other part of which constitutes the drying-closet. The latter is divided by a diaphragm of zinc from the portion immediately over the stove, but the flue of the stove passes just within the diaphragm, and serves to keep the closet at a good drying temperature. It is supplied with four trays, each measuring 20 inches square. The flue inclines from the top of the hood to the main chimney in the corner; a large outer pipe accompanies it, and serves to convey to the chimney any steam or vapour that may be produced either in the stove chamber or the drying-closet, the heat produced by the flue, which passes through its centre, causing a good draught.

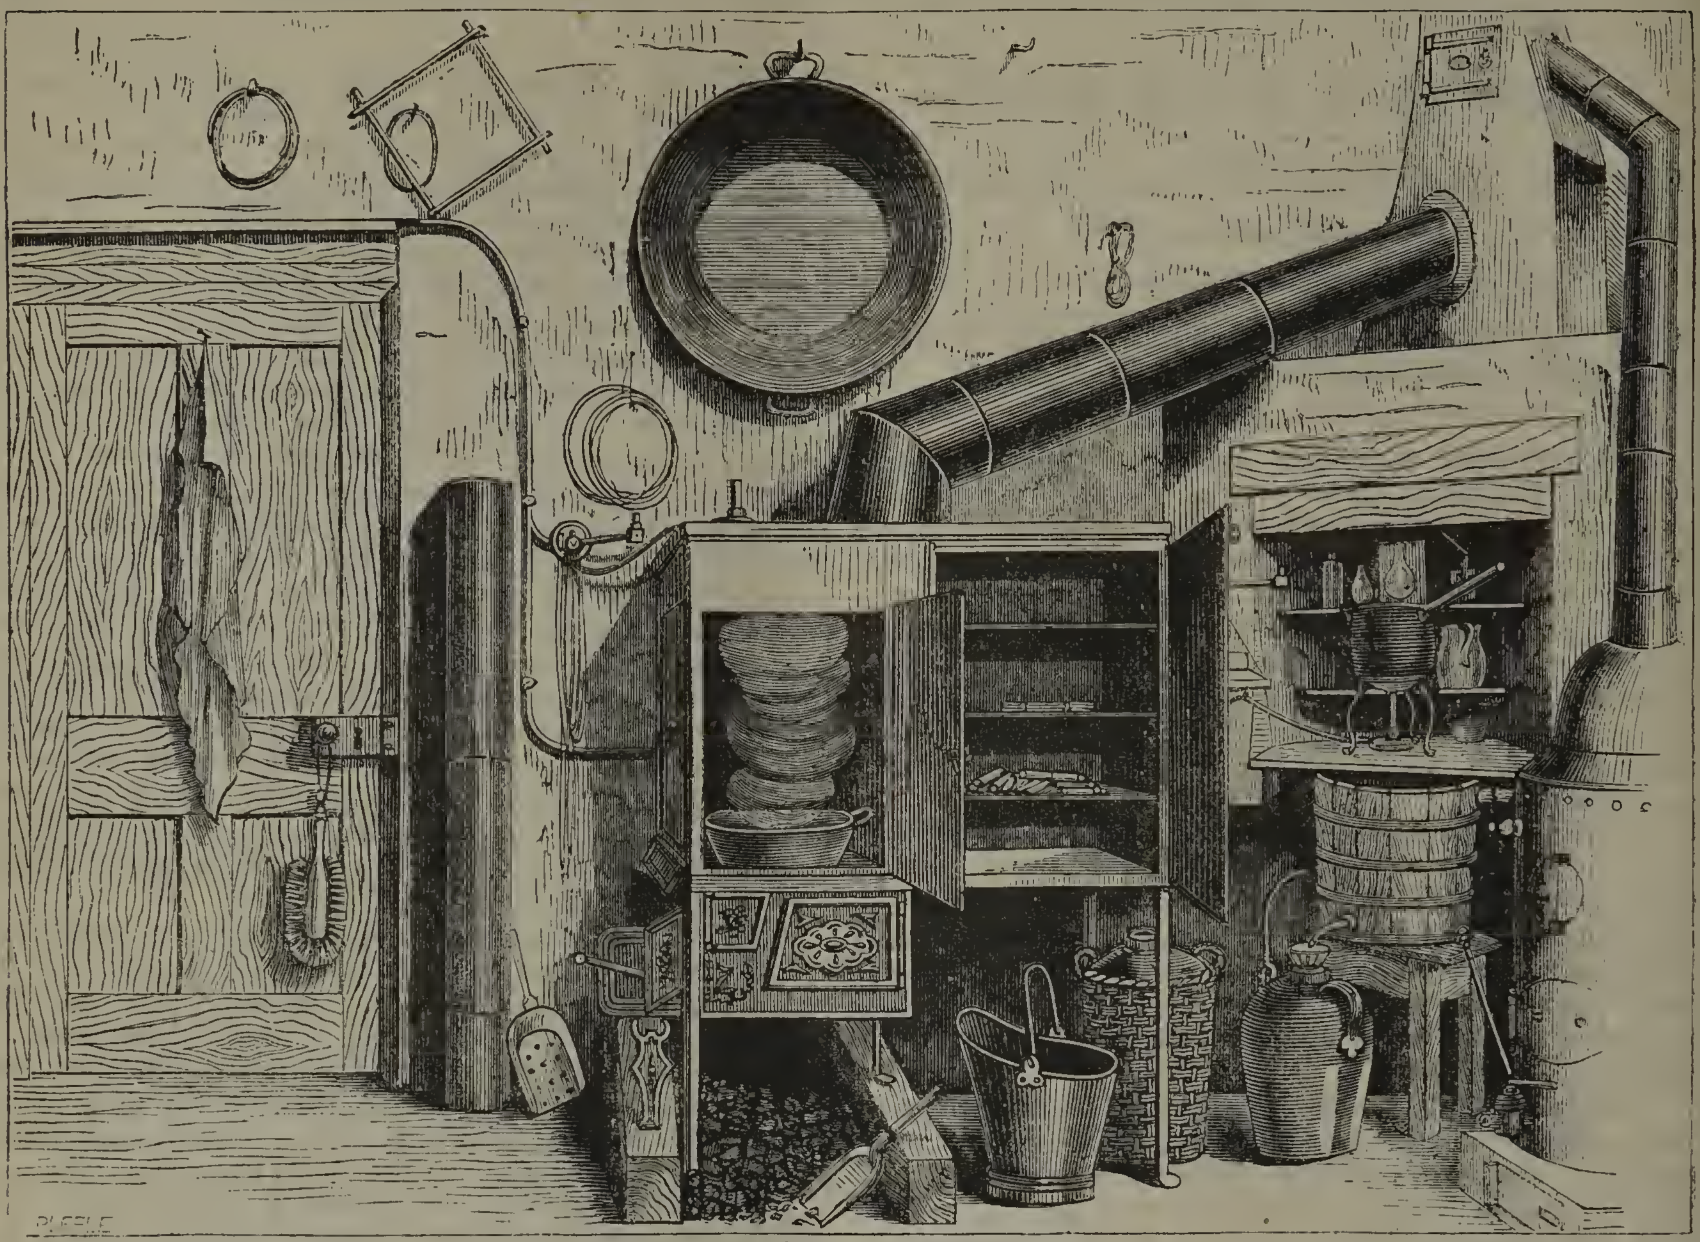
The large pipe at the side of the door is a ventilating shaft, and the space immediately under the stove is for fuel. A small desk for the laboratory book and the diary stands against the wall to the right of the closet.

In No. 2 (North Wall) we see the main chimney, beneath which and communicating with which is the fume-chamber. This, for the sake of getting a little greater depth, is placed diagonally to the two walls, and measures about 2½ feet in height and width, and is 1½ foot deep. Its floor and two shelves are of slate, and the walls are cemented. Beneath this is a worm-tub, diameter 16 inches, height 15 inches, for the condensation of superfluous steam. The boiler of iron is immediately to the right, its diameter is 15 inches, and its height 3½ feet. It holds about 8 gallons, and is filled by a pipe connected with the main. It is equipped with the usual appurtenances, fire-box, safety-valve, pressure-gauge, etc., and is supposed to be equal to a pressure of 100lbs. to the inch and more. The steam pipe passing off to the right is supplied with sundry cocks. When all these are closed, and the fire duly burning, the pressure within of course accumulates. If the cock at the back be opened, the steam escapes through the worm-tub already mentioned, and is condensed into distilled water. If that furthest from the boiler be opened, the steam passes into the jacketed apparatus which stands next. This consists of an enamelled iron pan or basin of 10 gallons' capacity, jacketed with iron, all of sufficient strength to withstand an internal pressure of 30lbs. or 40lbs. to the inch. Its outside measurement, exclusive of a 3-inch rim, is diameter 22 inches, depth 22½, and it is held in its required position by an iron tripod. The jacket is provided with a safety valve that blows off at about 20lbs. pressure, and at the bottom a pipe and stopcock communicates through the jacket to the pan, through which the contents may be drawn off.

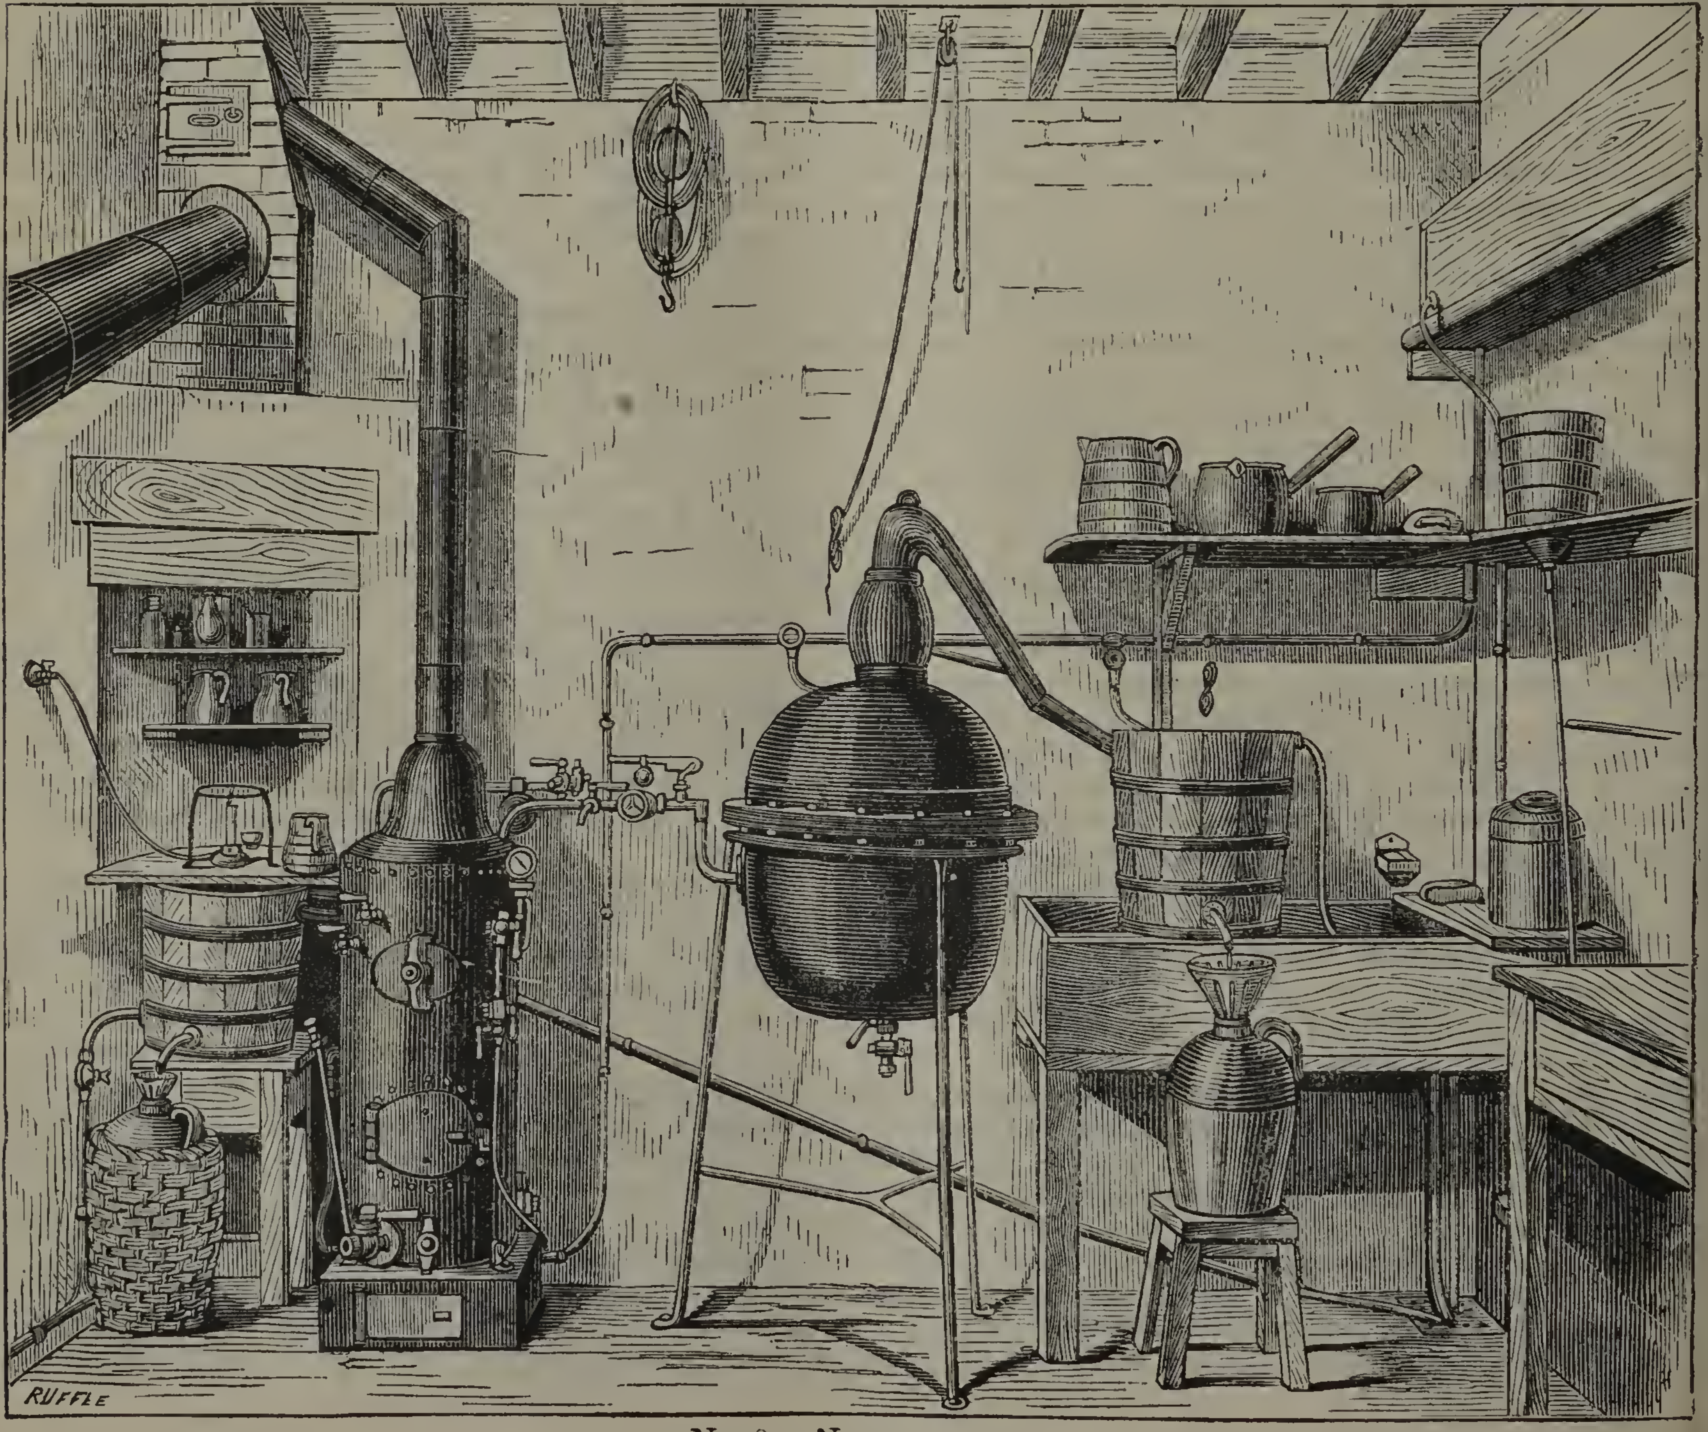
This pan or basin is converted into a still by lowering upon its rim the head and securing the joint with a little luting; the swan-necked extremity of the head passes into a condenser temporarily placed over the sink; the arrangement is convenient for the recovery of spirit, etc.

It will be noticed that the steam pipe is further provided with two cocks opening to the front. From these by means of good elastic tubing steam of moderate pressure can be conveyed to any separate piece of apparatus as we shall presently see.

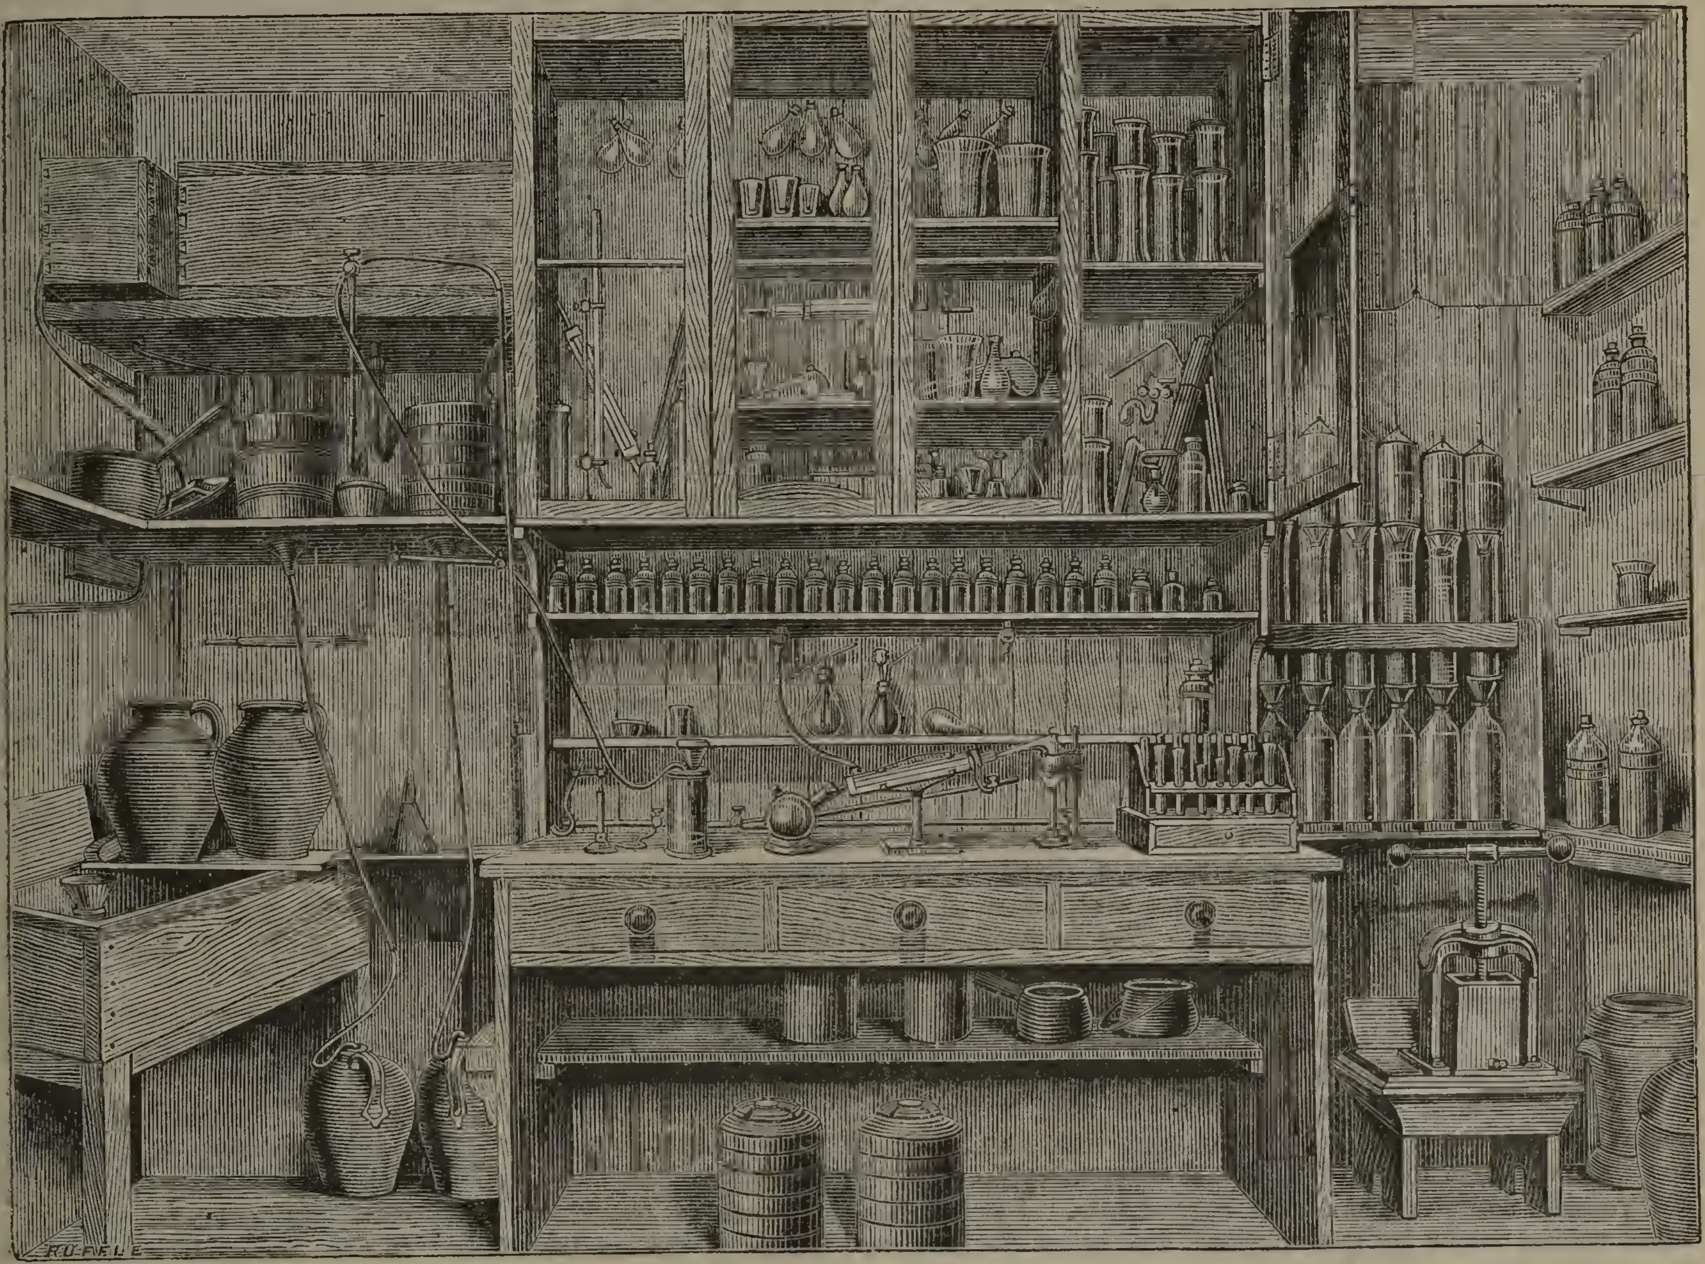
On the extreme right is a sink, 3 feet 6 inches by 2 feet. The water is introduced to the laboratory near the floor upon the west wall, and passes along the north wall over the sink to a small reservoir near the top of the east wall, and the pipe is supplied with taps at convenient spots.



No. 1.—North-west Wall.



No. 2.—North Wall.



No. 3.—East Wall.

No. 4.—South Wall.

No. 3 is the east side, and is mainly occupied with a deal counter, some drawers and shelves enclosed in glass. A gas-pipe with two taps runs along the back edge of the counter, and a water-pipe, also with two taps, from the reservoir is conveyed along the front of the second shelf. Further, a waste-pipe, also provided with two taps, passes along the wall and inclines downwards as it approaches the sink on the left. A Liebig condenser or any similar piece of apparatus can thus be kept in continous and cleanly operation.

By the side of the rack of shelves on the left is placed one of Mr. Fletcher's arrangements for producing an air-blast for blow-pipe—it can also be applied as an aspirator. Still further to the left, and in part over the sink, are placed two of my own filters, holding two gallons each, for which we have very nearly constant employment.

On the right of the shelves is a rack for six displacement-tubes with their accompanying receivers and reservoirs, and beneath them is a small press.

Along the south wall, No. 4, runs a counter and a series of shelves, they are fitted for purposes somewhat special, perhaps, to our own particular business, and might be replaced by anything thought to be more required.

Amongst the appliances here stowed away till required is the one employed in the preparation of distilled medicated waters. For this the two spare steam-taps already mentioned have to be employed. The ingredients are placed upon a colander within the small still, the body of which is immersed into a vessel that acts as a jacket to it. Steam is now introduced into this jacket, and when the whole is well heated to boiling point the other tap is turned and steam is passed into the still below the colander. It there traverses the ingredients and passes out for condensation in the usual way, carrying with it the volatile constituents of the ingredients. I think distilled waters made by this method are more delicate in flavour than if prepared by any other plan. The size of this apparatus is only that of a large saucepan, but it is sufficient for the preparation of one gallon of cinnamon or other pharmacopœial water.

One piece of apparatus more finds room in this large laboratory—it is a grinding-mill. The wall space being all absorbed, a stout stand was made for it, and when not in use for holding this mill it is covered with a top and converted into a table. It stands in the centre of the laboratory.

The large stone and iron mortars are in an adjoining wareroom, and are brought in when required.

I may further state that the floor of the laboratory is of Portland cement, the walls of brick faced with cement, and the roof is of open rafters boarded and covered with zinc. The roof contains a fanlight 4 feet square, capable of being opened at both sides for ventilation.

Now with regard to the cost. I find the building cost £48; the carpenters', plumbers', and gasfitters' work for the internal fitting amounted to £37; the boiler cost £20; the jacketed pan-head and worm-tub, £19; the worm-tub under the fume chamber, £4; the stove and drying closet, £8; the mill, 50*s*; the apparatus for distilling medicated waters, £2 17*s*.; the blow-pipe and accessories, £1; sundry fittings, £7; making a total of £150.

The expense of working is very small. I burn nothing but coke in either the boiler or the stove, and I can keep them both going for a whole day with a consumption of less than a half hundredweight of coke, which in my neighbourhood means about 5*d*. worth of fuel.

Thus at a cost for fire of 3*d*. I can supply 16 gallons of distilled water, or supposing other wants to be more urgent, I can for the same amount draw, say, 1 gallon of cinnamon water, 1 gallon of dill water, make a batch of 50 lbs of syrup, and still have 3 or 4 gallons of distilled water as a by-product.

To the many other purposes to which these appliances can be turned I cannot now refer, but I am sure they offer opportunities for doing many things with great convenience and as well as the intelligence of the operator chooses.

I hope all who see and hear this communication will be good enough to remember that it is addressed only to the average pharmacist. The "traditional houses" have long since supplied themselves with all that is good, and have not allowed the thought of cost to enter into the question. They are far past the necessity of any hint from me. But every house now "traditional" had its beginning, and my chief purpose is to show at how little risk this early step in progress may be made.

———

The PRESIDENT, in thanking Mr. Schacht for his paper, said the fitting up of a laboratory was something like ventilating a room, the means must be adapted to the circumstances of the case. Mr. Schacht had to put up his building first, but very often those who had to fit up a laboratory had a building ready to hand which they had to utilize in the best way they could. His own opinion was that it was not desirable to attempt too much the *multum in parvo*, but rather to confine one's self to a few simple pieces of apparatus, unless there was abundance of space.

A vote of thanks was passed to Mr. Schacht and to Mr. Thompson, who had so beautifully illustrated the paper.

Dr. ROWE (Redruth) agreed with the remarks of the President, and expressed the satisfaction he had received at listening to Mr. Schacht's paper.

Mr. MOORE asked if the purity of the water distilled in the simple apparatus described by Mr. Schacht was sufficient for all practical purposes.

Mr. GREENISH said it had been his privilege to see laboratories in many parts of Germany, Austria, St. Petersburg, and Moscow; in fact, a laboratory was almost universally found in those countries even in establishments of the smallest size. It was formerly required by law in Germany that every pharmacist should have a laboratory; latterly this rule had been relaxed, but the pharmacist was still held responsible for each article he sent out, just as if he had made it himself. With regard to apparatus, his own was very similar to that described by Mr. Schacht. He thought, however, there was the disadvantage in a drying cupboard, such as Mr. Schacht described, that if the stove or fire was not always in operation the drying process went on irregularly. Distilled water was always a difficulty with pharmacists, and he never could get any kind of apparatus which would give him the quantity he required until he made an arrangement in connection with his kitchen boiler, by means of which he now had more than he could use. He had a close range in the kitchen with a wrought iron boiler from which a 1½-inch pipe passed upwards and on to the chimney piece, where it was divided into two ¾ inch iron pipes; one passed into the area and had a valve upon it, and the other into the laboratory where it terminated in a large coil of block tin, placed in a tank of galvanized iron to form a condenser. He had had this in use for some time, and it answered admirably.

Professor ATTFIELD said there was a sectional sketch of a distilling apparatus connected with the kitchen boiler in the 'Year-Book' for 1871, page 604, in illustration of a paper by Mr. Staples. Mr. Bottle stated at the meeting at which that paper was read, that the plan was an old one, and that he had had a similar apparatus in use for twenty-five years.

Mr. CHIPPERFIELD remarked that such an arrangement was not compatible with a continuous supply of hot water to a bath, such as he had attached to his kitchen boiler.

Mr. GREENISH said in such case it would be necessary to have two boilers.

Mr. CHIPPERFIELD added that a very good drying closet could be made by passing the hot water pipe supplying the bath through a cupboard, forming the pipe into a coil at the bottom before it passed up to the bath.

Mr. SIEBOLD remarked that German pharmacists had in course of time found that it was by no means wise to make a great number of preparations on their own premises, and that in many instances it was better to purchase them from wholesale houses who made them on a large scale. When he was an assistant in German pharmacies he made many preparations which he was sure were not made there now, because it was much more expensive than buying them ready made. Laboratories were still found, but the number of preparations made was comparatively small, being chiefly confined to those articles the purity of which it was difficult to ascertain by testing, such, for instance, as the extracts, tinctures, and other preparations of a purely pharmaceutical nature. With regard to chemicals the existence of the smallest percentage of impurity could be readily detected and there was therefore no inducement to make them.

Dr. SYMES thought that as a matter of economy no pharmacist would ever attempt to make all his own preparations, because where these things were made on a large scale it paid persons of skill and experience to devote their whole attention to the operation, and thus better results were insured than could be obtained in a small laboratory with divided attention. There was, however, another side to the question. He had noted for many years the want of original research amongst English pharmacists, and the complaints made by the editors of the Journal that they had to go to a foreign source in order to present their readers with those interesting practical papers which all read with so much pleasure. So long as pharmacists confined their attention to examining the things they bought (which would often take almost as long as making them), they would never get a variety of experience brought to bear on the manufacture of many preparations, and this was what was required in order to effect any improvement. One man would try one thing, and another another, and though the results might appear contradictory, if they were all willing to learn the experiments would lead to improvements which would perhaps never be made if they looked at the matter merely from a pecuniary point of view.

Dr. PAUL described a form of still which he considered superior to that shown by Mr. Schacht inasmuch as the head could be fixed without luting. The body and cover were provided with accurately turned flanges, and by means of screw bolts a perfect joint could be made. At the bottom, in place of a cock which was always getting out of order, he had a conical hole fitted with a plug, on raising which the contents escaped. He also described and sketched a horizontal mill which was self-cleansing, the material ground in it falling down by the action of gravitation.

Mr. GROVES said that he employed an iron boiler with iron pipes for distilling water, but he found the result unsatisfactory, because some of the steam got condensed in the iron pipe and carried down impurities, but he got over that difficulty by passing the steam into a tin vessel something like a Wolff's bottle before it was admitted to the condenser. Still he found a large quantity of ammonia in his distilled water which was probably owing to the water used containing nitrates which were reduced by the iron of the boiler.

Professor ATTFIELD drew the attention of the Conference in connection with this subject to the patent process of Professor Barff for coating iron with black oxide, which so marvellously resisted the action of many substances that affected ordinary iron. He was quite sure this new material would come largely into use in pharmacy as it would in many industries, and he hoped before the next Conference some gentleman would be able to give the Conference some practical information on the subject.

Mr. COLES (Chippenham) said that if a small laboratory was not always a financial success it must give opportunities for research which no mere testing of chemicals would do, and would be of immense advantage to young men learning the business.

Mr. GREENISH said there was a very excellent American mill now imported into this country at a very moderate price, which was specially useful where percolation was employed to any extent.

Mr. SCHACHT said he had derived much satisfaction and instruction from the discussion which had taken place, and had very little to add by way of reply. He used gas sometimes, but generally coke because it was cheaper. His distilled water was perfectly pure, and though he would not say there was never any trace of ammonia he did not think it existed to any extent. The boiler was of iron, the pipes leading from it were of lead, and it was necessary in putting up a new apparatus to work it for some time before using the product in order to get rid of the oily matters used in fastening the joints. Dr. Paul's suggestions were very valuable, but it struck him that his arrangement for fitting the still head would be more applicable to a small than to a larger one; the difficulty would increase in proportion as the size increased. There was no question that Dr. Paul's mill was superior to his own, but he had found on inquiry that it would be more than six times as expensive. In conclusion he should be happy to show his laboratory to any one who happened to be in his neighbourhood.

Mr. UMNEY thought lead pipes very objectionable where either steam or condensed steam (pure water) was passing through them.

The next paper was a—

NOTE ON DIPHENYLAMINE AS A TEST FOR NITRIC AND NITROUS ACIDS.

BY N. H. MARTIN.

Attention having recently been called to diphenylamine as a test for nitric and nitrous acids, it has appeared to me the subject might not unworthily occupy the time of the Conference for a few minutes. The tests for nitric and nitrous acids, both free and in combination, at present in general use, are just so far unsatisfactory as to render welcome the addition of any reagent to the resources of the analyst, the more so when the proposed reagent is one easily applied and of considerable delicacy. This substance, in common with so many other aniline derivatives, has ceased to be a mere chemical curiosity, and being manufactured on a commercial scale there is nothing to prevent its finding its way into general laboratory use.

Diphenylamine, $C_{12}H_{11}N$ equals $NH(C_6H_5)_2$, is a "base produced by the action of various phenol compounds on aniline, the reaction consisting in the substitution of phenyl (C_6H_5) derived from the phenolic ether (C_6H_5OH) for an atom of hydrogen in the aniline ($N(C_6H_5)H_2$) molecule." This may be done in various ways—for instance, by heating aniline hydrochloride with phenol and fuming hydrochloric acid; but it may be that none of the published processes is that actually followed when manufactured on a commercial scale. Several of the aniline compounds have delicate reactions with various acids, but I only find that one of them has been used as a test for nitric acid, and that is the sulphate. A note on this subject will be found at page 164 of the 'Year-Book,' for 1870, but the author from whom it is quoted is not mentioned. The fact is simply recorded that sulphate of aniline is stated to be a "surprisingly delicate test for nitric acid." In a paper "On the Estimation of Nitrous and Nitric Acid," read before the Newcastle-on-Tyne Chemical Society, by its late President, Dr. Lunge (now at Zurich), and copied from the proceedings of that society into the *Pharmaceutical Journal* of last week, it is stated that diphenylamine "is the most delicate of all reagents for ascertaining the freedom of sulphuric acid from nitrogen compounds." Dr. Lunge's remark has lead me to try several experiments upon a number of samples of so-called pure sulphuric acid, and of these one only failed to give distinct indication of the presence of nitrogen compounds in greater or less quantity. I do not propose to enter upon the theory of the reaction or to occupy your time further than is necessary to explain and show the application of the test.

The method of using the test is as follows :—Take a small quantity (about the size of a mustard seed will do) of the diphenylamine, put it into a test tube and pour a little sulphuric acid over it, then add a drop or two of water so as to increase the temperature sufficiently to effect the solution of the diphenylamine, and the test is ready for use. Now add very gently the solution to be tested, and if only a trace of nitric or nitrous acid be present a beautiful and very permanent blue coloration is produced at the junction of the two liquids; but if there be any quantity of the nitrogen compound the colour becomes almost black. This reaction is so delicate and certain that in the case of a solution of nitric acid containing about one part B.P. acid in 10,000 of water the reaction is most distinct. One part of nitrite of potassium in 30,000 of water gives also most unmistakable evidence of the presence of the nitrogen acid.

The value of this test seems to me to consist in its being so readily used and in its indications being so quick and well defined. I have spoken only of diphenylamine being used as a qualitative test, but it will also make a very fair quantitative test, by comparing the coloration produced respectively by a given quantity of the acid to be tested and a given quantity of acid containing a known quantity of nitrous acid, with an excess of the reagent.

I have not been able to make out to whom we owe the first suggestion of the utilization of this reaction, but I take the chance of its being as new to many of the Conference as it was to myself.

———

A vote of thanks was passed to Mr. Martin for his paper.

Mr. ALLEN said he understood that Mr. Martin proposed to compare the colour with that furnished by a known quantity of nitrous acid. If the process answered for nitrates as well as nitrites, would it not be more convenient to use nitre in solution?

Mr. MARTIN said the process would certainly answer as well for nitrates as for nitrites.

The next paper read was entitled—

THE PILL MASSES OF THE B.P., WHICH ARE OF AN INCONVENIENT CONSISTENCE, OR ACQUIRE THAT CONDITION BY KEEPING.

BY JOHN C. THRESH.

This paper is an answer to query No. 36 in the list of subjects for research issued by the British Pharmaceutical Conference in May, 1877.

Of the twenty official pill masses the seven following have or acquire by keeping a consistence unsuitable for dispensing :—

Pil. Aloes et Assafœtidæ.
" Aloes et Ferri.
" Aloes et Myrrhæ.
" Cambogiæ Co.
" Coloc. Co.
" Ferri Carbonatis.
" Phosphori.

Of these the pil. aloes et assaf. is too soft, simply because too large a quantity of excipient is ordered. Increase the soap to $1\frac{1}{2}$ ozs., and take $\frac{1}{2}$ oz. conserve instead of 1 oz., and a good mass is formed corresponding to the B.P. form in strength. Pil. phosph., though perhaps in some respects objectionable, appears to be as good a form as has yet been proposed, and as I doubt whether I can improve it, it must needs be passed over. The other five masses all become hard by keeping, and it appeared likely that some excipients might be found adapted to all. The combination of glycerine and tragacanth is probably the best excipient for the purpose, but no single form for this mucilage is suitable for all the five masses. The pill of carbonate of iron, and the pill of aloes and iron, must be made with tragacanth and glycerine only, and not by Mr. Proctor's form (which contains water), as with the latter excipient they soon become hard. The following forms answer admirably, and the pills thus made will keep for a considerable length of time almost unchanged.

Pil. Aloes et Ferri.

Aloes Bbd. in powder	2 ozs.
Sulphate of Iron	$1\frac{1}{2}$ oz.
Comp. Pd. Cinnamon	3 ozs.
Powd. Tragacanth	1 dr.
Glycerine	1 fl. oz. Mix.

Aloes 1 in 4 nearly. Iron 1 in 5.

Pil. Ferri Carb.

Saccharated Carbonate of Iron .	$6\frac{1}{2}$ ozs.
Powd. Tragacanth	$1\frac{1}{2}$ dr.
Glycerine	$1\frac{1}{4}$ fl. oz. Mix.

The three remaining pills are best made with Mr. Proctor's excipient.

Tragacanth powder	3 drs.
Glycerine	9 fl. drs.
Water	4 fl. drs.

Mix the gum and glycerine till smooth before adding the water.

The specimens sent have been made nearly a year, are in excellent condition, and so far as I can tell as active as the freshly prepared masses. As pills made with this excipient are with difficulty disintegrated by action of water, it has been asked whether they are as active as those made with the B.P. excipients. To satisfy myself upon this point I have had administered purgative pills of both kinds, and I have failed to detect any appreciable difference in their action upon the bowels. (I could not say, however, that pills of opium, morphia, etc., act as speedily when made with tragacanth.)

For pil. coloc. co., use 1 oz. of mucilage instead of the water. In pil. cambogiæ co., 1 part of excipient may replace the syrup. Pil. aloes et myrrhæ requires a rather larger proportion of excipient, otherwise it becomes very tough. A good form is

Powd. Soc. Aloes	2 ozs.
" Myrrh	1 oz.
" Saffron	$\frac{1}{2}$ oz.
Glyc. Tragacanth	1 oz.

If it should be deemed necessary to make the form correspond in strength to the B.P. pill, $1\frac{1}{4}$ ozs. of some simple powder, as pulv. cinnam. co. might be added, and the $1\frac{1}{4}$ oz. of excipient would then reduce it to the desired strength.

———

The PRESIDENT said it was very desirable to ascertain the best method of producing these pill masses so as to keep for a reasonable time without becoming unduly hard.

Mr. GREENISH said Mr. Thresh appeared to have generally used the excipient introduced by Dr. Symes, tragacanth and glycerine, only he had first put in the tragacanth and added the glycerine afterwards to the mass. Mr. Thresh seemed to think that a pill which became hard from the introduction of tragacanth might perhaps not be readily soluble in the stomach, but when examining tragacanth for the cell tissue and starch in it he (Mr. Greenish) had been astonished to find how the hardest piece dissolved by the addition of the smallest quantity of moisture, more readily probably than any other gum.

Dr. SYMES, though he had used tragacanth and glycerine for some years for pill masses, could not claim any originality in the matter. He must take exception to the remark that the pil. phosphori of the B.P. was the best form that could be used, for he considered it one of the worst. He had heard from medical men and read that this pill passed through the system without being disintegrated.

The PRESIDENT said though he agreed with Dr. Symes' remark as to pil. phosphori if used in the form given in the Pharmacopœia, he could not in any other sense do so at all. On the contrary, he considered that form to be unobjectionable and in many respects an excellent one. He had stated over and over again that the pil. phosphori was not intended to be administered in the form in which it stood, but should be mixed with soap. The reason why soap was not introduced into the formula was that if the pill mass contained soap it could not be kept immersed in water, whereas in its present form the phosphorus might be kept ready for use for an unlimited time unoxidized. It was intended to be kept beneath the surface of the water and might be so kept for any length of time. Mr. Ekin had suggested that the balsam of tolu might be replaced by hydrated resin, which also might be incorporated with the phosphorus under the surface of water. The form given in the Pharmacopœia originated with Mr. Abraham, of Liverpool, and the balsam of tolu was selected because its specific gravity enabled it to be kept in a melted state in hot water, and the phosphorus could then be completely incorporated with it without any exposure to the air or any chance of oxidation.

Dr. SYMES thought it was a great misfortune that medical men had not been officially informed how this pill should be administered. He grounded his remarks on what he had heard and on letters which appeared constantly in the medical papers, pointing out that the pil. phosphori would occur in the fæces entirely unaltered.

The PRESIDENT said it would be no doubt an advantage if an addition were made to the formula, saying that soap should be mixed with the pill mass when administered.

Mr. GERRARD said he had had considerable experience in the making of phosphorus pills, and although he was the author of the suggestion that phosphorus was soluble in resin he now thought the best way was to use that solvent *par excellence* bisulphide of carbon. The great difficulty in every case was to prevent oxidation, but he had recently adopted the following method to meet this difficulty: Immediately the least trace of oxidation was perceived after the evaporation of the bisulphide of carbon, he added a little chloroform, which being a heavy vapour prevented contact with the oxygen of the air. While the materials forming the pill were surrounded by chloroform, water could be added and the pill mixed up with the loss of hardly any phosphorus by oxidation.

Thanks were voted to Mr. Thresh for his paper.

The next paper read was—

SOME FURTHER EXPERIMENTS UPON THE ALOINS.

BY WILLIAM A. TILDEN, D.SC. LOND.

When nataloin is digested with a ten per cent. solution of bichromate of potassium, acidified with the proper quantity of sulphuric acid, brisk effervescence occurs owing to the escape of carbonic acid gas; but an examination of the liquid led to the discovery of nothing else except acetic acid. In a former paper I pointed out that when nataloin is treated with nitric acid it yields carbonic and oxalic acids and a small quantity of picric acid. I have little doubt, therefore, that when chromic acid is the oxidizing agent employed, a small quantity of some benzene derivative, probably quinone, is formed, but in quantity too small to allow of its ready detection.

Barbaloin and socaloin, as I have already shown in a paper communicated to the Conference, have the same composition, and both yield chrysammic acid as the characteristic product of the prolonged action of nitric acid. When oxidized by bichromate solution they both behave in precisely the same way, yielding carbonic acid, a little acetic acid, and a yellow compound which, as it has proved rather interesting, I propose to describe.

Whether obtained from barbaloin or socaloin, or even by the oxidation of Zanzibar aloes, this compound has the same properties and composition. In allusion to its yellow colour, I call it "Aloxanthin." It is almost insoluble in acidulated water, but slightly soluble in the ordinary solvents, and is crystallizable with great difficulty.

After purification by repeated deposition from alcohol, acetic ether, or glacial acetic acid, it was analysed, and gave numbers agreeing with the requirements of the formula $C_{15}H_{10}O_6$. When heated with zinc dust this substance is reduced to a hydrocarbon, which turned out to be methylanthracene. The formula $C_{15}H_{10}O_6$ may therefore be written $C_{14}H_3(CH_3)(OH)_4O_2$, which represents a methyltetroxyanthraquinone. It is interesting to observe that this formula belongs to a third term in the series to which also belong chrysophanic acid and emodin, two yellow substances existing ready formed in rhubarb root and in the roots of various other plants allied to rhubarb. The relation between these compounds is manifest on comparing their formulæ, according to which they appear as di-, tri-, and tetroxyderivatives of methylanthraquinone.

Chrysophanic Acid.

$$C_{15}H_{10}O_4 = C_{14}H_5 \begin{cases} CH_3 \\ (OH)_2 \\ O_2 \end{cases}$$

Emodin.

$$C_{15}H_{10}O_5 = C_{14}H_4 \begin{cases} CH_3 \\ (OH)_3 \\ O_2 \end{cases}$$

Aloxanthin.

$$C_{15}H_{10}O_6 = C_{14}H_3 \begin{cases} CH_3 \\ (OH)_4 \\ O_2 \end{cases}$$

Aloxanthin agrees with chrysophanic acid and with emodin in yielding a cherry red solution in alkalies. It may be sublimed, though the greater part is charred and destroyed in the operation. When treated with cold strong nitric acid it yields a yellow nitro-compound which has all the characters of the aloetic acid described originally by Schunck in 1841, and which is formed together with chrysammic acid by the action of nitric acid upon aloes. Aloxanthin is also converted into chrysammic acid by boiling for some time with nitric acid.

A vote of thanks was passed to Dr. Tilden.

The PRESIDENT said the next paper was by Mr. Atkins, which would be read, but no discussion would take place upon it, as agreed yesterday.

Mr. GUYER (Torquay) asked if this was to be made a precedent. If so he should protest against its being read at all.

The PRESIDENT thought the decision deliberately come to on the previous day without any opposition could hardly be disturbed then.

The following paper was then read by Mr. Atkins, and the thanks of the Conference were voted to him.

A POINT IN PHARMACEUTICAL ETHICS.

BY S. R. ATKINS.

The advantages of such annual gatherings as the present one are manifold, not simply to post the day-book into 'The Year-Book of Pharmacy' and scientific research —registering the achievements of the past, possibly initiating new ones, but also enabling us more calmly and judicially to examine and review our ethical relations, home and foreign.

I have thought that it might be expedient at this Conference to refer to one of those questions now engaging the attention of pharmacists throughout the country, viz., their relation to the medical profession.

Confessedly we are in a state of transition; the old is giving place to the new. In this respect we are only sharing the experience of society generally; but from a variety of causes which a careful analysis enables us approximately to estimate, we, the pharmacists of to-day, are more especially influenced.

It is as difficult for us who are engaged in the strife and controversy of opinion to calculate the exact momentum and direction of the forces so employed, as it is for the individual soldier to discern which way victory leans, when the field is wide, and the combatants are numerous. We have, however, amongst us men of experience and capacity—men tried and true—whose lead we may safely follow; and, at least, let us who may belong to the rank and file evince a discipline and obedience worthy of our position.

But to come to the point. What are the true relations between pharmacy and the medical profession?

It is evident those relations at the present moment are not in a healthy condition. The extreme behaviour of the extreme section of either party has imperilled that respect and confidence which ought to exist between them. That such feelings are restricted to the extreme right and left is probably true; that the vast majority of medical men and chemists are innocent of such mutual antagonism is equally true; that the amount of noise such controversies make is frequently in the inverse ratio to their social and professional importance is equally certain. Still the bare existence of such schools of thought is a scandal, and their practical evolution before stipendiaries, and ultimately in courts of appeal, renders it imperative on all moderate and law-obeying subjects to seek to bring about a better understanding.

In this suit, pharmacists are the defendants. If Turks have fought bravely behind their own fortresses, so ought we; our position is impregnable.

We stand charged with counter-prescribing—so runs the indictment. To a certain extent we admit the charge and plead justification. That there are chemists who are in the habit of encroaching on the function of the medical men, we do not deny; such men never have been and never will be defended by the Council of the Pharmaceutical Society of Great Britain. As every flock is said to contain its black sheep, and every large family its odd member, so are the men of whom we speak, the exception and not the rule.

With such practices we have nothing to do. What, however, we are careful to defend, as our just and inalienable right, is that simple and moderate counter practice which has grown up without legal enactment, and, as we believe, contrary to none; but which is so embedded, not simply in the habits, but the very necessities of the people, that a blue book of prohibitions could no more extinguish it then an Act of Parliament could convert every Englishman into a Scotchman, however desirable in the abstract such a conversion might be.

We contend for a custom of long standing, as we find it in the vast majority of respectable well-conducted druggists' shops, the practice of prescribing across the counter for simple ailments. And altogether apart from personal and pecuniary considerations, we contend for this custom in the interests of the public. This is the only line of defence worth maintaining, and it is the one which parliament and our courts of law, our legislative and executive authorities, will ever respect.

If it be asked where the line of demarcation should be drawn, we reply, that it is impossible to draw one, but an honourable man will seek to avoid the very appearance of evil, and if parole, the law of honour, fails, no inquisitorial acts of a medical police will ever succeed.

We assert that the custom we are considering has grown out of public necessity, and not from proffered service on our part. We have not sought but been sought. And this, partly the result of higher education and more efficient training; knowledge winning reputation, confidence, and patronage, an order of natural induction. *Noblesse oblige;* the very position knowledge has thus secured will make its possessor all the more careful not to traverse forbidden lines.

What counsel then may we venture to proffer our brother pharmacists, and also, if it be not deemed impertinent, to professional men, so far as this discussion may reach them. We suggest that there is room for mutual courtesy and forbearance, the avoiding of tall-talk and bluster. We have, by a combination of firmness and conciliation, to convince the public and the profession that all we desire is fair play. In order that we may accomplish this, we must be prepared to invite the most thorough inquiry; there must be no back-parlour consultations, no minor acts of surgery, no semi-professional visits, in short nothing in excess of that ordinary counter practice the meaning of which we all recognize, however difficult the exact definition of the same may be.

Such rights must be defended with the united strength of the entire body of chemists throughout the kingdom. Time is assuredly on our side. Should a hasty decision adverse to our claims be snatched on *ex parte* evidence, or even on the legal interpretation of a statute that ought long since to have been swept away, such an event will prove no permanent disaster, but only hasten the conclusion we desire. One really good case, well argued before an intelligent jury must secure a verdict in our favour and definitely settle the question.

Such an arbitrament ought, however, not to be necessary; the House of Commons should anticipate any action of this sort by defining what are our privileges.

The day assuredly will come, when medical men and pharmacists will no longer regard each other as competitors but as fellow-workers, both engaged in the treatment of disease, the one in the preparation the other in the administration of remedies. Nor will the wise physician regard with jealous eye the growing culture of the pharmacist, for through it he works with greater accuracy and success.

We each may have something to surrender, if so, let the concession be mutual, gradual and complete.

At least let hostilities cease whilst the conditions of an honourable peace are being negotiated.

The next paper was read by Mr. Kingzett—

Presence of Metallic Compounds in Alimentary Substances.

BY B. H. PAUL, PH.D., F.C.S., AND C. T. KINGZETT, F.C.S.

1. *Introduction.*—Under the Sale of Food and Drugs Act a number of prosecutions have been instituted during the last few years, having regard to the presence of metallic compounds in articles of food. Meanwhile, the knowledge possessed by either chemists or medical men as to the behaviour of such compounds upon the human system is extremely meagre. There can be no doubt that many mineral substances exercise a prejudicial influence upon health, but the measure and nature of this influence is in most cases an undetermined quantity, while it is probable that owing to popular prejudices a number of harmless substances (considering the quantity taken into the system) are assumed to possess pernicious or poisonous properties.

2. *Preserved Peas and Copper.*—One of the most popular of foods, and one which has been most severely remarked upon, is preserved peas. This article of food is prepared for the most part in France, and in connection with it a very considerable trade has developed. The Paris merchants aver that the peas will not maintain their bright green colour unless a small amount of sulphate of copper be added to them, in which case they keep their colour admirably. The quantity thus added varies between one and two grains of the ordinary blue sulphate to the tin of peas, containing from $9\frac{1}{2}$ to $9\frac{3}{4}$ ounces of peas* and 150 c.c.

* Weighed after separation and draining from liquor as taken from the tins.

of liquor. The question of what influence this copper has upon health is one which has been hotly discussed and widely differing opinions have been expressed by medical men. Ordinarily, however, it has been assumed that the copper is injurious to health, and vendors of preserved peas have often been fined in consequence. This difference of opinions is readily explained by the imperfect acquaintance of those who expressed them with the scientific facts.

It appeared to us that in order to arrive at a proper knowledge of the physiological influence of the copper contained in preserved peas, it was desirable to determine the following points:—

(1). Is the copper in mere admixture with the peas, or is it in actual combination with the albuminous or other constituents?

(2). Does it pass into solution under the influences of the digestive processes?

(3). Is any part or all of the copper thus introduced into the stomach absorbed, or is it eliminated, and, if so, how?

3. *Presence of Copper in Organic Tissues and Products.*—Before proceeding to describe the experiments we have made relative to these questions, we may take note of the fact that from the time of Margraff, Gahn, and Vauquelin, chemists have been acquainted with the presence of copper in organic tissues and products, and in 1856 and 1857, Odling and Dupré made a number of experiments in which they detected traces of copper in bread, flour, wheat, straw, liver, kidney, blood, flesh, eggs, cheese, etc. Thus they found that 6925 grains of human liver furnished 0·013 grain of cupric oxide; while 6682 grains of sheep's liver gave 0·281 grain CuO; 1830 grains of human kidney gave 0·015 grain CuO, while human muscle and blood also furnished traces.

Again, Bergeron and Hôte (*Comptes Rendus*, lxxx., p. 268) have more recently demonstrated the presence of copper in the kidneys and livers of fourteen human bodies.

Brain matter also contains notable quantities of copper, which exists there in actual combination with various principles.*

In view of these facts we deemed it desirable to examine green peas for copper, and accordingly two experiments were made with this object.

4. *Method for Detection of Copper.*—The method pursued throughout this investigation for the detection of copper may be at once stated; it consists in burning the suspected matters with a mixture of pure sodic carbonate and potassic nitrate, causing complete destruction of all organic matter; solution of the fused mass in dilute acid and addition of excess of ammonia and filtration from alumina, phosphates, etc. If copper be present the filtrate exhibits a blue colour, and gives the other reactions of copper (such as the one with potassic ferrocyanide in acetic acid solution). If the fused mass be dissolved in water instead of dilute acid, then, when phosphates are present, the copper remains in the insoluble residue and may be detected in it as above.

5. *Examination of Green Peas for Copper.*—In the one experiment above alluded to, 80 grams of shelled new green peas were examined, and in the other the same quantity to which had been previously added 0·4647 grain $CuSO_4$ or 0·6526 grain $CuSO_4$ 5 H_2O. The natural peas were found to be absolutely free from copper, while there was no difficulty in determining the presence of copper in the case where it had been added, and as this is less than usually occurs in a tin of preserved peas, there should be of course no difficulty in establishing the presence of copper in such an event.

On a subsequent occasion another quantity of 80 grams of a fresh lot of peas was examined for the presence of copper also with a negative result.

6. *State of the Copper present in Preserved Peas.*—In this part of the research it was endeavoured to ascertain whether the liquor contained in the tins with the preserved peas holds any copper in solution or whether it is all in the matter of the peas, and whether during the process of boiling the peas, any copper passes into a state of solution. It was determined in two cases that the said liquor was practically free from copper, the merest vestige being found. This was ascertained by evaporating the liquor to dryness, and fusing the residue as already described with the soda mixture.

The water in which the peas were boiled contained also but the merest vestige.

The copper, therefore, present in preserved peas exists in actual combination, and is not removed by the process of cooking. In the two cases mentioned the quantity present exceeded 1 grain of sulphate of copper to the tin of $9\frac{1}{2}$ or $9\frac{3}{4}$ ounces (about 268 grams).

In the fused mass it exists exclusively in that part insoluble in water.

7. *What becomes of the Copper during Artificial Digestion?*—About 5 ounces of preserved peas of similar nature to those described in preceding paragraph were separated from the liquor, reduced to a pulp, and digested at 40° C. with 300 c.c. of solution containing 1·3566 grm. hydrochloric acid and 35 c.c. of a glycerine solution of pig's pepsin (Bullock's preparation), during 40 hours. The undigested portion was then separated by filtration and the process of artificial digestion repeated upon it under similar conditions during 18 hours. The mass was then again filtered and washed, and the bulky green undigested matter and white skins examined for copper, from which it was found to be now practically free. The whole of the copper had passed into solution, about equal quantities being present in the two digestive extracts.

It may therefore be presumed that in stomachic digestion preserved peas give up their copper to solution, but the extent, probably depends upon the acidity of the gastric juice, the activity of the pepsine ferments, and the time during which the process of gastric digestion is carried on.

8. *Is the Copper introduced into the Stomach absorbed, or what becomes of it?*—On the 13th July, the authors of this paper took each a dose of 0·3 grain $CuSO_4\,5H_2O$, and examined the urine eliminated during the next 48 hours; it was found to be entirely free from copper.

On the 27th July and six following days, we each took again daily, 0·3 grain of cupric sulphate, and examined the total urine for the presence of copper; none but the merest trace was eliminated through this channel.

The fæces secreted on the 30th by one of us was examined, and was found to yield abundant evidence of copper, forming indeed a very considerable proportion of a dose.

Therefore even if a part of the copper be absorbed into the system, another and probably the greater part passes out with the fæces? This corresponds with what is known of the action of ferric and mercurial preparations when taken into the system; a part appears to be absorbed, and locates itself at least temporarily in the organs of the body, while another part passes out with the fæces, colouring them in the one case black and in the other case, green.

9. *General Considerations and Conclusions.*—Inasmuch as copper is nominally present in certain organs of the body as stated above, it must get there in the first place through an introduction into the stomach. How then can we reconcile this fact with the partial secretion at least, of copper with the fæces? Apparently this is very easy of explanation. After gastric digestion and while the contents of the stomach are still acid, a part of the chyme is absorbed into the blood system, and this would seem to constitute the stage at which the copper is absorbed. The greater part, however, of the digested mass

* See 'Relations of Chemistry to Physiology and Pathology,' etc., By C. T. Kingzett. *Pharm. Journ.*, Feb. 26, and March 11, 1876.

passes on through the pylorus, and undergoes a further change in the duodenum where alkaline biliary fluid takes part in the process. The probable result as regards the copper would be its precipitation as phosphate, which would not be changed in the intestines, but would be passed as such with the fæces.

Now, if it be considered that ordinarily one person consumes only about two ounces of preserved peas at a meal, and that this quantity would contain only a fraction of a grain of cupric sulphate; and if it be further considered that only another fraction of this amount is ultimately absorbed into the blood system, it is impossible to defend the opinion of the prejudicial influence of such amount of copper upon health.

This represents our conclusion based upon the experiments we have described, and we think it probable that quite as much copper finds its way into the system through the handling of copper coins, the use of copper vessels in cooking operations, and in the consumption of pickles and such articles which are often prepared in copper vessels. At least we believe preserved peas are absolutely innocuous to health.

10. *Other Confirmatory Evidence of the Innocuous Nature of Traces of Copper present in Foods.*—In a prosecution case conducted before the Marlborough Street Police Court, on Monday, January 22, 1877, Dr. Pavy expressed the opinion that 0·31 of a grain of copper (sulphate ?) would not be injurious to health; this opinion was unsupported by any evidence.

In what has gone before we have supplied the evidence required, and these results are confirmed by and confirmative of other results recently communicated by M. Galippe to the French Academy of Sciences.* He has found that the administration of large doses causes vomiting, but that the same compounds may be taken in increasing amounts for prolonged periods of time without the attendance of any painful symptoms. Galippe cites the experiments of Burq and Ducom, who fed dogs with food that had been cooked and cooled in vessels made of copper and previously exposed to the action of vinegar and salt; the dogs were not at all affected. Moreover, Galippe and his family have lived on food similarly prepared, without experiencing any poisonous effects.

11. *Other Alimentary Substances containing Metallic Compounds.*—It has, in some recent cases of prosecution, been brought to public attention that so-called sugar-cured American hams are coated with a composition containing chromate of lead, which is ordinarily regarded as an irritant to the stomach and an accumulative poison.

Similarly, sweets have been met with which have also been coloured with plumbic chromate, and in one instance one-fifth of a grain of this substance was contained in an ounce of the sweets, while in another case, twice this quantity was detected.

It may be known, that a tolerably large business is now done in colours for sweets and other confectionery, and at various times very objectionable substances have been employed in compounding them, such for instance as salts of lead, chromium and arsenic, and more recently certain aniline colours.

Of late, stannic oxide has come largely into use for compounding these colours, its employment being liked on account of the bright tints which it induces when used as a lake. The colouring matters now chiefly employed are of vegetable origin; cochineal being almost the only animal colouring matter at all in use. Infusions of these colours are made, and they are then precipitated in various ways.

We have recently had occasion to examine a number of these colours of French manufacture, and found that they were largely contaminated with tin, the dry substance containing from 8 to 60 or even 75 per cent. of stannic oxide. Although a little of these colours goes a long way in colouring confectionery, it may nevertheless be very questionable whether the use of compounds containing so much tin should be considered admissible.

For some time past we have been engaged in an attempt to prepare colours of this nature, free from the objection attaching to the presence of such metallic combinations, and hope at no distant period to be successful in this object.

* *Comptes Rendus*, April 9, 1877.

The PRESIDENT, in inviting discussion on this paper, said that as he had been rather prominently connected with some of the cases of prosecution to which Mr. Kingzett had alluded he would prefer to hear observations made by others to offering any himself at present.

Mr. SIEBOLD understood Mr. Kingzett to say that he found a small trace of copper even in fresh peas, and in several other instances he spoke of the same thing; he should like to ask therefore if any utensil were used containing copper or brass, the bunsen burner, or the retort stand, for instance, because a German chemist, named Ulex, proved ten years ago that small traces of copper might be found everywhere--even where they did not exist, that large quantities of liquid could not be evaporated over a bunsen burner the tube of which was made of brass without finding ultimately small traces of copper. Secondly, he should like to know how the copper had been estimated quantitatively; if it was by the method of precipitation in sulphide of hydrogen, and comparing the colour produced with that from a standard solution of copper, it was to a certain extent objectionable. His experience did not extend to copper, but this method was used to determine minute quantities of lead, and he had found that different preparations of lead produced a different shade of colour, chloride, sulphate, or nitrate producing different results. Some time ago in testing a sample of tartaric acid with a small trace of lead in it the discoloration produced by sulphuretted hydrogen was of a slate colour, instead of the brownish yellow generally obtained from water with lead in it, and on trying various preparations of lead he found they all differed in colour. Lastly, he protested against the notion that because copper was readily eliminated, it could not have any injurious effect. There were numerous medicinal agents, such as iodide of potassium, which passed through the system very quickly, and yet they had a physiological action, and in a large dose would have a poisonous action. Morphia was eliminated with the fæces, and not a trace of it with the urine; yet no one would deny that it passed through the system and acted as a poison.

Dr. PAUL said this argument did not apply to the case in point because the copper did not pass through the system at all, it was eliminated without even getting into the system.

Dr. ROWE said he had examined water from a stream in the county of Cornwall, which had been drunk from for many years by the inhabitants in the neighbourhood, and he found it contained large quantities of copper, in fact, so much that it could be profitably precipitated from it by iron, and yet those who used it appeared to suffer no inconvenience. At another place, called Llanarth, water similarly impregnated was used. Metallic matters were sometimes taken in large quantities and eliminated through the alimentary canal without apparently entering the constitution; for instance, some persons were not at all affected by taking iron, while others were greatly benefited by it. These instances fully confirmed his own idea that copper was not a blood poison or irritant, unless it were taken in the form of sulphate, or in some combination which rendered it an irritant.

Mr. THOMPSON said he had given a dog a grain of copper a day, Sundays excepted, for eighteen months, and the animal appeared to be quite unaffected by it.

Mr. WILLMOTT said he had made some experiments with regard to the preservation of meat, and he came to the conclusion that it was absolutely necessary to exclude the air from it. He should like to know the results of the experiment undertaken by the President some time ago with paraffin, in this direction.

The PRESIDENT remarked that the general subject of meat preservation was not raised by the paper before them.

Mr. CHIPPERFIELD reminded the meeting that though vegetation was destroyed for miles round in the neighbourhood of copper works, and the flavour of copper could even be tasted in the air, still the longevity of those employed in the works would compare favourably with any other class of the population.

Dr. WRIGHT mentioned several cases which had been recently reported where persons had suffered more or less severely from partaking of preserved fruit or beverages, in which traces of lead were discovered. One was the case of a man who had been in the habit of obtaining beer at an early hour in the morning, which, from standing in the pipes during the night, had become contaminated, and after some months he showed well marked symptoms of lead poisoning. In the same way the daily taking of minute quantities of copper might produce evil results after a time, though one or two doses might cause no inconvenience.

Dr. STEVENSON MACADAM dissented from the statement of Mr. Siebold that there was any uncertainty in determining the quantity of metallic poison present by the colour test, if the operation was properly carried out. In the case of lead, if different acids were employed at different times a difference in the result might be found, but in water testing, which was specially referred to, if acetic acid were regularly used and sulphuretted hydrogen the results would be fairly comparable one with the others, and would indicate the quantity of lead present in the water. He had known several cases in which injurious effects had followed the use of preserved provisions, where it was evident the tin had been acted upon. He did not consider the presence of copper in the fæces as a positive proof that it had not been taken up by the system.

Mr. GROVES said there were some remarkable experiments on the use of copper salts reported in the *Journal de Pharmacie* a few months ago. In one case an individual had pushed it so far that his hair and nails became of a green colour, and yet he was reported not to have suffered in health.

Mr. ROBBINS asked if Dr. Rowe could state the quantity of copper found in the water he referred to.

Dr. ROWE said the sample he referred to last contained sixteen grains of copper in the form of sulphate per imperial gallon, and it was found remunerative to precipitate it by means of iron. He lived in the very heart of a copper mining district, in fact all the minerals spoken of that day were found within a thousand yards of his house, and all the streams were more or less affected. Still they were drunk of by animals, and more or less by human beings, though of course the water companies endeavoured to obtain their supplies from pure sources.

The PRESIDENT said the impression produced on his mind by the discussion was that the proposition that copper was not injurious to the system had been rather overproved. If they were to admit all that had been stated they must go to the extent of saying that not only copper but other admittedly poisonous substances might be introduced into the system, as no doubt they might be under certain circumstances, without producing any marked injurious effects. Mr. Chipperfield alluded to the effects which were not observed in the neighbourhood of copper works, where, as he said, you might taste the copper in the air. His own impression was that it was not copper but sulphurous and arsenious acid which one tasted; they knew that vegetation was destroyed to a very great extent, and by looking at the miserable horses and cows with swelled joints it was evident that animal life also suffered to an enormous extent. True, upon going into the works one saw both young and old not manifesting any signs of injury, but was it to be inferred from that that arsenious acid might be thrown into the atmosphere with impunity, and that it might be inhaled also without the risk of injury? He should hesitate long before coming to such a conclusion. The instances mentioned by Dr. Rowe were not conclusive to his mind, because he looked upon cases of that description as being of the nature of negative evidence, which told for very little when put against the positive evidence that had from time to time come under his notice. He might mention one very well authenticated case in which a merchant in London had been using, in his family, some preserved greengages. After some time he began to suffer in health with colicky pains, disagreeable taste in the mouth, swollen tongue, and other symptoms of metallic poisoning, and the preserved greengages being analysed at St. Bartholomew's Hospital were found to contain copper. Yet no other member of the family suffered at all. He could give another instance, where, the well being out of order, a family had for some time to make use of rain water from a leaden cistern, and the lady of the house suffered from lead poisoning, but no one else, although all used the same water. Positive evidence of this description was far more conclusive than mere negative evidence. There were apparently some persons who were highly susceptible to influences of this description, and they would suffer materially where others would be quite unaffected. There was a question which was still debated, as to the extent to which persons suffered in health from occupying rooms hung with arsenical papers; and here again there were individual instances in which ill effects were experienced, whilst others would escape. Now this was a practical question, and it had been so treated by Mr. Kingzett, who referred to prosecutions having taken place for the sale of green peas which were found to contain copper; and he (Professor Redwood) had been engaged more prominently perhaps than many in such prosecutions. He had found that green peas imported from France contained copper, to the extent of at least 2 grains of sulphate in a tin of 8 or 9 ounces, and when he considered that the public who purchased these articles did so in ignorance of the fact that they contained something which might be injurious, he had come to the conclusion that no dealer or manufacturer was justified in supplying an article of food which contained an unnecessary addition of a poisonous substance, put there merely to give a particular colour, without notice being given of its presence. He did not profess to form a medical opinion on the subject himself, but as many medical men considered this addition injurious to heath, he held that where such an article was sold, it should have a plain indication on the label that the contents were green peas "preserved with copper," and then the public might use them or act as they thought proper. This was the advice he had given to a dealer some time ago, who had a large stock of these articles on hand, and asked him what he should do with them. He said, if it was necessary that they should be sold, put a label on them indicating the presence of copper, and then the public would be responsible if any ill effects ensued.

Mr. KINGZETT in reply to Mr. Siebold's remarks said he had found that with ordinary care, the use of a brass bunsen burner did not cause the introduction of traces of copper into any matters which might be under examination for that substance, but to avoid even the possibility of an error arising from this source, Dr. Paul and he had employed an iron burner and platinum vessels. No great accuracy had been attempted in determining the amounts of copper, not deeming it a matter of great importance for their inquiry, but by ascertaining the intensity of colour presented by an ammoniacal solution of the copper, a good idea, better perhaps than by the sulphide colorimetric method, could be got. Dr. Wright had alluded to several cases of metallic poisoning that had been reported in the daily papers and with which they were all acquainted, but it was futile to institute comparisons between investigations which had been effected, and any it might be desirable to make. What Dr. Paul and he (Mr. Kingzett) had advanced in their paper were facts relative to copper and did not apply in any measure or manner to lead, tin, or zinc. One gentleman had suggested that although the copper was found in the fæces, it might previously have been in the system, but this idea was entirely opposed by the evidence. It should be considered that the various digestive processes take but a few hours for their completion, and that it is only during a particular part of that time, viz., while the food is yet in the stomach, that it is possible for the copper to be absorbed into the system. Now it had been shown that employing an imitative digestive process as much as forty or fifty hours were required to render soluble the small amount of copper contained in that quantity of peas which would be eaten at a meal. The probability therefore was that the greater part would pass through the intestinal canal, without experiencing any change at all, and if it were required to show that the copper is not absorbed in any considerable measure, surely the fact that it is found in the first fæces passed after such a meal as he had described was sufficient to prove this. It was gratifying to hear from the meeting so much negative evidence (as it had been termed by Professor Redwood), confirmative of the positive evidence adduced by Dr. Paul and himself. People were too much carried away by opinion, itself a stumbling block to investigation. What was medical opinion worth? nothing—unless it were based upon those precise facts necessary to its proper formation, and until Dr. Paul and he had investigated the physiological behaviour of the copper eaten with preserved peas, neither chemists nor medical men were competent to frame an opinion regarding it. The decisions arrived at in the various prosecutions referred to in the paper had depended upon the opinions of medical men or chemists, and inasmuch as these opinions were valueless, the decisions were unjust and affected trade in a mischievous manner. He (Mr. Kingzett) could not enter into the question as to whether a person was entitled to sell peas preserved green by the use of copper; that was irrelevant to the inquiry of Dr. Paul and himself; but he would say that if a person ate such peas, no harm could possibly result to his health from so doing.

A vote of thanks having been awarded to the authors of the paper, the Conference adjourned for luncheon.

Upon resuming, the next paper read was—

Analyses of Preserved Carrots, Potatoes, Cabbage, and Mixed Vegetables.

BY PROFESSOR ATTFIELD.

The influence of desiccation on vegetable substances and the extent to which preserved vegetables differ from fresh vegetables, if indeed they differ at all or in any important degree, are matters of much interest to the pharmacist and medical practitioner who frequently use dried herbs and dried parts of plants, and to the general public who largely use preserved vegetable foods. As regards actual chemical alteration probably little takes place if the perfectly sound and fresh fruit, root, leaf, stem, etc., be at once and rapidly dried at a moderately low temperature, or be quickly subjected to the selected process of preservation before any fermentative action commences. Possibly, however, active medicinal substances, such as alkaloids, may suffer alteration during reduction to the dry state, a point which will be cleared up as scientific investigation of these bodies becomes more extended. Of course, in cases where the process by which any given parcel of food has been preserved is not known, there will arise the suspicion that edible portions which do not readily lend themselves to the process may have been excluded, or that contusion of stems or bulky fruits, etc., may have resulted in partial loss of juice and of the alimentary bodies therein dissolved. The question also arises, does desiccation or other mode of preservation so physically alter constituents not chemically altered, as to impair the value of the vegetable substance, either as food or as medicine. The whole subject is a very large one, and to its full elucidation the present paper is only a very small contribution.

A few months ago, by request of the Chairman of the Admiralty Committee appointed to consider the causes of the outbreak of scurvy in the recent Arctic Expedition I analysed samples of vegetables taken from the residual stores of the "Alert" and the "Discovery," on the return of those ships to England.

The articles sent to me for analysis were :—

1. Fresh carrots, preserved in hermetically sealed tin cases.
2. Dried potatoes.
3. Dried compressed cabbage.
4. Dried compressed mixed vegetables.

These samples I so analysed as to admit of comparison being made between their composition and that of good average specimens of the respective vegetables recently removed from the ground.

The samples were all in good condition. The carrots from the tin were whole, sweet, juicy, and of full flavour; the dried fragments of potatoes were perfectly sound; the dried compressed cabbage was of good colour, crisp, and had the characteristic smell of the vegetable; the dried compressed mixed vegetables had an appetizing appearance, and the aroma of well-made vegetable soup.

1. *Carrots (cooked).*

The samples could not be distinguished in appearance from cold, soft, recently cooked carrots. Evidently they had been preserved in the tin by some mode of heating or steaming, similar to that employed in preserving meat in tins. Submitted to analysis they yielded :—

	In 100 parts by weight.	
Water	89·13	
Dry vegetable matter	10·21	10·87
Dry mineral matter	·66	
	100·00	

The 10·21 parts of dry vegetable matter consisted of :—

Albuminoid matter	·98
Celluloid matter or fibre	1·14
Fatty matter	·29
Other non-nitrogenous matter	7·80
	10·21

And the 0·66 of dry mineral matter yielded (together with other less important substances) :—

Alkalies (as oxides)	0·31
Phosphoric acid (that is, phosphoric anhydride)	0·08

Carrots, like some other vegetables, absorb large quantities of water when cooked in that liquid. A fair average proportion of water in uncooked carrots is 85 per cent., a proportion which does not naturally vary very widely. That is to say, if 100 pounds of uncooked carrots were thoroughly desiccated, 15 pounds of solid matter would remain, and 85 pounds of water be dissipated—passing away as steam. Now, 100 parts of the cooked carrots just analysed only yielded 10·87 parts of solid matter; or, in other figures, 15 pounds of solid matter would be contained in 138 pounds of these soft, moist, cooked carrots. But assuming, as one must do for purposes of comparison, that we are dealing with the carrots in the uncooked condition—assuming that we have, not 138 parts of cooked carrots, containing a quantity of water absorbed during cooking, but 100 parts of uncooked carrots in the natural condition—assuming, in short, that the carrots when fresh contained the average proportion of 85 per cent. of water, then the composition of the sample would be as follows :—

Composition of the Carrots when uncooked.

(Based on the fair assumption that the fresh carrots contained the average natural and normal proportion of water, namely, 85 per cent.)

	In 100 parts by weight.
Water	85·00
Dry vegetable matter	14·09 } 15·00
Dry mineral matter	·91 }
	100·00

The 14·09 parts of dry vegetable matter consisting of:—

Albuminoid matter	1·34
Celluloid matter or fibre	1·58
Fatty matter	·40
Other non-nitrogenous matter	10·77
	14·09

And the 0·91 of dry mineral matter containing (together with other less important substances):—

Alkalies (as oxides)	0·43
Phosphoric acid (*i.e.* anhydride)	0·11

But, in truth, whether preserved carrots contain more or less water, is a matter of inferior importance. The question of chief moment is whether or not the components of this food bear to each other a proper ratio, whether or not any of these components have been "washed out," so to say, during the preserving process, the food maintaining its sensible characters, but having lost some essential constituent, some valuable property. The answer to this question in the case of the sample analysed was at once afforded on comparing the figures (just given) with those (in the next table) showing] the average composition of good sound carrots freshly removed from the ground. It was then at once evident that the preserved carrots were as sound and good as the fresh natural vegetable, and that there was no practical difference between the carrots from the sample tin and carrots cooked within a few hours of their removal from the ground.

Average Composition of fresh uncooked Carrots.

(The figures give averages—calculated by Wolff and Knop—of all trustworthy analyses published up to August 1865.)

	In 100 parts by weight.
Water	85·0
Dry vegetable matter	14·0
Dry mineral matter	1·0
	100·0

The 14 parts of dry vegetable matter consisting of:—

Albuminoid matter	1·5
Celluloid matter or fibre	1·7
Fatty matter	·2
Other non-nitrogenous matter	10·6
	14·0

And the 1 part of dry mineral matter yielding (togeher with other less important substances):—

Alkalies (as oxides)	0·59
Phosphoric acid (*i.e.* anhydride)	0·12

Only in the proportion of "alkalies" was any important difference observable. Instead of an average of, say, 0·6 per cent., or a minimum of 0·5, there were only 0·43 per cent. in the original uncooked carrots. The deficiency is not great, and was quite accounted for on examining the small quantity of water which had exuded from the carrots in the tin. This water was rich in alkalies. But, as just stated, it was small in quantity, and, moreover, would probably be turned out of the tin with the carrots at meals, and be swallowed with the vegetable.

I may add that by direct experiment I find that carrots absorb large quantities of water during cooking, hence the assumption that the cooked carrots contained additional water to that occurring in them in the natural state was well founded.

2. *Dried Potatoes.*

The sample yielded:—

	In 100 parts by weight.
Water	12·17
Dry vegetable matter	83·57
Dry mineral matter	4·26
	100·00

The 83·57 parts of dry vegetable matter contained:—

Albuminoid matter	9·81
Celluloid matter or fibre	1·83
Fatty matter	·28
Other non-nitrogenous matter	71·65
	83·57

And the 4·26 of dry mineral matter yielded (together with other less important substances):—

Alkalies (as oxides)	2·36
Phosphoric acid (*i.e.* anhydride)	0·53

Composition of the original undried Potatoes.

(Based on the fair assumption that they contained the average natural proportion of water, namely, 75 per cent.)

	In 100 parts by weight.
Water	75·00
Dry vegetable matter	23·79
Dry mineral matter	1·21
	100·00

The 23·79 parts of dry vegetable matter consisting of:—

Albuminoid matter	2·80
Celluloid matter or fibre	·52
Fatty matter	·10
Other non-nitrogenous matter	20·37
	23·79

And the 1·21 parts of dry mineral matter containing (together with other less important substances):—

Alkalies (as oxides)	0·67
Phosphoric acid (*i.e.* anhydride)	0·15

Average Composition of Potatoes.

(The mean of many published analyses.)

	In 100 parts by weight.
Water	75·0
Dry vegetable matter	24·1
Dry mineral matter	·9
	100·0

The 24·1 parts of dry vegetable matter consisting of:—

Albuminoid matter	2·0
Celluloid matter or fibre	1·0
Fatty matter	·2
Other non-nitrogenous matter	20·9
	24·1

And the 0·9 of dry mineral matter containing (together with other less important substances):—

Alkalies (as oxides)	0·55
Phosphoric acid (*i.e.* anhydride)	0·17

A glance at the second and third of these three tables relating to the sample of potatoes, will show that the dried potatoes supplied to the ships were, from the chemical point of view, of good quality, containing all the chief components of the sound normal vegetable, and containing them in natural proportion. The first table interpreted in the light of the second and third shows, further, that one pound of such dried potatoes represented three and a half pounds of undried potatoes.

Not only were the potatoes chemically good, but their general condition was excellent. No trace of mouldiness, sourness, or other undesirable quality could be detected.

3. *Dried compressed Cabbage.*

The sample yielded :—

	In 100 parts by weight.
Water	19·93
Dry vegetable matter	74·18
Dry mineral matter	5·89
	100·00

The 74·18 parts of dry vegetable matter contained :—

Albuminoid matter	13·01
Celluloid matter or fibre	9·45
Fatty matter	2·56
Other non-nitrogenous matter	49·16
	74·18

And the 5·89 of dry mineral matter yielded (together with other less important substances) :—

Alkalies (as oxides)	1·75
Phosphoric acid (*i.e.* anhydride)	·64

Composition of the original undried Cabbage.

(Based on the fair assumption that it contained the average natural proportion of water, namely, 89 per cent.)

	In 100 parts by weight.
Water	89·00
Dry vegetable matter	10·36
Dry mineral matter	·64
	100·00

The 10·36 parts of dry vegetable matter consisting of :—

Albuminoid matter	1·43
Celluloid matter or fibre	1·03
Fatty matter	·28
Other non-nitrogenous matter	7·62
	10·36

And the 0·64 parts of dry mineral matter containing (together with other less important substances) :—

Alkalies (as oxides)	0·19
Phosphoric acid (*i.e.* anhydride)	0·07

Average Composition of Cabbage.

(The mean of several published analyses.)

	In 100 parts by weight.
Water	89·0
Dry vegetable matter	9·8
Dry mineral matter	1·2
	100·0

The 9·8 parts of dry vegetable matter consisting of :—

Albuminoid matter	1·5
Celluloid matter or fibre	2·0
Fatty matter	·4
Other non-nitrogenous matter	5·9
	9·8

And the 1·2 of dry mineral matter containing (together with other less important substances) :—

Alkalies (as oxides)	0·63
Phosphoric acid (*i.e.* anhydride)	0·20

The figures of these tables of the composition of the sample of cabbage, show that while the vegetable constituents are in good proportion, there is considerable deficiency of mineral matter, especially of the saline material termed alkaline phosphate. In the first place, 0·64 per cent. of mineral matter is not only about half the average proportion, but is much less than the minimum hitherto obtained from cabbage. And in the second place, only about one-third of this already small amount of mineral matter is "alkalies," whereas half the mineral matter should be of this character. Thirdly, the phosphoric acid, or rather phosphoric anhydride, is present to only about one-third the normal proportion.

As to the physiological import of so great a deficiency of alkaline phosphates in this sample of cabbage, I do not pretend to judge. At the same time, eminent authorities consider that these saline constituents of vegetables contribute very materially to the food value of the vegetables.

As to the cause of the deficiency, the chemical results are suggestive of loss of juice from the original cabbage. If the fresh cabbages were submitted to pressure before drying to such an extent as to bruise the leaves and cause an outflow of juice, that would exactly explain the facts revealed by the analysis.

I may add that experiments undertaken with the view of ascertaining whether the cabbage yielded as much organic acid as a sample taken from my own garden, also pointed to loss of juice from the original cabbage.

One pound of dried cabbage represents, in weight, seven pounds of the fresh vegetable.

4. *Dried compressed mixed Vegetables.*

The sample yielded :—

	In 100 parts by weight.
Water	15·61
Dry vegetable matter	80·29
Dry mineral matter	4·10
	100·00

The 80·29 parts of dry vegetable matter yielded :—

Albuminoid matter	8·11
Celluloid matter or fibre	4·94
Fatty matter	1·82
Other non-nitrogenous matter	65·42
	80·29

And the 4·1 of dry mineral matter yielded (together with other less important substances) :—

Alkalies (as oxides)	1·82
Phosphoric acid (*i.e.* anhydride)	·47

Composition of the original undried mixed Vegetables.

(Based on the assumption that they contained 85 per cent. of water.)

	In 100 parts by weight.
Water	85·0
Dry vegetable matter	14·3
Dry mineral matter	·7
	100·0

The 14·3 parts of dry vegetable matter containing:—

Albuminoid matter	1·5
Celluloid matter or fibre	1·0
Fatty matter	·3
Other non-nitrogenous matter	11·5
	14·3

And the 0·7 parts of dry mineral matter containing (together with other less important substances):—

Alkalies (as oxides)	0·31
Phosphoric acid (*i.e.* anhydride)	0·08

There are no published analyses of "mixed vegetables," and if there were, the mixture might not be similar to that of the sample. I should form the opinion that the sample of mixed vetegables, like that of the cabbage, though not to the same extent, had lost a portion of its original juice—perhaps by pressure—and, consequently, a portion of its valuable saline constituents.

Organic Acids.—Some experiments, commenced with the object of ascertaining the proportion of organic acids in the vegetables, led to no useful results. Comparative experiments with fresh and preserved vegetables were tried, but were abandoned. Larger samples of the preserved vegetables, and much time, would be necessary for such an investigation.

Conclusions.

The results of the analyses and general examination may be re-stated shortly as follows:—

1. The carrots were of good quality.
2. The potatoes were of good quality.
3. The cabbage was deficient in important saline constituents.
4. The mixed vegetables are probably somewhat deficient in saline substances.

Whether or not these conclusions may be applied to the similar preserved vegetables supplied to the public generally cannot be decided until more analyses have been published.

The PRESIDENT said he should like to know if Professor Attfield had any reason to suppose that these vegetables had been preserved by the method commonly adopted. Some years ago several papers were published on the preservation of vegetables by a process of drying as well as pressing, and if that method were adopted he could not understand how the deficiency noticed arose. He presumed the desiccation was mainly caused by pressing out the juice; if, however, vegetable substances could be preserved without the separation of any of the component parts and without any deterioration taking place it might be of importance in pharmacy. Dried medicinal herbs underwent considerable changes, and sometimes became inert, and attempts had been made to preserve them in a humid condition, but hitherto these efforts had proved failures.

Mr. GROVES asked if Professor Attfield had discriminated between potash and soda in his analyses, because it was supposed that scurvy was due to the absence of potash in the food.

The PRESIDENT said it would be interesting to know if any material change had taken place in the colour of the vegetables.

Mr. E. SMITH remarked with reference to the preservation of medicinal herbs that a great mistake is made in drying them at too high a temperature. Dry air at a comparatively low temperature was the best for such a purpose.

Mr. WILLMOTT asked what Mr. Smith considered a high temperature for preserving herbs.

Mr. SMITH said it was very common to have a room specially heated for drying hemlock, henbane, and such plants, but if a low temperature were employed with dry air there would be a much better product. It would be all the better if the air could be passed over ice if it were kept dry.

Dr. SYMES thought the thing to aim at was to strike the happy mean between the use of too high a temperature and keeping the plants about too long in the process. If vegetable substances were kept for any length of time, especially if they were not in very thin layers, a process of fermentation was likely to be set up, and although they might appear green they would be changed more or less in their character. It should be ascertained by experience how long it would be safe to keep them about and then as low a temperature as possible employed.

Mr. GREENISH said the green colour was due to the presence of chlorophyll, an active agent in the process of assimilation, and it was a question whether a temperature capable of acting on so delicate a substance as chlorophyll would necessarily have any influence on the product of assimilation previously formed; the loss of that bright green colour did not necessarily imply that the active principle was injured and he should question whether the loss of the green colour really injured the product. He should like to know if Mr. Smith had observed any instances of henbane being thus injured.

Mr. SMITH said this was not an easy question to answer; but he thought he had observed that a better tincture was obtained from hemlock and henbane when dried at a low temperature. It was fairly reasonable to suppose that a high temperature tended to produce a decomposition of the active principle.

Mr. UMNEY said he had had many years' experience in the drying of medicinal herbs, more especially those of conium, digitalis, belladonna, and henbane. Henbane was the most difficult herb to dry, on account of its extreme succulence. He generally employed frames made of cane threaded into thin pieces of deal about four or five feet long, the canes being arranged about half an inch apart. These were put into a room built round a steam boiler, and he had generally found if these frames were put into the room at two or three o'clock in the afternoon they might be taken out next morning with their contents perfectly dry, without any sign of decomposition. On the other hand he had seen large quantities of belladonna hopelessly spoiled from attempting to force the process. Henbane was chiefly supplied to the London market by growers in Lincolnshire and Cambridgeshire, and Oxfordshire, and the leaves came to market kiln dried. The temperature of the room about the boiler was from 140° to 150° Fahr., probably sinking to 110° during the night.

Mr. SMITH asked what Mr. Umney would consider a sign of decomposition in henbane leaves.

Mr. UMNEY said he had seen henbane leaves, when packed too thickly upon the drying frames he had described, quite brown and literally stinking, whereas a leaf properly dried maintained its green character and when it was touched it crumbled to powder. To finish the leaves elegantly they should be rubbed through a sieve and the midribs taken out.

Mr. BALKWILL asked whether in the case of a plant such as henbane, the leaves only of which were used, it would be better that the leaves should be separated from the stalk before drying, or in other words whether the sap receded during drying from the leaf into the stem or from a succulent stem into the leaf. In reference to drying herbs, his own experience this summer had been in drying digitalis, conium, and one or two others, that very unsatisfactory results were obtained by drying them in a room where there was not a thorough circulation of air. The remarks of the President had turned his thoughts to a preparation which was very important, and would no doubt be much more used, if it were not so uncertain, namely elaterium. If the juice or the fresh fruit could be preserved, it would be a very great advantage because practically no difference was observable between the active elaterium extract and the one inert from age. Again, would it not be possible to preserve the expressed juices of plants in hermetically sealed tubes without the addition of any spirit? In the presence of so many practical men he threw it out at a suggestion. He had a hope that the juices as freshly pressed from medicinal plants might in this way be preserved for dispensing. The Pharmacopœia expressed juices were unsatisfactory, inasmuch as they do not keep well.

Mr. WILLMOTT feared that any such attempt would prove a failure. He believed the sources of decomposition resided rather in the thing itself than in the atmosphere, and that unless the sealed tube was submitted to a temperature sufficient to destroy any germs present in the fluid it would be certain to decompose.

Professor ATTFIELD said he had no information how the substances he had examined were dried. The carrots in the sealed tins were perfectly fresh and juicy. With respect to colour, the dried cabbage had a green colour, though perhaps not quite so green as the fresh vegetable. When soaked for two hours in water it absorbed nearly the normal amount of water present in fresh cabbage, and had a most appetizing appearance. When the dried carrots were soaked for a few hours, they swelled up and were found to have absorbed about $\frac{9}{10}$ as much moisture as would be present in the fresh vegetable. He had reason to believe that nearly the whole of the alkali-metal salts present were those of potassium. He knew very little with regard to the best temperature for drying herbs, but from what he did know, he quite agreed with the remarks of Mr. Smith and Dr. Symes. He hoped the remarks of Mr. Balkwill, suggestive as they were of unequal medicinal activity of different parts of herbs, would be taken up by some pharmacist, and form the subject of a future communication to the Conference or to the Pharmaceutical Society.

(*To be continued.*)

Obituary.

Notice has been received of the death of the following:—

On the 11th of September, 1877, Mr. George Swire, Pharmaceutical Chemist, Brixton Hill, Surrey. Aged 55 years. Mr. Swire was a founder of the Pharmaceutical Society, having been an Associate from 1842 to 1853 and a Member since 1854.

We have to announce the sudden death of Mr. William Valentine Wright, Pharmaceutical Chemist, of Highland Bickley Park, senior partner in the firm of Wright, Layman and Umney, Wholesale Druggists, of Southwark Street, London, which took place on Monday last (17th inst.) at Dundee. Mr. Wright, who was on a tour with his son through Scotland, was attacked with erysipelas, which proved most rapidly fatal. Mr. Wright was 52 years of age. We are informed that the style of the firm will remain unaltered, and that the home management of the business will be conducted by Mr. C. Umney.

Correspondence.

The Composition of Essential Oils.

Sir,—Dr. Tilden in his letter of last week makes the following observation: "Mr. Kingzett's announcement that he had demonstrated the existence of a terpene of the formula $C_{10}H_{16}$ in the oils of caraway, bergamot, lemon, etc, is therefore superfluous." The justice of Dr. Tilden's remark will be best tested perhaps by a brief comparison of researches generally relating to essential oils.

Incidentally Dr. Tilden's investigations have covered much the same theoretical ground as my own, and his results being obtained after mine, and his conclusions being identical with mine, they are therefore confirmative of mine. On the one hand, I have shown that all hydrocarbons of $C_{10}H_{16}$ formula give peroxide of hydrogen when subjected to a process of limited oxidation. He has shown that the same hydrocarbons yield a derivative of the formula $C_{10}H_{15}$ (NO); I have shown that the $C_{15}H_{24}$ bodies do not give H_2O_2, and he has shown that they do not yield $C_{10}H_{15}$ (NO). From my results I predicted that certain $C_{15}H_{24}$ hydrocarbons would not yield cymene $C_{10}H_{14}$, inasmuch as I had previously ascertained that not only does cymene yield H_2O_2 as above, but that all hydrocarbons which contain it as a proximate nucleus give H_2O_2. Dr. Wright subsequently gave the proof to my prediction—for instance, in the case of the hydrocarbon $C_{15}H_{24}$—from clove oil.

Almost every worker upon the subject of essential oils has observed and recorded characters which indicate that even among the bodies of $C_{10}H_{16}$ formula, there are modifications. Dr. Tilden has confirmed this fact, and is enabled by the characters of his derivatives (all of the composition $C_{10}H_{15}$ (NO,)) to give greater precision to this truth. It will thus be seen that apart from the great practical interest of Dr. Tilden's work, it has advanced the theory of chemistry in no wise beyond confirming propositions already established.

Therefore, if anythiug be superfluous which has only a practical value, the whole of Dr. Tilden's research is superfluous, in the same sense as my observation is so characterized by Dr. Tilden. Dumas may have determined the vapour density of turpentine and similar oils including lemon, but that is not to say that he did also that of caraway, bergamot, and many others which were classed into a common group chemically identical, by means of a general reaction which I have worked out—a classification at which Dumas did not arrive, but one since confirmed by Dr. Tilden.

I do not even forget that Oppenheim, in 1871, showed that the terpenes yield one and the same cymene, but Oppenheim did not show that terpenes yield H_2O_2, because they also yield cymene, nor did he show that all hydrocarbons yielding cymene give peroxide of hydrogen.

In view of these facts, I must beg to differ from Dr. Tilden, and maintain that not only was my observation following the reading of his paper not superfluous, but on the other hand very significant.

I have no ambition to discuss the matter further, and while I acknowledge the value of Dr. Tilden's work, I attach an equal value to my own, even to that particular part of it which your correspondent has termed "superfluous."

Charles T. Kingzett.

1, *Victoria Street, S.W.*

The Conference Grants.

Sir,—There is not the slightest occasion for my friend Dr. Tilden to defend himself for accepting a Conference grant. That acceptance and its outcome are matters on which the Conference may be congratulated. Indeed respecting all highly chemical researches which may reasonably be expected to include truths interesting and useful to pharmacists, such as the aconitine investigations and the examination of many of the essential oils, I would say that the more the Conference is afforded the opportunity of aiding them the more will pharmacy be benefited. But beyond these is a well defined class of absolutely purely chemical subjects, as well as subjects which, annually continued, end in becoming purely chemical; and grants in aid of such subjects may, I think, now more appropriately be made from the more recently established and rich research funds of the more purely scientific societies. The Conference has but little money to spend. That little is subscribed by men who follow a branch of applied chemistry. Surely it is not too much to expect that the researches it aids should at least offer promise of pharmaceutical application.

John Attfield.

Asplands, Watford, Sept. 19, 1877.

P.S.—In giving Dr. Tilden's paper to the meeting at Plymouth, I am sorry I inadvertently overlooked the paragraph relating to Dr. Wright's cymenes.

E. W. Cleaver.—We are not acquainted with any such law.

S.—By redistillation of the oil of turpentine.

"THE MONTH"

Already the damp mists in the evening and morning betray the presence of autumn, and the rich yellow and red tints of the foliage show that the time of flowers is well nigh past and that fruits must now take their place.

Comparatively few medicinal plants are to be found in blossom this month, but several are still conspicuous by reason of their fruits. The baccate fruits of the belladonna, which look like black cherries, are now quite ripe and present a most tempting appearance. Probably few, except the residents in chalky districts, are familiar with this plant, the woody nightshade (*Solanum Dulcamara*, L.) being frequently mistaken for it. That plant has, however, bright scarlet fruits, which, like those of belladonna, are baccate, *i.e.*, berry-like, for they differ from the typical berry in being superior and having axile placentation.

Solanum nigrum, a weed in gardens and waste places, has leaves resembling those of *Dulcamara*, except that they are never auriculate, but differs in having white flowers, and the fruits arranged in a small umbel, and of a black colour. It is also a much smaller plant, being rarely more than eighteen inches high.

Several of the September plants are still in blossom, among which the hop with its handsome festoons of strobiles still forms a conspicuous object in the hedges; while the bright blue flowers of the borage and the cichory, and the white blossoms of the chamomile, feverfew, and yarrow are still to be seen here and there, where, owing to having less sunshine, they are a little later than usual.

Almost the only fresh plants in flower this month are the colchicum and saffron crocus. The former is a singular plant in several respects. The flowers arise from the ground before the leaves, the latter not appearing until the following spring. The plant, although generally distributed over England, is very local, and is only found abundantly in a few districts, apparently preferring damp calcareous meadows. The London market is said to be supplied chiefly from Gloucestershire and Oxfordshire. Its large pale purple, or reddish lilac blossoms are very like those of the common crocus, and as in that plant many of them arise one after another from the same corm.

The corm, or solid underground stem, is about the size of a tulip bulb, and is rounded on one side and flattened on the other. In the flat side there is a deep longitudinal furrow, which is occupied by the flowers. It is this furrow which gives to sliced colchicum corms the lateral indentation by which they are so easily distinguished. The blossom does not arise from the large corm, but from the young one at the base of the furrow, which after flowering enlarges, and forms the corm of the next year. On this account the flower appears to be placed laterally as regards the corm. That the large corm really belongs to the last year's plant is evident from the depression at its apex where the flowering stem of the former year arose. The dark brownish black tunic (consisting of modified leaves) surrounding the corm is prolonged a short distance above it, and the flower stem is enclosed in a white, membranous, sheathing or spathaceous bract. The six stamens are attached to the perianth, and are furnished with six versatile anthers, which are are commonly said to be extrorse. They do not, however, open dorsally, but at the sides, so that the pollen neither faces the style nor the perianth. If a flower be examined in the young state before the anthers have opened, it will be found that the filament is attached at the side of the anther facing the styles; this cannot so easily be observed afterwards, because of the versatile character of the anthers. The stigma is very small and the styles are very long and thread-like, and may be traced down below the surface of the ground, the three-celled ovary being hidden within the tunic of the corm, and not appearing above ground until the following April, when the tuft of broad leaves surrounding it is the only sign by which its presence may be detected. The capsule affords an excellent example of septicidal dehiscence, and is perhaps the best that could be selected for illustrating it. The seeds are ripe by the end of June. They consist almost entirely of very hard greyish albumen, the embryo being very minute; the cells of the albumen are remarkable on account of the thickness of their walls, which are furnished with large pores. The starch of the colchicum corm is also worthy of microscopical examination, the granules being mostly compound.

Colchicum is supposed to derive its name from Colchis in Asia, a district famed for the number of poisonous plants, and in which the plant was first used as a medicine. The name meadow saffron undoubtedly arose from the likeness of the flower to that of the true saffron.

The saffron crocus (*Crocus sativus*, L.) also flowers at this time of year, and not in early spring like the common crocuses of the garden. The leaves also do not appear until after the flowers have faded. The corm is round and without a furrow, the leaves are seven or eight inches long, very much narrower than those of colchicum, being linear, and traversed by a white midrib like those of the spring crocus. Although the flower is very similar in shape and size to that of the colchicum, it is easily distinguished by having only three stamens, which are attached to the outer segments of the perianth. There is only one style, three or four inches long, which is thread-like and terminates in three wedge-shaped stigmas, which are notched at the apex. The ovary, which must be looked for quite at the base of the flower tube, is inferior; *i.e.* the tube of the perianth does not easily separate from it as in the colchicum. Although formerly cultivated at Saffron Walden* in Essex, and Hinton in Cambridgeshire, it has not been grown in England for commercial purposes for nearly a hundred years, and has not only ceased to be found† in those localities, but is apparently very rare in botanical gardens, for we have not noticed it in either those of Kew, Regent's Park, or Chelsea. This is perhaps owing to the fact that the flowers, even though artificially fertilized, hardly ever produce seed, a circumstance which has been accounted for by supposing the plant to be a hybrid, or which may be due to long years of cultivation destroying its tendency to ripen seed. Although in scarce seasons much adulterated with the stamens and sometimes with a coloured mixture of honey and chalk, we have never seen either shreds of beef, safflower, or marigold petals mixed with it; occa-

* The device of the seal of the corporation of this town is a curious play upon the name, it consisting of three saffron flowers *walled in*.

† It is stated by Chapellier to be unknown in a truly wild state.

sionally, however, fragments of the perianth may be seen, but probably these have only been accidentally mixed with it; the stamens are undoubtedly the most frequent admixture. These as well as all other adulterations are easily detected by throwing a little of the saffron into cold water, when anything that differs in character from the tripartite stigma will easily be recognized.

In the Regent's Park Botanical Gardens the *Actæa racemosa* is now in full blossom. This plant has already been alluded to in the month of May. The scammony and tobacco plants are also in full flower, and the mango and Malay apple have both ripened fruits this year. At Kew there is nothing fresh except the Papaw tree (*Carica Papaya*, L.) in bud in the economic house. The juice of this plant is used in the Mauritius as a remedy for round and thread worms, and has the advantage of not possessing a nauseous taste. A decoction of the seeds or roots is said to answer the same purpose; a decoction of the root has also been used for hœmaturia and certain kidney diseases. The plant is stated to possess the curious property of rendering recently killed meat tender in a short time. For this purpose the meat is simply suspended to the plant for a few hours, according to Bouton, the author of '*Plantes Médicinales de Maurice*.'

Plantago Psyllium, a small kind of plantain, the seeds of which were formerly used as a remedy for dysentery, may now be observed in blossom in the open ground, both here and at the Chelsea gardens. The seeds are just the size and colour of a flea, and hence were called flea seed; their shape is exactly that of a boat in miniature. The seeds of a nearly allied species, *P. Ispaghula*, or Spogel seeds, are still official in the Indian Pharmacopœia for use in catarrhal and renal affections. The seeds themselves answer better for dysentery and diarrhœa than the decoction, since they possess the advantage of developing a quantity of mucilage by the time that they reach the lower intestines. Several rare British plants are now in blossom in the herbaceous ground at Kew, and will delight the eyes of those botanists who have not yet seen them and who have the opportunity of visiting these magnificent gardens. Among these may be mentioned *Linosyris vulgaris; Artemisia campestris;* and *Urtica pilulifera*. It would be a great boon to those who visit these gardens for the purpose of study if the British plants were placed by themselves instead of being so mixed with numberless foreign species that it is almost impossible in the short space of an afternoon to find out what plants of our native flora are in blossom. This plan has been adopted with regard to medicinal plants which may be found in front of the No. 2 museum. These gardens afford an opportunity for amateurs to become acquainted with our rarer species, and an arrangement of the kind alluded to would doubtless so familiarize beginners with the appearance of species that it would to a great extent prevent the recklessly lavish gathering of rarities which too often takes place when they are found for the first time by a young botanist.

A few American medicinal plants are also to be seen in blossom, of which we may notice *Liatris spicata*, a composite plant used in nephritic complaints and said to be used in the Southern States for snake bites, whence its name of button snakeroot. *Eupatorium purpureum*, the American "Queen of the Meadow," is also useful in urinary diseases, the root being known as gravel root. It is a tall handsome plant about seven feet high with flowers very like those of the hemp agrimony (*Eupatorium cannabinum*, L.), so common by damp waysides in this country, but it has whorls of three to six ovate leaves. *Xanthium spinosum* is now in fruit and is worthy of examination on account of its structure, which has already been explained in this Journal. The singular Compass plant, *Silphium laciniatum*, may be found among the Compositæ, and is now in full flower. The leaves of this plant are said by Dr. Asa Gray to present their faces uniformly north and south, whence its name. Certainly, most of the flower-heads and some of the leaves were directed towards the north in the plant at Kew when visited by us, but some of the leaves were spreading in various directions. It is a tall plant about six feet high with large deeply bipinnatifid leaves; the flower-heads are large and yellow, and somewhat resemble those of the sunflower.

At the Edinburgh Botanical Gardens the medicinal plants in flower, according to the list kindly furnished by Professor Balfour, include *Aconitum paniculatum; Argemone mexicana; Sinapis nigra; Opoponax Chironium; Fœniculum vulgare; Cuminum Cyminum; Anthemis nobilis; Erythroxylon Coca; Exogonium purga; Datura Stramonium; Nicotiana Tabacum; Anchusa tinctoria; Lavandula vera; Veratrum album; Dorstenia Contrayerva* and *Hyssopus officinalis*. With the exception of the alkanet and cummin all these have already been described. In the Glasnevin Gardens at Dublin, the list, kindly supplied by Dr. Moore, is a short one, and includes *Maranta arundinacea, Dorstenia contrayerva*, and *Cephaelis ipecacuanha*.

The medicinal plants figured this month in Bentley and Trimen's now well-known work, are as follows:—*Cæsalpinia Bonducella*, the seeds of which, known as bonduc seeds or grey nicker nuts, are official in the Indian Pharmacopœia; no recent or easily accessible figure of this plant exists. *Hydrocotyla asiatica*, another official Indian plant, which is used in leprosy; *Ferula Scorodosma*, which is the *Scorodosma fœtidum* (Bunge) of 'Pharmacographia,' and one of the plants yielding assafœtida. The authors consider that the calyx rim and entire petals are not sufficient characters to separate it from the genus Ferula, and observe that although Bentham states that vittæ are present in the fruits, that they are not able to discover them. This plant has only been figured previously by Borczow. *Rheum palmatum*, var. *Tanguticum*, drawn from a specimen gathered by Prejevalsky in Tangut, which is now in the British Museum; *Peumus Boldus*, the Boldo plant; *Euphorbia resinifera*, drawn from a plant which flowered at Kew; and *Elettaria Cardamomum*.

In the drug market we have noticed mafura seed (*Trichilia emetica*, Vahl.), a seed having a general resemblance to that of the croton oil plant, but rather smaller and more cylindrical. It yields an oil which is used by the natives of tropical Africa in cookery, and also a kind of tallow. The seeds are made by the Arabs into an ointment with sesame oil, and used as a remedy for the itch. The reddish, wrinkled, oblong pods of *Acacia concinna* have been met with. These contain a saponaceous principle and are used in India like soap berries, for washing the head. Shea or galam butter, a very pure fat obtained from the seeds of *Bassia Parkii*, and mentioned by Mungo Park in his travels, does not seem to have met with so ready a sale as its qualities deserve. When pure it has a white colour and a sweet taste, and keeps well. Sassafras bark which is much more aromatic than the wood, and is used in the United States in preference to the wood or root; hog tragacanth, in considerable quantity, better known to students of pharmacy under the name of Caramania gum; and Java galangal root, distinguished from the true kind by its large size and white colour internally, have also been offered. Another drug of unusual occurrence is "red seed from Antigua" (*Abrus precatorius*) used in India for necklaces, and as a standard of weight. In fact the weight of the Koh-i-noor diamond was ascertained by this standard. The seeds weigh, with tolerable uniformity, about two grains. A dark red wood, imported under the name of dragon's wood, we have not been able to identify.

The medical journals present but few novelties in the matter of drugs and their uses. The wood of the tupelo tree (*Nyssa villosa*, Mich.) has been recommended instead of sponge for making tents; the action of the alkaloid of pao pereira bark (*Geissospermum lœve*, Baill.) has been investigated, and found to paralyse all voluntary motion (the bark has long been used as a febrifuge and antiperiodic in Brazil); the use of chloride of calcium* in atrophy of infants, especially when arising from tuberculosis, has been revived by Dr. R. Bell, of Glasgow; coffee has been found to have antidotal powers against strychnia, and the inhalation vapour of nitrite of amyl has been successfully used in a case which nearly proved fatal from the use of chloroform. It has also been shown that linseed, almond, or mustard meal has the peculiar property of removing disagreeable odours from the hands.

The dearth of scientific news continues, and beyond what has been reported from week to week in this Journal, but few events of the past month are of an interest meriting special notice. Of course the journals of the various societies and those representing the several sciences are as full as ever, and this is not strange, for they must be published, and sufficient matter must always be obtained somehow or the other. Chemists have not nearly exhausted the number of substances which admit of bromination, or the substitution of hydroxyl, and there yet remain positions,—para-, meta- and ortho-,—to be taken and retaken. The discussion of Ladenburg's benzene formula (the prism), and of Kekulé's hexagon, yet occupies other chemists, and for many a day to come will the van't Hoffs of chemical science write and discourse on the vexed questions.

In other directions of science, opportunities yet remain; there are yet a few crystals left containing fluid cavities, and Professor Mallet describes one of them, in the *Journal of the Chemical Society* (August). Even more bismuth compounds exist than have been yet subjected to investigation, and pyrology will furnish matter for more essays than one. The public analysts also have not completed their function in the history of the nineteenth century; there still remain samples of arsenical treacle, starchy mustards, coppered peas, and highly aqueous milks; even new industries are started for their especial benefit, and butterine affords no mean scope for the scientific imagination, as Professor Tyndall has been pleased to qualify this power. In a sense, therefore, science is progressing. The origin of life and the germ theory of disease; the glycogenetic function of the liver and glycosuria; the place of salicylic acid in the order of nature; the theory of chemistry; the science of temperance; the pollution of rivers, and that bogy, sanitation, are subjects which will not be settled in our day. The greatest minds are attracted by them; the experimental and enterprising faculties of the lofty among the thoughtful are centred upon them, so there can be no doubt we are progressing. In spite of all this, however, there is a stagnation in scientific quarters, and not till November is ushered in by its fogs, will the lamps of science once more glow brilliantly, and the radiometer enliven Burlington House.

It is almost painful to come down from these heights to the facts of this mundane world, but it is imperative, and in chronicling the few points of interest presented by the experiences of the month, we will begin with the one which has impressed us in the greatest degree.

At a recent meeting of the Commisioners of Sewers, various plans were brought forward and discussed, relative to the destruction of the large quantity of diseased meat which is seized by the city inspectors. During August, no less than 50 tons were so seized, and the Sanitary Committee appears to experience some difficulty in its disposal. Dr. Saunders (the Medical Officer of Health) gave the meeting an account of experiments he had been making for some time, which had resulted in the discovery of a mixed fluid, powerful as a deodorizer, and which also turns the meat black and offensive to the taste. This fluid, of which it was stated 300 gallons could be produced for 17*s*., consists of a mixture of chloride of calcium, picric acid and sulphate of iron. Chemists might vainly imagine that these fluids in mixture would result in the precipitation of sulphate of calcium, but a city paper containing a full account of Dr. Saunders' plan, tells us that the use of calcium chloride is to form an insoluble albuminate of lime! Why such an unreasonable mixture should be proposed is not evident, beyond that it was proposed by a medical officer of health. A chemist could not have made such a mistake. If an antiseptic and disinfectant treatment is to be adopted, there are preparations known which are fully powerful to effect the object; but we should rather suggest a treatment which a critic once said certain Italian poets deserved, viz., having millstones hung round their necks, and being cast into the middle of the sea. Or the meat should be burned in a kiln; the law of nature's compensation provides for the return of the carbonic anhydride and water to the growing plants. Or could not a contract be established between the City Authorities and the Zoological Gardens?

Speaking of public analysts we are reminded of the report recently submitted to the District Board of St. Saviour's, Southwark, by Dr. A. J. Bernays. We do not propose to consider this report in detail nor to make any calculations of the relations between 105 analyses, and the number of shops or the articles sold in them, in St. Saviour's, Southwark; we merely propose to characterize one point in this report. Our readers know that quite recently it has been demonstrated to the full, that the traces of copper

* The necessity for keeping abreast of the novelties used by medical men is shown by the complaint in a recent medical journal that a chemist put chlorinated lime instead of chloride of calcium into a mixture in which the latter had been ordered.

present in preserved peas are innocuous to health, inasmuch as they pass through the alimentary canal, and out with the fæces without being absorbed. Yet in spite of this, and with a prejudice too common among such persons in the present day, Dr. Bernays speaks of these copper coloured peas as very dangerous to health. It is possible that he may not keep himself acquainted with the research of the times, but if that be so it is still a fault in a public analyst; if Dr. Bernays be acquainted with the research in question, then he is actuated by prejudice.

Salicylic acid appears to be coming down from the high position where it has been placed by medical men. According to recent papers* in the medical journals of England and America, the internal use of salicylic acid results in a detrimental action on the bones, and in consequence the urine is loaded with lime salts. Several instances of necrosis of the tibia have been assigned to the use of salicylic acid, and it appears that salicylate of sodium has a similar injurious effect. The confirmation of these facts should lead to the extirpation of salicylic acid from therapeutics. Dentists also state that the use of salicylic acid injures the teeth, and in such case it cannot be a safe agent for preserving meat, milk, and beer. The "most exhaustive experiments" which have been made relative to the use of salicylic acid by brewers are not therefore absolutely exhaustive, and before they can merit this title, the question of its influence on health must be better established.

At a recent meeting of the Romford Board of Health, the tender of Mr. Dietz to alter the public lamps according to his patent for burning petroleum oil in the place of coal gas was accepted, as was also a further tender for oil. In substituting oil burning for coal burning, Romford is imitating the town of Winchester where the thoroughfares are lighted by means of petroleum.

English chemists will deeply regret to learn of the unhappy death of A. Oppenheim, so well known for his researches in organic chemistry. He and his wife had been staying at Hastings for the benefit of her health, but she died while there. He then locked himself in the room and poisoned himself with prussic acid.

Mr. Sergius Kern has communicated some further experiments with the supposed new metal davyum to the *Chemical News*.† He finds that the platinum ores contain not more than 0·035 to 0·045 per cent. of davyum, the atomic weight of which appears from some preliminary experiments of Engineer Alexejeff to be nearer 154 than 100 as originally supposed. No spectroscopic characters are, however, yet forthcoming; this is unfortunate, because if the metal be a new one, these would greatly aid in substantiating the fact. Davyum chloride is said to furnish with potassium hydrate a hydrated oxide of the metal soluble in nitric acid. Mr. Kern also describes a crystalline double cyanide of davyum and potassium; a sulphide, and a crystalline sulphocyanide. The double chloride of davyum and sodium is nearly insoluble in water and alcohol, and this is represented as establishing an important difference between it and the corresponding salts of the platinum group of metals.

One of the most interesting discoveries effected of late is that of the presence of oxygen in the sun.* The substances which have hitherto been detected in the sun have revealed themselves by the black bands or absorption lines in the spectrum. By comparing the violet end of the solar spectrum with the bright spectrum of oxygen, Professor H. Draper has been able to indicate several remarkable coincidences. Mr. Hennessy had previously observed certain bright lines in the solar spectrum, but Professor Draper was the first to give an explanation. One of these lines appears to be coincident with one of nitrogen, and three others with those of oxygen. The great difficulty is to determine whether these are really lines in the solar spectrum, or merely intervals between dark lines, and the difficulty is rendered greater by the great battery power required to obtain sufficient brightness in the spectra; still there seems to be little doubt that oxygen exists in the sun, and Professor Draper believes that all the other non-metals will be subsequently discovered there also.

Mr. H. M. Stanley has solved an important problem in African geography. He has traced the river Lualaba from Nyangwe to where it discharges into the Atlantic Ocean, thereby proving that the lake district, previously explored by Livingstone and Cameron, drains into the Congo or Zaire. The latter river drains an area of 1,400,000 square miles and is surpassed only by the largest rivers of America.

Mallet has found† that when aluminum is heated to very high temperatures with carbonate of sodium a metallic carbide is not formed, but a yellow substance which proved on investigation to be a nitride of the metal. By exposure to moist air the substance gradually disintegrates, yielding alumina while ammonia is slowly evolved. The nitride is also decomposed by acids and alkalies. Its percentage composition was found to be

Aluminum	66·16
Nitrogen	33·84

from which the formula Al_2N_3 results.

In the September number of the *Philosophical Magazine*, Mr. M. M. P. Muir gives the second part of a hypothetical paper on chemical classification. At the onset he reviews the grounds of the two creeds, (*a*) that elements have a fixed and invariable valency; (*b*) that they have a variable valency; and of course comes to no conclusion beyond the known fact. In certain compounds the valency is one quantity; in other compounds it differs. The very existence of unsaturated compounds forbids a further conclusion. Then he goes on to show what is also well known, viz., that chemical composition has something to do with boiling points, latent heat, specific gravity, refractive indices, coefficients of diffusion, specific volumes, physiological action, etc. One may as well generalize and state at once that between all known properties of matter and matter itself there is of necessity some definite connection. Mr. Muir's paper goes no further. Afterwards, structure and constitutional formulæ are discussed but with no fresh conclusions and no new light. We may conclude that the structure of acetic acid is $CH_3CO\,OH$, or that glycocine is $C_2H_3NH_2O_2$. In the latter case glycocine is viewed as amido-acetic acid, but beyond preparing it from dibrom-acetic acid by alcoholic ammonia it can be made direct from cyanogen and hydriodic acid, and while the above formula may

* *Canadian Pharm. Journal*, August, 1877, and *Journal of Materia Medica*, August, 1877.
† September 14, 1877.

† *Ann. der Chemie*, 1877, clxxxvi.

express in some measure one way in which the compound may split up, it fails to convey an expression of the more direct method of formation. The chemical constitution of a body, whatever it may mean, is something equally related to the substances from which it is elaborated, and to those other secondary ones generally simultaneously produced; it also bears the same relation to bodies influenced by its reactions. Given a chemical mass, we have every right for thinking that it may be decomposed in any conceivable way, so long as the sum of its products is equal to the original mass; and there chemical theory begins and ends, and hence also any chemical equation is but a partial representation of the truth.

MUSHROOM KETCHUP.

A notice of the mushroom would hardly be complete unless it contained some reference to ketchup, one of the most popular economic products of the fungus tribe. Ketchup, or catsup, as some prefer to spell it, is by no means exclusively made from *A. campestris.* Not only is the Horse Mushroom (*Agaricus arvensis*), to which we shall shortly refer, largely used in its manufacture, but it is stated that almost any species with dark juice is indiscriminately employed. Ketchup made from the Morel (*Morchella esculenta*) is said to be especially delicious. Mr. Cooke says there is an extensive manufacture of ketchup conducted at Luddenham, near Market Harborough, but the great difficulty appears to be the prevention of decomposition. Messrs. Perkins receive tons of mushrooms from every part of the kingdom, and they find, even in the same species, an immense difference in the quality and quantity of the produce. The price of mushrooms varies greatly with the season, ranging from a penny to sixpence a pound. Messrs. Perkins are very careful in their selection, but little discrimination is used by manufacturers on a small scale, who use many doubtful species.

The derivation and meaning of the word "ketchup" are unknown, unless we accept Webster's statement that it is probably of East Indian origin, because it meant in the first place a kind of East Indian pickle. A real or supposed Japanese word, "kit-jap," has been thought to throw some light on it; but, in spite of Swift's enumeration of "catsup" as a foreign condiment, it does not appear to be known out of England except as an English export. If, however, "kit-jap" is an Eastern name for soy sauce, as has been stated, it is not difficult to see that it might have been transferred to our English condiment.

The making of ketchup, like most matters connected with the culinary art, is a work requiring some skill and experience. We offer the following instructions on the point, which we borrow from Mrs. Hussey's beautiful 'Illustrations of British Mycology':—

"All kinds of agaric of which it is proposed to make use should be sound. Decaying larva-eaten flaps are ignorantly preferred; but if the flavour be stronger, it is of a coarse, rank strength, and the smell soon becomes disagreeable—in fact, there is a tendency to putrescence in such agarics. Cut off the stems, for they possess no flavour, and afford little juice, but much dirt; if the caps are soiled, peel them, do not cut, but break them small, powder every portion with salt, and set the mass in an earthen colander, placed in a bowl. The precise quantity of salt is not of importance, excess is better than defect, it being only needful in cookery to remember that salt is not to be used when ketchup is. After twenty-four hours press the pulp gently down in the colander, all the liquor that thus runs off is to be preserved, and no more, for if you choose to squeeze the rest of the moisture out, although it may be used for any immediate purpose, it is not worth saving. It is a usual complaint that there is so much feculence to get rid of in ketchup; this is owing to the mass of salted pulp being left too long before it is strained, so that the very flesh of the agaric is melted down into the liquid, instead of its consisting merely of juices extracted from the solid parts. By this maceration there is a gain in bulk; but it is a deceptive gain as to value; the feculence is flavorless, causing fermentation, and pouring off and rebottling is injurious; it is much better to avoid the ketchup ever containing this sediment. The liquor extracted as above, will be a pure fragrant delicious ketchup. Many people would boil this till the aroma had disappeared, under an erroneous notion of 'making it fit to keep,' but to this end the boiling by no means conduces, and almost all agarics lose their 'bouquet' by the continued action of heat. But how then shall we keep the ketchup? A great deal better! *Probatum est.* And now to divulge the secret. Before the ketchup season comes, procure a quart of spirits of wine in a glass-stoppered bottle, put into this any spices you prefer, in sufficient quantity to flavour the spirit strongly. After the ketchup has been strained off, let it settle twelve hours, then put it in half-pint bottles, fill them up to the shoulder, add the spiced spirit to fill the neck, and cork the bottles tightly and steadily; they must not afterwards be shaken, because the spirit should be left floating at the top to exclude the air, and prevent the formation of that other incipient fungus which cooks call 'mother.' When to be used shake the bottle thoroughly, and put as much of the contents as you like into the waiting soup or gravy; it should not be boiled up in it. The small quantity of spirit is unappreciable in the bulk of ketchup, not affecting the flavour at all. All who try this plan fairly will acknowledge they never tasted ketchup before."

We must apologize both to Mrs. Hussey and our readers for this lengthy extract; but we believe that many of our lady readers will be glad to have a recipe for ketchup making, which is recommended from experience by so excellent an authority. Anyone who has ever tasted ketchup will acknowledge that—judging from results—there must be "more ways than one" of making it; and if that which we have given is only half as good as Mrs. Hussey's concluding observations would lead us to suppose, none of our readers will regret having tried it.—*Britten's "Popular British Fungi."*

ANALYSIS OF COTTON ROOT BARK.*

BY CHARLES C. DRUEDING, PH.G.

From an Inaugural Essay.

The analysis was partly made at the laboratory of the Philadelphia College of Pharmacy, and after a series of preliminary experiments the following course was adopted:—

Five pounds of the bark were exhausted with strong alcohol. About twenty-four pints of a beautiful dark red coloured tincture was obtained, which was reduced by distillation to sixteen pints, and precipitated with an alcoholic solution of acetate of lead (nearly ℥viii, dissolved in about Oiiss alcohol, were required for this purpose), leaving a light straw-coloured filtrate B.

The precipitate was diffused in about eight pints of alcohol, and sulphuretted hydrogen passed through it until completely decomposed. The filtrate from the lead sulphide and washings were of a very dark red colour; distilled to recover the alcohol, and evaporated, a *resinous* colouring principle was left, which yielded a dark brown-red powder, resembling powdered cochineal, wholly solu-

* From *The American Journal of Pharmacy*, August, 1877.

ble in alcohol, ether, and aqueous solutions of ammonia, soda and potassa, and precipitated from the three latter by an acid. With potassium hydrate it strikes a green colour; petroleum benzin seemed to dissolve only a portion of it. The resin was therefore treated with hot benzin; about twelve pints of a light yellow coloured solution was obtained which, on cooling, deposited a small quantity of a peculiar *yellow substance*, giving the same chemical reactions as the resin. I was unable, however, to obtain a sufficiently large quantity of it to thoroughly investigate it; the benzin solution, on being evaporated to one-half its bulk, did not deposit on cooling, as was expected, but remained clear. The evaporation was then continued until all the benzin was driven off; the result was about one ounce of a blackish, greasy, semi-fluid substance, which proved to be *fat*, mixed with colouring matter, and on being boiled with caustic potassa formed soap.

The filtrate and washings B were reduced by distillation to about ten pints, and freed from excess of lead by sulphuretted hydrogen and filtration. The sulphide of lead obtained was dried and marked C.

The filtrate was distilled to recover the alcohol, and evaporated to drive off as much as possible of the acetic acid, until about three or four ounces remained. This was mixed with six ounces of water, thrown on a moist filter, and the precipitate washed. The filtrate and washings D were of a brownish red colour, and a sweetish bitter taste; the precipitate E was dark greenish, semi-fluid and greasy.

D was precipitated with subacetate of lead, and the precipitate F washed with water. The filtrate was marked G. F was diffused in water, decomposed with sulphuretted hydrogen, and the filtrate evaporated; a dark mass was left, having a somewhat peculiar bitter and astringent taste. It was tested for tannin, and found to give a green colour with sesquichloride of iron and also produced a precipitate with solution of gelatin.

G was freed from lead by means of sulphuretted hydrogen and filtration; the resulting liquid, about two pints, was of a light yellow colour; it was evaporated on a water-bath to a semi-fluid consistence. Two ounces of a red coloured thick syrupy liquid was the result, having a sweet taste. Trommer's test gave an abundant red precipitate, proving the presence of *glucose*.

E was separated from the water, and washed with petroleum benzin until it ceased to pass through coloured; about two pints of the benzin solution were obtained, having a dark colour, yielding, after evaporation, about one ounce of *fixed oil* mixed with some *colouring matter*, and forming soap on being boiled with caustic alkalies. The portion left on the filter undissolved by the benzin was of a greenish-yellow colour and hard enough to be powdered; it was soluble in alcohol and found to be *chlorophyll*.

The sulphide of lead C was treated with hot alcohol, but besides a little sulphur, nothing was dissolved.

A portion of the dregs left after exhaustion with alcohol was dried, macerated with water for twenty-four hours, and expressed. The expressed liquid was mucilaginous and almost tasteless; evaporated to a syrupy consistence and mixed with an equal bulk of alcohol, an abundant precipitate of *gum* and an almost tasteless solution were obtained.

Five grams of the air-dry bark were ignited in a porcelain crucible; the ashes weighed 0·3 gram, or 6 per cent., and contained potassium, sodium, calcium, magnesium, iron, sulphuric and phosphoric acids.

The organic constituents of cotton root bark are a red and a yellow resinous colouring matter, fixed oil, gum, sugar, tannin and chlorophyll.

THE PHARMACOLOGICAL GROUP OF ATROPINE.*

BY R. BUCHHEIM.

As atropine, when treated with baryta water, decomposes into tropic acid, $C_9H_{10}O_3$, and tropine, $C_8H_{15}NO$, it may be viewed as tropine in which the only replaceable atom of hydrogen is replaced by the radicle of tropic acid, thus: $C_8H_{14}O.N.C_9H_9O_2$. In crude atropine a second base exists of the formula $C_{18}H_{25}NO_4$, called by Hübschmann *belladonnine*. The author obtained a quantity of crude belladonnine, prepared by precipitating atropine sulphate with potassium carbonate till the precipitate was no longer resinous, but a powder. From this syrupy dark-brown mass the belladonnine was precipitated by ammonia, well washed with water to remove brown colouring matter, and one-half was neutralized with sulphuric acid and added to the rest. From this mixture ether, or better, chloroform extracted pure belladonnine, leaving atropine and some belladonnine as sulphate. One-half of this residue was thrown down with ammonia, then added to the other half, and shaken with ether. The aqueous residue, on addition of ammonia, gave first a precipitate of belladonnine and then of atropine. The belladonnine, separated from its solution in ether, was dried; it was a yellowish-brown resin, almost insoluble in water, easily soluble in alcohol and in chloroform, and somewhat less in ether. It forms neutral salts with acids, the sulphate being a resin.

With alcoholic potash it decomposed into tropine and a resinous body, named by the author *belladonnic acid*, which differs in its properties from tropic acid. Belladonnine may therefore be regarded as a compound of this acid with tropine.

Tropine, obtained by distilling the residues from which the belladonnine had been separated with lime, is a liquid of the consistence of castor-oil, but after some time becomes crystalline. It is easily soluble in water and in alcohol, has a smell resembling that of tobacco, and a strong alkaline reaction. Its sulphate is easily soluble.

Benzoyl-tropine, prepared by adding benzoyl chloride to tropine, closely resembles atropine, which is tropyl-tropine.

Physiological experiments with these bodies showed that tropine has no action on the pupil, unless an atom of hydrogen is replaced by an acid radicle, but that this action depends on the nature of the radicle. Atropine possesses it more strongly than belladonnine or benzoyl-tropine. The exhibitory action also on the heart is recognizable in tropine, but to a less degree than when the hydrogen is replaced.

It is probable, from Geiger and Hesse's experiments, that the alkaloid obtained from the seed of the datura, called by them *daturine*, is a substituted tropine, the acid probably being an isomeride of tropic acid.

The same chemists isolated an alkaloid from henbane, and named it hyoscyamine, which, according to Höhn and Reichardt's experiments, is decomposed by baryta-water into hyoscinic acid, $C_9H_{10}O_3$, and hyoscine, $C_6H_{13}N$; the two formulæ when added together amount to that of hyoscyamine, $C_{15}H_{23}NO_3$. Either, then, the formula of the acid or of hyoscine, or of the alkaloid must be incorrect, as no water is evolved. The action of hyoscyamine is similar to that of atropine. Two samples of hyoscyamine were obtained by the author; one was crystallized, and acted physiologically as stated by Hellmann; the other was a syrup, and produced a reflex action of the nerves, which was not observable with the crystallized alkaloid; the probability is, therefore, that a second alkaloid was present. For this hypothetical substance, the author suggests the name *sikeranine*, from Sikerân, the Persian name of hyoscyamus.

"THE SCIENCE OF TEMPERANCE."

"THE Science of Temperance" was the subject of a lecture delivered by Dr. B. W. RICHARDSON, F.R.S., in the Ancient Concert Rooms, Dublin, on the evening of the 13th inst.

There are propably but few persons who are not acquainted with Dr. RICHARDSON'S views regarding the action of alcohol on the vital functions, and we venture to add there are probably also but few really scientific people who endorse them. This is by no means a bold statement; the audiences which assemble to hear the energetic eloquence of Dr. RICHARDSON are made up of Good Templars, and other quixotic creatures, who have no real knowledge to oppose against the gushing and crushing vehemence of their apostle; they therefore accept his teachings *en bloc* and with one united voice they take up their war cry, "All ye that thirst, come ye "to the waters."

It is oft-times a matter of consolation and congratulation to human nature, that it inherits certain instincts, or certain predispositions; and although churches may unite their efforts to prevent their practical realization or to obviate their results, and although the Dr. RICHARDSONS may work upon the popular ignorance and the love of the sensational element presented by the human mass, these efforts will never fructify; for nature has imbued in man the love of wine, and he will drink wine while he may.

Dr. RICHARDSON tells the public that alcohol cannot be considered as a food; on the other hand a greater than Dr. RICHARDSON has said that it is a food. "In a certain household," says LIEBIG, "it was "observed that from the day on which the servants "ceased to receive beer from their master, the con- "sumption of bread increased in a ratio correspond- "ing to the diminution of beer; so that the beer "was paid for twice, once in money, and the second "time in the form of an equivalent of another kind "of food yielding the same amount of carbon and "hydrogen."

The public may choose between these quoted authorities. We prefer the doctrines of LIEBIG; doctrines which have not received any measure of disproof.

Dr. RICHARDSON also says that common alcohol was not intended as a special gift any more than the other chemical bodies also termed alcohols. This statement presupposes an acquaintance on the part of Dr. RICHARDSON with the designs of Providence; how does he know alcohol was not intended as a special gift? Christians who have ever seen a vineyard or a hop-field, or who have read of the miracle of the transformation of water into wine, would scarcely agree with Dr. RICHARDSON; but even should they do so, it is easy to show how utterly sensational and false are his doctrines. We distinctly aver that humanity gives no special preference to ethylic alcohol above all other alcohols, for ordinary sugar is a chemical body and an alcohol, and all the world uses sugar, and all the world does not use ethylic alcohol, or at least not so much as it would like to use, because it is more costly than sugar. Dr. RICHARDSON, moreover, told his audience on the 13th inst., that physiologists and biologists could perceive no provision in the animal economy for the use of any fluid other than water. Ordinarily the animal economy gets more than a just measure of this essential fluid, even when it imagines it is taking alcohol; but more seriously we may say that if Dr. RICHARDSON'S view were correct, tea, coffee, and chocolate must be also eschewed. But the fact is that physiologists and biologists who know their science do perceive such a provision, and that provision consists in the power of oxidation which exists in the blood, and which is sustained by respiration, whereby alcohol is burnt up into carbonic acid and water with the evolution of animal heat, and animal heat is as important a factor in healthy life as a supply of flesh-forming food.

Dr. RICHARDSON then went on to say that ethylic alcohol acts on the body like other chemical substances and produces phenomenal effects. No doubt. Ginger, and bread and butter, and capon are also chemical substances, and these foods may also produce phenomenal effects. So wrong again, Dr. RICHARDSON.

The truth is, Dr. RICHARDSON talks to his audiences as if he were actuated by the gratuitous assumption that "all men are drunkards." Now this is not the case. There is the vast majority of the public which uses alcohol in the form of beer or wine, or both, as a food, and as a very enjoyable one too; it is a small minority which consists of drunkards, and there is no reason in the world why Dr. RICHARDSON should not waste his life upon these creatures if he deems it worth his while. But even then, public opinion should not be directed against vices always with us, by fits and starts, and by using sentimental and unscientific arguments; but it should be directed against them "uniformly, steadily, and "temperately;" "there should be one weight and "one measure."

Scientific men know well enough what is the action of alcohol in the system, so far as it has been determined, and Dr. RICHARDSON can hardly hope to run on in his wild freaks and receive no check from facts or those who know them. They are these. Alcohol taken in reasonable amount and by ordinarily healthy persons is entirely burnt up in the blood into carbonic acid and water, and with the simultaneous production of comfortable sensations. When larger quantities are taken a certain influence is exerted upon the nerves of the stomach which is prejudicial to digestion while it lasts. When yet larger quantities are consumed, traces of the alcohol are eliminated in the breath and urine, but still the mass is oxidized in the blood, although by its excessive amount its presence interferes with the proper functions of the body. Taken in madly large quantities, alcohol appears to exert a peculiarly chemical action upon the brain, which interferes with its functions and produces delirium-tremens.

A man may bring about worse things than delirium tremens by eating more nightingales or lampreys, or even bread and butter than the body can conveniently accommodate.

We, therefore, charge our glass (metaphorically) once more and drink to the non-success of Dr. RICHARDSON's sensational teachings and the annihilation of his more unscientific doctrines.

THE YORKSHIRE COLLEGE.

THIS Institution has recently issued its calendar from which it appears that two new subjects have been added for the fourth session about to commence; these are classical literature and history, and modern literature and history. This arrangement which has ensued upon the fusion of the work of the Leeds University Extension Committee with the College, is one which cannot fail to increase the useful purpose and noble function exercised by the College, although only a "three-year old." Science will lose nothing in its efficiency of treatment by this alteration, and indeed would seem to gain also through the fusion above adverted to, for a very extended system of outside lecturing is announced for the coming session. This arrangement which has been made with the GILCHRIST Trustees, through their Secretary, Professor W. B. CARPENTER, F.R.S., will consist of "Science Lectures for the People," to be delivered by the college professors in Leeds, Bradford, Halifax, and Keighley.

It is also stated that the Drapers' Company has made a grant with the object of enabling the College to provide practical instruction in coal-mining, a subject of great importance, more particularly for Yorkshire and the adjoining counties.

The Calendar of the College is full of useful information for intending students, and embraces the prospectus of the Leeds School of Medicine.

POISONOUS FUNGI.

A FEW days since some children rambling in Stanley Park, near Everton, came upon some fungi which they gathered and ate. A short time afterwards one of the children was taken ill, and appeared to be in a fit; the other children being soon in the same state. They were taken to a surgeon's in the neighbourhood, who administered emetics and applied the stomach pump. It was not until after some two or three hours' exertion that the children had so far recovered as to admit of their removal to their homes, and they continued to suffer from the effects of the poison for some time. This is the fifth case of poisoning by fungi that has occurred in the neighbourhood of Everton during the past week.

INFLUENCE OF THE BAMBOO IN PRODUCING FEVER.

WE have lately had occasion to refer to two extraordinary trees—the Wauga and the Rain tree—noticed in recent reports of the British Consul at Hayti, and a Consul of the Columbian Government in Northern Peru. From the report of Major PEYTON, one of the forest officers in the Bombay Presidency, a singular statement is given in connection with the flowering of bamboo. He states that for the last ten years he has noticed, in Kanara, that wherever the bamboos flower and seed, then fever, as an invariable rule, prevails. In 1866, immediately below the Guáts, and in 1867 and 1868, towards the eastern part of the district, it was so, and more recently around Yellapur, where the bamboos flowered and seeded, fever became general, few escaping it. The type of fever that at first prevails is not unlike hay fever at home, but this is when the flowering of the bamboos first sets in, and it changes into greater severity as the seeds begin to fall and ferment. We hope to hear something further about this.

THE MANCHESTER SCHOOL OF PHARMACY.

THE above school which is in connection with the Manchester Chemists' Association, has just issued its arrangements for the session 1877—8. Mr. LOUIS SIEBOLD, F.C.S., will deliver thirty-five lectures on Chemistry (including the elements of Physics); thirty lectures on Materia Medica and Pharmacy; and twenty lectures on Analytical Chemistry. Arrangements have also been made for the delivery of a course of lectures on Botany after Christmas. The condition of attendance at these courses is, that the students must be Associates of the Manchester Chemists' Association of which Mr. F. BADEN BENGER is the Hon. Sec.

A LIVERPOOL correspondent has forwarded some beans which he says are freely sold to children in that town under the name of castor-oil nuts or pea nuts. They are the pods of *arachis hypogœa* a leguminous plant, and are commonly known as ground nuts, monkey nuts, or pea nuts. Our correspondent believes they contain an acrid substance which may be somewhat dangerous, and it is a fact that these nuts sometimes produce diarrhœa.

The Chemical Constituents of Convolvulus Scammonia.

BY CHARLES T. KINGZETT, F.C.S., AND THOMAS FARRIES, F.C.S.

On what has been called the blue-list of the British Pharmaceutical Conference, Convolvuline from the roots of *Convolvulus scammonia* finds a place amidst the alkaloids of doubtful existence. It was with the view of arriving at more definite knowledge regarding this doubtful alkaloid that we commenced a research some months ago.

The roots (7 lbs. direct from Smyrna) were first of all extracted thoroughly with tolerably hot water, and after this with alcohol of 85 per cent., and finally with ether. The ether extract contained apparently only a little matter of similar nature to that extracted by the alcohol.

Treatment of water extract.—This was of a faintly acid reaction and dark colour. It was strongly acidified by nitric acid, whereby a bulky albuminous looking precipitate was thrown down, which afterwards proved mainly insoluble in water, and was not further examined. The clear filtrate was fully precipitated with phosphomolybdic acid solution, and the considerable precipitate thus obtained was washed first with dilute nitric acid, and finally with water acidified by sulphuric acid. The precipitate was then decomposed with excess of boiling baryta water, filtered from the baric-phosphomolybdate, and the excess of barium removed by carbonic anhydride; the last traces being taken out by an exact amount of sulphuric acid. The ultimate solution was alkaline in reaction, and was now neutralized by hydrochloric acid, and concentrated. The product gave no precipitate with aqueous solution of platinic chloride, but yielded a bulky one with alcoholic platinic solution, which was recrystallized from water. On analysis, it proved to be the pure double chloride of potassium and platinum. Therefore, *Convolvulus scammonia* contains no alkaloid soluble in water.

Examination of the alcoholic extract.—When concentrated, this formed a golden yellow syrup, from which water precipitated a stringy bright-yellow mass soluble in ether.

It was several times reprecipitated from alcohol by water, and it then gave both with sulphuric acid and sugar and with sulphuric acid alone, the purple reaction yielded, as Hake and one of us have shown, by most so-called glucosides and other bodies.*

A quantity of it was boiled with a two per cent. sulphuric acid solution during 20 hours, filtered, the sulphuric acid removed by baryta water, and the excess of this reagent by carbonic anhydride. The filtrate on evaporation to dryness left a glucose-looking mass containing barium in combination, and which gave the ordinary reactions of glucose; that is to say it gave with camphor and strong sulphuric acid the purple colour explained in the paper referred to above. It charred with sulphuric acid like sugar; its solution readily reduced Fehling's copper test, and also nitrate of silver. It was dried at 100° C., powdered and analysed. ·309 gram gave 0·137 gram H_2O, the carbon determination was ruined by an accident; ·4858 gram gave 0·286 gram $BaSO_4$.

These numbers give 4·92 per cent. H and 34·61 per cent. Ba.

From these percentages it will be seen that the barium stands to the hydrogen as 1 : 19·5 atoms. In a similar substance obtained by a like process from hederic acid, a corresponding barium salt was obtained when the relation of barium to hydrogen was also 1 : 19.

A barium salt of glucinic acid, having the formula $C_{12}H_{16}BaO_9$, would contain 31·06 per cent. Ba and 3·62 per cent. H; while glucosate of barium $2\,(C_6H_{11}O_6)\,Ba$ requires 27·8 per cent. Ba and 4·44 per cent. H. There can be little doubt that the substance whose analysis is given above, represents an intermediate state, occurring in the spontaneous change of glucosate into glucinate of barium. Of its relation to sugar there is no question.

A similar substance, which, however, we have not analysed, is obtained by treating the resin with strong sulphuric acid, diluting, filtering, and submitting the filtrate to the same process as that resulting from boiling the resin with dilute acid.

Again, the same substance appears to be produced in, and may be similarly extracted from the black and shining residue left in the retort when scammony resin is submitted to dry distillation.

Under these last named circumstances another product is also obtained as a distillate.

At 82° C. an oily body began to condense from the heavy vapours which formed, and between this temperature and 90° C. several grams of the distillate were obtained. It constituted a somewhat volatile liquid, of a yellowish colour, and pungent aromatic odour; its further examination and analysis is reserved for a future opportunity.

Cl. Marquart* has described the resin obtained from the root of *Convolvulus scammonia*, and believed he had separated a vegetable base, but from our observations it would appear that Marquart was in error.

Scammony resin has been described by a number of chemists, including Bouillon, Lagrange and Vogel, Planche, Johnston, Spirgatis, Mayer, Keller and Koomann.

From all accounts, scammony resin appears to differ little from jalapin. Some authors say that the resin derived from certain species of convolvulus is insoluble in ether; that which we obtained and examined was easily soluble in ether, and in this respect, therefore, resembled jalapin (from jalap stalks).

From the analyses of jalapin agreeing fairly among themselves, various formula have been constructed; that generally accepted is $C_{34}H_{56}O_{16}$, containing 56·66 per cent. C; 7·77 per cent. H, and 35·57 per cent. O.

Jalapin is stated, by various authors, to split up under the influence of dilute acids as follows:—

$$2\,C_{34}H_{56}O_{16} + 11\,H_2O = C_{32}H_{62}O_7 + 6\,C_6H_{12}O_6.$$

Jalapin + water = jalapinol + glucose, while jalapin from scammony resin is represented as splitting up in this way—

$$C_{34}H_{56}O_{16} + 5\,H_2O = C_{16}H_{30}O_3 + 3\,C_6H_{12}O_6$$

Scammony resin + water = jalapinolic acid + glucose. That scammony resin is a glucoside and yields glucose by proper treatment, is supported by the foregoing observations.

Mr. Williams asked if Mr. Kingzett had isolated the alkaloid in any way.

Mr. Kingzett said he had already stated that he had found there was no alkaloid; he got a platinum salt which proved to be a potassic combination only.

Mr. Groves said it was not a new fact that scammony contained both a resin acid and a resin glucoside.

Mr. Kingzett said that although certain kinds of jalap stalks had been examined, and a resin obtained which on boiling with dilute sulphuric acid reduced Fehling's test, he had not found any analyses of the sugar thus assumed to be produced. Chemists were too often satisfied with obtaining the reduction of Fehling's test as being sufficient to establish the presence of sugar, but he had analysed the substance itself.

---

* *Pharm. Journ.*, May 12, 1876.

* *N. Br. Arch.*, vii., 248; x., 139.

Mr. Williams reminded Mr. Kingzett that Dr. Williamson about twenty years ago published a very elaborate paper on this subject.

Mr. Kingzett said he believed he was acquainted with all the literature of the subject.

Mr. Umney thought every manufacturer must have noticed the presence of glucose in scammony root. During the past eight or nine years, he had operated on many tons of the root, and always found in the alcoholic extract a large quantity of uncrystallizable grape sugar, and he remembered the late Mr. Daniel Hanbury having 3 or 4 pints of this thick treacly substance from him to see if he could crystallize it. As he understood Mr. Kingzett's process, the whole of the saccharine matter would be removed by treatment with water at 70° C. He had generally allowed the crude resin as obtained by alcohol to stand two or three days in contact with water, in which it was boiled, the saccharine solution being removed again and again.

The next paper read was on—

Further Researches on Tea Hair.

BY THOMAS GREENISH, F.C.S.

Under the name of Pekoe Flower or Flower of Tea, this substance was brought before the Conference at Glasgow last year, by Mr. Groves, and on that occasion I gave the result of its examination, mainly microscopical, which I had previously undertaken. At that time but little was known either by Mr. Groves or myself of its history, the position it occupied in commerce, or its ultimate destination. I followed up the subject with the view of supplying for this meeting that more complete information which was wanting on these several points, as the tea hair may probably crop up again as a natural curiosity for a lover of science, or to supply a sensational paragraph for a public analyst.

The tea hair was said to have emanated from a house in the city, but the city is a large place in which to look for tea hair, and I found it so. For many months I worried with my inquiries tea brokers and tea merchants, but without result, until at last a friendly hint directed me to a tea broker's office where I found a member of the firm who, in addition to a very discriminating palate as regards the strength and flavour of tea, had also acquired a vast deal of collateral information about the teas imported from India and China.

It appears that tea hair finds its way into this country as an article of legitimate commerce, at tolerably regular intervals; its commercial name is "Pekoe Flower," and sometimes the "Bloom of the Pekoe Flower." It is a product of India teas, not of those of China. It is purchased somewhat as a curiosity, but there are those who buy it pretty regularly. Pekoe flower is never sold as tea simple or for mixing with tea. It is almost a necessity that it should be sold alone. If it be mixed with ordinary tea there is such a tendency to the separation of the tea hair and its agglomeration into lumps, that any attempt of this kind would probably result in the whole being returned as an adulterated tea.

In an essay on the cultivation and manufacture of Indian teas by Lieut.-Col. Money, and published in Calcutta, the whole process of the manufacture of the Indian teas is given, and it is not difficult to trace the condition in which this tea hair is found, to its origin. One part of the process consists in what is called "rolling" the leaves, when the juice is given out freely, and as to its results on the leaf he says, "If the leaves which give Pekoe tips are separated from the other leaves and rolled *very little* and *very lightly* there will come out Pekoe tips of a whitish colour; if *not* separated from the other leaves but manufactured with them the sap from the other leaves, expressed in the rolling, stains these said leaves, which are covered with a fine silky down, and makes them look like the rest of the tea." This is evidently the part of the process in the manufacture of Indian teas which gives to the otherwise greyish-white hair its brown colour, and also that extractive matter which is found adhering to it.

Mr. Wigner, in his analysis of the tea hair, gives theine 1·5 per cent. as compared with 3·5 per cent. for Pekoe tea, and Mr. Groves remarks in reference to this, that "it is interesting to find theine present in the tea hair." I doubted the correctness of this conclusion. The hair of the leaf is an extension of the epidermal cells covered by the cuticle; there is an absence of chlorophyll, the cells being empty; this layer prevents too rapid evaporation from the parenchyma of the leaf, but plays no part in the plant's economy. I have no doubt but that the theine obtained by Mr. Wigner was derived from extractive and parenchymatous tissue adherent to the base of some of the hairs. To determine this point, I took 100 grs. of tea hair, exhausted it with cold water and evaporated the liquid to dryness. It yielded 15 grs. of extract, this closely agrees with the result obtained by Mr. Wigner. My object was now qualitative, to determine the presence of theine in the extract, and for this I adopted the micro-sublimation process. A little of the extract was dissolved in water, to which was added some calcined magnesia; the solution was boiled and evaporated to dryness; part of it was then placed in a cell on one glass slide covered by another, and at a temperature of about 120° C. I obtained successive crops of theine in acicular crystals. I then subjected the hair from which the extract had been obtained to the same process, but there was no indication in the hair freed from extractive of the presence of theine. It is evident that this experiment on the exhausted hair could not be considered conclusive as to the absence of theine in the normal hair of the tea leaf. I further picked carefully clean hairs from young Pekoe leaves, treated them in the same manner by gently boiling with a little calcined magnesia, and employed the same micro-sublimation process, but failed to get the slightest indication of the presence of theine in the hair itself when free from extractive matter and parenchymatous tissue. These experiments are to my mind conclusive that the theine was obtained from the extractive matter and parenchyma of the plant, and that there exists no theine in the normal hair of the tea leaf, and I believe that there is no known instance of a simple hair, such as that on the tea leaf, containing the active principle of the plant.

A further careful examination of the tea hair, besides calcareous matter, shows the presence of minute particles of the elytra of beetles, the markings on which bear a close resemblance to the venation of a leaf, and which may easily be mistaken for fragments of some leaf other than tea.

I may add that the tea hair has created considerable interest, and I have been applied to from the continent for museum samples, which until lately I was quite unable to supply.

Thanks having been voted to Mr. Greenish for his paper,

Mr. Groves said he could have saved Mr. Greenish a great deal of trouble if he had known that he was in search of the importers of the tea hair. It was no mystery—he had known all about it from the first. The general impression was that this tea hair was worked up into the compressed tea as the only way of getting rid of it. As to the presence of theine the presumption was in favour of Mr. Greenish's theory that it was not present.

The next paper read was on—

Copaiba Testing.

BY LOUIS SIEBOLD.

All who have been frequently engaged in the testing of copaiba will have noticed that most of the tests described in standard works on materia medica and pharmaceutical chemistry, though applicable to some kinds of copaiba, are quite untrustworthy as general tests for the purity of this oleo-resin. I will deal with these tests one by one before giving what I conceive to be a simple and thoroughly reliable mode of ascertaining the presence or absence of adulterants in any sample of this substance.

1. The specific gravity.—This like the consistence of the balsam varies considerably according to the proportions of resin and volatile oil present in the samples. Some authors give it as ·95 to ·96, others at ·94 to ·97, and others again as ·94 to 1·0. Having experimented with a large number of samples of different origin, I am in a position to state that the range of variation is much greater than is generally supposed, as I find the limits to be ·915 and ·995. Equally variable are the relative proportions of resin and oil. The smallest proportion of resin I have ever met with was 18½ per cent., whereas the usual range is from 30 to 65 per cent. Such variations are by no means surprising considering that the oleo-resin is obtained from many different species of copaifera growing in different localities and under different climatical influences, and that these circumstances, together with the age of the trees, the time and mode of extraction, and the age of the balsam itself, are sure to have a material influence on its chemical composition.

2. Appearance.—All kinds of copaiba as imported are turbid, and require to be filtered before they can be sent out to retail dealers. The colour varies as much as the consistence and specific gravity. The British Pharmacopœia states that copaiba should not be fluorescent, and this statement occurs again in the majority of books I have consulted. Flückiger and Hanbury, however, admit that it is sometimes slightly fluorescent. My own experience is that very many genuine samples of copaiba are distinctly and many others slightly fluorescent, and that very few samples indeed are quite devoid of this property.

The benzol test.—According to the B. P. copaiba should be soluble in an equal bulk of benzol. This as a test is quite useless, since all the known adulterants of copaiba are likewise soluble in benzol.

The magnesia test.—Pure copaiba is stated to be capable of dissolving one-fourth of its weight of magnesium carbonate by the aid of heat, and remain transparent; if not, an adulteration with a fixed oil or with gurjun oil is to be inferred. The test, however, is quite fallacious as it only answers with the thicker specimens of Maranham balsam. The power of copaiba to dissolve that quantity, or anything approaching that quantity, of magnesium carbonate, depends on the presence of a large amount of acid resin (copaivic acid), and unless we are prepared to condemn all samples of Para and nearly all the thinner kinds of Maranham balsam as adulterated, the test must be dismissed as useless.

The ammonia test.—One part of copaiba with two and a half or three parts of solution of ammonia is to produce a clear mixture. This test is fallacious for the same reasons as the magnesia test.

The alcohol test.—The statement met with in some books that copaiba is perfectly soluble in rectified spirit is true only with regard to certain balsams. The great majority of samples of genuine copaiba are not soluble in that menstruum. Nearly all authors, however, agree that one volume of copaiba ought to form a perfectly clear solution with three volumes of absolute alcohol. Nevertheless this statement too is incorrect, for the thinner balsams, and especially those of Para, form a cloudy mixture with absolute alcohol, which after prolonged standing deposits some white or yellowish-white resinous flakes. Yet this test, if carefully applied, is of some value, for in the presence of a fatty oil other than castor oil, the sediment just mentioned, instead of consisting entirely of resinous flakes, will contain drops of the oil. On the whole, however, I do not care very much for this test; it fails with castor oil, and is in every respect inferior to the simple process of evaporation to which I shall refer presently.

Muter's test.—The details of this process were published in the *Analyst* of November 30 last year, and reprinted in the *Pharmaceutical Journal* of December 30. They may be briefly summarized as follows: The alcoholic solutions of a weighed quantity of the balsam is saponified with an excess of caustic soda, the soap solution mixed with water, then evaporated to a given bulk, the excess of alkali neutralized with sulphuric acid, the whole evaporated to dryness and the dry residue treated with a mixture of ether and alcohol, which will dissolve the sodium copaivate, leaving undissolved the sodium sulphate and any sodium oleate, which, in the presence of a fatty oil, must have been formed. The insoluble matter is then taken up with warm water, the solution decomposed by hydrochloric acid, and the liberated oleic acid carefully collected, dried and weighed. As copaiba contains a small quantity of altered resin, the soap of which is not readily soluble in the ether alcohol, Dr. Muter makes an allowance of 6 per cent. for this resin, which must be deducted from the percentage of oil, calculated from the analysis. Another correction has to be made in consideration of the slight solubility of sodium oleate in ether alcohol, which, according to M. Barfoed amounts to 1 in 1000. By means of this process Dr. Muter has obtained results showing a very high degree of accuracy. In two cases out of six, the amount of oil found agreed within $\frac{1}{10}$ of a per cent., and in the remaining cases, with the exception of one, within 1 per cent. of the amount actually present. I have carefully repeated Dr. Muter's experiments, thinking that though there are much simpler means available for the detection of fatty oils, the great accuracy attained would fully justify a somewhat tedious and troublesome process. My results, however, do not agree with those of Dr. Muter, as will be seen from the following numbers.

	Oil present.		Oil found.
No. 1	15·7 per cent.	(linseed)	12·1 per cent.
No. 2	38·2 ,,	(linseed)	29·5 ,,
No. 3	11·6 ,,	(castor)	5·4 ,,
No. 4	51·1 ,,	(castor)	39·6 ,,
No. 5	5·1 ,,	(linseed)	none
No. 6	27·3 ,,	(castor)	21·4 ,,

I have in all examined ten mixtures of balsam and oil, but am only quoting the numbers in those cases in which several analyses gave concordant results. My conclusion therefore is that the method is not accurate enough to warrant the trouble and expenditure of time. As a qualitative test it is very unsatisfactory and far too troublesome; in the presence of 5 per cent. of oil, it completely fails to indicate the adulteration, and with 10 per cent. it gives an indistinct result. On the other hand, it will be seen from the following, that the simple process of evaporation shows the presence of 1 per cent. of oil, and also admits of a rough calculation of the amount of adulteration.

Evaporation.—This is an excellent and exceedingly simple test, but is clumsily applied by many. Instead of boiling the balsam with water for many hours, a small quantity (about 1 to 1·5 gram) of the sample should be carefully heated in a watchglass until all the oil is driven off, which is the case as soon as the residue has assumed a rich brown colour. A few minutes suffice for the experiment. If the remaining resin is perfectly brittle and pulverizable, there is no fatty oil present, for 1 per cent. of oil would diminish the brittleness of the resin so that it cannot be reduced to a fine powder. One per cent. of oil is thus readily detected, and with larger quantities of the adulterant (3 to 5 per cent.), the resin feels quite sticky. On heating the resin, castor oil and linseed oil may be distinguished by the odour. By mixing the adulterated balsam with ten, twenty, thirty, forty, and fifty volumes of pure Maranham balsam respectively, and testing each dilution in this manner, it is easy to find in which the oil has been reduced to below 1 per cent., and thus to ascertain whether the adulterant amounted to more than 10, 20, 30, 40, or 50 per cent.; and this I think would be sufficiently near the mark for the purposes of public analysts. Mr. Conroy, of Liverpool, who has also had considerable experience in copaiba testing, informs me that he too relies on the evaporation as the best and by far the simplest mode of detecting fatty oils, and agrees with me as to the sensitiveness of the test. He places a drop of the hot resin (after evaporation of the essential oils), on a small piece of well glazed note paper; if the balsam be pure, the resin will fly off in hundreds of fragments on bending the paper when cold. I have examined upwards of twenty different samples of copaiba, each mixed with linseed oil and with castor oil in eight different proportions, and have come to the conclusion, that if a sample leaves a pulverizable resin on evaporation all further testing with alcohol and other reagents for fused oils, is merely a waste of time.

Detection of gurjun oil.—Flückiger's test with bisulphide of carbon and a mixture of nitric and sulphuric acids, as described in the Pharmacographia is a good one, especially if applied to a drop of the essential oil separated from the balsam by distillation with water. Its application direct to the balsam requires practice to prevent errors. Hager's test with petroleum ether, mentioned in the 'Year-Book of Pharmacy' for 1876, is also a good one; I have tried it extensively, and have every reason to be satisfied with it. A pure balsam when mixed with four volumes of petroleum ether yields a clear solution, which either remains clear on standing or forms an exceedingly slight deposit, coating the bottom of the tube like a thin film. In the presence of gurjun oil, however, a voluminous sediment is formed in the mixture after half an hour's standing. Benzol cannot be used for this test and is the more unsuited for it the purer it is, since pure benzol forms a perfectly clear solution with the adulterant. Dr. de Vrij, who recommended this substance for the detection of gurjun oil in copaiba has probably used an impure benzol in his experiments.

Detection of oil of turpentine.—This, I believe, is the only volatile oil likely to be used for adulterating copaiba. Any large admixture with this oil is easily found out by the odour on heating the balsam. For the detection of smaller quantities I rely on the difference in the boiling points of oil of copaiba and oil of turpentine, that of the former being 240°—250° C., and that of the latter about 160°. In distilling a small quantity of oil from the suspected balsam, oil of turpentine passes over before the oil of copaiba, and can be recognized by its odour on heating the first few drops of the distilled oil on a watch-glass. In this way I have been able to detect $2\frac{1}{2}$ per cent. of the adulterant.

I trust that in future editions of our standard works tests for the purity of drugs which experience has proved to be fallacious will be omitted, as through their occurrence in such books they are invested with a certain amount of authority likely to mislead those who are wanting in personal experience of the subject. The recent prosecutions for an alleged adulteration of copaiba serve as a good illustration of the sublime faith which analysts ignorant of the nature and properties of drugs may have in the authority of books. It appears strange too that persons without a proper knowledge of drugs can hold appointments under an Adulteration of Food and Drugs Act.

The PRESIDENT said Mr. Siebold's remarks were very interesting and valuable, although the whole subject had been pretty well worked out twenty years ago by himself and the results published in the *Pharmaceutical Journal.* Still the results then obtained, which entirely coincided with those found by Mr. Siebold, had been overlooked by writers on the subject, and tests which were then shown to be fallacious were still repeated. The result he then came to was that there was no test for the balsam which could be relied on, and that the only satisfactory mode of forming a judgment was first to separate it into its proximate component parts and to test the resin and the oil individually. His method for the separation of the resin was not quite so simple as that mentioned by Mr. Siebold—evaporation in a watch glass—because it comprehended not only the isolation of the resin but also the collection of the oil. Dr. Muter's test had certainly the appearance at first sight of being a very good one, and he had used it on some occasions with advantage, but he agreed with Mr. Siebold that it could never be entirely relied upon, especially in indicating a specimen as being entirely free from adulteration. With regard to the use of benzol as given in the Pharmacopœia it was introduced on the authority of a recent publication on the subject and only referred to the adulteration with gurjun balsam. The whole subject was well worthy the attention of pharmacists, and at a time when they were liable to have the articles they dealt in called in question it was especially important that they should repudiate tests which could not be depended upon.

Mr. MANBY asked if Mr. Siebold would mention what he considered the best vehicle for the entire solution of copaiba, without deteriorating its medicinal qualities.

Mr. EKIN asked how Mr. Siebold assured himself that the samples he analysed were genuine.

Mr. UMNEY was pleased to hear it acknowledged that there was variation in copaiba balsam; in his experience there was no drug which varied so much. Only last week a large quantity of Para balsam was offered for sale which was as limpid as turpentine. As had been said by himself and others, the variation would be as much as from 20 to 60 per cent. of volatile oil, and 20 to 60 per cent. of resin. He had, however, never seen copaiba resin which was easily pulverizable, as Mr. Siebold stated. He had taken 30 or 40 lbs from a still, fused it in a steam pan for six or seven hours, and found, even then, it refused to get brittle. He was not quite certain whether Mr. Siebold referred to benzol or benzoline when referring to Dr. Flükiger's test.

Mr. MOSS said that the limpid Para balsam was rarely to be found in the stock of the wholesale druggist, being used almost entirely for the distillation of the essential oil. He had not experienced the difficulty in using Flückiger's test for gurjun oil which had been referred to.

Mr. SIEBOLD, in reply, said benzol was a most excellent solvent for copaiba. He determined the genuineness of the sample by evaporating it on a watch glass, to show the absence of fatty oil; the next process was to separate a little of the essential oil and convince himself by its odour, and, if necessary, by taking the boiling point, that it was oil of copaiba and not oil of turpentine. He then performed the test for gurjun oil and not finding that, he was satisfied that the sample was pure, or at least free from all known adulterants. He had never met with an instance of adulteration with the oleoresin of Hardwickia pinnata. Probably the reason Mr. Umney had failed to obtain a brittle resin was because he had previously boiled it with water; if the water got into the interior of the resin it never turned out satisfactorily, but if it was evaporated in a dish or watch glass a brittle resin was always obtained, and it was this form of test which he recommended. Pure benzol was not a test for any impurity in copaiba, because it dissolved all known adulterants. Petroleum ether was very suitable for the detection of gurjun oil. In reply to Mr. Moss, he would add he did not say there was the slightest difficulty in detecting the presence of gurjun oil by Flückiger's test, if applied to the oil of copaiba. But if applied direct to the balsam, the test required some little practice to ensure correct results.

A vote of thanks was passed to Mr. Siebold, and the President stated that one of the samples he referred to as having been analysed by himself twenty years ago was still in the Museum of the Pharmaceutical Society, and side by side with it was a portion of the leaf, the sample having been collected by a member of the Society direct from the tree.

The next paper read was on—

A New Medicinal Solution of Phosphorus.

BY W. W. URWICK.

By the able paper Mr. Williams read on the administration of phosphorus, before the British Pharmaceutical Conference in 1874, giving a formula for the solution of phosphorus in glycerine and alcohol, and pointing out how a portion of the phosphorus became oxidized during the process, I was led to make one or two experiments with the desire to produce a formula not liable to change, for the administration of phosphorus in known doses and capable of administration without admixture if required. With this idea, I prepared phosphorus pills, and coated them with a solution of albumen; but after a time the pills ceased to be luminous on testing them, showing that phosphorus had disappeared and was no longer present in a free state. My friend Mr. Hampson has suggested that the albumen had become porous by drying. Though thus foiled, feeling I was on the right track, I turned my attention to making a solution that should be stable and contain known doses.

I adopted the suggestions made by Mr. Williams at the British Pharmaceutical Conference, with the following modifications:—I dissolved 2 grs. of phosphorus in absolute alcohol and glycerine at a temperature of about 170° Fahr., with the addition of a little cane sugar and sugar of milk, which addition, I have found, prevents any portion of the phosphorus passing into an acid state during the time of solution. When the solution is cold I add the albumen of one egg, first mixed with a little glycerine and alcohol, and then sufficient glycerine to measure 10 ounces; the strength of the finished product being $\frac{1}{40}$ of a grain to each drachm, which I find to be quite strong enough to admit of its being preserved a long time without change, and taken, if required, without dilution.

I have kept some solution for more than two years without the phosphorus passing into the amorphous state, or the solution becoming acid or losing its luminous properties when mixed with water and agitated.

In no case as yet have I found any change, except where it had been, for the purpose of experiment, exposed to the strong rays of the sun, day by day, for a period of near three months, when a slight trace of amorphous phosphorus became visible. So thoroughly does the albumen protect the phosphorus, that when the solution has been mixed with water, and kept for a week, it still shows phosphorescence on agitation.

Though the foregoing may have little in it worthy of mention, one or two points have presented themselves to my notice which I deem may be of interest. Wishing to make the solution somewhat more agreeable to the palate, I added a few drops of oil of neroli to the albuminated solution of phosphorus; when, to my surprise, in an instant the solution lost its smell and flavour of phosphorus, and also its power of showing phosphorescence when mixed with water and agitated—indeed the phosphorus seemed at once blotted out of existence; but blue litmus remained unchanged, pointing out that it had not been oxidized. The question, "How does the oil of neroli prevent oxidation?" is a very interesting one, and which I submit to the Conference. On this point, at present, I can give no satisfactory answer, but I found, on applying a strong heat to the solution with neroli, the peculiar ring-like fumes of phosphorus pentoxide formed. This may not be a crucial test, but points to the fact of the phosphorus being held in the solution with neroli in a free state. Yolk of egg deprives the solution of phosphorus of its luminosity, but still appears to hold the phosphorus in a free state. Indeed, the idea has occurred to me that the phosphorus natural to the egg occurs in the free state. Possibly it is the oily matter in yolk of egg that is the agent which absorbs the phosphorus from any solutions. On adding excess of the solution to the yolk, power of absorption is overcome and phosphorescence reappears.

Tincture of orange at once destroys the phosphorescence, smell, and flavour, as does also tinct. of gentian. With tincture of calumba and tincture of quassia, and tincture of nux vomica, the phosphorescence, smell, and flavour, remain unaltered.

Essence of lemon deprived the solution of its luminosity, but the smell and flavour remained in a modified form.

Oil of cloves also deprived the solution of its phosphorescence, smell, and flavour; but on agitation with water, and then standing, flashes of phosphorescence appeared at intervals, similar to electric sparks, and on keeping for two days the phosphorescence reappeared to a slight extent, but soon passed away.

With orange flower water the solution remains luminous nearly as long as it would with common water, retaining the smell and flavour of phosphorus. Milk destroys the phosphorescence, but the flavour and smell remain in a slightly modified state. Within this last week or two, these points have presented themselves to my observation, but to the present time I have not been able to trace the chemical change, if any, that takes place in the phosphorus, or what combination it forms with essential oils or milk.

The formula referred to is:

℞	Alcohol	$1\frac{1}{2}$ oz.
	Cane Sugar	$\frac{1}{2}$ oz.
	Sugar of Milk	$\frac{1}{4}$ oz.
	Albumen of one egg,	
	Phosphorus	2 grs.
	Glycerine to	10 oz.

The President said the mode suggested for the solution of phosphorus was almost identical with one he had himself recommended, the principal difference being that he had suggested the mixture of oil and phosphorus with yolk of egg and water, which, with the addition of a little spirit of chloroform made a mixture as palatable in his opinion as could be produced, and which would keep perfectly well without change for any reasonable time.

Mr. Williams said it was very interesting to find what an influence albumen and sugar appeared to have in preserving the phosphorus. The point of the paper was that the solution if examined with test paper was found to be in no way acid, proving that the phosphorus was not oxidized, but was really in its free state, which was not the case with most of the phosphorus solutions The fact that some essential oils appeared to have the power of destroying the active condition of the phosphorus was an observation that deserved to be recorded.

Mr. Greenish said the one great objection to all these fluid preparations was, that when taken the eructations were so exceedingly disagreeable. He thought the pill of phosphorus in cacao butter less liable to this objection, and if to this a little Canada balsam were added the pill was made more plastic, and passed lower down the stomach before dissolving, so that the unpleasant sensations to which he had referred were avoided.

A vote of thanks was recorded to Mr. Urwick.

The next paper read was on—

Albumin of Commerce.

BY CHARLES T. KINGZETT, F.C.S., AND M. ZINGLER.

As is well known, albumin is largely employed for fixing certain colours on cotton goods, such colours, for instance, as madder-red and indigo-blue, which are almost the only fast colours possessed by dyers.

For fixing these and other colours egg albumin is well adapted, and would be without fault, were it not for its high price. As it is, its use withdraws large numbers of eggs from the food market, and although blood albumin has to some extent taken its place in printing applications, yet this can only be employed for the inferior and darker colours.

It must be remembered that in printing, albumin serves a double purpose; it acts as a vehicle for the colour, and serves simultaneously as a varnish.

1008 eggs are said to yield* on an average six litres (1·3 gallons) of the whites in a fluid state, and four litres (·8 gallon) of the yolks. The white is evaporated upon zinc trays slightly greased with olive oil, and maintained at a temperature of about 30° to 35° C. The olive oil is used to prevent the adhesion of the albumin to the metal trays. In this way 14 per cent. of commercial albumin is obtained.

The evaporation is resorted to mainly, because, as is well known, solutions of albumin very soon undergo putrefaction. But before use, the albumin has to be re-dissolved, and this is best done by adding it in a powdered state to water at 113° to 122° F. (45° to 50° C.), keeping the mixture well stirred to prevent agglutination of the albuminous particles. The water should never be added to the albumin. The strength of the solution employed varies with the specific nature of the use, but on an average, a solution containing 300 grms. to the litre is used, or nearly 3 lbs. to the gallon. It is necessary to filter such solution through a fine silk sieve in order to absolutely free them from membranous tissue derived from the shells of the egg, otherwise the particles give rise to dark spots on the printed cloth. Egg albumin prepared as described, is used for fixing the better colours and for all finer purposes, but its high price militates against its universal employment, commanding as it does from 4*s.* to 4*s.* 6*d.* per lb. (dry scales).

Blood albumin occurs in commerce in various forms.

The most inferior variety is packed in casks in the liquid state, and consists merely of blood, which has been defibrinated by whipping. It is very dark red in colour, from the suspension of corpuscles, and soon putrefies, giving rise to stinking gases, which sometimes cause the casks actually to burst.

This same quality of blood albumin also occurs in the form of shining black scales, which on dissolving in water, yield a cheap but dark coloured albumin solution.

The purer forms of blood albumin are prepared as follows: The blood of slaughtered animals is collected in circular or square flat-bottomed and shallow basins with vertical sides. These are from 12 to 14 inches in diameter, and 4 inches in depth, containing about two gallons each. While standing in these vessels, during from two to six hours, the blood coagulates, and when this has happened, the clearer serum is run off into filters of a construction similar in form to the other vessels, but pierced with holes of about two inches in diameter, and lined with a dense cotton or linen cloth. The filtered liquor is allowed to subside during about twelve or fourteen hours, and the product is used for the lighter and brighter colours.

The clot is cut up and drained, and gives a further quantity of a somewhat darker albumin solution. To obtain the scales of commerce, these solutions are evaporated by a low steam heat, in thin films. The clot, consisting of the fibrin and corpuscles, is sold as a manure.

Five oxen, or twenty sheep, or thirty-four calves, are said to yield the same quantity of dry albumin, namely, 2 lbs. About 3*d.* is paid for the blood of each beast. Four gallons of blood, costing 10½*d.*, yield one gallon (or 25 per cent.) serum, costing 1*s.*; one gallon of serum yields fifteen ounces of dry albumin, of a quality which, at the present, is worth 1*s.* 2*d.* per lb. The price has rarely gone above 1*s.* 9*d.* per lb. It is thus seen that the market value of blood albumin barely covers the cost of production.

In producing blood albumin of commerce, the object to bear in mind, is the attainment of a substance whose solution is free from colour, possesses perfect coagulability, and which is cheap. On account of the superior price and value of egg albumin, it has for many years been a matter of desire to prepare a blood albumin of a similar whiteness and quality, and various attempts have been made in this direction. The only ones we need mention are as follows:

Animal charcoal is sometimes used in order to remove the colour to some extent, but the precise method of using it is kept secret by manufacturers.

Incipient coagulation is also resorted to by others, a given small amount of coagulated albumin carrying down with it a considerable amount of colouring matter.

Air rendered ozonic by means of electric induction has also been employed, but the quantity of available ozone thus procurable is not nearly sufficient for the purpose, if the element of cost be at all taken into consideration. Again, it has been proposed to add peroxide of hydrogen to blood albumin solution, but this reagent is far too costly to be employed, as ordinarily prepared. Another plan to which resort has been made consists in adding turpentine and allowing the mixture to stand during some time with occasional stirring.

None of these plans are competent to produce an albumin at all comparable in value to egg albumin.

We now proceed to describe the process for which letters patent have been granted to us. It may be conducted upon blood itself, or defibrinated blood produced by whipping or preferably upon the serum of blood prepared as described. When conducted upon the serum of blood, the product contains about 17 ounces albumin to the gallon, whereas, as already pointed out, the original serum contains about 15 ounces to the gallon; in other words there is a considerable concentration. This solution is strong enough for many purposes, but for certain other purposes it should contain from 30 to 40 ounces to the gallon, and such a strength may be obtained by dissolving in the serum before treatment the requisite amount of commercial dried blood albumin.

In any case the solution to be treated is placed in a suitable apparatus, and to it is added about 5 per cent. of crude turpentine; into the mixture maintained at about 30° to 60° C, a current of air is blown rapidly, the turpentine which is carried over as vapour being condensed by suitable means, and continually returned to the mixture. After a period varying (according to the quantity to be bleached) from two to ten hours, the operation is concluded, and all that remains to be done is to allow the product to settle, syphon off the albumin solution from any residual oil and complete the operation by filtration through French grey paper. In this way an albumin solution is obtained, which will keep well during the whole of the hottest summer, without the slightest decomposition, and which is as white as egg albumin.

We were led in the first place to this discovery by experimenting with the solution of "Sanitas," which is now being largely manufactured. It will be remembered that in a number of researches (a summary of which will be found in the *Society of Arts Journal*, Feb. 16, 1877) upon the oxidation of terpenes and allied hydrocarbons, one of us found that the aerial oxidation of turpentine resulted in the production of peroxide of hydrogen, camphor, camphoric acid, and other substances, which form the constituents of "Sanitas." This solution we found competent to bleach blood and blood albumin solution, but as the quantity which it was necessary to use was considerable, after-evaporation had to be employed to get the albumin of a strength suitable for its various applications. This method was therefore abandoned and the process above described resorted to, whereby the particular substances resulting from the oxidation of turpentine are produced *in situ*. In this way the albumin solutions are entirely bleached by the peroxide of hydrogen, while the camphor

* 'Handbook of Dyeing and Calico Printing.' By W. Crookes, F.R.S.

camphoric acid, and other bodies simultaneously formed exercise an antiseptic action, and preserve the albumin absolutely from decay and putrefaction.

We do not here propose to define the nature and function of an antiseptic or disinfectant, but taking an infectant to be that body which causes disease, and further accepting that which is ordinarily believed, viz., that disease is often caused by the putrefaction of albuminous principles, then we have in "Sanitas" a true antiseptic and disinfectant, for it absolutely prevents that putrefaction. It should be here stated that the presence of even traces of phenol is sufficient to almost entirely prevent the bleaching of blood albumin, either directly by "Sanitas" or by the oxidation process *in situ* already described.

The albumin solution prepared by our process is, in its general characters, analogous to ordinary forms of albumin. The coagulation which results on heating is, however, somewhat different; instead of being precipitated in flocks and flakes it entirely gelatinizes. Moreover, when dried down, the albumin is not so soluble as the ordinary forms; this, however, is no objection, and indeed is an advantage, for there is no necessity to evaporate it down, keeping perfectly fresh as it does in solution; moreover, by its use some colours are better fixed than by the ordinary commercial albumin. Besides the use of our albumin in printing there are various other applications of it, which we have also patented. For preparing photographic paper it appears to be admirably suited, while as a varnish when used either alone or in conjunction with other bodies as set forth in our specifications, for violins, pianofortes, and articles of furniture generally, it answers excellently, giving a beautiful gloss, and improving the timbre of musical instruments.

It admits of general use also for sizing and enamelling articles of wood, glass, or metal. For purposes of painting, the pigment is intermixed with the albumin solution and then applied in the ordinary way.

In pharmacy this albumin solution is extremely suitable for the precipitation of starchy matters in sarsaparilla and other decoctions, and of course possesses the advantage already stated, that it may be kept in the state of solution.

The cost of bleaching blood albumin by our process is but small, and is amply covered by the increased value of the product. It should also be stated that the above observations do not merely relate to laboratory experiments but also to larger experiments and to the actual manufacture.

As regards the chemical changes involved in the bleaching process we have very little to say. It is well known that fibrin has the power of decomposing peroxide of hydrogen into water and nascent oxygen; ordinary albumin, however, lacks this power, although the rationale of the bleaching process is, no doubt, very similar, the colouring matter of the blood assimilating the second atom of oxygen from the hydric peroxide which is reduced to water. To hematocrystalline (or cruorine), which constitutes the colouring-matter of blood the formula $C_{600}H_{960}N_{154}FeS_3O_{177}$ is ordinarily assigned, with an atomic weight of 13,280. No matter what amount of doubt may be associated with the idea of such a chemical individual, the fact remains that blood crystals of hematocrystalline always contain four-tenths per cent. of iron. From hematocrystalline, hematine may be obtained with the formula $C_{32}H_{32}Fe_4NO_6$,* and not unlikely it is this body which undergoes the oxidation under consideration, resulting in the bleaching of blood albumin solutions.

Of the relative constitution of hematine nothing is known.

* Thudichum and Kingzett on hemine, hematine, and phosphorized substance present in blood corpuscles.—*Journ. Chem. Soc.*, September, 1876.

Note on Pilocarpine (from Jaborandi).

BY C. T. KINGZETT, F.C.S.

A few weeks ago Professor Attfield kindly gave me a few crystals of the nitrate of pilocarpine, and a few grains also of the platinic chloride salt. These I have since examined as follows:—

The crystals of nitrate were large and hard; when a little was burnt on a piece of platinum foil it blackened, fused, emitted white inflammable vapours and left a little ash. This fact and the slightly yellow colour of the crystals signified that the salt was not quite pure.

The rest was dissolved in water and aqueous solution of platinic chloride added, when the mixture went solid by formation of crystals. More water was added and hydrochloric acid to decided acidity, and the solution thus obtained allowed to crystallize. Along with the crystals a little viscid uncrystallizable deposit was thrown down. The crystals were isolated, washed, and dried at 100° C.; there was only 0·125 gram when dry. It showed on analysis 24·8 per cent. platinum and 26·71 per cent. chlorine. (Relation 1:6). I have shown in a previous publication* that pilocarpine has the formula $C_{23}H_{34}N_4O_4$, and its dihydrochloride platinic chloride combination that of $C_{23}H_{34}N_4O_4\ 2\ HCl\ Pt\ Cl_4$ requiring 23·4 per cent. platinum, and 25·2 per cent. chlorine.

It would, therefore, appear (so far as could be ascertained from the extremely limited amount in my possession), that this salt prepared from the nitrate was identical with that I had previously analysed, but contained a slight excess of platinum chloride.

The platinum salt given me by Professor Attfield weighed 1·5 grams. This I distilled to dryness with an excess of pure caustic soda (made from the metal). The distillate was alkaline and had the odour of trimethylamine, whose reactions,† so far as could be determined, it gave, that is to say, it gave a very light blue precipitate with cupric sulphate insoluble in excess, and a faint precipitate with aqueous platinic chloride solution; both precipitates appeared soluble in boiling water.

It is, therefore, confirmed that (which I have previously demonstrated) jaborandi yields but one alkaloid, and it appears that this yields trimethylamine as stated.

The President drew the attention of the Conference to some samples of nitrate of pilocarpine, prepared by Mr. Gerrard.

Mr. Gerrard said there was a great difference in the appearance of the crystals when produced from water and from alcohol. When the nitrate was boiled in alcohol it recrystallized on cooling in perfectly white crystals, but on a re-solution in water and recrystallization they had not that beautiful white crystalline appearance. One of the samples on the table had been recrystallized from water four times. He had tried many processes for the preparation of this alkaloid, but with a slight modification had returned to the one by which he first obtained it, exhaustion with ordinary spirit of wine, only that the spirit should be acidified with a little tartaric acid, an addition similar to that in Duquesnel's process for obtaining aconitine. The Société de Pharmacie had adopted a very similar process, except that it used chloroform and the chloroform extract from the mother liquor was shaken up with dilute hydrochloric acid. That however would not work well commercially; it was better to distil off the chloroform and work with the residue.

The thanks of the meetings were awarded to Mr. Kingzett for his two papers.

(*To be continued.*)

Parliamentary and Law Proceedings.

Prosecution under the Arsenic Act.

At the Rugeley Petty Sessions, held on the 20th inst., before J. Spode, Esq., Lord Zouche and T. J. Birch, Esq., a police constable of the Staffordshire constabulary, named Ralph Ratcliffe, was charged with having on the 31st of August last at Rugeley, when purchasing and demanding certain arsenic from Thomas Greensmith, chemist of Rugeley, given false information in relation to the purpose for which the arsenic was required, which he, the said Thomas Greensmith, was authorized to inquire into from him, viz., by stating that the arsenic was for George Dinneford, for the purpose of poisoning mice, whereas it was not intended for such person or purpose.

Mr. Glaisyer, solicitor to the Chemists and Druggists' Trade Association, Birmingham, prosecuted, and Mr. Horatio Brevitt, clerk to the Wolverhampton County Magistrates, defended.

Mr. Glaisyer said, the summons was issued under the 15 and 16 Vic. cap. 13, sec. 1 and 4, commonly known as the Arsenic Act, which provided that any person selling arsenic should forthwith enter, or cause to be entered, in a regular manner, in a book kept by such person for that purpose, according to the form which was set forth, a statement of such sale, with the quantity of arsenic so sold, and the purpose for which such arsenic was required or stated to be required, and the day of the month and year of the sale, and the name, place of abode, and condition or occupation of the purchaser, into all which circumstances the person selling such arsenic was by the statute required, and authorized to enquire; it was also enacted, if any person purchasing such poison should give false information in relation to the particulars of the purchase, every person so offending should be liable to a penalty not exceeding £20, upon summary conviction before two justices of the peace.

He ventured to say that Mr. Greensmith had been summoned a fortnight previously for selling to this police constable a small quantity of arsenic without making use of all the formalities prescribed by the Act. The present charge was not taken up from spite against the policeman but ou public grounds, simply in order to show that the general body of chemists and druggists throughout the country could not be prosecuted with impunity on charges which were supported by means of falsehood and deceit. There could be no doubt that the offence had been committed, for not only should he prove by the evidence of Mr. Greensmith that the defendant went into his shop and purchased some arsenic, stating that he wanted it for Mr. Dinneford, head gardener at Wolseley Hall, for the purpose of killing mice in the greenhouses, but he should call Mr. Dinneford to prove that defendant was entirely unknown to him, that he did not send him for the poison, and that he had not used or required any poison for mice. This evidence was supplemented by the confession of the defendant when in the witness box at the last Petty Sessions, when he admitted the statement made to Mr. Greensmith was entirely false the Bench on that occasion considered that the offence was one of a very serious nature, and inflicted a penalty of £1, not so much, the Chairman had stated, as a punishment, but as a warning to other tradesmen to prevent them from acting in a similar way; but he wished to know if the present case was not quite as serious, or more so. In Mr. Greensmith's case, that gentleman was innocently led to supply poison for the use of a person who was a regular customer of his for a very usual purpose, but in the present case the police constable, under the direction of the chief constable, told lies in order to procure a case upon which to prosecute Mr. Greensmith. He argued that the man who told lies to obtain evidence upon which to found a prosecution would be the most likely man to tell lies on oath in the witness box to obtain a conviction. He was aware that public opinion was rather in favour of these methods of detection in order to procure cases, but that such practices could quickly turn the use of lies and deceit to still more serious purposes had been proved by the recent disclosures in the Bow Street detective's case. It might possibly be argued that the defendant was instructed by the chief constable to take the course he had followed, but if so, he thought this only aggravated the offence and showed that the chief constable was a man by whom falsehood was regarded with complacency, and who gave to his inferior officers encouragement in this line of conduct.

Mr. Brevitt remonstrated against this attack on the chief constable, who had nothing to do with the case.

Mr. Glaisyer said, on the contrary, the defendant himself admitted on oath in the witness box at the last Petty Sessions, that he was acting under the instructions of the chief constable in stating the poison was required for Mr. Dinneford for killing mice. He continued to say that the direction of the chief constable, although it revealed the practice of the force, did not justify the defendant for following such instructions, nor did the order of his superior officer justify the defendant in breaking the law. He concluded by saying that it was not often that a bench of magistrates had such an opportunity of expressing an opinion upon this system of detection, and he therefore asked the bench to pass a severe censure upon the conduct of the defendant, and to inflict a heavy penalty, to add force to their expression of dissatisfaction.

Mr. Thomas Greensmith, chemist and druggist, of Rugeley, stated that the defendant came into his shop in plain clothes on the 31st of August, and said he wanted some poison, particularly asking for arsenic. In reply to questions from witness, defendant said he wanted it for Mr. Dinneford, the head gardener at Wolseley Hall, for the purpose of poisoning mice in the greenhouse. As Mr. Dinneford was a regular customer, witness did not hesitate to supply him with the poison. He saw defendant in the witness box at the last Petty Sessions, when defendant said that he had acted upon the instructions of the chief constable, that he did not know Mr. Dinneford, and that the statement he made to witness in the shop was a false one.

Mr. Brevitt cross-examined the witness at some length.

Mr. George Dinneford, head gardener at Wolseley Hall, was called to prove that he knew nothing of the defendant, nor had he authorized him to purchase arsenic.

Mr. Brevitt, in his remarks for the defence, said the question before the Bench was, whether the defendant really made a false statement or not in answer to the questions which were asked him. The particulars required by the Act of Parliament to be demanded from the defendant were, first, the statement of the sale, and here there was no falsehood. The next questions were the quantity of arsenic sold, the date, month and year; these were correct as was also the name of the purchaser. The next was "for whom the poison is required or stated to be required," and he (Mr. Brevitt) said that Mr. Greensmith should have asked this question and not for whom it was required, a question which had no right to be put. He asked the Bench to give their most serious consideration to this fact, and not to convict the defendant because he employed these means in order to detect the plaintiff, who, according to his own evidence, showed great irregularity in the manner in which he had kept his poison book. In continuation, Mr. Brevitt said that notwithstanding these irregularities of the plaintiff the Bench were asked to convict the defendant, whose only fault appeared to be that he had obtained a conviction against Mr. Greensmith; he argued that there had been no false information given to the prosecutor in reply to questions asked of him. There was no evidence to show that defendant did not require the poison for the purpose he named, and even now he might hand it over to Mr. Dinneford for that purpose, whilst the question as to whom the poison was for was entirely an illegal one.

The Chairman, after some consideration, said the Bench considered that in the present case the act had been broken, and so far they were bound to convict, but at the same time they did not think defendant committed the offence with the slightest illegal intention, a nominal fine only would be imposed, namely, one shilling and costs.

Illegal Sale of Poisons.

At the Walsall Petty Sessions on Wednesday, 26th July, 1877, Major Newman in the chair, James Tyrer, 65, Upper Rushall Street, Walsall, Staffordshire, was summoned for "that on the 19th September, 1877, at the said borough, he unlawfully sold to William Frederic Haydon certain poison, to wit oxalic acid, in a certain packet, the cover of which packet did not set forth the name of the seller of the same, contrary to the statute in such case made and provided."

Mr. Henry Glaisyer (Solicitor to the Chemists and Druggists' Trade Association) appeared in support of the summons, and Mr. Williams (from the office of Messrs. Duignan, Lewis and Lewis, solicitors, Walsall) defended.

The case created great interest in the town, many chemists and druggists being present during the hearing of the charge.

Mr. Glaisyer, in opening the case, said he appeared to prosecute, the information being laid by Mr. William Frederic Haydon (Secretary to the Chemists and Druggists' Trade Association of Great Britain), under the instructions of the officers of that Society. The summons was issued under the 17th section of the 31st and 32nd Victoria, Chap. XXI, which enacts that "It shall be unlawful to sell any poison, either by wholesale or by retail, unless the box, bottle, vessel, wrapper, or cover, in which such poison is contained be distinctly labelled with the name and address of the seller of the poison." The section further stated that "Any persons selling poison otherwise than herein provided shall, upon a summary conviction before the justices of the peace in England, or the sheriff in Scotland, be liable to a penalty not exceeding five pounds for the first offence, and to a penalty not exceeding ten pounds for the second or any subsequent offence, and for the purposes of this section the person on whose behalf any sale is made by any apprentice or servant shall be deemed to be the seller." Mr. Haydon went to Walsall on the 19th inst., visited the shop number 64, Upper Rushall Street, and purchased from the defendant one pennyworth of oxalic acid. The label placed upon the packet stated "Edwin Constable, Chemist and Druggist," the seller. He should, however, be able to prove that James Tyrer was the seller within the meaning of the Act. He should put into the witness box Mr. Francis Keep, the landlord of the premises, from whom he understood defendant had taken a lease. He should prove that Mr. Tyrer purchased the fixtures from the previous tenant, also that the poor rates were assessed to the defendant, and that gas supplied to the premises was paid for by him. He need not, he said, point out the necessity of the requirements for the sale of poisons being adhered to, but he would point out that the defendant, who was not qualified, had been carrying on the business of a chemist and druggist under an assumed name. In conclusion, Mr. Glaisyer stated that the prosecution having been instituted upon public grounds the Secretary was instructed to ask for no part of the penalty.

William Frederic Haydon, examined by Mr. Glaisyer.

What is your name?—William Frederic Haydon.

Where do you reside?—At Birmingham.

What is your profession?—I am a pharmaceutical chemist.

What appointment do you hold?—The secretaryship of the Chemists and Druggists' Trade Association of Great Britain.

Did you come to Walsall on the 19th inst., and what then took place?—I came to Walsall on the 19th inst., and went to No. 94, Upper Rushall Street, where I purchased from the defendant one pennyworth of oxalic acid.

Who attended to you?—I was served by the defendant.

Was the poison wrapped in paper?—The oxalic acid was wrapped in this packet. (Packet produced, labelled "Oxalic Acid. Poison. Edwin Constable, Chemist and Druggist, 64, Upper Rushall Street, Walsall.")

Since the purchase of this poison have you tested it?—I have.

What is the result of your analysis?—I find it to be a good sample of oxalic acid.

Is the defendant qualified to sell poisons enumerated in the schedules of the Pharmacy Act?—He is not.

How do you prove this?—His name does not appear on the last published Register of Chemists and Druggists, nor has he passed any examination since this register (book produced) was issued qualifying him to trade as a chemist and druggist.

The name of James Tyrer does not appear on the register you have produced?—It does not.

You laid the information in this case?—I did, in my official capacity of Secretary of the Chemists and Druggists' Trade Association.

And you are instructed not to apply for any portion of the penalty?—I shall not do so.

Cross-examined by Mr. Williams: You went yourself to 64, Upper Rushall Street?—I did.

Is there any name over the shop door or window?—There is a name over the door.

What is it?—Constable.

Is it Edwin Constable, chemist and druggist?—No, simply Constable.

Did you see any placards or notices inside the shop, with the name Constable?—I did not.

Nor bill-heads?—No.

You noticed the labels on the bottles, I suppose?—Not particularly.

You had a glass tray with bottles under your nose, I presume?—I do not recollect either a glass tray or bottles under my nose.

Having gone in the character of an informer you did not look round and notice these things?—I did not.

And yet you went to find out what you could against this person?—I went to purchase oxalic acid.

With a view of issuing this summons?—Yes.

I suppose you did not have any bill for the oxalic acid?—I did not.

Look at the head of that, please (Bill head produced bearing the name of "E. Constable, Chemist and Druggist, Walsall.") You did not see any of these bill-heads, did you?—No, I imagine the defendant would not place bill-heads on the counter.

Yes, but they might have been hanging about. You did not see any?—No.

Have you opened the packet of poison?—Yes.

You opened it and took some out?—I did, for the purpose of testing it.

How did you test it?—By means of chemical tests.

Will you tell me the kind of tests you employed?—I dissolved a portion of the acid in pure water and filtered the solution. I dipped a strip of litmus paper into the filtrate, which turned of a red colour, proving the presence of an acid. I found no trace of any of the metals in the solution. A portion of the solution treated with solution of chloride of barium threw down a white precipitate of oxalate of barium; another portion of the solution treated with a solution of nitrate of silver threw down a white precipitate of oxalate of silver; a third portion of the solution treated with a solution of chloride of calcium, deposited a white precipitate of oxalate of calcium, insoluble in acetic acid, soluble in hydrochloric acid. I mixed a little of the dry substance with black oxide of manganese, free from carbonates, sulphuric acid and water, when carbonic acid gas was evolved, proved by passing the same into lime water, when a dense white precipitate of carbonate of lime was thrown down.

From the result of these tests you considered it was a good sample of oxalic acid?—The results of the tests I have enumerated proved the substance to be oxalic acid.

Yes, but how did you know it was a good sample?—By heating a portion of the dry acid to 350 degrees Fahrenheit's thermometer, when nearly the whole of it disappeared. Had the whole of it been dissipated it would have passed the British Pharmacopœia test for pure oxalic acid.

You are not a public analyst?—I am not.

You have not submitted this to an analyst?—No.

Do you know whose name is over the shop?—Yes.

Do you know he is a chemist?—His name does not appear on the printed Register of Chemists and Druggists, but I find on reference to the report of the proceedings of the Pharmaceutical Council, on May 2nd last, a certain Edwin Constable, 223, Green Lanes, Small Heath, Birmingham, was at the meeting of that Council ordered to be restored to the Register of Chemists and Druggists.

Do you know that as a chemist he is properly authorized to sell poisons?—Yes.

You have no doubt about it?—No, I have no doubt of it.

You have given a receipt for his annual subscription to your Association?—I am aware that his name appears on our list of members.

Have you received from Mr. Constable his subscription for the present year?—I have received from Mr. Elliott, chemist, residing at Walsall, the sum of five shillings paid to him by the defendant in the name of Edwin Constable. I may perhaps be allowed to explain—

This is the receipt is it not? (receipt produced)—Yes.

Re-examined by Mr. Glaisyer: You wish to offer some explanation as to the receipt. Will you please tell the Bench what it is?—I will do so. Our membership subscription is five shillings per annum, due in advance on the 1st of July in each year. The subscriptions are remitted to my office by the members themselves, or in many instances, where we have several members in a town, a friendly member will kindly undertake to collect the whole of the subscriptions in the town in which he resides, and forward the amount to me in one sum, thereby saving me a considerable amount of labour in forwarding to each member a direct application for his subscription. In this way Mr. George Elliott, chemist and druggist, of this town, collected the subscriptions of members residing here, and on the 7th August last he forwarded me a remittance to cover the subscriptions of eleven members, amongst the names of the new members being that of Edwin Constable. I have since ascertained that he is not in business at Walsall, but that the defendant is trading here in his name. Residing at Birmingham I had no means of ascertaining that Edwin Constable was not in business at Walsall, without making direct inquiries, for which, at the time his subscription was paid through Mr. Elliott to me, I saw no cause.

Does the name of Edwin Constable appear as a chemist and druggist residing at Walsall on any official register?—It does not.

Re-examined by Mr. Williams: You say it was resolved at a meeting of the Pharmaceutical Council to restore the name of Edwin Constable to the register?—Yes; the name of Edwin Constable, 223, Green Lanes, Small Heath, Birmingham.

No register has since been published?—No.

Then in the ordinary course of things his name will appear on the next published register?—Yes; as residing at Birmingham.

Francis Keep, Bank Buildings, Walsall, called and examined by Mr. Glaisyer.

Are you the owner of 64, Upper Rushall Street, Walsall?—I am.

Who is your tenant of that property?—James Tyrer.

Have you granted any lease to him?—Yes; (lease produced dated 30th December, 1876, for a term of twenty-one years at an annual rental of £60—a clause showed that the defendant had no power to sublet any part of the premises without the written sanction of the landlord).

Have you given the defendant permission to sublet any portion of the premises in question?—No.

Robert Leighton, Assistant Overseer for the Walsall Borough, appeared on subpœna and produced the rate book.

Mr. Williams remarked that to save time he would admit that defendant paid the rates.

Mr. Glaisyer: And the gas?

Mr. Williams: I will not say anything about gas.

Mr. Glaisyer: Then we will call Mr. Stackhouse the collector.

Mr. Williams: Very well; I will admit he pays gas also.

Mr. Henry Hobson, chemist and druggist, of 89, Ablewed Street, Walsall, attended upon subpœna. He testified to being a former tenant of the premises now occupied by the defendant, and upon leaving in March last, to selling the fixtures of the shop to the defendant. Since that time he had no dealings with him. He knew nothing of Constable, and was not aware that he ever saw him.

Cross-examined by Mr. Williams: When did you first see Mr. Haydon?—On Wednesday last.

Before or after this purchase was made?—After the purchase was made, and I wish it to be understood that I have had nothing to do with this prosecution.

Police-Constable Stringer, sworn and examined by Mr. Glaisyer, said on the previous Monday morning he went to 64, Upper Rushall Street, and asked for Mr. Tyrer; defendant replied, "I am the man." Witness gave him the summons, upon which he remarked, "I expected so." Witness said, "What have you been doing?" Defendant replied, "I have not passed my examinations; it was an error on my part; I am using Mr. Constable's name."

Mr. Glaisyer said this was the case for the prosecution.

For the defence, Mr. Williams submitted that the case had not been made out. He thought the magistrates would see at once that the prosecution had made a mistake, and that he had no case whatever to answer, they having chosen to proceed under the 17th section of the Act, instead of under an earlier section, viz., the 1st. They found Mr. Tyrer—at least, they said so, but he would not admit it—without a certificate, carrying on the business of a chemist and druggist, and they put a policeman into the box to say that defendant admitted to him having committed an error, in not having passed his examination, and still using Mr. Constable's name. He would deny that, if that were true, it would be an infringement of the Act. Persons might sell drugs, so long as they did not sell poisons, without having a certificate, and had the prosecution found that defendant had prescribed or done anything within the meaning of the Act, they might have proceeded under the 1st section, and charged him with illegally trading as a chemist and druggist. Instead of this, however, they had proceeded under the 17th.

Mr. Glaisyer: You are wrong, I think this section alone deals with the labelling of poisons.

Mr. Williams: That is not what I mean; chemists and druggists within the meaning of the Act may be persons who assist others "for the compounding of the prescriptions of duly medical practitioners, also of assistants and associates."

Mr. Glaisyer: Who have been duly registered.

Mr. Williams, resuming: So it was required to label the poison with the name and address of the seller and that "for the purpose of this (17th) section the person on whose behalf any sale is made by an apprentice or servant shall be deemed to be the seller." It was not simply because a men stood behind the counter that he was to be deemed the "seller." The "seller" was the responsible person against whom there would be a remedy in case of anyone being wrongly supplied. It had been admitted that Mr. Constable was a chemist and druggist, that the packet of poison bore his name, and that the name was also over the door. That being the case how could the prosecution say that Mr. Constable was not the "seller," and defendant had but simply supplied the poison on his behalf. The prosecution had no evidence that defendant had not sublet the premises.

Mr. Glaisyer: Yes, we have.

Mr. Williams: You have only the evidence that no lease or licence has been applied for. There was no evidence whatever that Mr. Constable was not the person on whose behalf the poison was sold, or that the requirements of the Act had not been complied with. For all they knew defendant might be in some way engaged by Mr. Constable, and it was for the prosecution to prove their case, not for him to prove a negative. It was all very well that Mr. Haydon was Secretary to the Society, but he was none the less an informer, and for the pennyworth of oxalic acid tried to make his client liable to a penalty of five pounds. He hoped the magistrates would require strict proof that the offence had been committed. He did not say that if the charge had been brought under the first or second section he might not have considered it necessary to put witnesses into the box, but being brought under the seventeenth section he should call no evidence but simply leave the case in the hands of the Bench.

The magistrates retired for consultation, on their return the Chairman said, "We consider the case proved satisfactorily, and as a high penalty is not asked for the fine will be twenty shillings and costs."

Dispensing Memoranda.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be conidered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.

Notes and Queries.

Mr. R. Goodwin Mumbray writes to say that he finds the best thing to preserve leeches is the addition of about a teaspoonful of salt to five gallons of water, and that during a very trying summer, when "all the leeches in the town were destroyed," his kept perfectly healthy and remained so many weeks with change of water.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE CONFERENCE GRANTS.

Sir,—I quite agree with Professor Attfield that it is not only desirable but necessary that discrimination should be practised with regard to the questions and papers which are to receive assistance from the funds of the Conference, and to be recognized at the meetings.

What I regret is the abrupt manner in which the Conference, as represented by the Senior General Secretary, has thought proper to indicate its altered views in connection with the particular cases to which I referred in my last letter. In the report of the Executive Committee, published in the last 'Year-Book,' as having been read at Glasgow, I read that, "On the motion of the President it was resolved unanimously to grant to the gentlemen named the sums mentioned; to thank them for undertaking the several researches, and to request them to communicate results," etc. In the report of the same Committee read at Plymouth, I find similar expressions of satisfaction, not only as regards the fact that grants have been awarded, but also apparently with the nature of the work undertaken.

I trust that in future a more strict censorship over the papers that are presented will be exercised by the publication Committee, so that no communications likely to prove unacceptable to pharmacists may find their way into the general meeting. The assembled members will thus be spared a trial of patience, and misguided authors the risk of discomfiture by an official reprimand.

WILLIAM A. TILDEN.

Sir,—I appeal to your sense of fairness to allow me to make a personal statement in reference to your leader of last week on the Conference papers. Whether the murmurings of discontent at their too scientific character, which you state have of late been floating in the pharmaceutical atmosphere, are tangible or not, I do not now discuss; and, if tangible, whether those murmurings are or are not worthy of official notice, I will not just now consider. But tangible, or intangible, important or unimportant, you are entirely in error in associating my name with them. Respecting one paper, and one only, read at the Plymouth gathering, I said that such investigations, that is future investigations like that one, might be supported by grants from the new funds of the Chemical or Royal Societies or by the British Association, rather than by the Conference, at all events for the present. And in my letter, which appeared in the same number as your long editorial, to make my meaning very plain, I expressly stated that amongst such investigations I did not include any like the aconitine researches or any of the character of most of those on the essential oils; in short, that I did not allude to any research, even highly chemical research, which (by its title or by remarks made by the applicant for the grant) offered promise, even promise of pharmaceutical application. That perception which detected murmurings floating in the pharmaceutical air should have seen that remarks which did not apply to the more highly chemical papers just mentioned did not apply to those you enumerated. I suggested that for the present the Conference should discontinue grants in aid of such purely chemical investigations as one particular investigation I alluded to, and which, though an excellent paper, was, I think I may say, devoid of pharmaceutical interest; you, in your leader, make me apply that suggestion to chemical investigations which most assuredly have pharmaceutical interest. How you could make such a mistake I do not understand, especially in view of my unceasing endeavours to keep up the scientific character of British pharmacy—largely by means of my position as one of the four founders of, and the Senior Honorary Secretary, during its whole life, of the British Pharmaceutical Conference. It pains me thus publicly to allude to my labours, but nothing will so well show the nature of the charge you bring against me; were that charge true, I should be stultifying myself after fifteen years of effort for the advancement of pharmacy—effort which has, I hope, at least been consistent.

It is apparently necessary for me to add that my remarks at Plymouth were not intended to have, and cannot fairly be made to have, the slightest retrospective application—not even to the paper on oil of sage, though they were more appropriately made after the reading of that paper than at any other time of the meeting. I mean to say that the Conference, with the best of pharmaceutical intentions, might possibly devote money to a research which might result only in a contribution to abstract chemical science. Such a disappointment might involve no blame to either grantor or grantee. The remarks were intended chiefly for the purpose for which alone you yourself more or less commend them, namely, "as a useful hint to future intending contributors." As for the promotion of abstract chemical science, grand though such an object is, and strongly as I elsewhere support it, I contend that it should not be, and I would venture to inform you that it never has been among the objects kept in view by the Conference. You notice the appeal that was made to scientific chemists to join the Conference and accept grants, but you do not say that the appeal was to scientific chemists "interested in pharmacy."

JOHN ATTFIELD.

Ashlands, Watford, September 26, 1877.

P.S.—You have twice told your readers that my own Conference paper was "published" before. The kinder word would have been "printed." I stated in the paper that the work was done for the Admiralty Committee on the Arctic Expedition. Of course the report of that Committee was presented to Parliament in a printed form. The Conference enabled me to rescue the paper from "Blue book" obscurity.—J. A.

T. P. Iliffe and H. S. Brathwood.—Your letters have been forwarded to the publishers.

G. Welborn.—Your paper shall appear as soon as possible.

W. Gabitis.—Orders for journals should be sent to the publisher to avoid delay. Your communication has been attended to.

G. Andrew.—The sale would be illegal if the article contained a poison within the meaning of the Act.

THE INTERNATIONAL MEDICAL CONGRESS AND THE UNIVERSAL PHARMACOPŒIA.

ALTHOUGH in the programme of the International Medical Congress, just concluded at Geneva, it was not disclosed that any subject presenting points of special interest to pharmacists would be discussed, it appears that the proposition for the creation of a "Pharmacopœia Universalis" attracted a considerable amount of attention and consideration. The result has been that once more this difficult work has been taken in hand, and certain fundamental principles upon which it is to be constructed have been agreed upon. Whether this latest effort will be attended with any greater measure of success than has followed upon the endeavours of the International Pharmaceutical Congress, the Commission of the Paris Société de Pharmacie, or the more private work of Dr. PHOEBUS and his colleagues, remains to be proved, but it is important to find that at a congress attended by above three hundred and fifty medical gentlemen from all parts of the world, the conclusions arrived at as to the desirability of having such a pharmacopœia, and the nature of it, are virtually the same as those of the international congress of pharmacists held at St. Petersburgh in 1874.

It is, indeed, claimed that what has been done by this Congress constitutes a real step in advance. This, however, is not at all evident. All that has now been done—and more—has been done before by other bodies. The desirability of having a universal pharmacopœia has been voted more than once; certain principles for the regulation of its construction have been drawn up; commissions have been appointed to carry out the work; and we believe that even schemes for some sections have been sufficiently matured to be placed in the printer's hands. Yet all this has been to such little purpose that it appears from the report before us it has now been thought necessary to start again *ab initio*. In our opinion it would have been wiser, and there would have been no loss of dignity, had the medical congress, instead of acting independently, taken steps for facilitating united action with the International Pharmaceutical Congress at its next meeting, which will be probably held at no very distant date in London.

However, the International Medical Congress has preferred to appoint another commission, consisting of five medical men and three pharmacists, to carry out its wishes. The medical members are Dr. WILKINSON, President of the British Medical Association; Dr. MARION SIMS, late President of the American Medical Association; Dr. SEGUIN, New York; Professor GUBLER, Paris; and Dr. PACCHIOTTI, Turin. The pharmacists are, Professor GILLE, Brussels; Mr. MADSEN, Copenhagen; and Professor BRUN, Geneva. The first duty allotted to these gentlemen appears to be to impress upon their respective governments the advantages of nominating official delegates to represent each country upon the Commission. It would have been as courteous, perhaps, to have waited until these delegates had been appointed before deciding so definitely upon the details of the work. How far this Commission is to proceed as at present constituted does not appear, but it is not impertinent to remark that a Commission can hardly be said to be representative of pharmacy whilst it includes no pharmacist from Great Britain, Germany, France, or the United States.

The principles adopted by the Congress as those to be followed in this projected pharmacopœia are formulated in fourteen articles, which may be recapitulated as follows: The International Pharmacopœia is to be written in the Latin language. The metric system of weights and measures is to be adopted. Temperatures are to be indicated on the centigrade scale. At first, only energetic medicines are to be included. The names of compounds, chemical or otherwise, are to be made as simple as possible. The minimum of active principle which the more important drugs should contain is to be rigorously fixed. The maximum of impurities that each chemical product should contain is to be indicated. Instruments used in medicine and in surgery are to be numbered, and graduated in a uniform manner. These articles are closely in accord with the recommendations adopted by the International Pharmaceutical Congress at St. Petersburgh; neglect to secure common action would appear therefore the more to be regretted. But perhaps the Medical Congress may see fit to repair this apparent oversight at its next meeting in 1879.

Whilst referring to the subject of pharmacopœias we may remark that we learn from Rome that the Commission (of which the Senator CANNIZZARO, Professor of Chemistry in the University, is chairman) for the compilation of the new Italian Pharmacopœia held its first sitting on the 2nd inst. at the Ministry of the Interior. His Excellency, the Minister (Baron NICOTERA) represented to the Commission that there was a general desire, which he fully shared, that the work confided to it should be brought as speedily as possible to a termination, in order that the new pharmacopœia might receive the revision of the Superior Council of Health, with a view to its being incorporated in the bill for the reorganization of the sanitary service which the Minister of the Interior intends to submit to Parliament a few days after the opening of the session.

THE AMERICAN PHARMACEUTICAL ASSOCIATION.

On the 4th of September this Association held its twenty-fifth Annual Session in the City Hall, at Toronto, Canada, this being the first time it had met upon British territory. We understand that the attendance was not quite so numerous as it has been on some previous occasions, but this is hardly to be wondered at, considering the enormous distances that some of the members would have to travel to be present. On the whole, however, the meeting, which lasted four days, appears to have been very successful. The papers, which we hope to refer to more fully on a future occasion, were fairly plentiful, pharmaceutical and good, and the hospitality of the Canadian pharmacists evidently made a very pleasant impression upon the visitors. The only approach to unpleasantness appears to have been a few mutterings of the storm that is still raging as to the preparation of future editions of the United States Pharmacopœia.

Unlike our own Conference, in which hitherto every President has presided over two complete sessions, the American Association usually indulges in two Presidents at each gathering. On the first day the present meeting was called to order, and presided over by Mr. Bullock, of Philadelphia, who also presided over the latter portion of the meeting last year in that city. In the course of the second day, Mr. William Saunders, of Ontario, Canada, was elected the new President, to whom Mr. Bullock at once gave place. The new President, who is Vice-President of the Ontario College of Pharmacy and an Honorary Member of the British Pharmaceutical Conference, is said to be a Devonshire man. The Association also re-elected Professor Maisch to the post of Secretary, which he has filled for so many years.

It was reported that the membership of the Association numbered 1160, against 1066 at the previous meeting. The receipts during the year had amounted to 6514 dollars, the disbursements to 5559 dollars, leaving a balance in the treasury of 954 dollars. A balance left from last year in the hands of the Centennial Entertainment Committee was offered, on conditions, as a nucleus for a scientific research fund.

An important feature in connection with this meeting was a conference between the representatives of the teaching pharmaceutical colleges present, in which an understanding was arrived at as to the standard to be adopted for matriculation, and upon various other subjects of a similar nature. On more than one occasion the want of uniformity of action by the various colleges has been the occasion of jealousy and consequent discord at the Association meetings, which it may be hoped will now be avoided.

The next meeting of the Association is to be held in Atlanta, Georgia, on the 3rd of September, 1878.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, October 3, 1877.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atherton, Atkins, Betty, Bottle, Brown, Churchill, Gostling, Greenish, Hampson, Hanbury, Hills, Mackay, Owen, Rimmington, Robbins, Sandford, Schacht, and Shaw.

The minutes of the previous meeting were read and confirmed.

Election of Women to Membership.

The first application for membership considered was that of Miss Isabella S. Clarke. The President inquired if any member of the Council would move the election of this lady. He said no doubt Mr. Hampson would have done so, but he had not yet arrived.

The Vice-President said he should be happy to do so.

Mr. Churchill said he would support the motion.

It was subsequently proposed by Mr. Gostling, and seconded by Mr. Churchill—

"That Miss Isabella S. Clarke, a pharmaceutical chemist, be elected a Member of the Society."

Mr. Robbins did not think the question could properly be brought forward until the former vote had been annulled.

The President said a former Council had no doubt refused to elect Miss Clarke a member, but he could not see that that bound the present Council.

Mr. Robbins said he referred to the vote of the general meeting of the Society.

The President thought the Council had nothing to do with the vote of a general meeting.

Mr. Sandford begged to be pardoned for saying that it was a vote of the Society, and he did not see how the Council could elect a lady as a member until that vote had been reversed.

The President said that fact would no doubt weigh with members of the Council, but he did not see that they were bound by it.

Mr. Bottle said he should always feel bound to carry out the views deliberately expressed at a general meeting.

Mr. Betty thought it was a fundamental principle of the government of the Society that certain matters of importance were referred to general meetings, and of course the Council was bound by the decision of the meeting. He did not see how the Council could go in the face of its constituents, and elect a lady as member until the vote had been formally reversed.

The President said the Council had the power in its own hands; it was merely a matter of courtesy taking the opinion of the general meeting on a question of this sort. He did not see that the present Council was bound by a decision arrived at some years ago, and it was very likely if the matter were placed before a general meeting again a different conclusion would be come to.

Mr. Betty repeated that this matter came before the general meeting in the most formal way from the Council itself; it was not raised incidentally by an individual member.

Mr. Gostling said that as he found the matter had been discussed and decided by a general meeting he must withdraw his motion until the question had again been referred to the Society.

Mr. Churchill also thought it would be better not to proceed further until the question had again been put before the members of the Society. He therefore withdrew from seconding the motion.

Mr. Greenish said he would support the election.

Mr. Bottle said he would move as an amendment, that the matter be referred to a special general meeting.

Mr. Gostling seconded the amendment.

The PRESIDENT ruled that this must be put as a separate motion, and it was subsequently dropped.

The election of Miss Clarke as a Member was then moved by the Vice-President, and seconded by Mr. Greenish.

Upon a division, four voted for the motion and eight against it. The motion was therefore lost.

ELECTIONS.

MEMBER.

Chemist and Druggist.

The following registered Chemist and Druggist was elected a Member of the Society :—

Parrington, William .... Batley.

ASSOCIATE IN BUSINESS.

Henry Patrick Taylor, of London, having passed the Minor examination, being in business on his own account, and having tendered his subscription for the current year was elected an "Associate in Business" of the Society.

ASSOCIATES.

The following having passed the Minor examination and having tendered or paid (as apprentices or students) their subscriptions for the current year were elected "Associates" of the Society :—

Pike, John........................... Yarmouth.
Todd, Matthew James............ Sunderland.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination and tendered their subscription for the current year were elected "Apprentices or Students" of the Society:—

Budden, George Alfred .... Wareham.
Chipchase, Charles Herschel ... London.
Collis, William Blow .... Arundel.
Cox, John Goodwin............... Bridport.
Hudson, James..................... Harrogate.
March, Richard .... Stamford.

The names of the following persons were restored to the register of Chemists and Druggists :—

John Lowe .... 294, Old Kent Road.
Charles Spicer...72, Penton Place, Newington Butts.

Seven persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants :—

£20 to one of the founders of the Society, aged 74, and suffering from incurable disease.

£10 to the widow of a pharmaceutical chemist and member—sick, and without hope of recovery. Applicant had a similar grant in February last.

£5 to a former member of the Society, aged 59, suffering from chronic rheumatism; he received £5 in December, 1876.

£5 to the widow of a chemist in business for forty-two years. Applicant had a grant of £10 in April last.

£52 10*s.* to be placed in the hands of Mr. Owen for the purpose of obtaining the election of an orphan boy, aged 7½ years, one of seven children of a registered chemist and druggist, to St. Anne's School.

£10 to a pharmaceutical chemist and former member, residing in Ireland, now earning a small salary as a clerk, and in distress from illness. Applicant had a grant of £10 in October 1873.

£10 to the widow of a chemist and druggist in business on his own account for many years.

Mr. BETTY drew attention to the proposed grant of fifty guineas, and suggested that a smaller sum should be given. He did so because the Committee had been equally divided on the question, which had been decided by the Chairman's casting vote. Considering all the circumstances of the case, especially the age of the child, he thought it would be well to reconsider the amount.

The PRESIDENT explained why he had supported the proposition. He thought it a case in which the Society would do well to secure the election of the child. He did not think it was desirable to give a small sum which might not be effectual, and on the other hand, if the desired object could not be ensured, Mr. Owen would not expend the money at all.

The VICE-PRESIDENT moved that the grant should be thirty guineas.

Mr. SCHACHT pointed out that the whole amount need not be expended if it were not necessary.

Mr. HAMPSON argued in favour of the amendment.

Mr. GOSTLING supported the original proposition.

The matter having been further discussed in detail the amendment was withdrawn and the report and recommendations of the Committee were agreed to.

LAW AND PARLIAMENTARY.

The report of this Committee included reports from the Solicitor of the progress of various cases which had been placed in his hands. The Committee also recommended that proceedings be taken in a case of alleged infringement of the Pharmacy Act, the particulars of which had been elicited by the action of the Chemists and Druggists' Trade Association in a prosecution reported in the *Pharmaceutical Journal* of the previous week (p. 257). A homœopathic chemist, who had used the title of "pharmaceutist" on his labels and over the shop, had paid the penalty incurred by his breach of the law, and promised to discontinue doing so in future. He had been warned on a previous occasion. Another question which had been before the Committee was that of prosecuting in the case of using methylated spirit for the preparation of tinctures, such as that of opium. On this point some discussion ensued preliminary to the adoption of the report.

Mr. GREENISH said instances had come before the Committee on several occasions of laudanum being prepared with methylated spirit. There seemed some doubt whether a conviction could be secured under the Pharmacy Act, but there was not the least doubt that the offender was liable to a penalty of £100 under the excise laws, and the question was whether the Council ought not to bring the matter before the revenue authorities. It was very unfair to an honest tradesman that he should be undersold by an unscrupulous neighbour who used methylated spirit for making tinctures for internal use.

Mr. BROWN said there was too much reason to believe that this practice was far from uncommon. He did not wish the Society to take the position of a common informer, but he thought it might be the duty of the Society to send a communication to Somerset House calling the attention of the authorities to the matter.

The VICE-PRESIDENT said there was no exclusive privilege granted to the Inland Revenue authorities; any one could prosecute in such a case.

Mr. OWEN remarked that it might lead to many vexatious visits by revenue officers to respectable chemists if the authorities were appealed to.

Mr. RIMMINGTON thought the excise authorities should have their attention drawn to this matter. It placed the honest tradesman in a very unfair position.

The PRESIDENT said it would open up a very large question if the Society became a public prosecutor for adulteration.

Mr. ATKINS hoped the Council would pause before setting the authorities to work in the way of exercising a more complete system of espionage than already existed.

After some further conversation on this subject the report was received and adopted.

The Benevolent Fund.

The discussion (adjourned from August last) was resumed on the following motion by Mr. Robbins:—

"That the benefits of the Benevolent Fund be further extended by making a provision for the orphan children of deceased members or associates of the Society, according to the intention of the founders as expressed in the Charter of Incorporation.

"That the surplus income derived from subscriptions be appropriated to the benefit and advancement of such children by the purchase of admissions into orphan institutions, or in any other way the Council may deem desirable.

"Candidates for admission by purchase to be nominated by the Council. The election to be by voting papers, and to take place at the same time and in the same manner as the election of annuitants."

Mr. Betty, in opening the adjourned debate, said he objected strongly to every paragraph in the motion. He considered it unnecessary, incongruous, impolitic, and unwise. With regard to the first paragraph he could only say that the object aimed at was already attained. There had been an instance that day in which a large sum had been voted by the Council for this object. If the second paragraph were carried the action of the Council would be hampered exceedingly in the administration of the fund, and he had yet to learn that the action either of the Council or Committee was open to any complaint. In no instance had a deserving case come before the Committee and been put on one side, and he saw no reason, therefore, why a hard and fast line should be laid down as to what should be done with the surplus. He thought it would be impairing their liberty of action in a way which neither the charter nor the wishes of the founders intended. Again, the last paragraph was the very climax of undesirableness. Under the guise of giving charity the Council would be putting these unfortunate applicants to the extreme trouble of an election. If there were one thing more than another in the action of the Benevolent Fund which required the serious consideration of every member, it was how to distribute the fund on grand charitable principles, not in accordance with electioneering practice. If the present evils of elections could not be put down, at any rate they should not be added to. He could mention a case known to himself in which concerts, a lottery, and every kind of device had to be used to get a boy into one of these orphan asylums.

Mr. Owen thought the case mentioned by Mr. Betty, in which fifty guineas had been granted, was a very excellent one. According to his experience, it required a great deal of hard work and earnest endeavour, besides no small amount of tact, to get a child into one of these asylums. At the same time, he agreed with him that this motion was quite unnecessary, and he should vote against it.

The President said all agreed that the benefits of the Benevolent Fund ought to be extended further.

Mr. Betty said he did not agree to the first paragraph of Mr. Robbins' motion.

Mr. Owen remarked that the Council had full power to do all that Mr. Robbins wanted.

Mr. Brown could not see the object of this motion. The operation of the Benevolent Fund had already been extended in the direction suggested, and though the motion might be a proper one to be brought before the Benevolent Fund Committee, it did not concern the Council in its collective capacity. That morning the Council had shown its desire to go in the direction Mr. Robbins wished, and he believed that in the future, without any such motion being adopted, it would continue to progress in that direction, so that it would be quite safe to leave the matter in the hands of the Committee. He could not consent to tie the hands of the Committee in the way proposed.

Mr. Mackay felt very much inclined to oppose every paragraph of the motion, sharing the feelings already expressed by other gentlemen, that it was totally useless, and he hoped, therefore, it would be withdrawn. If Mr. Robbins had been a new member, without experience, he could have understood his bringing forward such a motion, but, looking to the past and present, he felt sure he must have entire confidence in the procedure of the Benevolent Fund Committee for the future, and he failed entirely to see how, if this motion were adopted, it would confer greater power on the Committee than it had at present. The Committee already gave full attention to every case that came before it.

Mr. Hampson thought some gentlemen were rather hard on Mr. Robbins, for his object was a very good one, but he disapproved of his motion nevertheless, mainly from the fact that it would extend the already vicious system of voting and touting for votes. He would rather the Society bought admissions at once, if it took any step in that direction, than throw the turmoil, discord and expense of electioneering on those whom it wished to aid.

Mr. Hanbury thought what was new in the motion was objectionable, and what was not new was naturally superfluous.

Mr. Atherton agreed with Mr. Mackay, and thought the Council might have every confidence in the Committee which distributed the Benevolent Fund. At the last sitting the Committee gave away more money than it had ever done before.

Mr. Robbins said the bringing forward of this motion had already done a great deal of good, and he did not see why he should be taunted with having done so, and be told of what had been done yesterday, or that morning, when in fact his motion was brought forward two or three months ago, and it was only since then the Committee had given away eighty guineas for the benefit of orphans, which had never been done before. At the commencement of the Society the founders could not do all they intended to accomplish in the future, and therefore contented themselves with giving only grants of money to those in distressed circumstances. Time went on, and after more than twenty years they began to provide for annuitants, and so they had gone on up to the present time, providing for annuitants and casual grants, but as yet there had been no regular provision made for orphan children. No doubt provision was made for orphans in the regulations of the fund, but according to the reading of these regulations it appeared to be only for those who had lost both parents and were in completely destitute circumstances, and his motion did not apply to those. His object was when a poor woman, who formerly occupied a respectable position, was left with a large family she should be assisted to place one or more of her children in a good school.

The Vice-President reminded Mr. Robbins that seven or eight years ago £100 was given to a school for this very purpose.

Mr. Robbins said this idea had been acted on once, showing that what he now proposed had been considered by the Council at a former time the proper thing to do, but he wished to see it done oftener, as he considered the fund could not be applied to a better purpose. He did not insist upon the third paragraph, but if the Council were going to provide for orphans in the future it would be necessary to draw up some rules, for at present there was no form for such cases. The case which came before the Committee on the previous day would never have arisen but for his motion.

The President remarked that it came before the Committee six months ago.

Mr. Robbins said Mr. Sandford had stated that it was absurd to talk of the surplus income; if that was so he would call it excess of income over expenditure, which came to much the same thing. Going back to the year 1868, he found that in one year only had this surplus sum been less than £500, and he considered that with this money some special provision should now be made for orphan children, and if the Council were going to do so it must come to some decision on the matter. Other societies, with no better income, made more provision for orphans; and he contended the Pharmaceutical Society ought to do the same.

The PRESIDENT said that Mr. Robbins' reading of the word "orphans" in the regulations was not correct as applying only to children who had lost both parents.

Mr. ROBBINS said there was no form provided in which application was to be made in the case of orphans. However, he had no objection to withdraw his motion as he had the satisfaction of knowing that his object, to a great extent, had been attained.

Mr. SANDFORD said the case already referred to in which an orphan child had been provided for was not the only case of the kind. Others had occurred long before Mr. Robbins was a member of the Committee. The whole machinery was ready to their hands; they only had to carry it out.

The motion was withdrawn.

TRAVELLING EXPENSES TO COMMITTEES.

Mr. SCHACHT next moved the following resolution, of which he had given previous notice:—

> "That the members of Council resident in the provinces be reimbursed their travelling expenses incurred in attending meetings of the Committees other than those on the day preceding the Council meetings."

Mr. SCHACHT said that the grounds on which he thought it right to give this notice of motion were quite simple. The work of the Society was very various, and for its proper fulfilment it was divided into sections for dealing with which committees were appointed. He thought it was desirable that the gentlemen constituting those committees should not be taken from one portion of the Council only, but should include in all cases gentlemen who were as variously circumstanced as could possibly be. As some committees met in the middle of the month, gentlemen living in the country were handicapped by the amount of their travelling expenses; if, however, there should appear on the face of things anything like an attempt to raise a difference between country and town members he should be prepared to show that he had no such desire by proposing that all members of the Council should be paid their travelling expenses of attending the meetings. He knew of no objection except that it might cost the Society so much more per annum, but the amount would be very small as compared with the large amount which individual members were sometimes called upon to pay.

Mr. BROWN seconded the motion.

Mr. MACKAY asked that Mr. Schacht would name the committees on which he thought it imperative that members from the country should sit in the middle of the month. As far as he knew, the principal committees were the Benevolent Fund, the Finance, and the Law and Parliamentary, and it seemed to him a far better way for the members of the Council to come up the day previous to the Council meeting than in the middle of the month. If a positive necessity for meeting in the middle of the month could be shown it would be a different thing.

Mr. BROWN said he had seconded the motion in the hope that if it were adopted it might bring about what he had long and earnestly desired, the more frequent meeting of the committees. He believed that great advantage would result from the Parliamentary Committee meeting in the middle of the month, because there were a great number of questions coming before the Council on which a considerable time was spent. Sometimes questions came up which it was not desirable to discuss in public, but he had a great objection to the suppression of any portion of their proceedings in Council, and, with that view, some years ago a General Purposes Committee was instituted, but had not fulfilled its duties, simply because it had not had time to do so. It was held late on the evening preceeding the Council, when all the other business had to be done, but if more time could be given for that a great deal of unnecessary discussion in Council would be avoided and the Law and Parliamentary Committee, which he believed would for some time to come be the most important committee in connection with the body, might meet in the middle of the month. It ought to be known that country members had to spend a great deal of money, as well as time, in attending the Council meetings, which they were never reimbursed.

The PRESIDENT remarked that the Parliamentary Committee consisted of the whole of the Council.

Mr. GOSTLING thought it was most undesirable to multiply committee meetings for the benefit of country members. If it were desirable to have more country members on the committees it would be better to have three committees on the day previous to the Council rather than come up in the middle of the month. He quite agreed with Mr. Schacht that if the work was necessary country members should be reimbursed their railway expenses; but as the important Committees were generally held the day before the Council meeting it seemed to him almost unnecessary that such a motion should be passed. He should therefore be obliged to vote against the motion, though he agreed with the spirit of it.

Mr. BROWN asked leave to add one thing he had forgotten with reference to meetings in the middle of the month. The Benevolent Fund Committee was held on the day previous to the Council meeting and had a number of cases brought before it. He had repeatedly advocated inquiries being made with reference to the applicants, and if this committee could be held in the middle of the month, the subject of the grants and the names would come before the country members, and they would have an opportunity of inquiring into the cases before the question was brought before the Council.

Mr. BETTY said Mr. Brown's last argument seemed to be that if the Benevolent Fund Committee met in the middle of the month, its duties would be more efficiently performed. Now, he might remind Mr. Brown, who had not the opportunity of frequently attending the meetings of this committee, that every case which came before it was fully considered and not decided on without ample evidence. The general question as to payment of the railway expenses of country members was a large one, and one which no one had had the courage to bring forward for many years. On many occasions he had had to admire the originality and boldness of Mr. Schacht's views, and it was certainly a bold thing to advocate an increase of the Society's expenses in paying themselves. He did not wish the matter to be looked at in a narrow spirit, but as it affected the Society financially, politically, and practically. He found the expenditure incurred last year for the travelling expenses of members of Council was £244, in 1873 it was £331; so that the expenses had not been increasing, as he supposed, but still that was only an additional reason for persevering in the same course of economy. The majority of members lived in the country, and this motion would enable them to come up more frequently, but would cause large expense to be incurred. The one committee which met in the middle of the month, the Library, Museum and House Committee, was a comparatively unimportant committee, being essentially one of administration. It might happen, if this motion were carried, that the expenses of this committee would amount to upwards of £200 a year. The position of members of Council had hitherto always been looked upon as honorary and honourable, and they ought to hold by the old traditions of the Society, according to which members of Council were the representative men of the trade, to whom a few pounds a year more or less was not of much importance, but who came there as public men not contented to shine, however brilliantly, in their own neighbourhood, but desirous also of taking public part in proceedings in London. It was a question now whether they should abide by these old traditions or should make it a matter of pounds, shillings, and pence. He hoped the old feeling still existed, and that the Council would pause before adopting this motion. This was as to the financial part of it. Then as to what practical end would be attained. It was merely to enable certain gentlemen to come from the country to attend one committee in the middle of the month which was made as uninteresting and dull as possible. It was occupied some three or four hours, not with questions of policy or principle, but whether a few mops, more or less, should be ordered for the basement, whether a ventilator should be opened or shut, whether certain books should be ordered for the Library, and to hear formal reports from the Professors; whilst once a year members went over the house to see where the paint was rubbed off, and so on. That was the main business of the committee, and if the Council paid £200 or £300 a year for gentlemen to come from a distance to attend it, he would ask whether the best interests of the Society were really being consulted. Then the question was put forward whether the Law and Parliamentary Committee should meet in the middle of the month. Did the Council believe that if the Parliamentary Committee were summoned twice a month there would be one member less, or more, in attendance simply by paying the railway expenses of those who attended? He asserted, however, that one meeting in the month was ample, at least under present circumstances, and that the day before the Council meeting was the best time to hold it because then the matter came before the Council fresh in their recollection. They had no proof that more business was brought before the committee than could be dealt with. He knew Mr. Brown had a grievance that the General Purposes Committee did not do its duty, and whenever any proposition came forward for any reform in the arrangement of the committees he urged that the General Purposes Committee was not fulfilling its functions. With that he agreed, but the way to get over the difficulty would be, if the Library and Museum Committee had any business other than that of the most formal character brought before it, that a special meeting of the General Purposes Committee should be convened, and that it should come before that committee before being submitted to the Council; every member would then be present and would have an opportunity of reviewing the work done by the committee in the middle of the month. In conclusion he saw no reason why this extra expense should be thrown upon the Society.

Mr. Atherton said as he understood Mr. Schacht's proposal it was simply this, that if any member chose to be a member of a committee meeting in the middle of the month he should not have to pay his own railway fare in attending. So far he should go with Mr. Schacht entirely, but if he thought by carrying this motion there was to be a compulsory attendance on committees twice a month, he should most certainly vote against it, because it would be most inconvenient to country members to be summoned twice a month.

Mr. Hampson said it would have been desirable if Mr. Schacht in introducing this question could have shown the necessity for committees meeting twice a month, or for some other arrangement than the existing one, and he thought the question had better be deferred until the rearrangement of the committees, when it could be seen exactly how the committees would work. If it was desirable that the Law and Parliamentary Committee should meet in the middle of the month any country member attending it should most decidedly have his railway expenses paid. He certainly had an impression that such a change would be desirable, because he had frequently attended a committee on the day before the Council and found one committee treading on the heels of another and there was not always as much time as could be desired for the business to be efficiently conducted.

Mr. Mackay asked whether Mr. Schacht wanted all the committees to meet in the middle of the month, or that one committee should be selected to meet at that time.

The President said the motion was simply that the country members on a committee which met in the middle of the month should have their railway fare paid: it did not contemplate any change in the committees.

Mr. Shaw said the circumstance which gave rise to this motion was that a year or two ago a complaint was made that on the Library, Museum and Laboratory Committee no country member's name was placed, and it was suggested that some member from the country should be put upon the committee, and it was also suggested that those who did take special interest in educational matters should be appointed. That was taken into consideration, and this year Mr. Schacht was appointed on the committee; under these circumstances, if the Council thought it desirable that a country member should be appointed to sit on a particular committee, it was only just that his railway fare should be paid. He did not think it desirable that the Parliamentary Committee should meet in the middle of the month. That committee comprised the whole of the Council, and he thought it very important that as many members as possible should be present at its meetings, because matters came before it frequently on which local knowledge was very desirable. The same consideration applied to the Benevolent Fund Committee.

Mr. Atkins thought a great deal of irrelevant matter had been introduced into this discussion; the question was simply whether those who came up to committees should have their railway fare paid; and if the larger question of rearranging the committees was raised it was a totally different thing, on which he should like to hear a great deal said before coming to any decision, and should therefore have been prepared to move that it be referred to a committee for full consideration. He hoped it would be distinctly understood that country members were not paid, and that the references made to the good old times and old traditions when men came there simply from pure love of the Society and their kindred were as applicable now as they ever were. But if country members had to make large sacrifices of their time, the least they could expect would be to have their railway fare reimbursed.

Mr. Sandford thought there could be no doubt that the question of the rearrangement of the committees would come up if such a resolution were passed. They all knew the inconveniences arising from cramming nearly all the committee work into the day previous to the Council, and if this proposition were passed the ground for this arrangement would be entirely removed and it would be right, he thought, to fix the meetings at some reasonable time in the course of the month, as was now the case with the Library, Museum and Laboratory Committee, which committee, by the way, he had been very sorry to hear one gentleman characterize as unimportant. He did not see how that could be said when Mr. Schacht had been continually told that committee was so important that it must meet in the middle of the month. He, therefore, thought the matter should be referred to a committee, because this larger question was intimately mixed up with it, and if Mr. Atkins would move such a resolution he would second it.

The President thought this should be a separate motion.

Mr. Hampson submitted that if Mr. Schacht's motion were referred to a committee, only the question of the payment to members could be discussed, and the committee could not take into consideration the further question of the rearrangement of the committees.

Mr. Sandford said he thought it desirable that Mr. Schacht's motion be referred to a committee which should consider it in all its bearings, especially as to the effect it would have in facilitating the sitting of country members on committees.

Mr. SCHACHT hoped the simple proposition he had brought forward would not be mixed up with anything else. If it were carried it would then become of necessity the duty of the Council to consider or refer it to some committee to consider what rearrangement of committees should take place.

After some further conversation as to the propriety of putting the amendment,

Mr. SCHACHT replied: He thought that neither the London members nor the country members as a section should be left to do anything by themselves, but that the committees should be taken from the entire Council. He was never more astonished than when he heard that his proposition was a bold one; it would seem to him the simplest possible expansion of the acknowledged system. Up to a certain point it was understood that gentlemen living in the country should not pay their own travelling expenses when attending to the Society's business, and it was not fair to characterize the increase of £5 or £10 which might be made, to the immense amount of £244, mentioned by Mr. Betty, as a payment to country members. What led him to move the resolution was the stir about the appointment of the Library, Museum and Laboratory Committee. He agreed entirely with Mr. Sandford that it was incorrect to describe the work of that committee as being unimportant; on the contrary, a wish had been expressed more than once that he himself should be placed upon it. Up to the present time he had not been able to afford a second journey to London per month on the Society's business, but during the last year he had allowed his name to be included, and he believed the work done by that committee was of a very important description. But he did not see why he should have to pay the travelling expenses in attending that committee any more than when attending the Council, it being equally the Society's business. If the frequency of the committee meetings was thought desirable to be discussed let it be so, but it was a matter quite apart from his motion.

Mr. ATKINS having seconded the amendment proposed by Mr. Sandford, several members expressed their opinion that it was not, strictly speaking, an amendment to the proposition, and ultimately it was withdrawn.

Mr. BETTY said he considered this as a matter which appealed directly to the country members, and, as a London member, he should leave the matter in their hands.

Mr. SCHACHT said he would withdraw the proposition if there was a general feeling in the Council that it was desirable to modify the arrangements of the committees, but it was the first time he had heard such an opinion.

Mr. HILLS said he had been for seventeen or eighteen years a member of the Council, and he had never known any business slurred over, or done improperly. Although he lived in London, he had the interests of the country members at heart as much as any one else. He was neither for the country nor for London, but for the Society at large. He should like to see gentlemen residing in the country on the committees, but he should decline voting on this question.

The PRESIDENT also said the question had become rather a delicate one, and he should himself prefer not voting upon it, and probably many London members would feel the same.

Mr. SCHACHT said he had brought forward the motion from no selfish motives whatever, and he hoped if gentlemen did not agree with it they would vote against it.

Mr. RIMMINGTON said he did not see how country members could vote if London members abstained.

Mr. CHURCHILL expressed the same view.

Mr. SCHACHT said under such circumstances he must withdraw the motion.

Mr. ATKINS thought Mr. Schacht had only acted with becoming dignity. He was perfectly surprised to hear the remarks which had been made, and he thought no one living in London had a right to make such observations. It would be a great misfortune if in that Council they had anything like Guelph and Ghibelline factions.

Mr. BROWN, as seconder of the motion, said he could do no other than agree to the action taken by Mr. Schacht; at the same time, he did it under protest, and thought the motion had not been fairly treated by being made the subject of the antagonistic remarks which tended to create a feeling between London and country members. He was quite satisfied it would not be long before it would be necessary to call more frequent meetings of the Parliamentary Committee, and it was exceedingly unfair to country members that they should be put not only to inconvenience and loss of time, but to expense also.

The PRESIDENT said he would ask Mr. Schacht still to press the motion, and would appeal to all London members to give their votes. He was quite sure Mr. Schacht had no intention of making it a question of town and country members.

Mr. BETTY said if Mr. Schacht would amplify his resolution, to include the travelling expenses of all members of the committee, he should be inclined to reconsider it. At present it looked as if it was a question who should be paid, town or country; and although the expenses of London members were very small, still, if they gave their time,—and on an average town members gave three times as much time as country members—they ought to be all included in the motion.

Mr. BROWN said if Mr. Schacht did consent to take that course he should give notice of a motion for the next meeting that country members should not be reimbursed their travelling expenses when attending the Council meeting. Personally, it made but little difference to him whether it cost him £50 or £100 to be a member of the Council, irrespective of his railway fares, but he looked upon it as a question of principle, and as such it ought not to be imposed on country members that they should be called upon to attend committee meetings at a large loss of time and money, when London members could attend at much less.

Mr. SCHACHT said he had withdrawn the motion and he hoped the discussion would be closed.

PROSECUTIONS UNDER THE APOTHECARIES ACTS.

Mr. SCHACHT then moved the following resolution, of which he had given notice:—

> "That an effort be made by this Society to arrive at a distinct understanding with the Society of Apothecaries as to the class of cases of alleged infringement of the Apothecaries Act which should be open to prosecution; and that a committee be appointed to confer with the Society of Apothecaries to give effect to this resolution."

Mr. SANDFORD suggested that the Council should go into committee on this matter.

Mr. SCHACHT said he did not wish the discussion to take place in committee, and he hoped gentlemen would limit their observations to such as might properly be published. The reason he wished to be the medium of introducing this proposition was that he had found it necessary to give an adverse vote to a proposition to rectify an evil when it had arrived, which he now wanted to prevent. He was one of the minority who had voted systematically against the policy of the Society taking up the defence of gentlemen who, whether rightly or wrongly, were under prosecution on behalf of the Society of Apothecaries, and he was very anxious to introduce this motion in order that it might be seen that it was quite possible for him to give such a vote, and yet be equally anxious to do the best he could for the interests of the trade at large, his belief being that every member of the Council was equally desirous of arriving at such a happy result though they differed as to the processes by which that result could be attained. In this dilemma he fell back on the old maxim that prevention was better than cure; and it occurred to him that seeing the dilemma in which they were placed by the wording of the Apothecaries Act it would be better for some representatives of the Council to have an interview with the representatives of the Apothecaries' Company, and come to some mutual understanding as to the interpretation which should be put upon that Act. It was no use shutting their eyes to the difficulty which existed, a difficulty which was plainly seen by Mr. Baron Bramwell, and he thought it was their duty to try and overcome the incongruities which existed. The next question which arose was, whether there was any chance of success, was it likely that the Society of Apothecaries would meet their request for an interview, and if so, were there any lines they could take as indicating that which should divide legitimate from illegitimate pharmacy? On the former point he did not think the Council had a right to anticipate an unfavourable answer, since it would be an act of discourtesy from one body to another, which was not at all likely to occur; the latter point he admitted was one of great difficulty as to the exact ground the Council itself should take up, but nevertheless there were one or two positions which seemed to him grounded in common sense which it would be only fair to speak of. In the first place, there was a distinct right on the part of the public to go wheresoever they pleased for medicine, or for anything else. No one in the world thought that a person who went to the veriest charlatan or quack for advice was actionable at law, yet it would be extremely difficult to prove logically that the receiver was not just as guilty as the giver. If a person knowing him not to be a medical man, chose to take his opinion on a medical question, if there was any offence at law the person who consulted him was as much to blame as he; the only point of importance being that the person who asked for advice should not be deceived as to the pretensions of the person giving it. This was such palpable common sense that it appeared to him there might be founded upon it some ground for inferring what was the difference between legitimate and illegitimate pharmacy. He thought it would be infinitely better that the Council should endeavour to prevent these difficulties than to defend actions after they were instituted.

The President said the two questions to be considered were whether the Council was likely to be successful in this application, and next, what were the arguments to be adopted by any deputation which might be appointed. The first consideration, of course, was whether it would be wise to attempt it at all.

Mr. Atkins remarked that the last Conference at Constantinople was not very encouraging.

Mr. Bottle said he had brought this matter forward some three months ago, but the feeling of the Council then was that it was not expedient to move in it whilst the Shepperley persecution was still pending.

No member of the Council volunteering to second Mr. Schacht's motion, it fell to the ground.

Chloral Hydrate.

The proceedings in reference to placing chloral hydrate on Schedule A of the Pharmacy Act, 1868, were again deferred.

PHARMACEUTICAL MEETING.

Wednesday Evening, October 3, 1877.

The first Evening Meeting of the Session was held at 17, Bloomsbury Square, on Wednesday last. The chair was taken at half past seven o'clock by the President of the Society, Mr. John Williams.

The minutes of the previous meeting having been confirmed, the following Donations to the Library and Museum were announced, and the thanks of the Society voted to the donors:—

To the Library.—'Year-Book of Pharmacy and Transactions of the British Pharmaceutical Conference, 1876,' from the Conference; 'Chemical Notes for Pharmaceutical Students, including the Chemistry of the Additions to the Pharmacopœia,' by A. Rivers Willson, 1875, from the Author; 'Papers read before the School of Pharmacy Students' Association of the Pharmaceutical Society of Great Britain, 1874—6,' 2 vols. MSS., from the Association; 'Report on the Transport of the Sick and Wounded by Pack Animals,' by G. A. Otis, 1877, also, 'Pamphlets issued in connection with the Exhibit in the Hospital of the Medical Department, U.S. Army,' from the Surgeon-General, U. S. War Department; 'Thirteenth Annual Report of the Alumni Association of the Philadelphia College of Pharmacy,' and 'Fifty-seventh Annual Announcement,' of the College, from the College; 'Proceedings of the American Pharmaceutical Association, 1876,' from the Association; 'Annual Report of the Board of Regents of the Smithsonian Institution, 1875,' from the Institution; 'Calendars of the Universities of London, Durham, and Glasgow, 1877,' from the respective Universities; 'Calendar of the Yorkshire College,' with 'Prospectus of the Leeds School of Medicine, 1877—8,' from the College; 'Selection of Prescriptions,' by J. Pereira, with a 'Synopsis of the Chemical Decompositions that take place in the London Pharmacopœia,' 1822, also, Mead's 'Mechanical Account of Poisons,' 1702, from Mr. F. W. E. Shrivell; 'Rapport sur les Médicaments nouveaux par une Commission composée de MM. Baudrimont, Gobley, Marais, Schaeuffèle, et A. Petit,' also, 'Conservation et Dosage de l'Acide Cyanhydrique,' 'Chlorhydrate de Narcéine,' 'Recherche des petites quantités d'Albumine dans l'Urine,' and 'De la Triméthylamine au point de vue Chimique et Pharmaceutique,' par A. Petit, from Mons. Petit; 'Recherches pour servir à l'Histoire chimique de la Racine de Gentiane, Présence d'un Tannin,' par J. Ville, 1877; 'Etude sur les Térébinthines et Spécialement sur la Térébinthine de Bordeaux,' par A. Fronsac, 1877, from Professor J. L. Soubeiran; 'Beiträge zur Chemie der wichtigeren Harze, Gummiharze und Balsame,' von E. Hirschsohn, 1877; 'Ueber die Alkaloide des Delphinium staphisagria,' von Provisor Marquis, 1876; 'Bestimmung der Alkaloïde in den Chinarinden,' von E. Johanson, 1877: 'Ueber Calcaria phosphorica,' von E. Hirschsohn, 1877, from Professor Dragendorff; 'Disease Germs, their Nature and Origin,' second edition, 1872; 'On Life and Vital Action in Health and Disease,' 1875; 'The Machinery of Life,' from Dr. Beale, F.R.S. (the Author); 'Guy's Hospital Reports,' third series, vol. 22, 1877, 'St. Thomas's Hospital Reports,' new series, vol. 7, 1876; and 'Statistical Tables of the Patients under Treatment in St. Bartholomew's Hospital during 1876,' from the respective Hospitals; 'De l'Usage Thérapeutique de l'Acide Salicylique ses composés et accessoirement de la Salicine,' par W. Douglas-Hogg, M.D.; 'Register, Charters, and Bye-Laws,' etc., of the Royal College of Veterinary Surgeons, from the College; 'The Materia Medica of the Hindus,' by Udoy Chand Dutt, with a 'Glossary of Indian Plants,' by G. King, M.B., and the Author, from the Author; 'Pharmacopêa Portugueza,' 1876, from Señor A. A. Andrade; 'Experiments and Observations on Electricity, made at Philadelphia, in America, to which are added, Letters and Papers on Philosophical Subjects,' by B. Franklin, LL.D., F.R.S., fifth edition, 1774, from Mr. B. Heald.

To the Museum.—A fine specimen of Cuttlefish Bone, and one of Spurious Chiretta, from Mr. A. H. Squire; Specimens of Bombay Santonica, Stony Assafœtida, Toot (fruits), Mangalore Cardamoms, Mafura Seed, Dragon Wood, Baridche, Pods of *Acacia concinna*, and Rosia Root, from Mons. C. Chantre; Specimens of Wood Oil, Quillai Bark, Diwool Gum, Alcornoque Bark (*Bowdichia virgilioides*), Bark of *Dryobalanops aromatica*, and Ceylon Gamboge, from Dr. Trimen; Specimens of Double Cocanut, Japanese Isinglass, and a Specimen of Seaweed used in lacquering, from Mrs. Reeves; Specimens of Physic Nuts, Gum Acroides, and Crab Nuts, from Messrs. Battley and Watts; Specimen of Nepaul Pepper, from Mr. Bullock; Specimens of Koost shirin, false Koost, and of the Aloes Wood of Indian commerce, from Dr. Forbes Watson; Specimen of Saligenin, from Professor Attfield; Specimen of Chaulmoogra Seeds and Kernels, oil expressed without heat from the seeds, and oil obtained by boiling the seeds after expression, from Mons. E. Lumean, Mauritius; Specimens of Biennial Henbane, Annual Henbane, and dried root of *Rheum officinalis*, from Mr. Rufus Usher, of Banbury.

The following specimens have been received from Dr. Dymock, of Bombay:—

Roots.—Bikhma, Ulti, Geeno, Maregama, Asgund, and Roklee roots; the roots of *Xanthoxylon Rhetsa*, *Boerhavia diffusa*, *Tinosphora cordifolia*, *Asclepias currassavica*, *Sida acuta*, *Holarrhena antidysenterica*, *Aristolochia indica*, *Polypodium quercifolium*, and *Cissampelos Pareira*.

Barks.—*Mimusops elengi*, *Abutilon indicum*, *Mesua ferrea*, *Salix tetrasperma*, *Rhamnus Wightii*, *Ailanthus excelsa*.

Plants.—*Physalis somnifera*, *Erythræa Roxburghii*, *Microrhynchus sarmentosus*, *Tiaridium indicum*, *Vitex Negundo*; leaves of *Dœmia extensa*, and flowers of *Mesua ferrea*.

Seeds.—*Corchorus trilocularis*, *Abutilon indicum*, *Hydnocarpus inebrians*, *Phyllanthus madraspetalus*.

Specimens of Abusharee Hing and Candahar Hing, of the gum resin of *Balsamodendron Roxburghii*, and of wood oil obtained from *Bignonia xylocarpa*.

The President, having alluded to the fact that the opening of the session was coincident with that of the School of Pharmacy, called upon Professor Redwood to make his

Report on the Chemistry and Pharmacy Class.

Professor Redwood said, he and his colleagues had appeared there so frequently for a similar purpose that he feared they might be accused of repeating a thrice-told tale. Their object was to introduce to the meeting a number of gentlemen who had been devoting themselves during the past session to the acquirement of that practical acquaintance with the science and practice of pharmacy which it was the object of that school to impart. They had been gradually endeavouring to increase the qualification of those who were authorized by law to become pharmacists; but without occupying further time, he would say that during the past session the students had very satisfactorily acquitted themselves. The instruction given by means of the lectures was divided into two courses, examinations being held at the end of each. At the end of the first course a bronze medal and certificates of merit were awarded, and the same at the end of the second course, as well as a silver medal and certificates of honour to those who had studied for the whole ten months' session. At the end of the first course there were five competitors, the first of whom obtained 92 marks out of a possible total 100, and the four others obtained respectively, 88, 84, 82, and 77. Several of these gentlemen continued their studies during the second course; and one of them, Mr. Bullen won the silver medal with 90 marks, whilst others obtained 89, 88, 77, 72, and 68. He could only add that all these gentlemen were fully entitled to the distinctions conferred upon them. The list of names are given below.

The following is a list of the students in this class to whom prizes had been awarded:

Ten Months' Session.

Silver Medal	George William Bullen.
Certificates of Honour	Robert Henry Parker. Geo. Fredk. Gutheridge. Rawson Parke Francis.
Certificates of Merit	David Avison. Robert Brown Betty.

Five Months' Courses.

First Course.

Bronze Medal	George Fredk. Gutheridge.
Certificates of Merit	Rawson Parke Francis. David Avison. George William Bullen. Henry Peirson.

Second Course.

Bronze Medal	Robert Henry Parker.
Certificate of Merit	Robert Brown Betty.

The following were the questions for the examinations:

Chemistry and Pharmacy.

First Course. Bronze Medal.

Time allowed: Three Hours.

1. What is the length of a pendulum that oscillates in seconds of time, in a vacuum, at the latitude of London, and at the level of the sea?
2. What is the length expressed in inches of the French metre?
3. What is the weight of a cubic inch of water at 62° F.
4. What are the weights in grains of the gramme, decagramme, and centigramme?
5. What relations do the gramme and the litre bear to the metre?
6. How would you determine the specific gravity of calomel? Specify all the required details of the process.
7. What relation does the rate of diffusion of a gas bear to its specific gravity?
8. Describe the methods of producing ozone, and state what its composition, properties, and supposed influence in the atmosphere are.
9. Describe the production, composition, and properties of hydriodic and iodic acids.
10. Explain the Pharmacopœia process for the production of sulphate of copper. Describe the characters of this salt, including its crystalline form, and point out the means of detecting the presence of iron in it.
11. Describe the production of chloroform and hydrate of chloral.

Second Course. Bronze Medal.

Time allowed: Four Hours.

1. Explain the meaning of the terms density and specific gravity.
2. Describe minutely the apparatus you would employ, and the method you would adopt in taking the specific gravity of a liquid at 60° Fahr., while the temperature of the surrounding air is at 70° Fahr.
3. What is the force to which capillary attraction is due, and how do you explain the ordinary phenomena of capillarity?
4. Describe the process of clarification as applied to liquids of different kinds.
5. State what you know with reference to nitric acid, including its production and properties.
6. What are the distinguishing characters of metallic as compared with non-metallic bodies?
7. Describe the production of caustic potash, and soda in solution, and also in the solid state, representing the conditions under which the products may be most advantageously obtained.
8. Explain the action of diluted sulphuric acid on zinc, iron, lead, copper, and mercury.
9. Describe the composition and properties of cane and grape sugar, and point out the sources and methods of production of these sugars.
10. What are the changes that occur in the production of malt from barley, and in the production of spirit from malt?

SESSION. SILVER MEDAL AND CERTIFICATES.

Time allowed: Three Hours.

1. Describe the process of dialysis, and the facts which form the basis on which this process is founded.

2. Explain the dynamical theory of heat, and give the meaning of the terms conduction, convection, radiation, and transmission of heat.

3. What is meant by the term latent heat? What are the latent heats of water and of steam, and are these constant or varying amounts?

4. Describe the spectroscope, the purpose for which it is used, its mode of action, and some of the results obtained with it.

Time allowed: Three Hours.

5. Describe sulphur, its sources and allotropic conditions; also sulphuric anhydride and acid, with the processes by which they are obtained, and their properties.

6. Describe the salts to which the generic term alum is applied, distinguishing the alum of the Pharmacopœia, and representing generally the mode of production of commercial alum.

7. How would you define an organic body, and how distinguish such from an inorganic body?

8. Give a sketch of the class of organic compounds to which the generic name of alcohol is applied, and describe the production of the one which is commonly called alcohol or ethylic alcohol.

9. Describe oxalic acid, giving its composition, modes of production, natural sources, and properties.

10. Describe cyanide, ferrocyanide, and ferridcyanide of potassium, and the processes by which they are obtained.

The PRESIDENT then called upon Professor Bentley to make his

REPORT UPON THE BOTANY AND MATERIA MEDICA CLASS.

Professor BENTLEY said that it had been his honour and pleasure for more than a quarter of a century to come forward on similar occasions to the present and make a most gratifying report as to the classes entrusted to him. Without going over the ground already covered by his colleague who had preceded him, he might say that his students during the past year had fully maintained the high character of the School of Pharmacy, not only as to their regularity and punctuality of attendance, but also as to their good conduct and the proficiency they had attained. It was often said that lectures in themselves were no test of education, and should in all cases be supplemented by examinations, and it had always been his practice to follow this plan, and he could therefore speak of the proficiency of the students very safely. Every week he held *vivâ voce* examinations, which enabled him to test the progress of the students, and enabled them to apply to him for further information. Thus he was able, he hoped, to be not only the teacher, but the friend and adviser of his pupils. He could speak also not merely of the conduct of the students in the school, but also in the Botanical Gardens in Regent's Park, and he could conscientiously say that he had never found a body of students more ready to gather information than those of the School of Pharmacy. He might also say, having had considerable experience, that he knew what certificates and medals were, and that no medal or certificate was awarded here, unless a certain standard of merit was reached, that standard being 80 marks out of 100. Those who were familiar with competitive examinations would bear him out that this was a strong test of efficiency. After giving the names and number of marks obtained by the respective competitors, Professor Bentley concluded by stating that he had never had six gentlemen at one examination obtaining so high a number of marks as on the present occasion, and he was quite sure they would reflect honour on themselves, their teachers, and the calling they were destined to pursue.

The following is a list of the students in this class to whom prizes were awarded:

TEN MONTHS' COURSE.

Silver Medal	Robert Henry Parker.
Certificates of Honour	George William Bullen. Geo. Fredk. Gutheridge. Henry Peirson. David Avison. Rawson Parke Francis.

FIVE MONTHS' COURSES.

FIRST COURSE.

Bronze Medal	Geo. Fredk. Gutheridge.
Certificates of Merit	Rawson Parke Francis. George William Bullen.

SECOND COURSE.

Bronze Medal	Robert Henry Parker.
Certificates of Merit	Stewart Hardwick. Robert Brown Betty.

The following were the questions for the examinations:

BOTANY AND MATERIA MEDICA.

FIRST COURSE. BRONZE MEDAL.

Time allowed: Three Hours.

1. State generally the characteristic distinctions in structure between the stems of dicotyledonous, monocotyledonous, and acotyledonous plants.

2. Describe the general characters and chemical composition of starch and chlorophyll.

3. Describe the structure of the seed, and explain the process of germination.

4. What are the supposed botanical and geographical sources of the official rhubarb root? Describe the general characters and chemical composition of this drug, and enumerate its official preparations.

5. What are the botanical and geographical sources of scammony? What are the characters of pure scammony? How is it obtained? With what substances is it adulterated, and how may they be detected? Enumerate its official preparations.

6. What are the botanical and geographical sources of Pareira root? Describe its general and chemical characters, the means of distinguishing it from spurious roots, and enumerate its official preparations.

SECOND COURSE. BRONZE MEDAL.

Time allowed: Three Hours.

1. Define the following:—Pitted, spiral, and annular cells; and reticulated, scalariform, and laticiferous vessels.

2. Give the distinctive characters of roots and stems; define the corm, bulb, and culm, as applied to stems; and the terms tubercular, fasciculated, and adventitious, as applied to roots.

3. Define the following kinds of inflorescence:—Spike, raceme, capitulum, umbel, cyme, and verticillaster.

4. Give the characters of cruciate, papilionaceous, labiate, and personate corollas.

5. What are the botanical and geographical sources of buchu leaves? Describe the leaves of the different official species; mention their medical properties, and their official preparations.

6. What are the botanical and geographical sources of copaiba? Describe its general and chemical characters.

Mention the substances used to adulterate it, and the means whereby they may be detected.

7. What is the botanical and geographical source of cinnamon? How is it obtained? What are the characters by which it may be distinguished from cassia? and what are its official preparations?

SESSION. SILVER MEDAL AND CERTIFICATES.

Botany.

Time allowed: Three Hours.

1. Describe the general characters and chemical composition of starch and chlorophyll.
2. Define the following terms as applied to leaves:—Fascicled, equitant, revolute, dentate, crenate, pinnate, pedate, pinnatifid, decompound, phyllode, ligule, and decurrent.
3. Define the following terms:—Cupule, glume, spathe, exserted, declinate, gynandrous, syngenesious, didynamous, corona, disk, receptacle, and thalamus.
4. Describe the structure of the embryo, and explain the process of germination.
5. Give the essential characters of the following natural orders:—Ranunculaceæ, Umbelliferæ, Scrophulariaceæ, Labiatæ, Orchidaceæ, and Melanthaceæ.

Materia Medica.

Time allowed: Three Hours.

1. Describe the botanical sources, modes of extraction, general characters, varieties, and adulterations of guaiacum resin. How may it be detected when employed to adulterate scammony?
2. Mention the botanical and geographical sources of *annulated*, *striated*, and *undulated ipecacuanhas.* Describe their general characters, and enumerate the various official preparations into which ipecacuanha enters as an ingredient.
3. Describe the general characters of myrrh; mention its botanical and geographical sources, the substances used to adulterate it or which are substituted for it, and its official preparations.
4. Describe the physical and chemical characters of the seed of *Strychnos nux vomica*; mention its official preparations and their doses.
5. What are galls? how are they produced? Describe the general and chemical characters of the official galls, and enumerate the preparations in the B. P. in which they enter as an ingredient.
6. Describe the general and chemical characters of white hellebore rhizome, and show how it may be detected when mixed with valerian.

The PRESIDENT then called upon Professor Attfield for his

REPORT ON THE PRACTICAL CHEMISTRY CLASS.

Professor ATTFIELD said, the cheering with which the professors were always greeted on these occasions was, in his own case, in part at least, to be awarded to his excellent assistants. He regretted that the senior demonstrator of last year, Mr. Davies, had left the laboratories, but he had no doubt that Mr. Davies would find his new sphere of action as public analyst congenial, and that from his knowledge of the exigencies of business he would at least do that which some public analysts did not succeed in doing, namely, check adulteration without unduly worrying the trader. Professor Attfield said that he would not trouble the meeting with the elaborate statistics which he laid before the Council in July, but he might say that the periods of study had been about the average, that the attendance was very good, and the conduct of the students that of gentlemen. Of course, it would be understood that where a number of young men in the prime of youth and health were gathered together day after day, ebullitions of animal spirits would sometimes arise which might be considered slight breaches of discipline, but they had very seldom occurred in past years, and when they had he never found any difficulty in checking their extension. During the session he had had eighty-eight students, which was slightly below the average of the past ten years, but twelve above the average of the fifteen years during which he had been Professor of Practical Chemistry. Considering that the number of students entering pharmacy was smaller than in previous years, that the regulations of the school excluded—most properly—those who wished to be merely "prepared," as it was termed, for examinations, and that their doors were also shut to those who wished to be instructed in prescriptions, the recognition of galenical preparations and actual dispensing, etc., and that, therefore, their pupils were drawn from a comparatively small class, he did think 90 or 80, or even 70 or 60 was a very satisfactory number. He concluded by reading the names of the successful competitors, and the number of marks obtained by the first nine, viz., 95, 90, 85, 80, 78, 76, 70, 65, and 60.

The following are the names of the students in this class to whom prizes were awarded:

Silver Medal	Robert Henry Parker.
Bronze Medals	Geo. Fredk. Gutheridge. Rawson Parke Francis.
Certificates of Honour	George William Bullen. William Ralph Atkins. William Bevan.
Certificates of Merit	David Avison. Walter Barber Tuck. Fredk. Wm. W. Corden.

The following were the questions for this examination:

PRACTICAL CHEMISTRY.

Two Days' Examination.

Hours 10 to 5 on each day.

(*Books and Memoranda permitted.*)

FIRST DAY.

1. Report on the quality of the "chloroform" supplied to you.
2. You have a "lotion": What saline matters are present?
3. Ascertain the proportion of quinine in the sample of "citrate of iron and quinine."

SECOND DAY.

4. Is there any sugar in the accompanying "urine"?
5. Is there any potato starch in the "flour"?
6. What is the percentage of citric acid in the "lemon juice"?

NOTE.—Manipulation as well as results will be scrutinized.

The President next asked Professor Bentley to report upon

THE BOTANICAL PRIZE.

Professor BENTLEY, in speaking of the Herbarium competition, desired to impress on young students not to neglect the opportunities afforded them at this period, which they would never have again, to obtain a certain amount of practical knowledge, not only of their actual calling, but of its scientific bases. He referred especially to botany, and at the present moment he believed this science had a home amongst the students of pharmacy, who knew its value in the future practice of their calling. This was long ago foreseen by the Council who instituted prizes for a practical knowledge of botany. On the present occasion there were three very meritorious collections sent in. He had examined them with great pleasure, especially the one to which the silver medal had been awarded, consisting of 715 specimens, which Mr. Williams, who sent it in, informed him had been collected entirely before 8 o'clock in the morning, and during one week's holiday.

The following were the awards that had been made:

Silver Medal......................J. T. Creswick Williams.
Bronze Medal ....Thomas Francis Elton.
Certificate of Honour ....John William Ellis.

The PRESIDENT then asked Mr. Carteighe to state the result of the competition for

THE COUNCIL EXAMINATION PRIZES.

Mr. M. CARTEIGHE said, the Council prizes were offered for competition to those who had passed the Major examination during the year. It was obvious that the number of competitors was somewhat limited by the conditions and by a kind of natural selection, but the number who came forward this year, viz., twelve in London, and one in Edinburgh, was in no way discouraging. It was not likely that in future years the same examiners would be called upon to conduct these examinations, and therefore he had much pleasure in stating that the general character of the knowledge shown by all the candidates was much better than last year. It was very gratifying to find that one of the prizes had been taken by a gentleman north of the Tweed, and he had no doubt that on some future occasion the examiners would feel pleased to be able to place a candidate from some school not much heard of at the top of the list.

The following were the awards that had been made:

PEREIRA MEDAL (*Silver*); *and Books value £5, presented by Thomas Hyde Hills, in Memory of Jacob Bell.*
George William Bullen.

PHARMACEUTICAL SOCIETY'S MEDAL (*Silver*) *and Books value £3, presented by Thomas Hyde Hills, in Memory of Jacob Bell.*
Henry George Greenish.

PHARMACEUTICAL SOCIETY'S MEDAL (*Bronze*) *and Books value £2, presented by Thomas Hyde Hills, in Memory of Jacob Bell.*
William Inglis Clark.

The following were the questions for this examination:

MATERIA MEDICA.

1. What is salicin, and how is it made? State its relations to salicylic acid.
2. What is ergot; how produced; and what are its active constituents?
3. Describe the varieties of buchu, and how to distinguish them from other leaves that may be substituted for them, or mixed with them.
4. What is camphor? State its sources,—geographical and botanical, method of purification, and chemical relations.

BOTANY.

1. Describe the varieties of æstivation; giving an example of each.
2. Describe the inflorescence and fructification of wheat.
3. Describe, botanically, the fruits of the dog rose, strawberry, raspberry and plum.
4. What are the distinguishing characters of the orders Labiatæ, Scrophulariaceæ, and Polygalaceæ?

Time allowed: Three hours for both of the above papers.

CHEMISTRY.

Time allowed: Three Hours.

1. The silver salt of an organic acid contained 62·44 per cent. of metallic silver. It also contains 17·34 per cent. of carbon, and 1·73 per cent. of hydrogen. From these data endeavour to find a formula for the acid.
2. Define the terms, *allotropy*, *metamerism*, *polymerism*. Illustrate each definition by several examples.
3. Give a concise account of the manufacture of cast iron, wrought iron, and steel.
4. How are the metals, barium, calcium, and magnesium respectively prepared in a state of purity? Describe their physical and chemical properties.
5. Describe the best process for *separating* from each other antimony, arsenic and tin.

The PRESIDENT then asked Mr. Umney to report upon the examination for

THE JACOB BELL MEMORIAL SCHOLARSHIPS.

Mr. UMNEY said, it gave him much pleasure, as an old Bell Scholar, to say a word or two on the examination for the Jacob Bell Memorial Scholarships. There were fourteen candidates; the questions were set by two members of the Board of Examiners, and were sent to the various centres to be answered, and the marks upon which the award of the prizes was based were not given to the young men themselves, but, in the first instance, to the mottoes affixed to the examination papers, the envelopes of the successful candidates corresponding to the mottoes being afterwards opened by the President to discover the names. The two gentlemen who were successful showed very high excellence indeed, especially in arithmetic, Latin, and chemistry. He had only one regret to express, and that was that more students did not compete for these valuable prizes, which really contained in themselves three rewards. There was first the honour; second, the excellent instruction given in that building gratuitously; and last, the money prize. He hoped, therefore, that in future a much larger number would compete. In conclusion he had to report that the successful competitors were

HENRY ALLAN, and
JOHN GRAHAM SANGSTER.

The following were the questions for this examination:

CHEMISTRY AND PHARMACY, AND BOTANY.

Time allowed: Two Hours.

CHEMISTRY AND PHARMACY.

1. State all you know of the element *bromine*.
2. Give the symbolic formulæ for all the compounds of phosphorus with oxygen and the processes for their production.
3. How many grammes of chlorine could be produced from 100 cubic centimetres of hydrochloric acid (Brit. Pharm.) when made to act upon lead dioxide? and state how many litres it would occupy at 0° Cent.
4. Describe minutely the official process for the manufacture of citrate of iron and quinine, its appearance as met with in trade and the tests necessary to prove the absence of impurities.
5. Describe the official processes for the preparation of liquid extract of ergot, extract of stramonium, tincture of acetate of iron, and syrup of iodide of iron.

BOTANY.

6. Name the *nutritive organs* of plants, and state thei functions.
7. State the meaning of the following words:—*phyllotaxis, ovule.*

Latin, etc.

Time allowed: Three Hours.

LATIN.

1. Translate into English:—

Namque ipsa decoram
Cæsariem nato genetrix, lumenque juventae
Purpureum, et laetos oculis afflarat honores.

2. Parse fully *ipsa, nato, juventae, laetos.*

3. Translate into English:—

Cum aquâ parcè coit, et limpidus perstat; scilicet ratione fluidunciæ in aquæ octario dimidio.

4. State the present, perfect, supine and infinitive of *coit, perstat.*

5. Translate into Latin:—

It is very soluble in sulphuric æther, less in alcohol, but very slightly in water.

ARITHMETIC.

6. By how much does $\frac{5}{8}$ of $\frac{4}{10} - \frac{7}{9}$ of $\frac{4}{21}$ exceed $\frac{5}{6}$ of $\frac{2}{15} - \frac{3}{8}$ of $\frac{4}{18}$?

7. Divide to four places of decimals 37·24 by 2·9, ·0719 by 27·53.

8. Find the number of solid inches in a cube the length of whose side is a decimetre.

9. The price of ·0625 lb. of balsam of tolu is ·4583 shilling, what quantity can be bought for £61 12*s.*, and what will be the value per lb.?

10. A druggist buys two chests of manna containing 2 qrs. 17 lbs. at 3*s.* $1\frac{1}{2}$*d.* per lb, and two chests each containing 3 qrs. 7 lbs. at 3*s.* $5\frac{1}{2}$*d.* per lb., what will he gain per cent. by selling a mixture of the cases at 4*s.* per lb.?

ENGLISH.

11. Parse the following:—

The pleasures of the imagination, taken in their full extent, are not so gross as those of sense, nor so refined as those of the understanding.

12. Write a short essay on *War.*

FRENCH AND GERMAN.*

13. Translate into English:—

Louis Quatorze, qui régna près de soixante-douze ans, détruisit les duels, protégea les sciences, et récompensa toujours le mérite; il réussit à maintenir son petit-fils Philippe Cinq sur le trône d'Espagne, malgré plusieurs rois ligués contre lui. Louis Seize assembla les états généraux en 1789, pour réparer l'état de ses finances; cette assemblée a opéré la révolution Française, dont l'histoire seule demande dos volume entiers.

And translate into French:—

They have the power to make peace and war; they locate the army and navy; they alone can assemble, prorogue, and dissolve Parliament.

Or translate the following into German:—

Everything that is new or uncommon raises a pleasure in the imagination, because it fills the soul with an agreeable surprise, gratifies its curiosity, and gives it an idea of which it was not before possessed. We are, indeed, so often conversant with one set of objects, and tired out with so many repeated shows of the same things, that whatever is new or uncommon contributes a little to vary human life, and to divert our minds for a while with the strangeness of its appearance.

The President next proceeded to deliver the prizes and certificates to the successful competitors, adding in each case a few appropriate words of counsel and encouragement.

At the conclusion of this portion of the proceedings, Mr. William Southall, F.L.S., of Birmingham, delivered the following—

* The Candidate is at liberty to choose either French or German, and is not required to show a knowledge of both.

Inaugural Sessional Address.

When I was informed by the Secretary that the Council had done me the honour of an invitation to deliver the inaugural address, two conflicting emotions occupied my thoughts; the first was that of gratification at the reception of such a proposition; the second, and by far the most powerful, was the feeling of utter inadequacy to fulfil the task in a manner that should be at all equal to the importance of the occasion, and that would maintain the honour of the Society and my own self-respect. At length I decided to make the attempt, and must beg you to receive with kind consideration the result of my efforts. It is a considerate thing on the part of the Council to call up to this office provincial druggists like myself, men who entered the trade when the great changes in its position were only commencing and who did not obtain the benefit of the academic training which many of its members now enjoy.

I conclude that those gathered before me are brought here by a desire to inform and educate their minds and to obtain knowledge; not merely the technical knowledge which by dint of hammering out may be sufficient to enable them to pass their examinations, but to obtain some true insight into certain of the laws of nature, and a practical acquaintance with certain productions of nature and art. The special sciences here taught are chemistry and botany, and the technical instruction given for the purposes of your profession is comprised in materia medica and pharmacy. Short I fear is the time that many of you propose to set apart for this worthy undertaking. Short, perhaps, not of your own choice, but through the imperative requirements of circumstance; nevertheless, short though it be, compared with the vastness of the field before you, much will depend upon yourselves and the use you make of the time allotted. Many of you I know come here grounded in your studies by your previous labours, and it is an injustice to your professors and to yourselves to suppose that any can come here with a mind like a sheet of white paper and have the necessary instruction written thereupon in the course of a few short months, and, I may further add, without much trouble to himself. Much time may be saved by a judicious method of working, but the great matter is to have your heart in your work. According to the latest philosophic views in which the doctrine of heredity bears so large a part, there is no intellectual knowledge, properly speaking, no acquisition at all, but every mind simply develops into activity all the potency within it. Touch, then, the true chord and you will find a responsive answer. Whether these notions be true or not as regards original endowment, it is clear that we have an intellectual heritage in the gathered fruits of other men's labours, and that we who live in these latter days are in a vastly better position as learners than those who have gone before us. The scheme of knowledge as regards the sciences alluded to is presented to you in a manner clearer and more definite than ever before. It is true that the ocean of organic chemistry is a great deep, but its depths have been sounded, the laws of its navigation are daily better understood, and false beacons have been removed out of the way. The great mass of details that is published in works on these sciences may alarm some minds, but it must be remembered that knowledge of details beyond those specially required must be a gradual and accumulative work.

It seems to me that I cannot do better than occupy your attention this evening with a few desultory remarks about the "nature of things," especially in connection with chemistry and botany, in which you may, perchance, hear something that will catch your attention, and incline you to press forward in the chase after knowledge.

The science of chemistry is a modern creation, and if we look back one hundred years, we meet with the names of many great men to whom its development is due. Centennial anniversaries are now the fashion, and three years back we in Birmingham did ourselves the honour of celebrating the discoveries of our townsman Priestley. He was a prophet without honour in his own time, burned out of house, and driven from home and country by the Church and King mob of 1791. The Nemesis soon followed, and having cast aside tradition, Birmingham rejoices at present in being the foremost representative of rational views.

You will remember that the best known of the discoveries of Priestley was his discovery of oxygen, which he called phlogisticated air; but notwithstanding this discovery of the gas most eminently adapted for supporting combustion, he, with Cavendish and Scheele, and other great chemists of his time, continued to hold erroneous views respecting combustion. They considered combustion to be a decomposition, and believed in the presence of an imponderable matter, termed phlogiston, asserting that the functions of the air consisted in removing phlogiston from combustible bodies. Phlogiston, said they, differs from gross forms of matter in being specifically light, and when taken from a body increases its weight. Lavoisier was the first to see clearly that these views were erroneous, and that in every chemical process, increase of weight means increase of material, and loss of weight loss of material. Boyle, first of the true chemists (and Geber, the Arabian, hundreds of years before him), had previously noticed the fact that metals increase in weight when calcined in the air, but he attributed it to the heat absorbed. Lavoisier showed its true significance, and confirmed it by the discovery that there was a diminution in the volume of the air when lead was converted into litharge in a closed vessel. From this time the part played by the air in the phenomena of combustion was clearly established, and a new era may be said to have opened in chemistry. A remarkable and important research by Dr. Black, of Edinburgh, made at a rather earlier period, on the difference between mild and caustic alkalies, is of much interest in this connection. The mild alkalies (carbonates) were at that time regarded as simple substances which became caustic by combination with a fiery matter. Lime was supposed to take up this fiery matter in the process of burning, and to be capable of transferring it to other alkalies. This hypothesis further explained the fact that lime after being used to render mild alkalies caustic is no longer itself caustic, having transferred its own fiery matter to the alkali. Black, however, discovered from observations that caustic lime when exposed to the air becomes heavier, at the same time that it loses its causticity; he therefore rejected the doctrine of a caloric or fiery substance. His researches also led him to the conclusion that effervescing earths and alkalies contain as one of their essential constituents a gas which can be expelled by heat from the former but not from the latter, from both, however, by acids; that the alkalies and earths when freed from this gas, which he called fixed air, became caustic, and therefore that their causticity does not depend on the presence of a peculiar substance, but upon the absence of the fixed air, and that caustic lime does not render mild alkalies caustic by imparting any caustic or fiery principle, but by abstracting their fixed air. This admirable research, which may be considered as the first that showed the importance of quantitative relations in the interpretation of chemical reactions, was also the inauguration of those ideas of chemical combination and decomposition which were afterwards extended to the whole range of chemical phenomena. Black, however, did not at first perceive the analogy between the results of this investigation and the antiphlogistic view of the theory of combustion, but ultimately he became a convert to Lavoisier's views.

The battle between the phlogistic and the antiphlogistic chemists has almost passed out of mind, but in a certain sense it might almost be said that the phlogistic chemists were right, for although a body in burning may gain in weight, it loses something, that is the power of emitting a certain quantity of heat; in other words it loses a certain amount of potential energy. As Black and the chemists of his day showed that the chemical changes of matter were simply changes of form, and not loss of substance—so about the year 1840, Joule and other physicists brought forward the doctrine that the thermal changes evidenced in combustion, etc., were but manifestations of the transference of energy, and that, like matter, it was never put out of existence, but disappearing in one form, it reappeared in another. The physical philosophers of the present day would now call every power, and force and influence, that is felt, seen, or heard, merely a form of energy. Muscular or mechanical power is that form of energy called work; whilst heat, light, and electricity, are simply transformations of the same. The pendulum exhibits in a simple manner two forms of energy, potential and kinetic. When the pendulum is vibrating there is constantly a transformation of energy of the simplest kind. By raising it with the hand it acquires energy of position, or potential energy, which it gradually loses as it falls, acquiring instead energy of motion or kinetic energy. This again is lost as it rises, and were there no friction and no resistance from the air, the process would repeat itself perpetually. Potential energy is stored up in the wound-up spring of a watch, a bent bow, or in gunpowder; kinetic energy is exhibited in the motions of the winds and waves, and currents of water, or currents of electricity.

The old plan of obtaining fire by boring rapidly a piece of soft wood with a pointed piece of harder wood is a simple and plain example of the transformation of energy into heat. The transformation of heat into energy is shown in the working of a steam engine. Begin with work and you can transform it all into heat. Begin with heat, however, and you cannot, for reasons well understood, transform it all into work. If it were possible to so convert it and to avoid friction you might construct a reversible engine in which the heat might as it were be pumped back again. The equivalence, however, between heat and work definitely subsists and has been accurately determined. It has been ascertained by Joule that a pound of water which has fallen 772 feet and had the whole mechanical force of its fall converted into heat, is one degree Fahrenheit hotter than before falling.

In muscular energy you have an animal engine performing work. Its fuel is, of course, food, and for the amount of fuel employed it will produce a greater amount of work than any other engine. Part of this fuel is employed in work, and part in producing the heat that is given off in large measure by the body.

This food is principally supplied by the vegetable products of the earth, and there is as it were a constant pendulum process going on between animals and vegetables, the latter using, as we may say, the ashes and burnt up material of the former, in the shape of carbonic acid, etc., the sun at the same time supplying radiant energy, to make up for that dissipated in the various processes of animal heat, muscular exertion and decay.

The same applies to electricity. Whenever an electric current passes through a galvanic battery a certain quantity of zinc is consumed, or as we may put it, a certain quantity of potential energy in the battery is converted into the kinetic energy of a current of electricity; pass that current through an induction coil and a portion is converted into magnetism, whilst a further induced current can be used to produce heat, light or sound. In this case the transformations are more complicated. Work is directly converted into electricity by the electroplater who employs a steam engine to drive an electro-magnetic machine; and in all these cases the energy so transformed is capable of measurement.

In the case of chemical action the same principle holds good. To undo a direct chemical union the potential energy which the bodies have lost in combination must be restored; for example, to separate hydrogen from its combination with oxygen, in other words, to unburn it, a certain amount of heat or its equivalent of energy in some shape must be employed. Where hydrogen combines with oxygen to form water a certain quantity of potential energy in the form of heat is dissipated, and this must be restored. This may be effected by oxidizing a body such as zinc in contact with the water. Now, when zinc is acted upon by acidulated water it is oxidized at the expense of the hydrogen, which is set free as gas, and this oxidation is attended with considerable loss of heat in addition to that acquired as potential energy by the escaping hydrogen. The same restoration of heat may be effected by muscular energy in the shape of work applied to the handle of an electro-magnetic machine, the current from which when passed through water will effect the separation of the oxygen and hydrogen. But the most direct way of restoring the heat lost in the combination is that of passing the vapour of water through a coil of platinum wire intensely heated by the flame of an oxyhydrogen blowpipe, when the vapour is resolved into oxygen and hydrogen gases, which may be collected over water. The potential energy is directly transferred from one portion of hydrogen burned outside to that previously in combination with oxygen within, and effects its separation.

We saw in the first place that a great truth was brought to light by the chemists of the latter part of the eighteenth century, viz., that matter is indestructible, however it may change its form. As Faraday expressed it, "a particle of oxygen is ever a particle of oxygen, nothing can in the least wear it. If it enter into combination and disappear as oxygen; if it pass through a thousand combinations, animal, vegetable, and mineral; if it lie hid for a thousand years and then be evolved, it is oxygen with its first qualities. Neither more nor less. It has all its original force, and only that; the amount of force which it disengaged when hiding itself has again to be employed in a reverse direction to set it at liberty." To this must now be added another great central truth which though more recently discovered is not less far reaching or important, namely, that energy is indestructible and is measured by work. To quote Faraday again, "All that we have that is good and safe, as the steam-engine, the electric telegraph, etc., bear witness to that principle. It would require a perpetual motion, a fire without heat, heat without a source, action without reaction, cause without effect to displace it from its rank as a law of nature."

The ancient Greek philosophers in their studies of the world were profoundly impressed with the majesty of the operations of nature. I am not about to intrude upon your notice the astronomers, mathematicians, and geometers of Greece, but just to mention that in the works of one of her philosophers, Democritus, we have the first glimpses of the atomic theory. But before entering upon this subject I will, by the way of a pleasant digression, call your attention to the fact that Aristotle, the prince of philosophers, the author of the inductive mode of research, and the father of natural history, was a druggist at Athens. I do not say that this can be asserted without dispute, though the well-known American author, Dr. Draper, states it without reservation. Bayle says it cannot be proved that he was a "pharmacien." Dr. Smith considers the statement that he had run through his parental estate and become a "*φαρμακοπώλης*," a calumnious charge; let us hope he meant as regarded his loss of fortune and not as to the nature of his respectable profession. At all events, what a thrill it should send through your souls to call up the idea of Aristotle, a druggist of Athens, attending the lectures of Plato.

Aristotle's pupil, Theophrastus, wrote on materia medica and botany, and it seems natural that he should have drawn his inspiration from his master. But we will return to Democritus only to observe that the views he foreshadowed were taken up by the Latin philosopher and poet, Lucretius. Lucretius has acquired a bad reputation because his intellect revolted against the absurdities of a worthless set of so-called divinities. It is true that the reaction carried him too far in the opposite direction. The editor of my copy, dated 1743, thinks it necessary to apologize for his work, which the rank of the writer alone as a classic poet caused him to undertake, and says, "What danger can any man apprehend while he reads that ridiculous doctrine of the Epicurean philosophers, concerning their atoms or minute indivisible corpuscles which they held to be the first principles of all things? an opinion so absurd that only to mention is to confute it."

The first great principle laid down by Lucretius is that "Nothing was by the gods of nothing made,"* and as a natural corollary "that nature does dissolve all bodies into their principles again; nor can reduce things into nothing." Now the notion of that day was that anything could be made out of nothing or of anything else almost, just as it happened. Pliny, a few generations later, in-

* *Lucr., De Rerum Naturâ*, Lib. I., 151, "Nullam rem e nihilo gigni divinitus unquam."

serted in his excellent 'Natural History' all sorts of stories of this kind, and down to our own times such pleasant histories as the genesis of geese from barnacles (you have the whole story in Gerard, with a plate), and pikes from pickerel weed, have passed current. In varied terms Lucretius repeats and affirms the view of the indestructibility of matter. After this he shows how the small particles and seeds of things are too subtle to be at all discovered by the eye. "What every day and nature do bestow on beings to make them grow by just degrees, not the most piercing eye could ever find, nor yet the particles that fly and waste by age or by decay. . . . Thus nature works by bodies not discerned." Had I time I could quote much more about his views respecting atoms. This early light upon "the nature of things" was however soon obscured, and remained so until Dalton revived the view that all bodies are formed of small individual particles termed atoms. To the old vague notion he attached a meaning by supposing on the one hand that the atoms of each kind of matter possess a constant weight, and on the other that combination between two kinds of matter takes place not by penetration of their substance but by juxtaposition of their atoms. This fundamental hypothesis being established, the general laws of definite proportions and of multiple proportions followed, and this hypothesis of atoms forms at present the foundation of all our theories, the solid base of our system of chemical knowledge. It gives a striking simplicity to the laws relating to the composition of bodies; it enables us to look into their intimate structure, and intervenes in the interpretation of their properties, reactions and transformations.

Now I do not want to give a lecture, but just to call your attention to some parts of the bill of fare that will be set before you, and if I can show that there are points of interest you may not have noticed in this wonderful "nature of things" it is all I desire. Let us take our text from our Latin poet again; I condense a little. After speaking of solid bodies he alludes to those that wander through the void. "These compose the thin air and the sun's brighter light. When the sun's light shoots its rays through a narrow chink into a darkened room, you shall see a thousand little atoms dance a thousand ways through the empty space and mingle in the very rays of light, engaging as it were in endless war; drawing up their little troops, never taking breath, but meeting and exercising their hostile fury with constant blows." Now, "it appears by these disorders that there are certain secret principles of motion in the atoms themselves,—and this variety of motion is certainly in the very particles. . . . There is nothing wonderful in this, that when all the primordial elements of things are in continual motion, the whole should at the same time seem to be at perfect rest, though every particular body has a sort of motion peculiar to itself, for the nature of the first particles is so subtle that they lie far beyond the reach of our sense."

Now I do not pretend to say how far this beautiful description is founded upon true insight or how far it is expanded by imagination, or indeed to what extent it relates to the air itself, but it reads singularly like the present molecular or kinetic* theory of gases. It is now considered that there is absolute proof that gases consist of particles of matter which are perfectly free and detached from one another, and which are constantly free and flying about in all directions. The simplest proof that we have of this is obtained by considering the way in which one gas diffuses through another, as, for instance, when any volatile substance in the form of vapour or gas is allowed to escape into a room, we find that, independently of all currents, it gradually mixes itself thoroughly with the air of the room. To permit of this perfect admixture the particles of a gas must be infinitely small and enormously numerous. The particles of one gas diffusing through another cannot move in straight lines, but must be constantly subject to incessant collisions with other particles. The rate at which diffusion of gases takes place can be ascertained by analysis, and from this rate may be calculated the number of collisions between the particles which take place in a single second. The calculations of mathematicians far transcend the most fertile imaginations of poets, and in sober earnest it is affirmed that the number of particles in a cubic inch of hydrogen is expressed by the figure 3 followed by twenty ciphers,* and that each particle moving at the rate of seventy miles per second is subject to seventeen thousands of millions of collisions in that same space of time.

In air the number of particles is not so high, but is amply sufficient to account for the admixture of the particles of oxygen and nitrogen in the atmosphere, and to render unnecessary any fear least the gases should become separated.† Chemists have but little to do with high numbers, but when we consider the precision of the calculations of astronomers, there seems no reason why there should not be the same exactitude with the calculations of what appears to our understandings as the infinitely small, as of the infinitely great, or of the infinitely distant, for it must be remembered that there is no such thing as absolute size; there is relative greatness and smallness—nothing more. I had the pleasure of hearing some months back a paper by one of our first mathematicians on the kinetic theory of gases, and I gathered that, although the correctness of the theory might be considered as proved, we might expect considerable modification in details, and, of course, its great extension.

Hitherto we have been considering not living matter only. We have seen that there is a rational explanation of the laws affecting matter, its combinations, motions and conditions; a genuine philosophy of matter, not metaphysical and speculative, dealing in occult and mysterious powers, but a scheme that is based upon deductions from solid facts. We have also seen that by availing ourselves of the knowledge and experience that have been gained of the working of these laws, we are enabled to regulate, control, and turn to our own account, the phenomena produced by their action. Let us now shift our ground a little, let us take a step further in our inquiry into the nature of things. We still have matter, but mostly in new forms; we still have energy exhibited in physical and chemical changes, but we find also superadded a new energy, an influence of a different kind, that we may to a certain extent assist or retard, but which we cannot initiate; an influence the origin of which transcends, and perhaps ever will transcend, all human research; I mean vital energy or life. Not the infinitely variable forms of the sun's

* κινητικός, putting in motion.

* 300,000,000,000,000,000,000.

† By this theory the other physical phenomena of gases are also explained.

energy have, unassisted, the power of producing the transformations of matter that take place under the influence of vital energy, nor can this itself be brought into play without the presence of the single germ that determines as it were the flow of the current of life.

In our first introduction to this altered state of things, we come upon a vast debateable region, one in which there are only glimmerings of life, and of which there is as yet but little definite knowledge. Its existence was mostly unknown in old times, its inhabitants as individuals being generally invisible to the naked eye. In the lowest and crudest forms we first meet with little lumps of contractile slime—monera, protamœbæ—without structure, without any definite form, and entirely without any hard or formed parts. Different observers make mention of lumps of sarcode, protoplasmic matter, plastic or formative material, matter of life; but the exact spot where it can be said, Here life begins—this is the lowest form of life,—has yet to be found. These slimy bodies, notwithstanding they are destitute of visible structure, nevertheless assimilate materials from their environment and grow. They constantly change their form, and are capable of executing slow movements, and by division they reproduce their kind.

A little higher in the scale and a nucleus is apparent, and by differentiation of the outward layers of the protoplasm a covering membrane or skin is formed. Little living cells with tails are now met with possessing powers of rapid motion—flagellata or whip swimmers—frequently changing their shape. Of these the little bright green euglena is constantly met with in fresh water pools, sometimes by its numbers giving to the water a green appearance. This green colour is chlorophyll, the colouring-matter of vegetables. Others swim by cilia, rings of rapidly vibrating hairs, after the fashion of ciliated infusoria; infusoria are, however, true animals. Then another class are called diatoms, cells with flinty shells, often of great beauty. Nor are these minute beings of no importance in the economy of nature for their vast numbers in some cases make up for their individual minuteness, and in some places we find rocks composed mostly of the skeletons of diatoms. I said it was a debateable region, for it is not as yet determined with any precision whether its inhabitants be animals or plants. For instance, the slime moulds (myxomycetes), inhabitants of tan pits and damp forests, whose spores can crawl many feet, were formerly considered to be real fungi, but are now considered by Haeckel and others to be akin to the lower animals.* It is sometimes said that the botanists call the plants animals, and the zoologists call the animals plants. By some naturalists these beings have been exalted into an intermediate kingdom, called Protista.

As these minute bodies dwell as it were on the boundary line of life and present the simplest forms of organization, they are earnestly scanned by those who would inquire *whether vitality is a result of organization, or whether organization follows because life has begun*. Whether, in short, the vital influence be something quite independent, or whether it be a mere property of matter. In attempting to solve this inquiry a great debate has arisen as to spontaneous generation; can any of these living beings come into existence without the aid of germs? At present the answer is pretty clearly in the negative. A second inquiry has arisen respecting the proof or the disproof of heterogenesis, that is, can living organisms be developed from germs springing from organisms dissimilar to those which are reproduced? It will be seen that both these questions have an important bearing upon the theory of evolution, and for the present heterogenesis also remains largely unproved. It must, however, be said that the metamorphoses and transformations of some of these bodies are so complex that a large field is still open for observation and research, and very much regarding them remains to be settled.

But it is time we left this debateable region, where speculation, theory, and research also, are so busy at work, and proceed to the more direct consideration of the second science which is taught in your school, namely, botany.

What is now understood by the science of botany is something very different from what it was when I was young, at least, as far as it was then taught in schools. At that time the knowledge of the Linnæan system of arrangement of plants was supposed to constitute the science, and a great charm there was in hunting for plants on the hills and roadsides, and by the brooks, carefully examining all their exterior characteristics, naming them with their botanical names, to the discovery of which the Linnæan system was a very good guide, making note of the wild spots whence they came, and then depositing them in our herbaria. Now, as my introduction will have shown you, botany is a section of biology, a plant is a life, a member of the great family of living beings, and in its simplest and earliest forms differs from animals in their simplest and and earliest forms, only as fingers might do on the same hand. A plant is now studied as a separate existence, endowed with all the powers necessary for its life, growth, and reproduction. The outward changes that take place in plants are by no means devoid of general interest. The manners and customs of plants are as diverse as those of men, and a volume might be written on their sociology. Dr. Erasmus Darwin long ago sang of the loves of plants (conducted strictly according to the Linnæan arrangement) in artificial verse suited to the days of powder and hooped petticoats. His descendant, the Darwin of to-day, has fashioned a far more romantic story of those loves in the sober words of truth. We learn from him how the bees and other insects carry messages of love and are rewarded with honey for their pains. How precautions are taken to prevent too early marriages, to preserve pure blood and to produce a healthy offspring. We also are shown the wonderful provisions and adaptations of different organs to diversified requirements.

Comparisons are sometimes made between men and trees, oaks or willows, as the case may be, but the resemblance may be traced in the other directions also; for are there not baobab trees as corpulent as the traditional alderman? Scotch thistles are the types of Scotch terriers. Is the mockery on the part of the higher order or the lower? It is certain that in our own land, and far more wonderfully in other lands, there are insects that imitate for protection's sake the leaves of the plants on which they feed. Plants breathe after their fashion, cut them and they will bleed, bruise them and you produce congestion, parasites of their own order hang about them,

* "Whether the myxomycetæ should take their place in the animal or vegetable kingdom, is a question which in the present state of our knowledge it is impossible to answer."—*Allman, Journal Linnean Society, Zoology*, September 1877.

and animal parasites infest them. They are even subject to clubbed limbs and other deformities, and Dr. Masters is their teratologist and orthopædic physician. Plants have their distinctions of race and pedigree, their aristocracy and tribes of low degree, their families and relationships, which systematic botanists now trace out and follow instead of an artificial arrangement. The laws of Malthus are a necessity with them, as dwarfing is a constant result of over population, and like men, plants often break down in the struggle for existence. Wanderers are some by air and by sea, whilst others travel more slowly underground. Peaceful are they as a rule but sometimes strange tribes harry the land like Huns and Vandals, and drive out the old inhabitants.

In the matter of voluntary movements plants seem but sluggards, but they have nevertheless many modes of motion of their own. The closing and dropping down of the pinnate leaves of the sensitive plant (*Mimosa pudica*) are well known. The leaves of the Dionœa clasp its prey—many flowers open or close with the changes of the sun and shade. The spores of some algæ swim freely. and those of many vascular cryptogams have distinct motions. Capsules scatter their seeds with force, and the new shoots of climbers revolve in a circle until they grasp a fresh support. But in some respects more noticeable than these, is the grand slow movement by means of which heavy loads are lifted by soft-bodied fungi, and rocks are riven by the roots of trees, and this is accomplished not by violence but by the steady growth and onward march of tender little cells that in their sinuous course follow the lines of least resistance. The attack once opened they expand with enormous power, making room for fresh aggression. There is a lesson for students in this; if you meet difficulties and obstructions, do not charge them indiscriminately, but compass them about quietly,—by following the line of least resistance you will gain a point here, another there, and at last find sufficient leverage to remove the obstruction. If I were a moralist I should enlarge further upon this doctrine.

The general course of your studies in botany will be to gain an acquaintance with the construction and external conformation of plants—with their physiology and chemistry, and also of the systematic arrangement of plants, their genera and species. Good manuals of botany are not unfrequently rather heavily weighted with structural details somewhat repellent to the general student, but here you have the advantage of receiving direct from the professor instructions as to the necessary amount of detail required for the intelligent comprehension of your subject. It is not for me to indicate any mode of study, but as I have somewhat playfully alluded to the lives and habits of plants, it seems to me that the best advice I can give you is constantly to bear in mind that a plant is a living existence, and that all its parts are formed and fashioned for some purpose connected with its life. Some people take up the leaf of a plant as if was a piece of leather with some lines on it. "How pretty!" say they, "it looks as if it was stamped;" but when you know that it is, as it were, one of the lungs of a plant, you have a direct interest in learning its construction, its anatomy, and how it breathes.

My second and last piece of advice is, always to obtain specimens, especially of British plants, whenever possible, for private study; and by all means accustom yourself to the use of the microscope.

It is sometimes asked, Why should we as pharmacists study botany? I answer that plants are an important part of the apparatus of the great laboratory of nature, and in them is made a large proportion of the substances we as pharmacists employ. By vegetable alchemy are produced gums, sugar, wax, oils fixed and volatile, resins, etc., and also those active medicinal properties residing in many parts of plants, which may in certain cases be isolated as alkaloids. The knowledge of new plants and of new products increases, and it seems to me that materia medica and botany are indissolubly linked together.

But vegetable chemistry is not altogether occult. The action of diastase, by which starch is converted into sugar, has long been known and turned to account; and recently there has been discovered in beet-root juice a ferment which has the remarkable property of converting sugar into cellulose or woody fibre. That the laboratory of nature is constantly at work is shown by the evidence of photographic pictures of foliage. In this case a portion of the energy of the chemically active part of the sun's rays is absorbed by the leaves, and is used in the work of the decomposition of carbonic acid and water. In consequence of this the salt of silver on the photographic plate is not decomposed, and the result is seen in the dark, almost black colour of the foliage in the picture.

Within the last few years chemists have succeeded in preparing artificially a number of what were formerly supposed to be exclusively organic products, and it is now known that those naturally formed in plants do not owe their origin to any mysterious energy, but that the materials of which they consist are subject to the same laws as mineral matter. But I cannot enter upon this deeply interesting subject. My object, as I at first stated, was to bring before you a few points of interest which might have a more or less direct bearing upon the sciences of chemistry and botany, and which I thought would to some extent show that there was a charm in these studies for their own sake. If I have to any extent succeeded, my object so far will have been gained, and I leave you to discover for yourselves the beauties of materia medica and pharmacy. I said also that my remarks would be desultory, a mere skimming over the surface, and I must apologize to some of my friends present for a want of precision in some of my statements.

And now, gentlemen, I beg to thank you for your patient hearing, and commend you to the excellent instructions of your professors, trusting that if the Council so wills and the fates decree, I may meet some of you again in another room of this house, and that our meeting and parting may be equally pleasant with the present.

At the conclusion of the Address,

Dr. Greenhow rose to propose a vote of thanks to Mr. Southall for his very philosophic and erudite address, from which he could not doubt many young men would gather some of the suggestions he wished them to gather and learn to love chemistry and botany for their own sake as well as for the sake of making progress in their business calling. He had listened with great interest to the reports of the professors, and it was very gratifying to hear the high standard of marks obtained by the competitors for prizes: it showed that the students of that school were pressing onward in the pursuit of science, and were not satisfied with merely acquiring so much knowledge as would enable them to pass the Major or Minor examinations. The latter was only a test of the minimum qualifications required of a person who was to perform the important duties of dispensing prescriptions; but the gentlemen who had gained prizes showed an amount of knowledge far exceeding that necessary to pass this examination. He agreed with what had been remarked by a previous speaker, that the School of Pharmacy was valuable as a sort of model on which others might be founded, and he hoped there would be such a number of these schools carried on in the same spirit, as would encourage competition, and thus secure excellence in teaching. Mr. Carteighe's remark that on some future occasion he hoped the examiners would be able to award the Council prizes to gentlemen who had been educated in some comparatively unknown school was but another mode of expressing the same wish. Before sitting down he wished to say, as Government visitor of the examinations, that they were conducted in the fairest possible manner; they were not too strict, nor did they go too much into science, as was sometimes said. A man could not be a pharmacist without science. It was an easy thing, perhaps, to compound a prescription if a man had all his drugs ready to hand; but the public required more knowledge than that—a knowledge of the genuineness of drugs, and of plants, and this could only be acquired by a thorough knowledge of chemistry, materia medica, and botany. In conclusion, he thought Mr. Southall deserved great credit for having succeeded in striking out a novel line of address—no easy task, considering that such addresses had been given year after year for so long a period—and one which, if novel, was very useful, and would no doubt have the effect of striking out some sparks of love for science in the minds of his audience.

Parliamentary and Law Proceedings.

Extensive Robberies of Patent Medicines, etc.

At the Birmingham Public Office, on Friday, Sept. 28, Jacob Hugh Payne, 26, chemist, 15, Princess Road, was charged with stealing a large quantity of patent medicines belonging to his employers, Messrs. Philip Harris and Co., wholesale chemists, of the Bull Ring; and Sidney Willliam Parker, 36, parcel clerk, Victoria Terrace, Birchfields, and Horace Bygrave, 41, traveller, of Norwich, were charged with feloniously receiving the same. Mr. Powell appeared for the prosecution, Mr. Cheston, for Bygrave and Parker, and Mr. Bickley for Payne.

Mr. Powell stated that the prisoner Payne had been employed by the prosecutor as warehouseman, his duty being to receive parcels to label them, and compare them with the invoices, but not to send anything out under any circumstances. On the 6th ult., Parker, who was manager at the Globe Parcels Office, Birmingham, went to a Mr. Brown's, chemist, of Hockley Hill, and produced a quantity of patent medicines, telling Mr. Brown he had been sent by the Globe Parcels Company to dispose of them at 25 per cent. under cost price, as they had been received for a debt from one of their agents. Believing the representation to be correct, Mr. Brown purchased the goods. On the 14th ult. Parker called at his shop again with some more goods, which Mr. Brown purchased under similar circumstances. A short time subsequently one of the prosecutors' representatives called upon Mr. Brown for the purpose of obtaining an order for similar goods. Mr. Brown said he should not want any more for a considerable time, as he had been making purchases from Parker at a much lower price than he could get them from the prosecutors. This led to inquiries being instituted, and it appeared that the prisoner Payne on the 4th ult. had sent a parcel from the prosecutors' warehouse to Parker's, whose place of business was in Temple Street. Upon that Mr. Heeley, of the firm of Messrs. Harris, called the prisoner (Payne) into the office and questioned him about the parcel, the result being that he was given into custody. The matter was placed in the hands of Detective Seal, who had an interview with Parker and took him into custody. The two prisoners were taken before the magistrates and remanded. Payne subsequently made a clear breast of the transaction to Mr. Heeley. His statement inculpated Parker and the prisoner Bygrave, who was accordingly apprehended. The latter when arrested said he had been drawn into it by Payne, who had requested him to take a shop for the disposal of the goods he said he could purloin. Payne said to him on one occasion, "I can get about £100 worth of goods a week, as it is all under my control and is only yet in its infancy."—Prisoners all pleaded guilty to stealing. Payne was committed to gaol for six calendar months, and the other two to four months with hard labour.—*Aris's Birmingham Gazette.*

Poisoning by Opium.

On Wednesday, September, 19, an inquest was held at Battersea, on the body of Minnie Heath, eleven months old, before Mr. Carter.

The mother of deceased said that on the previous Saturday morning she gave deceased a pill. On the previous day the child was affected with bad breathing, and had the diarrhœa, and she took her to Dr. Cronin, a homœopathic doctor, of Clapham Common, who gave her some pills, and ordered her to give the child one every two hours. He also gave her three, at the time she was at the house. As the diarrhœa did not continue she did not give the deceased any pills during the night. On Saturday morning as her husband was about to leave home, witness, who was in bed with the child, asked him to give her the pills, and he then gave her a box containing some pills. She gave one to the child, who immediately after began to choke, and she at once saw that she had given the child the wrong pill. She had given one of the pills which were given her about twelve months before to lull the pain in her legs, which were then very bad. The two boxes of pills were placed in conspicuous places, one lying on the shelf and the other on a chest of drawers.

Robert Fair Fraser, a surgeon, said he saw deceased on Saturday; her breathing was then very feeble, and her face was of a livid hue. The mother of the child told him she had given the child the wrong pill. He had supplied the mother the pills, which contained opium, as at that time she was in great agony. The pills contained one grain of opium in each He managed to revive deceased for a short time, but it died from the effects of opium on the same evening.

The jury returned a verdict of "Accidental death."

Poisoning by Carbolic Acid in a Workhouse.

An inquest was held on Saturday, Sept. 29, before the Liverpool deputy borough coroner, touching the death of Emma Greenwood, aged 44 years, an inmate of the Brownlow Hill Workhouse. It appeared that on the previous Thursday, Miss Spicer, the ward matron of the receiving-house, found that she had run short of cough mixture. For the purpose of getting a fresh supply she made application in the usual way, and sent down the empty cough mixture bottle by an inmate. The bottle was given to Mr. Hunt, the dispenser, and he proceeded to fill it, when his attention was called away. On returning he inadvertently filled a bottle containing carbolic acid, which was standing close by the bottle marked "cough mixture."

The messenger at once returned with the bottle given him, but the officer who usually received the medicines from him was absent, and he handed it to an old woman named Catherine Cain. Having a cough, the old woman said she took a little drop out of the bottle, and finding it warmed her very much, she handed it to the deceased, who was cleaning windows at the time, remarking that "it would do her good." The deceased then drank twice, according to Cain's evidence, from the bottle, became unconscious, and soon afterwards died. The jury returned a verdict "That the deceased was accidently poisoned," and accompanied their verdict with a presentment that there had been very gross carelessness on the part of the dispenser, and that in public institutions like the workhouse more care ought to be taken, so that such fatal mistakes would be impossible. The jury also said they quite agreed with the coroner that carbolic acid should not be kept in bottles the same size and of the same colour as those used for less fatal medicines.—*Liverpool Daily Courier.*

Correspondence.

ILLEGAL TRADING UNDER THE PHARMACY ACT, 1868.

Sir,—One of the earliest published objects of this Association was to defend the trade from encroachment by unauthorized dealers in poisons, and as the Association has now been in existence upwards of twelve months, it may interest many of your readers to be informed of the steps that have been taken to effect this object.

I have been repeatedly instructed by the Executive and Law Committees to collect evidence of infringements of the Pharmacy Act, 1868—in other words to make purchases of scheduled poisons from unregistered persons—and report the results to the Registrar of the Pharmaceutical Society. In compliance with these instructions, I have, from time to time, collected evidence of some twenty cases of illegal trading, and forwarded particulars of the same to the Registrar of the Society, with a request that he would submit them to the Council. The cases have been duly laid before the Council, but in no single instance, as far as I am aware, have proceedings been taken against the offenders, although in one case I have on two occasions—at an interval of several months—made purchases of poison from the same person.

What has been done is this: The Registrar, acting under the instructions of the Council, has written the offenders a "caution letter," informing them that he has received information that they are dealing in poisons contrary to the provisions of the Pharmacy Act, 1868, and giving them notice that unless they desist from so doing proceedings would be taken against them.

Now, in some instances, traders infringe the Act in ignorance, when the caution letter possibly puts a stop to the evil; but in the majority of cases I am convinced the statute is being wilfully broken and then such a letter does mischief, inasmuch as the illegal trading still continues and it then becomes a most difficult matter for *a stranger* to obtain the requisite evidence on another occasion. In proof of this, I have three times during the last six months purchased a scheduled poison from a person openly infringing the Act. On the 30th of June last I reported this case to the Registrar of the Society forwarding him particulars of the third purchase; the offender was warned in due course; on Thursday last I endeavoured to make a fourth purchase of poison from the same establishment, when the assistant refused to sell it me, saying they had ceased to sell poisons except to persons they knew as customers.

It is an admitted fact that there are at the present time a large number of persons contravening the provisions of the Pharmacy Act in this country, the Registrar himself admits that "the Council has no idea of the enormous number of cases constantly reported to him, there was scarcely a day which did not bring information of some alleged infringement." (See Report of Meeting of the Council, July 4, 1877, *Pharmaceutical Journal*, No. 367, page 14.) I am continually receiving letters from members, reporting cases and soliciting my aid to put a stop to them. In many instances the Executive Committee of the Association would have instituted proceedings against the offenders under the 15th section of the Act, but the authority to take action under this section is vested in the Registrar of the Pharmaceutical Society who can sue only "in the name and by the authority of the Council of the said Society."

The Council of the Society having taken no steps to make use of the evidence collected at the expense of the Association, beyond warning the offenders, the Law Committee, at their meeting on the 3rd ultimo, unanimously resolved to take action, under the 17th section of the Act, against illegal traders who were selling poisons improperly labelled, and instructed their solicitor to proceed in such cases as he thought expedient.

The first prosecution took place at Walsall on the 26th ultimo, a full report of which appeared in your last issue; the result was highly satisfactory as unmasking the proceedings of an unregistered person trading under the cloak of a duly registered chemist and druggist. I have taken out summonses against two persons residing in this town, who, I believe it will be found, are infringing the Act in a similar manner. The cases will be heard at the police court on Tuesday next. A report of the proceedings shall be forwarded to you in due course. The effect of such prosecutions will probably be to cause unregistered men, when selling scheduled poisons, to declare distinctly on the covering of the packet, bottle, or wrapper containing the poison their name and address, when it will be an easy matter for the Council of the Pharmaceutical Society to sue under the 15th section of the Act, provided that the Council deem it expedient to proceed against them.

W. F. HAYDON, *Secretary.*

Birmingham, Oct. 3, 1877.

THE CONFERENCE GRANTS.

Sir,—As regards research-grants, Dr. Tilden regrets the abruptness with which the "altered views" of the Conference were expressed by me at Plymouth. The future welfare of the Conference induces me to ask you to give me space to assure all interested in the Conference, that the Conference, so far as I know, has not altered its views in the slightest degree.

JOHN ATTFIELD.

Ashlands, Watford, Oct. 14, 1877.

TO THE BENEVOLENT.

Sir,—Allow me to thank you for the publicity which you have given to the case of Mrs. Fowler, and to add to the amount already announced, viz.:

	£	s.	d.
	50	4	0
Mr. Barclay, Birmingham	0	10	6
,, Hullell (Meggison and Co.)	1	1	0
,, Reynolds (Leeds)	0	10	6
,, W. Wickham, 509, New Cross Road	0	5	0
	£52	11	0

Since the first appeal was made, Mr. Bremridge and I have endeavoured to obtain sufficient evidence to justify us in taking legal proceedings against the railway company, but the long time that has elapsed since the accident occurred, and the subsequent information obtained from a reliable authority that the present mental affliction of Mr. Fowler may be hereditary, and not the result of the accident, has induced us to think it would be a great risk to venture on law proceedings. This being the case I would rather, with the consent of the subscribers to the fund, apply the amount received in a way most likely to benefit the poor woman.

The fund will, therefore, be so appropriated unless any objection is made by the subscribers before the 1st of November next.

W. D. SAVAGE.

"*Dispenser for more than Twenty Years.*"—Quite as much would be implied in the instruction "Misce."

A. T. Green.—The book is published by Groombridge, Paternoster Row.

"*Medicus.*"—See a paper by Mr. Pocklington on the preparation of glycerine jelly for microscopical purposes, in *Pharm. Journ.* [3], vol. v., p. 401.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Hemstead, Mr. Dunn, Dr. Brown, Mr. Whitfield, Mr. Milner, Mr. Pearce, Mr. Smith, Mr. Abraham, Mr. J. T. Fox, Mr. Wallis, Mr. Masson, Mr. Hicks, Mr. Gale, Mr. Gibson, Mr. Gibbs, Syrupus, McFigo, Natura, Gulielmus J. S.

GLYCERINUM TRAGACANTHÆ, AS AN EXCIPIENT.

BY G. WELBORN.

The subjoined remarks are in continuation of a paper read last year at the Pharmaceutical Conference at Glasgow, and printed in the *Pharmaceutical Journal* of September 23, 1876.

(1) The present condition of a mass of Pil. Aloes et Ferri weighing about two ounces, and prepared on May 26, 1876, is as follows:—Aroma, very good and fresh; consistency, rather hard, but yields to pressure of the thumb and fingers. A section exhibits numerous minute crystals of ferrous sulphate interspersed throughout the mass. A portion being cut off from the mass and rolled upon a pill-machine, crumbles down and does not admit of being formed into pills. Nevertheless, if it be worked for a short time under a pill-pestle it still forms an exceedingly good and plastic mass—capable of easy extension for cutting into pills, which are beautifully rounded off, and present the appearance of having received a coating of varnish. I may add that the above mentioned mass retained its original consistency for some six months, until, in fact, it had been exposed for some time to the heat of a very warm room during last winter.

(2) A small mass (about one ounce) of Pil. Aloes et Myrrhæ, prepared twelve months ago, has become too hard to roll out without being first subjected to some amount of labour in the pill-mortar. It then becomes soft and plastic, but displays a want of adhesiveness apparently due to the essential oil contained in the myrrh, so that, when the pills are cut they frequently split into halves. The aroma of the mass is as fresh and powerful as when first compounded.

(3) A small mass of Pil. Rhei Composita, now fifteen months old, still retains a nice consistency, and may be readily cut with a pill-knife. It does not, however, roll well, the cause of failure manifestly being due to the oil of peppermint, since the oil has a tendency to ooze out and form a non-adhesive surface. If the precaution be taken of previously working up the requisite quantity of mass in a pill-mortar, it speedily becomes soft and may be readily rolled out.

From a careful consideration of the foregoing observations, it may be gathered, that although the glycerin and tragacanth excipient preserves certain of the official pill-masses in good condition for a much longer period than those ordered in the Pharmacopœia, yet it has not altogether sustained the expectations formed of it; for while it succeeds admirably—nothing better, for making up nine out of every ten of physicians' prescriptions met with in the daily routine of a dispensing establishment, it must be confessed that the official formulæ thus prepared gradually assume a condition, after being kept several months, which necessitates the use of the pill-mortar before they can be formed into pills.

I avail myself of this opportunity for saying that the grounds for a statement contained in my letter which appeared in the *Pharmaceutical Journal* for October 14, 1876, respecting a mixture simply of glycerin and powdered gum tragacanth, that it does *not* gelatinize in the cold, was founded on experiments made with a sample of gum obtained from an undeniably first-rate source. The said gum when mixed with pure glycerin did not show signs of gelatinizing after remaining for several hours in contact; and, even after being heated together on a water-bath was not by any means tenacious. The addition of water, however, imparted the quality of adhesiveness to a remarkable degree. Within the past year, however, I have met with powdered tragacanth which assumed a stiff and tenacious condition in a few hours after being mixed with glycerin without the application of heat, in the proportion of one part of gum to six parts of glycerin.

Experiments were undertaken with the view of ascertaining the solubility of pills above mentioned when merely exposed to the action of cold water. Three grains each of the following pills were taken: —Pil. Aloes et Ferri, Pil. Aloes et Myrrhæ, and Pil. Rhei Composita. These were placed in separate test tubes, containing a small quantity of cold water, in the evening, and allowed to stand undisturbed during the night. Next morning the Pil. Ferri and Pil. Rhei had increased in bulk, and upon slightly shaking the tubes the pills were completely disintegrated and diffused through the liquid. The Pil. Aloes et Myrrhæ was not so much acted upon by the water; it was, however, easily broken up and diffused when stirred with a glass rod.

The physiological activity and therapeutic efficacy of pills made up with the tragacanth excipient is placed beyond doubt when taken in the diminished dose of three grains for five grains of the B.P. formula.

As to the important question of defining doses for any amended formulæ which may be inserted in the Pharmacopœia of the future, I would respectfully submit that part of the subject is a matter to be left to the decision of the Committee appointed by the Medical Council for revising our national text-book.

It may, perhaps not be thought irrelevant to observe here, with reference to another excipient for Pil. Aloes et Myrrhæ, that a mixture of one part of glycerin and three parts of treacle possesses the property of preserving the above mass in perfect condition for the space of six years with every probability of keeping good and fresh for another like period.

It is, therefore, a subject worth serious consideration, whether the use of a mixture of glycerin and treacle as an excipient, in easily regulated and suitable proportions might not advantageously be extended to other official pill-masses, *e.g.* Pil. Rhei Composita, Pil. Colocynth. Composita, and Pil. Assafœtidæ Composita.

E.: European or Common Larch.—G.: Lärche, Lärcher Fichte; Gemeiner Lerchenbaum; Terpentinbaum; Europaischen Ceder; Weisser Lerchenbaum.—Méleze commun; Méleze d'Europe.

"The larch will grow rapidly upon almost any soil, and in any situation, for the first 20 or 30 years; but it is only in a clear dry atmosphere, on a cold bottomed soil, somewhat moist on the surface, that its timber is brought to perfection. In plains and near the sea it grows rapidly for 30 or 35 years; but when felled in such situations, the wood is found rotten at the heart, and unfit for any purpose except fuel. This decay of the wood is much aggravated when the larches are planted thick, so as to expose but a small portion of their foliage to the sun, and to retain among their lower branches an atmosphere surcharged with moisture. The larch will grow, and become valuable timber, at a much greater elevation above the sea than the Scotch pine, thriving at a height of 1800ft. in the Highlands, where the Scotch pine does not attain a timber size at a greater elevation than 900ft. In Switzerland it is found in the highest perfection in soil composed of the debris of calcareous rocks, as well as in granite, argillaceous, and schistose soils."

The bark of the larch has very great analogy with that of *Pinus sylvestris*, as well in its exterior aspect as in its organization and mode of development; it is only rather less red and less scaly. It contains utricules which, without having any analogy with the glands of the fir, become filled with resinous matters. The true glands disappear with the green envelope during the earlier years of the life of the larch.

Extraction.—It is essentially in the various layers of the sap wood that the resiniferous canals are met with; the bark contains but very few, and these are but little developed. According to Flückiger and Hanbury, "larch turpentine is collected in the Tirol, chiefly about Meran, Botzen, and Trent. A very small amount is obtained occasionally in the Valais in Switzerland, and in localities in Piedmont and France, where the larch is found. The resin is obtained from the heart wood, by making in the spring a narrow cavity reaching to the centre of the stem, at about a foot from the ground. This is then stopped up until the autumn of the same or of the following year, when it is opened and the resin taken out with an iron spoon. If only one hole is thus made, the tree yields about half a pound yearly without appreciable detriment. But, on the other hand, if a number of wide holes are made, and especially if they are left open, as was formerly the practice in the Piedmontese and French Alps, a larger product, amounting to as much as 8lb., is obtained annually, but the tree ceases to yield after some years, and its wood is much impaired in value.

"Mohl, who witnessed the collection of this turpentine in the Southern Tirol, observed that when a growing larch stem was sawn through, the resin flowed most abundantly from the heart-wood, and in smaller quantity, though somewhat more quickly, from the sap-wood, and that the bark contained but few resin-ducts. The practice of closing the cavities is adopted, not only for the sake of preserving the wood and for the greater convenience of removing the turpentine, but also because it tends to maintain the transparency and purity of the latter."

A tree 50 or 60 years of age can yield 3 to 5 kilograms of turpentine annually for 5 or 6 years in succession, if care be taken to reclose the cavities exactly for the winter.

Characters.—Venice turpentine, freed from all its impurities, is a thick liquid of a pale yellow colour and slightly fluorescent. It is very slightly turbid, and neither granular nor crystalline; it always remains translucid. Its odour is less pronounced than that of common turpentine, recalling slightly the scent of nutmeg, but less agreeable. The taste is acrid, bitter and aromatic. Planchon remarks that this bitterness is perhaps due to a principle named "pinipicrine," the presence of which has been recognized in the needles of the *Pinus sylvestris* and of certain Thujæ.

Venice turpentine, of all the turpentines, presents the least decided siccative properties. When spread in thin layers it thickens very slowly in contact with the air; but there is no doubt that desiccation does take place, and that Herlant is wrong in considering it a non-siccative turpentine. Moreover, this author sets at nought its proper classification and ceases to be exclusive in his description when he says that the product remains sticky indefinitely, or at least during a very long time.* When it is mixed with calcined magnesia, it does not acquire a pilular consistence.

Venice turpentine is completely soluble in alcohol, forming a clear solution that reddens litmus. When treated with cold water the resulting liquor also has a slightly acid reaction, which is due to formic acid and probably to succinic acid. It is perfectly miscible with glacial acetic acid, alcohol and acetone. Dissolved in benzine or in alcohol it rotates the plane of polarized light 9·5° to the right; this rotatory power, however, is due to the resin it contains, since the essential oil is lævogyre to the extent of 6·4°.

Composition.—By submitting Venice turpentine to distillation there is obtained about 15 per cent. of an essential oil that boils at 157°C., and which when saturated with hydrochloric acid gas yields crystals having the composition $C_{10}H_{16}+HCl$. The resin that is obtained as a residue of the distillation is soluble in 2 parts of hot 75° alcohol, but is much more soluble in concentrated alcohol. Berzelius examined a "Venice turpentine," but it is not certain that he had to do with a genuine specimen, as the name was also borne by the turpentine from *Pinus maritima*.

Unverdorben has analysed a true specimen quite recently. According to that chemist, Venice turpentine contains two essential oils, one being much

* Etude sur les Principaux Produits Résineux des Conifères, p. 19.

more volatile than the other; two resin acids (pinic and sylvic); a neutral resin; a bitter extract; and, finally, succinic acid mixed with a little formic acid. Pinic acid is present in considerable quantity and this explains why it is that this turpentine is not granular (crystalline).

Uses.—According to Merat and De Lens, Venice turpentine is the best and the only one that should be used in medicine. However, its employment in this direction is very restricted, other turpentines being much preferred to it; in fact, as a rule the product met with in commerce under the name does not merit recommendation, as it is frequently nothing more than a mixture of common resin and oil of turpentine. This mixture is easily distinguished from Venice turpentine, because it possesses very marked siccative properties and its odour is more decided. In the pure state Venice turpentine would merit preference in the preparation of plasters, because it is so slightly siccative.

V. HUNGARIAN BALSAM (*Térébenthine de Hongrie*).

This turpentine is yielded by the dwarf or mountain pine (*Pinus Pumilio*, Harnck). It is still known under the name of Hungarian balsam (*baume de Hongrie*). It is a pale yellow, clear liquid, having an herbaceous odour and a piquant flavour. At present it is scarcely met with in commerce.

VI. CARPATHIAN BALSAM (*Térébenthine des Monts Carpathes*).

This turpentine is yielded by the *Pinus Cembra*, L., known in this country as the Cembran Pine, or the Siberian or Swiss Stone Pine; in Germany, under the name of *Zürbelkiefer;* and in France as the *Cembrot*, *Gouve*, *Tinier*, *Aloies*, or *Auvier*.

The tree attains a height of from 19 to 20 metres, and grows at a very considerable altitude, 2000 metres at least, forming the last zone of forestal vegetation. In France it is met with only in the Brionçonnais Alps, and even there it shows a tendency to disappear. Its bark is of a greenish grey colour, smooth or warty, presenting resin reservoirs that can be emptied.

The turpentine is liquid, colourless, and limpid; it has a pleasant odour, and an acrid and bitter taste. It is rarely met with in commerce.

VII. TURPENTINE FROM THE ALEPPO PINE (*Pinus Halepensis*, Mill. *Pin d'Alp; Pin de Jérusalem; Pin blanc*).

"In Provence this pine is tapped in the same manner as the maritime pine in the West, and the same products are obtained, but of less value. In general the tree is tapped when it has obtained the dimensions of 20 or 30 centimetres in diameter. If properly attended to, it will yield for 19 or 20 years 6 or 7 kilogrammes of turpentine annually per tree. The notches which are made in the bark to induce the flow of the sap are about 10 centimetres wide, and are called "surlés." Every 19 days the flow is invigorated by a small fresh cut at the upper part, until, in the course of the year, the incision or notch reaches the length of 30 centimetres. The turpentine is received in holes opened in the earth at the foot of the tree. It is known under the name of *Périme Vierge*. After preparing and cooling in cakes the resin so obtained is called "*rare.*" After exhausting the tree for turpentine, the trunk and root are distilled for tar, etc."

(To be continued.)

A NEW PROCESS FOR THE PREPARATION OF EXTRACTS WITHOUT HEAT.*

BY PROFESSOR ALPHONSE HERRERA.

Since the progress of organic chemistry has made us acquainted with many proximate principles of plants and their various properties, the processes for most medicinal preparations have been considerably improved, and diverse apparatus and methods have been designed with the view of obtaining them in a more energetic form and of preventing the alteration of the proximate principles, as well as to secure greater economy and a more convenient form for their administration. Of all the medicinal preparations none have attracted more the attention of the pharmacists than the extracts, which offer the advantage of being conveniently administered, and, if well prepared, of representing in a small bulk the properties of the drugs. By the action of heat and air the organic principles are generally more or less altered, and hence in the ordinary way of preparing extracts, the active ingredients are more or less modified, or if volatile, evaporated, and the preparations do not fully represent the drug. To obviate this difficulty, it has been proposed to evaporate the liquids at rather low temperature, and if possible excluded from contact with the air, and with these objects in view, ingenious apparatus and contrivances have been adopted,—like evaporating in many capsules heated by steam, as in the process of Henry; or keeping the liquid continually in motion to promote the evaporation, as in the process of Bernard; or effecting the concentration *in vacuo* by means of special apparatus, constructed by Laurent, Granval, Berry and others.

I do not propose to discuss the advantages or disadvantages of the different methods proposed, for they are well known. It merely remains to state that the best results have been obtained by evaporation *in vacuo*, in which process the exclusion of air and the low heat prevent any great alteration of the soluble principles; but the high price of such an apparatus is a great obstacle to its general use.

For many years, sodium chloride and ice have been employed in Europe with the object of utilizing the property of water when freezing to separate the salts which are contained in solution. In 1862 Robinet presented to the Paris Academy of Medicine a memoir, in which he demonstrated the application of this behaviour in the analysis of waters. Afterwards Mr. Ossian Henry applied it to the concentration of mineral water for the purpose of facilitating its transportation. I have utilized the same property for the concentration of vegetable juices, and, in general, of aqueous solutions of organic principles.

The results of my observations have satisfied me that, when the water partially congeals, the dissolved principles remain in solution in the mother liquors, and that two or three congelations are generally sufficient for obtaining the solutions concentrated enough to finish the extract by exposure upon plates to the heat of the sun or of a drying closet, heated to about 30° C. (86° F.) The extracts prepared by this method accurately represent the properties of the plants, and the principles which are changed by the influence of heat remain unaltered; even the volatile constituents are not dissipated, though most of the water be removed by freezing. Owing to the small cost of the necessary apparatus, it appears to me that my process for preparing extracts should be preferable even in those countries where ice is less readily obtainable than combustibles.

Extract of conium, prepared with unpurified juice by the process mentioned, has preserved the characteristic odour of conia, and by dissolving it in water I have obtained a solution exactly representing the juice of the plant in appearance and properties, and giving, when heated, an abundant coagulation, proving that even albu-

* From the *American Journal of Pharmacy*, September, 1877.

men had remained unaltered. 1750 grams of cow's milk, of 9° B., left, after three congelations, 750 grams of a liquid having a density of 14°, and by evaporation in the sun this left a dry extract of milk, which again formed that liquid on being dissolved in water. A number of other liquids, similarly treated, gave corresponding results, and it seems to me, therefore, that medicinal extracts are best prepared by congelation. It may be objected that the vegetable juices should be previously purified; but it should be remembered that coagulated albumen always encloses a considerable portion of the active principles, and that the heat necessary to effect the coagulation and the evaporation by means of a water-bath is sufficient to change many principles; also, that the extracts thus prepared are sometimes inert or less active. The careful experiments made by Orfila and the clinical experience of others demonstrate that extracts prepared with unpurified juice are stronger.

The results of the experiments just mentioned will show that my process may be advantageously used for the preservation of vegetable juices, which are obtained by dissolving the extract in sufficient water until the solution is of the same density as the natural juice. The method is also advantageous in the preparation of syrups in serving to properly concentrate the liquors from which the syrups are made.

For the extracts prepared from juices by the method indicated, the author proposes the designation of opopycnols (opopicnolées), derived from the two Greek words *οπος*, the juice, and *πυκνοω*, to condense.

In obtaining artificial extractive solutions, the process of infusion should be used, unless the active principles are sparingly soluble in water, in which case digestion or even decoction may be resorted to, but in whichever way obtained, the solutions are treated alike for preparing the extracts. Extract of rhatany, prepared by the process of congelation, dissolves completely in water, with a red colour, and has a much more astringent taste, compared with the extract which was prepared with the utmost precaution by evaporation in a water-bath. Similar comparisons were made with the extracts of catechu, aloes and others, and in all cases a very notable difference was observed, which is explained by the final evaporation in the proposed process being conducted by the heat of the sun or of the drying closet, which is insufficient to effect a change or to volatilize the volatile principles in any appreciable degree.

The apparatus employed by me is the so-called sorbetière;* for larger quantities the apparatus of Gougaud is preferable. The frigorific mixture is composed of ice and sodium chloride, or preferably of crystallized calcium chloride. After a large portion of the solution has congealed, the mass is enclosed in a cloth and subjected to pressure, the presscake of ice is broken and again pressed, to separate the mother liquor as completely as possible, and the congelation is repeated two or three times, with the precaution that it be not carried far enough to cause the precipitation of the sparingly soluble principles. The mother liquor is then put into shallow dishes and exposed to the heat of the sun or of a drying room, the temperature of which does not exceed 30° C. (86° F.) until the extract has attained the desired consistence.

In conclusion, it may be stated that the concentration of aqueous solutions by congelation appears to be preferable—

1. For the preparation of aqueous extracts in general.
2. For the preparation of syrups containing juices, in which case the concentration should be carried far enough that after mixing with the simple syrup the requisite density is obtained.
3. For the conservation of juices, and
4. For chemical analysis the process may be used with advantage.

* Similar to the apparatus used for ice-cream.

SOPHORA SPECIOSA (BENTH.).*

This newly described medicinal substance is a small red bean, irregularly oval or roundish, about one-third of an inch in length, and having a slightly bitter taste, with an after-feeling of numbness when chewed. Some of these beans have been sent to the Smithsonian Institute, at Washington, by Mr. Edmund Billinger, sen., of Texas, who stated that they were occasionally used by Indians in the neighbourhood of San Antonio, South-western Texas, as an intoxicant; that a half-bean would produce delirious exhilaration, followed by sleep lasting two or three days; and that it was asserted that a whole bean would kill a man.

Some of these beans having been sent to Professor Horatio C. Wood, of Philadelphia, he obtained other samples from Mr. Billinger, and together with the latter some of the flowers of the plant. Dr. Rothrock, Professor of Botany in the University of Pennsylvania, after an examination of the latter, pronounced the source to be the *Sophora speciosa* of Bentham.

Professor Wood has obtained a small amount of organic principle from the beans, which is extremely active as a poison, the minutest speck producing, in two minutes, almost entire paralysis in the frog. One-twentieth of a grain of a very impure specimen produced, in a half-grown cat, deep sleep lasting many hours.

As the substance is not soluble in water, but is soluble in acidulated water, and is precipitated by alkalies, and as it dissolves freely in ether, imparting to it a decidedly alkaline reaction, Professor Wood looks upon it as an alkaloid, and gives it the name *sophoria*.

The sample obtained by Dr. Wood was of greyish white colour, but he did not succeed in crystallizing either it or its acetate. Its reactions, so far as he had examined them, were as follows (the tests being made by placing a speck of the alkaloid upon a porcelain plate and applying the reagent):—

With concentrated sulphuric acid, no colour.

With chromic acid and concentrated sulphuric acid, a dirty, deep purple, passing rapidly into bright green, then into bluish, and finally into yellowish brown.

With tincture of chloride of iron, a deep almost blood red, after a time acquiring an orange tint.

With nitric acid, no colour.

With chromic and nitric acids, a very faint evanescent, reddish colour.

With nitro-muriatic acid, a dirty, reddish brown.

From the solution of its acetate, compound tincture of iodine throws down a yellowish precipitate.

The experiments, made by Dr. Wood upon lower animals, with a view to determining the effects of the remedy upon them, show that frogs rapidly lose reflex activity and power of voluntary movements. Further experiments demonstrated that this effect was due to the action of the drug as a spinal sedative, and that it had little or no effect upon either motor or sensory nerves.

Upon *mammals* the effect varies somewhat according to the dose. An amount of the extract estimated at two grains produced in a full grown cat, in one minute, marked weakness in the hind legs; in two minutes, inability to stand, with evident effect upon the respiration; in three minutes, convulsive movements, with loss of consciousness, continuing with increasing embarrassment of breathing for three minutes, when all attempts at respiration ceased. The heart kept on beating for one and a half minute longer. The pupils were unaffected at first, afterwards dilated. In small quantity the extract produces, in the cat, vomiting, great muscular weakness, profound quietude, and deep sleep lasting some hours and ending in recovery. Similar symptoms occurred in dogs. Death always took place through stoppage of respiration, In a single cardiac experiment the drug had no decided effect upon the blood-pressure until towards death, but appeared to accelerate the heart-beat.

THE CAUSE OF PUTREFACTION AND LACTIC FERMENTATION.

IN delivering the inaugural address at King's College Medical School last week, Professor LISTER adopted a novel course towards such an audience, and instead of occupying the time at his disposal with the usual recommendations to the students about to enter upon their medical curriculum, he preferred to treat of a special subject in the hope that he might be able to say something which should interest and possibly instruct his audience. The subject chosen by Professor LISTER is one that has long been of deep interest to the cultivators of several branches of science, and his own efforts to make a practical application of the knowledge acquired by studying the phenomena of fermentation have given to that subject a wider significance than it had before.

The particular kinds of fermentation which were the subject matter of Professor LISTER'S address were those which take place in blood and in milk the question to which his attention had been directed having regard to the cause of the change which takes place when either of these liquids is kept for some time in contact with the air. In the case of blood the fermentation which ensues under these conditions is of the kind termed putrefaction; in the case of milk it is characterized by the formation of lactic acid, and is consequently termed lactic fermentation. In the experiments by which Professor LISTER sought to illustrate the nature of the changes which take place in these liquids care was taken to collect both the blood and milk in such a manner as to exclude the access to them of living organisms. It is unnecessary here to enter upon a description of the precautions observed to attain this result, the important fact being that blood so collected had been kept for six weeks without undergoing putrefaction, and that the air in contact with it was quite sweet. From this observation Professor LISTER inferred not only that blood has no inherent tendency to putrefy, but also that atmospheric oxygen is not capable of causing it to putrefy as has been supposed. Some kind of action was exercised by the oxygen upon the blood, as was indicated by the change of colour from that peculiar to venous blood to the crimson colour of arterial blood, but it was not until the blood thus preserved had been touched with an extremely minute quantity of putrescent blood on the point of a needle that putrefaction commenced.

The result in this case was exactly parallel to that which takes place in alcoholic fermentation, and the inference is that putrefaction is in fact a kind of fermentation characterized, like the alcoholic fermentation, by the reproduction of the ferment by which the change is produced.

As is well known there is a conflict of opinion on the point whether the bacteria which are unquestionably constant concomitants of certain kinds of fermentation are also the cause of the change or merely accidental. It was suggested by Professor LISTER that one of the causes of doubt as to the influence of bacteria in causing fermentation is the extreme minuteness of these organisms.

With the object of investigating this question more fully, experiments were made with another form of fermentation, that of milk, which on exposure to the air turns sour and curdles; the sugar it contains being converted into lactic acid. At the same time microscopic observation always reveals the presence of minute organisms of the nature of bacteria in the coagulated milk. By collecting a number of samples of milk in separate glass vessels, with suitable precautions to prevent the access of organisms, the milk in a few of the glasses was found, after some weeks, to be entirely free from change, destitute of any acid reaction, and under the microscope no indications of the presence of bacteria were to be found.

The next step in the investigation was to find evidence to decide whether the particular bacterium found in sour milk was or was not the cause of the lactic fermentation. For this purpose, Professor LISTER endeavoured to estimate the number of bacteria in a given quantity of sour milk by placing one-fiftieth of a minim of the milk on a slide, and counting the number of bacteria in the field; then by diluting the milk to such an extent that a single drop of the liquid would probably contain, on the average, one bacterium, a liquid was obtained, with which a number of separate quantities of boiled milk were inoculated by adding a single drop of the liquid. The result was that out of five glasses of milk treated in this way only one curdled, and on examination that one was found to contain the bacterium lactis, while the four others, which did not curdle, had no bacteria in them.

In another series of experiments, five specimens of milk were each inoculated with a drop of the liquid calculated to contain two bacteria; other five specimens were inoculated with drops calculated to contain one bacterium; another set of five open glasses were inoculated with drops calculated to contain one bacterium; and one with a drop calculated to contain four bacteria. The result was that the last specimen curdled in a few days, and all those calculated to have two bacteria curdled in a few days.

Of the five glasses calculated to have one bacterium, three remained liquid. On opening one of these glasses the milk was found to be perfectly sweet; it had a slight flavour of suet, similar to that which PASTEUR has described as resulting from the oxidation of the oleaginous constituent of milk.

The result of these experiments proves conclusively that the ferment which caused the curdling of the milk was not in solution but in the state of suspended particles, otherwise every drop of the inoculating liquid should have produced the same result. Again, the fact that some drops were destitute of the ferment proves in like manner that it was not in solution.

AMMONIACAL FISH.

A CORRESPONDENT of the *Lancet*, who professes to have a partiality for the skate, tells how he was recently not only disappointed with his favourite dish, but almost suffocated also by the pungency of the ammoniacal vapour evolved when the fish was placed upon the table. Evidently this gentleman's piscivorous propensities have not yet become fully developed, or they suffer from imperfect training, for we have it on authority that this ammoniacal peculiarity is considered by certain *gourmets* to be the crowning excellence of the skate, so much so that they do not eat the fish until it has become sufficiently odorous to be smelt from one end of a ship to the other. However, it will be remembered that a few years ago, a prominent pharmacist, Mr. T. B. GROVES, also failing to appreciate this choice perfume, took his revenge by submitting the fish to distillation with water, and this wrung from it a considerable quantity of trimethylamine, a body which was just then more talked about than it is now.

UNIVERSITY COLLEGE, BRISTOL.

WE have been favoured with a copy of the Calendar of this new educational institute for the West of England, and are glad to notice that some of the arrangements are favourable to the promotion of local pharmaceutical education. During the forthcoming session there will be a course of day lectures on Inorganic Chemistry, and another on Organic Chemistry. The Laboratory will be open daily for instruction in Practical Chemistry. There will also be a course of evening lectures on the Principles of Chemistry and the Non-Metallic Elements, and it is further proposed to form a Practical Class for instruction in Qualitative and Quantitative Analysis, to meet on two evenings a week in the Laboratory. The Professor of Chemistry is E. A. LETTS, Ph.D., F.R.S.E., and the Lecturer is W. W. J. NICOL, M.A. A Botany class will commence after Christmas, to be conducted by Mr. A. LIEPNER; Materia Medica will be taught at the Bristol Medical School, which is in connection with the College.

Detailed information respecting the fees, etc., is given in the Calendar, copies of which may be obtained from Mr. EDWARD STOCK, Secretary to the College.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The annual meeting of the twenty-eighth session was held at the Royal Institution, September 27, 1877.
