In the unavoidable absence of the President, Mr. A. H. Mason, F.C.S., Mr. Edward Davies, F.C.S., was voted to the chair. The minutes of the concluding ordinary meeting were read and confirmed.

Mr. Alfred Scott was elected an associate. The Hon. Sec., Mr. Thomas Williams, F.C.S., read the following report of the Council for the past session:

ANNUAL REPORT, TWENTY-EIGHTH SESSION.

"At the termination of the official year, your Council have pleasure in presenting the twenty-eighth annual report of the proceedings. The prosperous working of the Liverpool Chemists' Association has seldom been more marked than at the present time.

"Your Council have elected John Williams, Esq., F.C.S., etc. (President of the Pharmaceutical Society of Great Britain), an honorary member of the Association.

"During the session fourteen members and five associates have been elected, four members and three associates have resigned (owing to removal from the town and inability to attend the meetings) and two members have died, leaving the numerical strength of the Association at the present time 150, comprising 17 honorary members, 122 members, and 11 associates.

"Your Council desire to pay a tribute to the memory of the late Mr. Martin Murphy, F.C.S., whose contributions to the Association, and whose ability in discussions, have done much to maintain its scientific standing. A vote of condolence passed in Council, including that passed at a general meeting, has been duly acknowledged and appreciated by his widow and family.

"Your Council provided a course of lectures in chemistry and in botany; but it is still a matter of regret that the School of Pharmacy does not receive that support from the students in the town and neighbourhood which it deserves. Mr. Thomas Williams, F.C.S., the teacher of chemistry, reports that eight students entered for his classes; their attendance and progress were satisfactory. Five consented to enter into a competitive examination, but when the necessary arrangements for holding this had been completed, it was found that the majority of the candidates had gone to other towns and could not meet together. Two students only attended the botany classes which were held in conjunction with the Liverpool School of Medicine. Lecturer—Dr. Carter, B.Sc., LL.B., M.R.C.P. Lond. Arrangements have been completed for the coming session, in accordance with the notices already circulated, and your Council hope that the next session of the Liverpool School of Pharmacy may be more successful than of late years, and that employers will stimulate and enable students to avail themselves of the privileges offered.

"Your Council desire to acknowledge with thanks the kindness of Professor Attfield in supplying the examination papers.

"During the past session twelve papers have been read on subjects of interest to scientific chemists and pharmacists. The originality and importance of these papers, and the practical discussions which followed, bear very favourable comparison with those of any previous session.

"The 'Miscellaneous Communications' have been numerous and instructive, and give evidence of life in the Association.

"The average attendance at the meetings has been good, and shows increasing interest in the prosperity of the Association.

"The library has been enriched by several additions, including the usual scientific periodicals; and your

Council desire to acknowledge their obligation to Mr. Abraham for his handsome donation of Howard's 'Quinology of the East Indian Plantations.' A revised catalogue has been prepared, and will be distributed gratuitously to the members on payment of the subscription for next session.

"Arrangements have been made for renewing a portion of the museum. Applications made to some of the leading manufacturers of chemicals have met with a liberal response, and several new specimens will shortly be laid before you.

"It is a matter for congratulation that your thirteenth conversazione, held during the past session, proved so successful. Perhaps on no previous occasion have more of your members and friends assembled to participate in the enjoyment which these scientific entertainments afford. The principal exhibitors and demonstrators during the promenade were, Messrs. T. F. Abraham, J. Abraham, J. T. Armstrong, J. Andrew, G. F. Chantrell, E. Davies, J. H. Day, Charles Jones, A. H. Mason, J. T. Moore, A. H. Samuel, C. H. Stearn, and Dr. Symes. The following firms contributed objects of scientific and artistic interest for exhibition:—Messrs. Abraham and Co., Brown, Barnes, and Bell, Chadburn and Sons, Doulton and Co., Elkington and Co., Fearnall and Co., Symes and Co., etc.; and Mr. W. E. Bickerdike, F.C.S. (of Church), delivered an interesting popular lecture, illustrated by very successful experiments, on 'The Atmosphere.' Your Council desire to acknowledge their high appreciation of the gratuitous services of these gentlemen, and are the more encouraged for the future from the fact that the ultimate result proved the conversazione to be financially self-supporting.

"In compliance with an invitation, your Council appointed Messrs. Mason, Shaw, and Symes, as delegates to the British Pharmaceutical Conference, held at Plymouth.

"Your Council regret that the members have not more generally availed themselves of the opportunities for obtaining information which the Question Box affords; and they hope that this method of providing discussion will receive more support in the coming session; the admissibility of the queries being subject to the ruling of the President.

"The ballot for the appointment of President for next session resulted in the unanimous election of Mr. Thomas Fell Abraham, A.A.

"The following members of Council retire by rotation and are eligible for re-election:—Messrs. Abraham, Redford, Shaw, and Sumner.

"Your Treasurer will present a report of the finances of the Association, which shows a credit balance of £6."

The Hon. Treasurer, Mr. Robert Sumner, read the financial report, which showed that the expenditure during the year had been £47, and the receipts £49 16*s.* 5*d.* and that there was a balance in hand amounting to £6.

Mr. John Abraham moved:—"That the reports as read be adopted, and, together with the list of members and abstract of proceedings of the past session, be printed and circulated among the members." He said he could not let that opportunity pass without congratulating the retiring President, Mr. Mason (who, he regretted to say, was absent that evening through illness) upon the satisfactory state of the Association. Mr. Mason had presided over the Association for three consecutive sessions in a most creditable manner, and the success which had attended his skilful management of its affairs deserved the warmest thanks of the members.

Mr. A. E. Tanner seconded the motion, which was carried unanimously.

The meeting then proceeded to the election of four members of Council. Messrs. Abraham, Redford, Shaw, and Sumner were unanimously re-elected.

Dr. Charles Symes moved "That the best thanks of this meeting be given to the donors to the library and museum, and to the authors of papers during the past session."

Mr. Redford seconded the motion which was carried unanimously.

Mr. G. H. Damsell proposed "That the best thanks of this meeting be given to the officers and Council for their services during the past session."

Mr. Arthur Haddock seconded the resolution, which was carried unanimously.

Mr. Edward Davies, F.C.S., in highly eulogistic terms moved "That a special vote of thanks be conveyed the retiring President for his valuable services rendered to the Association during his three years of Presidency."

The Hon. Treasurer, Mr. Robert Summer, expressed the warmest satisfaction in seconding the motion, which was carried by acclamation.

A cordial vote of thanks to the Chairman brought the meeting to a close.

HULL CHEMISTS' ASSOCIATION.

The winter course of lectures on chemistry, in connection with the above Association, was inaugurated on Wednesday evening, September 26, at the Laboratory of the Lecturer, Mr. James Baynes, jun., F.C.S., Borough Analyst, in Scale Lane. More than the average number of students have entered, and it is hoped that the session will be a thorough success.

Mr. C. B. Bell, President of the Association, introduced Mr. J. F. Smith, the Vice-President, who delivered the following address:—

"Gentlemen,—In the address I have been requested to make, I wish to bring before you the necessity of determined and continuous study on the part of all connected with our trade, and especially of you students, who are, as it were, just commencing the race of life. It is only by such means that it is possible for us to keep fairly up with the time in the science of chemistry, of which you to-night begin a new course.

"I notice that three or four classes for the study of this science are placed before the general public by various educational bodies in the town, so you will see by this that we, as chemists and druggists, cannot afford to stand idle in such matters, for if we do, we shall, I am afraid, soon lose the confidence of our customers, or at any rate, of such of them as may have any knowledge of chemistry, and the number of these must become larger every year. I cannot conceive anything more calculated to make a chemist look foolish than having questions connected with his trade put to him by a customer, which he is unable to answer, besides the loss of self-respect such a thing must entail on himself. You may be sure that the customer thinks very much less of him than he did before. Such questions will naturally be more frequently asked of us as the science of chemistry is studied by the general public. There are, however, much higher and more exalted reasons why we should study thoroughly those branches of science which are inseparably connected with our trade; one, a desire that I hope is implanted in all of us, of improving and enlightening our own minds; another, and, in my opinion, a most important one to us, as chemists, is that, without such knowledge, we are totally unable to do our duty to our customers, especially to those presenting prescriptions for preparation, and also to the writers of the prescriptions.

"No doubt those of you who have been connected with the trade any time, have seen instances in which it would have been very dangerous for the patient to have taken medicines that might have been dispensed to them but for the chemical knowledge of the dispenser to whom it was presented; several such cases have come under my notice.

"As one of the examiners of this class for the past two years, I was glad to notice the very evident progress made during the last session. Mr. Stoakes, my co-examiner, and myself were greatly pleased with the quality of the papers, compared with those of the previous session, and I congratulate Mr. Baynes on the success which has attended his teaching. I must also express the hope that in the session now commencing you will take "Progress" for your motto, and reflect credit on yourselves and your teacher.

"The advantages afforded you in this course are very great, as in addition to the evening lecture, I understand that Mr. Baynes allows you the free use of his modern and most convenient laboratory, for which liberality he deserves the thanks of the committee and of yourselves; the fittest manner in which you can evince your gratitude for these advantages is by doing justice to your teacher, and taking care that each of you competes for the prizes offered at the end of the session, for although you cannot all obtain prizes you can each prove that you have thriven earnestly and done good honest work.

"Before I conclude allow me to say how very desirable it is that you should not sit down contented on succeeding in passing the Minor examination; it is as you all know the qualifying examination, and is without doubt an efficient test of a man's knowledge, but I would earnestly exhort you not to content yourselves with passing the qualifying examination, but by overcoming the higher voluntary examination place your names on the register of pharmaceutical chemists."

The President proposed a vote of thanks to Mr. Smith for his excellent address, which was seconded by Mr. Luslett (a student) and carried.

Mr. Baynes hoped that the students would be punctual in attendance, and it would be better to endeavour to be present ten minutes before the time than to come in a little after the lecture had commenced. He urged all to take notes during the lecture, and to read up the subjects at home. He also offered the use of his laboratory, as well as to assist those who would make use of it. He would give a prize to the student to attended most regularly, his position on the list at the examination being taken into consideration.

ABERDEEN SOCIETY OF CHEMISTS AND DRUGGISTS.

A meeting of the Society was held in the Rooms, St. Nicholas Lane, on Thursday the 4th inst., for the purpose of receiving the reports of the Library Committee and the Committee appointed to consider Mr. Paterson's motion on April 19th last. Mr. Cruickshank, President, in the chair. Minutes of former meeting were read and confirmed.

The Secretary then laid on the table the report of the Library Committee, stating that the Committee had sanctioned the purchase of a list of books to the extent of £5 sterling, the amount voted for that purpose at last meeting. The Committee also suggested that if members of the Society possess any suitable books, which they would be willing to present to the Library, the books would be very thankfully received by any member of the Committee. The report was adopted, and, on the motion of Mr. Paterson, a vote of thanks was passed to the Committee.

Mr. Paterson then laid on the table the following report of a Committee:—

"Your Committee have to report that they have taken steps to ascertain the feeling of the assistants and apprentices as to coming into closer relationship with this Society. It was explained to them that while the Society would retain the full power of the funds and transact its ordinary business as usual, yet, that any subscription received from them would be applied as far as practicable in increasing the library or in promoting lectures of interest to the trade. That in order to induce them to take an interest in the Society, a joint Committee, from the Society and the assistants and apprentices associating themselves, should be formed to arrange for lectures and any other object in which they are jointly interested. The Committee understand that at a pretty fairly attended meeting of the assistants and apprentices the proposal was warmly taken up. They would recommend that a body of associates be formed in connection with the Society, and that assistants contributing 5*s.* per annum, and apprentices 2*s.* 6*d.* per annum, be admitted associates thereof."

The matter was remitted back to the Committee, and in the meantime the Secretary was requested to send a copy of the report to the representative of the young men and inform him that the Committee would be most happy to meet with the assistants and apprentices on Thursday (Oct. 11), to discuss the matter and form a joint Committee to make further arrangements as contemplated in the report.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Tuesday, October 2, a lecture was delivered at the rooms of the above Association, Halford Street, by W. J. Harrison, Esq., F.G.S. Subject, "Fermentation." Mr. W. B. Clark occupied the chair.

After a few introductory remarks by the chairman, Mr. Harrison proceeded to notice the amount of knowledge possessed by the ancients with regard to alcoholic fermentation; also the process of brewing in this country and upon the continent. Yeast and other ferments were then described. The lecturer also referred to the germ theory and the use of carbolic spray by surgeons during surgical operations.

The lecture was listened to with great interest and pleasure, and at the close a vote of thanks to the lecturer was carried unanimously.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Concluded from page* 255.)

The last paper read was on—

Effects of Variations of Temperature on Boiled Putrescible Liquids.

BY W. WILLMOTT.

The experiment which has been devised to solve the question of the possibility or otherwise of life being evolved from dead matter, is of a very comprehensive character. The question itself is of the deepest interest, not only to the scientific physician, but to the chemist, the physicist, and, perhaps, above all, the biologist. As a matter of speculative thought, it dates far back into the past, and as one of scientific investigation it has received the attention during many generations of "an almost unbroken succession of inquirers." Two hypotheses are held respecting it: "One, the germ theory, which declares that no life has ever been evolved (except in the remotest periods of the earth's history) otherwise than from a living parent or a living germ; the other, the spontaneous generation theory, which declares that now, as of old, life does also spring *de novo* from molecular rearrangements of the atoms of dead organic materials."

To test the truth of one or other of these hypotheses, we are told "there is absolutely nothing to be done but to take dead matter, isolate it from all contact with life, place it under favourable conditions for development, and watch the result;" and yet it is said, "this task has seemed to defy the efforts of as keen a body of inquirers as ever attacked any problem of nature."*

The method of experimentation almost uniformly adopted involves the employment of certain putrescible infusions or other liquids in which bacterial life in its many forms is well known to appear in conjunction with any fermentation or putrefactive change which such liquids may be allowed to undergo. The behaviour of

* *Vide* very able article by "Inquirer," in the April number of the *Contemporary Review*.

the freshly prepared fluid after it has been submitted to a boiling heat and protected, by one of many well devised methods, from fresh sources of life in the surrounding atmosphere, is carefully noted. If bacteria* make their appearance it is conjectured that they must have arisen *de novo* from the supposed dead organic material of the infusion. The question is simple in statement, but, nevertheless, is beset with difficulties, which are not unfrequently of an embarrassing character. Of the many eminent experimenters who have recently devoted their earnest attention to the subject, "by far the most conspicuous" is Professor Tyndall. He has gone over the ground so much in detail, and subpœnaed so curious a "cloud of witnesses," that some danger has been incurred of the investigation passing from the sublime to the ridiculous. In his laudable desire to grasp the whole truth he has multiplied and repeated his experiments, with a great variety of putrescible substances, almost *ad infinitum.* Thus we find amongst the number operated upon, infusions of "mutton, beef, pork, hay, turnip, sole, haddock, codfish, salmon, turbot, mullet, herring, eel, oyster, whiting, liver, kidney, hare, rabbit, barn-door fowl, pheasant, and grouse." And all this to show that putrescible fluids, when once sterilized and properly protected from the floating dust *(i.e.,* the germs) contained in the air, are incapable of spontaneously generating life in any form.

But Professor Tyndall's results are by no means unreservedly accepted, and the objection is entertained that he denies the conclusions of other investigators "mainly on the strength of his own unconfirmed experiments." It was this consideration which, in part, induced me to branch off from the inquiry I was, some time since, pursuing, to supply, so far as the means at my command would permit, a corroboration or the reverse of the Professor's ably achieved results. The introduction of an entirely different method of procedure might, as I thought, possess some value, whilst the experiments, if reduced to the utmost possible simplicity, would probably not be without their due weight in the balance. The *Pharmaceutical Journal* (Feb. 19, 1876) significantly refers to *temperature* as being an important consideration in this inquiry.† That it is so in the highest degree there cannot be a doubt, and indeed without a due regard to this point experiments are of little value as indicating perfectly reliable results. The three temperatures, or ranges of temperature, which I have chiefly employed for working out my conclusions are the following:—130° to 160°, 90° to 110°, and 60° to 80°, all on the scale of Fahrenheit. At each of these ranges a different result is often obtained with the same infusion, and it is desirable, therefore, to connect them all closely with the inquiry.

With regard to the microscope, where such aid has been thought necessary, I have been fortunate enough to receive the assistance of a gentleman who for many years past has made microscopy his special study; and I am much indebted to him for the great service he has rendered me. The microscope, in this inquiry, is an all-important auxiliary, though in the majority of instances the unassisted eye will suffice to determine the question of life or no life.

We have spoken of numerous well devised methods for the purpose of protecting or isolating the prepared fluid after it has been boiled a sufficient length of time. It matters little which of these methods is selected, provided the operation is adroitly performed, for when the fluid is completely sterilized they will all be found sufficiently perfect to keep it so. It is quite probable, if indeed there is any difference at all in their value, that, by a sort of paradox, the worst may be the best, since, if the fluid is *not* sterilized, its condition of vitality will be thereby the more readily manifested. This, then, is one of the chief points to be determined. Is the liquid, after experiment, completely sterilized or only partially so? Much misconception has, I think, arisen from an insufficient consideration of this particular feature in the inquiry.

After a number of experiments with cotton wool, an old but efficient medium in completely arresting germs and ultra-microscopic particles, I found that in the apartment in which I was working, my specimens were by this process completely preserved; but on submitting others similarly prepared to a high incubating temperature, viz., 90° to 110° F., they broke down without exception in a very decided manner. I may state here that, at this temperature, protected infusions which are not sterilized usually begin to change within twelve hours, and whenever they are found intact at the close of the third day, almost invariably remain so for an indefinite period of time. Many of my specimens protected with wool, have evaporated to an extract without the slightest putrescent change.

On seeing the effect of the higher temperature on the prepared infusions I was in doubt as to the power of the cotton wool sufficiently to filter the air; but on substituting pear-shaped flasks for the form of vessel I was using, the effect was entirely reversed. All the infusions remained sound, and there was not a single delinquent amongst them. From pear-shaped flasks I soon passed to conveniently shaped bottles; for I had no intention of departing from the plan, which I had from the first adopted, of boiling the liquids in an open vessel of a suitable construction. Later on, I employed tinfoil almost entirely in the place of cotton wool, finding its preparation for the purpose intended far more rapid and convenient.* Thus my process was extremely simple, and I think wholly to be depended upon when carefully performed.

I had experimented in this way on hay, gentian, calumba, and also turnip. The next substance to be dealt with was cucumber. This was one of the most refractory of all Professor Tyndall's "witnesses," because of its great proneness to decomposition. I took, therefore, unusual care in preparing the specimens, using glass stoppers and cotton wool as protecting media, the former having been specially made for me with tapering points, so as to admit of their introduction into the neck of the bottle without even the smallest modicum of air.† Though one minute only was allowed as the time of boiling, the specimens remained perfectly pellucid, and without the slightest indication of change. It is fair to say that magnesium carbonate, and not potash, was here used as the neutralizing agent; and this I subsequently found to be a method of treatment to which cucumber is in a very marked degree amenable.

From this point I passed on to *old* hay and soon encountered my first real difficulty. There could be no

* "Bacteria" is a very convenient term, including numberless forms of animalcules belonging to the "Infusoria."

† "The range of temperature in Professor Tyndall's experiments was less than that directed by Dr. Bastian in the 'Beginnings of Life.' Whatever may be the actual value of this difference it is unfortunate that it should have existed."

* To make this material secure, as it is apt to be perforated with minute pin holes, a sheet of tinfoil is brushed over with a thin coating of mastic varnish. On this is laid a covering of waxed paper, and another sheet of varnished foil being then placed smoothly on the paper, the whole is introduced into a powerful press, and by this means firmly united together. The sheets thus prepared are as impervious to the atmosphere as glass itself. The precaution is not really necessary if the foil be used doubled, but its adoption will serve to dispel all doubt. Though this process does not admit of a complete vacuum between the surface of the liquid and the tinfoil, the air is quite sufficiently excluded to render it in this respect entirely free from objection. The danger resides more in the liquid itself than in the air above it.

† It is well known that at ordinary temperatures boiled infusions may be perfectly preserved by means of glass stoppers.

possible mistake about *the age* of the sample (1874) I was fortunate enough to secure. It will be remembered that it was *old* hay which caused such an infinity of trouble at the Royal Institution, and so infected the atmosphere with its germs that it was only by "the gradual but irresistible interaction of thought and experiment" that the true cause of the many failures experienced was at length brought to light. In dealing with this substance, therefore, I was specially careful to avoid accidental error in isolating the specimens. Several of these, prepared with slight differences, were placed in the usual temperature, and all broke down within twenty-four hours. The same thing was repeated with additional precautions and again every specimen broke down. I now became very much interested in the old hay, and my next plan of procedure was to submit it to the vapour of a powerful germicide for twenty-four hours; but this proved of no avail, the infusions broke down as badly as before. I then tried careful filtration through various media. This effected some good but was not entirely successful. The hay was next subjected, in its dry condition, to a high temperature for several days. There was evidently an improvement after this, though bacteria still continued to put in an appearance. What, then, was to be done? Long periods of boiling were not to be thought of, but if an agent could be found which would suspend putrefaction in the liquid and yet entirely pass off without causing any change, the germs might, in due time, become "softened," and the five minutes' boiling accomplish the rest. Such an agent was to be found in chloroform. Chloroform is one of the most perfect antiseptics we possess, but it does not kill the germs or destroy the putrescent tendency of the infusion. Accordingly, a suitable quantity of the latter containing two minims of chloroform to each fl. oz. was prepared and placed in the incubating temperature for a week. It was, of course, at the end of that time, in perfect condition; a small portion protected with wool gave way as soon as the chloroform had passed out of the fluid, showing that the infusion was not changed in any way. Protected specimens of this preparation were tried as before but altogether without success. The theory of *softening*, even in a warm temperature, received no illustration or countenance from this experiment, so that the question forces itself upon the mind, is it a particulate germ at all which causes putrefaction? If so, it must be of remarkable tenacity since it may be asphyxiated indefinitely by the chloroform without being softened in the slightest degree by the heated fluid.

How, then, was the old hay conquered? The infusion was boiled for one minute and placed in a *continuous* temperature ranging from 130° to 160° Fahr. At the end of a week it was removed and the whole thing was accomplished. As the organisms became developed, or, in fact, before this occurred, they were summarily disposed of by the heat, the infusion being thereby left in a permanently pellucid condition.

But after this success, I found on further trial with other substances, that my previous results were not again obtainable. This was precisely an analogous case to that of the Royal Institution. I commenced, therefore, a systematic attempt better to understand the conditions which governed these erratic changes. A great deal had been said about *potash*. What was the real part played by this substance in the production of the observed results? The experiments as shown in the following table gave me the answer:—

Infusion.	Time of Boiling.	Quantity of Liq. Pot. to ℥j.	Reaction.	Temp.	Result.
Cucumber.	1 min.	None.	Acid.	95° to 110° F.	Broke down within 48 hours.

* Contradictory Result.

Here, then, seems to be revealed the whole secret of the potash. If the fluid is completely sterilized, it is perfectly immaterial how much or how little potash is added. On the other hand, if the potash is added in sufficient quantity to prevent the fluid from becoming acid, it is of no consequence whether it is sterilized or not. The action is perfectly consistent throughout. The potash simply plays the part of an efficient antiseptic. Like all substances of this class, the effect it produces bears an exact relation to the quantity used.

The following table shows the wide difference in effect between a temperature of 70° F. and 100° F., in relation to bacterial development:—

No. 1. TEMPERATURE, 70° Fahr.

Infusion.	Time of Boiling.	Result.
Turnip.	1 minute.	Slightly cloudy.
,,	2 ,,	Clear & pellucid after a month.
,,	3 ,,	Do. do.
,,	4 ,,	Do. do.
,,	5 ,,	Do. do.

No. 2. TEMPERATURE, 100° Fahr.

Infusion.	Time of Boiling.	Result.
Turnip.	1 minute.	Broke down within 48 hours.
,,	2 ,,	Do. do.
,,	3 ,,	Do. do.
,,	4 ,,	Do. do.
,,	5 ,,	Do. do.
,,	6 ,,	Do. do.
,,	7 ,,	Do. do.
,,	8 ,,	Do. do.
,,	9 ,,	Do. do.
,,	10 ,,	Remained Intact.

The above seems to show that error may be caused by concluding that an infusion is sterilized because it remains pure at certain temperatures. Unless protected infusions are submitted to a temperature of 100° to 110° F., they can scarcely be said to have undergone the severest test of their assumed sterilized condition.

We now return for a moment to the old hay. In order definitely to test the question of infection of the air by hay particles or germs, Professor Tyndall had a shed erected on the roof of the Royal Institution. In this shed infusions were prepared precisely as before, but the experiment, we are told, resulted in complete failure.* The shed was then disinfected, the infusions were again prepared, suitable clothes were worn, and "the result was similar to that obtained at Kew, viz., organic liquids which in the laboratory withstood two hundred minutes' boiling were rendered permanently barren by five minutes' boiling in the shed." A rod thirty feet in length would stretch from the infusions in the shed to similar infusions in the laboratory. "Either," says the Professor, "we infer that at one end of the rod animal and vegetable infusions possess a generative power which at the other end they do not possess; or we are driven to the conclusion that at the one end of the rod we have infected and at the other end disinfected air." I cannot say that I am prepared to accept unreservedly either of these inferences. The professor had at one end of the rod a powerful weapon which he did not possess at the other, namely, carbolic acid. Carbolic acid is not only a disinfectant, it is a powerful antiseptic. Organic liquids placed sufficiently long in the vapour of this antiseptic would absorb it and thus become preserved. To test this I made a somewhat similar experiment. The floor and walls of a small room a few yards distant from the laboratory were well washed with a 2 per cent. solution of carbolic acid, the odour of which was perceptible in the air of the room for several days. In a small box or chamber, protected by cotton wool, were placed tubes of cucumber and turnip infusion, the whole being left in the room charged with the carbolic vapour. In six days the tubes were removed from the box, and it was quite evident from their sound condition, as well as from their subsequent behaviour, that sufficient acid had been absorbed to render it highly probable that, under favourable circumstances, a condition of permanent stability would be thereby imparted to them. I do not offer the foregoing as an explanation of the wide difference experienced at the two ends of the hypothetical rod, but simply as a third inference arising out of the circumstances of this particular experiment. Whether in my own case, the hay dust was capable of infecting the air and contaminating the infusions I was preparing, it was my special care to determine by actual experiment. Taking, on several occasions, cucumber and turnip infusions of a strength known to be sterilized by five minutes' boiling, I placed them in wide open vessels in a confined space in which old hay had previously been shaken. After twelve hours they were boiled and protected in the usual way and almost uniformly foreign organisms were developed. I now applied the same process to a fair sized room. Hay was tossed and shaken in this room until there was a perfect haze of dust. The next day nothing could be seen of this dust in the air, but it had not all fallen. Infusions were prepared in the room and clearly developed the organisms, though not so extensively as in the former experiment; indeed, one specimen which was not submitted to the high temperature remained free from all signs of life. Where this infection ends it is not easy to say, but I am disposed to think it does not extend very far. Infusions prepared in the same room a day or two later became very slightly cloudy, but otherwise remained intact, though the same dusty garment was worn by the operator. Nor does this hay infection appear to resist determined treatment. Twenty minutes' boiling, or very careful filtration specially conducted, will destroy or remove the "plague" if it has not removed itself by falling to the ground. This I give as my experience.

* See *Nature*, June 14th 1877, p. 127.

There can be no doubt that many circumstances combine to influence the erratic and often unaccountable behaviour of these vegetable organic fluids. Among them may be enumerated the following:—(1) Condition and age of the substance employed; (2) strength of infusion; (3) method of filtration; (4) insolation, or exposure to the sun's rays; (5) chemical constitution; (6) time and manner of boiling; (7) temperature previous to protection; (8) temperature after protection; (9) method of isolation; and (10) completeness in the performance of the process involved. We have already referred to the *strength* of infusions as influencing their sterilization, and amongst the causes enumerated above this is a very prominent factor. Five minutes' boiling will usually be found sufficient if the strength is regulated accordingly. I give the following as proportions from which, *cœteris paribus*, something approaching uniform results may be looked for:—

Infusion.	Strength Employed	Time of Boiling.	Temperature.	Result.
Cucumber	ʒij in ℥j	5 minutes	90° to 110° F.	Breaks down.
,,	ʒj ,, ℥j	,,	,,	Remains intact.
,,	ʒss ,, ℥j	,,	,,	,,
Turnip	℥j ,, ℥j	,,	,,	,,
,,	℥ss ,, ℥j	,,	,,	,,
,,	ʒij ,, ℥j	,,	,,	,,
Old Hay	1 oz.,, Oj	,,	,,	Breaks down.
,,	½ oz.,, Oj	,,	,,	Remains intact.
,,	¼ oz.,, Oj	,,	,,	,,

If, on the other hand, we take strong or refractory infusions, and direct our attention to the time of boiling required to sterilize them, we may regard the following as starting points from which we may branch off into more exact experiment:

Infusion.	Relative proportions as protected.	Temperature.	Time of boiling required for sterilization.
Cucumber.	1 oz. to 1 floz.	95° to 110° F.	Within ½ hour.
Turnip.	1 oz. ,, 1 floz.	,,	,, 10 minutes.
Old Hay.	4 oz. ,, Oj	,,	,, ½ hour.
Cucumber charged with old Hay dust.	½ dr. ,, 1 floz.	,,	,, 20 minutes.

We may observe that particularly strong infusions are sometimes sterilized with greater facility and in less time than those prepared in a weaker form. A good example of this is turnip, which when prepared in the above proportions may usually be sterilized without difficulty by five minutes' boiling; and this, moreover, even if prepared in an atmosphere charged with hay dust, provided the filtration be conducted away from the compartment so infected. The reason is that the particulate matter is very perfectly retained by the pulp, leaving a brilliantly clear liquid, which is specially free from motes and ferments of a solid character.* Thus we may, by repeated and continuous experiment, reduce all this apparent contradiction to something like law and order. At present, the operator is puzzled beyond measure by the erratic behaviour of his prepared fluids under varying circumstances of a scarcely appreciable character, from causes which he can neither see nor grasp. But one thing seems clear. A putrescible infusion in which the ferment has once been destroyed by heat, is deprived of the ability to undergo in itself those chemical changes with which low forms of life are so abundantly associated.

Before leaving the class of experiments which has received such marked attention from Professor Tyndall, we note that, referring to the germs of old hay, he remarks with very laudable concern, "It is a question of obvious interest to the scientific surgeon whether those powerfully resistant germs are amenable to the ordinary processes of disinfection. How would they behave in the wards of a hospital?" This, I think, is not a difficult question to answer. They would behave very much as they behaved in the Professor's own shed, that is, they would be rendered harmless by the disinfectant if it happened to be present in any appreciable quantity. To illustrate this, the following experiment was made:—Old hay was cut very fine and introduced into two separate wide-mouthed bottles. The bottles were then shaken so that the dust from the hay, in quite a cloud, might completely fill them. Infusions boiled one minute only were introduced into the midst of the dust in open vessels resting on the solid hay. In each bottle was placed a small quantity of cotton wool moistened in one case with carbolic, and in the other with sulphurous acid, so that the vapour might distribute itself through the fine particles of dust which were of course fast falling into the infusions. Let us suppose the bottle to be the ward, the infusion the susceptible patient, and the dust-laden air the medium through which the disinfectant was distributing itself and exerting its influence. Now, did the infusions change and putrefy or did they not? They did not, and they remain in each case clear and translucent to the present day; not because the desiccated germs were destroyed by the disinfectant, but because the penetrating vapours were absorbed by the liquids and exerted their antiseptic properties. Disinfectants are not all antiseptics, and *vice versâ*, but here they combine the two effects. The favourable conditions, however, of this experiment could not be secured in a hospital ward, since they would be interfered with by the currents of air passing through the ward from the open doors and windows; but the good to be derived from carbolic acid *dressings* is already achieved to the fullest extent.

Speaking purely from a chemical point of view, it is a question for the scientific surgeon whether obstinate and fœtid wounds would not heal rapidly in a high and antiseptic temperature, such as 130° F., where no putrefactive change ordinarily so called can go on, provided always it be possible to subject the patient, or the wound itself, to its continuous influence. The clear, smooth, and healthy surfaces of men who are constantly in the "calidarium" seem to point to good, rather than harm, from such an ordeal; and we all know the extraordinary adaptability of the human system to changes of a severe character when gradually introduced.

We now pass to "turnip and cheese." Turnip and cheese! That it should be necessary to introduce such substances into a scientific discussion! "Oh, the pity of it, Iago, the pity of it!" But thus it is, for we have here a highly nitrogenous compound exceedingly prone to decomposition. Of turnip and cheese it is said, "it is established beyond dispute that a turnip infusion with cheese dust added, will produce life after having been boiled and protected from contact with the atmosphere or anything it may contain." This is perfectly true, but as we have seen that all these things are apt to differ in their power of resisting a boiling temperature the value of the statement from its indefiniteness on this point is clearly detracted from. "After having been boiled." True, but how long boiled? This is important because amongst the compounds which seem to favour the theory of spontaneous generation, this one of turnip and cheese holds a very prominent place. Cheese *dust* is the substance mentioned, but whilst the dry powder was managed without any great difficulty, moist cheese was found to be very intractable. The latter was mixed in the proportion of 10 grs. to each fl. oz. of turnip infusion. The mixture was boiled five minutes and then carefully filtered. The filtrate was opalescent and charged with casein. When this was boiled and placed as usual in the incubating temperature it could not be preserved, but, on the addition of liq. potassæ, q. s., to prevent the separation of the casein, or to hold it in solution, there was no apparent change. Here, again, we have the potash showing itself antagonistic to germ life and development. Ultimately this obstinate mixture of turnip and cheese was successfully dealt with, as in the case of the old hay, by placing it in the extreme high temperature (130° to 160° F.) for six days. When removed it was found free from change, having acquired a condition of permanent barrenness.

We have, lastly, to deal with a fluid which has very recently been the subject of dispute between Dr. Bastian and M. Pasteur. The fluid in question, viz., urine, is a highly complex chemical compound and, therefore, imparts to the inquiry a purely physico-chemical character. The difference betwen the two philosophers named, has reference to the production of life in this fluid after it has been boiled and neutralized with potash. The former asserts that under such circumstances "swarms of bacteria" are invariably generated in it, whilst the latter, M. Pasteur, emphatically denies this, conditionally upon the potash having been previously heated for a few minutes to 110° C. to destroy the germs which he states are introduced with it. The arrangement for the experiment has been very ingeniously devised. The potash is heated to the required degree in a small sealed tube which is then introduced into the flask containing the fluid to be boiled. After the boiling (the time unfortunately is not specified) and sealing of the flask hermetically, the tube is broken and its contents mingling with the acid fluid, renders it about neutral, in which condition it has been found by one experimenter very fruitful, and by the other altogether barren. The difference is made to turn upon the potash, as to whether it has been heated sufficiently to destroy the supposed germs which it is said to contain. But I hold from what I have observed in reproducing this experiment that the potash plays a negative part only. The fluid is kept from undergoing decomposition by the free acid it contains. When this is removed by the potash, always in certain relative proportions to it, its antiseptic effect is removed also, and the fluid is free to undergo the putrefactive change, either if it is capable of generating life anew, or if the germs which it previously contained have not been destroyed by the boiling process. This view of the case is borne out by the fact that too much,

* The effect of filtration through various media on putrescible fluids is a subject for further experiment. Would porous porcelain arrest and retain *all* particulate matter in a translucent and freshly prepared organic liquid, and would the ferment whether particulate or not be capable of being so retained?

or too little potash will interfere with the result and prove fatal to the production of life. In the former case the potash itself will be the antiseptic, and in the latter, the acid will still be present in sufficient quantity to retain its effect. Here, again, we see that the question becomes one of *quantity*, supposing either of the above conditions (spontaneity of generation, or non-destruction of germs) to be present in the liquid. But now let us ask a question upon which we have already laid great stress, viz., when the potash is added to the cooled fluid, is the latter sterilised or is it not? The fact that the fluid remains barren before the addition of the potash, even if the latter be delayed for weeks, is no proof whatever of its being in a sterilized condition, since the free acid is there to preserve it from change and prevent it from becoming fertile. That it is of a very refractory character and very resistant to heat seems from experiment abundantly clear. When exactly neutralized with liq. potassæ and boiled for five minutes, the alkali, to a greater or less extent, is dissipated, and the acid reaction becomes re-established. The fluid is also turbid from the deposition of earthy phosphates. Therefore, to secure a bright and neutral liquid we proceed as follows. Three separate boilings are often sufficient, but we give an instance of five:—

1.	Filter and Neutralize with m xj L. Pot. to ℥j.	Boil 5 minutes.	Result. Turbid. Acid to Test Paper.
2.	Re-filter and Neutralize with m v L. Pot. to ℥j.	Boil 5 minutes.	Result. Turbid. Acid to Test Paper.
3.	Re-filter and Neutralize with m iv L. Pot. to ℥j.	Boil 5 minutes.	Result. Turbid. Acid to Test Paper.
4.	Re-filter and Neutralize with m iiiss. L. Pot. to ℥j.	Boil 5 minutes.	Result. Bright. Very slightly acid to Test Paper.
5.	Neutralize with m j, L. Pot. to ℥j.	Boil and Protect.	Result. Negative at 120° and upwards, and at 60° to 80°; but positive at 90° to 110°.

The result here shown is exceedingly instructive. Life is manifested at the medium temperature, but fails to appear at 70° and 120°, thus illustrating in a marked manner the importance of a few degrees of heat more or less in influencing the result. At 120°F. and above, all my results were negative. The changes were purely of a chemical character. Earthy phosphates and triple crystalline deposits were thrown down in the presence of the potash by the action of the heat, as in the case of boiling, all being freely soluble in nitric and hydrochloric acids. At the same time ammonia was rapidly generated from the breaking up of the urea. The formation of ammonia is usually associated with putridity. Putridity, in a sense not generally so understood, may here be present, but it is unaccompanied by vibriones, or bacterial life of any kind. This phenomenon has not, that I am aware of, been noticed by any writer on the subject. To show the resistant power to sterilization of this organic fluid, it may be stated that a specimen boiled for twenty minutes and neutralized, as already shown, was submitted to 150°F. for about 72 hours, then again boiled and protected and placed in the incubating temperature. Yet, notwithstanding this, it gave distinct evidence of life within the usual three days. It is clear, therefore, that to render urine completely barren it requires very prolonged and active treatment. Nor must it be forgotten that it is only when the potash is added in certain definite proportions that bacteria make their appearance. The reason of this, as before intimated, is sufficiently obvious. The free acid and the alkali are both antiseptics. Should either predominate over the other in sufficient quantity to exercise its antiseptic action, the result will be negative. On the other hand, if this action has been nullified in each instance by proper proportionate quantities the reverse will be the case, *i.e., if the fluid remains in an unsterilized condition.* It will be seen that in carrying out this experiment, except by the thoroughly experienced expert, at least six flasks should be taken containing the potash in different proportions to the ounce, from five minims up to fifteen. The correct quantity will then be secured, for normal urine differs very widely in the amount of acid it contains. Exact neutralization, or a little below it, is the condition to be aimed at. Under such circumstances we get results similar to the following:—

Boiled 5 minutes.		
Liq. Potass to each ℥j	Temperature.	Result.
v m.	100° to 115°F.	— *
vij „	„	— *
ix „	„	+ ϕ
xj „	„	+ ϕ
xiij „	„	+ ϕ
xv „	„	— *

Boiled 1 Hour.		
Liq. Potass to each ℥j	Temperature.	Result.
ix m.	100° to 115°F.	— *
x „	„	— *
xj „	„	+ ϕ
xij „	„	+ ϕ
xiij „	„	— *
xiv. „	„	+ ϕ

* — Negative, indicating no change.
ϕ + Positive, showing development of life.

It will be observed, that in each of the above experiments (boiling respectively for five minutes and one hour) three flasks broke down, whilst three remained intact. This singular outcome was no doubt entirely due to the relations between the acid and the alkali present in the unsterilized fluid. How long it would be necessary to continue the boiling to secure entire immunity from these "break downs," if such a result is to be accomplished at all, I am not prepared to say; but if life can be detected after eight hours' boiling in the case of old hay infusion, we may, perhaps, fare but little better in the present instance. Nor is it all necessary to determine this, for we fall back upon our infallible treatment, and all ambiguity disappears. The result is slowly and unobtrusively, but yet decisively, worked out for us. Six days quietly devoted to the destruction of the germs at the bacterial death point, will set the question completely at rest. We shall have our earthy phosphates deposited by the action of the heat; but no matter. Physics and chemistry may step in to alter and rearrange, but the question is,—Can life be generated *de novo* in any fluid which is, in reality, the dead organic matter we are necessarily required to secure? And this can only be answered by having the absolute assurance that it *is* this *dead matter* from and out of which the new life comes actively into being.

The outcome of all this will no doubt have been anticipated. I propose, in fact, to do away with boiling as a means of sterilization, and substitute continuous heating at a lower point on the scale. We shall thus do away with all complication and liability to "grave error," and reduce the test to one of extreme simplicity. For the moment, we lay aside flasks, boxes, chambers, retorts, bulbs, tubes, *et hoc genus omne*, and call to our aid accurately fitted stoppered bottles. Robbins' 4 oz. anhydrous ethers answer admirably. The prepared fluid is boiled for one or more minutes where the decomposition is usually found to be rapid, and then introduced into the phial to about two-thirds of its capacity. The air space is left, to allow of subsequent expansion in the case of unboiled liquids. Having introduced the stopper and secured it firmly in its place, the phial is labelled and placed immediately with its contents in an atmosphere heated to 150° Fahr., or above. There it is left, the heat being continuously maintained. The exact time which should intervene in each case to secure subsequent immunity from change must be determined by experiment. To make assurance doubly sure I have usually allowed six days for the operation, and not in any single instance, after the lapse of that time, have I observed the slightest indication of bacterial development. Thus, I have infusions of gentian and calumba, old hay, new hay, turnip, cucumber, beef, turnip with cheese, and the test-fluid referred to, with and without potash, all perfectly sound and translucent, and apparently in a condition of permanent barrenness. If we have any affection for hermetically sealed flasks and glass bulbs, we may prepare these in the usual way and substitute the comparatively low but continuous temperature for our lamps and oil-baths. The experiment is entirely novel and something more. It is, so far as I have carried it out, *conclusive* as to the point at issue. With great earnestness and ability Dr. Bastian has made clear to us the degree of heat in which all bacterial life is extinguished.* It follows, as an irresistible conclusion, that if this heat be sufficiently prolonged, the most indurated and resistant germ will ultimately succumb and cease to be. If, at this point, life cannot be reinstated without contact with fresh sources of vitality, we may, perhaps, be permitted to say of spontaneous generation, as Macbeth said of his immortal dagger, "There's no such thing!" My experiments irresistibly tend in this direction, and as they are extremely simple they may be gone over and verified by all who have the requisite technical knowledge for conducting the processes involved. The result will probably be shadowed forth to them in the old Latin proverb, *E nihilo nil fit.*

In conclusion, it will be readily understood that in this investigation there is a great deal behind the scenes, both of failure and success, of hard, profitless, and yet encouraging work, which must necessarily remain unrecorded. But most assuredly in this, as in all physical and chemical research, the results will be accurate and reliable in proportion as the means selected for their achievement are zealously worked out, and adequately and impartially fulfilled.

The PRESIDENT thought Mr. Willmott had thrown some new light on the subject, indicating that time was an element in the application of heat to destroy the vitality of low forms of life.

Mr. KINGZETT, having followed the discussion on this subject fairly well, could see nothing new in the paper which had been read. The dead lock in the controversy depended on what had been discovered by Mr. Dallinger, namely that although the heat employed by Dr. Bastian or Professor Tyndall might be sufficient to kill germs, it was totally insufficient to kill spores. He did not see how Mr. Willmott's method would affect this question.

Mr. WILLMOTT said he had the pleasure of hearing the lecture given at the Royal Institution by the Rev. Mr. Dallinger, who stated that he found germs or spores of bacteria were killed only at a temperature of 300° by dry heat, and also gave a description of the mode in which he experimented. His (Mr. Willmott's) method was totally different. The germs or spores, for he did not refer to developed bacteria, were not submitted to dry heat but to moist heat, and Dr. Bastian had correctly pointed out that the temperature necessary to destroy the germs or spores of bacteria in a *moist* heat was 158°. The method of keeping up the heat to this point for a length of time, not boiling at all, except (in some instances) for one or two seconds, was perfectly new.

The PRESIDENT in moving a vote of thanks to Mr. Willmott said this concluded the list of papers.

Professor ATTFIELD read a list of names of gentlemen desiring to become members, who were elected unanimously.

PLACE OF MEETING IN 1878.

Professor ATTFIELD then moved that the Conference meet next year in Dublin on the days immediately preceding the meeting of the British Association. He said he had had a communication from the Secretary of the Pharmaceutical Society of Ireland, enclosing a resolution to the effect that the Council of the Society desired that the Conference should meet in Dublin next year. He had also had many letters from leading pharmacists in Ireland expressive of the same desire. And he thought that the representative members of the Conference were in favour of meeting in Dublin in 1878.

Mr. WILLIAMS seconded the motion. He did so with all the more pleasure because when the British Association met in Belfast there were reasons which prevented the members of the Conference visiting their friends in Ireland, but things were altered now, and he had no doubt they would have a pleasant and profitable meeting.

Mr. PAYNE (Belfast) was very sorry to find he was the only member of the Conference present from Ireland, but he thought probably the days on which the meetings were held had something to do with it, being rather inconvenient for the Steam Packet Service. Professor Tichborne had been thus prevented arriving in time to give a formal invitation from Dublin; but he could assure the Conference that the Irish pharmacists would do all they could to give their English friends a hearty welcome.

The resolution was carried unanimously.

The following officers were then elected for the ensuing year:—

President.

G. F. SCHACHT, F.C.S., Clifton.

Vice-Presidents.

Professor TICHBORNE, F.C.S., Dublin.
R. REYNOLDS, F.C.S., Leeds,
R. W. PRING, L.A.H.D., Belfast.
J. WILLIAMS, F.C.S., London.

Treasurer.

C. EKIN, F.C.S., Bath.

General Secretaries.

Professor ATTFIELD, F.C.S., London.
F. BADEN BENGER, F.C.S., Manchester.

Local Secretary.

W. HAYES, Dublin.

Other Members of Executive Committee.

M. CARTEIGHE, F.C.S., London.
A. P. BALKWILL, Plymouth.
H. N. DRAPER, F.C.S., Dublin.
B. S. PROCTOR, Newcastle-on-Tyne.
E. SMITH, F.C.S., Torquay.
W. A. TILDEN, D.Sc., F.C.S., Clifton,
C. UMNEY, F.C.S., London.
J. T. HOLMES, Dublin.
J. C. THRESH, F.C.S., Buxton.

Auditors.

S. B. TURNEY, Plymouth.
W. ALLEN, Dublin.

Mr. SCHACHT said he very much appreciated the honour done him in electing him President. It would be affectation not to say that he had looked forward to the possibility of some day occupying this distinguished position, and at a distance the fact did not look very alarming; but when it came closer the difficulties appeared in a

* 158° Fahr. Bastian. Moist heat.
300° Fahr. Dallinger. Dry heat.

stronger light, especially as he had to follow Dr. Redwood's very able presidency. However, he could only throw himself on the indulgence of the gentlemen who attended the Conference with a promise to do his best.

Mr. SCHACHT again rose to propose a vote of thanks to the Local Committee who had exerted themselves so much to make the meetings pass off well, and were on the morrow intending to do still more in the same direction in connection with the more social aspect of their gatherings. He would move—

"That the cordial thanks of the non-resident members of the Conference be given to the members residing in Plymouth and surrounding towns generally, and especially to Messrs. Clark, Balkwill, Codd, and Turney, and the other members of the Local Committee for their kind and most successful efforts in organizing the present meeting."

Mr. GROVES seconded the resolution, which was put and carried unanimously.

Mr. R. J. CLARK (Local Secretary) briefly responded, and Mr. BALKWILL also spoke of the good which these meetings did in bringing more closely together the chemists of the locality in which the Conference met, and making them feel that there were higher thoughts than those which merely belonged to their business, and that they were linked in some degree with the students in other fields of literature and science.

Mr. TURNEY proposed a hearty vote of thanks to the President for the ability and courtesy with which he had conducted the business of the meeting.

Mr. FRAZER (Glasgow) seconded the motion, which was was put by Mr. Groves, as Vice-President, and carried unanimously.

THE PRESIDENT in reply, said it had been to him a source of very great gratification to be allowed the opportunity of meeting with so many of his old friends and associates, if he might so speak of his old pupils, and with others whose names had been familiar to him, but with whom he had not been personally acquainted. He could only assure the meeting that if his services had contributed in any way to the advancement of the object which they all had in view, no better reward could be afforded him for anything he had done, which he was sorry to say had been too little. He might say, however, that the manner in which he had been received throughout would be an encouragement to him to devote himself to the interests and objects of the Conference to a greater extent than he had hitherto done.

Parliamentary and Law Proceedings.

SUICIDE OF A CHEMIST AND DRUGGIST.

On Monday the 1st inst., an inquest was held at the Railway Hotel, Southport, before C. E. Driffield, Esq., coroner, respecting the death of Mr. Thomas Makinson, chemist and druggist, of Chapel Street. From the evidence adduced it appeared that the deceased for the previous three weeks had been drinking. On the Thursday he began to wean himself from the drink, and on Friday he commenced to ramble and appeared low spirited. On Saturday night he got the idea into his head that he was being followed, and gave order that the assistant was to drive a man away. On Sunday he was very low spirited, and Dr. G. A. Woods was sent for, and he seeing the condition of deceased suggested the advisability of his friends being communicated with. Shortly after dinner on Sunday deceased got possession of a key which fitted the shop door, and took two doses of something which he said was to cool his head. Shortly after the housekeeper had got him from the shop, he sprang out of the chair in which he was reclining, and exclaimed, "I have taken poison." Dr. Woods was sent for, and on his arrival he found the deceased perfectly unconscious from opium poison, and in convulsions. He applied the stomach pump at once, and removed a quantity of brownish fluid. He had him walked about for a short time to keep him awake, and put some strong ammonia to his nose, and remained with him until he died. He had no doubt as to the cause of his death. It was a distinct case of poisoning from strong poisons, and most probably from two distinct poisons. A mixed dose of strychnia, or nux vomica, and opium, would produce all the symptoms found in this case. On a former occasion, when deceased was getting better, nux vomica was one of the articles prescribed as an ingredient in his medicine to relieve his head. Chemical knowledge would tell him that an overdose of this would cause death; but his mind was in such a state that instructions were given to his housekeeper.

The jury returned a verdict to the following effect:—"That the deceased came by his death from the effects of taking a deadly poison whilst in a state of insanity rom delirium tremens."

ALLEGED ADULTERATION OF CITRATE OF MAGNESIA.

At the Central Police Court, Glasgow, on Thursday 4th inst., before Stipendiary Gemmel, George Smith, M.D., 112, Renfield Street, Glasgow, was charged under the Sale of Food and Drugs Act, with having sold to Inspector Walker half a pound of citrate of magnesia, which was not of the nature, substance and quality demanded by the purchaser.

Dr. Smith pleaded not guilty, and at the outset questioned the legality of the prosecution on the ground that the drug mentioned in the summons was citrate of magnesia, while that which he supplied was "citrated magnesia" and was so labelled and declaration made to the inspector at the time of sale.

The Court overruled this objection, the two names being considered synonyms.

Inspector Walker and assistant proved the sale.

William Wallace, Ph.D., city analyst, deposed that the citrate of magnesia contained ·37 grain of lead per pound, which he considered might be injurious to health. Lead was a cumulative poison.

Dr. Smith: Are you aware that citric acid, which enters into the composition of citrate of magnesia, cannot be had free from lead.

Dr. Wallace: I can prepare it free from lead.

Dr. Smith: So can any intelligent chemist, on a small scale, but (to the Court) I assert that commercial citric acid invariably contains lead as a necessary contamination from the present mode of manufacture. The acid sent out by the best houses always contains a small proportion, and I do not think, speaking from a medical point of view, that the quantity present in this sample could be injurious.

Mr. Robert R. Tatlock, city analyst, corroborated Dr. Wallace's evidence.

Dr. Russell deposed: I am medical officer of health for the city. Lead is a cumulative poison, and small repeated doses often produce symptoms of poisoning. The quantity found in this citrate might prove injurious.

Cross-examined by Dr. Smith, he admitted that he had frequently prescribed citrate of magnesia in his private practice, and had not observed any poisonous symptoms follow its use, nor had he heard or read of such.

This closed the evidence for the prosecution.

Dr. Smith, on being called upon to produce his witnesses, complained of being taken unawares by the prosecution, as the summons did not state particulars and he was in ignorance of the point on which the case would turn till he appeared at the bar. He happened that morning to meet Mr. Howie of Edinburgh who might be able to tell them something, and Mr. McAdam, managing partner of the Glasgow Apothecaries' Company, was also in attendance.

Mr. W. L. Howie deposed: I am a pharmaceutical chemist. I know that citric acid and citrate of magnesia contain lead in small proportions.

The Fiscal (Mr. Lang): But this contains ·37 grain per pound.

Mr. Howie: That is about one-third of a grain per pound.

The Stipendiary: One-third of a grain?

Mr. Howie: Yes. A small fraction over the third of a grain. I do not think this is a large proportion. I have sold in the usual way of wholesale business large quantities of citrate of magnesia, and am brought into contact with those who are constantly selling it. I have never heard of injury resulting from its use. I would not consider ·37 grain per pound injurious, but this is a medical question, of which I have no special knowledge. Citric acid almost invariably contains a trace of lead from the vessels used in its manufacture.

The Fiscal: You say, "almost invariably." Can it not be made free from lead?

Mr. Howie: At present, I believe it is not so made commercially. This is a question to which makers have been giving a deal of attention, and it has been discussed in the trade journals for the past few years. The difficulty has not yet been overcome. A pure citric acid would be looked upon as a chemical curiosity.

Mr. Robert McAdam deposed: I am aware manufacturers have a difficulty in producing a pure citric acid. I have always believed citric acid, and therefore good citrate of magnesia, contained lead. I have sold Dr. Smith's article largely to druggists and doctors throughout the country, and have never had complaints; in fact, I have always had great satisfaction in selling this article. I have never heard of injurious effects being produced by the use of citrate of magnesia.

Dr. Smith craved that the case be dismissed. He, in the course of his manufacture, sent out many tons annually, and had never heard of injury caused by the use of citrate of magnesia, and, speaking as a doctor of medicine, he would be the last man to send out what he suspected might be injurious, and considered this trace of lead could not be so accounted. As a manufacturer who had a name at stake, he purchased his materials only from standard houses, his citric acid being procured from Howards and Son, London, a house whose position was second to none in this or any other country, and more than that he could not do.

The Stipendiary continued the case for a week.

Presence of Lead in Citric Acid.

At the same court, John Campbell, chemist and druggist, 83, Stobcross Street, Glasgow, was charged with having sold one and a half ounces of citric acid, adulterated with lead to the extent of ·4 grain per pound.

Mr. Campbell pleaded not guilty, and, after proof, stated that he had no witnesses to call. The assistant who sold the acid had since become insane, and was at present confined in Gartnavel Asylum, but he hoped that, as in the previous case, decision would be delayed, as the cases were parallel.

The Fiscal: No, no. This is a much more gross case.

Mr. Campbell: Just as the difference between thirty-seven and forty. I think it is very hard that I should be made a victim for the sale of an article the same as you can procure in any shop in Glasgow.

The Fiscal: That is just the reason why the adulteration should be put a stop to.

The Stipendiary: The case will be continued till this day week.

Illegal Sale of Poisons.

Prosecution under the 17th Section of the Pharmacy Act.

At the Birmingham Police Court on Tuesday, the 9th inst., before G. Goodrick, Esq., and H. Manton, Esq., Anson Edwin Martin, trading as a chemist and druggist, at 136, Broad Street, Birmingham, was summoned by William Frederic Haydon, 23, Burlington Chambers, New Street, Birmingham, Secretary to the Chemists and Druggists' Trade Association, for "That on the 27th day of September, 1877, at the said borough, he unlawfully sold to the said William Frederic Haydon certain poison, to wit, oxalic acid, in a certain packet, the cover of which packet did not set forth the name of the seller of the same, contrary to the statute in such case made and provided." Mr. Henry Glaisyer (Solicitor to the Chemists and Druggists' Trade Association), instructed by Mr. William Frederic Haydon, prosecuted, and Dr. Sebastian Evans appeared for the defendant.

Mr. Glaisyer said he was rather surprised to see that his friend, Dr. Evans, appeared for the defence, because he held in his hand what he took to be a confession that the defendant had infringed the Act. However, as the defendant appeared by his counsel he must go into the matter. The information was laid by William Frederic Haydon, Secretary to the Chemists and Druggists' Trade Association of Great Britain, and the summons was issued under the 17th section of the Pharmacy Act, 1868, which provided: "It shall be unlawful to sell any poison, either by wholesale or by retail, unless the box, bottle, vessel, wrapper, or cover, in which such poison is contained be distinctly labelled with the name of the article and the word poison, and with the name and address of the seller of the poison, and for the purpose of this section the person on whose behalf any sale is made by any apprentice or servant shall be deemed to be the seller."

The facts of the case were very simple. On the 27th of September (that was, last month), Mr. Haydon went to defendant's shop, 136, Broad Street, and purchased some oxalic acid from him personally. The package containing the oxalic acid was labelled "Oxalic Acid—Poison. Morris and Co., Chemists, 87, Islington, Birmingham." Subsequently the defendant called upon Mr. Haydon and they both came to him, and defendant at that interview wrote the following letter.

"136, Broad Street,
"October 4, 1877.

Dear Sir,—With regard to the proceedings which have been commenced against me under the 17th section of the Pharmacy Act 1868, I have to say that I have been for some time past trading as a chemist and druggist at 136, Broad Street, under the name of Morris and Co.; under this name I sold the poison (oxalic acid) to Mr. W. F. Haydon, the Secretary of Chemists and Druggists' Association. In future I will trade under my own name and will abstain from selling poisons until I am duly qualified to do so.

"Yours truly.
"Anson Edwin Martin.

"To Henry Glaisyer, Esq., Solicitor,
"Waterloo Street."

Dr. Evans said they admitted the facts of the case.

Mr. Glaisyer said then he did not know what defence his friend could set up, because he thought the provisions of this section were clear.

Dr. Evans said he thought that the Bench would have seen what the defence of this was. They were charged in this summons that they did unlawfully sell a certain poison, namely, oxalic acid, on the cover of which they did not set forth the name of the seller. They did set forth the name of the seller. Stamped on that packet was the name of Morris and Co., with their address in Islington, the only point in the case was, this firm of Morris and Co. had passed through several hands. Morris and Co. established a considerable reputation as chemists and druggists a good many years ago; and when, he believed, Mr. Morris died he sold the business to Mr. Proctor. Mr. Proctor being well aware of the value of the name of Morris still retained the name of Morris, and traded under that name, and sold poisons under that name. When his client purchased the business from Mr. Proctor he still retained the name of Morris and Co., and he traded as Morris and Co. He contended that the provisions of the Act were fulfilled in that label, that, in fact, the name of the seller was upon that packet The provisions of the Act were for the purpose of identifying persons from whom poisons had been obtained; and the name of Morris and Co. being upon the packet, any person who wished to identify the seller could do so by going to the shop in Islington, and asking, who were Morris and Co.? Morris and Co. were Mr. Martin. There was no other Morris and Co. Mr. Martin was perfectly entitled to use the name of Morris and Co., as well as Mr. George Dixon was to use that of Rabone Brothers, in trading as a merchant in the town. It had been over and over again decided that it was lawful for any persons to trade under the name of what firm they pleased, whether there was a person of that name in the firm or not. And he said both the letter and spirit of the Act had been fully carried out by giving such an address as that. It was impossible that any person could be mistaken by such an address as that. They knew he kept a shop and was trading under that name. He said further than that; if Mr. Martin had put his own name upon that packet he would not have been so readily identified as by having the name of Morris and Co. upon it. The object of the Act had been more fully carried out by having that address upon the packet than it would have been had the name of the individual who actually sold it appeared. With regard to Mr. Martin writing that letter in a lawyer's office, he was taken there for the purpose of writing it. It was the most natural thing in the world for a man to do. He took it any person not knowing that it was legal for him to trade under another name would naturally write that letter. He was told by a legal gentleman that he had infringed the Act by trading under another name. But he had been doing nothing of the kind. It was under that incorrect impression that he wrote that letter. He should not carry the case any further, as in his opinion neither the spirit nor the letter of the Act had been infringed.

Mr. Glaisyer said that as his friend had rather opened up the question of the intentions and scope of the Act, he should like to offer a few remarks, and, with the permission of the Bench, he would direct their attention to the 15th section.

Dr. Evans said they were not summoned under that section.

Mr. Goodrick requested Mr. Glaisyer to proceed.

Mr. Glaisyer said he would only refer to the 15th section to show what the object of the Act really was; with regard to the identification of the seller, Dr. Evans' argument admitted of some explanation. He could not see that a man could be better identified by assuming a name that was not his own. Then again, they would see in a moment, by assuming the name of Morris and Co., and trading under that title, he was using the assumed name as a shield for the sale of poisons. The name and address of another person were assumed by unregistered men for the sole purpose of enabling them to evade the 15th section of the Act, as a subterfuge. He was perfectly aware it was lawful for a person to trade under an assumed name, except as a chemist and druggist. Dr. Evans had carefully avoided the nature of that Act, and it was under that Act alone that a person could not conduct his trade under an assumed name. He said a person could not so trade in poison, but it was for the Bench to decide the question.

Mr. Manton said they thought the Act of Parliament was clear in compelling the person who sells poison to put his name on the label. With regard to a mercantile house, they could trade under an assumed name; there were many instances of that, but they thought the Act of Parliament before them made it very clear that a person who sells poisons should put his name on the label; they would therefore fine the defendant ten shillings and costs.

John Stuart Careless, trading as a chemist and druggist at 44, Horse Fair, Birmingham, was summoned for a similar offence.

Mr. Potts appeared on his behalf, and the prosecution was conducted by Mr. Henry Glaisyer, instructed by Mr. William Frederic Haydon, the plaintiff in this case.

Mr. Potts said, having heard the last case he was prepared, on behalf his client, to plead guilty, because he believed it was quite clear in the Act of Parliament that the seller of poison should put his name on the packet. He mentioned, however, that the defendant kept in his shop a qualified registered chemist.

Mr. Glaisyer said the defendant himself was not a registered chemist and druggist, and was consequently not permitted by the Act to deal in poisons; the fact of a qualified assistant being employed in the business had nothing whatever to do with the matter. The facts of this case were very similar to those of the case preceding it, the defendant was illegally trading as a chemist and druggist at 44, Horse Fair, Birmingham, under the assumed name of Josiah Topp, a gentleman who had been dead some six years. He handed to the Bench a confession similar to the letter read in the last case signed by the defendant.

A fine of ten shillings and costs was imposed.

Obituary.

Notice has been received of the death of the following:—

On the 13th of August, 1877, suddenly, Mr. Thomas Daines, Pharmaceutical Chemist, King William's Town, Kaffraria. Mr. Daines was formerly a student in the School of Pharmacy, where, in 1852, he took the first Botany prize, the first Materia Medica certificate, and the first Chemistry and Pharmacy certificate. Mr. Daines filled for some years the post of Dispenser to the Grey Hospital, and, so highly were his services esteemed, that the Local Government, upon hearing of his death, forwarded to the family an expression of regret and condolence. Mr. Daines had also taken a very active part in many philanthropic movements, and, on the occasion of the funeral, most of the stores and shops in King William's Town were closed, as a mark of respect.

On the 23rd of September, 1877, Mr. William Davies, Chemist and Druggist, Brynmartin. Aged 28 years.

Review.

Fownes' Manual of Chemistry, Theoretical and Practical. Vol II. Chemistry of Carbon Compounds, or Organic Chemistry. Twelfth Edition. Revised and Enlarged by Henry Watts, B.A., F.R.S. London: J. and A. Churchill. 1877.

Scarcely have the pleasurable impressions left by the perusal of the first volume of the work before us died away, before they are renewed by the appearance of the second and final volume. This division into two volumes has given the editor an opportunity of treating the chemistry of carbon compounds in a more complete manner than was formerly possible.

In arrangement, the work resembles other modern treatises upon the same subject, dealing first with some general considerations and the methods of analysis practised in organic chemistry, while a most useful section on the physical properties of organic compounds brings this part of the book to a conclusion.

The study of the physical properties of homologous series of bodies is one which gains daily in importance and necessity, and it is not a little to this branch of chemical science that we must look for some explanation of the meaning of isomerism.

The greater part of the volume is occupied with the chemistry of carbon compounds, commencing with the hydrocarbons represented by the formula C_nH_{2n+2} (the paraffins), and passing on to those of the formulæ C_nH_{2n} (olefines), C_nH_{2n-2}, C_nH_{2n-4}, and C_nH_{2n-6}. The substitution products and other derivatives of these various classes of bodies are studied, and these lead naturally to azoparaffins, nitrils or cyanides, after which come the studies of alcohols, ethers, acids, amides, and carbamides.

Benzene derivatives, or the aromatic group, as its members collectively are still often termed, receive special attention, and the isomeric relations of these bodies are exhibited in a manner as precise and complete as it is yet possible to treat them. But here we cannot quite agree with the editor, who says that the classical researches of Koerner and other chemists have given "a high degree of precision and completeness" to our knowledge of isomeric relations. What we know of isomeric relations is not much, and we know yet less of isomerism itself.

The application of the theory of structure or "positions" to carbon compounds is an exposition of views, but it affords no real explanation of isomerism; it is possible to give a symbolic representation of certain facts, but the moment that this representation is stated to exhibit the structure of the bodies in question, it becomes the purest hypothesis. It is often urged that the chemists who use structure formulæ do not intend them as absolute expressions of the true structure of the molecules they are dealing with, but merely as instruments of teaching to exhibit plausible relations existing between various compounds. But in spite of this, the editor of the volume before us writes: "The structure of these isomeric hydrocarbons may be illustrated by the following figures." He is here writing of methyl-, dimethyl-, and ethyl-benzene, etc., and he uses the expression "structure" as if chemists were really acquainted with the structure of bodies. They are not. They know of the existence of large groups of compounds and their methods of preparations; also how by substitution or replacement or otherwise these may be changed one into the other or made to yield a number of other new compounds. From the methods thus employed, and the composition of the products, certain relations between compounds become more or less visible, plausible, and established. This knowledge often enables one to understand why two bodies, *a* and *b*, should be isomeric, but there our knowledge ends; we know no more of the structure of bodies than we do of the beginnings of life, and less than we do of vital force.

The naphthalene, phenanthrene, and anthracene groups, as also those of the terpenes and camphors, glucosides and alkaloids, are described later on in the work. Although a few pages are devoted at the end of the treatise to bile constituents, albuminoids, and brain constituents, yet to all intents and purposes physiological chemistry is omitted in the present edition of Fownes' 'Chemistry.' This cannot be considered otherwise than as an improvement, for physiological chemistry is a department of the science at once as important and requiring special treatment as comprehensive as that of general organic chemistry. The observations on bile and brain chemistry, although so brief, are not free from error, and are not even well chosen in our opinion. Otherwise, the volume as a whole is particularly sound in the knowledge it imparts, and recommendable, and, as may be immediately perceived on perusal, it embraces even very recent researches.

Notes on the Treatment of Skin Diseases. By Robert Liveing, A.M., and M.D., etc. Fourth Edition. London. Longmans. 1877.

Dispensing Memoranda.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be considered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.

[28]. O. Wallis has overlooked the action of sulphates on acetate of lead. The clear liquor after subsidence made according to his suggestion will give no sign of lead with iodide potassium. It occurs to me that amongst a number of analyses of hair restorers in a paper in the Journal one was found which gave no precipitate with iodide potassium—may not the ordinary lac. sulph. containing calcium sulphate have been used here?

I remember it was suggested that hyposulphite of soda might have been used, but am I wrong in supposing it would, equally with calcium sulph., render the lead insoluble?

If Mr. Brookes moistens the sulph. præcip. and plumb. acet. with spirit or tinct. canth., and rubs smooth with a portion of glycerine, I think his difficulty will vanish.

J. Savage.

[31]. I have had a prescription brought me this week to be made up, the writer of which is a qualified "doctress," and of which the following is a copy. I thought perhaps some of your readers might tell me the best way of dispensing it, having tried many ways to get the camphor even suspended, without success. Should I be justified with using one drachm instead of ounce?

℞ Pulv. Camphoræ . . . . . . ℥j
Hydrate Chloral . . . . . . ℥j
Mix and dissolve in glycerine, ℥vi.

Sig.—To be applied to the spine, once or twice daily, with a brush.

J. S. P.

Cambridge.

[32]. Lin. Saponis.—I made, a month ago, two pints of Lin. Saponis, B.P., but with soap marked, "Sapo Animalis, B.P." In a few days it was solid, but became a thick liquid by brisk agitation. I added to it the quantity of ingredients necessary to make another Oij, omitting the soap; but no amount of agitation will now move it, it is so solid. No heat was employed save that developed by the admixture of the spirit and water. If any one will inform me as to the best way of making this fluid, I shall be extremely obliged.

Burton.

Notes and Queries.

[555]. LIP SALVE.—N. S. H. will be obliged for a good formula for Lip Salve.

[556]. SYR. FERRI PHOSPH. CO.—In making this preparation from Mr. E. C. Saunders' formula (*Pharm. Journ.*, July 15, 1876), as well as from nearly all others published, I find the process successful and promising a good result up to the stage of adding the sugar; as soon as this is dissolved failure appears to be the result. The product, instead of being the nice clear syrup Mr. Saunders speaks of, is a frothy, muddy one, containing what seems to be a gelatinous precipitate, and is deficient in depth of colour, and I think rather too sour.

Mr. Saunders' formula seemed to promise well, but turns out the same as others; the syrup can be cleared by filtration, but this is a tedious process, and involves the loss of the precipitate.

I should be glad to learn what is the cause of the difficulty and what the remedy, also how the deep red colour is obtained, as I can only get a brownish pale red from the published forms.

PHOSPHATE.

COUNTER PRESCRIBING.

Sir,—An important contribution to the discussion of this subject (see report of late Council meeting) may be thus paraphrased.

"In the first place, there is a distinct right on the part of the public to go wheresoever they please for poisons or anything else. No one in the world thinks that a person who goes to the veriest huckster or grocer for poisons is actionable at law, yet it would be extremely difficult to prove logically that the receiver is not just as guilty as the vendor. If a person, knowing me not to be a registered chemist, choses to purchase poisons from me, that person is as much to blame as myself; the only point of importance being that the person purchasing poison should not be deceived as to the registration of the person selling it. This is such palpable common sense that it appears to me there might be founded upon it some ground for inferring what is the difference between legitimate and illegitimate sale of poisons. I think it would be infinitely better that the Council should endeavour to prevent these difficulties than to bring actions afterwards."

Or for poisons, read wines, spirits, tobaccos, or any other restricted commodity. FUI.

October 8, 1877.

"WHAT IS THE CHEMISTS' ASSISTANTS' ASSOCIATION DOING?"

Sir,—The above question is, I am told, very frequently asked; kindly allow me space in your Journal to give an answer which I venture to think will be satisfactory to all interested.

The Committee of the Chemists' Assistants' Association are not idle, but are endeavouring to find rooms suitable for their purpose, and to obtain members, whose subscriptions will enable them to render more immediately apparent the benefits to be derived from this association.

The Committee have considered the desirability of renting rooms during these summer months, and seeing that assistants generally are enjoying their annual relaxation from "white slavery," and that most of the societies of the metropolis observe the months of August and September as a time of rest, they have thought it best to husband the funds and commence their first session in October, when assistants will be back in town and the various pharmaceutical schools full of students.

It may be rather premature to set forth a project which has been discussed by the executive of the association, but not yet decided upon. In the hope of obtaining suggestions and opinions I will make it known: The idea is to commence the session with a social and scientific meeting, to be open to employers as well as assistants. Many will remember with pleasure the soirees, formerly held under the auspices of the Pharmaceutical Society, which have developed into the present conversazione at South Kensington. This conversazione is considered by some rather too "stiff" an affair, and a more social gathering arranged and managed by themselves would perhaps find favour with assistants.

A rumour obtained currency in June last, and was referred to by your correspondent, "A Public Servant," that this association would provide a register of houses which are not closed at or before a certain hour, and other matters which are considered drawbacks to assistants' comforts, or that the projectors intend to regulate hours of business, salaries, etc. These reports, I, as one of the originators of the movement, may state are entirely without foundation. The Committee have met frequently, but I have failed to discover any tendency to trades' unionism in the utterances of the members. In fact, the general opinion is that more may be done to benefit assistants by bringing them in contact with each other, and by creating if possible a better feeling between themselves and their employers, than by coercion. Moreover, it would be inconsistent for assistants to attempt coercion to-day who would a few years hence be liable to receive similar treatment from the hands of their own employees.

A singular feature has come under the notice of the Committee, viz., the almost universal sympathy afforded the movement by employers, who, while acknowledging the desirability of such an association, which they say would have been useful to them when assistants, are unwilling to supply pecuniary aid, but in lieu thereof some have dispensed "cold water *ad libitum*," one well known and generally respected pharmacist having expressed his opinions so strongly that one of his assistants when asked to become a member of the Chemists' Assistants' Association, he replied, "I should like to, but the governor would not like it!" Does not this sound very like coercion on the part of one employer? This statement, I am happy to say, does not apply to all, and those gentlemen who have kindly given more than sympathy have the best thanks of myself and colleagues.

As a public journal is not the place to enter into particulars fitted more for an advertisement, I shall be pleased to answer all questions concerning the association, and trust your correspondents will address their inquiries to me instead of troubling you with anonymous communications to which they can hardly hope to receive answers. Apologizing for taking so much space.

E. CARDWELL,
Hon. Sec. to the Chemists' Assistan's' Association.

92, *Kirk Dale, Upper Sydenham, S.E.*

OLEUM FOLII PINI SYLVESTRIS.

Sir,—There are, I think, few natural orders yielding richer supplies and presenting a greater number of points of interest to the pharmacist and manufacturer than the coniferæ order. In this opinion I am, I believe, supported by the late Mr. Daniel Hanbury, who so frequently selected the turpentine and resinous products as a subject for close examination of candidates for the Major qualification of the Pharmaceutical Society.

But considering the very able and exhaustive series of papers which are in course of publication in the Journal, by Dr. Julius Morel, of Ghent,* it would clearly be out of place for me to contribute more on the present occasion than that which is the object of this little note.

In 1872, the 'Throat Hospital Pharmacopœia' was published, under the editorship of Dr. Morell Mackenzie, and in the materia medica portion of it, p. 18, oleum folii pini sylvestris is mentioned as entering into a preparation called vapor pini sylvestris.

This vapour is now ordered to a considerable extent, and my own experience has shown me many instances in which the oil has simply been written ol. pini sylvestris, and but a short time ago, a case occurred in which the dispenser used oil of turpentine prepared by incision and puncturing the trunk of the sylvestris pine, and subsequent distillation

* *Pharmaceutical Journal*, August 4, p. 81, and two previous weeks.

—instead of that prepared by distillation from the leaves of the common Scotch pine, which preparation was presumed to have been understood.

The fault, however, was not altogether on the part of the dispenser, for, as a foot-note in the T. H. P. points out, this oil (ol. folii pini sylvestris) is not to be confounded with oil of turpentine; it is prepared from the leaves of the *Pinus sylvestris*, and is well known in Germany, whence it is imported as fir wool oil. It is also largely sold in this country and on the continent as a patent medicine for external use in rheumatism.

Under these circumstances, the conclusion to which one naturally arrives is, that physicians should in all cases when they order this vapour, do so precisely according to the directions given at page 86 of the 'Throat Hospital Pharmacopœia,' namely, *vapor folii pini sylvestris*.

A. W. POSTANS.

35, *Baker Street, W.*

THE USE OF TURPENTINE AS A BLEACHING AGENT IN LAUNDRIES.

Sir,—For some time I have been aware of a fact which, in the light of recent investigations, possesses new interest.

In some laundries a little turpentine is added to the pan containing the boiling solution of soap and the linen, ebullition being kept up briskly for a little while; the result is stated to be very satisfactory in producing additional whiteness and cleansing.

I had other theories to account for the effect, but, since the publication of Mr. Kingzett's experiments and the introduction of his "Sanitas," I think we may be justified in saying that while the washerwomen have been loud in their statement of "no chemical used," they have unwittingly secured the action of peroxide of hydrogen, and in one of its developments anticipated an interesting discovery.

It appears to me that this method adopted for bleaching is worthy of publicity; also as a very simple, easy, and effectual process for the domestic disinfection of linen, etc.

JOHN WHITFIELD.

Scarborough.

DANGEROUS COLOURED FIRES.

Sir,—As in the report of the unfortunate accident to Mr. Lloyd, in a recent issue, the last paragraph might lead some of your readers to conclude that by mixing the coloured fire upon paper perfect security is obtained, I think it is my duty to warn my brother chemists that such is not the case. Last evening a similar thing happened in my shop from the spontaneous ignition of a coloured fire which (as in Mr. Lloyd's case) had been made for the theatre; but happily it was unattended with any more serious results than the destruction of the mats, etc., which were immediately thrown upon the burning mass, and causing some alarm to the neighbourhood. I wish to draw attention to the fact that the compound was mixed upon paper, with a bone spatula. As it is probable that some formulæ may be more dangerous than others, it may be of interest to mention—particularly with the Guy Fawkes anniversary approaching—that the mixture in question was made according to form No. 5 for Green Fires, in Beasley's 'Druggists' Receipt Book.'

JOHN T. WINDLE.

Chesterfield, Sept. 26, 1877.

Mr. R. O. Fitch writes, in reference to the recent prosecutions under the Apothecaries Act, reporting the details of a case which illustrates the fact that medical assistance cannot always be obtained when required. This is so self-evident, as well as the inference to be drawn from it, that we refrain from publishing the letter *in extenso*.

F. J. B.—(1) See a paper by Mr. Bickerdike on the chemistry of the tar antiseptics, in *Pharm. Journ.* [3], vol. v., p. 541. (2) For dialysed iron, see formula in present volume, p. 27, using solution of ammonia, sp. gr. ·924; also pp. 48 and 84.

T. P. Iliff.—Your post-card has been handed to the Secretary, to whom all communications respecting change of address or non-receipt of the Journal should be sent.

Mr. Howie is thanked for his communication.

Fides.—Although we wish to allow considerable latitude to the Dispensing Memoranda they can hardly be made to include notes on the "making of artificial or real rum, brandy, or gin." Such information, however, is not difficult to find if sought in the proper place.

F. Gall.—*Polygala vulgaris.*

J. T. Fox.—(1) *Galium palustre;* (2) *Veronica Buxbaumii;* (3) *Linaria Elatine.*

"*Syrupus.*"—(6) *Hypnum cupressiforme;* (7) *Hypnum resupinatum;* (8) *Didymodon rubellus;* (9) *Didymodon rubellus*, mixed with *Anomodon viticulosus.*

J. Houlton writes to suggest that the Medical Defence Association might turn its attention to the prosecution of village parsons who prescribe to their own parishioners, wives of country squires, who are apt to fly to their medicine chests in cases of emergency, or even Giles, the ploughman, who has his panacea in the shape of pills made from turpeth mineral, gamboge and calomel.

"*Neanias*" writes to complain of the little or no result that has followed the meeting held some months since in respect to early closing, and that promises made at that meeting have not been carried out.

St. Ignatius.—No provision is made in either the Pharmacy Act or the Arsenic Act for the exemption of the sale of small quantities of scheduled poisons from the operation of the ordinary regulations applying to the sale of such poisons.

T. B.—The description given is too indefinite to allow of the expression of an opinion. You are recommended to submit the substance to analysis.

Chamomile.—We are unable to give you the information asked for, but we do not think that the electric light can at present be applied economically to the lighting of dwelling houses.

T. S. Edwards.—We are aware that a rule exists prohibiting candidates from passing the Minor examination until they have attained the age of twenty-one years; but as the passing of this examination is the legal qualification for carrying on the business of a chemist and druggist we cannot agree with you in stigmatizing the rule "as an injustice and an insult to human nature and common sense." Probably as your judgment matures your opinion will approximate more closely to our own.

J. J. C. asks is it not time to "protest, as a body against such palpably unfair decisions as magistrates have been giving lately in the cases of soda water and castor oil pills? for although the next generation learning wisdom by our experience will no doubt be more careful in their nomenclature, surely there must be some way of shielding ourselves from such unjust attacks upon vested interests." Our correspondent thinks, however, the task may prove to be harder than would at first be expected.

"*Pharmacist*" also writes criticizing a recent letter from "A Druggist of nearly Half a Century," on the same subject, and says that if the latter gentleman would put aside an unkind prejudice he might learn that the proprietor or proprietors of these articles were not culpable in adopting their names, and had no desire to deceive. If our correspondent would show what argument could be advanced in favour of the practice of giving such misnomers it would, in our opinion, be more to the point.

"*Quaesitor Sum.*"—We do not know.

W. L. Pearce.—We suspect a misreading of the prescription and would like to have an opportunity of examining the original.

H. Hemstead.—Garrod's 'Materia Medica' is published by Messrs. Longman and Co.

G. C. Walton.—Probably *Prunus Avium*; it is not possible to say from the leaves alone. The grass is rightly named; it is not uncommon.

G. R. Durrant.—A gall produced by *Rhodites Rosæ*, L., and known as Bedeguar, or Sweetbriar Gall.

W. R. Fowler.—(1) Any of the leading Manuals of Chemistry might be followed. (2) The conditions that obtain in different localities are so various that it would be impossible to draw up rules that would be applicable in all cases; these must be decided upon by those residing on the spot.

W. G.—Your question is not sufficiently definite.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Kinnimont, Mr. Barnard, Mr. Fowler, Mr. Gilmour, Mr. Schacht, Nemo, Malva, B.B.B., B.J.K.

THE CULTIVATION OF MEDICINAL PLANTS AT HITCHIN.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

The neighbourhood of Hitchin is one which is interesting on many accounts. The spot which Dickens has immortalized as Tom Tiddler's Ground is within a few miles of the town. The geologist will notice here the outcrop of the London basin, and the antiquary will meet with much to examine in the way of flint implements and other ancient relics. The botanist will find in the spring abundance of the rare *Anemone Pulsatilla* within a few miles of the town, and cannot fail to admire the row of ancient box trees, with trunks fully a foot in diameter, and about twenty feet high, which are conspicuous by the roadside near the centre of the town. These are probably the largest and oldest box trees in England. A curious feature in this district is the straw plaiting, which is carried on almost mechanically by women, even as they walk along the streets or through the fields to their work; their eyes keenly observant of all around them, and their talk seasoned with remarks, often more shrewd than polite, upon the passers by. On a Tuesday, which is the market day, the town often presents a busy scene, sometimes as much as £1000 worth of straw plait changing hands in one day. This is chiefly bought up by middlemen from Luton and Dunstable, who supply the peasantry with prepared straws for the purpose. For the pharmaceutist, however, the chief attraction of course lies in the fields of medicinal plants which are scattered all around the town.

The plant which is most extensively grown in the neighbourhood of Hitchin is the lavender (*Lavandula vera*, D.C.). The cultivation of this plant was commenced in 1823, by Mr. Perks, and at the present time is carried on by his son, and also by Mr. Ransom, who commenced its cultivation in 1847. It is to these two gentlemen that our readers are indebted for most of the interesting facts which are embodied in this paper. Both these gentlemen have received medals for the excellence of their productions, Mr. Perks for oil of lavender, and Mr. Ransom for essential oils and pharmaceutical products generally.

The crop at present grown is much affected by the presence of a disease which attacks the plants just as they are beginning to flower, and causes them to wither away by degrees. This disease occurs not only at Hitchin, but also at Mitcham (in fact, it appeared at Mitcham before it was known at Hitchin), and so far as I have been able to ascertain at all the localities in which lavender is grown. To such an extent has it occurred at Market Deeping in Lincolnshire that Mr. Holland, who formerly cultivated lavender there, has now ceased to grow it. The disease prevailed to a considerable extent this year, and on this account and by reason of the smallness of the crop, the price of oil of lavender will probably be unusually high.

The history of the cultivation of lavender reveals some curious facts which may perhaps throw a little light upon the probable cause of this disease. Formerly the plant was propagated by slips taken from the branches, for the plant does not ripen seed. Whether or not it has lost the property of ripening seed through cultivation, as has been the case with the rhubarb plant at Banbury, I have not been able to ascertain.

In the winter of 1860, owing to a very severe frost, nearly all the lavender plants were killed, and to secure a crop for the next year, instead of taking slips, the roots were parted, and from that time to the present the same mode of propagation has been continued. About this time (1860), the disease first appeared.

Plants which are obtained by parting the roots of one year old plants are much more vigorous and less liable to the disease than those obtained by dividing the roots of those of two years' growth.

The first appearance of the disease is indicated by the leaves of one or more branches drooping and withering away; and the remainder of the plant becomes affected by degrees. When the root of a diseased plant is pulled up the rootlets appear fewer in number than in a healthy plant, and the woody portion from which the rootlets spring is often covered with a white filamentous mycelium, but sometimes only presents a dark colour and wet appearance internally.

The appearance of the disease just as the plant has begun to flower, and the fact that the plants now come to maturity in about three years, whereas they used to last five or six years, seems to indicate that the tendency to produce flower and foliage has been stimulated to a greater degree and caused a greater demand upon the root than it is able to meet. The vitality of the plant has probably been lowered by years of reproduction from the stem instead of in the way that nature has appointed, viz., by the seeds. The method of propagating at present adopted is certainly one that is very likely to continue the disease, since it may be latent in the divided root of apparently healthy plants. That the disease is not likely to be owing to difference in soil is shown by the fact that fresh soil or otherwise, manure or no manure, make no difference in its appearance.

The method of cultivation is as follows:—

The harvest of lavender flowers is rarely over until the middle of September, so that it is not possible to get the ground cleared and ready for the fresh plants before the end of October or beginning of November. The ground which is to be planted is generally manured beforehand with thirty to forty-five tons of stable manure per acre, but manure is not applied afterwards until a fresh planting takes place. The roots of the old plants are parted sometimes from two, but preferably from one year old plants, and the sets dibbled in rows about eighteen inches apart. The young plants make a start in growth in March, if the weather be mild with gentle showers, and increase considerably in size in April and May, so that the tufts become on an average about a foot in diameter. If, however, there occur heavy rains so that the leaves are much splashed with soil, the growth is somewhat stopped. In hollows, or where the damp is liable to remain, the young flowering stems, if there be frost in May, are frequently nipped, and the plant either dies or does not send up fresh flower-stalks until the end of June, making the harvest a late one. Black frosts do not, however, injure the plants.

The sets, if made by parting the roots, flower the first year; if, however, slips from the branches are taken, they are not allowed to flower the first year lest the young plants should be weakened thereby, but the flower shoots are clipped down close to the stem.

In the second year every alternate plant is removed in the autumn and planted elsewhere, leaving the others one yard apart. The second year the plants attain a diameter of about 15–18 inches, and in the third year the tufts are from 2 to $2\frac{1}{2}$ feet across.

Shade has a pernicious effect upon the plants; under the shadow of trees they become starved and produce scarcely any flowers. The growth of other plants between the rows also injures the crop. Weeds too have to be kept down. In order to prevent injury to the roots of the lavender plants while removing the weeds, Mr. Perks uses an instrument of sufficient width to pass easily between the rows, and composed of a number of hoe-like blades, the upper portion of the instrument being like a plough. By means of this apparatus he is enabled to cut off the weeds just below the surface of the ground, and at the same time to avoid injuring the tender roots of the lavender. The plants grow best and produce most blossom when they have plenty of room and sunshine. If too crowded, flowers are only produced from the centre of the tufts and not from the sides where the plants come in contact with each other.

The weather has considerable influence upon the yield of essential oil. If the days are bright and sunshiny during June and July the yield will be a good one, but if wet and dull very often not half the average will be obtained. Mr. Perks informs me that a 200 gallon still will yield about $1\frac{1}{4}$lb. of essential oil in a good season, but in a bad one, as in the present year, barely twelve ounces.

The time at which the flowers are gathered also appears to modify the yield, Mr. Ransom giving as the result of his experience that the product is very much reduced if gathered after the first week in September, the largest quantity of oil being obtained about the middle of August.

In collecting the harvest, which usually begins about the first week in August, the flowerstalks of one plant are grasped as far as may be with one hand and a sickle is used with the other. They are (by Mr. Ransom) then packed in eight-bushel sacks, and carried direct to the still, about fourteen sacks going to a 1000 gallon still; or they are tied up in bundles weighing about twenty-two pounds (by Mr. Perks) and as much as possible of the stalks afterwards cut off and the still then filled up with the flowers. The distillation is commenced at four or five o'clock in the morning, and the still is filled four times a day, the men leaving work at 10 p.m.

The distillation of each quantity takes about two and a half hours, the largest portion of oil coming over during the first hour and a half. A considerable time is of course taken up in filling and emptying the still. The flowers are trodden down in the still by boys, who for the first day or two are often severely stung by the bees which cling most pertinaciously to the blossoms, and appear to be quite intoxicated with the honey of the lavender, especially towards the end of the season.*

The water which comes over with the oil during the first hour, being slightly impregnated with oil, is returned to the still, but that which comes over afterwards is allowed to run away.

The oil which comes over after the first hour and a half is either redistilled or sold as inferior quality. The refuse when removed from the still is thrown into heaps, and when decayed is returned to the lavender fields. In a good year the lavender yields from four to six Winchester quarts* of essential oil per acre, and as about fifty-three acres altogether are cultivated the average yield of oil for the whole of Hitchin is about two hundred and forty Winchester quarts per year.

The quality of the oil is said to be affected by the soil and situation in which it grows, so much so that Mr. Ransom informs me he can distinguish the oil obtained from different fields by the odour alone. The oil is improved by keeping, up to three years, after which it begins to deteriorate unless mixed with spirit.

Redistillation also improves the quality of the oil, but unless conducted by steam heat the loss sustained is not compensated for by increase in commercial value, the loss being nearly one pound in the gallon.

The stems are not distilled, as the oil obtained from them is of very inferior quality, and is so small in quantity that it does not pay for labour and fuel.

The lavender grown by Mr. Ransom is distilled by steam heat, by which any tendency to an empyreumatic odour is avoided.

Belladonna.

About eight acres are grown of this plant, from which extract is made on the spot. The plants are raised from seed, and being perennial are grown on the same ground from seven to ten years, when they are replaced by fresh ones.

The crop is not cut the first year, but in the middle of June of the second year, and again at the end of September. The plants usually attain the height of rather more than two feet, but if heavily manured they will grow much larger. It is found, however, that in plants which show large leaves and grow rapidly the medicinal properties are less powerful in proportion, even the odour of the plant being weaker.

This is somewhat analogous to what is known of the cinchona trees, in which as a rule, the smaller the leaves the larger the yield of alkaloid. About five pounds of extract are obtained from one cwt. of herb.

Hemlock.

Very little hemlock is grown, the wild plant being preferred. It is said to be plentiful in the neighbourhood, nearly twenty tons of it being sometimes made into extract in one year by Mr. Ransom. From four to six pounds of extract are obtained from one cwt. of herb.

Squirting Cucumber.

Only two to three acres of this plant are grown every year, there being comparatively little demand for elaterium in this country. The plants are earthed up in winter like celery and require plenty of manure applied annually. The yield of elaterium depends much upon the weather, very little being obtained in a wet season. If the month of August is fine and dry the yield is not only larger but of superior quality. The drug as pre-

* After the first day or two, according to Mr. Ransom, the boys become so insensible to the poison that they feel but little pain when stung.

* A Winchester quart holds about five pounds avoirdupois.

pared by Mr. Ransom is of a fine ash green colour and comparatively sweet odour. This result is obtained by pouring off the supernatant liquor as soon as possible after the elaterium has deposited. If this be not done, fermentation is soon set up and the product depreciated in quality. Although Mr. Ransom probably grows more than any one else in England, the demand is so small that some wholesale houses have often not purchased more than two ounces in twelve months. That which is exported goes chiefly to Russia.

HENBANE.

About five or six acres of the biennial plant are grown on the average; but the quantity varies very much, being almost a total failure in some years. Mr. Ransom's experience corresponds with that of Mr. Usher of Banbury as regards the uncertainty attending the appearance of the plant from the seed. Indeed in one of the fields at Hitchin, in which lavender plants two years old were in blossom at the time of my visit, only the biennial henbane had come up, which had been sown before the lavender was planted there.

A small quantity of marshmallow is also grown by the riverside, where it does well.

The above are, I believe, the leading medicinal plants which are grown in the neighbourhood of Hitchin.

Mr. Ransom produces at his extensive laboratory a very large number of extracts, essential oils and liquors, and many of these in very large quantity, using as much as 40 tons of dandelion root per annum. Some of the extracts are such as are rarely asked for in retail shops, but for which there must be local demands. Among these were noticeable the extracts of sarsaparilla, *Actœa racemosa*, *Chelidonium majus*, *Datura Tatula*, *Saponaria officinalis*, wormwood (*Artemisia Absinthium*), angelica (*Archangelica officinalis*), centaury (*Erythrœa Centaurium*), pulsatilla (*Anemone Pulsatilla*), blessed thistle (*Carduus benedictus*), walnut (*Juglans regia*), white horehound (*Marrubium vulgare*), buckbean (*Menyanthes trifoliata*), St. Ignatius's bean (*Strychnos amara*), senega, and the alcoholic extract of belladonna and ipecacuanha. The extract of Ignatius's bean is used for epilepsy and goes chiefly to Australia and China. To give an idea of the extent to which some of these uncommon extracts are used, it may be stated that as much as thirty or forty pounds of extract of *Ignatia amara* is turned out annually. All these extracts are made in steam evaporating pans, the juice being in many cases expressed from the plants or roots under an hydraulic pressure of 300 tons.

A prominent feature in the laboratory is the apparatus for making scammony resin from the root. This is obtained by percolating hot spirit through the powdered root. As expression of the root after percolation would involve considerable loss, and the last portion of spirit has to be displaced with water, considerable trouble has to be taken in freeing the resin from aqueous extract. In dissolving the resin of scammony of commerce in ether a small amount of insoluble matter will often be found, which is probably matter of this kind. Economy of fuel is provided for as far as possible by causing the hot water from the steam pans, etc., to pass into a large tank from which it is pumped by the engine into the boiler, etc., as required. The latest improvements have been adopted, even to the use of a patent for preventing the escape of steam while allowing the hot water to escape.

In conclusion, one word of caution is necessary to those who may feel inclined to visit Hitchin. The lavender fields are a sight well worth seeing when in full flower; the handsome red admiral (*Vanessa atalanta*), the tortoiseshell (*V. urticæ*), the gorgeous peacock (*V. Io*), the brimstone (*Gonepteryx rhamni*), and even the clouded yellow butterfly (*Colias edusa*), as well as many commoner species, are to be seen in great force hovering over the lavender flowers. But let not the visitor be tempted to chase the lovely insects, for most formidable and by no means beautiful is the harvest insect, which seems to have an equal predilection for lavender fields and manifests a peculiar desire to leave an impressive reminiscence with all who venture among the blossoms, and no one who has made its acquaintance there will ever forget Hitchin.

THE FLUID EXTRACT OF JABORANDI.*

BY FRANCIS V. GREENE, M.D., U.S.N.

In the experiments undertaken to test the therapeutic effects of jaborandi, which was introduced to the notice of the profession in Paris in 1873, by Dr. Coutinho, of Brazil, as a powerful sialogogue and diaphoretic, Rabuteau, Gubler, Rolin and other physicians of that city employed the remedy in doses of from four to six grams, infused in hot water, the dregs being swallowed along with the liquid. The same plan of administration was adopted in other parts of the Continent. In England, Ringer and others prescribed a tincture representing thirty grains to the fluidrachm, which necessitated the administration of two fluidrachms, as the equivalent of the four grams used in making the infusion.

Having, in September, 1875, received from Pernambuco, Brazil, a sufficiently large supply of the leaves for an extended trial of the new drug, I determined to employ a fluid extract in the investigation I purposed making in regard to its action on the economy, and, after several failures, succeeded in making a preparation which, in every instance it was administered, produced all the effects obtained from the infusion made from a drachm of the bruised leaves. The results obtained with this fluid extract in a series of experiments, conducted mainly at the U. S. Naval and St. Joseph's Hospitals in this city, were so satisfactory and so confirmative of the experience of foreign observers, in regard to the efficacy of the jaborandi, that I communicated them to the Bureau of Medicine and Surgery, Navy Department, in the form of a report, which was subsequently published in the *Philadelphia Medical Times*, of October 30th, 1875.

In the investigation pursued at St. Joseph's Hospital, I was very kindly assisted by Dr. John M. Keating, who, on entering upon his term of service as Visiting Physician of the Philadelphia Hospital, in January, 1876, immediately introduced the use of jaborandi into the wards of that institution, where its application and action have since been carefully investigated by himself and colleagues. In a late very interesting clinical lecture on the subject, which has been presented to the notice of the profession through the columns of the *Philadelphia Medical Times*, of June 23rd, Dr. Keating states that the conclusions arrived at are strongly in favour of jaborandi as a safe and effectual remedy in various forms of disease. In the above-mentioned hospital it has become the practice to administer the drug in the form of an infusion of the leaves, as it was found that the preparations in the market could not be depended on to produce the desired action on the skin and salivary glands. As the same complaint has been made by a number of the profession, who have not succeeded in obtaining the proper effects of

* From *The American Journal of Pharmacy*, August, 1877.

the medicine with the preparations used by them, and as I know by experience that, as far as the fluid extract is concerned, a convenient and reliable preparation can be made with very little difficulty; I deem it advisable to call attention to some points in regard to physical characters of the jaborandi leaves, which, I believe, will account for the failures that have been experienced in making the fluid extract.

On examining a leaflet of jaborandi, we find that it is coriaceous in texture, and that, in addition to a prominent midrib, it contains a large number of veins which, leaving the midrib at an angle of about 60°, run in a parallel line to within a quarter of an inch of the margin, where they anastomose. The cellular tissue, which is covered with a tough epidermis, is studded with numerous receptacles of secretion, which give the leaflets their pellucidly punctate appearance, when held up to the light. As the result of this peculiar construction, when the leaves are ground in a mill, the woody structure is readily reduced to powder or very fine fibres, while the cellular portion is merely broken up into small fragments, still covered by the epidermis. If the material be moistened in this state with the menstruum, and placed in a percolator in small quantities at a time, it will be found in packing it, that it will spring up against the fingers as soon as the pressure is removed, and if, notwithstanding this fact, the percolation is proceeded with, on the addition of more menstruum the material will separate into several portions or layers, and the operation be thus rendered a failure. To prevent this separation, I have found it to be essential to reduce the leaves to a *moderately fine* powder; but, as even in this condition the cellular tissue was not so thoroughly disintegrated as to entirely overcome the tendency to the formation of channels in the packed mass, I furthermore adopted the plan of placing a thick layer of well-washed sand on top of the cloth covering the material, and in this way succeeded in obtaining a satisfactory precolate.

The menstruum that I have used to exhaust the jaborandi leaves has invariably been a 50 per cent. alcohol, which extracts the active principle promptly, as it is quite soluble in both alcohol and water.

With the above explanation of what I consider to be the cause of the failures that have hitherto occurred, I would suggest the following formula and directions:

FLUID EXTRACT OF JABORANDI.

Take of
Jaborandi leaves, in moderately fine powder, 16 troyounces.
Alcohol (50 per cent.), ... a sufficient quantity.

Moisten the powder thoroughly with the menstruum, pack in a conical glass percolator, place a layer of two inches of well-washed sand on top of the cloth covering the material, add menstruum until the liquid begins to drop from the percolator, when the lower orifice is to be closed with a cork, and the percolator, securely covered, set aside in a moderately warm place for four days. At the expiration of this time remove the cork, and add more menstruum by degrees until the material is exhausted. The first fourteen ounces of the percolate are to be reserved, and the remainder evaporated on a water-bath, with constant stirring towards the close, to two fluidounces, which are to be added to the reserved portion. If the percolation and evaporation have been properly performed, the fluid extract will not require to be filtered.

As the use of sand in the manner mentioned above appears to be called for theoretically in the case of a material like jaborandi, for the reason that in furnishing the required pressure, it secures the uniform distribution of the menstruum from the surface of the material through the whole extent of the mass, which point constitutes the essence of the process of displacement, its employment might be very advantageously extended to the percolation of various other substances, where difficulty of a similar nature is experienced.

THE CARRAGEEN CROP.*

To the great majority of people, carrageen, under the more familiar name of Irish moss, is known chiefly as the basis of a pleasant and wholesome drink for the sick room, or as an article of use in the preparation of delicacies for the table. Comparatively few are aware of its wide and varied use in the arts, or that the thousands of barrels of it employed annually by our manufacturers of paper, cloth, felt and straw hats, etc., and by brewers, is not an Irish, but an American product, and, strictly speaking, is not a moss, but a seaweed.

Carrageen (*Chondrus crispus*) is to be found, more or less abundantly, all along the northern coast of the United States, ranging between the low water line and the depth of forty feet or so; but, as a rule, its fronds, which correspond to the leaves of air plants, are so numerously inhabited by small mollusca that they are spoiled for other use. The clean-growing article seems to be limited almost wholly to certain ledges in the neighbourhood of Scituate, Massachusetts—a section of coast guarded by the celebrated Minot Ledge Lighthouse, and famous for its danger to shipping. Here, where the waves of the Atlantic dash with full force upon the rocky coast, the carrageen grows to perfection; and, wherever it escapes the spawn of mussels and other shell-fish, is gathered during the summer season in vast quantities.

The harvest begins in May, and ends about the first of September. The gathering is made in two ways—by hand-picking, during exceptionally low tides, and by means of long-handled iron-toothed rakes, at ordinary tides. Of course, the work cannot be carried on except during fair weather. Hand-pulling is possible only during the bi-monthly periods of spring tides, that is, when the moon is full, and again at new moon. At such times, high tide occurs about midday and midnight, and the ledges are exposed for moss gathering morning and evening. The mossers' boats are rowed to the rocks where the finest grades abound, and the gatherers select with great care the growths that are freest from minute shells and other foreign matter. This portion of the crop, if properly handled afterwards, generally goes to the apothecary, and fetches a price two or three times that of the common grade.

As the tide rises, the pickers are driven to their boats, and proceed to the outer moss-bearing rocks, where the rake is used, as it also is during ordinary low tides. Moss taken in this way is not so clean as the hand-picked, and is always mixed with tape grass, which must be removed during the process of curing and packing.

The curing of the moss is the most critical part of this peculiar farming. On being brought to the shore, the moss is black and unsightly; it must be bleached, as well as dried. The bleaching is effected by repeated wetting and drying in the sun; and as the moss is readily soluble in fresh water, the bleaching beds are situated near the banks of the salt creeks that abound along the shore. After drying, the moss is packed in tubs and rolled to the water, where it is thoroughly washed, then rolled back to the bleaching bed, to be dried again in the sun. Five or six such exposures are usually sufficient. On the bleaching ground the moss is carefully spread and turned, and watchfully guarded against wetting by rain. In this process it turns from black to red, then to the yellowish-white of the perfected article. When properly cured, the moss is stored in bulk, in shanties, where, as time permits, it is picked over and packed in barrels. The crop averages about half a million pounds a year; and, thanks to the brighter and more abundant sunshine of our coast, the moss has a brighter colour and is of finer quality than the Irish product.

STRAINING THE LAW.

THE feat of driving a coach and four through an Act of Parliament, though proverbially possible, is one more calculated to illustrate the ingenuity of the operator than to redound to his credit or to prove useful to the community, and consequently it is fortunate that we have but few instances of the kind. But the opposite performance of making the provisions of an Act a pretext for instituting prosecutions which have no sound foundation in fact, or any reasonable desirability, is unfortunately at the present time by no means uncommon. First among the offenders in this direction are public analysts, as we have already had to point out on several occasions, and it is with much regret that we find in the reports of two cases lately brought before the Glasgow magistrates, continued evidence of the same tendency to overdo the working of the Food and Drugs Act, so as to convert a provision for the protection of the public into an engine for persecuting the individual trader.

The cases we refer to were partially reported in the Journal of last week under the head of "Alleged Adulteration of Citrate of Magnesia," and the charge made against the persons accused was that they had sold citrate of magnesia which was not of the nature, substance, and quality demanded by the purchaser. The evidence by which it was sought to support this charge was to the effect that the article sold contained lead; in one case, to the extent of about one-third of a grain (0·37) in 7000 grains, in the other case, to the extent of four-tenths of a grain in the same quantity of the citrate.

It may be gathered from the reported remarks of the Stipendiary Magistrate and of the Fiscal, that the facts given in evidence as to the presence of lead in the citrate of magnesia were construed as indicating the perpetration of a gross adulteration of the article, and the committal of a reprehensible offence against the Food and Drugs Act. Under the influence of these impressions—which even led the Fiscal to consider the case where the presence of four-tenths of a grain of lead was testified to, as being one "much more gross" than that in which the alleged quantity was ·37 of a grain—the evidence given for the defence was apparently little regarded, or at most estimated only as what might be urged by a dishonest tradesman to justify or excuse his misdeeds.

This evidence for the defence was, however, very much to the point, and in our opinion it ought to have secured the immediate dismissal of both cases. The witnesses called were Mr. HOWIE and Mr. McADAM, both persons well conversant with the trade and with the nature of the article in question. Both of them stated that citric acid was well known to contain minute traces of lead as an impurity arising from the method of manufacturing it, and as citric acid is an ingredient of citrate of magnesia it was thus rendered evident that the lead contained in the citrate was not an adulteration in any sense. It had not been added fraudulently to increase the bulk, weight, or measure of the article sold as citrate of magnesia, neither had it been added to conceal the inferior quality of that article, or in any other way to prejudice the purchaser; but it was precisely one of those impurities or extraneous substances which become unavoidably mixed with articles of food and drugs in the process of preparation, and this is one of the cases in regard to which the Act very properly provides that an offence shall not be deemed to be committed.

Under these circumstances, we think that Dr. SMITH and Mr. CAMPBELL have much reason to regard themselves as sorely aggrieved by being made the objects of a prosecution so entirely without just foundation. And after having been held for a week under the suspicion of being the perpetrators of a fraudulent offence, there is but small consolation in being told that the case was "not proven," instead of being exonerated from reproach. However, that was the extent to which the magistrate went in delivering judgment, as will be seen from our report, at p. 317, while Dr. SMITH and Mr. CAMPBELL had to bear the expense of producing evidence in their behalf, as well as the inconvenience of attending at the police court.

Another case of a similar nature was heard at Barnard Castle, last week, in which Mr. COOKE, of the Commercial Inn, Galgate, was sought to be punished, under the Food and Drugs Act, for selling soda water which did not contain the full quantity of fifteen grains of bicarbonate of soda in the half-pint, as directed by the British Pharmacopœia. In this instance the absurdity of expecting an innkeeper to be governed in the sale of articles by rules laid down in the Pharmacopœia was apparent to the magistrates, and they dismissed the charge, on the ground that the soda water was sold as a beverage and not for medicinal purposes.

With every desire to aid the repression of practices of adulteration or substitution which are reasonably to be regarded as injurious to the public, we cannot but protest against the idea that the Pharmacopœia definitions should be made to apply to ordinary articles of commerce, not intended for medicinal use. In the case of impurities also, such as the presence of lead in citric acid, where the amount is so small, and, where considering the conditions under which citric acid or citrate of magnesia is used, the probability of its being injurious is so slender, we consider it is in the highest degree unfair to subject the trader to the trouble of defending a prosecution.

We are by no means unmindful that in the cases above mentioned, medical evidence was given to the effect that the lead in the citrate of magnesia might prove injurious. This however was merely an opinion, and its inconsistency with the witness's own experience was manifested by himself in cross-examination when he stated that he frequently prescribed citrate of magnesia and had neither observed any symptoms of poisoning following its use, nor heard or read of such a result. To any one cognisant of the enormous extent to which the preparation known as "citrate of magnesia" is consumed, the fact that no case is known, even of suspected injurious effect, should be sufficient to prove the absurdity of these prosecutions. They are in fact purely speculative, and being altogether outside the objects for which the Act was passed such prosecutions should never be instituted unless it shall have been previously demonstrated that a particular impurity is prejudicial. Until this is authoritatively established and due notice has been given to that effect, the trader should be exempt from the attacks of over zealous analysts and medical officers of health whose opinions are often more decided than well founded. It is time some measures were adopted for repressing in this way the acts of the analysts, which are fast tending to bring the Food and Drugs Act into ridicule, and to deprive the public of that protection which it was intended to afford.

ILLEGAL USE OF METHYLATED SPIRIT.

Our readers will have observed that this subject was recently under the consideration of the Law and Parliamentary Committee of the Council, and that some members of Council expressed the hope that no occasion might arise for vexatious interference by revenue officers, while at the same time the unfair position in which an honest tradesman might be placed by an unscrupulous neighbour was not overlooked.

We understand that complaints have been addressed to the Board of Inland Revenue, which have induced the Board to issue a specific order in reference to the use of methylated spirit, with the object of giving full publicity to the restrictions under which it is permitted. The order referred to was issued on the 16th August last, and runs as follows:—

Methylated Spirit.

Officers surveying Manufacturing Chemists who are allowed to receive methylated spirits, must immediately inform such traders, in writing, that the use of methylated spirit in the preparation of "absolute alcohol" is clearly illegal, as involving the purification of the spirit; and if after this warning it is discovered that any such process is still carried on by any person, the fact must be stated to the Board, in order that legal proceedings may be taken for the penalty incurred.

"NOTHING NEW UNDER THE SUN."

It has often been remarked, when some fact new to science has been disclosed, that the world has already had a sufficiently real, though unacknowledged and unexplained, prescience of its existence to justify the above quoted adage of the wise man. A fresh illustration of this has just occcurred. The statement of Mr. Whitfield last week (p. 300) as to the practice in some laundries of adding turpentine to the washing water, and that of Mr. Druce this week (p. 320) as to the sprinkling of some turpentine on floors before scrubbing them, only show that the washerwoman and the charwoman had so far unconsciously anticipated Mr. Kingzett's researches on the properties of the products obtained by the oxidation of turpentine which are now being applied as a disinfectant under the name of "Sanitas." Our contemporary, the *Lancet*, recently appointed one of its "Special Commissions" to report on the subject of laundries as a possible source of infection, and one result of the disclosures made in this report is the projected establishment of laundries to be conducted on strictly sanitary principles. We take the liberty of suggesting to the managers who are to be entrusted with the scientific drilling of the laundresses that in the custom above referred to their unscientific pupils *in futuro* provide them with a valuable hint as to the scientific disinfection and washing of linen.

BENEVOLENT FUND—ELECTION OF ANNUITANTS.

We take the opportunity of reminding our readers that on Wednesday next, at noon, a meeting is to be held at 17, Bloomsbury Square, for the Election of Six Annuitants on the Benevolent Fund of the Pharmaceutical Society. As there is always a considerable amount of work to be done in connection with the details of these elections, it is hoped that the Chairman will be supported by the attendance of a goodly number of the Subscribers to the Fund.

THE CHEMICAL SOCIETY.

The first meeting of the Chemical Society for the forthcoming session will be held on Thursday, November 1st, at 8. The papers to be read are: "On some Hydrocarbons obtained from the Homologues of Cinnamic Acid," W. H. Perkin, F.R.S., "On Anethol and its Homologues," W. H. Perkin; F.R.S.; "On Two New Methods of Estimating Bismuth Volumetrically," M. M. P. Muir.

LIVERPOOL CHEMISTS' ASSOCIATION.

The School of Pharmacy in connection with the Liverpool School of Pharmacy commenced its operations for the present session on Friday of the present week, with the first of a course of lectures on Chemistry, delivered by Mr. Thomas Williams, F.C.S. Arrangements are also made for the teaching of Practical Chemistry. Lectures on Materia Medica, Therapeutics, and Botany are to be delivered during the summer months. In connection with this school the President of the Association, Mr. T. Fell Abraham, offers two prizes of the value of one guinea each for the students who shall pass the best examination in Chemistry and in Botany respectively. The Honorary Secretary is Mr. Williams, Royal Institution, Colquitt Street.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held in London on Wednesday, October 17th, 1877, the Report of the College of Preceptors on the Examination held on October 1st was received.

Two hundred and thirty-two candidates had presented themselves for examination of whom *One hundred and twenty-four* had failed. The following *one hundred and eight* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

(Arranged alphabetically.)

Arthur, Samuel ....Redruth.
Baker, John Edward ....Bristol.
Ballard, Walter ....Abingdon.
Bartlett, Geo. Fredk. Handel...New Wandsworth.
Bayly, James Hodgson ... .Liverpool.
Beck, Nathan George ....Lyme-Regis.
Beeby, Robert Berry ....Coventry.
Bennett, Frank William.........London.
Bennett, John William ....Leigh.
Bernstein, Moses ....Sunderland.
Berridge, Oliver Gillett ....Leicester.
Biggam, William ....Sunderland.
Booth, Daniel ....Heage.
Brett, William George...........Grantham.
Brown, Alexander ....Dumbarton.
Burton, Edmund ....Totnes.
Clark, Harry ....London.
Cobb, George Myhill ....Nottingham.
Collier, George Patrick ....London.
Comer, Ernest Edward ....East Dereham.
Crummy, Thomas.................Douglas, I. of W.
Dan, John...........................St. Clears.
Dancy, Ralph ....Turner's Hill.
Davies, Thomas ....Hirwain.
Diamond, Harry Scott ....Pembroke Dock.
Donald, Joseph.....................Newton Arlosh.
Douglas, William.................Woodside.
Dyball, Thomas Walter ....Ipswich.
Elmitt, Samuel Frank ....Horncastle.
Farrer, Edward ....Kendal.
Field, Cornelius ....Cheshunt.
Fletcher, James Edward.........Saltley.
Fowler, Thomas Webb ....Nottingham.
Gatward, Oswald ....Hitchin.
Gray, John ....Dundee.
Grieve, Charles Frederick ......Edinburgh.
Hake, James ....Taunton.
Harburn, Alfred ....London.
Hawdon, James Alexander......London.
Haythornthwaite, William......Giggleswick.
Hedley, Robert Cecil ....Newcastle-on-Tyne.
Hewitt, Joseph........... ....York.
Hick, Thomas Matthew ....York.
Higgs, Frederic Charles ....Newbury.
Howe, John Michael W..........Hitchin.
Humphrey, John Thurlbeck ...Sunderland.
Ison, Harry John..................Wellington.
Jarvis, Joseph Henry E..........Ashford, Kent.
Jenkins, Charles Major ....Crosswen Cottage.
Johnston, David Leslie ....Forres.
Jowett, William Hall ....Blackburn.
Lamplough, Frederick Wm. ...Great Driffield.
Lees, James ....Leighton-Buzzard.
Le Sueur, Charles ....Exeter.
Lockwood, Thomas .. ..York.
Lockyer, Joseph Ernest ....Deptford.
Lyon, William Charles ....London.
McPherson, William ....Dufftown.
Maddock, Richard ....Broad Clyst.
Mann, Numa.............. ....Ilkley.
Mays, Herbert ....Wellingborough.
Melwin, James, jun. ....Aberdeen.
Mill, Percival Fenwick ....Buxton.
Miller, David ....Brechin.
Milton, William ....Aberdeen.
Molz, Hermann Adolphus ......Sheffield.
Moore, Frank ....Mirfield.
Morris, David Henry Martin...Sunbury.
Nicol, John Kininmouth.........Leslie.
Nobbs, Arthur Perkins ....Newport, I. W.
Panton, John Edward............Horncastle.
Pask, Thomas Edward ....Newark.
Pass, William Hall ....Macclesfield.
Phillips, Sidney ....Wolverhampton,
Pinder, Robert ....Bourne.
Platt, Joseph ....Stalybridge.
Pocock, William Frederick H. Cape Town.
Preston, Henry.....................Mansfield.
Pritchard, Elias Roberts ....Aberdaron.
Provis, Charles ....Emsworth.
Rann, Millichamp Leonard J. Malvern Link.
Ray, Charles...................... ..Eastbourne.
Roberts, David ....Aberystwith.
Roberts, Roderick ....Crickhowell.
Rohan, Robert Aldor ....Mauritius.
Salmon, Ernest Frederick ......London.
Scammell, Luther Robert ......Adelaide.
Seymour, George ... .London.
Seys, Frederick Arthur ....Newport (Mon.).
Shawyer, John James............Clevedon.
Sill, Silvester Arthur ....Stratford-on-Avon.
Simpson, Robert ....Alnwick.
Spratling, Walter..................Boston.
Sykes, Thomas Hindle, jun. ...Southport.
Tait, Robert ....Edinburgh.
Taylor, George ....Fairfield.
Tucker, William Thomas M. ...Exeter.
Wade, Arthur Malakhoff ......Wakefield.
Warren Evan Mays................Wellingborough.
Waters, William Allen ....Emsworth.
Waymouth, Thomas Staddon...Exeter.
Webb, George Frederick ....London.
Wigg, James.........................Streatham Common
Willett, Frank Augustine ......Oxton, Birkenhead.
Wood, John ....Leighton-Buzzard.
Worsley, Albert George ....Folkestone.
Wynne, William Palmer.........Birmingham.
Young, Thomas ....Cheddar.

The Questions for Examination were as follows:—

First or Preliminary Examination.

October 1st, 1877.

(*Time Allowed: Three hours for the three subjects.*

I. LATIN.

1. Translate into English:—Cum sæpe ultro citroque legati inter eos *mitterentur*, Ariovistus postulavit, ne quem peditem ad colloquium Cæsar *adduceret*; vereri se ne per insidias ab eo circumveniretur: uterque cum equitatu veniret: alia ratione se non esse *venturum*. Cæsar, quod neque colloquium interposita causa *tolli* volebat, neque *salutem* suam Gallorum *equitatui* committere audebat, commodissimum esse statuit, omnibus *equis* Gallis *equitibus detractis*, eo legionarios *milites* legionis decimæ, *cui* quam maxime confidebat, imponere, ut præsidium quam amicissimum, si quid opus facto esset, haberet.

2. Decline *salutem, equitatui, equis, equitibus, milites*, and *cui*.

3. Give the present, perfect, supine, and infinitive of *mitterentur, adduceret, venturum, tolli, detractis*.

4. Select the nouns and pronouns in the first sentence, "*cum—venturum*;" name the case of each, and give the reason for the case in each instance.

5. What instances of the "ablative absolute" have we in the above extract? When may this construction be used? Why is it called "absolute"?

II. ARITHMETIC.

(The working of these questions, as well as the answers, must be written out in full.)

6. (*a*) How are the unit of weight (gramme) and the unit of capacity (litre) derived from the unit of length (metre) in the Metric System? (*b*) How many English inches does the metre contain? (*c*) Without actually performing the calculation, state clearly how you can calculate the number of cubic inches in a litre.

7. What unit is common to the three English measures of weight? Find the value of 3 cwt. 3 qrs. 5 lbs. at £4 14*s.* per cwt.

8. Find the value of $\frac{15\frac{1}{2}}{16}$ of $\frac{11}{62\frac{1}{2}}$ (*a*) as a vulgar fraction, (*b*) as a decimal.

9. If 30 cwt. are carried 15 miles for £5 8*s.* 9*d.*, how far ought 80 cwt. to be carried for £29?

10. In the Centigrade thermometer the freezing point is zero, and the boiling point is 100°; in Fahrenheit's the freezing point is 32°, and the boiling point is 212°; what degree C. corresponds to 68 F.?

III. ENGLISH.

11. Distinguish (*a*) the use of the Adjective from that of the Adverb; (*b*) the use of the Preposition from that of the Conjunction.

12. Give the past, indefinite, and the complete participle of the following verbs:—*wind, show, shake, catch, freeze, throw.*

13. Give in full the future of *write*, (*a*) as a simple future, (*b*) as an emphatic future.

14. Parse the following lines:—

"Who but must laugh, if such a man there be?
Who would not weep, if Atticus were he?"

15. Write a short account of Thomas à Becket or Sir Walter Raleigh; *or* a short essay on the Electric Telegraph, *or* the War in Turkey.

The following is a list of the Centres at which the examination was held, showing the number of candidates examined at each Centre, and the result:—

	Candidates. Examined.	Passed.	Failed.		Candidates. Examined.	Passed.	Failed.
Aberdeen	7	5	2	Leeds	14	5	9
Aberystwith	2	1	1	Leicester	3	2	1
Barnstaple	1	1	0	Lincoln	2	1	1
Birmingham	12	4	8	Liverpool	4	2	2
Boston	4	3	1	London	40	19	21
Brighton	4	1	3	Macclesfield	2	1	1
Bristol	5	3	2	Manchester	11	2	9
Cambridge	2	0	2	Newcastle-on-T.	11	5	6
Canterbury	2	2	0	Northampton	6	4	2
Cardiff	4	1	3	Norwich	2	1	1
Cardigan	1	0	1	Nottingham	9	4	5
Carlisle	4	2	2	Oxford	4	1	3
Carmarthen	2	1	1	Peterborough	2	1	1
Carnarvon	2	1	1	Plymouth	1	1	0
Cheltenham	1	0	1	Portsmouth	2	2	0
Chester	2	0	2	Preston	4	3	1
Colchester	1	1	0	Reading	3	1	2
Darlington	1	0	1	Salisbury	1	0	1
Douglas	1	1	0	Scarborough	1	0	1
Dundee	2	1	1	Sheffield	3	1	2
Edinburgh	10	4	6	Shrewsbury	3	1	2
Exeter	5	4	1	Southampton	1	1	0
Glasgow	8	1	7	Swansea	6	3	3
Hereford	1	1	0	Taunton	1	1	0
Hull	2	1	1	Truro	2	1	1
Inverness	1	1	0	Worcester	1	1	0
Leamington	2	1	1	York	4	3	1

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The first general meeting of the twenty-ninth session of this Association was held at the Royal Institution, October 11, 1877.

At the opening of the meeting Mr. A. H. Mason, F.C.S., the retiring President, occupied the chair.

The minutes of the annual meeting were read and signed.

The Secretary announced the officers for the present session; President, Mr. Thomas Fell Abraham, A.A.; Vice-President, Mr. Joseph Woodcock; Hon. Treasurer, Mr. Robert Sumner; Hon. Secretary, Mr. Thomas Williams, F.C.S.

Mr. Mason in a cordial manner introduced the President, who upon taking the chair was greeted with a hearty applause. Various donations were announced to the library and museum, and votes of thanks accorded to the donors.

Messrs. W. H. Allen and T. H. Johnson, F.C.S., were unanimously elected members, and Messrs. J. Aston, H. Burrows, and R. Brown, were elected associates.

In the absence of Mr. J. T. Armstrong, F.C.S., the President exhibited the otheoscope, a new form of radiometer, and explained its construction.

Dr. Charles Symes exhibited an electric gas lighting apparatus. He said he exhibited that instrument not because it belonged either to chemistry or pharmacy, but as an interesting practical application of frictional electricity. It consists of a gas burner supported on a movable disc of ebonite, over which is fixed a metallic disc lined with leather and surmounted by two wires terminating in points (but not touching) exactly over the orifice of the jet. The electricity developed by the friction of the two plates is communicated to one of the wires by a little chain, and in passing from one point to the other produces a spark which ignites the gas. Its object is more especially to obviate the necessity for matches in works and warehouses where their use would be dangerous. He also exhibited a specimen of asbestos cardboard, which substance he said has been recently introduced as a packing for pistons, etc., of machinery, and is also an acquisition to the chemical laboratory. It was shown and described some months since by Mr. Noel Hartley at a meeting of the Chemical Society. When wetted it is quite soft and pliable, and may be bent or pressed into any form desired. As a small mat on which to place hot flasks or crucibles, or moulded round the bottom of a flask to protect it from the direct action of the flame and to diffuse the heat of a Bunsen lamp, it is equally valuable. He exhibited pieces he had worked into different shapes, and in a crucible of this material readily melted some lead before the audience.

Mr. E. Davies, F.C.S., thought it would prove highly useful for luting retorts and to prevent the bumping which occurs in certain distillations.

The President, Mr. T. Fell Abraham, A.A., delivered his inaugural address.

Inaugural Address.

Gentlemen,—When I was informed that your Society had honoured me by conferring upon me the office of President, I shrank from its acceptance.

It was pointed out, however, that such a course would be inconvenient, as, under the new laws the President is elected by the members present at the last ordinary meeting prior to the recess.

Had I so declined to act I should certainly have consulted my own comfort and, probably, also the interests of the Association, for I feel myself, both as respects my powers and my opportunities, quite incapable of doing justice to the obligations of the office which you have so honoured me by conferring.

However, having accepted the duties I must trust that you will look with indulgence on my many deficiencies, and grant me your cordial assistance in any endeavours I may put forth to conduct the business of the session to a successful conclusion.

To the members of the Council of your Association I may perhaps be permitted to make a more special appeal. Mine is the first instance in which a president has been appointed from amongst the body of the members. They have hitherto, invariably, I believe, been previously members of Council, and therefore to a greater or less degree acquainted with the internal administration of the Association.

I therefore look to the members of the Council for that kindly assistance which their experience will enable them to give me, and which my inexperience will make me so dependent upon.

With your permission, gentlemen, I will now proceed briefly to refer to some matters which have been, some to a greater and some to a lesser extent, occupying the minds of pharmacists and chemists during the last few months.

First, as to the much discussed and probably rather hackneyed subject of "counter-prescribing."

At the outset, it is necessary to remember that laws are made, or at all events should be made, not for the protection of particular classes but for the protection of the public. Thus the various Medical Acts are not intended for the benefit of medical men primarily, though really they may be so; they are intended to protect the public from the injury arising from the false pretences of unqualified persons. So with the Acts relating to pharmacy. These Acts have not been made to apply to the sale of simple drugs or other remedies. It is only when one comes to deal with dangerous substances and prescriptions that the law steps in and requires a special qualification.

Now let us try to apply these two general rules to our special case.

In the first place, what is prescribing? Some would say that prescribing for a patient is, writing what we call a prescription for him. In one, and perhaps its strictest, sense, this definition is correct. Practically, however, it is only very partially correct. A physician may prescribe change of diet, of occupation, of scene, or of clothing for his patient without writing a word. The instructions the physician gives his patient form his prescription; the writing of a portion is merely a means.

The person who administers a stimulant to another whose symptoms he thinks demand such treatment, we consider does a kind action and we would laugh at the idea of such an action being an encroachment on the duties of the physician. Similarly the chemist who gives a dose of chalk mixture to a person who complains of diarrhœa, an antacid draught to one who feels sickly, or applies plaster to the wound of a person knocked down by a passing vehicle, does not step beyond the reasonable bounds of his calling. But when a chemist undertakes to give advice in serious or complicated cases he does, unless the circumstances are very exceptional, what is unjustifiable, because he does, or rather, professes to do, that which in ninety-nine cases out of a hundred his education and training have not qualified him to perform, and for which another portion of the community, specially educated for the purpose, is so qualified.

On the other hand the public often overrate our ability to advise them, and it is very difficult to refuse compliance with requests which to them seem no more than reasonable.

Let those of us then who are pharmacists, whilst firmly declining to undertake responsibilities which we are not qualified to fulfil, be equally determined to defend ourselves from enactments, if they should be proposed, which would render it almost impossible for us to carry on our business.

The fact that a large proportion of our members, myself amongst the number, are pharmacists, must be my excuse for troubling you with a few words on two matters which are probably of but little interest to those outside our ranks.

First as to the Patent Medicine Duty.

How or when it came originally to be imposed I have been unable to ascertain, and it is probably of but little import to inquire.

The use of the word "patent" is in the first place absurd. A moment's consideration will show this. The word means—open, subject to inspection, free from concealment. Now it is to just such preparations as fulfil these conditions that the so-called "Patent Medicine" duty does not apply. The element of concealment of composition is invariably present in the case of those medicines which the public and the Inland Revenue department call "patent." Can anything be more paradoxical?

But a much more serious matter is that the public, utterly ignorant as nine-tenths of them are as to the law on such matters, have got a sort of hazy notion into their heads that because a thing bears a government stamp it has therefore received some sort of official sanction and may safely be administered. They do not know that anything, be it as mild as ditchwater or as deadly as aconite, is equally eligible for the dignity conferred by a government stamp.

In the third place, the duty is inequitable and almost prohibitory in the case of imported articles. For example, a preparation is intended to sell in France at $4\frac{1}{2}$ francs; add the various charges, and we might sell it for *4s. 6d.* If, however, there be any paper or label about it that brings it within the clutches of the Medicine Duty, the price is forthwith pushed up to *5s. 6d.* by the *1s.* stamp., an addition of 22 per cent. to its cost. Of course in many cases such an addition is prohibitory.

The objections which I have urged are those which most naturally present themselves to the pharmacist. The student of political economy would of course condemn the tax for reasons of a totally different nature, to which I need not refer. I would, therefore, most respectfully urge on your consideration whether the time has not come when a movement should be made in the direction of obtaining either the remodelling, or better still, the abolition of the tax to which I have referred.

One more matter, interesting to us exclusively as retailers of drugs. A chemist has recently been mulcted in a nominal amount for selling as castor oil pills, pills which did not depend for their activity on castor oil.

In his defence, it may be said that he was asked for an impossibility, that he gave what many chemists would have given under similar circumstances, and that his customer was not in any way defrauded or injured at his hands.

On the other side it may be urged that his customer did not, and possibly, could not, be expected to know that pills which depend for their activity on castor oil are not available, that it was the chemist's duty to explain that to him, and not to let him go away with an idea that he was taking medicine the action of which would be due to castor oil, or to that principally, when its active ingredients were various purgatives, doubtless very good in their way, but totally different in their nature and properties from the article named.

The sooner such shams as citrate of magnesia without magnesia, castor oil pills without castor oil, elixir of horehound which contains no horehound, extracts of linseed in which linseed is the least important ingredient, and many others which might be named, are become things of the past the better will it be, both for the public and for the trade or profession to which we belong. Let us encourage truth and despise falsehood, whether it be in name or any other form.

But to pass on. The past six months have not been particularly fertile in pharmaceutical novelties, or, perhaps

I should say, in novelties that have proved themselves of practical use.

Hydrobromic acid, or rather the impure solution thereof as produced by the process described by Dr. Fothergill, seems to have firmly established itself as a useful agent in combination with quinine. It is found that in many cases when the use of quinine causes headache or other disagreeable symptoms the addition of fifteen or twenty minim doses of hydrobromic acid entirely removes the difficulty. Whether its administration as an independent remedy will be found desirable I think still remains to be seen.

It must be, however, a matter of regret that the name should have come in pharmacy to be applied to an impure and somewhat indefinite product. It is to be hoped that in our next appendix to the Pharmacopœia a form will be introduced that, while keeping pretty closely to the strength of Fothergill's acid, which I think has been found convenient, will furnish a fairly pure and definite product.

Speaking of definiteness, I trust I may be excused for remarking that little can be done in the way of securing greater accuracy in the administration of medicines until the present practice of ordering drops, teaspoonfuls, and tablespoonfuls is abandoned in favour of that of ordering minims, drachms, and ounces. The prescriber calculates to a nicety the quantity of a drug he wishes to give; the druggist conscientiously prepares the medicine, using the most approved appliances to ensure accuracy, and then the patient completely defeats his doctor's intentions by using as a measure a vessel which may be inaccurate to the extent of 50, 60, or even 100 per cent.

Nor is the difficulty confined to spoon measures. What is meant by—say twenty measured drops? It is not very easy to tell. Some would say at once that "twenty measured drops" meant twenty minims, and probably generally that is meant; but, on the other hand, some would say that "twenty measured drops" were twenty counted drops, which in many cases would represent less than half twenty minims, while the Board of Trade would define twenty measured drops as equal to half a fluid drachm, which, in the case of many liquids, as laudanum, chloroform, and some essential oils and tinctures, would make not less than fifty or sixty actual drops.

Chemists can do but little towards bringing about a change for the better in this respect. Till the use of definite terms becomes usual, and the public has been taught to know their meaning and the importance of accuracy in the matter, we must be content as occasion offers to point out the undesirability of continuing the present system. One of the principal difficulties in the way of a reform has recently been overcome by the introduction of the very portable and most inexpensive medicine measures of Mr. Proctor and also of Messrs. Mawson and Swan.

Indian hemp has recently been examined by Dr. Preobraschensky, a Russian, with the result that he attributes its activity to the presence of nicotine. Whether this is the truth or only a portion of the truth remains to be seen.

The low price at which a pure glycerine can now be obtained is having the effect of encouraging the introduction of several new glyceroles. Amongst them may be named those of subacetate of lead, nitrate of bismuth, salicin, salicin and pepsine, pepsine, castor oil, rhatany, and tar. Whether any of these, except the first two, will be found to be really valuable additions to our already too extensive list of pharmaceutical preparations is, I think, very doubtful.

The scarcity of the cinchona bark and consequent high price of its preparations, more especially of quinine, have been fruitful sources of annoyance to pharmacists. Mr. Howard's paper, read at the Pharmaceutical Conference, held out but little hope of a speedy return to normal prices, notwithstanding the extended cultivation of the cinchonas in different parts of the east. It is, to my mind, a matter much to be regretted that so little attention is given by prescribers to the cinchona alkaloids other than quinine, some of which are pretty clearly shown to produce excellent results. If their value was more fully recognized by the medical profession many persons who are now deprived of the use of quinine by its high price would gladly use them. The more extensive use of these alkaloids would also have an excellent effect in reducing the price of quinine and thus leaving it available for use in the special cases where experience may show that it stands pre-eminent.

Much has lately been said with reference to the best means to be adopted to prevent, as far as possible, accidents with chloral hydrate. Its position as a valuable sedative is so fully established that any regulations that would interfere with its use will not be tolerated either by the profession or the public. It has been suggested that it should only be supplied on the order of a medical man, but such a regulation would not have prevented the accidents that have occurred, because it is unreasonable to expect that the patient must get an order for each individual dose of the remedy and the accidents that have arisen have occurred to persons for whom the chloral had been ordered by their medical adviser, but who, not finding a first dose produce the desired effect, have had recourse to a second or a third. So long as a poison such as chloral stands at the head, or nearly at the head of our list of available sedatives, so long must mishaps of a more or less serious nature occur from its use or rather abuse. Regulations as to registration are all very well in their way, but it is my conviction that no good would arise from their application to a substance of such extensive use and so wide a range of dose as chloral hydrate. On the contrary, such regulations would deter some persons from using it, who might fairly and with benefit do so, and would tend to make the public look with less dread, if I may use the term, on those dangerous substances now included in Schedule A of the Poison Act.

The cry for stringent regulations, which simply means in many cases prohibition, seems to my mind nearly akin to that which would prohibit the sale of alcoholic drinks because some persons indulge in their use to an excess, or would close our parks on Sunday because some few persons misbehave themselves, or would abolish theatres because occasionally performances of a degrading character are given therein.

Mr. H. Greenish has recently drawn attention to the fact that commercial oxalate of cerium is sometimes largely contaminated with the oxalate of lanthanum and didymium derived from the mineral from which it is always prepared. He has also shown that the proportions of cerium, lanthanum, and didymium, vary largely in different samples. To so great an extent is this the case and so difficult is it to prepare a perfectly pure salt that a suspicion arises as to whether the good effects attributed by some writers to oxalate of barium may not really be due to the oxalate of lanthamum or to didymium. The very widely varying opinion as to its value as a remedy entertained by different practitioners may probably be traceable to the facts thus pointed out by Mr. Greenish, who states that the Pharmacopœia test of purity would not exclude the presence of the two metals named.

Amongst new drugs may be named Coto bark, said to be a good remedy and indeed a specific for diarrhœa. It is found to contain a volatile aromatic oil, a volatile alkaloid with an odour like propylamine, a soft resin, soluble in alcohol, ether, chloroform, and sparingly in benzole, precipitated by alkalies; a hard resin also soluble in alcohol, insoluble in ether and chloroform, and of five crystallizable bodies to which the names cotoin, paracotoin, leucotin, oxyleucotin, and hydrocotoin, have been given. Coto may be administered as powder, or in the form of an alcoholic 10 per cent. tincture.

Salicylic acid, of which such great expectations prevailed, seems to make but slow progress. This is probably in great measure due to the fact that it is so sparingly soluble in water. This difficulty is readily overcome by the addition of either borax, solution of citrate of ammonia, or of acetate of ammonia. A contribution to the American Pharmaceutical Conference proposes as a convenient and inexpensive method of purifying the commercial pinkish coloured acid its solution in glycerine and subsequent precipitation therefrom by the addition of water.

Attempts have been made to substitute the salicylates of soda and ammonia, which are freely soluble in water, for the acid itself, but these attempts have not met with success, it being pretty clearly shown that the salicylates do not possess the properties of salicylic acid. Probably, as often is the case with new remedies, its value was at first considerably over estimated, and it is now suffering from the consequent revulsion of feeling which overtakes many medicines until their proper application has been correctly ascertained.

Lactopeptin, of which a good deal has recently been heard, has been carefully examined by Mr. E. Scheffer. From his reports, presented to the American Pharmaceutical Conference, it would appear that the statements as to its composition and powers, set forth so boldly on its labels and circulars, are not borne out by facts. It professes to consist of a mixture of pepsine, pancreatine, diastase, hydrochloric and lactic acids, with sugar of milk as a diluent. The conclusions arrived at by the writer of the paper are that lactopeptin contains pepsine, but that its activity is very inferior to that stated; that the pancreatine and pepsine being incompatibles the former is destroyed, and that diastase and hydrochloric acid are also incompatibles; the diastase, if originally present, is destroyed. These results are, as far as I have had opportunities of comparison, confirmed by my own experiments. I found that my sample did not dissolve the quantity of albumen stated, nor one-fourth of it; did not convert the starch into glucose, and that fifteen grains did not emulsify four ounces of cod liver oil.

Calabar bean has been the subject of fresh investigations by Messrs. Harnack and Witkowsky, at Strassburg, with the result of isolating a new alkaloid, to which the name Harnack's calabarin has been given. It differs from eserine, or physostigmine, as it is proposed to rename it, in that it is insoluble in ether and more readily soluble in water.

The discordant effects noted by different experimenters with the preparations of calabar bean are ascribed to the fact that those preparations contain, in varying proportions, these two alkaloids, which are in their action totally different the one from the other.

The Pharmaceutical Society of Paris has recently adopted a large number of new processes and formulæ. Amongst the most important may be mentioned those for syrup of lactophosphate of lime; infusion, wine, elixir, extract and syrup of coca; the corresponding preparations of eucalyptus globulus and of jaborandi; bromide of iron, in solution and pills; dialysed iron, syrup of pyrophosphate of iron and soda, diastase, eserine and its salts, tar water and syrup, extract of malt, mustard paper, pancreatine, syrup of bromide of potassium and phosphide of zinc.

Messrs. Dragendorff and Podwissotzky, as the result of long continued researches, assume that sclerotic acid is the active principle of ergot and that excellent effects have followed its administration. Whether its use will in time displace that of Bonjean's ergotine which has been found so efficient and convenient in practice remains to be seen.

I have now in conclusion to beg your forgiveness if the matters to which I have so very briefly referred have been of an almost exclusively pharmaceutical bearing, and to express a hope that the session on which we are now entering may not be inferior in interest to any of its predecessors.

Mr. John Shaw said he had listened with pleasure to the interesting and practical address which had just been delivered. He reminded the audience that the father of their new President was one of the founders of the Association, nearly thirty years ago, and had been actively engaged ever since in promoting its objects, and he trusted that the son would follow in his respected father's footsteps for many years to come. The address contained many topics of especial interest to chemists and druggists at the present time. The question of prescribing by chemists, or rather of counter practice, as he preferred to designate it, had yet to be settled, if such could be done by administrative or legislative authority. In times past, the fact of a person leaving his shop to visit people at their own homes was considered almost a necessary element in all cases of action against chemists and druggists for infringement of the Apothecaries Act; not so now, however, for the recommendation of any remedy in very simple ailments was in the opinion of some persons quite sufficient to establish the charge, and should such an opinion be endorsed and carried out by the authorities, he thought that much inconvenience would be experienced by the general public. With reference to the so-called patent medicines they were specially exempted from the operation of the Pharmacy Act and it did seem an extraordinary anomaly that the most stringent regulations should be placed upon the sale of poisons, and yet their distribution broadcast be permitted under cover of a three-halfpenny medicine stamp. The immense interest involved in the sale of this class of remedies was such as to necessitate the most careful consideration. The revenue to the Government derived from medicine stamps alone, realizing upwards of £117,000 per annum, was some indication of the amount of money passing across the counter in connection with that department of their business. Allusion had been made as to the propriety or otherwise of placing chloral hydrate on schedule A of the Pharmacy Act. Opinions vary much on this question. However, this matter was still under the consideration of the Council of the Pharmaceutical Society, with whom the initiative rests. The parties most anxious to have it included amongst the scheduled poisons were certain coroners and medical practitioners, as well as the medical press. Whilst speaking of chloral hydrate he could not help calling attention to the deaths caused by carbolic acid. For some years past he had taken note of the fatalities arising from that powerful and deadly poison, so far as he had noticed them in the public prints and journals, and found the number to be seventy. Twenty of these were caused by drinking the acid in mistake, instead of spirits, beer, wine, or water, etc. Twenty in mistake for medicine (eleven of these being in hospitals and other public institutions). Eighteen by suicide, and the rest from a variety of causes. Accidents have arisen in several cases from ignorance of the powerful character of the poison; mothers, in some instances, giving bottles containing the acid to their children to play with. It was extensively used as a disinfectant, and the question would be, "Is the number of deaths produced by it of sufficient urgency to necessitate legislative restrictions as to its sale?" With these few remarks he begged to propose that the best thanks of the meeting be presented to the President for his address.

Dr. Symes said that whilst fully appreciating the value of a poison schedule in the Pharmacy Act he felt it his duty, in reply to the last speaker (Mr. Shaw), to protest against its undue enlargement. Many powerful poisons are at present excluded from it for the sake of public convenience,—the strong mineral acids, to wit,—and yet public convenience does not seem to receive one moment's consideration with regard to chloral hydrate, a substance comparatively innocent, concerning which we have eminent medical testimony, based on experiment, that two drachms can be taken in twenty-four hours by a person of ordinary constitution without its acting as a poison. To his mind the proposition to place this in the same category as prussic acid, strychnine, and such potent substances, amounts to an absurdity. With regard to carbolic acid a larger number of accidental deaths have occurred through its being taken by mistake; these have usually arisen from its not being kept in proper poison bottles, but he might safely assert that not a single case of poisoning by chloral hydrate, and few, if any, by carbolic acid, would have been prevented had these articles been a part of the Poison Schedule. He had great pleasure in seconding the vote of thanks to the President for his address.

The motion was supported by Mr. Davies, and being put to the meeting by the Vice-President, was carried by acclamation.

The President announced that at the next meeting, which will be held Oct. 25, Mr. Edward Davies, F.C.S., will read a paper on "The Influence of the Nascent State on Chemical Action," illustrated with experiments.

BLACKBURN CHEMISTS AND DRUGGISTS' ASSOCIATION.

The second annual meeting of this Association was held in the rooms, Church Street, on the evening of Wednesday, October 10. Mr. W. Farnworth, President, in the chair.

After reading a statement of the current accounts for the past year, which showed a small surplus in the hands of the Treasurer, the President remarked that this was a fitting opportunity to take a retrospective view of their doings and progress for the short time they, as an association of chemists and druggists, had been in existence. The first question arising, how comes this Association to be in existence? It appears to have originated in the first instance from an anxious desire by the assistants and apprentices to secure the assistance of such an association in the prosecution of their studies, so as to enable them to meet with credit the demands that will, in the future, be required from them. No institution could have a more worthy birth, and he hoped its progress would be prosperous, and that it would render great service to its members. Shortly after the formation of the Association, it was hinted that some of the wholesale houses would be pleased to contribute to its funds, and aid in the formation of a library, etc. The suggestion was acted upon, and several of the wholesale firms being communicated with, the following handsome contributions were received:—

	£	s.	d.
Messrs. Woolley, Sons and Co., Manchester	5	5	0
Mr. James F. Wilkinson, Manchester	1	1	0
Messrs. Hodgkinsons, Stead and Treacher, London	2	2	0
,, Barron, Harveys, London	2	2	0
,, F. Newbery and Sons, London	1	1	0
,, Clarke, Bleasdale, Bell and Tollinson, York ..	2	2	0
,, Maw, Son and Thompson, London	1	1	0
,, Langton, Harker and Stagg, London	2	2	0
,, Bourne and Taylor, London	1	1	0
Mr. Gibson, Manchester	2	2	0
Messrs. Ayrton and Saunders, Liverpool	1	1	0
,, Southall, Brothers and Barclay, Birmingham, a Cabinet of Specimens of Organic Materia Medica—value	1	10	0
Messrs. Evans, Sons and Co., Liverpool, a Cabinet of Specimens of Organic Materia Medica and Pharmacopœial Preparations	7	7	0
Messrs. Hirst, Brooke and Hirst, Leeds—vols. 1 and 2 of Miller's 'Chemistry,' with promise of vol. 3, as soon as attainable.			

These were all presented with much cordiality, and best wishes for the success of the Association.

In regard to the educational arrangements, many of the younger members were attending the science classes, presided over by Mr. Isherwood, and it was in anticipation to form a class for botany at a later period. He concluded by saying that the opportunity must not be allowed to pass without an expression of thanks to Mr. Whewell, F.C.S., for three gratuitous lectures during the last session.

This Association now numbers twenty members, nineteen associates, and three honorary members.

MANCHESTER CHEMISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The ninth annual meeting of this Association was held at the Memorial Hall, Albert Square, on Wednesday evening, October 10, Mr. Councillor Brown, President, in the chair.

The minutes of the previous meeting were read and confirmed.

The senior honorary secretary, Mr. Benger, then read the following report of the Council, and the treasurer, Mr. G. S. Woolley, the statement of accounts.

"Your Committee have but few matters of interest to lay before the members in this their ninth annual report. In the absence of any threatening or very exciting attempts at pharmaceutical legislation many members of the trade in this district appear to be indifferent to any attempts which are made to provide opportunities for useful and pleasant intercourse with each other, and the efforts which have for some years past been directed towards this end by the executive of your Association, have, they regret to say, been met by much discouragement. A large proportion of those who willingly pay their annual subscriptions never attend the meetings of the Association; under such circumstances the difficulty experienced in finding gentlemen willing to read 'to a beggarly array of empty benches' papers which have cost them much time and thought can be well understood.

"During the past session the meetings were held in the Memorial Hall, tea being provided. It is proposed to continue this arrangement, and to devote one or two evenings during the year to the discussion of trade questions, which it is hoped may have the effect of bringing together some who have hitherto taken no interest in our proceedings.

"An encouraging item in the year's work has been the success which has attended the School of Pharmacy in connection with the Association. It is gratifying to note that, as was anticipated at the last annual meeting, it has not been found necessary to apply to the Pharmaceutical Society for a grant of money to supplement the fees paid by students as remuneration to the lecturers. At the termination of the session in May, Mr. Siebold and Mr. Grindon presented their reports; these, with the list of questions set in the examination for prizes, were published in the *Pharmaceutical Journal*.

"Courses of lectures for the session 1877-8 have already commenced. The attendance is, as yet, smaller than last year. . .

"It is proposed, subject to the approval of the present meeting, to alter the existing regulations respecting the issue of books from the library of the Association. Many members and associates find it inconvenient or impossible to make use of the library at the hours during which it can be kept open, and a gentleman having kindly consented to act as honorary librarian it is intended to give out the books once a week, on Thursday evenings, from 7 to 8·30 p.m., under certain conditions, such as being returned or exchanged within definite and stated times, etc. Some standard works of reference will of course be retained in our rooms, where they may be consulted at any time on application to the secretaries. It is believed this course will render the existing library more widely useful and perhaps induce members to contribute either donations of books, or of money, to our special library fund. Some much needed additions may then be made to our shelves.

"In the general account there is still a balance due to the treasurer, but as some of the subscriptions due have not yet been received it is hoped that another year will put the balance on the right side.

"At the meeting of the British Pharmaceutical Conference, held in Plymouth, Messrs. Benger and Siebold attended as delegates from this Association.

"In conclusion, your Committee would again urge the chemists of this district to assist them in maintaining the Association in an active and healthy condition, and to show by their presence at the winter meetings that they believe in the importance of the educational and other aims which the Association was established to promote.

Audited and found correct.

C. A. Johnson,
S. Paine.

The Chairman, in moving the adoption of the report and Treasurer's statement, commented on the want of interest in the Association shown by the bulk of the trade in Manchester. It was disappointing to find that in such an important district there should be a gradual falling off, instead of a steady growth in the number of those who took an active part in the affairs of this Society. It had been a reasonable hope that after nine years' work there would have been younger men coming forward willing to relieve those who had established the Association of some of the official duties connected with it. He was glad to see around him the same faces he had met for so many years, and a few new ones also. Perhaps the present gathering was as fairly representative as any of their annual meetings had been for some time; still it was far from what it ought to be. The Manchester Association had enjoyed the reputation of being one of the largest and most active in the country, and it had done in past years important service to the trade. It was gratifying to notice the continued success of their school of pharmacy. This success was largely owing to the excellence of Mr. Siebold's teaching, and as in few towns was such a teacher available, the possession of so good a school ought to induce large numbers to join the Association by whose efforts and agency the arrangements were effected, and under whose supervision they were sustained. It would be grievous if the Association were to break down simply because there were no burning questions affecting their trade interests to be discussed, when otherwise some good was being effected. He did not think the report spoke too strongly of this general apathy.

Mr. Robinson alluded to the unwillingness to subscribe which he had frequently met with in his district, even amongst old members of the Association, who "did not see what good they got from it," forgetting that they shared in the general advancement of education as well as business interests.

Mr. Benger said he feared that many who subscribed to the Association regarded the payment as a sort of investment which might in some mysterious way benefit themselves, and, being only a small sum, they did not trouble themselves to look after the way in which it was applied; such men would of course be disappointed in their return, and some would cease to invest. There was a common impression abroad that the subjects discussed at the monthly meetings were not practical, and were therefore useless. Anyone who would read Mr. Southall's excellent address to the students, at the opening of the School of Pharmacy, Bloomsbury Square, might learn what delights a little wider scientific culture than is *necessary* to the chemist and druggist can confer; and how much nobler is he who can deliver such an address, or even fully and intelligently follow it, than one who devotes his whole time and energy to mastering that somewhat difficult, though popularly considered elementary, acquirement of the chemist, how to make $11\frac{1}{2}d.$ profit in the shilling. With a reasonable prospect of an audience, there were plenty of men in Manchester—or, if not, they could be imported from elsewhere—who would bring before them some of the results of modern scientific thought. Their library might soon become a great common stock of knowledge, available for all. Their school of pharmacy might be still further developed, and their Association might be a strong and compact body, capable of exerting powerful influences under circumstances which were not altogether beyond the imagination of the chemist and druggist to conceive. He was as willing as he had been any time during the past ten years to devote time and trouble to the Association, if in doing so he could be of any real service to the trade in Manchester and district.

Mr. Bloor proposed, and Mr. George Wilkinson seconded, the re-election of the following gentlemen, as officers for the year 1877–8:—

President, Mr. W. Scott Brown; Vice-Presidents, Mr. J. T. Slugg, F.R.A.S., and Mr. W. Wilkinson; Treasurer, Mr. George S. Woolley; Hon. Secretaries, Mr. F. Baden Benger, F.C.S., and Mr. Hermann Woolley; other members of the Council, Messrs. Barnaby, Blain, Botham, Fisher, Hargraves, Hughes, Kay, Mumbray, Payne, Robinson, and Slack.

It was then proposed by Mr. Benger, seconded by Mr. Hughes, and unanimously resolved, that Mr. T. Swindells be appointed honorary librarian, and that the books be lent to members and associates, as suggested in the annual report.

Arrangements for the winter meetings were then discussed, Messrs. G. S. Woolley, Siebold, Payne, W. Wilkinson, and others taking part.

Proceedings of Scientific Societies.

AMERICAN PHARMACEUTICAL ASSOCIATION.

The following *résumé* of the proceedings of the Association at its recent meeting is abstracted from the *Druggists' Circular*:—

The twenty-fifth annual meeeting of the American Pharmaceutical Association was held in the City of Toronto, Ontario, September 4, 5, 6, and 7.

The first session was called to order by the President, Mr. Charles Bullock, of Philadelphia, on Tuesday afternoon, 4th ult., at 3.45 p.m. By that hour some sixty or more members had registered their names as present, and the majority of delegates from the various colleges and other organizations had arrived.

The meetings were held in the City Council Chamber, which had, by a unanimous vote of the City Council, been granted for this purpose. In the absence of His Honour the Mayor, Alderman Wright, in the name of the Mayor and City Council, extended a hearty greeting to the officers and members of the Association, to which the President returned thanks on behalf of the Association.

The President, in his annual address, reminded the audience that, although the Association was composed mainly of pharmaceutists of the United States, yet it was now "at home" in Her Most Gracious Majesty's dominions, and that the occasion should be one of interest to both visitors and visited. The major portion of the address was an historical sketch of pharmacy.

The address elicited warm applause, and subsequently was referred to a committee consisting of Dr. E. P. Nichols, Newark, N.J.; John Ingalls, Macon, Ga.; and T. J. Casper, Springfield, O.

Invitations were received to visit the Bank of Toronto, and from Messrs. Gooderham and Worts to visit their distillery, which were accepted with thanks. Invitations were extended to the professors of the Toronto University and the Medical Faculty of the city to take seats with the Association during their sessions.

The Committee on Credentials reported upon the credentials received, accrediting delegates to the Association.

The Local Committee from the meeting of 1876, in Philadelphia, presented a report stating that, after the expenses incurred by their committee last year were all paid, there still remained in their hands an unexpended balance of 525 dollars; and after consultation with the donors they had decided to present this amount to the American Pharmaceutical Association, with the following proviso: that a similar sum or larger should be raised by the Association, that it be securely invested, that the revenue arising from this fund be used for defraying the expenses of members in making original investigations for the Association, and that it be called the "Centennial Fund."

The report was accepted, and on motion was referred to a committee. It was subsequently approved of, and during the later sessions the Treasurer received subscriptions from members present towards that object.

Mr. Geo. W. Kennedy read the report of the Executive Committee. This report recited the work accomplished in preparing and issuing the last volume of Proceedings, gave information as to membership, revenue, and expenses, and concluded with obituary notices of twelve members deceased during the year. It stated that the present membership is 1164, and the revenue of the Association is also adequate to meet its annual expenses, leaving no accumulation of funds; and suggested that some method should be devised for increased revenues.

The various organizations present were each requested to name one person to act on the committee to nominate officers for the ensuing year.

The reports of the various committees were read by title, and the Permanent Secretary read in full his report as to duties performed during the year, and it, with the report of the Executive Committee, was referred to a committee.

The meeting then adjourned to Wednesday morning at 9 o'clock.

WEDNESDAY MORNING—SECOND SESSION.

Soon after 9, the meeting was called to order; after the reading of the minutes of the previous meeting, and their approval, the report of the Nominating Committee was called for. The report was accepted, and on motion the nominees were balloted for, the Secretary, by direction of the Association, depositing an affirmative ballot for the several nominees separately. The principal officers thus chosen were:—President, William Saunders, London, Ontario; First Vice-President, Ewen McIntyre, New York; Second Vice-President, John Ingalls, Macon, Ga.; Third Vice-President, Emlen Painter, San Francisco; Treasurer, Charles A. Tufts, Dover, N.H.; Permanent Secretary, John M. Maisch, Philadelphia; Reporter on Progress of Pharmacy, C. Lewis Diehl, Louisville, Kentucky.

Mr. William Saunders was now presented, and by the retiring President was introduced to the Association and to the duties of the presidental chair.

The Treasurer, Dr. C. A. Tufts, then read the report of the finances of the Association for the past year, which may be briefly summarized as follows:—

	Dollars.
Balance on hand at last report . . .	941 33
Receipts for the year	5573 04
	6514 37
Expenses and disbursements for the year	5559 98
Balance in treasury	954 39

The report was accepted, and referred to auditors. At a subsequent session they reported the accounts of the Treasurer correct. They also recommended an increase of 100 dollars to the salary of the Treasurer.

Professor C. Lewis Diehl read the introduction to his report on the "Progress of Pharmacy."

The report of the Committee on Legislation was next read by Professor Maisch. From this we glean the following facts:

In Kentucky the law requires an examination after three years, and assistants must be sober and of good character. The fee for examination is ten dollars. Any one can own a registered pharmacy, but only one who has passed the examination can use the title. Graduates of medicine are exempt from the regulations of the law. Patent medicines can only be retailed by regular pharmaceutists.

In Maine the State is to be placed under the charge of three commissioners, to be appointed by the Governor. The candidates for examination must be graduates of colleges of pharmacy, or at least three years in the business, before they can be examined.

In New Jersey a law has been passed, after a struggle of seven years, and the examiners were appointed by the Governor.

In Nova Scotia a pharmacy act has been recently inaugurated.

The Committee on Adulterations and Sophistications presented a report.

In the afternoon session an amendment of the by-laws: "A motion to expel a member shall be laid over to the next session succeeding that at which the motion is made,"—was adopted by a three-fourths vote.

The discussion and vote on place of meeting then occurred, which resulted in the selection of Atlanta, Ga., on the first Tuesday in September, 1878, at 3 o'clock.

The greater part of the afternoon was occupied by the reading of replies to queries and discussions.

THURSDAY—MORNING SESSION.

The Association met at 9.15 a m., and, after the opening routine of business, the reading of replies to queries was resumed.

President Saunders then read the report of the Committee on the Drug Market, of which, during the preceding year, he was chairman. The report was of interest, especially as showing some contrasts between English and American goods to the Canadian market, and also giving much information as to the Canadian products used in pharmacy and the arts.

The Business Committee then called up the unfinished business of last year arising out of the discussions and resolutions relative to the proposition of the revision of the U. S. Pharmacopœia by the joint action of the American Medical Association and the American Pharmaceutical Association. In response to this, Dr. E. R. Squibb stated that, in the present condition of the matter, it needed no action. The American Medical

Association had decided that they would not take up the matter, therefore it would be impossible under the resolutions offered last year for this body to proceed further. For his part, after the ignominious manner in which he had been treated, he had no desire to further pursue the matter. His entire object had been only with the intention of securing a better work, and in accord with the advance of science, but he had been misunderstood, and pursued as if he had been guilty of some flagrant wrong. If the medical profession were satisfied with the work as it exists, he was willing that it should be so, and he therefore moved that the whole matter be dropped.

A resolution conveying the thanks of the Association to Dr. E. R. Squibb, of Brooklyn, New York, for his efforts during the past two or three years to inaugurate an improvement in the plan of revision of the United States Pharmacopœia, was carried unanimously.

Dr. F. Hoffman then offered the following preamble and resolutions :—

Whereas, The plan and method adapted for the elaboration of the first edition of the United States Pharmacopœia, and subsequently continued for its decennial revisions, in consequence of the improved means of intercourse, and, moreover, by the altered conditions, resources and requirements of the arts, sciences and practice of medicine and pharmacy, require a reform ; and

Whereas, The Pharmaceutical Convention, as yet the only authorized body for revising and publishing the Pharmacopœia, is so constituted that it meets for this purpose only once in ten years, and has not acted in time, notwithstanding the recognized necessity for an earlier revision, to make the Pharmacopœia conform with the progress and present status of materia medica and the practice of pharmacy; and

Whereas, The American Medical Association, after a full and elaborate presentation of this subject and of a mature plan for action, at its recent meeting in Chicago, has failed to take any action in the important subject of pharmacopœial revision; therefore

Resolved, That the President of this Association appoint a committee of five to take into consideration the advisability and feasibility on the part of the American Pharmaceutical Association, as the national representative organization of the profession of pharmacy, to prepare a complete Pharmacopœia, which may be submitted to the criticism of the medical and pharmaceutical professions, and may be proposed to the final Committee on Revision ; and that that Committee be instructed to report early at the next session, so as to leave time for definite action at this meeting.

The preamble as first proposed was the cause of some discussion by several members, and was modified as above. After some further remarks it was adopted unanimously, and the President appointed a Committee on the resolution.

Some volunteer papers were next read.

In the afternoon session, after the opening business, the Business Committee brought forward the alteration of the by-laws necessary to meet the recommendations relative to the Treasurer's salary, and it was so altered as to make his salary 500 dollars per annum, when it was adopted.

During the afternoon a volunteer paper and replies to queries were read.

The Permanent Committee on the U. S. Pharmacopœia being called upon to report, the chairman, Professor B. W. Bedford, stated that he regretted that he had no satisfactory report to present as to the action of the Committee. Some of its members had done considerable work toward the common cause, but as the body is constituted, with its members at entirely separate localities, and with no place of reunion save at the annual meetings of the body, and where it has been impossible to meet as a whole Committee, he had found great difficulties to overcome, and felt convinced after his efforts that the Committee would fail to accomplish the work as they desired. In view of these facts, and in order to leave the Association free to act in the matter of arranging a more comprehensive plan, and with the entire concurrence of the members of that Committee who were present, he tendered the resignation of the Committee.

The resignation of the Committee was accepted, and the thanks of the Association were tendered to the Committee for the labours they had performed.

The Business Committee then called upon the Committee on Dr. Hoffman's resolution to report, when the following was read:

The Committee appointed to consider the proposition contained in the resolution offered at the previous session, to the effect that the American Pharmaceutical Association prepare a Pharmacopœia which may be proposed to the final Committee of Revision of the National Convention, and to be submitted to the criticism of the medical and pharmaceutical professions, report that they believe that such action is advisable at this time, and they offer the following resolution :—"That this Association appoint a Committee on the Revision of the U. S. Pharmacopœia, consisting of fifteen members, who shall, by a plan to be determined by themselves, be instructed to prepare the text of the proposed new Pharmacopœia, and that they report progress at each subsequent meeting, and finally lay before the Association at its meeting in September, 1879, a complete result of their labours."

After the reading of this report, a little discussion ensued, when it was adopted, and the President was requested to name the Committee, which he promised to do at the next session.

The meeting then adjourned.

FRIDAY—MORNING SESSION.

The meeting was called to order by Vice-President Ingalls, the minutes were read and adopted.

During the morning session, which was the last one of the Association, replies were read to queries, also volunteer papers.

The President named as the Committee on Revision of the U. S. Pharmacopœia, in accordance with the resolution adopted at the last two sessions: Charles Rice, Chairman; F. Hoffman and P. W. Bedford, New York; J. M. Maisch, J. P. Remington and C. Bullock, Philadelphia; G. F. H. Markoe and S. A. D. Sheppard, Boston; J. F. Hancock, Baltimore; A. E. Ebert, Chicago; C. L. Diehl, Louisville; E. S. Wayne, Cincinnati; W. H. Crawford, St. Louis; Charles Mohr, Mobile; and E. Painter, San Francisco. By unanimous request of the Association the name of William Saunders was added.

The Committee was empowered to draw upon the Treasurer for the sum of fifty dollars.

The Committee on the Exhibit of Chemical and Pharmaceutical Products read the report, which was accepted and referred.

Mr. H. S. Wellcome suggested that the object of the annual exhibitions was becoming promoted into a sort of display for pecuniary gain, and thought they should be abandoned in future. After some remarks the subject was referred to the Executive Committee to report on next year.

Several replies to queries and volunteer papers were read during the session.

The remainder of the time was taken up in the passing of various votes of thanks, etc. The "Health of Her Majesty Queen Victoria," was followed by three hearty cheers from the members.

Finally, the President put the motion that this Association do now adjourn to meet in Atlanta, Georgia, September 3 (the first Tuesday), 1878, at 3 p.m., which was carried.

The following are some of the replies to queries:—

Veratrum viride.—As several different conclusions have been reached by late investigations in regard to the active principles of this drug, an accurate analysis is desired in order to definitely settle the subject. By C. A. Robbins, New York.

The writer claimed to have made a very careful and thorough examination of reliable veratrum viride. The results do not appear to agree in all respects with other investigators. While jervia, veratria, resin, and colouring matter were obtained, the mother liquor (from which some of these principles had been separated) yielded still another alkaloidal principle soluble in ether, and separating in the form of crystalline scales. This, he believed to be a substance different from any heretofore described, but from the small quantity obtained, as yet no definite results could be deduced. The name *veratridia* is suggested for this body, which is said to be quite poisonous, but still different in its action from the usual known products of veratrum. The claim to its different character seems to rest mainly on *colour tests*, which are said to be quite distinct from similar reactions with jervia, veratria, etc.

Confection of Senna.—The present officinal formula for the preparation of confection of senna directs the use of cassia fistula, a drug not always easily obtained, and consequently has caused the substitution of other and less active drugs. Cannot this formula be modified or the cassia fistula substituted by some drug more generally in use? By Adolph W. Miller, Philadelphia.

The writer suggested an alteration of the formula, using the following proportions of materials:—

Senna, in fine powder	8 parts.
Coriander	4 „
Tamarinds	16 „
Prunes	17 „
Sugar	30 „
Water, sufficient.	
The final product to weigh	96 „

The tamarinds and prunes are first treated with boiling water, strained through a fine sieve, this process repeated, the sugar is dissolved, excess of water evaporated till reduced to eighty-four parts by weight when the powdered senna and coriander are incorporated.

Dr. Squibb said that cassia fistula could always be had of good quality. The difficulty lay more in the proper exhaustion of it. His practice was to dry it till the pulp was free from excess of moisture, then crush it very fine, when it was readily exhausted.

Cantharidal Collodion.—Mr. Joseph Roberts, Baltimore, recommended the following formula:—

Powdered cantharides, 8 troy ounces.
Stronger alcohol, a sufficient quantity.
Stronger ether, „ „
Pyroxylon, 144 grains.

Mix equal bulks of stronger alcohol and stronger ether. Moisten the cantharides with eight fluid ounces of the mixture, pack in a percolator and add enough of the mixture to obtain fifteen fluid ounces of percolate. Set this aside, and continue the percolation with the same menstruum until four fluid ounces more are obtained, evaporate this to one fluid ounce, and add to the reserved percolate. In this dissolve the pyroxylon.

Dr. E. R. Squibb said that the greatest difficulty was with the pyroxylon of the market. There were several grades of "cotton" and they varied in solubility. He thought that acetic acid or acetic ether should be used in the percolation as a more perfect solvent for the cantharadin.

White Wax.—Professor P. W. Bedford, New York. The writer stated that from examination and inquiry he was lead to believe that fully 75 per cent. of all the "white wax" sold was adulterated. The bulk of this adulterated wax finds its use through other commercial outlets, and is employed by artisans and for domestic purposes, and a much smaller percentage of what is sold by druggists is adulterated. Nearly every wax bleacher, perhaps every one, makes a lower grade or cheaper priced white wax, which is usually sold with the understanding that it is not pure. The impurities are confined almost entirely at the present time to stearin, paraffin or ceresin. These adulterants give wax a much *whiter* appearance than the usual sun-bleaching can ever do. Pure sun-bleached wax is of a cream colour, and when chewed does not cohere together. When of a dead white colour it is never pure. Paraffin and stearin are both of a lighter specific gravity than wax. Bleached or white wax which is of a lighter gravity than ·950 or heavier than ·970 should be rejected. Pure bleached wax is soluble in five parts of chloroform at 85° F., but at a slight reduction of temperature it has the appearance of a smooth emulsion. Stearin may be detected by its ready saponification when a small piece of suspected wax is heated in a tube with dried carbonate of soda and water. Paraffin and ceresin are not destroyed by sulphuric acid, while wax is entirely carbonized.

Oleates of Mercury, Morphia, etc.—Mr. W. S. Thompson, Baltimore, gave a series of formulæ for these preparations, of which the noticeable features were the preparation of freshly-precipitated oxide of mercury, and, in the case of some of the alkaloids, these were dissolved in alcohol before adding them to the oleic acid. He used purified oleic acid, and also advocated the use of cosmolin as a substitute for a portion of the oleic acid.

Dr. Squibb stated that in his experience he had not failed to accomplish satisfactory results by taking the yellow oxide of mercury and dissolving at once in the oleic acid, *without the use of heat.* A twenty per cent. solution of oleate of mercury, which has the consistence of good butter or lard, is the most stable. Alkaloids were perfectly soluble in oleic acid, and it was unnecessary to use alcohol. He deprecated the use of cosmolin or other patented articles when equally good substitutes can be had cheaper.

Both Professor Remington and Professor Markoe said that both vaselin and cosmolin are liable to change and rancidity, and opposed their use.

Mr. George W. Kennedy, Pottsville, stated that boiling water yields a larger quantity of extract than cold water will. Extract made with cold water is, however, much more active, and this kind should alone be made.

Salicylic Acid.—Mr. David Hays, New York, had examined solutions of salicylic acid made with various solvent salts which were added to facilitate the solution of the acid, and found that the results are not simple solutions of the separate bodies, but that some change takes place by which the acid combines with a portion of the alkaline solvent. When phosphate of sodium is added to the acid in definite quantities and the solution examined, there is found in it a noticeable quantity of salicylate of sodium, free salicylic acid, and the original monohydrophosphate of sodium is changed to hydrophosphate of sodium.

In every case a similar change is effected by the usual solvents.

Dr. Squibb, commenting on the subject of salicylic acid, said that the *dialysed* acid was the best form of commercial acid, but this still retained some impurities, which were separated by sublimation. The process for sublimation was almost identical with that for benzoic acid, but that it must be done over a carefully regulated steam-bath, when it left a residue of dark colour. If done by dry heat, it readily decomposed. As an antiseptic he had used solutions of salicylic acid with great success in preventing the growth of microscopic fungi in alkaloidal solutions.

In another paper Mr. R. V. Mattison, Philadelphia, gave a *résumé* of the various processes for manufacturing this acid, the chemical changes occurring and the various tests of purity. The aid of the various solvents recommended were in his opinion of more than doubtful use, as he thought their therapeutic value injured thereby. The opinion was expressed that, aside from its use in preventing decomposition, fermentation, and similar purposes.

that there was but little other pharmaceutical use for salicylic acid.

Ergotin by Bonjean's method.—In determining the yield by this method when using alcohol of different strengths for the extraction of the aqueous extract, Mr. George Zellhoefer, New York, found that the weaker the spirituous strength of the menstruum, the larger the yield of so-called aqueous extract. Ergot was exhausted with water, and the liquid was evaporated so that each fluid-ounce represented the soluble principles of four ounces (av.) of ergot. The liquid was then divided in portions, and each portion treated with alcohol of different strength, and the liquids evaporated separately to the consistence of a soft extract. The yield was as follows:—

Alcohol sp. gr.	·817,	yields	9	per cent.
,, ,,	·832,	,,	11·5	,,
,, ,,	·860,	,,	15·0	,,
,, ,,	·893,	,,	24·5	,,

The following working formula was suggested:—

Fine ground ergot, 16 troy ounces; cold distilled water, 3 pints; macerate twelve hours, strain and express; to the ergot residue add cold distilled water, 3 pints; proceed as before, mix the liquids, evaporate by water-bath to 4 ounces by weight, then pour it into 1 pint of alcohol, sp. gr. ·832. Mix. At the end of twenty-four hours filter, and evaporate by water-bath to the consistence of a soft extract. Yield 11·5 per cent. This has a dark-red colour, is perfectly soluble in water and should be kept in a cool dark place.

Glycerine in fluid extracts.—Mr. J. U. Lloyd, Cincinnati, is of opinion that glycerine can be used advantageously in the preparation of the following fluid extracts: Cinchona, dogwood, geranium, gossypium, matico, pipsissewa, prunus, rhatany, rubus, uva ursi. For the following it is not deemed better than water: Belladonna root, colchicum root, colchicum seed, colombo, digitalis, ergot, gentian, hydrastis, hyoscyamus, sarsaparilla, sarsaparilla compound, senega, spigelia, taraxacum.

The writer is of the opinion that glycerine extracts vegetable astringent principles and holds them in better solution than does water.

The relative therapeutic value of Aloin as compared with Aloes.—Mr. A. P. Brown had used Tilden's process for obtaining aloin. The result was a fair yield. *Aloin* has the advantage that it *does not gripe*. It has the disadvantage that it is not more active than aloes when given in the same doses, and is much more expensive. The resin which is obtained after the deposition of aloin has no purgative effect. Having noticed a statement that the mother liquor after the deposition of aloin was still an active purgative, a portion was evaporated to dryness with care, and administered, but without any effect whatever. He concludes, therefore, that aloin is the purgative principle, and after its removal the residue is inert as a cathartic.

What knowledge of therapeutics should the properly educated pharmacist possess?—Continued to Benjamin T. Fairchild, New York.

This paper was read only in part. The writer assumes that as the pharmacist should never assume the *rôle* of the practitioner, that there is no necessity for any special training in therapeutics. He should of course be conversant with the general use of remedial agents, and their average doses, but beyond this the pharmacist does not need therapeutical training.

The Bromine production of the United States.—Mr. H. S. Wellcome, New York, stated that the Ohio and Kanawha springs yield a brine which holds twice as much bromine in solution as any other known. The principal factories are located at Parkersburg and Mason city, W. Va., and at Pomeroy, Ohio. The product is about 1000 lbs. per day, although their capacity is about three times as great. About 50,000 lbs. were exported the past year. Bromide of potassium is now becoming the favourite product for exportation.

Oil of Bay.—Mr. G. F. H. Markoe, said that during the past year he had worked up nearly four tons of the leaves. From two to three hundred pounds was the usual charge in a 200 gallon still, and from this from 80 to 100 gallons of liquid were drawn off. The oil as obtained at first is colourless, but soon becomes darker, acquiring in time a light brown colour. The oil readily separates into two portions during the process, and from the first fifteen gallons of distillate, by separating it fractionally, the oil had a varying specific gravity of ·870, ·930, ·946, ·964, ·982, ·990. From the following 65 gallons the oil was heavier than water, was much less abundant, and slower to distill. This portion had the sp. gr. 1·023, 1·035, 1·037. The oil when fresh is quite rank and requires several months to "mellow." The crude heavy oil, redistilled fractionally, gives portions varying from 1·025 to 1·048, the portions up to 1·048 being colourless, then a light brown, and finally a dark oil nearly black in colour. The heavy oil has the odour of clove, is pungent and tingling to the taste; is soluble in alcohol of 95 per cent., in ether, petroleum benzine, chloroform and caustic alkalies, with the latter forming crystals, and is doubtless identical with eugenic acid. Other interesting details were given.

Cologne Water.—Mr. William Saunders, having received numerous requests for a formula for a good cologne which resembled the "Farina" variety, had made the attempt and submitted the following:

Oil of neroli	5 drachms 20 minims.
Oil of bergamot . . .	1 ounce.
Oil of rosemary flowers	1 drachm 20 minims.
Pure alcohol	6 pints.
Water	2 pints.

It is stated that the fragrance of this cologne when compared with the foreign was scarcely distinguishable.

It was suggested that acetic ether was an excellent addition to such a cologne for the sick room. In some comments made upon the quality of alcohol, cologne spirits and deodorized alcohol as found in the market, several persons gave their views, and the different methods employed for purification were alluded to. It is generally conceded that what is sold as cologne spirits is the first twelve hours' run of a clean still, and that this portion of an alcohol run is as good as any artificially purified.

Aniline in Syrup of Iodide of Iron.—Mr. L. M. Connor having reason to suspect some syrup of iodide of iron as imperfect, the colour being of an unusually fine green, the syrup was examined and the colour was found to be due to the presence of aniline green.

Dialysed Iron.—Dr. William H. Pile, noticing the fact that chloride of sodium is one of the most rapid crystalloids to dialyse, had used a solution of carbonate of sodium to add to the solution of ferric chloride in place of the ammonia so generally recommended, and with great success. The solution of ferric chloride which has been neutralized by a cold solution of carbonate of sodium is poured into a floating dialyser. Starting with one pint of solution of ferric chloride, which, on being treated with the sodium solution and ready to dialyse, had a sp. gr. of 1·175, it had in five days increased to five pints. The water in which the dialyser floated was changed daily. At the end of five days it had passed through the membrane all the crystalloids, was free from taste of foreign substances, and owing to increase of bulk had now the sp. gr. 1·0295, and on evaporation yielded 5 per cent. dry oxide of iron. Too long dialysation will cause the solution of iron to become gelatinous.

Parliamentary and Law Proceedings.

The Alleged Adulteration of Citrate of Magnesia.

The charge against Dr. George Smith, M.D., 112, Renfield Street, Glasgow, for selling citrate of magnesia alleged to be adulterated with lead to the extent of ·37 grain per pound, continued from last week, was brought up for disposal at the Central Police Court, before Stipendiary Gemmel, on the 11th inst.

The Stipendiary having intimated that no further evidence could be taken,

Dr. Smith said: I have yet had no opportunity of bringing forward witnesses. I was taken quite by surprise by the prosecution, and, quite accidentally, last court day was able to put two gentlemen into the witness-box, but I had no time then to get up a defence. Understanding, however, that the case was continued, and as it is one of a purely technical and chemical nature, I have been at considerable expense in bringing witnesses into court for the vindication of my character, which has been very seriously injured.

The Fiscal: If you had any intention of leading witnesses, you should have intimated that before now.

Dr. Smith: How could I? I supposed at least that I would get a fair hearing, and never supposed for a moment that the case was closed; and from the nature of the prosecution and the publicity given to it,—to the damage of my good name, as I have already had reason to feel,—I almost demand of the Court, as a right, that I shall be allowed to have the case fully investigated on its scientific, medical, and legal merits.

The Fiscal: Hear what the Court has to say.

The Stipendiary: I think it is quite unnecessary to call witnesses. The case was completed last court day, and continued only for judgment, so that no further evidence can now be led. I think, however, that the defender will be satisfied that this is unnecessary. The evidence given in the case was to the effect that Dr. Smith or his servant, for whom Dr. Smith is responsible, had sold to Alexander Johnston Walker, food inspector, half a pound of citrate of magnesia, not of the nature, quality, and substance demanded, and the section of the Act, under which the present prosecution had been instituted, requires that no person shall sell, to the prejudice of the purchaser, any article of food or drugs not of the nature, substance, and quality demanded, under a penalty. The article asked for was citrate of magnesia, and, according to the certificate of analysis, it consisted of citric acid and magnesia, contaminated with lead to the extent of ·37 grains to the pound. It was brought out in evidence that the article became contaminated with lead in consequence of leaden vessels being used in the manufacture of the citric acid, and that citric acid could not be made without the use of such vessels, nor procured free from lead contamination. It having been established that citrate of magnesia could not be obtained without a small proportion of lead, I cannot hold that an offence has been committed, the article not being sold to the prejudice of the purchaser, and could not be said to be not of the nature, quality, and substance demanded. What was demanded was citrate of magnesia, and what was sold is the only article of that name which can be obtained. The person who purchased the article stated in his examination that he did not know what were the component parts of citrate of magnesia, and therefore it could not be said that what he got was not of the nature, quality, and substance demanded. The quantity of lead found in the citrate was infinitesimal. The pound avoirdupois contains seven thousand grains, so that the quantity of lead present would be about the twenty-three thousandth part. There is no doubt that lead is a cumulative poison, but the quantity in this case was very small, and there was no evidence to prove that it was injurious.

The Fiscal: What of the medical evidence?

The Stipendiary: Under the Act I have no power to find the charge proven. There is a remedy for any evil that might arise from the use of the article. The public are warned by this prosecution that citrate of magnesia contains lead, and that lead is a cumulative poison, and the remedy is not to use the article known as citrate of magnesia. I therefore must find the charge not proven.

Dr. Smith: Am I to be allowed expenses?

The Stipendiary; No expenses can be allowed.

The charge against John Campbell, for selling one and a half ounces of citric acid containing ·4 grains of lead in a pound, was also found not proven, being held as decided by the evidence in the previous case.

The Sale of Soda and Potash Waters.

On Wednesday, October 10, James Cooke, of the Commercial Inn, Galgate, was charged at Barnard Castle with selling soda water containing only 3·64 grains bicarbonate of soda, the British Pharmacopœia directing that an imperial half-pint of soda water should contain 15 grains of bicarbonate of soda.

For the defence it was submitted that the liquid was sold as a beverage, and not for medicinal purposes, and therefore the British Pharmacopœia did not apply.

The Bench concurred, and dismissed the case.

J. Hargroves, of the Coach and Horses Inn, Galgate, was charged with vending "soda water" containing no bicarbonate of soda. A fine of 6*d*. and the costs was imposed.

On Friday, October 12, at the Gateshead Borough Police Court, before the Mayor (Mr. Wm. Galloway), Ald. Biggar, and Ald. Charlton, Mrs. Alice Campbell, soda water and potass manufacturer, was summoned for having sold one bottle of potass water to Mr. Robert Nesbitt, inspector of nuisances, to the prejudice of the purchaser, it not being of the nature, substance, and quality of the article demanded. Mr. Swinburne, the Town Clerk, addressing the Bench, said the object of these prosecutions was to induce a better state of things in the manufacture of potash water. With one exception, in all the cases they were to hear that day there were traces of lead in the samples; this, he was instructed, arose from the carbonic acid gas, which, of course, was a necessary ingredient in this article, being generated in a lead tank, and also conducted from the tank in leaden pipes. In some cases block tin had been used instead of lead, which had proved effective, and would be a great benefit if universally adopted.

Mr. Nesbitt proved that the potass was purchased of the defendant, and on being analysed was found to contain 3·65 grains of solid matter per half-pint, part of which was lead.

Mr. Edgar informed the Bench that 3·65 grains of potass in a half-pint bottle was much less than the quantity that should be present. He should expect that, as a beverage, it should contain five grains at the least. There were, however, mere traces of lead. Lead was poisonous; but he did not think it was present in a poisonous quantity. It was an accumulative poison, however, and if taken constantly it might be injurious. As a medicine he would expect 15 grains of potass.

Mr. Joel, in defence, contended there was no evidence showing what really was the standard. Mr. Edgar thought it should contain five grains as a beverage, but there might be people who only wished for three grains in their potash water.

The case was dismissed.

John Middleton and Thomas Pearson, soda water manufacturers, were charged with selling soda water which was not of the nature, substance, and quality demanded by the purchaser. In the samples purchased by Mr. Nesbitt there was a total absence of bicarbonate of soda, and the water was merely charged with carbonic acid gas.

A fine of 20*s*. and costs was imposed in each case.

Ralph Campbell, R. H. Dawson, and Joseph Todd were similarly charged by Mr. Nesbitt. The evidence showed that there was a portion of bicarbonate in each sample, and no standard being proved the cases were dismissed.

POISONING BY CARBOLIC ACID.—A FATAL MISTAKE AT CHESTER.

Mr. John Tatlock, coroner for the city of Chester, held an inquest on Monday, Oct. 15, on the body of Alice Ann Ainsworth, wife of a beerhouse keeper, who died on the previous Saturday from the effects of poison. From the evidence it appeared that the deceased was addicted to drinking whisky, and her husband stated that she drank a great deal of it, generally about half a pint a day. On Saturday evening, having been working rather harder than usual, she went to bed, and was seen before doing this to take a drink of something on the stairs going up. The tumbler out of which she drank was brought down by her son, and as it smelt very strong, the husband became alarmed and went up stairs, where he found his wife speechless. He then called in a doctor. On the sill of a little window on the stairs was found a small bottle containing carbolic acid, which had been used in disinfecting the house; and as the contents of the woman's stomach smelled strongly of that poison, there is no doubt she drank some of it in the dark in mistake for whisky. The jury found to that effect.—*Liverpool Mercury.*

Dispensing Memoranda.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be considered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.

---

[31]. In reply to the query of J. S. P., Cambridge (No. 31), I beg to say that I have frequently dispensed camphor and hydrate of chloral with lin. saponis or glycerine. J. S. P. will find, what I understand a great many other dispensers are ignorant of, that if he rubs the camphor and hydrate of chloral together in a mortar for a few minutes, they form a thin liquid (why, is easily explained), (*sic*) to which he can add the glycerine, without any trouble. Very often the hyd. chloral and camphor are prescribed alone, and as some of us wild Irishmen can testify is unsurpassed as an anodyne liniment.

HENRY TARAFFE.

Londonderry.

---

[31]. Reduce the camphor to a fine powder with spirits of wine, and dissolve the chloral hydrate in a small quantity of glycerine with a gentle heat. Mix the two solutions with the remainder of glycerine.

CHEMIST.

---

[31]. If J. S. P. will take the trouble to rub the chloral and camphor in a mortar until dissolved, then add the glycerine, he will obtain an opaque mass about the consistency of vaseline, with the camphor in a state of fine division. If he applies a gentle heat to the mass until it becomes clear, on cooling, he will have the veritable glycerine jelly.

J. L.

---

[31]. If J. S. P. powders the camphor finely, and then mixes it with the chloral, he will obtain a damp pasty mass, which when rubbed with glycerine in a mortar gives a substance resembling glycerinum amyli; this must be sent out in a wide-mouthed bottle.

PHARMACEUTIST.

Cambridge.

---

[32]. LIN. SAPONIS.—In reply to Mr. Burton I would recommend him in future to use sapo mollis, B.P. This gives a satisfactory liniment without any trouble. I have found sapo cast. and sapo animal. very unmangeable after they once become hard by keeping.

G. B.

---

[33]. Could any correspondent kindly inform me the best way of making the following prescription up so as form a clear mixture without filtering it?—

℞	Spirit. Æther. Nit.	ʒj.
	Bicarb. Ammoniæ	ʒiss.
	Tinct. Hyoscyam.	ʒj.
	Sp. Camphor.	ʒiij.
	Liquor Ammon. Acet.	ad ℥viii.

Make an eight ounce mixture.

J. B.

---

[34]. What would be the proper way for dispensing the following, which was brought us to day?—

℞	Hyd. Bichlorid.	grs. ij.
	Ext. Opii	,, ij.
	Confect.	q. s..
M.	Ft. pil.	Mitte xxx.

GULIELMUS.

---

[35]. FERRI CIT.—When "Ferri" Cit. is ordered in a prescription should Ferri et Ammoniæ Citras be used?

BURTON.

Notes and Queries.

[555]. LIP SALVE.—

℞	Ceræ Albæ	℥j.
	Ol. Amygd. Dulc.	℥iss.
	Ol. Rosæ Conc. (Allchin's)	ʒiij.

Melt, and when nearly cold, add six drops of otto of roses.

CHEMIST.

---

[556]. DRUG MILL.—Can any of your readers recommend a small mill in which chemists could grind their own linseed for poultices?

W. S.

---

[557]. WHITE OILS.—Will any reader favour me with a formula for White Oils, for horses and cattle, which will be perfectly white, about the consistence of cream, will not separate, and will do to apply to fresh cuts, broken knees, etc.? It must not contain ammonia.

N. W. S.

[558]. COPYING PAPER.—Can any reader inform me as to the mode of preparing a paper for copying tracings, producing a blue ground and white lines after exposure to direct sunshine and washing in water?

NEMO.

Correspondence.

PROSECUTIONS UNDER THE PHARMACY ACT.

Sir,—The *Pharmceutical Journal* of the 13th inst. contains a report of two prosecutions under the Pharmacy Act, of 1868, in the Birmingham Police Court; one against Anson Edwin Martin, the other, John Stuart Careless.

The decision of the magistrates throws a new light on the working of that Act. Had either of the parties been prosecuted under the 15th section, doubtless a conviction would have resulted; but I put aside the non-registration as irrelevant to their alleged offence under the 17th section, and submit that they are actually guiltless of offence under that section.

The object to be attained is primarily the safety of the public. To insure that, it is provided that bottles or packages containing poison shall bear evidence to direct the police to the source from whence the poison has been obtained; to give a clue to the offender if crime has been committed, but no less to avert mischief, if possible, by an immediate discovery of the nature of the poison.

Surely, where a business is conducted under the name of a well-known firm, whether a firm still existing or one which has sold its interest, and probably the right to continue its name, that name on the label points more instantaneously to the establishment at which the article was obtained than would the name of an unknown man who has become the proprietor of the business, keeping the old title over his door, on his invoices, and probably using it as a business signature. I might cite many such cases, as examples, but at the moment one specially occurs to me.

If laudanum be purchased at the Apothecaries' Hall, I believe no name will appear on the label, save the title of the establishment, and, indeed, no other could be needed. Why, then, ask for more, especially when the addition would rather confuse than enlighten? It may be the letter of the law would be more positively obeyed, but certainly not the spirit. I think the magistrates at Birmingham fell into this error, and I regret exceedingly that the gentlemen who were employed to defend the accused did not ask leave for an appeal to a higher court.

Looking back thankfully to the advance which has taken place in the condition of chemists and druggists since the establishment of the Pharmaceutical Society, and onward hopefully for good effects to arise from the temperate administration of the Pharmacy Acts, I can but view the course taken by the prosecutors in these cases as trivial and impolitic, tending only to bring the Acts into ridicule, as some over zealous persons have brought the Adulteration Act, by treating unavoidable impurities, consequent on the "process of collection or preparation," as fraudulent admixtures.

M.P.S.

October 15, 1877.

DANGEROUS COLOURED FIRES.

Sir,—Possibly the following hint may be of some use to those who are in the habit of making coloured fires. I am told that in making fires which contain chlorate of potash and sulphur, their safety from explosion depends upon having the sulphur free from acid; this can be accomplished by washing it in two or three charges of hot water, then with a solution of carbonate of soda, and finally with water again. I adopt this plan and have had no accident, although I have kept for a year coloured stars, etc., made with a similar composition to the one spoken of by Mr. Windle.

In conclusion, I think it would be a boon to a many if the subject were freely discussed by your columns.

G. W. WALTER.

BLEACHING ACTION OF TURPENTINE.

Sir,—It is to the production of peroxide of hydrogen that turpentine probably owes its power as a cleanser and bleacher of wood, and as such it has been used for some considerable time with very good results; the process simply being to sprinkle some turpentine over the staircases, floors, etc., preparatory to the "spring cleansing," but of course, from the inflammatory nature of the material its use as a household cleanser is to be by no means recommended.

That the ol. folii sylvestris contains the peroxide of hydrogen in considerable quantity may be expected from the powerful bleaching effect upon the cork of the bottle containing it and its great tendency to oxidation.

G. C. DRUCE.

Northampton, October 15, 1877.

T. S. Edwards.—You appear to have read our answer of last week carelessly; the sentence placed between inverted commas in your letter does not occur in it, and your strictures are therefore unwarranted. Any information you may possess respecting a breach of the Pharmacy Act should be communicated to the Registrar. We have no objection to your resolution to stamp out what you humbly believe to be wrong, provided that you take reasonable precaution that you yourself are right.

"*Magnes. Sulph.*"—As the questions were optional, and both were moderately easy we do not think it probable that any of the candidates suffered under any disadvantage. Thanks for the correction.

"*Plevna.*"—The only book bearing the title with which we are acquainted is published by Groombridge and Co.

A. Mitchell.—The liq. ammonii caustici spirituosus of the German Pharmacopœa is prepared by passing gaseous ammonia into alcohol of sp. gr. 0·830 until the solution has a sp. gr. of 0·808 to 0·810, when it will contain about 10 per cent. of NH_3.

F. B. L.—(1) We are not aware that the Society has made any arrangement for the publication of its proceedings. (2) The Registrar is Mr. H. J. Fennell, College of Physicians, Kildare Street, Dublin.

B. J. K.—The questions are published as communicated to us officially. We have no other knowledge of what takes place in the examination room. If you wish for further information you are recommended to write to the chairman of the Board.

K. R.—The form is frequently used by physicians and should be translated "every four hours."

E. A.—We do not know; apply to the Secretary of the Society referred to.

Student.—The solubility of salicylic acid in water is considerably increased by the addition of ammonium citrate; borax and sodium phosphate have also been recommended. See however p. 316 of the present number.

"*Associate.*"—Huxley's 'Lessons in Elementary Physiology' (Macmillans).

R. J. M.—*Œnanthe crocata.*

"*Malva.*"—The specimen is a white variety of *Malva moschata.*

J. G. Oliver.—We are unable to say. You are recommended to write to the editor of the *Gardeners' Chronicle* or the *Garden.*

N. W. S.—Blaine's 'Outlines of the Veterinary Art,' (Longmans).

"*Natura.*"—(1) The passage probably occurs in one of the works of Dr. Thomas Thomson on Chemistry. (2) No.

A. Tomline.—Rodwell's 'Birth of Chemistry' (Macmillans).

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Moore, Mr. Howie, Mr. Wallis, Mr. Sparshott, Mr. Edwards, One who has been a Chemist, Associate, J. L., J. W. A.

"THE MONTH."

The reign of flowers is over. No indigenous medicinal plant comes into blossom this month. The trees have been stripped of their leaves by the equinoctial gales, and the early morning frosts have nipped the more tender plants, leaving little but berries, with here and there a bright-tinted leaf, to adorn the now almost naked hedgerows. Flowers must now give place to plants more ephemeral, but often vying with them in beauty of tint, and occasionally in odour also. Fungi are now the order of the day, and mycologists are now hastening from all quarters to their annual festivals and social gatherings at Paris, Hereford, Dunkeld, and elsewhere. Inviting as some species may be to the palate of experienced mycophagists, fungi can scarcely be said to be general favourites, and but few of them possess pharmaceutical interest.

One of the most beautiful of our native species, however, the Fly Agaric, *Amanita muscaria*, Fr., has of late attracted attention on account of the muscarine which it contains, an alkaloid which has been found to have an effect upon the system opposite to that of atropine. This fungus is not uncommon in this country, but is more abundant in the north than in the south of England. It grows most frequently in fir, beech, or birch woods, and may be at once distinguished by the bright vermilion cap or pileus, studded with white, or slightly yellowish warts, the pure white gills and tall white stem, swollen at the base into a kind of bulb, and furnished with a loose ring a short distance below the pileus. Several other British fungi have a bright red cap, but are without the warts and ring, and have a shorter stem not bulblike at the base. When young the whole of the fungus is enclosed in a thin white envelope, which is called a volva; as the stem elongates this envelope is burst, and the upper portion of it, remaining adherent to the cap, is split up by the further growth of the cap into the warts, which form so prominent a feature in this species. A figure of the plant is given by Pereira, who mentions that many Siberian tribes use it as an intoxicating agent. Muscarine also derives further interest from having been considered as identical with an oxidation product of choline or neurine, a substance found both in bile and in the brain.

This is also the time of year when fresh supplies of ergot are coming into commerce. Ergot must not be confounded with the perfect plant of *Claviceps purpurea*. The ergot of commerce, as may be seen by microscopical section, consists only of delicate threads closely felted together into a hard mass or sclerotium, which corresponds in some measure to the spawn of a mushroom or the prostrate threads of mildew. These threads are formed at the expense of the grain and replace it, and the sclerotium so formed is the means by which the plant is kept alive throughout the winter. In March or April the sclerotium gives rise to one or more plants of the true fungus which look like miniature mushrooms, but differ altogether in structure, the spores not being placed on gills but in little sacs, in cavities in the little rounded head of the fungus. This structure is well illustrated in Pereira's 'Materia Medica.'

The hedge banks, although not yielding flowers, yet offer a few fruits of pharmaceutical interest. The dog rose, *Rosa canina*, is now covered with scarlet "hips," familiar to schoolboys as an instrument of torture to their unlucky fellows. The hairs inside the fruit are almost as irritating as those of cowhage. The fruit in this case consists of more than the ripened ovary, since it includes the calyx tube and the thalamus which lines it. It should be stated, however, that what is here spoken of as the calyx tube, is by some botanists regarded as the hollowed out pedicel.

If the fruit be carefully split open it will be found that what appear to be seeds have each a style, terminating in a stigma, and are therefore carpels, which, from their one-seeded indehiscent character, are called achenes. These styles will be seen to pass through an opening at the top of the fruit, where the calyx tube is not perfectly closed. The fruit, on account of its curious structure, has been called a cynarrhodon, from two Greek words, meaning dog and rose. It has, however, exactly the same structure as the etærio, or collection of achenes in the buttercup and clematis fruits, except that the achenes are enclosed in a calyx tube, and it may be therefore regarded as an inverted etærio.

The fruits of *Rhamnus catharticus* are now in good condition for gathering. The structure of the fruit and the difference in shape of the endocarps of the fruit, have already been alluded to in the June number of this Journal.

One plant still remains to be noticed, *Ricinus communis*, L., the castor oil plant. Under the name of palma christi, it is cultivated in gardens and shrubberies as an ornamental annual, the foliage being the chief attraction. In this country the plant usually reaches the height of 5—10 feet. Its large handsome leaves and succulent-looking stem, covered with a fine grey bloom, render it a striking object. The leaves are palmate, and have lanceolate serrate segments. At the point where the leaf-stalk joins the leaf will be found a saucer-shaped gland. The leaves have been used in the shape of a poultice for reducing hard swellings, and are still used in the form of fluid extract, with considerable success, as a galactogogue. The spike of flowers is not very conspicuous; the staminate flowers, which occupy the bottom of the spike, consist of a calyx with 3—5 ovate concave segments, and enclose a great number of stamens, the filaments of which are combined into a number of bundles (polyadelphous); each of these bundles consists of several stamens, the filament of which are united together at different distances, giving each bundle a corymbose habit. The pistillate flowers, which are at the top of the spike, have a more deeply cut calyx and a somewhat globular bristly ovary, surmounted with three long, flattened, forked, bright red, hairy stigmas. Were it not for the colour of these stigmas the inflorescence would scarcely be noticed. The three-celled fruit, when ripe, somewhat resembles that of the thorn apple in appearance, but splits loculicidally and septicidally into six valves, exposing the three seeds. The seeds have a strong resemblance in shape and appearance to the insect known as a sheep tick, whence the Latin name of the plant, *Ricinus*. Although only an annual in this country, one of its varieties, in the north of Africa, attains the height of a tree, and lives for several years. The plant is extremely variable in size and character, and the seeds also vary in size, no less than thirteen varieties being offered for sale by some London florists. The capsule also, in some forms, is quite free from bristles.

The seeds vary exceedingly in size, marking, and colour, the oil obtained from the smaller kinds being supposed to be the best. At the point where they are attached to the carpophore, which occupies the centre of the capsule, they are furnished with a caruncle or strophiole, a growth which is formed from the edge of the hilum. From the caruncle a line (raphe) proceeds along the flatter surface of the seed toward its opposite end where it forks and disappears, the point of its disappearance being where it passes through the testa to the inner coat or urdoplura, on which a dark spot indicates where the veins of the chalaza radiate. These veins can be readily seen by slicing off this part of the nucleus and holding it up to the light. When the seed is split open the veins on the two thin cotyledons can be distinctly seen. These cotyledons adhere so closely to the albumen that they cannot easily be separated, but a similar structure is easily seen by splitting open a croton seed, in which the cotyledons can readily be separated from the albumen. Castor oil seeds were formerly known as *Semina cataputia majora*, those of *Euphorbia lathyris* L., being called *Semina cataputia minora*. The castor oil plant possesses an additional interest from the supposition that the "gourd" spoken of in the book of Jonah was no other than this well-known plant. Certainly the Greek name of the castor oil plant (Kiki) has some similarity in sound to the Hebrew Kikajon, translated "gourd," and the castor oil plant is remarkable for its rapid growth, attaining a height of twenty feet in a single year in hot countries.

The 'Medicinal Plants' for this month contains one American and six Indian plants. *Hydrastis Canadensis* is official in the American Pharmacopœia as a tonic, and like the two next on the list, *Coptis trifolia* and *Berberis aristata*, is remarkable for containing berberine. *Abrus precatorius*, *Cassia fistula*, *Alstonia scholaris* and *Calotropis procera*, are the other species figured. *Cassia fistula* receives a double plate, on which the pod and structure of the seed are well shown. The seed of this plant is remarkable for containing a quantity of horny albumen, which is not common in leguminous seeds. *Abrus precatorius* yields a root which is used as a substitute for liquorice in India. To this plant belong the small pretty scarlet seeds, with a black spot at one end, which are often seen in necklaces, etc. *Alstonia scholaris* yields a bitter tonic bark, and *Calotropis procera* a root bark which is used as an alterative. *Berberis aristata* yields a bark, the extract of which has been long highly esteemed as an application in diseases of the eye. The execution of the plates in the present number is rather above the average.

The *Gardeners' Chronicle* reports that the superintendent of the botanical gardens at Gunesh Khind, Poona, has published a list of the drug-yielding plants cultivated in the garden, with a view to their being utilized by the public in cases where the fresh plant is difficult to procure in the bazaars, etc. The list comprises about one hundred plants.

An interesting discovery has recently been made of a fossil fungus, bearing a close relation to that which causes the potato disease, and which has been named *Peronosporites antiquarius* by Worthington Smith, whose name is so well known in connection with the discovery of the resting spores of the potato fungus. The fungus was discovered by Mr. Carruthers, of the British Museum, in the stem of a gigantic fossil clubmoss (*Lepidodendron*) from the coal measures. The occurrence of a fungus in which the delicate threads and fructification are preserved in all their delicacy of outline offers a hint to microscopists of the possibility of preserving similar structures in a solution of silica. The occurrence at so early an age in the world's history of forms almost identical with those found at the present day, appears to indicate that, however much evolution may cause the appearance of new forms, the weakest do not always go to the wall.

In the medical journals there is very little to be gleaned for pharmacy. The use of salicylic acid in the preservation of leeches is advocated, in the proportion of thirty drops per litre of a three per cent. solution; Dr. Farrar recommends chloride of calcium in solution, containing sixteen grains to a drachm, as the most convenient form for dispensing purposes; a saturated solution of bicarbonate of soda has been spoken highly of as a remedy for burns and scalds, if promptly applied; Dr. Dougall has found that an "ointment," or liniment, made by emulsifying one part of gurgun oil, with three parts of lime-water, is a very convenient form for external administration in leprosy, and he administers internally an emulsion of equal parts of each ingredient in half-ounce doses; choleate of sodium is recommended by Dr. Van Biber, in chronic jaundice, deficiency of bile, and as a preventive of gall stones; and, lastly, picric acid, in the proportions of 30 parts in 1000, is said to have been used with success in mammary fissures.

At the drug sales matico, largely mixed with a smooth-leaved species, probably *A. adunca*, has been noticed, whilst the fruits of the plane tree have been offered as cowhage, and tamarisk galls under the name of African berries.

The "Dispensing Memoranda" column has to acknowledge indebtedness to several correspondents for friendly hints which, though not formally acknowledged, have been thankfully received, and when available, utilized, and embodied in the month's review. A continuance of such suggestions is invited, because the questions, being generally of a varied character, the more freely such a course is taken, the more valuable will be the results. Information coming from different sources will serve to indicate the prevailing customs in several localities, and probably under different circumstances, and if certain correct principles be laid down for general guidance, it may reasonably be hoped that uniformity of practice, to a greater degree, will be the ultimate result.

No. 19 is headed "Cinchonine Preparations." In an eight ounce mixture there is prescribed ℨiv. syr. cinchon. for which a good formula is required. Probably the writer of this prescription meant syrup of cinchona, or syrup of cinchona bark, not syrup of cinchonine; if so, there is no official formula for this preparation in the British Pharmacopœia. About the earliest formula is that in the 'Pharmacopeia Manuelis Antwerpii,' 1812:—"Recipe cinchona coarsely powdered, 1 ounce; distilled water, 8 ounces; macerate 24 hours, express strongly, and add 14 ounces of sugar." Brande gives ext. bark, ʒij.; syr. of orange peel, ℥ij. Other writers on pharmacology give methods for making a syrup of cinchona in a more circuitous way, but as there is no official formula, and the ext. cinch. liq., B. P., a reliable preparation, is always at hand, this syrup may be extemporized by adding ʒj. of the fluid extract to ʒvij. of simple syrup. If syrup of cinchonine be intended, there is a published form in Majendie's formulary, ℈j. of cinchonine and ℥xvj. of syrup, but this proportion of cinchonine is much too small to be of any value in the doses in which syrups are usually given. When a preparation is prescribed, for which there is no official or generally recognized formula, it must be expected that if the prescription is dispensed in different places it will be with different results, and as the first was sent out from the prescriber's own establishment and pleased the patient because it was sweet, it may be accepted that the writer of the prescription succeeded in hitting the patient's taste if he did not succeed in diagnosing the patient's disease.

No. 20.—The aq. caryoph. of this mixture is not in the B. P., and a dispenser would be justified in making it in the same manner and in the same proportion as the aq. menth. pip. or aq. menth. vir. are ordered to be made, by adding the oil to the water and distilling. With aq. caryoph. thus made, this mixture would be almost clear; but if the aq. caryoph. be drawn from the cloves instead of the oil the result will be an opaque water which must necessarily make a more or less opaque mixture, but not a *thick* opaque mixture as described.

Aq. caryoph. drawn from the cloves themselves is more grateful than any one of our medicated waters, with the exception of cinnamon, with which it compares favourably, and is to be hoped that in a future edition of the British Pharmacopœia this water will take its proper place, either as an addition to, or still better, as superseding the inf. caryoph., for which it will be an efficient and elegant substitute.

No. 21.—In dispensing a prescription containing a powder thus, ℥j., the apothecaries' ounce should certainly be used; the symbol ʒj. represents 60 grs. and ℥j. eight times 60 or 480 grs.

No. 23 contains a gargle with tinct. myrrh. and alum. If this prescription contained tinct. myrrh. only, with the diluent, it would be sufficient to fill the bottle three parts full of the fluid, to add the tinct. myrrh. and shake, when a homogeneous mixture would be the result; but on the addition of alum the resin separates and adheres to the sides of the bottle. In this mixture, as in others of a similar character containing tinctures of resins or gum resins the addition of a little mucilage from ʒij. to ℥ss. in an eight ounce mixture will cause a perfect emulsion; it should be added to the bottle three parts full of fluid, and before the tincture is poured in, the subsequent addition of alum will not then cause a separation. The second under the same number, containing tinct. guaiac. am. may be made by filling the bottle three parts with the water, then adding the tincture and finally the chlorate of potash; the mixture is for the time perfect, but in twelve hours or so, there will be a flocculent deposit. This may be avoided and a permanent mixture made by a course of procedure as in the preceding prescription, the addition of ʒij. to ʒiv. of mucilage. There is no occasion in either case for trituration in a mortar.

No. 24.—Pills can be sugar-coated without difficulty, provided that the proper plant be brought into requisition, and the same method adopted as is employed by confectioners for sugar coating almonds and various other confectionery. The pills are put into a jacketed pan, heated by steam, and kept continually in motion, hot syrup being added at intervals until a sufficient coating of sugar has been obtained. There is a small American apparatus, mentioned by Professor Markoe at the Brighton Conference, for sugar coating pills extemporaneously. The apparatus is heated by a spirit lamp; but as it has not been introduced into this country, there is no opportunity to express any opinion as to its value. With regard to the white coating other than sugar, the subject has been frequently discussed in this Journal, and reference should be made to its back numbers. The method usually employed is to coat the pills with the tolu varnish, let them well dry, then moisten the surface of the pills with a mixture of gum and syrup, and roll in French chalk, at the same time applying a little heat. This process should be repeated until the coating is satisfactory; still, however satisfactory at first the appearance of the pills may be, one objection seems to apply to this kind of coating, it cracks and exposes the uncovered surface of the pill.

There is a future for coated pills of two kinds, one that will bear being shaken about without injury, of these the sugar coated pills of the United States may be taken as a type; the other of a more temporary character, elegant specimens of which are also occasionally met with. For the preparation of the former, time may be of little importance, and permanence necessary. For the latter, the coating may be of a more extemporaneous character and quickly done, satisfying the requirements of the dispensing counter by a moderate degree of permanence. These are desiderata not yet supplied, wants felt, but not yet satisfied, remunerative problems for solution, within the reach of an enterprising pharmacist.

No. 25. An important question this, but one not difficult to answer. The emplast. canth. is ordered to be spread for a blister, and if properly made and kept, will usually produce vesication, but to add powdered cantharides, or any other vesicating substance, to the surface of a blister, is not admissible, without the order or sanction of the medical attendant. In fact, this practice is not unattended with danger; the application of powdered cantharides to the surface of a blister has produced strangury, for which the pharmacist would certainly be held responsible. If the emp. canth. of the British Pharmacopœia be unsuitable, or of insufficient strength, to produce the desired result, reliable evidence to this effect would most probably induce a change in the formula in a future Pharmacopœia. The manner of spreading a blister may be a question of taste, or usage, but when once spread, any further addition is going beyond the record, and censurable; it should also be unnecessary otherwise than in exceptional cases, for which it is the duty of the prescriber to make adequate provision by any addition he likes. Many practices of this description owe their birth to unreliable blistering plaster, and the remedy should commence where the evil dates its origin.

No. 26. A formula for ung. hyoscyami is required. In the British Pharmacopœia there is one for unguentum belladonnæ: 80 grs. ext. to ℥j lard, and the same proportions may be adopted in making ung. hyoscyam., more especially as in the German Pharmacopœia there is a formula for ung. hyoscyam. just in these proportions. Another method of making it has been referred to, but as this preparation is not likely to be kept in stock, and cannot be made extemporaneously, the dispenser would be justified in adopting the ung. bellad. proportions in making ung. hyoscyam.

No. 27. Aq. camph. conc. A reference to the early numbers of this Journal will answer this question; the subject was fully discussed in its pages about thirty years ago, and even since that time it has occasionally cropped up. To determine a question of this character, no pharmacist with an atom of self-reliance should sit still and ask questions. A solution of camphor is required, which when added in the proportion of one to seven, of water, will make an extemporaneous aq. camph. The aq. camph., B. P., contains (Squire) gr. ½ to the oz.; to make aq. camph. conc., one to seven, each drachm of this essence must contain half gr. of camphor, dissolved in spirit and diluted to a state that will best mix with water. A few experiments will readily determine the requisite proportions.

No. 28. The difficulty has most likely arisen from the use of precipitated, or *pure* milk of sulphur, which should, probably, now be called the "cream" of sulphur, in contradistinction to the impure milk of sulphur, for which the appellation of "skim milk" of sulphur would be very appropriate; the latter will mix, deposit, and shake up, as required, and is better adapted for making this lotion than the pure precipitated preparation official in the British Pharmacopœia.

While the month of October was yet but a new-born infant the words of science—popularly so termed—dinned in its ears. Professor Tyndall, at Birmingham, was expounding his views of the inherent order and energy of the universe as opposed to those assuming them to be "imposed from without" by arbitrary will exercised, as the professor remarked, "by what Carlyle would call an Almighty Clockmaker." It was the study of the conservation of energy, which the lecturer took up in illustration of his meaning. The human body was to be regarded as a machine possessing no creative power, but capable of doing work in virtue of the combustion process occurring in the blood and in the muscles, or, to put it in Mayer's own words, "As an engineer by the motion of his finger in opening a valve, or loosening a detent can liberate an amount of mechanical energy, almost infinite compared with its exciting cause; so the nerves, acting on the muscles, can unlock an amount of power out of all proportion to the work done by the nerves themselves." Helmholtz, in 1851, affirmed nervous transmission to be a comparatively sluggish process—messages being transmitted at the rate of only seventy feet a second, while light travels at the rate of one hundred and ninety thousand miles a second. The power of doing work in the human body is, beyond doubt, referable to the oxidation process effected in the blood and in the muscles: it is a dynamical problem. But granting this, we are still left without an adequate appreciation of consciousness and will, of emotional and intellectual action; these are properties possessed by no other machines, whether we regard them or not as of an ordinary dynamical nature. This became the sticking point with Professor Tyndall, who asked himself the question, was he not forced by his own exposition "into the hypothesis of a free human soul?" He confessed he could not answer the self-imposed problem, nor could science decide how far every man was a free agent, how far capable of impressing or creating circumstances, or how far the creature of circumstance. But reflection, said the lecturer, would prove that human beings are "not complete masters of the circumstances which create their wishes, motives, and tendencies to action;" there may be a predetermined condition, but it is one which admits of cultivation, perversion, development and repression.

The beginning of the month, saw too, the opening of the winter session of the various metropolitan medical schools, when introductory addresses were delivered to the students; the only one possessing any interest for these columns, namely, that by Professor Lister, has been already noticed.

The Sanitary Institute of Great Britain held its first congress at Leamington early in the present month, its whole conduct being imitative of the plan pursued at the British Association meetings. A very successful exhibition of sanitary apparatus and appliances was simultaneously opened, and various addresses and papers were read to small audiences. Some of these had better never been written, for, beyond the propagation of unproven hypotheses and untrue statements arising from ignorance of the subjects therein treated, they served no other purpose save that of the false glorification of their authors. Dr. Richardson gave the inaugural address and speculated upon the origin and dissemination of zymotic disease. Rejecting the germ theory, he maintained that the poison characteristic of each disease originates in the subjects affected, as the product of a perversion of the process of secretion, just as in the cobra a poison is produced by natural secretion. The change in the secretory process may be brought about or accelerated by such conditions as are afforded by starvation, bad food, overcrowding, etc., and the secretion thus rendered poisonous, independently of any innoculation from without, is capable of being communicated to a second person.

This theory, rational enough so far as it goes, is, like the germ theory, entirely an unproven doctrine as yet; it may be true, but it is as probably untrue. To time and the extended application of chemical and histological methods of research, the decision of such matters must be left. Till then an imperfect knowledge of the relation between the sanitary conditions of individuals and the circumstances of their lives will be the only guide in arresting and exterminating zymotic disease. Mr. Brudenell Carter dwelt upon this matter in a charming piece of oratory on the last day of the congress, and insisted upon the institution of a complete registration of infectious disease, and other matters within the legislative power to effect.

King Sewage came out at the congress with his usual importance and train of followers, but in relation to him it is only requisite to mention one paper, which suggested that since no process of chemical treatment *per se* can efficiently purify sewage, the effluent waters shall be passed through filter beds of "sanitary carbon," the debris remaining after the destructive distillation of kimeridge shale, and constituting practically a kind of animal charcoal. It is stated that as a purifier of sewage its value has been tested at various places; it costs about £3 per ton, and the exhausted filter beds mixed with the sludge give, according to the paper, a portable, cheap, and useful manure.

Dr. Moffatt read a paper on "Turpentine and Terebene as Disinfectants," in which he stated that some years ago he had found turpentine, juniper oil and other essences to be ozonizers. He had compared terebene with common turpentine and found it to be far less efficacious as an ozonizer, and therefore as a disinfectant; next to phosphorus he therefore recommended turpentine as an ozonizing agent. It might shock Dr. Moffatt's science to learn that neither turpentine, terebene, nor phosphorus, are either ozonizers or disinfectants; nevertheless, such is the case. These substances by aerial oxidation in the presence of water all give peroxide of hydrogen and no ozone whatever. If we cannot all be original we should at least curb the passion for authorship.

A recent number of the *Wine Trade Review* has an article on "Australian Wine, and English Duties." It will be known that the English custom-house authorities refuse to admit any Colonial wines exceeding 26 per cent. of spirit as natural wines. As the Australian wines reach this country they contain more alcohol than this, and hence the duty imposed upon them prohibits the Australians from offering their wines in this country at a cheap rate. According to the journal quoted, the English authorities base their action upon the dictum of Dr. Thudichum to the effect that no natural wine exceeded twenty-six per cent. of spirit, and if this be so, the dictum is at least correct. Experiments that have been made with the view to produce an artificial wine containing more than this amount of alcohol, have all failed and led to the same conclusion that fermentation cannot proceed beyond the point at which this proportion of alcohol is attained. The *Wine Trade Review* and the Australian discontents must therefore find another basis for discontent than the dictum of Dr. Thudichum. They maintain that the wine growers of Australia can produce natural wines containing from 28 to 29 per cent. spirit, and even more. If so, they should have no great difficulty in establishing the truth, but in the meantime it is to be regarded as more likely that any such wines are fortified by the addition of brandy.

The *Analyst* for October shows evidence of a fit of indignant virtue, and with a trait of character peculiarly its own, calls attention to an alleged case of poisoning as affording a practical commentary on the paper published in this *Journal* refering to copper in preserved peas. The statement of the *Analyst* would not merit attention, except as an example of the sort of illogical reasoning and precipitate conclusions to which public analysts attain. Mr. Gatehouse, of Bath, analysed the stomach and viscera of the deceased, and found that the liver contained 1·16 grains of copper, and the other viscera 2½ grains. The *Analyst* then goes on to say "It certainly appears that this one case is worth far more than all the experiments made by the authors of the paper in question." The fact is that the possibility of poisoning by a large quantity of a soluble salt of copper was never called in question; but it was shown that the minute traces contained in preserved peas—owing to a number of conditions, one of them being the insoluble combination in which the copper exists—passed through the body without having entered the system at all. Where then is the commentary to which the *Analyst* alludes? Is it sustained by the fact that as much as 0·3 grain of sulphate of copper was taken daily for nearly a fortnight without harm, or by the fact that nearly the whole of this copper passed out with the fæces? Nothing would perhaps afford the authors of the paper in question more enjoyment than an attempt on the part of the *Analyst* to poison them with preserved peas!

Speaking of analytical troubles, it appears that a certificate given by Dr. Muter relative to a sample of suspected butter has been considered insufficient to establish the alleged adulteration to which it referred. The grocer who was summoned obtained a certificate from Somerset House which set forth that the butter was genuine, and accordingly the case was dismissed. Without characterizing Dr. Muter's certificate, or that from Somerset House, in any way, it must be regretted that as yet there is no good method of butter analysis known which would prevent the lamentable exhibition of two or more analysts giving diametrically opposite results.

This is not the only day lost of late by the analysts. A grocer at Goole was prosecuted on the strength of Mr. Allen's certificate for selling adulterated mustard, and the certificate was as follows:—"The sample was a very peculiar one. The usual adulterations of mustard were absent. The sample had a disagreeable taste and smell and dark colour, distinct from those of pure mustard. The taste and smell resembled those of rapeseed and an oil (probably rapeseed oil) had been added to the mustard. I am unable to suggest any reason for such an addition, unless it was made to replace fixed oil of mustard previously removed. On distillation of the sample with water no appreciable amount of essential oil was obtained. I am of opinion that the sample was unfit for food." An analysis from another source stated that the mustard had evidently got spoiled by the addition of oily matter, probably accidentally admixed, and as a warranty was proved with the article the case was dismissed, there being no intention to impose on the public.

At Glasgow another grocer has been prosecuted for selling honey which contained a piece of honeycomb, surrounded by a syrupy substance, which was glucose, "a preparation of starch which had very much the appearance of dropped honey." The analysis of Dr. Clarke certified to the presence of 50 per cent. of glucose, and the grocer was fined accordingly. On chemical grounds it would be interesting to learn how Dr. Clarke can tell which is glucose and which is honey.

In a letter to the *Medical Times and Gazette* of October 20, Mr. Metcalfe Johnson calls attention to a case of poisoning by bichromate of potassium where a French polisher who took two scruples of the salt in mistake for a dose of medicine, and Mr. Johnson is of opinion that had it not been for the prompt measures taken, the case might easily have proved speedily fatal. This case possesses an increased interest now that public attention has been directed to the use of chromate of lead in colouring articles of food, such as American cured hams, etc.

Professors Macalister, Macnamara and Reynolds have recently issued a report on the question whether the flesh of cattle affected with pleuro-pneumonia should be used as food. The Dublin Sanitary Association has also reported on the subject, and has come to the conclusion that such flesh should not be used as food under any conditions, notwithstanding that it has been proposed to render it less liable to putrefaction by careful bleeding. The reasons assigned are that the disease is a specific contagious fever, affecting the entire system, including the flesh and milk, the flesh being particularly prone to putrefaction, that there is also no evidence of a scientific nature to prove that such flesh has not produced injurious results when taken as food.

Professor A. H. Church* has found in the watery extract of the leather scraped off the backs of some volumes from a public library a large amount of sulphuric acid derived from the combustion of coal gas in the library. He obtained the following figures:

	Per cent.
Free sulphuric acid in decayed leather .	6·21
Combined " "	2·21
Total " "	8·42

The injurious action of the products of combustion of coal gas upon leather bindings is well known, Faraday having called attention to the fact many years ago as explaining the destruction of the books in the library of the Athenæum Club, as Professor Church has done in the above instance.

Professor Albert B. Prescott† reports that he has succeeded in decomposing some metallic sulphates by hydrochloric acid. His method of operating consists in treating 1 gram of each metallic sulphate with 4·035 grams of aqueous hydrochloric acid containing 1·251 grams of HCl. (3·5 c.c. of acid of 1·153 sp. gr.) and evaporating to dryness in the water-bath.

The *Popular Science Review*, for October, contains, as usual, much matter of general interest to the scientific reader; the only paper, however, to which attention can be devoted here, is one by Dr. Walter Flight, on "Meteorites and the Origin of Life." It will be remembered that, some six years ago, Sir William Thomson suggested, in his Presidential Address to the British Association, that life on this earth was of meteoric origin. If the theory be accepted, that in the distant ages of the past the earth was a red-hot melted globe, it is necessary to account in some way or another for the existence of life, the history of which is at least contemporary with that of mankind; but although it is not impossible that the earth was itself a mere fragment broken off from a larger mass by collision, yet there is no proof of this, nor can it be said with certainty that it has ever existed in a red-hot state. But Sir William Thomson accepts the latter assumption, and endeavours to account for the widely existing fauna and flora of to-day. He supposes that, by collision of masses moving through space, fragments bearing seed or moss were broken off, and falling on this earth gave rise, by a process of evolution, to the circumstances of to-day. This theory did not only not escape scientific criticism at the hands of Zöllner of Leipzic, and others, but it received also public criticism, and caused not a little ridicule to be directed against science generally, for men said, even if Sir William Thomson's hypothesis be granted, the problem most desirable of solution is not solved, for there still remains the difficulty of understanding how life originated on those masses whose meteoric fragments are assumed to have innoculated this world with life. At the last meeting of the British Association (at Plymouth), Professor Allen Thomson also pointed out this difficulty, and made his observations the substance of a further communication to one of the sections. The discussion that ensued was, to say the least, funny, one speaker having expressed the wish that when Papa Colorado Beetle came down to the earth upon a meteorite he had left Mamma Colorado Beetle behind!

Dr. Flight proceeds to describe the general character of meteorites and their chemical composition, and it is curious to observe that nearly all analysts have isolated from them small quantities of a volatile and crystalline sulphurized hydrocarbon, melting at about 120° C. But reviewing the general results, it appears, from Dr. Flight's remarks, "there is not a particle of evidence to prove the persistence of living germs on meteorites during their passage through our atmosphere;" at the same time, from the composition of meteorites, it is not improbable that the original cosmical bodies from which they were derived may have borne on their surface some forms of organized beings.

In the *Quarterly Journal of Science*, for October, Mr. M. M. P. Muir gives a paper on "Scientific Method," and surprises the scientific reader by his opening sentence, which is as follows:—

"Whether we turn our attention on ourselves, or seek to pursue the study of mankind in general, or on the other hand, confine our view to the natural world around us, there is in each case one method, by pursuing which we arrive at exact knowledge: that method is the scientific." Further on, Mr. Muir says, "there is nothing peculiar in this method; it is but common sense reduced to rule." It must, however, be admitted there is something peculiar in Mr. Muir's paper, though that is not altogether common sense reduced to rule. The bulk of the paper is occupied with extracts from Jevon's 'Principles of Science,' and Charles Babbage's ninth 'Bridgewater Treatise,' as well as Thomson and Tait's 'Oxford Pamphlet,' and other works of erudition, together with observations naturally flowing from them. Any scientific man having read the paper would lay it down and be none the wiser, though perhaps the sadder, for having read it. Where Mr. Muir is correct he is writing what all workers in science know and feel; but he is not always correct, especially in the opening passage above quoted, for if we may accept the views put forward at Birmingham by Professor Tyndall, or those of J. Stuart Mill, the study of mankind and of society involves weighty considerations which cannot be dealt with by science.

The *Practitioner* for October contains a paper on the "Propagation of Scarlet Fever through the Agency of Milk." The outbreak in question occurred at New Barnet and, according to the paper referred to, it "was apparently caused by infected food, in this instance presumably milk." It is endeavoured to prove this in a way which has been attempted before, viz., by first of all assuming the milk to be the cause, and then showing that most of the sufferers were supplied by a certain milk dealer. Such a method is as illogical as the attempt to find out the true cause is commendable. The total number of cases which happened during the two months was 140, and of these 140 cases, 131 were supplied with the same milk. This certainly looks plausible, but against concluding that the milk thus supplied really carried the infectant, the following considerations must be borne in mind. The 131 cases of scarlet fever occurred in fifty-eight houses, but the same milk was supplied to seventy-seven houses in which there was no fever! Again, in houses supplied by other milk vendors nine cases of fever occurred. It is also seen that the one particular

* *Chemical News*, October 19, 1877.
† *Ibid.*

milk vendor whose milk was thus suspected had a considerable monopoly of the trade, and assuming the outbreak to have commenced in the district supplied by him, it would follow as a matter of course that the disease should be chiefly located in that geographical region. There is therefore no safe foundation—as yet no plausible ground even—for assuming that milk was here, or ever has been, the originating cause or the propagating agent of scarlet fever or any other disease.

"Does Vaccination afford any Protection against Small Pox?" is the subject of a pamphlet by T. B. Sprague, M.A., etc., reprinted from *The Journal of the Institute of Actuaries and Assurance Magazine.* The author attempts to arrive at a satisfactory conclusion by an examination of carefully compiled statistics, but he is baffled to some extent by their incompleteness. The general conclusion seems to be that with lapse of time there is a gradual wearing out of the protection afforded by vaccination. It should be mentioned that in this pamphlet the author, who is a spelling reformer, adopts the plan of spelling words according to their pronunciation, and as a result the pamphlet is interesting in more senses than one.

Dr. C. H. Ralfe has reprinted from the *Lancet* his paper on the "General Pathology of Scurvy," and among his inferences are these: that the primary change which occurs in scurvy is a chemical alteration in the quality of the blood, and that—so far as can be judged by analysis of urine passed by patients suffering from the disease, and analysis of what are considered to be "scorbutic," and "antiscorbutic" diets—this alteration points to a diminution of the alkalinity of the blood.

The high commendation given by Sir Henry Thompson to natural mineral water, as a medicnal agent of much greater efficacy than the salts contained in it are when prepared by the manufacturing chemist, has naturally contributed in no slight degree to increase the demand for the water of various mineral springs, enjoying a reputation for specific virtues. Among those kinds most in vogue with the ailing and medicine-loving public, the mineral water occurring on the banks of the Danube has lately become highly popular, and it is therefore worth mention that according to an article published in the *Pester Med. Chirurg. Press* by Dr. S. Hermann, the water obtained from different wells is not in all cases the same in character, though it unquestionably originates from one and the same source. He ascribes the difference to the infiltration of fresh water, which mixes with and dilutes the water of the true mineral spring, and he points out that by adopting suitable precautions this has been prevented in the case of the well bearing the name of Hunyadi Laszlo, with the result that the water obtained from it contains, according to the certificate of the official analyst of Pesth, a larger amount of salts than that obtained from other wells in the neighbourhood, and is in fact the richest water of this kind known.

Considering the cost of transporting mineral water from such a distance as Hungary, it is of course important to avoid, as much as possible, dilution of the true mineral water. Another mode of counteracting this obstacle to the general use of the water has been adopted, and an extract consisting of the salts dissolved in the natural water has been introduced into use in Hungary and Austria, which admits of being sold at a much cheaper rate than the corresponding quantity of the water, while at the same time presenting the saline constituents exactly in the same quantitative and qualitative proportions as in the original water.

Another contribution has been made towards the removal of the difficulty in the administration of medicines in proper doses, which has been repeatedly discussed in these columns. Messrs. Mawson and Swan have forwarded some samples of accurately graduated cylindrical glass measures, which they are about to manufacture for this purpose, holding one and two teaspoonfuls. From their size and lightness these measures are very portable and can be conveniently carried in the pocket by medical men.

It is satisfactory to note that various endeavours are being made to introduce into use the alkaloids so abundantly accompanying quinine in certain kinds of cinchona bark. In addition to the pure salts of cinchonidine and quinidine, made by Messrs. Howard and Mr. Whiffen, as well as the combined alkaloids manufactured in India, and in this country under the designation of quinetum, practical effect is being given to the recommendations of Dr. De Vrij that the entire soluble constituents of cinchona bark should be used. Thus Mr. Schacht's recently introduced alcoholic syrup of cinchona will serve to render usefully available as medicine, the total active constituents of the bark, and another excellent preparation, now introduced by Mr. Umney, under the name of fluid extract of cinchona, furnishing the constituents of bark in a very concentrated form, is an additional step towards obviating the waste of the valuable remedial powers of bark which has resulted from confining attention too exclusively to quinine. These applications of Dr. De Vrij's views are especially important now that Indian cinchona bark is becoming so considerable an article of commerce, though it is not so well suited for the manufacture of quinine. The testimony of various authorities to the medicinal value of the other constituents of bark besides quinine, is so decided that these efforts to provide for their administration are not only creditable to pharmacy but deserving of recognition.

ARSENICAL CAPPING PAPER.

BY J. B. BARNES.

There is in use a magenta-coloured capping paper which contains arsenic to a large extent. The colour of this paper is evidently the product of the oxidation of aniline by arsenic acid; it is very soluble, and I have seen an imperfectly corked bottle of medicine, which had been capped with this paper, coloured pink by its means. The paper in question is rose-coloured, has a smooth surface, and is very nice to use, being strong, thin, and pliable, but it loses its brilliancy when exposed to the light; it is, on that account alone, not the best which can be selected for the purpose, even if it did not contain a deadly poison.

It is needless to enlarge upon the danger attending the use of this paper, as the bare suspicion of extraneous arsenic finding its way into *medicine* must be sufficient to ensure its instant abandonment by those who have not already suspected that it contains arsenic.

THE TANNIC ACID OF GUARANA.*

BY FRANCIS V. GREENE, M.D.

Although guarana has been known in Europe since the year 1817, when it was described by Cadet de Gassicourt, it does not appear that any complete chemical analysis of the substance has as yet been made, or that the component parts have been examined with sufficient care to afford an explanation of its peculiar action on the economy, when used as a therapeutic agent.

The chemical investigations of Theodore Martius, in 1826, proved that it was not a gum-resin, as had been supposed, but a mixture of the seeds of the *Paullinia sorbilis* with starch, and that it contained a crystalline principle, which he styled guaranin, under the supposition that it was a new principle. The true nature of guaranin was not detected until 1840, when Berthemot and Dechastelus submitted it to an ultimate analysis, which established the fact that it was identical in composition to caffeina. Their very valuable researches on the subject (*Jour. de Pharm.*, 1840, p. 578) were, however, confined to the extraction and determination of the characters of the caffeine, and they merely refer incidentally to the gum, starch, tannin and oleaginous matters which exist in the guarana. The *Journal de Pharmacie et de Chimie*, vol. xxxix., 1861, p. 291, gives an extract from a note of M. Fournier in regard to an analysis he had made of guarana; but as it is only stated that he had found gum, starch, a fixed green oil, three volatile oils, a peculiar principle not fully determined, tannate of caffeine, and free tannic acid, without any reference to the relative proportions of the different substances, or the methods that had been employed to separate them, it can hardly be said that the analysis added anything of importance to what was already known in regard to the chemical composition of guarana. It is to be regretted that M. Fournier did not communicate his methods of isolating the different constituents, as an investigation of the physiological action of the component parts in a separate state might have afforded much information in regard to the value of the preparation as a curative agent. As far as I have been able to ascertain, no later chemical investigations of guarana have been made. It is possible, however, that Dr. Peckholt, who has examined a great number of the medicinal plants of Brazil, may have reinvestigated the subject and given the results in his work, 'Analyses de Materia Medica Brazileira.'

During an investigation lately made, with a view to the extraction of the caffeine from guarana, several of the reactions of the accompanying tannic acid were so strikingly dissimilar from those of the tannic acids in general, that I determined to isolate it and examine it carefully. For this purpose a quantity of guarana in fine powder was treated with successive portions of boiling alcohol (75 per cent.), the alcoholic solutions filtered when cold, and the alcohol driven off on a water-bath. The aqueous solution was then diluted with distilled water, and a slight excess of basic acetate of lead added, which threw down a voluminous flesh-coloured precipitate. This was thoroughly washed with distilled water, decomposed by sulphuretted hydrogen gas, and the sulphide of lead removed by filtration. The filtrate, after being heated on a water-bath to drive off the excess of sulphuretted hydrogen, and filtered, gave a clear solution with a scarcely perceptible tinge of yellow. Evaporated to dryness, this solution yielded an amorphous, slightly yellow, semi-transparent, partially scaly mass, which had the peculiar taste of tannic acid. This mass dissolved very readily in alcohol, and on allowing the alcohol to evaporate spontaneously, it was still found in the amorphous condition. That it is not incapable of crystallization, however, was proved by drying a small quantity of the aqueous solution over sulphuric acid under a bell-glass, when acicular crystals, radiating from amorphous centres, were formed.

The following is a brief description of the behaviour of this acid with different reagents:—

With ferric salts it gives a greenish precipitate, turning to brown on standing; with ferrous salts no precipitate is produced, but the colour of the liquid is changed in a short time to a dark green. The fixed alkalies give the solution a dark, reddish-brown colour; with ammonia it forms a lighter brown, while with lime water it gives a greyish-brown precipitate. It gives a green precipitate with acetate of copper, which is soluble in an excess of the precipitant. It does not precipitate the neutral sulphate of copper solution, but reduces the alkaline sulphate slowly in the cold, and rapidly when heated; it also reduces nitrate of silver by the aid of heat, and decomposes auric chloride in the cold. It gives dull white precipitates with barium salts (distinction from caffetannic acid), and a white precipitate with stannous chloride. It resembles caffetannic acid in not precipitating tartrate of antimony and potassa, and by readily precipitating both cinchona and quinia, but differs from it in precipitating gelatin from solution. Its reactions with the alkaloids and gelatin serve to distinguish it from catechuic acid. With lead acetate it gives a dull white precipitate. It quickly decolorizes the solution of permanganate of potash, and gives a dark red colour with molybdate of ammonia, which is discharged by oxalic acid.

It produces white precipitates with morphia and strychnia, and with aconitina and veratria with hydrochloric acid; it does not precipitate atropia, either in neutral solution or in presence of an acid. It gives no precipitate with salicin or santonin, but produces a bright yellow precipitate with piperina, in presence of hydrochloric acid.

As these experiments show that the tannic acid of guarana does not give reactions precisely similar to those produced by any other of the tannic acids treated with the same reagents, it is but reasonable to conclude that it differs from them somewhat in chemical composition, and it should on this account have some distinguishing appellation. It might very properly be termed *paullinitannic acid*, which would be preferable to guaranotannic, as future investigations may show the acid of *Paullinia cupana*, which is used as a diet-drink, and probably of other species, to be identical with that of the *Paullinia sorbilis.*

*From *The American Journal of Pharmacy*, August, 1877.

JAVA RHUBARB.*

BY PROFESSOR HUSEMANN.

Upon the Gunung Unarung and other mountains in Java there grows, at an elevation of two thousand to four thousand feet, a species of *Rheum*, the root of which forms an article of commerce, and is used by the Javanese as a purgative under the name of "*akar kelomba.*" Three varieties of this drug are met with in commerce: (1) *akar kelomba bras*, the top part of the root, with fragments of stalk still adhering; (2) *akar kelomba ketan*, the middle portion of the root; and (3) *akar kelomba keteba*, the bottom portion. Of the three the second named kind is the most valuable, whilst the top portion of the root combined with fragments of stalk is of the least value.

A detailed description of the best kind of Java rhubarb has been given by J. H. Schmidt in the *Tydschrift voor Nederlandische Inde* (xvii., p. 98), according to which the root is fleshy, and long conical, or somewhat napiform. In some places it is still covered with a dark-brown rind, whilst the remainder is peeled, and appears marbled with white and red. In a transverse section the rays run from the centre to the circumference, traversing the concentrical red-coloured rings, and appearing to break off at the cambium, which forms a dense dark-brown, resinous looking layer from 1·1 to 1·5 millimetres thick. The most central concentric rings are bright red and alternate with yellow ones. At the centre, in some fissures resulting from the drying, are seen some fine white felt-like

* From the *Pharmaceutische Handelsblatt*, No. 94.

threads, having a silky lustre; the structure of these can be recognized under the microscope. In a longitudinal section are seen in the centre the almost rectangular parenchyma cells, partially filled with chrysophanic acid. With the aid of a glass cells containing crystals of oxalate of lime can be detected.

The Java rhubarb resembles the Chinese in smell and taste almost completely; but according to some experiments made by Dr. v. Vogelpoel its activity is one-fourth less.

In 1874, Schmidt brought under the consideration of the Dutch East Indian Government the advisability of experimenting whether it was possible to increase the activity of this species of *Rheum* by cultivation, and thus to obtain a drug equal to the Chinese rhubarb but very much lower in price. The plant appears to be very abundant in Java, and the best kind of root, the *akar kelomba ketan*, is sold there at about 1*s.* 8*d.* per kilogram. As the therapeutic value of the Chinese rhubarb root increases, within certain limits, with the age of the plant, even if the experiment be carried out it will be some years before the result is known, but it would be possible in this way to secure roots of one age instead of a mixture of roots of all ages as at present.

The comparative analyses carried out by Schmidt between the official rhubarb and the best Java rhubarb show, however, some differences, and raise a doubt as to how far the Java root possesses the tonic properties of Chinese rhubarb.

In the first place the amount of ash differs. Calcined in a platinum dish the official rhubarb gave 12·15 to 12·24 per cent. of ash; the Java root yielded 6·27 to 6·91 per cent. A more detailed representation of the proportion of the inorganic constituents is given in the following table, in which unfortunately oxalic acid does not appear, the analyst having been prevented from completing the estimation:—

	Radix Rhei officinalis.	Radix Rhei Indicæ Javanicæ.
CaO	46·80512	41·68051
MgO	4·24359	5·26484
KO and NaO	7·35024	16·89486
CO_2	35·34188	19·25190
SO_3	1·11452	2·82191
PO_5	5·11709	6·78689
Cl	0·60683	2·09575
SiO_3	0·59828	1·97869
Carbon and Sand	0·76923	2·98934
	101·94678	90·76469

Schmidt has also attempted to estimate quantitatively some of the organic bodies which play a part in the therapeutic action of rhubarb; the result is shown in the following table:—

	Radix Rhei officinalis. per cent.	Radix Rhei Indicæ Javanicæ. per cent.
Rheotannic Acid	2·106	0·430
Phaeoretin	0·151	0·090
Chrysophan	0·056	0·107
Chrysophanic Acid	4·700	1·646
Emodin	0·580	2·000

From this it would appear that the rheotannic acid and the chrysophanic acid are present in the Java root in much smaller proportion than in the Chinese, whilst chrysophan and emodin are present in larger proportion in the Java root. Although the figures in this table cannot be taken as absolutely correct, in consequence of the great difficulty attending the separation of the organic constituents of rhubarb, it may be assumed that to a degree it is an expression of the differences between the two kinds of rhubarb. If chrysophanic acid be the active principle, then the inferior activity of the Java root depends probably upon the smaller quantity of chrysophanic acid present in it, and the activity might have been still further reduced if it were not for the simultaneous diminution in the proportion of tannic acid, which by its antipurgative action might act antagonistically to the chrysophanic acid. Professor Husemann considers it highly probable that the relative proportions of these constituents might be altered by cultivation so as to approximate the two rhubarbs more closely.

At present no information exists in botanical literature as to the plant from which the Java rhubarb is derived. Rosenthal's 'Synopsis Plantarum Diaphoricarum' does not refer to any species of rhubarb growing in Java. Still the Dutch East Indian botanists ought not to find any difficulty in deciding how far the plant should be treated as a new species or as one of the many continental East Indian species. But certainly this investigation throws no light upon the origin of the true rhubarb root.

THE RELATIVE VALUE OF COLCHICUM ROOT.*

BY THEODORE F. BECKERT, PH.G.

This subject was suggested by several pharmacists, who of late have found it a difficult matter to obtain colchicum root which on breaking presented a clear white colour. The recently imported article, as obtained from the wholesale druggists, consisted of tubers which had been sliced very irregularly. Out of a one pound lot not less than seven whole tubers were taken, the remainder varying from one-sixth to one-half inch in thickness. These pieces, when broken, presented quite a varied appearance, their colour being all shades between white and black; and it was noticed that the lighter coloured roots were mostly easy to break, and many of them of a mealy character, whereas the darker ones were difficult to break, and had a somewhat resinous appearance. A quantity of the root was broken piece by piece, and then separated into three grades, according to colour, white, slate-coloured and brown or blackish, particular care being taken in the sorting. Upon weighing, it was found that the white root constituted only one-sixth, while the grey root comprised not quite two-sixths, and the black root a little over three-sixths of the article examined. These results also agree with the observations of several resident pharmacists.

The methods used to determine were as follows: Two troyounces of each of the three grades of roots were exhausted by means of alcohol, yielding in each case about twelve fluidounces of tincture; these tinctures varied in colour according to the grade of root used, that from the white root being lightest. This indicates the solubility in the alcohol of the foreign colouring matter present in the grey and black roots. In preparing these tinctures, care was taken to percolate them under as similar circumstances as possible.

The tinctures obtained were separately evaporated by means of a water-bath, the residue was treated with distilled water, and poured upon a filter, in order to separate resinous matter; the filtrate was washed with slightly acidulated water until each filtrate measured 100 c.c. Dilute sulphuric acid was used for acidulating the solutions, which were volumetrically tested with Mayer's solution, in quantities varying from 5 to 15 c.c. In the preliminary experiments the solutions were variously diluted, and it was observed that the results were very considerably influenced thereby, an observation previously made by Dragendorff. To serve a sa basis for comparison, the experiments were afterwards made with solutions of uniform strength, as stated above, partly without any other addition, and partly as recommended by Dragendorff, after the addition of a concentrated solution of chloride of sodium, to increase the distinctness of the reaction. The three grades of the root required for 1 c.c. respectively ·0403, ·0414 and ·0462 of Mayer's solution.

Five troyounces of each of the roots were next exhausted by alcohol, percolation in each case being carried on until the liquid passed tasteless. The alcohol was eva-

* From *the American Journal of Pharmacy*, September, 1877.

porated, and the residues were treated with water, filtered and precipitated by a solution of tannin. These tannates of the white, grey and black roots, which, after having been dried, weighed respectively ·32, ·265 and ·27 gram, were decomposed by oxide of lead, and then treated with alcohol, in order to separate colchicia. The three alcoholic solutions were carefully evaporated to dryness, then placed over sulphuric acid for several days, and then their weight taken: the product from the grey root weighing ·115 gram, the black yielding ·104 gram, while the product from the white was unfortunately lost.

I next obtained some colchicum root from Professor Maisch, which was not less than ten years old, it having been in his possession at least nine years. It had quite a handsome appearance, very little dark root being present, and in all respects was a much better looking article than that previously employed. Two troyounces of this root were treated as stated above, and an acid solution obtained, measuring 100 c.c., and which, when treated with Mayer's test, in a similar manner as before, required ·0300 for the precipitation of 1 c.c.

The various results thus obtained are more concisely presented in the following table:—

	1st grade or white root	2d grade or grey root	3d grade or black root	Very old root
Mayer's solution necessary to precipitate 1 c.c. of the solution	·0403	·0414	·0492	·0300
Percentage of alkaloid in air-dry root	·205	·210	·219	·152
Tannate precipitate obtained from five troyounces of root	·320	·265	·270	
Amount of crude colchicia obtained from the tannates	lost.	·115	·104	

By the above table it will be seen that the results obtained with tannin and by Mayer's solution do not agree as to the amount of colchicia indicated. This may be due to the slight solubility in water of the tannate of colchicia, as noticed by Hübler and others, and to the varying amount of water used in the last experiments. But the results seem to indicate that it apparently matters little whether the root has a white, grey or black colour, but that the *age* is of primary importance, and none but a fresh-looking root should be purchased; if this is done I think no fault can be found as to the quality of the preparations made from it.

EXAMINATION OF COMMERCIAL COPAIBA.*

BY CHARLES A. BOWMAN, PH.G.

The author discusses the natural causes of the different appearance of commercial copaiba, which are due to its being obtained from different species of Copaifera, in thd probable mixture of the products of different species, ane in the loss or oxidation of the volatile oil from exposure. The principal varieties used in the United States are Maracaibo and Para copaiba, the former of which is a thicker liquid than the last. Specimens of both kinds were procured for examination from reliable houses.

Para copaiba yielded a clear solution with a small quantity of absolute alcohol and a slight flocculent precipitate with a large quantity. With little alcohol, sp. gr. ·817, a separation into two layers took place; but with a large amount no separation occurred, and the solution was nearly clear. Alcohol, sp. gr. ·835, gave in all proportions two layers, the lower of which was transparent, the upper cloudy. Agitated with half its bulk of ammonia, a perfectly clear solution was obtained. On evaporating a little from paper, a resinous spot without greasy margin was obtained, and when evaporated in a capsule 44·4 per cent. of a hard resin was left.

The Maracaibo copaibas behaved differently; they were cloudy and without flocculent separation with absolute alcohol; milky and without separation with little alcohol, sp. gr. ·817, and cloudy with more. They separated into two layers with alcohol, sp. gr. ·835, gave a permanent milky mixture with half the bulk of ammonia, left on paper a resinous stain with a greasy margin, and on evaporation from a capsule a plastic or soft residue.

The Para copaiba was then adulterated with, first, 30 per cent. of castor oil; second, the same amount of linseed oil, and, third, 20 to 50 per cent. of Venice turpentine. With these mixtures the following behaviour was observed:—

Tests.	Behaviour of First.	Second.	Third Mixture.
Alcohol, absolute . . .	Clear solution.	Clear solution.	Clear, with much alcohol flocculent.
Alcohol, sp. gr. ·817 . .	Slightly cloudy.	Separation; upper layer yellow.	Very slight separation.
Alcohol, Ammon sp. gr. ·835 . .	Separation when cold.	Separation, hot or cold.	Separation, hot or cold.
bulk ia water, half	Milky with 5 per cent. oil.	Milky with 5 per cent. oil; yellowish.	Clear solution.
Dropped on paper . .	Greasy margin.	Yellow greasy margin.	Well defined resin stain.
Boiled with water . .	Soft; with little oil, plastic residue.	Residue soft or plastic.	Hard resin.
Heat	Odour of copaiba, then of burning fat.	Odour of copaiba and of burning fat.	Distinct turpentine odour.
Petroleum benzin, 1 to 4 parts	Clear solution, even in presence of 2 oil to 1 copaiba.	Clear.	Dense floccules with 4 parts of turpentine.
Petroleum benzin, 10 to 12 parts	Separation, even with 10 per cent. oil.		Dense floccules with 4 parts of turpentine.

The oil separated from the first mixture indicates pretty nearly the exact amount of castor oil present, but little remaining dissolved in the benzin. The solution of Para copaiba in petroleum benzin was clear until about eight parts of the solvent had been added, when some floccules separated; the Maracaibo balsams gave clear solutions.

Experiments were also made with acids, oxidizing agents, various chemicals and solvents, without observing any distinguishing characteristic reactions; and though I have failed, as others have before me, to find a reliable test for the purity of the different varieties of copaiba, by which the presence of all adulterations could be detected, yet I may state that petroleum benzin, properly applied, will detect the presence of Venice turpentine, and not only the presence, but also very nearly the percentage, of castor oil.

PROTECTIVE SANITARY LEGISLATION.

IF the value and utility of the Food and Drugs Act can be gauged by the extent to which the general public have manifested an appreciation of its objects, and availed themselves of the power of self-protection placed within their reach by its provisions, no other conclusion can be arrived at than one decidedly unfavourable to this measure. That this is the case is evident to any one who takes the trouble to note from time to time how prosecutions under the Act are instituted, and the fact is rendered still more patent by the recently issued annual report of the Local Government Board.

It appears from this report that, acting under the 19th section of the Act, the Board issued a circular letter requesting copies of the analysts' quarterly reports to be sent in. The reports thus collected have been subjected to careful examination, and as the result it appears that nearly all the samples referred to in those reports were procured by the officers appointed under the 13th section, so that the extent to which the Act has been enforced has depended mainly upon the action taken under that section, while section 12, which gives power to private purchasers to have samples analysed on payment, appears to have been comparatively but little used.

In some districts it is stated that a large number of samples have been submitted to analysis; in others no samples, or scarcely any, have been sent in any town to the analysts appointed there.

The reports from the Metropolitan districts show that 4177 samples of food have been submitted for analysis, out of which 515 were pronounced adulterated, and out of 110 samples of drugs only seven were found to be adulterated.

Omitting the cases of food, it appears that in Staffordshire out of 17 samples of drugs analysed, 8 were adulterated; in Surrey, 2 out of 3 samples of drugs were adulterated; in Warwick, 1 out of 5 samples; in Liverpool, 1 out of 3 samples; in Birmingham, 9 out of 25 samples; in Brighton, out of 6 samples none were found adulterated; in Bradford, 3 samples out of 6 were adulterated; in Salford, 11 samples out of 33; in Southampton, 5 samples out of 21; in Nottingham, the only drug sample examined was unadulterated; and in Sheffield, the 11 samples examined were all unadulterated. In reference to these cases and those of food, it is added that in a considerable number of them the extent to which adulteration existed did not appear to be such as to require that proceedings should be resorted to. In this enumeration of cases no mention is made of the number of cases that have been decided to be infringements of the law without adequate proof of adulteration, nor is any account given to show that in the cases not taken into Court the assumed adulteration could have been sustained.

These data furnish a very important practical commentary upon the outcry that was raised about the time the Food and Drugs Act was before Parliament as to the poisoning of the public with adulterated articles. At that time we ventured to express the opinion that there was no adequate foundation for many of the alarming statements that were made as to the prevalence of adulteration, and it is with much satisfaction that we find the working of the Act has itself borne testimony to the correctness of the views we then expressed.

From the report before us, we also gather further evidence of the absence of real interest in the Food and Drugs Act, for in many counties and boroughs it is practically disregarded. In Berkshire, Cambridge, Cornwall, Essex, Glamorgan, Nottinghamshire, Oxfordshire, and several other places for which analysts have been appointed, no samples, or scarcely any, have been submitted for analysis. It is, however, some consolation to find that the possibility which existed of making the public analyst a useful official has not altogether been lost sight of everywhere in the pursuit of the *ignis fatuus* of presumed adulteration. This is shown by the reference made in the report to the employment of public analysts to make analyses of water, which is mentioned as being an incidental advantage of their existence, though water is not within the scope of the Act.

Closely connected with the objects of the Food and Drugs Act are those contemplated by the Rivers Pollution Prevention Act, 1876, which gave new and very important powers to the Local Government Board, to Urban and Rural Sanitary Authorities, and to the general public, with the view of preventing the pollution of streams. This Act has for the first time rendered the pollution of streams a statutory offence, in respect of which the County Courts may make a summary order requiring the offender to discontinue the practice.

This is a matter affecting the health and well-being of the community, perhaps much more seriously than any supposed practices of adulteration, and it is eminently satisfactory to find that it has at length received effectual legislative consideration, and as the protection of our watercourses from contamination hurtful to health is a subject of interest to all classes, we give the following *résumé.*

According to the provisions of this Act, sanitary authorities are empowered, subject to certain restrictions, to enforce its provisions in regard to any stream within their districts, or passing through any part of them, and the expenses thus incurred in the execution of the Act are to be payable in the same way as those incurred in the execution of the Public Health Act, 1875.

In addition to this public action of the sanitary authorities, proceedings may also be instituted by individuals aggrieved by the commission of offences against the Act, except in cases where the offence is pollution of a stream by the liquid refuse from a manufactory, or the solid or liquid refuse from a mine. These cases are properly to be dealt with by the local authority, but if on the complaint of any person interested that body refuses to take action for the suppression of any pollution by a manufactory or mine, the Local Government Board is empowered by the Act to commence proceedings on receiving complaint from the persons aggrieved.

As regards the very important and frequent pollution of streams by the drainage of solid and liquid sewage material, by liquid refuse from manufactories, and by solid or liquid refuse from mines, the Act came into force on the 15th of August last, and among the provisions relating to such cases, the Act authorizes properly qualified inspectors appointed by the Local Government Board to grant certificates that the means used for rendering harmless any sewage or other noxious material discharged into a stream are the best or only practicable means under the circumstances of the particular case, and such certificates are to be conclusive evidence of the fact in all courts and proceedings under the Act.

The inspectors appointed for this purpose are Mr. R. Rawlinson, and Dr. Angus Smith, and a hope is expressed by the Board that the enactments above mentioned will conduce in no inconsiderable degree to the mitigation of the existing pollution of streams, as well as to its prevention in the future, and at the same time that these enactments may not be found to have imposed undue restrictions upon either the local authorities or the manufacturing and mining interests of the country.

As regards three main conditions requisite for the maintenance of a good sanitary state throughout the kingdom we may, therefore, congratulate ourselves that legislation has made some progress. There is evidence that the supply of food and drugs is not open to serious suspicion, the Alkali Acts have provided, to some extent at least, against contamination of the atmosphere by noxious gases; and the Act to which attention has just been directed will help to secure greater purity of our rivers and streams than has hitherto been attained.

A NEW FEATURE IN CO-OPERATIVE TRADING.

A Co-operative Stores Company (Limited), trading in the Edgware Road, announces in its price list the institution of a Medical Department, and that the Directors have made advantageous arrangements with a gentleman, who is a member of the Royal College of Surgeons, a Licentiate of the Apothecaries' Company, and a Fellow of the Obstetrical Society, to give professional advice at the Stores, or otherwise, at a fixed tariff. The tariff, which is subject to a reduction of 20 per cent. to members and their families and servants, includes a midwifery fee of one guinea and upwards. We commend this fact to the consideration not only of the newly formed Malthusian League, but also of the Medical Defence Association, as affording a fair field for the exercise of its protective energies.

THE ELECTION OF BENEVOLENT FUND ANNUITANTS.

The result of the election of Annuitants on the Benevolent Fund of the Pharmaceutical Society, held on Wednesday last, will be found in the official report on p. 334. It will be noticed that the number of voting papers received was less than last year, but it may be as well to state that this indicates no falling off in the interest excited by the election. Last year, papers representing votes to which voters were entitled as Members or Associates of the Society were issued separately from those accruing to them by virtue of subscriptions or donations to the Fund, so that in many cases two voting papers were sent in by one person. This year, in all cases where voters have been entitled to both classes of votes, they have been included in the same voting paper.

At present, however, it would be difficult to define very exactly the relative amount of interest in the two elections, as at the time of writing, two days after the election, voting papers are still being received by every post, and probably stragglers will make their appearance occasionally during the next fortnight.

We regret to have to add that one of the annuitants, Mr. Thomas Novis, elected in 1866, died on the 18th instant at the age of 75 years.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The Council of this Association announces that arrangements have been made—dependent upon a sufficient number of students coming forward—to commence two classes for the study of Chemistry, in the first week of November. In one class, meeting on Tuesday evenings, a course of lectures on Theoretical Chemistry will be delivered; the other, meeting on Thursday evenings, will be devoted to "Practical Pharmaceutical Chemistry." Both these classes are to be conducted by Dr. Milne. A "Tutorial Class," for instruction in Arithmetic, English, and Latin, will also be conducted on Monday and Friday evenings, by Mr. A. Fairlie. Further information may be obtained from the Vice-President of the Association, Mr. J. M. Fairlie, 1, St. George's Road, Glasgow.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

October 17, 1877.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, and Taylor.

Dr. Greenhow was present on behalf of the Privy Council.

MAJOR EXAMINATION.

Six candidates were examined. *One* failed. The following *five* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Betty, Robert Brown ....London.
Blunt, Thomas Porter ....Shrewsbury.
Dear, Theophilus ....Hornsey Rise.
Nicholson, Richard ....Darlington.
Savory, Arthur Ledsam ....London.

MINOR EXAMINATION.

Twenty candidates were examined. *Ten* failed. The following *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Barfoot, John Richard Doughty Chesterfield.
Clower, John........................Nottingham.
Corden, Frederick William W. Streatham.
Cousens, John Stather.............Hull.
Dyer, Edward Henry ....Horncastle.
Kendrick, Alfred ....Limehouse.
Richardson, Joseph ....Birmingham.
Robinson, John Edward ....Boston.
Russon, Henry Albert ....Birmingham.
Whitlock, Draycott Kelly ......Southampton.

MODIFIED EXAMINATION.

Three candidates were examined. *One* failed. The following *two* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bloxam, William Eagleston ......Oxford.
Fouraker, Thomas Edward .....Exeter.

October 18, 1877.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, and Taylor.

Dr. Greenhow was present on behalf of the Privy Council.

MAJOR EXAMINATION.

Six candidates were examined. *One* failed. The following *five* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Bayston, George Coryndon ......Guildford.
Cluett, Benjamin....................Kingston-on-Thames,
Fell, John James ....Lancaster.
Peirson, Henry ....Banbury.
Robinson, William Prior ....Waterloo.

MINOR EXAMINATION.

Twenty-one candidates were examined. *Fourteen* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bessell, James Walter...... .....Ludlow.
Davies, David ....Merthyr Tydvil.
Godsell, Philip George............Great Malvern.
Hugill, John Howden ....Edmonton.
Matthews, John Henry ....London.
Minshull, Rose Coombes.........London.
Stammwitz, Louisa ....Wandsworth Common.

October 19, 1877.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, and Taylor.

MINOR EXAMINATION.

Twenty-seven candidates were examined. *Twelve* failed. The following *fifteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Baker, Matthias ....Hanley.
Bell, John Waller ....Todmorden.
Billinton, Arthur ....London.
Bowness, William..................Wokington.
Clayton, John William ....Preston.
Cocksedge, George Bloomfield...London.
Cridland, Francis Edwd. John Devizes.
Halstead, Harry ....Blackburn.
Keith, John ....Forres.
Lakeman, Stephen ....Norwich.
Owen, Henry..........................Gravesend.
Roberts, David Prosser ....Hereford.
Savory, John Field ....London.
Sugden, Samuel.....................Newchurch.
Taylor, George ....Brinsley.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's examination:—

Certificate of the College of Preceptors.

Bray, Percy Dean.................

Certificate of the Faculty of Physicians and Surgeons of Glasgow.

Bryson, James ....Middlesborough.

Certificates of the University of Cambridge.

Coley, William Henry ....Wednesbury.
Pemberton, George William ...Blackburn.

Certificate of the University of London.

Haythornthwaite, F. Metcalfe...Kirkby Lonsdale.

Certificate of the University of Oxford.

Pridmore, Sydney Spencer ......Hinckley.

EXAMINATIONS IN EDINBURGH.

October 17, 1877.

Present—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson, and Young.

MAJOR EXAMINATION.

One candidate was examined and declared qualified to be registered as a Pharmaceutical Chemist:—

Gorrie, Daniel ....Perth.

MINOR EXAMINATION.

Eleven candidates were examined. *Two* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bean, John ....Edinburgh.
Butters, Robert......................Leeds.
Carter, Henry Ayling ....Winchester.
Cowgill, Benjamin Rangdale ...Bingley.
Delamar, Edward Thomas ......Musselburgh.
De Nance, William Clarke ......Glasgow.
Fraser, Jonathan Innes ....Elgin.
Hammond, Henry...................Bradford.
Jones, Edmund......................Hanley.

October 18, 1877.

Present—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson, and Young.

MINOR EXAMINATION.

Ten candidates were examined. *One* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Laing, Alexander Gordon ......Turriff.
Macdonald, Ewen..................Inverness.
Macdonald, John ....Edinburgh.
Mackirdy, John......................Glasgow.
McNaught, Louis Arthur.........Dumfries.
Paris, Walter ....Bathgate.
Plumer, William Cork............St. Albans.
Rohan, Robert Aldor ....Mauritius.
Smith, Charles Albert .... Leeds.

MODIFIED EXAMINATION.

Three candidates were examined. *One* failed. The following *two* passed, and were declared qualified to be registered as Chemists and Druggists:—

McLean, A. Leith Hay Adams...Aberdeen.
Milne, George ....Montrose.

GENERAL MEETING—BENEVOLENT FUND.

ELECTION OF ANNUITANTS.

A General Meeting of the Members, Associates in Business, and Associates of the Pharmaceutical Society, and of the Subscribers and Donors to the Benevolent Fund, was held at the house of the Society, 17, Bloomsbury Square, on Wednesday, October 24th, at twelve o'clock, for the Election of Six Annuitants.

Mr. John Williams, President, in the chair.

The notice convening the meeting was read.

Scrutineers were appointed, who examined the voting papers, and brought up the following report:—

Scrutineers' Report.

We, the undersigned Scrutineers, appointed at the thirteenth election of Annuitants on the Benevolent Fund of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us and report the following result:—

Bensley, George David	**1904**
Braithwaite, John Charles	**4901**
Gilbert, Edward	**1956**
Knight, Charlotte Elizabeth	1122
Naftel, Elizabeth	**2338**
Nichols, Mary	662
Parsons, Ann	**1980**
Short, Martha	**2462**
Whitehead, Annie	514

3557 voting papers were received, of which number 62 were informal, and were disallowed.

John Williams, *Chairman.*
T. P. Gostling.
John Robbins.
W. R. Atkins.
G. W. Sandford.
John Carr.
Matthew Pound.
Thomas Greenish.
William Cornell.
Ralph Rawlinson.
Charles E. Turner.

October 24, 1877.

The Chairman declared the following six duly elected Annuitants:—

Bensley, George David.
Braithwaite, John Charles.
Gilbert, Edward.
Naftel, Elizabeth.
Parsons, Ann.
Short, Martha.

Votes of thanks were given to the Scrutineers and to the Chairman.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

The annual general meeting of the Bristol Pharmaceutical Association was held at the Museum and Library, Queen's Road, Bristol, on October 1.

In the absence of the President, Mr. Boorne (whose health is unfortunately still impaired), Mr. Schacht was requested to take the chair.

The following report having been read, its adoption was moved from the Chair, seconded by Mr. Barker, and carried unanimously:—

"Report 1876–7.

"The report which the Council has now the pleasure to offer presents points of somewhat unusual interest to the members and associates.

"The arrangements long pending between the Council and the Committees of the Bristol Museum and Library, were brought to a fortunate conclusion about the end of last year. The details were explained in a circular which was immediately issued; but the Council would once more remind the members and associates that, in virtue of that arrangement, connection with this Association conveys the right to enjoy, within the premises, the entire resources of the museum and the library in Queen's Road.

"The Council of the Pharmaceutical Society of Great Britain, in reply to an application on behalf of this Association, most generously accorded it a double grant. This consisted of a valuable collection of drugs for the technical museum, and a sum of £50 for the purchase of books for the lending library. The former was placed in the hands of a sub-committee, consisting of Mr. Stoddart and Mr. White, for proper arrangement, and the money was handed to Mr. Schacht, with instructions for its disbursement.

"Messrs. Stoddart and White report as follows:—

"'The glass case for holding the materia medica collection is now in its place and ready for the specimens, many of which are deposited on its shelves. The dimensions of the case are 23 feet long by 8 feet high and 2 feet deep. The greater part of the shelves are placed in a sloping position, so that a better view may be afforded of the specimens. The remaining shelves are horizontal, for the reception of bottles and other preparations that must be kept standing upright. Our Bristol Association is greatly indebted to the parent society and other kind friends for the donation of various beautiful specimens, many of them of great rarity. Almost all are now ready for arrangement in the case, which, although a large one, is manifestly too small for a complete systematic series of materia medica. It has been therefore thought advisable to confine the samples to those drugs and chemicals most rarely met with, leaving the ordinary ones to be studied in the stock of ordinary business. Several rare and uncommon samples are already received, both of an organic and inorganic nature. The case, it is hoped, will soon be completely fitted up, and be a credit to the Bristol Pharmaceutical Association.'

"Mr. Schacht reports thus:—

"'The books enumerated in the list submitted to the Society were all ordered, and, with the exception of a few volumes in the course of publication, have been all purchased. I have still in hand £9 18*s.*, with which to pay for those already ordered, and such others as may be deemed useful additions to the list. The books, duly catalogued (a list of which is enclosed), have been placed in a convenient department of the Bristol Library, in Queen's Road, under the charge of its librarian; and the conditions on which they may be removed for home study are stated on the first pages of the catalogue.'

"The prize scheme of the Association for the past session was as follows:—Two prizes in Inorganic Chemistry; two prizes in Botany; three 'Hills' Prizes' in Materia Medica and Pharmacy.

"For the 'Hills Prize,' all associates of the Bristol Pharmaceutical Association were eligible who had not yet passed the Minor or the Modified; for the others it was required in addition that the candidate should have attended one of the systematic courses of instruction now open to him, either at University College, Bristol, or at the Mining School, in the subject in which he competed. The examinations were conducted by a committee nominated by the Council, and which consisted of Mr. Stoddart, Mr. Schacht, and Mr. White, and it resulted as follows:—

"*Chemistry.*—1st prize, £3 3*s*., Mr. Morris; 2nd prize, £2 2*s*., Mr. R. S. Cuff; extra prize, £1 1*s*., Mr. W. Stroud.

"*Botany.*—2nd prize, £2 2*s*., Mr. W. Stroud.

"*The 'Hills Prizes.'*—1st prize, £3 3*s*., Mr. S. W. Hall; 2nd prize, £2 2*s*., Mr. W. Stroud; 3rd prize, £1 1*s*., Mr. W. Powell.

"The course of monthly evening lectures for the past session was limited to three in number, but, being most kindly undertaken by gentlemen of high scientific repute in the city, they were full of interest, and attracted large audiences. The Council were careful to record their sense of obligation to Dr. Tilden, Mr. S. P. Thompson, and Dr. Letts, at the time of their lecturing and are glad to repeat it now.

"The number of members now enrolled on the books of the Association is fifty-three, and that of associates is thirty-three. These numbers compare favouraly with the experience of past years.

"The financial position of the Association will be seen to demand the special attention of the next Council, but in other respects the Association may be fairly congratulated upon its past work and its prospects for the future."

The financial statement showed that the receipts during the year had been, 53 members' subscriptions, at 10*s*. 6*d*., £27 16*s*. 6*d*.; 33 associates' subscriptions, at 5*s*., £8 5*s*.; total, £36 1*s*. 6*d*. The expenditure, including a payment of £5 14*s*. 10*d*., due to the Treasurer on the previous year's account, amounted to £47 9*s*. 4*d*., leaving a balance due to the Treasurer of £11 7*s*. 10*d*.

A ballot having been taken, the following gentlemen were declared elected as the Council for the current year:—

Mr. Stoddart, President; Mr. White, Vice-President and Treasurer; Mr. Tucker, Hon. Sec.; and Messrs. Berry, Boorne, Boucher, Pitman, Plumley, Schacht, Stroud, Towerzey, and Townsend.

Parliamentary and Law Proceedings.

Prosecution under the Pharmacy Act.

The Council of the Pharmaceutical Society of Great Britain *v.* Robert Hird.

This case was tried on the 17th instant, at Brigg County Court before the Judge, Mr. J. Stephen, LL.D.

Mr. Lucas, from the office of Messrs. Flux and Co., appeared for the plaintiffs. The defendant did not appear.

George Birkett proved that on the 7th April last, he went to the grocer's shop, kept by the defendant at Ashby, near Brigg, and asked for two pennyworth of white precipitate, and was supplied by the defendant with two packets, for which he paid two pence. The packets purchased he took to Mr. Thomas Couldrey, and left them with him.

Mr. Thomas Couldrey, M.R.C.S., proved that he practised at Scunthorpe, near Brigg. He received from George Birkett the packets produced, and subsequently tested the contents and found them to be ammoniated mercury, commonly known as white precipitate of mercury. The packets were labelled "Precipitate—Poison. From Spouncer and Son, Chemists, Gainsborough."

The Learned Judge gave judgment for the £5 penalty with costs.

Prosecutions under the Sale of Food and Drugs Act.

Adulterated Cream of Tartar.

At the Huddersfield Borough Police Court on Tuesday, October 16, Mr. Charles Oates, chemist and druggist, Longroyd Bridge, was charged with selling 4 ozs. of cream of tartar which was mixed with a certain material which affected injuriously its quality. The defendant, through Mr. Morrison, pleaded not guilty.

Mr. Kirk said that the information was laid under the 4th section of the Sale of Food and Drugs Act, which stated that any person who should sell any drug mixed with a foreign ingredient, so as to injuriously affect the quality, was liable to a penalty not exceeding £50. On the 5th of October he went to the defendant's shop and purchased 4 ozs. of cream of tartar, for which he paid 5*d*. He told the young man in the shop that he had made the purchase for the purpose of having the cream of tartar analysed, and asked if he would accept a part, and he said he would. Witness divided the cream of tartar into three parts—one he gave to the young man, one he retained, and the third he submitted to the borough analyst. In cross-examination, he said he bought 6 ozs. of spirit of nitre, but he did not put it to any test, and he had not yet got the analyst's certificate with regard to it. He did not know that the defendant bought his goods from a wholesale firm at York.

Mr. George Jarmain said he was public analyst for Huddersfield. On the 5th October he received a sample of cream of tartar, and he found that of 100 parts 97·6 parts were cream of tartar and 2·4 parts were ground heavy spar (sulphate of baryta). He was of opinion that the addition of ground heavy spar had been wilful, and that the same affected injuriously the quality of the drug. In cross-examination he said it was not at all probable that a foreign ingredient could get into the drug in course of preparation. He was of opinion that the foreign ingredient had been put in wilfully.

Mr. Morrison said the defendant had been a chemist and druggist for thirty-five or forty years, and had dealt with Clark, Bleasdale, and Co., York, wholesale dealers. In the month of February he bought from them 14lbs. of cream of tartar, and he had no reason to believe that it was not proper cream of tartar. The fifth section of the Act said that a person should be exempt from fine if he showed to the satisfaction of the justices that he did not know the drug had been mixed, and that he could not with reasonable diligence obtain that knowledge. The defendant would tell them that he had no knowledge that there was the slightest adulteration in it. He (Mr. Morrison) was instructed that the cream of tartar was not adulterated. The defendant said he did not know that the cream of tartar was mixed with any foreign ingredient. Had he known that he should not have sold it. He tasted the cream of tartar when it came, and it seemed all right. He further stated that he tried the cream of tartar and found a slight sediment at the bottom, but it appeared that he did not ascertain this until after the inspector had been to the shop.

The Bench said they thought the defendant had been guilty of a legal offence, and he would have to pay 20*s*. and the expenses.

Sale of Adulterated Sweet Spirit of Nitre at Co-operative Stores.

At the same Court Benjamin Parker, manager of the Co-operative Stores, Bradford Road, was charged with selling 6oz. of sweet spirit of nitre which was adulterated.

Mr. Armitage appeared for the defendant and pleaded not guilty.

Mr. Kirk said that on the 25th September he went to the shop in question and purchased 6oz. of sweet spirit of nitre, for which he paid 1*s.* 6*d.* He told the defendant who he was, and for what purpose he bought the material. He gave the defendant a part and he submitted another part to the borough analyst, who had given a certificate showing that of 100 parts 56 parts were sweet spirit of nitre and 44 parts were of water. The witness said he did not know there were two qualities recognized. The defendant told him he got the article from Mr. Dickinson, Kirkgate, and that they had been particular to sell nothing but what they believed to be genuine articles.

Mr. Jarmain said that the liquid was adulterated with water to the extent named in the certificate he had given. In cross-examination, he said he believed that the defendant had done his best to sell articles that were pure, but people should not sell articles which they did not understand.

The defence was that the society had discontinued selling certain articles, and the defendant had done his best to sell only articles which were pure. He had managed the shop for twelve years, and he did not know but that the sweet spirit of nitre was pure. It was sold exactly as it was supplied to the society. In cross-examination, he said he did not know that any water had been added to the sweet spirit of nitre. After further evidence, the Bench said it was necessary that they should make a mark, as it was very important that the people should have drugs of a pure nature. The defendant was fined 10*s.* and the expenses.

Fred. Sykes, manager of the Beehive Co-operative Stores at Paddock, was charged with selling 6oz. of sweet spirit of nitre, which was adulterated. Mr. Kirk stated that on the 5th inst. he purchased from the defendant (who was represented by Mr. John Thornton) 6oz. of sweet spirit of nitre. He gave the defendant a part and sent one part to the borough analyst, who gave a certificate showing that the liquid was made of 60 parts of sweet spirit of nitre and 40 of water.

Mr. Jarmain gave evidence as to the quality of the drug.

Mr. Thornton said the drug was purchased at Mr. Dickinson's, and was sold as it was bought. No water was added to the drug in their shop that he knew of, and they had no desire to sell any article that was not pure.

The Bench fined the defendant 10*s.* and the expenses, and expressed the opinion that they ought to give up selling drugs if they knew nothing about them. Mr. Thornton said he was inclined to agree with the Bench.—*Huddersfield Daily Examiner.*

Poisoning by Eye-Water.

An inquest was held on Tuesday, by Dr. Hardwicke at the Buffalo Head, Marylebone, on the body of James Dooley, aged 2½ years. Deceased had been under treatment for nine weeks for ophthalmia, medicine and a belladonna lotion for the eye being prescribed. The lotion was put in a large bottle by the dispenser at the Marylebone General Dispensary, Welbeck Street, but, according to the mother's statement, it was never labelled "poison." On Saturday morning the mother administered to deceased a dose from the lotion bottle, believing it to be the medicine bottle, there being a similarity in the bottles. The mother saw a great change come over the child and found out her mistake. and ran with it to the dispensary, where it was seen by Dr. Lendon, the medical officer, who gave an emetic. Deceased, however, got worse and died at ten the same evening, having been delirious nearly all day. The cause of death was poisoning by atropine. The dispenser of the eye-lotion would not admit that the word "poison" was not on the bottle, but after due inquiry the jury returned the following special verdict:—"That deceased was poisoned by atropine contained in an eye-water lotion, which lotion was given by the mother in mistake for medicine, and the death was from misadventure. The jury are of opinion that carelessness was shown by the dispenser of the eye-lotion in not affixing a label with 'poison' written or printed on the bottle, and that the bottle was not a proper one for a small quantity of lotion as prescribed."—*Standard.*

Poisoning by Strychnine.

An inquest has been held at Marrow, near Wisbeach, on a young woman poisoned by strychnine. It appeared from the evidence that deceased before her death had stated that her sister's husband was the father of her unborn child and had given her a powder. On the other hand the brother-in-law, who is in custody, asserts that he bought the strychnine to kill himself, because deceased had said that she was *enciente* by him, and that she snatched the poison from him. The jury found that deceased died from the effects of taking strychnine, but how it was administered there was not sufficient evidence to show.—*Bristol Times.*

Alleged Poisoning of a Child.

On Monday, A. F. Vulliamy, Esq., held an adjourned inquest, at Needham Market, on the body of Robert Hall, an infant aged seven months, who died on Saturday week.

Margaret Hall, the mother of the deceased, re-examined, said: I gave one of Steedman's powders to my other child, two and a half years, two or three days before I gave the half to the deceased. The elder child had been slightly sick, I believe from eating unripe grapes, without diarrhœa, and I gave it the powder in consequence. The sickness got worse. I called in Mr. Griffin, who attended him a couple of days, and then he got quite well. The deceased suffered very much from diarrhœa during his illness. I have several times before given Steedman's powders to both my children. They always caused the child to sleep more soundly afterwards, and slight diarrhœa the next day. The diarrhœa was such as would be caused by an aperient medicine.

Mr. Thomas Griffin, surgeon, Needham, re-called, said I have made a *post-mortem* examination of the deceased. I found patches of congestion in the stomach and inflammation in parts of the bowels, which in some portions had gone on to the extent of mortification. Remembering the symptoms of the deceased's illness I believe the condition I have described of the stomach and intestines was induced by the action of an irritant poison, and I believe that poison was the cause of death. In certain states of the system calomel in medicinal doses have been known to prove fatal, even in as small a dose as a quarter of a grain. This would happen in very exceptional instances. The state of the intestines could not have arisen from natural causes, because acute inflammation of the stomach and intestines as a disease is almost unknown. In the case of the deceased child there had been vomiting and diarrhœa, and that circumstance, combined with the condition of the bowels found after death, caused me to ascribe death to the action of an irritant poison. The change of food arising from the weaning may have caused some general disturbance in the child, but the symptoms I found could not have arisen from mere change of food.

Albert James Bernays, Professor of Chemistry at St. Thomas's Hospital, deposed to making an examination of the stomach and intestines of the deceased. He said: The stomach appeared to be perfectly healthy, and did not exhibit the slightest sign of inflammation. The same remark applies to the intestines, with the exception of a few occasional brown patches, which I have understood are very common in cases of dysentery and typhoid. All that could be obtained from the whole of the intestines only weighed 226 grains. This was as nearly neutral as possible to test paper, which could be accounted for by the chalk found in the contents of the intestines. There were a few yellow stains, too small in quantity to recognize their exact character. I have not been able to discover the presence of any of the so-called irritant poisons. I found a trace of morphia, but in quantity too small to weigh. By electrolysis I found the merest trace of mercury in the tissues, but not in the contents of the intestinal canal. From what I have heard from Mr. Griffin, I consider that it is more than possible that the greater part of any irritant poison would have been removed. I have analysed Steedman's soothing powders, and I know them to contain a small dose of calomel, but I have never heard the quantity. I do not think it amounts to a quarter of a grain. I never heard of half a grain of calomel causing death. Steedman's powders seem to be carefully prepared. I have examined them three times, and the result has been the same in each case. If I had not been told that the person died from an irritant poison, unless I had been ordered, I should not have thought it worth while to make an analysis, on account of the perfect healthiness of the stomach.

Mr. J. Wiggin, public analyst, made a report on the sample of Steedman's powders forwarded to him, which showed that the powder contained a small quantity of calomel, it was about 25 per cent. of the powder, but the quantity was too small to say exactly.

The jury, after a long consultation, returned a verdict of "Died from an irritant or irritants, but what or when taken the jury were unable to say." They desired to add the expression of their opinion that no blame attached to any one in connection with the death of the deceased.—*East Anglian Daily Times.*

PAPERS PRESENTED TO PARLIAMENT.

Report of the Warden of Standards.

The eleventh annual report of the Warden of the Standards, Mr. T. H. Farrer, on the proceedings and business of the Standard Weights and Measures Department for 1876–7, has just been issued, and an abstract of its principal points may not be without interest to the readers of this Journal.

The main business of the office is (*a*) the custody of the imperial standards of length and of weight; (*b*) the periodical verification of these primary standards; (*c*) the maintenance of exact secondary standards for official use; and (*d*) the periodical verification of the local standards used by the inspectors of weights and measures.

In carrying out that portion of the business included under the first two heads, during the past year the three "parliamentary copies" of the imperial standards, which are deposited severally at the Royal Mint, with the Royal Society, and in the Royal Observatory at Greenwich, were temporarily removed to the Warden's office from their places of deposit, and compared with the imperial standards and with each other. It was found that no change had occurred in the relative lengths of the imperial yard or of its three parliamentary copies since their original verification in 1855, and that no appreciable change had occurred in the relative weights of the imperial pound or of its three parliamentary copies.

The department has also to take care that the "Board of Trade standards" are duly compared with the imperial standards at least once in every five years. During this year the Board of Trade standards requiring such legal comparison were the gas-meters, the "fluid ounce" measures, the "liquid measures of grain weights of distilled water," and the "cubic inch" measures.

The use of weights of one-third and of two-thirds of an ounce avoirdupois was legalized by Her Majesty's order in council of 4th June, 1870, for foreign postal purposes, in consequence of the postal convention of 1869, by which the postage upon international letters was charged by a scale of ten grams, or one-third of an ounce. As this convention is no longer in force such weights are not now required.

The number of inspectors' standards verified or reverified during the past year is slightly below the average. It appears that several counties and towns have neglected to comply with the law and have not had their inspectors' standards duly reverified. The department therefore calls the attention of these counties and towns to such omission, as any conviction for using false weights and measures in these places would appear to be illegal.

The erection by local authorities of public standards of length, although recommended by the department in the last report of the Warden of the Standards, has not been carried out so generally as could be desired, owing probably to the large expense of standards of the form at first proposed. It is announced therefore that with the view of facilitating the erection of such public measures of length the Board of Trade is prepared to approve standards of much less cost and of lighter form than those exhibited at Trafalgar Square. To engineers such standards are of undoubted use. Sir J. Whitworth has always contended that available standards of length in the form of end-measure bars with plane ends should be placed in the care of corporate bodies in large cities, and should be accessible for the use of the public, and the convenience to land surveyors, tradesmen and mechanics of having public standards of length by which they may at any time test their chain, yard, and foot-rule measures, is evident.

The attention of the Board of Trade having been called to a public and official announcement by the municipal authorities of Dublin, declaring certain measures of length laid down on the floor of the City Hall "to be correct and opened for the verification of all measures throughout the country," it was deemed necessary in respect to this instance of "home rule" to call the attention of these authorities to the laws regulating weights and measures which authorize the Board of Trade only to verify standards for such purposes, although the Board of Trade fully appreciated the example set by that city in the erection of measures for public use.

The Government of Russia, through General Gloukhoff, having expressed its desire that the department should verify the Russian primary standards of length and of weight, the Board of Trade authorized such verification. By the Russian imperial ukase of November, 1830, it is enacted that the *sagéne* of seven English feet, divided into three archines, each *archine* being of twenty English inches, or fifteen *verchocs*, should be the Russian unit of measure.

The amount of accuracy obtained by different methods of weighing was well shown during the verification of a standard kilogram for the Norwegian Government. The kilogram was weighed both by Dr. Broch and at the Warden's office, and the observations of the weighings were reduced to a vacuum by Professor Miller's method, and also by that of Dr. Broch. The difference between the weighings of the kilogram by the two methods amounted to only 0·015 milligram.

To meet the requirements of modern science a balance is needed by which the weights of bodies may be determined most accurately and quickly. Professor Mendeleef, of St. Petersburgh, and Herr Bunge, Mechanicus, Hamburg, have shown that it is possible to weigh quickly and accurately by the use of a balance whose beam has much shorter arms than those now in general use. A practical test of the relative merits of a beam with long arms and of one with short arms has been made in the department. By this test as well as from the mathematical consideration of the question, it has been ascertained that whilst the probable error of a weighing made with the short-arm balance is slightly greater than the probable error of a weighing made with the long-arm balance, yet a weighing by the long-arm balance occupies twice as much time as one made with the short-arm balance. Consequently great economy of time is obtained by the use of a short-arm balance. Only those chemists, physicists, inspectors of weights, etc., who have sat for hours watching the motion of a pointer moving slowly over a balance index can fully appreciate this economy of time.

Professor Barff's process for preventing the corrosion of iron appeared to the department to be likely to prevent the oxidation of standard weights made of iron, and Professor Barff has undertaken to submit some specimens of iron weights to this process. It is intended to place these weights in the hands of some local inspector of weights and measures so that it may be ascertained whether iron standard weights thus protected could safely be used in place of the expensive bronze or brass standard weights at present used.

The department has been recently applied to by engineers for the weight of a cubic foot of water. The legal weight of a cubic foot of water depends on the interpretation of the Acts 5 Geo. IV. c. 74, ss. v. and xiv., and 22 and 23 Vict. c. 66, s. ii. By the latter Act the cubic foot is declared to weigh 62·321 lbs. when the water is of the temperature of 62° Fahr., and the barometer is at 30 inches. The weight of a cubic foot of water adopted in this country differs, however, from the weight of the cubic foot calculated in terms of the scientific units adopted in other countries, and further inquiry into this matter appears therefore desirable.

All weighings of standard weights in this department in which special accuracy is required are reduced to a vacuum, and such reduction necessarily involves the question of the volume of air displaced by the standard weight. The weight of the volume of air which would fill the metric measure of capacity of a litre, the unit of measurement in these calculations, taken at the temperature of 0° C., and under a pressure of 760 mm. and weighed at the Standards Office, has been found to be 1·2938146 gram. In ordinary air of the temperature of 62° F., when the barometer is at thirty inches, a cubic foot of air would appear therefore to weigh 531·33 grains.

In consequence of an application made last year by Mr. Brunel, the Commissioner of Inland Revenue, Canada, for information respecting Sikes's hydrometer, the legal instrument used by the revenue authorities in Canada as well as in this country for ascertaining the strength of spirits, some researches have been made at this office, with the view of ascertaining the correct indications of this hydrometer when placed in spirits of temperatures below 30° Fahrenheit. In Canada, where the temperature of the spirits to be taxed falls occasionally to 0° Fahrenheit, it is stated to be of fiscal importance that such indications should be known.

The annual trial of the pyx took place this year, as usual, at Goldsmiths' Hall, and the trial plates of gold and silver, together with the standard weights, were severally produced by the Warden of the Standards, as required by law, and were referred to by the jury then empannelled by the Queen's Remembrancer to test the accuracy of the coins of the realm, such testing being conducted with that care and attention to scientific details which so important an inquiry demands.

The testing of the coin by an improved method of weighing in air and in water, was referred to by the Queen's Remembrancer in his charge to the jury. The recent researches of the Chemist of the Mint show that it is possible to assay a coin most accurately without destroying it, as in the present method of assay.

The standard weights of the Royal Mint have been duly reverified, as required by law.

Although the Coinage Act, 1870, declares that all weights used for weighing coin shall be compared at this office, yet the number of coin weights compared here continues to be very small. This year only sixty-one coin weights have been stamped. Any one using a weight not so compared and stamped is liable to a penalty of £50.

In carrying out the duties of the department under the Sale of Gas Acts, the models of the standard gas measurers or gas holders sent in 1860 to the Lord Mayor of London, to the chief magistrates of Edinburgh and of Dublin respectively, in pursuance of sect. 3 of the Act 22 and 23 Vict. c. 66, have now been reverified by comparing them *in situ* with proper standards, sent for that purpose to each city, in charge of an officer of this department. The results of these comparisons were communicated to the authorities of these cities, with a statement of the error of each model, and an expression of the satisfaction of this department at the state of the valuable models thus committed to their charge. The Sale of Gas Act, however, makes no provision for the use of these models, and it is a matter of regret that such instruments should have been sent to these cities without some instruction as to their probable use.

During the visit of the officers of the department to the gas-meter inspector's offices, at London, Edinburgh, and Dublin, they had the opportunity of examining also the condition of the working standard gas-measurers used by the inspectors of these cities in the actual testing of gas-meters. It was found that in no case had these working standards been reverified since their original verification in 1860. The condition of the working standards issued to other places is probably similar. After a period of seventeen years, the errors of these working instruments may now be considerable, and the accuracy of any results obtained from them is doubtful. The attention of the department has been called by inspectors of gas-meters and others to the omission in the Sale of Gas Act to provide for the verification of their gas-measuring standards.

An important question brought under the notice of this department is the question of testing the index of a gas-meter. At present the inspector of gas-meters is not required by law to examine into the accuracy of the index, and consequently gas-meters are stamped as correct although the inspector's examination is a partial one. Three recent instances have been reported to this departmart in which consumers of gas were charged for gas much in excess of what they had consumed, owing, as it was subsequently accidentally discovered, to the inaccuracy of the index only. In one instance a "3-light" meter registered five times more than was really consumed; in a second instance a "300-light" meter registered three times more than was really consumed, and in a third instance, Mr. W. B. Davis of Torquay complains that his meter although stamped as correct had been found to register 86,000 feet in excess.

There is in the office a collection of ancient standards of the time of Henry VII. These ancient weights and measures are interesting, both as works of art and on account of their historical associations. It is proposed to transfer them to the South Kensington Museum so that they may become more accessible to the public view than they are at present.

The engraving machine, by which it was intended to engrave the official stamp of verification on measures of length and capacity instead of by the present rude method of impressing the office stamp upon them by a hammer, has become practically useless owing to the failure of the water company to deliver a sufficient pressure of water throughout the day to the turbine which works the engraving machine. The Office of Works cannot consent to the introduction of a gas-engine, and as no other motive power is available at present it appears impossible to introduce in this building this improved mode of certifying the inspectors' standards of length and capacity.

There have been presented to the department by Messrs. Thomas and Bryan Donkin several standard measures of length, formerly the property of the late Mr. Bryan Donkin, F.R.S. These standards are nine in number; they were placed in boxes specially fitted for their reception, and are valuable on account of their accuracy and of the expeiiments on expansion of metals made with them by the late Mr. Donkin.

Applications have been made by the India Department and by several hydrometer makers also to verify hydrometers, but although for its own purposes the department has provided itself with acurate hydrometers, it has no authority to verify copies of them.

The question of the contents of a sack of coke has been this year several times brought under the notice of this department. It has been already shown (*vide* 10th report) that the capacity of a sack varies in different localities. The size of a sack should depend on the construction of the Acts 5 George IV. c. 74. s. VII., and 5 and 6 Will. IV. c. 63. ss. VII., VIII., as to whether "heaped measure" is abolished or not. The gas companies who make coke sell it generally by "heaped measure." Three heaped bushels make a sack whose capacity is 8446·4661 cubic inches. The retail dealers appear generally to sell coke by "stricken measure." Three stricken bushels equal only 6654·576 cubic inches. This difference of capacity is considerable.

During the past year no question has arisen relating to the metric system of weights and measures. In this country the use of metric weights and measures in shops, etc., is illegal. The metric system, however, may by the Act 27 and 28 Vict. c. 117, be referred to in contracts and written agreements, and its use for scientific purposes by chemists and others is now almost general. This department has found it desirable, therefore, in aid of scientific research or otherwise, to maintain accurate weights and measures of the metric system.

The rude and antiquated method of teaching weights and measures in our schools has been referred to in previous papers of this department. It would appear, however, from present arithmetic books that the student may still be taught the particulars of weights or measures which can be of no possible use to him in after-life. The student may be taught, among many other useless terms, that 8 lbs. make a stone of butcher's meat, although the stone is expressly declared by 5 and 6 Will. IV. c. 63, to be equal to 14 lbs.; that cloth is measured by the Flemish ell which expired forty years ago; that the hide is a measure of land, although the hide was obsolete in 1701; that coal is sold by measure called the chaldron, although coal can only be sold by weight.

On the retirement of the late warden, the department was revised with the assistance of a committee appointed by the Treasury and Board of Trade, and it was arranged that the office of Warden of the Standards should no longer be held as a separate paid office, but should be associated with that of the Permanent Secretary of the Board of Trade. The business of the Standards Department has, in pursuance of the usual practice of the Board of Trade, been connected with one of the divisions of that office, viz., the Harbour Department, and the practical duties of this department are discharged by Mr. H. J. Chaney, who is in immediate charge of the standards.

Dispensing Memoranda.

[31]. In answer to the above I beg to say that a few days ago I dispensed a similar prescription to one under observation, of which I give a copy—

℞ Camphoræ . . . . ʒj.
Chloral Hydrate . . . . ʒj.
M. Ft. Lin.

Sig. To be applied with a brush as directed. I found that after reducing the camphor to powder by the addition of a little S.V.R., and rubbing well together, and placing in a phial, that it was some time before it became liquefied. I think "J. S. P." would be quite correct in using ʒj instead of ℥j camphoræ, as I do not see how ℥j could unite with ʒj of chloral to form a liniment.

J. N. C.

---

[34]. I do not see any difficulty in dispensing the prescription as it stands. I suppose the stumbling block is the dose of hyd. bichlor., and should recommend the return of the prescription to the prescriber with a query.

FRANK ROOKLEDGE.

Easingwold.

---

[36]. Can any one inform me the way to mix the enclosed receipe without separating?

ASSISTANT.

℞ Ol. Macis . . . . ʒj
Ol. Olivæ . . . . ℥ss.
Liq. Ammon. . . . . ℥iii.
Spt. Rosmar. . . . . ℥ii.
Aq. Rosæ . . . . ℥iv.
M.

---

[37]. In dispensing the enclosed prescription should the double sulphate of the B. P. be used?—A. P. S.

℞ Aluminiæ Sulph. . . . . gr. ij.
Bismuthi Subnit. . . . . gr. ij.
Ext. Gentianæ . . . . q.s. ad pil.

Notes and Queries.

[558]. COPYING PAPER FOR PRODUCING WHITE LINES ON A BLUE GROUND.—Take 1. Red prussiate of potash, 120 grains, water, 2 ounces. 2. Ammonio-citrate of iron, 140 grains, water, 2 ounces. When dissolved, mix together, and filter. (This solution should be kept in the dark.) Now take some good note paper and give it an even coating of the above solution by means of a flat camel's hair brush. (This operation should of course be done by gas-light.) Then hang up the paper in the dark, and when dry it is ready for exposure to light, under a negative, tracing, etc., placed in a photographic printing frame.

G. W. WALTER.

Correspondence.

THE JACOB BELL MEMORIAL SCHOLARSHIPS.

Sir,—Not long ago an experienced examiner (I think it was Professor Huxley) made some useful remarks upon the character of questions proper for examinations. His observations went strongly against the system of "catch questions," which permit me to say are both a cause and a justification for "cram." My own experience of pharmaceutical examinations in the remote past does not altogether acquit them of this tendency, and I have observed a similar propensity in the published questions of later years. A year or two ago I called attention to the question put in a Preliminary examination paper "What is the plural of *die*?" and I asked *which* answer the examiners wanted, as they did not explain what "*die*" their question referred to. Probably the "lucky" answer would have been "*dice*," which I hold to be wrong, unless the word "*die*" is used in a limited sense, and this was not stated. I know that one candidate, who passed well up in the list, made the inexcusable mistake of taking the word for the Latin ablative for "*day*," which he rendered into its nominative plural "*dies*," but whether he scored off his blunder I never knew, as the examiners did not condescend to explain their meaning when appealed to. Neither does it appear that they have taken my protest much to heart, for I observed that the questions for the Bell Memorial Scholarship are of a similar "catch" character.

Agreeing with the views so well expressed by Professor Huxley, I think those questions generally too difficult, and calculated to throw the prize into the hands of the lucky rather than the meritorious candidate. Passing over the scientific and arithmetical questions, to which, however, my remarks equally apply, I take the difficult Latin passage from the first book of the Æneid,* difficult because separated

* See Journal, Oct 6, p. 273.

from its context and made still more perplexing by the presence of the extremely rare word "Cæsariem," which occurring at the beginning of a line and therefore spelt with capital "C" is calculated, and I should think intended, to "catch" the unwary. To the youth fresh from his Virgil the passage offers no difficulty; to a much better Latin scholar who happened not to have met with this identical passage it would most likely be fatal. Is that a proper characteristic of a test passage of four lines in which no opportunity is afforded of compensating for a misapprehension sufficient to spoil the sense of the whole sentence? It is no good to denounce "cramming" if our examiners adopt a system directly calculated to encourage it.

DETUR DIGNIORI.

PROSECUTIONS UNDER THE PHARMACY ACT.

Sir,—I sympathize with the closing remarks of your correspondent "M. P. S." in to-day's Journal in reference to the "over zealous" conduct of some analysts in their working of that Act, but I cannot in any case agree with him in the strictures he makes against the recent prosecution of unregistered men trading as chemists and druggists under assumed names. The two cases are very different. On the one hand, there is a staff of highly scientific men, who in most cases know little or nothing of the details of trade or of a manufacturing business, placed in a position, that with a stroke of their pen, a prosecution is instigated against perhaps the most respectable of business men, and in most cases without their knowing who the parties are. On the other hand, there is a class of usurpers, who are either too ignorant or too lazy (or both) to go forward and qualify themselves by passing the Pharmaceutical Society's examinations, carrying on a legitimate business; but must needs adopt some plan which will enable them to evade both the spirit and the letter of the law. The instance of the Apothecaries' Hall, given by "M. P. S." does not apply to the cases tried at the Birmingham Court. The Apothecaries' Hall is a registered and licensed place, or at all events the Company is so, and in the event of any accident occurring, the manager who is known to be a qualified person, is there to represent the Company. The same may be said of many old established firms in and out of London, who cannot be expected to change the title of the firm with every change in the partnership; but it is imperative and I think necessary, in common fairness to the great bulk of the trade, that such old-established firms should place on all poison labels, and on the door of their establishments, the names of the responsible managers, who, of course, must be qualified. Mr. Martin was the responsible manager of the business in question, and as such was he liable to prosecution, being unregistered himself. I think the officers of the Trade Association deserve the best thanks of the trade for their energy and perseverance in instigating and carrying through successfully prosecutions which ought long ago to have been carried through by the Pharmaceutical Society.

JAMES M. FAIRLIE.

Charing Cross Corner, Glasgow,
October 20, 1877.

COLOURED FIRES.

Sir,—The preparation of coloured fires has been attended with several severe accidents, and is, when sulphur and chlorate of potassium are included as ingredients, always accompanied with danger. Any one interested may, on referring to the back numbers of this Journal, see various reports of accidents arising from the mixing of red fire, even when apparently great care has been used.

But what especially impressed the danger of these mixtures upon my mind, was an explosion which occurred in this town some few years back, in the house of a firework maker, who had placed for extra security a quantity of firework cases containing a mixture of sulphur, sulphuret of antimony, nitrate of potash, and gunpowder in a closet in his bedroom, where during the hot summer night they spontaneously exploded, and in the furious fire that ensued some six or seven people lost their lives. In the inquiry which followed, it was proved pretty conclusively that the explosion was owing to the spontaneous ignition of the mixture above mentioned, probably accelerated by the unusual heat and disturbed state of the atmosphere.

This occurrence acted as a warning to have nothing to do with the mixing of fires containing sulphur, though possibly Mr. Walter's plan of washing the sulphur might somewhat reduce the chance of accident.

But why use these mixtures when the formulæ for coloured fires given in vol. ii., n. s., *Pharmacectical Journal*, and originally contributed to the Journal of the Chemical Society, by J. R. Bramschweiger, give better colours, yield no choking sulphurous vapours, and are free from the risk of spontaneous combustion?

For convenience the forms are here reprinted:—

Red Fire.

Nitrate Strontia	9 parts
Shellac in powder	3 ,,
Chlorate Potash	1½ ,,

Green Fire.

Nitrate Baryta	9 parts
Shellac	3 ,,
Chlorate Potash	1½ ,,

Blue Fire.

Ammonio-Sulph. Copper	8 parts
Chlorate Potash	6 ,,
Shellac	1 ,,

These have given great satisfaction for some time past, and I should strongly recommend them to the notice of your readers.

G. C. DRUCE.

Northampton.

Erratum.—On page 310, col. ii., line 19 from the bottom, *for* "oxalate of barium" *read* "oxalate of cerium."

"*A Country Assistant.*"—The preparation of the article in question is the subject of a patent, a copy of the specification of which may be obtained at the Patent Office, Chancery Lane.

F. G. Gough and W. H. Baldwin.—Your communications have been forwarded to the Publishers, Messrs. Churchill, 11, New Burlington Street, to whom all advertisements and payments for copies of the Journal should be sent.

J. S. Hicks.—The letter was considered unsuitable for publication.

F. H. Alcock.—*Polygonum Persicaria.*

A. P. S.—*The Sale of Quinine Wine.*—No licence is required for the sale of quinine wine, if made according to the B. P. formula and not sold as a proprietary or patent medicine. See before, vol. iii., p. 327.

W. Johnson.—(1) *Orobus macrorrhizus;* (2) *Petroselinum segetum;* (3) *Lapsana communis.*

W. Bray.—See a formula for Phosphorized Cod Liver Oil in the *Pharmaceutical Journal* for March 31st last, p. 808.

T. Lewis.—As a mere matter of individual opinion we should say that a stamp is required; but if you wish for an authoritative decision the best plan will be to apply to the Inland Revenue Board.

A. P. S.—Church's 'Laboratory Guide' or any other manual of analysis.

G. Taylor,—Apply to the Secretary for a copy of the pamphlet, 'Hints to Apprentices and Students.'

R. Watson.—The proof has been received.

H. W. Story.—The advertisement agents are Messrs. Churchill, 11, New Burlington Street, to whom we must refer you.

A Tamed Saxon.—We presume that the statement was the result of a slip of the pen.

"*A Chemist and Druggist.*"—In reference to your letter we do not think it expedient to discuss the merits of a case that is still pending; but if you were to communicate your suggestions to the persons conducting the defence of the case in question it is possible they might consider them useful.

COMMUNICATIONS, LETTERS, etc., have been received from Ms. J. L. Thomson, Mr. Reynolds, Mr. Williams, Mr. Evans, An Indignant Chemist, Assistant, Operarius, Mr. J. Laurie and Mr. Gostling are thanked for their communications, A. P. S.

SWEET SPIRIT OF NITRE.

What it Was—Is—And Ought to Be.

BY F. M. RIMMINGTON.

From the very unsatisfactory state in which I found the literature of this subject I have had to answer these questions for myself. And as some of the data and the facts I have made out may be of interest to others I presume to give them in this paper. In doing so I am fully conscious that there are some who may probably know more of the subject than myself. But my main hope is that I shall convince the trade and the medical profession that the spiritus nitri dulcis as at present ordinarily sold ought to be discarded from every respectable pharmacy as a worthless and useless preparation.

Spiritus nitri dulcis was introduced into English pharmacy some time in the early part of the eighteenth century, and it appeared in the London Pharmacopœia of 1746, the formula for its preparation being as follows:—

℞ Sp. Vinosi Rect. . . . M. Libras duas.
Sp. Nitri Glauberi . . P. Libram dimidiam.

M. Misce infundendo nitri spiritum alteri, et distilla leni calore, quamdiu, quod prodit, fermentationem cum sale lixivioso non suscitat.

The spiritus vinosi here ordered is by measure, as indicated by the small letter M, and the sp. gr. ·825, or of the strength of excise alcohol. The acid is by weight, and would measure less than five fluid ounces. With these proportions the operation is one of no little risk. The product is a highly ethereal fluid, of fragrant odour, and yellow colour, and yields 18–20 per cent. of nitrous ether.

The same formula was retained in the Pharmacopœia of 1788, with the modification that only twenty-six fluid ounces were to be distilled.

The difficulties and mishaps that would be frequently encountered in those primitive days of chemical science by the pharmacist, would neither be few nor trifling, and there can be no doubt that a strong reason was felt for an alteration of the formula. Therefore, in 1809, the Pharmacopœia ordered the acid to be reduced to three ounces, or one half, and only twenty-four ounces to be distilled. No other change was made until the Pharmacopœia of 1836 appeared, when the proportions of alcohol and acid were again altered to four troy ounces of acid, and three troy pounds of spirit. vini rect., sp. gr. ·838, and the distillate was to measure thirty-two fluid ounces, and have a sp. gr. not to exceed ·834.

The remarkable feature about this formula is, the fact that it was framed by a chemist of no mean reputation, and that the process is directed to be stopped just at the time when the chemical action, which is the object of the process, is about to commence. The result being that the product is little better than alcohol, and hence may have arisen the anomalous and unsatisfactory character this article has so long possessed.

The British Pharmacopœia of 1867 has attempted to restore this preparation to something like a respectable and useful position, as a therapeutic agent in the list of materia medica, but the process given is unnecessarily complex and probably does not meet with universal adoption. It does, however, fulfil one duty by specifying what the preparation ought to be, and gives three tests by which to determine its nature and quality.

Four or five per cent. of nitrite of ethyl, the quantity contained in the spirit of the British Pharmacopœia is, I think, a fair standard to adopt, and contains as much ether as can, perhaps, be conveniently kept without loss. This proportion of ether, too, is sufficient for all the medical uses required of it. Nitrite of ethyl contains about half its weight of nitrous acid and is easily decomposed when introduced into the stomach. It is easy to conceive the probable effects of such an agent in certain febrile or zymotic diseases. Its antiseptic power must be very considerable, but its diuretic properties are probably mythical.

Spirit of nitre when free from aldehyde and other oxidized products, will keep four or six months with but little change in bottles filled and well stoppered; any addition of water greatly accelerates decomposition, which may go so far as to annihilate all the ether.

I may, perhaps, be pardoned for pointing out one or two defects in the process of the present Pharmacopœia. The direction to suspend the process after twelve fluid ounces have distilled until the retort and contents have cooled, for the introduction of the second portion of the nitric acid, is quite impracticable on a larger scale. Supposing a manufacturer operating on ten or twenty gallons in an earthen still by means of a steam heat, it would require some hours for such an apparatus to cool a few degrees, and during this period of suspension, an active and destructive chemical action would all the while be in operation in the body of retort. Many compounds that are injurious to the purity and quality are generated under such conditions. The question may suggest itself to some, why has this article remained so long in so unsatisfactory a condition? I think, the answer must be, that tradition, prejudice, and the price at which it has been sold for so many years, have all tended to prevent any improvement in the quality being made. Any attempted improvement has been at once condemned and rejected, on one or other of the grounds I have named. The sooner this state of things is changed the better, or this agent, so venerable for its antiquity and respectable for the hold it has taken of the affections of the public and the profession, must ere long be consigned to oblivion.

NOTES ON MALTESE DRUGS.

BY ROBERT WATSON,

Apothecary (Malta).

The following are a few of the vegetable drugs in use in Malta. For the local names I am indebted to my esteemed friend Signor Guido Abela Pulis, of Valletta.

Ruta graveolens.—*Local name*, Feigel.

Used by the lower classes for abrasions and contusions. The leaves are powdered and mixed with olive oil and applied hot to the parts affected.

Borago officinalis.—*Local name*, Fidlokkom.

Used in infusion and syrup in cases of cough.

Hyoscyamus albus.—*Local name*, Mamma Zeiga.

Grows in great quantities in all uncultivated parts of the island. Used mixed with bread as a poultice in tumours on the breast.

MARRUBIUM VULGARE.—*Local name*, MARRUBIA BAIDA.

Used in infusion in cases of cough.

PAPAVER SOMNIFERUM.—*Local name*, XAHXIEH.

An infusion of the dried fruit is given to allay pain in young children. Many cases of death occur from its use.

MYRTUS COMMUNIS.—*Local name*, REHAN.

The leaves dried and powdered are used as violet powder in excoriation in young children.

PUNICA GRANITUM.—*Local name*, RORNMIERR.

An infusion of the peel of the root is used as an anthelmentic.

SMILAX ASPERA.—*Local name*, SALSA PAISANA.

A decoction of the root is used by the lower class as a remedy to cool the blood in skin diseases.

SAMBUCUS NIGER.—*Local name*, SEBUKA.

The boiled leaves are used as an antidote for erysipelas.

PLANTAGO MAJOR.—*Local name*, BISBULA.

This plant is to be found in cultivated parts during November. The lower superstitious class attribute imaginary virtues to it.

VERBENA OFFICINALIS.—*Local name*, BUKEX-RERN.

The boiled plant is used in cutaneous eruptions in children.

GLECHOMA HEDERACEA.—*Local name*, EDERA TERRESTRI.

The infusion of the leaves is used as a preventive against pectoral and other complaints.

SCILLA MARITIMA.—*Local name*, GHAUSAL.

This plant is very abundant on the island; the bulbs are exported.

THE TURPENTINES AND RESINOUS PRODUCTS OF THE CONIFERÆ.

BY DR. JULIUS MOREL,

Professor of Chemistry in the Industrial School, Ghent.

The *Abies excelsa*, like the fir, is a tree found in mountainous regions, where the atmosphere is humid, but it supports a lower degree of cold; it is also disseminated over a wider area towards the north and it attains in the mountains a greater altitude, which would doubtless be increased did not the dryness of the atmosphere interfere with its growth. It is abundant in the Jura and the Alps, rather common in the Vosges, and rare in the Pyrenees. If a certain degree of lightness and freshness be present it developes with an equal vigour upon the granitic or silicious ground of the Vosges and the calcareous soil of the Jura. It attains a height of 100 to 160 feet.

The bark is intermediate between fir bark and that of the pines. After the fall of the epiderm it presents a reddish and fragile suberous tissue, a green envelope in which can be seen resiniferous glandules, and the liber, which is composed of nacreous fibres, the oldest of these appearing to be transformed on the exterior into a hard and compact reddish cellular tissue. At the age of about thirty years an internal periderm is organized; this becoming dried causes all that covers it to fall off, producing a reddish suberous rhytidome that finally cracks and exfoliates on the surface in small superposed more or less rounded flakes, covered with fine pellicles that are constantly separating.

Extraction.—According to Flückiger, Burgundy pitch is produced in Finland, in the Black Forests, in the Grand Duchy of Baden, Austria and Switzerland. On the estate of Baron Linder, at Svarta, near Helsingfors, it is obtained by melting the crude resin in contact with the vapour of water, and straining. In the neighbourhood of Oppenau and on the Kniebis mountain in the Grand Duchy of Baden, the stems of the firs are wounded at equal distances by making perpendicular channels, one and a half inches wide, and the same in depth. The resin which exudes from these channels is scraped off with an iron instrument made for the purpose, and

* Under this name the Belgian Pharmacopœia describes a preparation obtained by melting white resin (galipot) with water, and filtering while hot.

purified by being melted in hot water and strained. This is performed in three or four small establishments at Oppenau and the neighbouring village of Löcherberg. In this state the resin, which is opaque and contains much moisture, is called *Wasserharz.* By a further straining and evaporating a portion of the water, its quality is improved.

The manufacture in that part of Germany is on the decline, partly in consequence of the timber being injured by the wounding of the trees, so that the collection of resin is not permitted in the large forests belonging to the Governments of Basten and Würtemberg. Flückiger has had the opportunity of observing that in the establishments in question, French turpentine, or galipot, imported from Bordeaux, as well as American resins or colophony, are used in quantities certainly exceeding that of the resins grown on the spot.

Characters.—Purified Burgundy pitch is an opaque resinous substance, yellowish-brown in colour, hard and brittle when cold but softening slightly in time and taking the form of the vessel in which it is kept. Its odour is strong, agreeable and aromatic, especially when it has been warmed, recalling then the odour of pine forests. The taste is sweet, aromatic, and without bitterness. Its texture is not at all crystalline, although it is not rare to observe the resin crystallized upon the branch of the tree.

Burgundy pitch is very soluble in glacial acetic acid, acetone, absolute alcohol, and even 75 per cent. alcohol; but its solubility is considerably modified when it contains water and essential oil. This character is sufficient to distinguish clearly between Burgundy pitch and the artificial product prepared with white pitch and water. The modification is more evident still when the resin contains much abietic acid. The same causes which modify its solubility influence its fusing point. The resin of *Abies excelsa,* freed from the essential oil it contains, and brought to the state of Burgundy pitch, when dissolved in one part of absolute alcohol, rotates the plane of polarized light 3° to the left. The essential oil rotates it 8·5° in the same direction.

Chemical Composition.—In 1864, Maly made an analysis of Burgundy pitch, according to which it is constituted, like most of the exudations from the plants of this genus, of an amorphous resin ($C_{44}H_{62}O_4$) and essential oils, represented by the formula $C_{10}H_{16}$. Burgundy pitch contains only a relatively small quantity of these essential oils; colophony contains none.

Uses.—In this country Burgundy pitch is used in the making of plasters; it forms the basis of Emplastrum Picis, B. P. Herlant properly observes that this product ought to be substituted for white pitch in the making of plasters, as the latter substance is a mixture of variable composition. In Germany it is much used, mixed with colophony and galipot, under the name of *Brauerpech,* for coating beer vats.

Adulterations.—Upon this subject Flückiger and Hanbury remark:—"No drug is the subject of more adulterations than Burgundy pitch, so much so that the very name is understood by some pharmacologists to be that of a manufactured compound. The substance commonly sold in England is made by melting together colophony with palm oil or some other fat, water being stirred in to render the mixture opaque. In appearance it is very variable, different samples presenting different shades of bright or dull yellow, or yellowish-brown. Many when broken exhibit numerous cavities, containing air or water; all are more or less opaque, becoming in time transparent on the surface by the loss of water. Artificial Burgundy pitch is offered for sale in bladders; it has a weak terebenthinous odour and is devoid of the peculiar fragrance of the genuine. The presence of a fatty oil is easily discovered by treatment with double its weight of glacial acetic acid, which forms a turbid mixture, separating by repose into two layers, the upper being oily."

In Belgium an artificial Burgundy pitch is prepared, to which the name "*poix blanche*" is given, by melting galipot with water, stirring the mixture and filtering while hot. In France this artificial pitch is also called "*poix blanche factice,*" and is obtained by melting a mixture of galipot and turpentine with water, stirring whilst hot, and after thoroughly incorporating the ingredients with each other the mixture is allowed to cool; or better still, the galipot, or pitch resin, is melted with a little oil of turpentine or Bordeaux turpentine. Guibourt recommends that the galipot should be replaced by colophony and the turpentine by oil of turpentine.

Guibourt mentions the following means of distinguishing this false pitch from the true Burgundy pitch. The resin which exudes from the *Abies excelsa,* either naturally or artificially, is colourless, at first semifluid and cloudy, and its odour has considerable resemblance to the Strassburg turpentine; but upon drying in the air it undergoes a singular change. Some parts remain white and soft, and preserve their citron-like odour, whilst others become reddish and take a peach-flower colour or that of wine dregs, similarly to asafœtida. The latter portions also contract a stronger odour, which without being disagreeable presents some analogy with that of castoreum. The whole melted together with water, as is done in all countries where the resin from the *Abies excelsa* is worked, gives an opaque pitch of a rather dark fawn colour. Its odour is quite characteristic, rather strong and balsamic; its taste is sweet and aromatic, not bitter. Apart from the impurities that may be present in this resin it does not dissolve completely in rectified alcohol, and although the quantity of insoluble resin is not very great, it is sufficient to distinguish it from the factitious pitch, which dissolves completely. The alcoholic solution of the natural pitch has a rather dark reddish colour, and it has a rather bitter taste, although the undissolved resin appears insipid.

The "*poix factice,*" which is obtained from the maritime pine is pale yellow, and its colour becomes blanched in proportion as it is beaten up with water. It readily becomes dry and brittle on the surface, and is less tenacious and less adherent than Burgundy pitch. It has a very marked bitter taste even when not dissolved in alcohol, and it possesses the strong and disagreeable odour of Bordeaux turpentine and its oil. It is entirely soluble in alcohol.

The true Burgundy pitch has a more pronounced and much more uniform irritant action than the false, which cannot replace it in any case. It is a very grievous substitution, depriving the medical practitioner of an efficacious medicament. For this reason the author has not followed the example of Herlant and made a special article of the false Burgundy pitch, which is recommended only in some very rare pharmacopœias and these of ancient date.

With the false Burgundy pitch may be connected the boiled turpentine, still known under the name of "Greek pitch" of the ancients, "yellow resin," "pitch resin," and according to Lemère, "colophane de 1ere sorte." It is obtained by stirring colophony melted with water, or, preferably, stirring with water the residue of the distillation of turpentine before it has lost the whole of its essential oil; lastly, by boiling a mixture of galipot or turpentine with water until the mass becomes solid and whitish.

It will be seen that this product approaches the false Burgundy pitch in its composition and it is only when it has been prepared from turpentine that it contains a large quantity of the essential oil.

This pitch resin is solid, variable in consistence according to the temperature, yellowish in colour, opaque, and has a more or less pronounced odour of Bordeaux turpentine, that turpentine being most frequently employed in its preparation. It is a preparation no longer met with in modern pharmacies.

XI. GALIPOT.

Synonyms. — Garipot, Barras, Torche, Résine blanche, Résine commune, and Encens marbré, when the source of the galipot is the *Pinus maritima*, Poir., *Pinus sylvestris*, L., or the *Pinus Laricio* of Europe; and Serape, Common Frankincense, Gum Thus, Thus Americanum, Thus vulgaris, when it is yielded by the *Pinus australis* or *P. Tæda* of America.

Botanical Origin.—This substance is yielded by the different pines which give common turpentine.

Extraction.—In the Landes department galipot is collected just as the turpentine working for the summer is finished. The oleo-resinous juice, much impoverished, still runs from the latest wounds, but as the temperature is not sufficiently elevated to cause the resin to run down quickly to the foot of the tree, or because the essential oil is present in it in less quantity, it dries in the air on the trunk from the incision to the base, forming upon the tree a white nacreous substance in stalactiform tears. It is collected in winter. According to Mathieu, "galipot" is the matter solidified along the squares, and which is detached in pieces without being mixed with the *débris* of the bark. The name of "barras" is specially reserved for the solidified and adherent matter that cannot be obtained without scraping, and which is only an impure galipot, mixed with chips, fragments of bark, etc.

Characters.—In commerce galipot is met with in solid masses, yellowish white in colour, of a granular texture, and having a strong and terebinthaceous odour and a bitter and aromatic taste. Its granular texture is explained by the presence of small crystals of abietic acid, quite visible under the microscope. This galipot is completely soluble in alcohol.

The American galipot, the common frankincense or gum thus, consists of soft or solid masses, yellowish or slightly greenish yellow, resembling in this certain American elemis. Its odour and taste recall those of *Pinus Tæda* and *P. australis*. It, also, is entirely soluble in alcohol. Pine leaves, chips of wood, and other impurities occur in it, so that it requires to be filtered before being used. By keeping it becomes dry, brittle, darker, and less strong in odour. Examined under the microscope crystals of abietic acid may be discovered in it.

Chemical Composition.—Galipot is very poor in essential oil, either because the oil evaporates during the exudation, or because it becomes resinified; and probably also because at the period of its exudation the essential oil is less abundant in the tree than during the time the tree is worked for turpentine. When galipot is soft, and consequently richer in essential oil, it is not dried in the open air, but it is distilled with water, and the essential oil thus obtained is known as "*huile de rase.*" The odour of this oil is more aromatic and not so strong as that of oil of turpentine; the oil is less esteemed by painters, but without the cause being known.

Uses.—Galipot is employed in the preparation of some plasters. In Belgium it is very rarely used. Formerly, common frankincense was employed in English churches as a substitute for more expensive incense.

XII. PITCH.

Synonyms.—E.: Black Pitch.—L.: Pix sicca, vel solida, vel navalis, vel vegetabilis; Arida Pix. —G.: Schiffpech; Schwarzes Pech; Schusterpech.—F.: Poix noire; Poix navale des anciens.

XIII. WOOD TAR.

Synonyms.—L.: Resini pini empyreumatica; Terebinthina empyreumatica; Pix liquida.—G.: Flussiger Theer. Holztheer; Fichtentheer.—F.: Goudron de Norwége; Goudron Tare; Brai liquide; Pissa; Goudron végétal; Poix liquide.

XIV. JUNIPER TAR.

Synonyms.—E.: Cade Oil.—L.: Pyroleum Oxycedri; Oleum Juniperi empyreumaticum; Oleum Cadinum.—G.: Cade Oil.—F.: Goudron de Cade; Huile de Cade.

The last-mentioned three products,—especially pitch and wood tar, are so admirably described in Flückiger and Hanbury's 'Pharmacographia,' a work probably within reach of most English pharmacists, that the author does not think it necessary to repeat the description here.

(*To be continued.*)

NOTE UPON A REACTION OF EMETIA.*

BY FREDERICK B. POWER.

Towards the many reagents commonly employed for the ready recognition of the principal alkaloids, by means of which their presence and identification may be unmistakably proven, emetia seems to maintain a neutral character, and independent of its emetic properties, and of the characteristic sparing solubility of its nitrate, no reaction has been observed by means of which its presence could be readily identified in the course of forensic analysis.

Although probably never having met with an intentional criminal application, yet in view of the frequent and extended application of ipecac root, a marked reaction of its active principle seems deserving of notice, especially as reliance upon physiological experiments might possibly lead to its confusion with veratria, which possesses equally powerful emetic properties.

Chlorinated alkalies, which were proposed some time since as a test for morphia, and the behaviour of a solution of chlorinated lime toward morphia and some other alkaloids and neutral principles, more recently examined by Wellcome,† afford with emetia a reaction which is apparently characteristic of this body. While most of the alkaloids examined by Wellcome were found to

* From *The American Journal of Pharmacy*, August, 1877.

† *American Journal of Pharmacy*, vol. xlvi., No. 7, page 305–7.

assume a reddish coloration with a solution of chlorinated lime—and to the number of these, according to Dragendorff, may be added physostigmia—it was observed that a solution of chlorinated lime produces with emetia a bright orange or lemon yellow coloration, and is conveniently employed by touching a trace of the alkaloid upon a porcelain plate with a drop of the alkaline solution; the reaction being much favoured by the addition of a drop of acetic or other weak acid, to insure the liberation of the hypochlorous acid, upon which the reaction apparently depends, as chlorine is incapable of producing the coloration, which is permanent and may be quite indefinitely retained.

A few drops of a solution of one part of emetia in 1000 parts of water, when evaporated to dryness and brought in contact with a drop of the alkaline solution, readily produces the coloration; and with a solution containing one part of the alkaloid in 5000 parts of water the yellow coloration is still perceptible.

In view of the isolation of the alkaloid when mixed with complicated organic substances, it must be remembered that it is not absorbed from acid, but very readily from alkaline solutions by amylic alcohol, chloroform, benzol and petroleum benzin.

The reaction may also be employed as a means of testing the value of various species of ipecacuanha. If a gram of the root of *Cephaelis ipecacuanha* in fine powder, or the cortical portion therein contained, be treated according to the process described by Professor Flückiger,* for the isolation of emetia, *i. e.*, mixed with a small amount of quicklime and a few drops of water, the mixture allowed to dry upon the water-bath, subsequently exhausted by chloroform, and the filtrate allowed to evaporate in a capsule containing a few drops of dilute acetic acid, the nearly colourless residue thus obtained affords with the alkaline solution the characteristic coloration.

The root of *Richardsonia scabra*, Lin., or undulated ipecacuanha, which is occasionally quoted as a source of emetia, when similarly treated does not produce this reaction, and which may confirm the supposition already entertained, that this root is destitute of alkaloid.

COMMERCIAL DRUGS OF THE CHINESE PROVINCE OF KUANG-TUNG (CANTON).†

BY DR. F. HIRTH DU FRENES, OF AMOY, CHINA.

(*Concluded from p. 88.*)

In reference to *Galangal* or *Galgant* root, it may not be out of place to remark that its botanical source has been ascertained only a few years ago by Dr. H. F. Hance, English vice-cousul in Whampoa, and probably the greatest living authority on the flora of Eastern Asia. He found specimens of the plant in the neighbourhood of the city of Hai-an-so, on the south shore of the peninsula Lei-chou, which runs out towards the island of Hai-nan. The results of his investigations were published in the 13th volume of the *Journal of the Linnæan Society*.‡ According to these, the plant is a new species of Alpinia designated as *Alpinia officinarum*, and is found native in Kao-chou-fu, in the district Hsü-wen (situated in the most southern part of the peninsula), and upon Hai-nan. A Chinese work on the geography, products, etc., of this district, entitled, "Kuang tung hsin-yü," or "New Reports on Canton," contains the following passage on *galangal:* "The root of this plant resembles ginger, and is used as a drug; the seed occurs in the market under the name of 'red cardamoms' (hung-tou kou-tzu), and is said to have purgative properties, when eaten in an unripe state. The natives use these red cardamoms pickled in sweet sam-shu (a Chinese rice- or fruit-wine), as condiment for meats or fish. Towards the end of winter, that is, in January and February, the seed looks like a piece of amber, has a bitter aromatic taste, and forms a grateful addition to chopped meat. The root is not used as food, but only as medicine; hence it bears a name different from that of the plant."

The list of commercial drugs which form important articles of exportation, is, according to our showing, not very large; but the home-trade in domestic products is exceedingly active and extended. Among these, *sugar* undoubtedly occupies the front rank, although the market of Canton cannot bear comparison, in this respect, with those of Swatow, Amoy, and Takow.

Plantations of sugar-cane are found along the shores of nearly all the rivers of the province, chiefly along the Eastern River; and in the districts of Pan-yü (Eastern Canton), Tung-Kuan and Tseng-cheng, nearly 40 per cent. of the arable soil is planted with sugar-cane. In the centre of this region lies the city of Shih-lung (or Sheklung), which is the principal market for this industry. Another important sugar district extends along the shores of the small river Mo-yang, which empties into the sea opposite the island Hai-ling-shan. In the district of Yang-chun, which occupies about the middle course of this river, where it flows through a fertile valley between low mountain chains, six-tenths of the cultivated soil are made to produce sugar.

Next to sugar *betel* deserves particular mention. The areca-palm, from which betel is obtained, is found abundantly upon the island of Hai-nan, upon the opposite peninsula of Lei-chou, and in the department of Lien-chou-fu, which extends along the northern shore of the bay of Tung-King (Tonquin). The betel produced in the district of Hui-tung, at the west coast of Hai-nan, is considered the best; next to it is said to rank that coming from Lo-hai.

The neighbouring sea furnishes *Agar-Agar*, a gum-like mass obtained from a species of algæ, which is used for sizing and calendering paper and silks, for giving a transparent coating to the gauze-covering of lanterns, and many other purposes. It is principally collected by the fishermen of Hui-tung (at the seaport Sha-lao), on the east coast. Upon the small rocky islands of the south coast, near Ai-chou are obtained the well-known *eatable swallow-nests*, and large quantities of shells, often of great beauty and rarity.

THE ACTION OF CICUTA VIROSA AND SOME OTHER POISONOUS PLANTS.*

The most poisonous part of the plant, according to Trojanowski, is the root. The ethereal oil contained in this has no poisonous action, but the activity appears to reside in certain bright yellow drops contained in the resinous cortical zone, and from this a homogeneous, tenacious, non-drying amorphous highly poisonous resinous material can be obtained. Two or three milligrams are sufficient to poison a frog, and a cat is killed by the intravenous injection of ·007 of a gram. It is proposed to name it "Cicutoxin." It is absorbed slowly, the symptoms only appearing after twenty minutes, and sometimes not till after the lapse of several hours. The mode in which it gains entrance into the blood when ingested is not clear, since it is insoluble in water. In medico-legal cases, where no part of the structural elements of the plant can be discovered, it may still be possible to obtain sufficient of the resin by macerating the stomach in ether to make a physiological experiment on a frog. The actions of cicutoxin are remarkably similar to those of picrotoxin (from the *Anamirta cocculus*), of coriamyrtin (from *Coriaria myrtifolia*), of the resin of digitalis and taxus, and those of the baryta salts. These collectively form the so-called "group of

* *Der praktische Arzt*, June, 1877. From the *Practitioner* for September, 1877.

convulsive poisons." They act as violent excitants of a limited region of the medulla oblongata near the apex of the calamus scriptorius; of the convulsive centre discovered by Heubel in the frog, the existence of which has also been demonstrated by Nothnagel in mammals, and also to some extent to all the other centres situated in the medulla oblongata. The general symptoms produced by these poisons are well shown by the injection of a small quantity of cicutoxin beneath the skin of a frog. After twenty minutes the hind legs become stiff, the thighs are thrust out at right angles to the body, and the toes separated. The respiratory movements are much accelerated (irritation of the vagus centre), and owing to the inspiratory acts preponderating over the respiratory, the abdomen is blown up; whilst in consequence of the convulsive contraction of the abdominal muscles the air is forcibly driven through the contracted glottis with a very characteristic shriek. Tonic-clonic contractions of the muscles generally now supervene, the respiration is arrested, the movements of the heart are retarded, and death occurs with general paralysis after some hours or days. In mammals, after a period of restlessness of variable duration and abundant flow of saliva, the respiratory movements become more rapid and deep, and soon the most violent tonic and clonic convulsions of the voluntary muscles set in, during which the respiration is stopped by tetanus of the diaphragm, the cardiac beats are rendered much more energetic, and in the height of the attack are, with the circulation, brought to a standstill. The urine and fæces are expelled with convulsive violence. The attacks occur with increased frequency, and the animal dies exhausted from inadequate respiration. During the whole period the reflex excitability is enormously increased. Dr. Planat has suggested the employment of picrotoxin in the treatment of epilepsy. He commences with small doses and gradually increases them. In twenty-two cases thus treated more or less complete cures were effected.

THE PREPARATION OF DIALYSED IRON.*

BY E. B. SHUTTLEWORTH.

As there appears every probability that dialysed iron will become quite popular, at least for a time, a few practical directions, unincumbered by unnecessary facts or speculations, may serve a useful purpose.

Many methods and modifications of methods have been proposed for obtaining the solution for dialysis, and most of them may be followed successfully. The object is to prepare a solution tolerably concentrated, fully saturated with ferric hydrate, and containing as little acid as possible. I shall describe two methods, each of which has its peculiar advantages. Where time is not an object, as far as the duration of the process is concerned; and also in point of economy of labour and materials, the first may be adopted. Where it is desirable to produce a solution that may be finished quickly by dialysis, the second process has the advantage, and, taken altogether, I believe it to be the best.

The first consists in adding ammonia to a solution of perchloride of iron so long as the precipitate formed is redissolved. A solution is produced which contains ferric hydrate dissolved in ferric chloride, with free chloride of ammonium. Either the *liq. ferri perchlor. fort.*, B. P., or the *liq. ferri chloridi*, U. S. P., may be conveniently used, and the liq. ammoniæ, sp. gr. ·959 or ·960, of either pharmacopœia, will be found a convenient strength. It will be remembered that this is made by adding to the strong ammonia of commerce about twice its bulk of distilled water. If the ammonia be added to the strong solution of iron, considerable heat is evolved, and, on cooling, the preparation becomes gelatinized—often so much so that the vessel containing it may be inverted. It is better to avoid this result, and to this end the solution of perchloride must be diluted until of a specific gravity of about 1·300. This degree may be nearly enough approached by diluting two measures of the B. P. liquor with one of water; or adding one measure of water to five of the U. S. P. preparation. This solution will generally remain permanently bright and fluid. The amount of liq. ammon. required will of course vary with the acidity of the perchloride. The liquor ferri, B. P. will sometimes bear as much as an equal volume. A gelatinized solution, even when made from the undiluted liquor, will often become fluid when put upon the dialyser, but, as I have said before, it is better to work with bright solutions.

The second method consists in adding to either solution of the perchloride a quantity of recently precipitated ferric hydrate. Mix any given quantity of the liq. ferri with about five times its bulk of water and add excess of liq. ammon., also diluted with water. I think a more soluble hydrate is produced when the iron is added to the ammonia, as remarked in the case of the hydrate precipitated from the persulphate; but, in order to proceed in this way, it is necessary to know, approximately, the amount of ammonia required. The precipitate should be washed well, by decantation, with several waters, and then thrown upon a filter to drain for a short time. It may then be dissolved, by the aid of a gentle heat, in as much strong liq. ferri as may be required for solution. The exact quantity cannot be stated, but, in no case will it exceed the volume of the liquor precipitated, and sometimes only one-fourth of this amount will be necessary. The solution is now ready for dialysis.

With the majority of pharmacists the dialyser will have to be extemporized out of such materials as may be at hand. The hoop may be a bell-jar, an inverted glass funnel, or what is even simpler and handier, made from one of the flat hoops of an ordinary flour barrel. This may be smoothed a little with a knife, or sand paper, and made to the required diameter; ten or twelve inches is a convenient size; if much larger the dialytic septum is liable to belly in the centre and thus make the layer of liquid too deep at that point.

Parchment paper is generally used for forming the septum. This is not the paper that stationers in this country generally supply under this name, but a paper made less pervious, and strengthened by being dipped in sulphuric acid. Some of the strong and well-sized papers, as those used for legal documents, may be made to answer. It is absolutely necessary that there be no holes in the septum, and to ascertain this it is best to sponge with water the upper side of the paper and then carefully examine the other side. If any drops appear, the places should be marked, and a little white of an egg may be applied and coagulated by heat; or a drop of collodion or shellac varnish may be put upon the spot. Bladder, previously washed, may be used, and will be found to work well, especially if divested of its outer coat.

The septum should be two or three inches larger than the hoop, and should be secured around it, with twine, not bound tightly, and the edge should be allowed to stand up around the hoop, so that if any liquid escapes through the joint or hoop, it will be retained by the paper. The dialyser will now resemble a drum or sieve, and into this the liquid to be dialysed is poured, to a depth of, at most, half an inch. It is then floated on the surface of some distilled water contained in a suitable vessel. If the hoop be of some heavy material it must be supported so that the septum is but barely below the level of the water.

The time required for dialysing either of the solutions whose preparation has been described will vary with the nature of the septum, its extent of surface, the depth of liquid, the frequency of changing the water beneath, temperature, and other conditions which need not be enumerated. If everything works well, and the water

* From the *Canadian Pharmaceutical Journal*, October, 1877.

is changed daily, the process will be finished in one or two weeks. Distilled water is always preferable, and indeed necessary, especially, for the first two or three days. Clean rain water is the best substitute. The process may be said to be complete when the water no longer shows traces of chlorides, and the preparation becomes nearly tasteless, or, at least, not ferruginous.

A pig's bladder, completely filled with the iron solution, securely tied, and immersed in water, frequently changed, answers well for making this preparation. The process requires a longer time than with a carefully regulated and properly conducted dialysis, but it entails considerably less trouble. When I first tried this plan I was not aware that Professor Dragendorff, of Russia, had some five years ago suggested its application to dialysed iron. I can, however, corroborate all that he says. I may also mention that I think it an advantage to procure the bladder perfectly fresh, as it is then easily cleaned by pure water, and alkaline ley need not be used. Great care is necessary in tying the neck carefully. This can be best accomplished by a few turns of iron wire. Above this may be secured a piece of twine to suspend the bladder, by means of a stick or rod, placed on the edge of the vessel containing the water. The bladder should be perfectly full, and immersed altogether in water. The attraction of the solution for the water is so great that considerable pressure is manifested, and should any weak parts, or holes, be in the bladder, the liquid will be forced out, water will take its place, and failure result.

As to the strength of the dialysed solution I can say nothing, except that with care, and by using the solutions above mentioned, it may be kept over 5 per cent., the quantity of oxide which appears to have been chosen as the standard. One hundred grains of the liquor should be placed in a tared capsule, and evaporated to dryness. The residue should weigh about five grains. If more, distilled water must be added in the calculated proportion. If less, the solution may be placed in a warm and dry place until reduced to the proper volume. If much heat is employed, and often in any case, the oxychloride of iron will be deposited as normal oxide, and the preparation will be spoiled. The evaporation of the solution may, as a rule, be considered a very unsatisfactory process, and every care should be taken to render it unnecessary.

HISTORICAL NOTES ON OPIUM.*

(*Concluded from Vol. VII., page* 1042.)

The most thorough and important study of opium, so far as the progress of science permitted at that time, was made by Wedel or Wedelius,† the author of the celebrated 'Opiologia,' or treatise on opium, from which the following abstract is taken:—By heating opium in a retort, Wedel obtained: (1) a residue; (2) a volatile spirit; (3) a blackish oil, to which opium owes its narcotic power. According to the mode of expression then in use among chemists, opium contained therefore a good deal of "sulphur" (the oily substance), "mercurius" (the volatile matter), and besides, "aqueous, earthy, and salty ingredients." Wedel employed opium with preference in the form of tincture, in doses of ten to twenty drops. In cases of poisoning by opium he administered first an emetic, then *essentia castorei, elixir cephalicum,* and principally *spiritus formicarum*‡ internally and externally afterwards aloe pills. He also mentions that others had recommended camphor and lukewarm baths. He recounts many instances of accidental poisoning, and unmercifully rebukes the authors of these accidents, "the *medicaster parochus*" (parish quack) and the "*tonsor*" (barber). Occasional accidents are also attributed to the physician's writing *opium* instead of *apium.* He also quotes remarkable instances of opium-eaters; among others, that of a French ambassador who took opium by the ounce. The maximum dose he puts at five grains, and gives general directions as to its administration. "Above all, the condition of the patient must be taken into consideration; if this is low and the vital powers feeble, all other indications are placed into the background. Opium is a life-anchor for him who uses it properly and with circumspection, but in the hands of the unskilled it is a semblance of Charon's boat, and pernicious as a sword in the hands of a madman. Great care is therefore to be exercised, that the *narcotic* may not be converted into a *necrotic.*"* After a general introduction, the author discusses the diseases of all parts of the human body in which opium may be used. His principal indications are about the same as those which obtain in our days. The work is accompanied by an appendix treating of the *Maslach*† of the Turks; by its use before a battle, the Turkish soldiers were said to have been excited to such a reckless and fanatic courage as to make them a terror to their foes. This was said to have contained opium. The great traveller, Thurnhäuser, one of the most adventuresome followers of Paracelsus, pretended to know its mode of preparation.

In opposition to Wedel, his celebrated pupil, Stahl,‡ the founder of the phlogiston theory, discouraged the use of opium, as well as that of cinchona and of alteratives.

But the teachings of the celebrated English physicians, Sydenham,§ Cullen,|| and Brown,¶ raised opium to the highest importance. The first one of these termed opium and blood-letting the "*crura medicinæ*" (the legs on which medicine stands), and preferred opium to all other

* From *New Remedies,* July, 1877.

† Georg Wolfgang Wedel, born 1645, at Golzen, died, 1721, at Jena. Celebrated physician and professor at the university. Wrote many medical, pharmaceutical, and chemical works; his 'Opiologia' appeared first in 1674.

‡ *Essentia Castorei:*—1 lb. of castoreum is cut up fine, 6 lbs. of alcohol are added, and after allowing to macerate for eight days the alcohol is distilled off and reserved. The residue is treated with strong wine vinegar, the mixture filtered, and the vinegar distilled off. The residue lef from this distillation is then dissolved in the reserved alcohol.

Elixir cephalicum:—Rad. Pæoniæ, ℥i; Galangæ, Valerianæ, Doronici, Fol. Rosmarini, Mari veri, Salviæ, āā ℥ss; Flor. Anthos, Lavandulæ, Liliorum convall., Pæoniæ, Stœchados Betonicæ, Cubebarum, Succini, āā ʒvi; Visci corylini, Ligni Aloes, Ladani, āā ʒiij; Costi veri, Anacardiorum, āāʒi. Comminute the whole and extract them with alcohol.

Spiritus Formicarum (Cnœphelii):—Urticæ Rom. recent, *man.* i; Betonicæ c. flor., Chamædryos, Salviæ, Rosmarini, Majorani, āā *man.* ss; Flor. Lavandulæ, Sambuci, Primulæ veris, āā *man.* i; Flor. Basilici, Stœchados Arab., āā *pug.* ij: Rad. Rhœados. Confect. Anacardiorum, āā ℥i; Tartaris crudi, ℥iss. Comminute the whole, add 10 lbs. of alcohol, and, after macerating, distil. Then add to the distillate 3 manipuli (handfuls) of living ants and ℥i of crude alum, and after twenty-four hours distil again.

* Lest the ναρκωτικόν (narcotic) become a νεκρωτικόν (death-producing).

† Maslach, or Malach, is a vulgar name for *hemp,* used by the Egyptians and Turks. The intoxicating properties of *Cannabis* seem to have been but little known in Europe at Wedel's time.

‡ Georg Ernst Stahl, born 1659, at Anspach, died 1734, at Berlin. His phlogiston theory, which attempted to explain the various phenomena attending light and combustion, maintained its authority for seventy years, when i was exploded by Lavoisier.

§ Thomas Sydenham, born 1624, at Winford Eagle, died 1689, in London. He is sometimes called the English Hippocrates.

|| William Cullen, born 1712, in Lanarkshire, died 1790, at Edinburgh.

¶ John Brown, born 1735, at Bungle, died 1788, in London, a victim to his own teachings, in a state of chronic intoxication.

narcotics. According to him the three principal indications for its use are: (1) sharp pain; (2) persistent vomiting or purging; (3) considerable disturbance of vital powers. But he rejects it in cases of "inflammation of the blood, upon which many acute diseases depend." Cullen declared fever to be a weak condition of the nervous system, accompanied by an increased heart's action, and he recommends in such cases opium, wine, cinchona, and tonics. But the chief votary of opium was John Brown, who used to say that Sydenham would certainly be a follower of his theory, if he were still alive. His ardent and fanatic worship of opium originated from the soothing effect which he found it to have upon his gout, and he was frequently in the habit, during his lectures, of taking brandy and opium. His system, usually termed Brownianism, may briefly be explained as follows:—Life is a series of actions, which the body is compelled to perform in consequence of its irritability, by external or internal irritations. The disturbances of vital action—that is, diseases—may be consequently divided into sthenic or asthenic conditions, caused by excessive or deficient irritation. The latter condition may have two causes: either the irritability is normal, but irritation is absent, in which case an irritant remedy will furnish relief; or, in consequence of previous over-irritation, the irritability has become diminished; in this case a series of gradually decreasing irritants must be employed until the normal condition is restored. Among the sthenic remedies opium occupies the front rank, besides musk, volatile alkali, camphor, and ether.

Brownianism soon gained a host of adherents; it even was made the official basis of treatment in the Austrian army. A military surgeon praised the cheapness of this method of treatment, as the cure of intermittent fever required only eight kreuzers' worth of opium and thirty-two kreuzers' worth of brandy.* As a counterpart of this may serve the report of another, who states that of six hundred patients treated by this method, two hundred died in the course of twenty-one days, chiefly from alcoholism.

The excitant powers of opium had been observed and pointed out, before Brown, by a German physician, Balth. Ludwig Tralles, of Breslau. The Italian physician, Carminati,† although differing from Brown in the mode of accounting for the operations of opium, nevertheless also acknowledges its excitant properties.

A new epoch in the history of opium begins with the time when chemistry was endowed with better methods of investigation, the immediate consequence of which was the discovery of the alkaloids. The most important of these is morphia, which was discovered by Sertürner,‡ in 1804. From this time to the present the repeated examinations of opium have proved it to be an exceedingly complex substance, and it is likely to prove a fruitful source of research for a long time to come.

* 100 kreuzers (=1 florin). It is hardly necessary to remark, that the system was, after a while, rejected, and that no obligatory "system" has been in use since.

† Bassian Carminati, born 1750, at Lodi, died 1830, at Milan.

‡ Friedrich Wilhelm Adam Sertürner, born 1783, at Neuhaus, died 1841. Apothecary at Eimbeck, afterwards at Hamlin. His researches on morphia and meconic acid, which he had discovered in 1804, were not made fully known until 1817.

TINTED PAPER FOR COVERING CORKS.

Tinted paper may be prepared in any desirable shade as follows: 1 gm. of any aniline colour is dissolved in 30 gms. of strong alcohol, 300 gms. of distilled water are added, and finally a solution of 1½ gm. of tannin in 15 gms. of alcohol. The tannin acts as a mordant. Moderately-sized white paper is spread on a marble slab, or other smooth, hard surface, and the colouring liquid is applied in even horizontal lines by means of a small sponge. The paper is then hung up to dry, and may be covered after a few days with a concentrated solution of sodium silicate, to every 100 parts of which 10 parts of glycerine have been added, if it is desired to impart to it a gloss.

LIST OF PROPOSED ADDITIONS TO THE UNITED STATES PHARMACOPŒIA.

Crude Drugs.—Arum (maculatum and triphyllum), Aurantii folia (Citrus Aur.), Baptisia (tinctoria), Cactus (grandiflorus), Calendula (officinalis), Chelidonium (majus)?, Coca (Erythroxylon Coca), Eriodictyon (Californicum), Eucalyptus (globulus), Fucus (vesiculosus), Galanga (Alpinia officinarum), Galium (Aparine)?, Grindelia (robusta and squarrosa), Guarana (Paullinia sorbilis), Hamamelis (Virginica), Pilocarpus (pennatifolius), Kalmia (latifolia)?, Malva (rotundifolia, etc.)?, Pulsatilla (Anemone Pulsatilla)?, Rhamnus (Rhamnus Frangula), Sumbul (Ferula Sumbul), Symphytum (officinale)?, Thea (Chinensis), Thuja (occidentalis)?, Tilia (ulmifolia; flowers), Trifolium (Menyanthes trifoliata)?, Triticum (repens), Tussilago (Farfara), Verbascum (Thapsus)?, Viburnum (prunifolium).

Chemicals.—Acidum Hydrobromicum dilutum, Acidum Oleicum, Acidum Salicylicum, Acidum Thymicum (or Thymol), Æther aceticus, Amyl Nitris, Apomorphia, Auri Chloridum, Bismuthi Citras, Bismuthi et Ammonii Citras, Chloral butylicum (Croton chloral), Caffeinum, Calcii Bromidum, Calcii Hypophosphis, Calcii Iodidum, Calcii Saccharas, Calcii Sulphuretum, Camphora bromata (monobromated C.), Cinchonidiæ Sulphas, Codeia, Colchicia?, Conia, Emetia, Ferri Bromidum, Ferri Carbonas saccharata (dry), Ferri Hypophosphis, Lithii Bromidum, Magnesia ponderosa (Heavy Magnesia; "Magnesia" might be made to denote the heavy variety alone), Morphiæ Hydrobromas, Paraffinum, Piperinum?, Platini Chloridum, Potassii Arsenias, Potassii Hypophosphis, Potassii Sulphocarbolas, Propylamia?, Quiniæ hydrobromas,—Salicylas,—Tannas, Quinidiæ Sulphas, Salicinum, Sodii Arsenias, Sodi Bromidum, Sodii Chloras, Sodii Hypophosphis, Sodii Iodidum, Sodii Santonas, Sodii Sulphocarbolas, Sodii Sulphovinas?, Trimethylamia?, Zinci Bromidum, Zinci Iodidum, Zinci Phosphidum, Zinci Sulphocarbolas.

Pharmaceuticals.—Acetum aromaticum, Apiol?, Argenti Nitras fusa diluta (⅓ arg. nit., ⅔ pot. nit.)?, Chinoidinum (objected to by some on account of its varying composition), Dextrinum, Elæosacchara, Elixiria—various, Emplastrum ichthyocollæ, Emplastrum fuscum, Extractum carnis, Extractum ergotæ (the fluid extract evaporated), Extractum jalapæ alcoholicum, Extractum malti, Extracta sicca (various), Extractum capsici fluidum, Extractum castaneæ fluidum, Extractum cocæ fluidum, Extractum euphatorii fluidum, Extractum petroselini fluidum?, Extractum tritici fluidum, Extractum vanillæ fluidum, Fel bovis depuratum, Glyceritum vitelli (or Glyconinum = Glyconin), Liquor ammonii anisatus, Liquor chloroformi compositus (Chlorodyne)? Liquor opii compositus, Liquor sodii silicatis. Hydrargyri oleas, Aconitiæ oleas, Morphiæ oleas, Quiniæ oleas, Veratriæ oleas; (being solutions of the salts in excess of oleic acid, they cannot well be classed among chemicals; perhaps it would be best to put them under a special heading "Oleates"). Oleum phosphoratum, Oleum santali?, Opium denarcotisatum (in powder, and of standard morphia strength), Pepsinum, Pulvis glycyrrhizæ compositus, Pulvis morphiæ compositus (Tully's powder), Spiritus odoratus (Cologne), Syrupus calcis lactophosphatis, Syrupus hypophosphitum, Syrupus manganesii iodidi, Tinctura calami, Tinctura calendulæ, Tinctura chinoidini (objected to by some for the same reason as in the case of chinoidine), Tinctura eucalypti, Tinctura ferri acetatis, Tinctura gelsemii, Tinctura thujæ?, Unguentum diachylon (Hebra's Oint.), Unguentum paraffini (or Oleoparaffinum in place of the patented "Vaseline"), Vinum ferri amarum, Zinci nitras fusa.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 3, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal. MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

AMERICAN VIEWS OF PHARMACOPŒIA REVISION.

WE have on several occasions* placed before our readers a *résumé* of the proceedings of the various bodies concerned in the revision of the *United States Pharmacopœia*, inasmuch as the subject is not only of general interest to the pharmacists of this country, but also because the discussion of it presents special features of interest as regards the position pharmacists should hold in the execution of the work involved in the revision of a pharmacopœia. A further step of some importance is now being taken by the pharmacists of the United States which we think will be of interest.

At the late meeting of the American Pharmaceutical Association at Toronto, a committee was appointed for the purpose of preparing a complete pharmacopœia, which was to be submitted to the medical and pharmaceutical professions, and laid before the final Council of Revision at the Convention of 1880. The short time that is available makes it necessary that the work should be commenced at once in a systematic manner, and that those who take part in its execution should each promptly enter upon his share of the work. The committee consists of C. RICE, W. SAUNDERS, F. HOFFMANN, P. W. BEDFORD, J. M. MAISCH, J. P. REMINGTON, C. BULLOCK, G. F. H. MARKOE, S. A. D. SHEPPARD, J. F. HANCOCK, A. E. EBERT, C. L. DIEHL, E. S. WAYNE, W. H. CRAWFORD, C. MOHR, E. PAINTER. In order to save time six of the members living in New York and Philadelphia and nearest to each other have discussed the general principles which they consider should be followed in the preparation of the new pharmacopœia. A statement of their conclusions has been published in the hope that they will meet the views of other members of the committee as well as the general body of pharmacists.

In the first place it is suggested that the present distinction between materia medica and preparations in both the primary and secondary list shall be abolished, and that all articles shall be described in one alphabetical order, retaining them however under such subordinate headings as acida, aquæ, decocta, etc., whenever it is found useful to give general directions relating to a particular class of preparations, but all formulæ for the preparation of single members of the several classes are to be made complete in themselves. It has also been suggested that the name of a part of a plant should be put first so as to make classes of flores, folia, radices, etc.

Acting on the principle that it is advisable to have a pharmacopœia too full rather than to have it defective, it is proposed not to omit any article at present officinal, but to leave the responsibility of cancelling to the final Committee of Revision; at the same time, however, a list of remedies to be discarded is to be submitted to that committee.

A preliminary list of new drugs and new preparations is put forward by the Committee, comprising most of those which have been recommended for reception during the last ten years, but since some of them are only of questionable value they are mentioned chiefly with a view to eliciting the expression of opinion. The list is, of course, incomplete, and criticism of the list as it stands is invited as well as suggestions of other additions.

The descriptions of all crude drugs are recommended to be concise and clear, sufficient to indicate the istinctive characteristics immediately apparent to the eye, and, when necessary, those visible with a good pocket lens. Common sophistications and admixtures are to be mentioned, and the differences pointed out. The botanical names of plants are to be accompanied by the names of the botanists by whom they were determined and by the name of the natural family. Chemicals are to be described and defined only by tests of identity and of purity, except in cases where differences of preparation may furnish different resnlts. The only cases in which it is considered that processes are required are the following solutions:

Solutions of chemicals (liquores, etc.), Acid. benzoic., Acid. nitro-muriat., Acid. phosphor. dil. (should be made stronger), Acid. hydrocyan. dil., Acid. hydrobrom. dil., Acid. sulphurosum, Aconitia, Arg. nitras fusa, Bismuthi et ammon. citras, Calcii phosphas ($CaHPO_4$), Calcii saccharas, Ferri et quin. cit., Ferri et strych. cit., Ferri citras, Ferri et amm. cit., Ferri et ammon. tart., Ferri et pot. tart., Ferri iodid., Ferri oxid. hydrat., Ferri pyrophosph., Ferri sulph. exsicc., Ferrum redactum, Hydrarg. iod. vir., Hydrarg. oxid. flav., Hydrarg. ammon. chlor. Hydrarg. sulphuret. nig., Potass. sulphuret., Quiniæ salicylas, Quiniæ tannas, Sulphuris iodid., Sulphur. præcip., Antim. oxysulphur., Arsenici iodid., Digitalinum, Acidum oleicum depuratum, Zinci phosphidum.

Temperatures are to be expressed in degrees of both Fahrenheit and Celsius, and under the names of those chemicals which admit of it, the formulæ according to the new notation and the atomic weights are to be given.

All measures of capacity are to be abandoned, and quantities expressed only in parts by weight. As regards the difficulty in carrying out this rule in the case of galenical preparations if it be required to preserve their present strength, it is considered that those tinctures, wines, etc., where a slight variation of dose is of no

* See vol. vii. of the present series, pp. 159 and 597.

account, should all be made of uniform strength, but in the case of aconite, opium, nux vomica, veratria, etc., the present strength of the tinctures should be as nearly as possible retained.

In the case of liquid extracts it is proposed to ascertain, by examining a carefully made series of samples representing minim for grain, the weight of the product obtained from drugs of known hygrometric condition, by means of menstrua of known strength, and the figures thus determined are to be adopted as those indicating the proper weights of liquid extracts. Although the figures thus obtained will vary among themselves, the result will be that these preparations will conform to the rule of being made by weight, and they will represent the drug minim for grain.

Under all officinal articles directly used as remedies the average adult dose is to be stated. In case a remedy, such as opium, has a peculiar effect upon infants, the maximum infant dose is likewise to be stated.

It is also suggested that the Pharmacopœia should comprise tables of the maximum single and daily doses of powerful remedies—poisons and antidotes; the solubilities of officinal chemicals in water and alcohol at 60° F. (15·5° C.), and at the respective boiling points of those liquids; an alcoholometric table; specific gravities of officinal liquid acids; a table of reagents and their proper dilution, and a list of volumetric solutions; a table of the relation between weight and measure in all liquid preparations, in order to facilitate prescribing by weight alone; a table of the various kinds of mineral water used medicinally, showing the nature and amounts of the chief constituents; a comparative table showing the strength of powerful galenical preparations as prepared in America and in other countries; and another table showing the differences in strength of the preparations made by the previous Pharmacopœia and by the new one.

Since the work to be done by the Committee is naturally divided under the three heads of pharmacognosy, chemistry, and pharmacy, it has been thought best to form a Sub-Committee of three, to be called the Expert Committee, each member of which will take charge of one of these departments when necessary, awaiting the co-operation of other members of the General Committee. Professor J. M. Maisch has consented to take charge of pharmacognosy, and Dr. F. Hoffmann has consented to take charge of chemistry. The department of pharmacy includes some open questions requiring settlement and it will be for the present taken charge of by Mr. C. Rice, the Chairman of the Committee, who will also conduct the general management of the business and the codification of whatever is contributed.

ALLEGED ADULTERATION OF MORPHIA.

A paragraph which appeared in the *Lancet* of last week, recommending medical men to be on their guard against adulterated or spurious morphia at present in the drug market, is calculated to cause some alarm. We have not been able to ascertain the authority upon which the statement was made, nor to learn what salt of morphia was referred to, or what kind of adulteration, although it would be very desirable to make these particulars known. Failing in this, however, we have examined several samples of morphia salts obtained from the stocks of wholesale druggists and from retail establishments, but in no instance has any trace of adulteration or impurity been discovered. So far therefore as our inquiry has extended there does not appear to be any ground for apprehension that the salts of morphia are in any way open to suspicion, nor is there any reason to think that there is any difficulty in obtaining these articles in a state of purity. At the same time we endorse the suggestion of our contemporary as to the propriety of exercising caution, not so much in this particular case, however, but as a constant quantity in reference to the purchase of drugs, and we believe that this course will be no less appreciated by the vendors of them, than useful to those who purchase.

IMPURE CREAM OF TARTAR.

Consequent upon the recent case of prosecution under the Food and Drugs Act, at Huddersfield, we have received communications from correspondents which seemed to indicate that the contamination of cream of tartar with barium sulphate had been met with at other places, and that there was reason to fear it might be more general than was supposed. We have therefore had six samples of this substance, obtained from various sources, submitted to analysis, with the result that two out of the six were found to contain barium sulphate in addition to the small amounts of lime and silica which are generally present in cream of tartar, and originate from the grape.

We therefore think it desirable to warn our readers that there is in the market cream of tartar which contains barium sulphate, and to advise them to exercise especial care in regard to this article.

THE NEXT EVENING MEETING.

An Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, the 7th inst., when a paper will be read by Professor Redwood, "On the Poisonous Properties of Yew Leaves." The chair will be taken at half-past eight o'clock precisely.

COUNTER PRACTICE IN THE STATES.

According to the Chicago *Pharmacist* a skirmish of resolutions has taken place between the Medical Society of Alleghany and the druggists of that State. The medical body having passed a resolution that it was the duty of its members to withdraw their prescriptions from any druggist who puts up nostrums, or "who prescribes or recommends any patent or other medicines for any class of cases whether grave or trivial," the druggists have retorted with another to the effect that they will, "in the alleviation of suffering amidst all classes," pursue, as heretofore, the legitimate mode of conducting their own affairs.

PYROTECHNICAL PHARMACY.

A circular has been issued by the Chief Constable of Oldham, addressed to "Chemists and Druggists and all Shopkeepers who sell any fireworks or other explosives," requesting them not to supply such articles to boys or other persons likely to make use of them improperly.

Transactions of the Pharmaceutical Society.

Addendum.—At the examination in Edinburgh, reported on p. 333 of last week's Journal, Professor Maclagan was present on behalf of the Privy Council.

HULL CHEMISTS' ASSOCIATION.

The annual meeting of the above Association was held at the Cross Keys Hotel, on Thursday evening, October 18. The President, Mr. C. B. Bell, occupied the chair. The minutes of the previous meeting having been confirmed and two new members elected, the President called upon the Secretary to read the following annual report:—

"The officers of your Association have pleasure in presenting the usual annual report, at the termination of the official year, and hope that it will meet with your approval. During the session seven members have been elected, two have resigned, and one has died, leaving at the present time fifty-five members.

"The first matter requiring the attention of the Committee was the introduction of the suicidal policy of selling patent medicines and proprietary articles to the general public at reduced prices. This was commenced by a firm of grocers with whom the Committee were unable to deal. Had it, however, been confined to them it would not have been of much consequence. Unfortunately, a chemist in the neighbourhood adopted the same plan, and it has been followed by some few others. Your Committee have reason to believe that it has not been found to answer as expected, and would strongly urge all to continue selling at the legitimate prices, feeling sure that it will be found to be the best and safest plan in the end.

"The annual supper was held at the Cross Keys Hotel, in December, and your Association was honoured by the presence of the Mayor, K. King, Esq., M.D., and other gentlemen.

"The chemistry class has been conducted by Mr. J. Baynes, F.C.S., Borough Analyst, at his laboratory, in Scale Lane. He reports that the session comprised a series of twenty lectures, attended by eight students, and that good progress had been made by those who attended regularly. The examiners, Messrs. J. F. Smith and Stoakes, report that five students competed for the prizes at the end of the session, Mr. T. Brown carrying off the senior, and Mr. Barlow the junior prizes.

"It had been thought advisable that the following session should commence earlier. The class has, therefore, been inaugurated by an address from Mr. J. F. Smith, and from the fact that twelve students have joined already, your Committee feel justified in having commenced thus early.

"Mr. Niven reports that the botanical class consisted of a series of twenty-six lectures, commencing on May 9, and terminating on October 5. Thirteen students attended, six of whom rarely missed a lecture, and the attention paid was everything a lecturer could desire. The competition for the herbarium prize, given by Dr. Sawdon, consisting of books, to the value of thirty shillings, has been most satisfactory. Three students competed all showing admirable specimens, the most important difference being in the number. Mr. T. Brown stood first, with a collection of more than four hundred species, beautifully dried, mounted and arranged, scarcely one plant being wrongly named. It represented more than one-fourth of the flowering plants indigenous to Britain. Mr. A. D. Markham stood second in order of merit with a collection of three hundred and ten species, equally as well selected and mounted as the previous one, only two or three trifling errors occurring in the naming. Mr. O. Lambert, the youngest competitor, stood third with a collection, although inferior to the others in point of numbers, consisted of one hundred species, and was most commendable, and in former competitions would have taken a better position. Dr. Sawdon expressed himself as more than satisfied with the result, and for himself, Mr. Niven felt bound to endorse his good opinion in a practical way, by giving books to the value of a sovereign as second prize, and recommended the Association to give a book of the value of ten shillings for a third prize.

"For the prize offered by Dr. J. H. Gibson to the student who passed the best examination in physiological botany, a sufficient number of students did not come forward, and it was therefore withheld.

"The annual meeting of the Pharmaceutical Society, also the annual meeting of the Chemists and Druggists' Trade Association, both being held in London, were attended by your President. The Conference was not attended by any member of your Association.

"In March a resolution was unanimously carried at one of the meetings, and a copy forwarded to the Secretary of the Pharmaceutical Society, calling the attention of the Council to the fact that opium and its preparations, put up in the form of patent medicines, and bearing a government stamp, were being sold by unregistered persons. Your Committee have since noticed with satisfaction, that a grocer who had been selling the same, and against whom the Pharmaceutical Society commenced proceedings, had paid the penalty of five pounds; and it is hoped that proceedings will also be taken against many others who are doing the same thing.

"In April your Association had the pleasure of receiving S. U. Jones, Esq., the President of the Chemists and Druggists' Trade Association, as a deputation from that Society. A trade meeting was held at the Hull Church Institute, your President occupying the chair. Resolutions were unanimously carried pledging the meeting to support by every means in its power the Trade Association in its aims and objects.

"In May, Dr. Lush, M.P., proposed to introduce into Parliament a Bill intituled "A Bill to amend the Medical Act of 1858." Had this Bill become law, no chemist could have recommended any drug or medicine to a customer, for the most trivial complaint, or in the most simple case, without infringing the Act. It therefore called up strenuous opposition throughout the country, the Chemists and Druggists' Trade Association taking the initiative, and your Committee are glad to say it was abandoned.

"Your Committee also notice with great satisfaction that the much vexed milk of sulphur question has been settled, and trusts that such cases will not again be brought forward by the public analysts.

"The trade has also been harassed by the Medical Defence Association on the question of the legality of counter practice, and it is hoped that when the Court of Queen's Bench decides the case which will be brought before it in November, the decision will be found to be on the side of common sense and public expediency. Should it be otherwise your Association will have more work before it immediately. In this, as in the milk of sulphur case, also in reference to Dr. Lush's Amended Bill, the thanks of all chemists are due to the Chemists and Druggists' Trade Association, and your Committee would urge all who have not hitherto joined it to become members at once.

"Your Treasurer will present a report of the finances of the Association which shows a credit balance of 20*l*. 11*s*. 1*d*.

The annual report and the balance-sheet were then adopted, and the following gentlemen elected as officers of the Association for the ensuing year:—President, Mr. C. B. Bell; Vice-President, Mr. G. Myers; Secretary and Treasurer, Mr. B. M. Stoakes; Committee, Messrs. J. Bradley, J. Grindell, J. Oldham, and J. F. Smith.

LEEDS CHEMISTS' ASSOCIATION.

The winter session of this Association was inaugurated by a tea in the Assembly Room, Queen's Hotel, on Wednesday evening, October 17th; the President, Mr. Peter Jefferson, occupying the chair.

The Secretary having given a *résumé* of the minutes of the annual meeting, held in May last, the prizes given by the Association to the four most successful students attending its classes on chemistry and botany last session were distributed; Mr. Robert Stewart taking the first and Mr. George Coverdale the second in chemistry, and Mr. S. N. Tredwell the first and Mr. James Banks the second in botany. Mr. Pierson was then elected a member, and Mr. Cowgill an associate.

The inaugural address was delivered by Mr. Jefferson. Having expressed his regret that the office of president of the Association and more especially of that meeting had not fallen into abler hands, though doubtless the selection had been made on account of his long career as a chemist and druggist in the town—a period of over forty years—he proceeded to refer to the practice of retail chemists formerly powdering and preparing a very much larger number of articles than now, and expressed his regret that such was the case, especially in the interests of learners. The change taking place in other countries as well as our own in this respect was doubtless on account of its being more economical to buy than to make; the wholesale manufacturer, owing to greater facilities and larger experience, being able to supply at cheaper rates. Reference was also made to the practice of chemists and druggists, especially those situated in the outskirts of large towns and in country places, dealing in such articles as grocery, oils, paints, colours, brushes, perfumery, etc., which might be considered as belonging to other branches of trade, and which he thought might be done without its being considered derogatory to the profession of a chemist and druggist. The dealing in patent medicines, although apparently belonging more to the trade, was fraught with a good deal of what was certainly of a character not very elevating to the business. Their sale was formerly very largely, and still continued to some extent, in the hands of the booksellers, whilst shopkeepers of other classes were now going into the trade very considerably, to which no very plausible objection could be made as no skill was required, and the government stamp removed all responsibility from the seller. With reference to the recent attempt at legislation to prevent the druggist giving advice to his customers in his own shop, which had been a long established usage, he considered that any such measure would not only interfere with their interests and cause a good deal of annoyance, but would in a much larger degree affect the interests and convenience of the public, especially of the poorer classes, who would in many cases be driven to pauperize themselves by having recourse to the various charitable institutions. The druggists ought not, however, to court any such practice, either by advertizing or any other similar means, as any such proceedings would not only injure their cause, but would be a departure from their legitimate profession. As to the complaints heard from many in the trade that neither the Pharmaceutical Society nor the Trade Association attempted to prevent grocers and others selling drugs, he replied that no government would so far interfere with the interests and convenience of the public and the freedom of trade unless it was shown that the practice was dangerous to the community. A limitation of such sales had been accomplished by the Poisons Bill, and the list of articles scheduled therein might be further increased, but it was impossible to prevent the sale of the great majority of drugs by any one who might choose to do so. The address was concluded by an appeal to those present not to be dissatisfied with their calling as chemists and druggists, as it might safely be classed amongst the most useful and interesting, and its character was continually improving; at the same time the younger members were reminded that its requirements were likewise increasing, and that it was incumbent upon them to keep well up with the times, in the matter of chemistry more especially, that science being taught in many of the schools and most of the institutions for mental improvement.

Mr. Alderman Stead, in a vigorous speech, proposed a vote of thanks to the president for his address. He said it was forty years since he first tied on the white apron, and contrasted the times then and now. More was expected of young men now than then; the classes on chemistry were then badly attended, on account of the length of the hours of business, but now matters were much improved, and he advised the young men to make good use of their greater privileges. The Sale of Food and Drugs Act, he thought, was right in some points, but it would take some time to educate the public up to the appreciation of a pure article. With respect to counter prescribing, he thought the line of demarcation betwixt legality and illegality, right and wrong, was very difficult to draw, but that in low districts more especially chemists should be allowed to prescribe for children and the poor.

Mr. Abbot, in seconding the vote of thanks, dwelt upon the value of learning thoroughly, not from books only, but also from practical work.

Mr. Barclay, of Birmingham (who happened to be in Leeds on business at the time), expressed the pleasure he had in attending meetings of this class, and in giving what encouragement he could to this and similar associations, considering them of the greatest importance to the well being of the trade. He then gave an account of the doings of the Chemists' Trade Association with which he is more immediately connected, amongst other things stating that good counsel had been secured for the Nottingham appeal case expected to come off in the Queen's Bench early in November, and that the Medical Defence Association appeared to be in rather low water at present, from the summary method they had recently adopted of issuing writs.

The proposed vote of thanks having been put to the meeting by Mr. Yewdall, was carried by acclamation, and duly acknowledged by the Chairman.

EDINBURGH UNIVERSITY CHEMICAL SOCIETY.

Deleterious Action of Syphons on Aerated Waters.

BY JOHN STUART THOMSON.

Notwithstanding the numerous and searching investigations of which the presence of lead in aërated waters has been the subject, there is one very important source whence the poisonous metal is frequently derived, namely, syphons, which has to a great extent been overlooked by experimenters. The use of these vessels being now so common, it seemed to me to be of vital interest to determine whether the storing of aërated water in them had the effect of in any way increasing the quantity of lead in the beverage. Some time before I began this investigation, Sir Robert Christison had condemned their use for lemonade, owing to the action which the free tartaric acid present in the lemonade has on lead and by this advice some of the leading manufacturers have entirely given up filling syphons with anything containing a free acid, such as tartaric.

Knowing the above, I directed my attention solely to the examination of potash and pure aërated water; the samples I operated on were obtained from one of the chief manufacturers in this city, so that I could be certain that every possible precaution had been taken to keep them as free from lead as possible. The first sample examined was that of the water used for the manufacture; this was taken direct from the cistern, and was found to contain somewhat less than 0·0014 gr. of lead per gallon, consequently no fault could be found with it. Potash water drawn direct from the syphon-machine was next tested, and was found to contain 0·0175 gr. of lead per gallon, which, according to Miller, is not an unusual amount for average cistern water. After it had been in a syphon, however, the amount began to rise in a rapid manner. Thus, in potash water, drawn from a syphon, 0·0408 gr. of lead per gallon was found to be present, being nearly 2·5 times the quantity found in the same water before it entered the syphon. Pure aërated water again drawn in a similar manner from a syphon, gave 0·0816 gr. of lead per gallon, or exactly double the amount found in the potash water, showing at once the well-known protective action that salts of the alkalies and alkaline earths have on lead.

Although these results are sufficiently high and alarming, still when the water is drawn off in small quantities at a time, as is frequently the case with invalids, the results are found to be still higher; thus when potash water was so treated 0·0455 gr. of lead per gallon was found, while aërated water, drawn off in small quantities, gave 0·0933 gr. of lead per gallon, showing a very marked rise in both cases.

The cause of this increase in quantity of the lead appears to be owing not so much to the lengthened period of contact between the liquid and the metal, as to the fact that the nozzle of the syphon, being exposed to the atmosphere in a moist state, becomes rapidly oxidized or carbonated, and is thus left in the most suitable condition for entering into solution, so that when merely small portions of the liquid are drawn off each time a comparatively concentrated solution of lead is obtained.

As much has been said about the metal or alloy of which the nozzles are composed, I examined a portion of one, and found it to be composed of tin and lead only; the tin was estimated, and gave 53·99 per cent. Sn., leaving 46·01 per cent. Pb.

Thinking that it might be interesting as well as instructive to examine into the solubility of carbonate, or rather bicarbonate of lead, in carbonic acid water, freshly precipitated hydrate of lead was suspended in distilled water, and well-washed carbonic acid was then passed through for about one hour at ordinary temperature and pressure. The filtered liquid thus obtained was found to contain 29·11 grs. of lead per gallon. As a final experiment clean unoxidized lead chips were treated in a precisely similar manner to the above, when the liquid was found to give the following results:—

After	2 hours' contact	0·175 gr. Pb.	per gallon.
„	26 „	0·350 „	„
„	46 „	0·380 „	„
„	96 „	0·510 „	„

showing clearly that in the case of the pure unoxidized metal the length of period of contact has a very marked effect.

SOMERSETSHIRE ARCHÆOLOGICAL AND NATURAL HISTORY SOCIETY.

English Names of Wild Flowers and Plants.*

BY REV. W. TUCKWELL.

Eight years ago I was piloting a famous botanist from the east of England among the fields and lanes round Taunton, when he asked me the name of a plant which he did not at the moment recognize. I answered that it was the gipsy-wort, and received a prompt rebuke. "This is the third time," he said, "that I have inquired the name of a flower, and you have answered me in English. The Latin names are universal, the English, at best, are local. It is to be wished that all English names of plants could be forgotten, and their scientific names become popularized instead." Unquestionably a foolish utterance, it was of great service to myself, for it set me to consider the real value of those names which my pedantic guest despised, and from that time to this I have never encountered the popular name of any English wild flower without questioning it closely as to its etymological history and meaning, and noting the passages in our literature where it occurs. It would be a great pleasure to me to believe that the knowledge gained by these inquiries, put together to the best of my power, could interest you to-night as much as it has interested myself.

It is no new thing to infer from the terms in use at the beginning of a nation's history the arts and customs of the nation using them. Thus, the fact that in all or nearly all the Aryan languages the words for the Supreme Being, for the king, for brother and sister, for ploughing, grinding, building, closely resemble one another, is admitted to show that our common forefathers in times when they were still one people, and had not yet scattered into India, Persia, Europe, had the beginnings of religion and government, possessed the family life, knew the simple arts which are most needed for the comfort of home life. Let us see what light will be thrown upon the habits of our Teutonic forefathers if we apply their method of investigation to the popular names of plants.

Teutonic names.—The following words are common to all the Teutonic languages—must have been known, that is, to the race from which we ourselves, with the Germans, Danes, Swedes, and Norwegians, are descended, on their first settlement in Europe, and before they broke up into subdivided nations. The first I will take is birch, the rind of which must, we find, have been used for boat building and for roofing houses; for boat building, since the word "bark," from the same root as birch, stands for ship in English, Dutch, Icelandic, Danish; for roofing houses, since the old English *beorgan* and the German *bergen*, also from the same root, mean to cover, protect, or shelter. From this simple word, then, we gather that our ancestors possessed the arts of building boats and of roofing or thatching houses. Houses could not be built without timber, and we find the word "tree" in almost every Aryan language standing for three things—for a tree, for timber, and for an oak, extending the use of oak wood for building purposes back to the first formation in Asia of our mother language, and presenting us with the additional facts that our European ancestors built of oak timber the houses which they roofed with birch. In hazel a fresh fact lies buried. It is in all Germanic dialects the instrumental form of *hæs*, command or behest, a hazel stick having been used, as Jacob Grimm informs us, in the earliest times as a sceptre or baton to keep order among slaves and cattle. Without dwelling on the fact that the old word, *hælsian*, to foretell, indicates the use of the hazel rod for purposes of divination, we have the additional probability revealed in a single word that

* Lecture by Rev. W. Tuckwell before the Somersetshire Archæological and Natural History Society. *Gardeners' Chronicle* for September 22, from *Nature*.

our remote ancestors possessed slaves and cattle. In hawthorn, common to Swedish, German, and English, we have testimony to the use of a haw, *hæg*, hedge, or fence, "honouring the holy bounds of property," and consequently to the division and appropriation of land, in the earliest Teutonic time. My next word makes some demand upon your etymological credulity. Without tracing particulars, I will ask you to believe that the Sanskrit *kshi*, to dwell, passes through various forms—in one direction to the English "home," in another to the word "heath;" now meaning the plant which grows wild on open land, standing originally for the land itself. "My foot," says Rob Roy, "is on my native heath"; and the same idea was enshrined in the same word to the first Teuton settler. In the forest he fought his enemies, hunted his prey, hewed timber for his fences, and peeled timber for his roof; his home was in the open land, or heath, from which, again, when ages had passed away and Christianity possessed the towns, he still worshipped his father's gods upon his father's heath, and gained, as Trench thinks, his ancient name of heathen. A sixth word lifts him higher than all the rest. The word beech, in Gothic, old High-German, modern German, Norse, Danish, Dutch, English, is identical with book, the Runic tablets of our ancestors having been carved upon this wood. In sloe, the wild plum, we have the root of "slay," its tough wood having been used for bludgeons; dog-wood is dagger-wood, from *dag*, to strike; from ash, whose wood was therefore used for spear-shafts, came the old English *æsc*, a spear; sedge is allied to *sæcg*, a sharp small iron sword. And let us observe that while all these plants, bearing purely Teutonic names, extend far into Northern Asia, trees which stop short at a more southern limit—the elm, chestnut, holly, sycamore, plum, pear, peach, cherry—all have Latin names, showing that the Teuton squatters came from a colder country than that in which they are supposed to have settled near the Roman provincials on the Lower Rhine. The knowledge that wheat, barley, oats, corn, rye, are all Teutonic words, completes the historical picture given by the first list of names. They show us a race of men coming from a northern to a southern region, dwelling in timber houses, roofed and thatched, launching boats upon the rivers, possessing cattle and slaves, recognizing the rights of property and the sacredness of home, fighting with cudgels, swords, and spears, familiar with cereal agriculture, in some way not ignorant of letters. All these facts, just hinted at here, but challenging minute investigation, we owe to a dozen common names of English plants, whose Latin equivalents teach and commemorate nothing of any national interest to ourselves.

Greek and Latin names.—These names, and a few more, are as old as the English language; but from the conquest to the sixteenth century botanical inquiry ceased in England, and the rest of our popular names are little more than 300 years old. Most of these come to us from the Greek and Latin. Any scholar will detect in acacia the Greek word for guilelessness; in the amaranth, with which Milton's worshipping archangels wreathed their brows, the Greek for unfading; in the periwinkle, the *pervinca* used to bind about the head; in lettuce, the meaning of milky; in geranium, the descriptive name, crane's bill. In the plane he will see the *platanus* of the poets; in the rose, the *rhodon* of Homer and the *rosa* of Virgil; in the sycamore, the wild fig of the Bible, transferred in mediæval miracle-plays to the tree which now bears the name; in the vine, the *oinon* and *vinum*, whose Sanskrit root is still present in our words twine and twist. He will understand that the basil, which poor simple Isabel planted in the pot which held her murdered lover's head, was the regal plant, used perhaps of old in some royal bath or unguent; that the angelica, which now flavours our soups, and was once a specific against the plague, was given to mankind by angels; that the belladonna was applied as a cosmetic to make ladies beautiful for ever; that the cyclamen, which still grows wild in Devonshire, owes its name to its prominent circular tuber. He will not so readily discover that the tansy of our cottage gardens is the Greek *athanasia*—immortality, administered to Ganymede that he might become fit for his life in heaven; that the common milfoil yarrow is the *hiera*, or holy herb, pledged to heal all herbs with its fragrant leaves; that nasturtium means nose-twister, from its pungent smell; that our quantock whortle-berry is a corruption of *myrtillus*, myrtleberry; that eglantine is *aculenta*, the prickly rose, or sweet briar; that the herb-bennett or *avens*, is the *benedicta*, blessed herb, kept in houses to prevent the entrance of the devil; that the hip of the dog-rose is a form of the Greek and Latin words which people afflicted with sore throats know as jujubes; that liquorice is an Anglicism of the Greek *glycyrrhiza*, sweet-root; that the larch is from the Latin *lar*, a house, in consequence of its use in building; that lavender, from the Latin *lavare*, to wash, was in the twelfth century Scotch and northern English for washerwoman, because then as now its sweet spikes were laid amongst fresh linen; that the service-tree is the Latin *cerevisium*, beer—its leaves having been used to flavour ale before the virtues of the hop were known; that the little squinancy-wort was the ancient remedy for the disease *kynanche* or dog-choker, which we know in its modern sound as quinsy; that the mushroom is the muscarius or flybane, because a particular agaricus, pulverized and mixed with milk, was used in Southern Europe as we now use the poison called "Keating's Insect Powder." Least of all will our scholar be quick to admit that the narcissus owes nothing to the love-sick youth over whom Ovid sang and Bacon moralized, but is connected with the Greek *narkodes*, sluggish, a derivative from *narke*, the torpedo, itself sprung from the Sanskrit *nark*, hell; cited by Sophocles (Œd., Col., 682), as crowning the gods of Hades; gathered by Proserpine before her wedding tour into the same dark region, because its heavy odour (for by it the ancients meant the hyacinth) blunts the nerves and makes men sleepy and torpid.

French Names.—I can find comparatively few names which we have borrowed from the French. Dandelion is, of course, the lion's-tooth. Mignonette is applied by us to a very different plant from that which bears the name in France. Woodruffe, known to travellers in Germany as flavouring the pleasant drink called *maitrank*, takes its last syllable from *roue*, a wheel, its verticillate leaves being set like a wheel or rowell on the stone. Pansy is *pensée*, thought, from its significance in the language of flowers: "There's pansy," says Ophelia—"that's for thoughts." Gilliflower is *giroflée*, from *caryophyllum*, a clove, a name originally given to the carnation, but now transferred to the wall-flower. Tutson is *toute-saine*, the oil in its leaves having made it a remedy for wounds. Most curious of all is apricot, from *abricot*, which at one time I contentedly referred to the Latin *apricus*, sunny, ripening as it does on sunny walls. It is, in fact, traceable to the Latin *præcox*, early, the fruit being supposed by the Romans to be an early peach. The Arabs took the Latin name and twisted it into *al burquq*; the Spaniards altered its Moorish name into *albaricoque*; the Italians reproduced it as *albicocco* the French as *abricot*, and we get it next in England curiously enough as apricock, so spelt in Shakspere's time, and finally as apricot.

Legendary Names.—Many curious bits of myth and history reveal themselves as we excavate down to these old meanings. The pæony, or healing-plant, commemorates the Homeric god Pæon, the first physician of the gods, who tended the bellowing Ares when smarting from the spear of Diomed. The centaury is the plant with which the centaur Chiron salved the wound inflicted by the poisoned arrow of Hercules. The ambross, or wormwood, is the immortal food which Venus gave to Æneas, and Jupiter to Psyche—the Sanskrit *amrîta* which Kehama and Kailyal quaff in Southey's splendid poem. The anemone, or wind-flower, sprang from the tears wept by Venus over the body of Adonis, as the rose sprang from his blood—

αἷμα ῥόδον τίκτει, τὰ δὲ δάκρυα τὰν ἀνεμώναν.

The daphne, syringa, and andromeda tell their own tales; the last, which you may find in the peat-bogs round Shapwick station, is due to the delicate fancy of Linnæus, who first discovered and named it, blooming lonely on a barren, rocky isle, like the daughter of Cepheus, chained to her sea-washed cliff. The juno-rose, or tall white lily, was blanched by milk which fell from the bosom of Juno, the tale being transferred in Roman Catholic mythology to the Virgin Mary and the milk thistle. The yellow carline thistle is named after Carl the Great (in Mr. Freeman's county I must not call him Charlemagne), who, praying earnestly for the removal of a pestilence which had broken out in his army, saw in vision an angel pointing out this plant as a heaven-sent cure. The herb-robert healed a disease endured by Robert, Duke of Normandy, still known in Germany as *Ruprecht's-plage*. The filbert, though this is disputed, commemorates the horticultural skill of one King Philibert. The treacle mustard, a showy crucifer resembling wallflower, was an ingredient in the famous Venice treacle, compounded, as you will remember, by Wayland Smith to treat the poison sickness of the Duke of Sussex. The word treacle is corrupted from the Greek *theriacum*, connected with wild beasts, whose blood formed part of the antidote. It was at first made up by the physician to Mithridates, king of Pontus, and is still in many parts of England known as mithridate mustard. The flower-de-luce, or *fleur-de-lys*, is the flower of King Louis, having been assumed as a royal device by Louis VII. of France, though legend figures it on a shield brought down from Heaven to Clovis, when fighting against the Saracens. It is probably a white iris.

Not a few strange superstitions and beliefs are embalmed in well-known names. The celandine, from *chelidon*, the swallow, exudes a yellow juice, which, applied by the old birds to the eyes of young swallows, who are born blind, or have lost their sight, at once restores it. The hawk-weed has the same virtue in the case of hawks. The fumitory, *fume-terre*, was produced without seed by smoke or vapour rising from the ground. The devil's-bit is a common scabious, with a premorse or shortened root, which was used so successfully for all manner of diseases, that the devil spitefully bit it off, and for ever checked its growth. The eyebright, or *euphrasy*, was given to cure ophthalmia.

"Michael from Adam's eyes the film removed,
. . . Then purged with euphrasy and rue
The visual nerve, for he had much to see."

The judas-tree, with its thorns and pink blossoms, was the tree on which Judas hanged himself. The mandrake gathered round itself a host of wild credulities. It was the *Atropa mandragora*, a plant nearly allied to the deadly nightshade, but with a large forked tuber resembling the human form. Hence it was held to remove sterility, a belief shared by Rachel in the Book of Genesis, and was sold for high prices in the middle ages with this idea. In fact, the demand being greater than the supply, the dealer used to cut the large roots of the white bryony into the figure of a man and insert grains of wheat or millet in the head and face, which soon sprouted and grew, producing the semblance of hair and beard. These monstrosities fetched in Italy as much as thirty gold ducats, and were sold largely, as Sir T. Brown tells us, in our own country. It was thought that the plant would only grow beneath a murderer's gibbet, being nursed by the fat which fell from his decaying body; hence it formed an ingredient in the love-philtres and other hell-broths of witches, and, as it was believed that the root when torn from the earth, emitted a shriek which brought death to those who heard it, all manner of terrible devices were invented to obtain it. The readers of Thalaba will remember the fine scene in which the witch Khawla procures the plant to form part of the waxen figure of the destroyer. I have seen the plant growing in the Cambridge Botanical Gardens; it is not uncommon in Crete and Southern Italy; its fruit is narcotic, and its name is probably derived from *mandra*, an enclosed, over-grown place, such as forms its usual home.

The medical beliefs revealed by many names are not less curious than their legendary associations. It was the opinion of the old herbalists or simplers that God had not only provided special plants as a cure for every disease, but had made their curative power evident by stamping them with some resemblance to the malady they were meant to heal; and this faith, known to students of our older botany as the "doctrine of signatures," lurks or reveals itself in many an English name. The lung-wort, spotted with tubercular scars, was a heal for consumption; the liver-wort, liver-shaped in its green fructification, was a specific for bilious maladies; the scaly pappus of the scabious for cutaneous eruptions; the throat-like corolla of the throat-wort, or Canterbury bell, caused it to be administered for bronchitis; the saxifrage, cleaving the hard stones with its penetrating fibres, was efficient against calculus; the scorpion-grass, now known as the forget-me-not, whose flower-spike dimly resembles a scorpion's tail, was an antidote to the sting of that or other venomous creatures; the moon-daisy averted lunacy; the birth-wort, kidney-vetch, nipple-wort, spleen-wort, were all appropriated, as their names suggest, according to resemblances, real or fancied. The pretty toad-flax of our walls and hedges owes its names to a strange mistake. Believed to be the cure for a complaint called buboes, it received the Latin name *bubonium*. A confusion between *bubo* and *bufo*, which is Latin for a toad, gave birth to its present name; and stories were not long wanting that sick or wounded toads had been seen to eat of it and to recover health.

Similar distortions occur in non-medical names, and it is most curious to notice how soon a story springs up or a belief asserts itself in confirmation of the mistaken identity. The common fumitory, which we have already noticed, received its name of *fume-terre*, "earth-smoke," from its causing the eyes to smart and water when applied to them, as smoke does. The meaning was lost as time went on, and was supplied by the belief that it was produced without seed by smoke or vapour rising from the earth. Buttercup was said to give colour and flavour to butter, as being eaten by cows, when in blossom, the facts being that it is a corruption of *bouton-cop*, button-head, and that cows eat the grass all round it, but always, if possible, avoid it. Meadow-sweet is a corruption of mead-wort, honey-wine plant, a beverage being still extracted from it by cottagers. Bullrush is pool-rush, as growing in pools, not in mud; snap-dragon is snout-dragon, from its shape; marigold is marsh-gold; sweet-william is *œillet*, a little eye; pink is the lower German *pinksten*, pentecost, from its flowering at Whitsuntide, the name being transferred first to the colour of the flower, then to a method of working flowers on muslin, called pinking; and so to the sword stab in a duel, piercing or pinking an adversary as the needle pierced the cambric. Nightshade is *night-scada*, soother, or anodyne; samphire is St. Pierre, from its love of rocks; sanicle is St. Nicholas, the restorer of the three murdered children, from its healing powers; poplar comes from the Indian pepul, whose leaves, when varnished and painted, closely resemble those of the large Spanish poplar; primrose was anciently the daisy, and is called by Chaucer primerole, from the old French *primererole*, the first spring flower; primerole was changed to primrolles, then to primrose, the first rose of spring, and it was not till the sixteenth century that it attached itself to the familiar flower which now bears its name. Cowslip is more strange still. It was originally "hose-flap," and belonged to the mullein, whose great flannelly leaf might well be likened to the flap or skirt of a woollen under-garment. Later on it was transferred to the wild primula of our meadows, and the mistake was stereotyped by the unlucky botanist, who, in ignorance of its origin, gave the name of oxlip to its pretty congener, the *Primula elatior*. The Jerusalem artichoke is a sunflower, not an artichoke; but the tubers resemble the artichoke in flavour. From its Italian name *girasole*, turn to the sun, came Jerusalem; and by a further quibble the soup made of it is called Palestine soup. The forget-me-not was originally the "Germander Speedwell," whose blossoms, falling of and flying away as soon as it is plucked, gave emblematic force to the name. It was known in the days of chivalry as the "flower of souvenance," and was embroidered into the collars of the knights, a fact still recalled by its German name *Ehrenpreis*, prize of honour. About 200 years ago we find the name given to the ground pine, *Ajuga chamæpitys*, whose nauseous taste once realized can never be forgotten. Finally it was seized upon by the river-side myosotis, and forthwith sprung up a charming legend, created obviously to suit its latest identification—how that while two lovers loitered by a lake, the maiden saw and longed for the bright blue flowers, the knight plunged in to get them, but, unable to regain the shore, had yet agility enough to fling them into his lady's lap, and then, with a last devoted look and the words "forget me not," sank below the waves for ever.

(*To be concluded.*)

Parliamentary and Law Proceedings.

Poisoning by Hydrocyanic Acid.

On Saturday, the 27th October, an inquest was held before Mr. G. F. Harrison, coroner for Leicester, respecting the death of Mr. Sydney Ellis. It appeared that the deceased was a member of a firm of woolspinners, of which his father, the chairman of the Midland Railway Company, is the head, and that he had under his charge the machinery and dyeing departments. In connection with the latter there was a chemical laboratory in which deceased frequently worked. On the previous day he had been found lying insensible on the floor of the laboratory and shortly afterwards died. There was a bottle containing hydrocyanic acid on the table, and a work on chemistry open at the part which treated of cyanide of hydrogen. In the opinion of the medical witnesses his death was caused by inhaling hydrocyanic acid.

Mr. Frederick Parsons, chemist, Gallowtree Gate, said he had supplied the deceased with chemicals for four or five years, and on going into the laboratory he found many bottles of chemicals, including cyanide of potassium, cyanogen and hydrocyanic acid.

Dr. W. S. Emerson, analyst for the county, said he saw the deceased, whom he had attended previously for six years, on the floor of the laboratory. There was no appearance of any struggle, the limbs were placid, and the pupils of the eye were dilated. There was no smell perceptible from the mouth, which was open, and the lips were not marked. He added that the deceased was very short-sighted, and he thought might have placed his nostrils too close to the gas.

A verdict in accordance with the evidence was given.

Robbery at a Chemist and Druggist's.

At the Marylebone Police Court on Monday last, Henry Howard, 21, described as a betting man, was charged on remand before Mr. Mansfield with having broken into and entered the house of Mr. Frederick Andrews, a chemist, and keeper of a post-office at 34, Leinster Terrace, and having stolen therefrom about £34 in money and £10 in postage stamps. Mr. B. Osborne prosecuted on behalf of the Post Office authorities. The evidence showed that on the morning of the 20th inst., a constable who was on duty near the house saw a light inside, and being suspicious that all was not right he obtained the assistance of some other constables, and having stationed them in the front and at the back of the house he rang the bell. The light was immediately extinguished, and shortly afterwards the prisoner and another man were seen at the rear of the premises. As soon as they caught sight of the police they darted back and got into an adjoining garden. Pursuit was given, and the prisoner was apprehended near Lancaster Gate, Hyde Park. The prisoner was remanded.

Review.

A New London Flora. By E. C. De Crespigny, M.D., etc. London: Hardwicke and Bogue, 192, Piccadilly, 1877.

The title of this book is evidently a misnomer. It had better have been called the 'Young Botanist's Handy Guide to the Collection of Flowering Plants in the Home Counties.' While it will not bear comparison with such carefully executed works as Trimen's 'Flora of Middlesex,' or Roper's 'Flora of Eastbourne,' it has evidently been written by one who knows what the requirements of young botanists in London are, and who has endeavoured to meet them. The first requisite for the amateur is necessarily to become acquainted with all the plants growing in Britain, or at all events, excepting those which are alpine. Bearing this in mind, the author has not limited himself to giving the localities immediately around London, nor hesitated to include those rich in plants which are within a two hours' ride by rail. Thus we find Guildford, Godalming, Tunbridge Wells, Windsor, and even Reading among the localities quoted. This latitudinarian tendency will render the work of great utility, as it will enable not merely residents in London but also those residing in the various towns around it to find many plants, of the habit and mode of growth of which they might otherwise remain in ignorance.

A very useful list of synonyms and of forms or doubtful species placed opposite to their type, or true species, gives at a glance the differences in opinion between the "lumpers" and "splitters" among British botanists. As the synonyms have special relation to the 'London Catalogue of Plants' (by the same publishers) and are arranged in the same order, this list must be very handy for reference. But the very dogmatic assertions of the author, with regard to the right of certain plants to rank as species, which occur throughout the 'Flora,' are, we think, quite out of place in a work like this, which cannot pretend to take a classical rank.

In the flora proper all the plant names are arranged alphabetically. This is an excellent plan, as it saves both time and trouble; indeed, we believe that private herbaria would be much more frequently used for reference if they were arranged in the same way. All the localities which the author has visited, and in which he can certify the occurrence of the plants recorded, are marked by an asterisk; this feature gives a special value to the book, for every field botanist knows how localities becomes destroyed in the course of a few years. The labour attending upon verifying localities must have been immense, and the seven years during which the author has been carrying on these his investigations must have been fully occupied whenever weather permitted. The references to localities not visited by the author are less reliable than could be wished, and appear to have been chosen with but little judgment.

The book being of small size can easily be carried in the pocket, and the botanist who is wise enough to have it interleaved and to carry Hayward's or Notcutt's 'Handbook of British Plants' in another pocket, if he records his observations may do useful work on every trip he takes, instead of, as is too often the case, taking many more plants than he requires and keeping no record of the forms he meets with.

In the cryptogamic portion, errors are not unfrequent;

indeed, considering the constant change of names during the past few years, it is scarcely possible, unless attention be wholly directed to these plants, to keep pace with the latest ideas and names. Mosses, scalemosses, lichens, and fungi are studied by comparatively few amateur botanists, and we think this portion had better have been left out than only half done, or at least that the author would have done well to have had the proofs revised by an authority upon these groups of plants. As it stands it is useful neither to the amateur nor to the advanced cryptogamist.

The second half of the book is devoted to localities, a short description of the soil, and of the nature of the district being given and followed by a list of the plants to be found in each locality. Thus a botanist visiting Hampstead Heath sees at a glance what to look for. This portion of the work will probably be found very useful to young botanists. We can recommend the book, as a handy pocket guide, to all Londoners who are interested in flowering plants. We hope that each visitor to localities of rare plants will remember that many others may follow in his footsteps, and that if he helps himself too liberally the rarer species will rapidly disappear, and the present edition will soon require revision.

Dispensing Memoranda.

[21]. Apothecaries' or Avoirdupois.—In the series of valuable articles under the head of "The Month" in the Journal of Saturday last (reply to dispensing query No. 21) it is stated that when the sign ℥j occurs in a prescription, "the apothecaries' weight consisting of 480 grains should be used." Being under the impression that this question had been finally settled in the opposite direction some ten years since, I was somewhat surprised at the reply. It is true that when ʒj is written we use sixty grains, but we have pharmacopœial authority for so doing (quoting from the preface of the B.P. p. 13), "but it will be optional for the physician in prescribing to use the symbols ℈ and ʒ, the former representing twenty and the latter sixty grains, if such should be found to conduce to accuracy or convenience." Now the omission of the ℥ in this paragraph implies unquestionably that when it occurs in prescribing, the avoirdupois ounce of 437·5 grains is the only one to be recognized. The apothecaries' weight is not used, either in buying, preparing, or selling our medicines, it is practically unknown in commerce, and why the writer of the above named article should recommend its retention in dispensing I must confess my inability to understand.

Liverpool. Charles Symes.

[21]. Apothecaries' or Avoirdupois?—In the article entitled "The Month" in the Journal of Saturday last, on page 323, you say "In dispensing a prescription containing a powder, thus, ℥j, the apothecaries' ounce should certainly be used; the symbol ʒj represents 60 grs., and ℥j eight times sixty, or 480 grs." There are those who are of opinion that in such a case the apothecaries' ounce should certainly *not* be used. ʒj and ℈j respectively represent not the eighth or twenty-fourth part of an ounce, as an ounce is understood nowadays, but simply 60 and 20 grains. The troy ounce and pound are practically obsolete. If a physician prescribe ℔j, would you dispense a troy pound? I hope not. Why then when he prescribes ℥j would you dispense a troy ounce? A customer asks you for an ounce of Epsom salts, or a physician for an ounce of quinine. Do you give either of them a troy ounce? I fear not. If a physician writes to you for a number of articles, and one item be, say, quinine ℥j, would you understand him to mean, and supply to him an ounce of 480 grs.? I venture to think that you would not. Yet when you get a prescription for ℥j you dispense an ounce of 480 grs.! It would seem that "℥j" has got one value commercially and another professionally.

What follows is from the preface to the Pharmacopœia:—

"The avoirdupois ounce and pound being the weights practically used in the sale of medicines, and generally in commercial transactions, were adopted in the edition of 1864, and are still retained in preference to troy weights of the same denominations. . . . It is strongly urged upon all medical men to avoid the use of the terms ounce and pound with reference to any other than the avoirdupois or imperial standard weight."

In the light of the foregoing it seems to me that, if a physician when he writes ℥j means 480 grs., he has no business to do so. What good is there in throwing overboard, in theory, the troy weight, if in practice we retain it? What I would like to ask, in conclusion, is "How do you know that when a physician writes a prescription for ℥j, he intends 480 grs. to be dispensed?" I shall be glad to hold myself indebted to you or any one else who may be conversant with the "latent" intention of prescribers, if you or they can give me some good reasons why "in dispensing a prescription containing a powder thus, ℥j, the apothecaries' ounce should certainly be used."

Glasgow. P. B.

[24]. Some Remarks upon a Method of Coating Pills.—Noticing from time to time inquiries concerning pill coating, I have thought that a few remarks as to the method I have applied and found to be successful, will be acceptable to some of my *confrères*, who wish to coat pills for sale. In the first place, the pills must be dry and round; and to have a pill, which when coated preserves its white pearly appearance, it must contain no essential oil—this is essential; gingerine is sometimes used as a substitute. Place the pill in a covered pot, and moisten with some of the following solution:—Rosin, 30 grains; Bal. Tolu, 20 grains; Eth. Sulph., 1oz. Having shaken them together, turn them out on a slate to dry; when dry, place them in another pot, and moisten with syrup (ʒj Syrupus B.P. to ʒvij water), then throw them into a tin box with closely fitting lid, about the size and shape of an eight-ounce covered pot, containing some finely powdered French chalk; agitate the box briskly for a minute or two, or until the pills become coated; then turn them into another box, giving it a rotary motion sufficient to render the pills round, and to give them a smooth surface.

Care must be taken not to make the pills too moist, at the same time the surface must be thoroughly covered with the solution.

By following the above directions, and with a little practice, any one can coat pills, equal in appearance to those met with in the market.

51, *Judd Street, W.C.* Felix Stevens.

[24]. Pill Coatings.—In your monthly article of Oct. 27 were some valuable and suggestive remarks on pill coating, from which I quote the following sentence:—"There is a small American apparatus, mentioned by Professor Markoe at the Brighton Conference, for sugar coating pills extemporaneously."

This recalls to my mind a fruitless quest upon which I once entered, and I crave permission to relate it.

Having always regarded sugar as *à priori* the best pill coating, and lamented the difficulties which stood in the way of its everyday use, I caught eagerly at the suggestion of an apparatus for overcoming these, and wrote both to Professor Markoe, and to Professor Wayne—who accompanied him—asking the favour of further information about it.

Not receiving a reply from either of these gentlemen, and after numerous vain attempts in other quarters, on the recommendation of Mr. H. Brandreth, I applied to the well-known firm of Messrs. J. F. Henry Curran and

Co., of New York, who sent me a copy of their catalogue' superbly printed, full of interest to the pharmaceutist, but—giving not the faintest clue to the object of my search.

Lastly, I wrote to a firm who advertized themselves as importers of American machinery, and they courteously promised to forward the inquiry to the other side of the Atlantic; from whence, however, no response has ever reached me.

Under these circumstances, may I be pardoned for asking—Did the Professor evolve the apparatus in question from the depths of his own inner consciousness?

Dover. T. F. BROWN.

---

[27]. AQ. CAMPH. CONC.—Experimenting upon the solubility of camphor in dilute spirit for the purpose of obtaining an aq. camph. concentrated for the extemporaneous production of camphor julep, I arrived at the following conclusion:—In the first place I made spiritus camphoræ by dissolving

Camphor	16 scruples in
S. V. R.	4 ounces
Water	1 ounce.

One ounce of the above contains sixty-four grains of camphor, which diluted with seven ounces of proof spirit will contain eight grains in one ounce, or one grain in each fluid drachm. One such fluid drachm added to two ounces of water, mixes readily and forms, according to Squire, aq. camph. B.P., *i.e.*, half a grain camphor in each fluid ounce. In fact the result is a more satisfactory preparation, since the quantity of camphor held in solution is definite and certain.

If aq. camph. fort. is required, the diluted solution is miscible up to one and a-half fluid drachm in one ounce of water; beyond this a slight precipitate takes place.

Brighton. W. CORNISH.

Obituary.

Notice has been received of the death of the following:—

On the 20th of September, 1877, Mr. Jabez Fowls, Chemist and Druggist, Kensington Road, Southport. Aged 46 years. Mr. Fowls had been an Associate of the Pharmaceutical Society since 1870.

On the 29th of September, 1877, Mr. James Shacklock, Chemist and Druggist, South Caves, Yorkshire. Aged 45 years.

On the 30th of September, 1877, Mr. Thomas Makinson, Chemist and Druggist, Chapel Street, Southport. Aged 31 years. Mr. Makinson had been an Associate of the Pharmaceutical Society since 1870.

On the 13th of October, 1877, Mr. Edward Charlwood, Chemist and Druggist, Dale End, Birmingham. Aged 46 years.

On the 20th of October, 18.7, Mr. James Parnell. Chemist and Druggist, Berry Street, Wolverhampton Aged 40 years.

Correspondence.

THE BELL SCHOLARSHIP EXAMINATIONS.

Sir,—I quite agree with "Detur Digniori" respecting catch questions, but I fail to see what exception can be taken to the passage from Virgil given for translation at the last Bell Scholarship examination. "Detur Digniori" attaches some importance to the capital letter, C, in Cæsariem, and says it "is calculated, and I should think intended, to 'catch' the unwary." What can justify this remark? Does he give the examiners credit for an attempt to lure candidates into concluding (on account of the capital C) that it was a proper name, and so render it "Cæsar?" I scarcely think the examiners could expect such an exhibition of ignorance on the part of any young man who felt justified in competing for a "Scholarship." Would not such a candidate's translation of any passage in Virgil be rather curious? "Detur Digniori" says, "to the youth fresh from his Virgil the passage offers no difficulty." I take it that all candidates for the Bell Scholarships are fresh from Virgil, or would stand but a poor chance of success in competing for a prize the first subject of which is plainly stated in the regulations to be "Virgil; the three first books of the Æneid." The passage in question is not an unusually difficult one, nor is it removed from its context so far as to destroy its sense or prevent it (from *namque* to *honores*) being quoted by one of our best and greatest lecturers on rhetoric and belles lettres as a fine example "where Virgil, from the feeling of his subject naturally runs into smooth, liquid, and flowing numbers." Though I yield to none in condemnation of "catch" questions, or any tendency to encourage "cram," I cannot think that "Detur Digniori" has maintained a case against the examiners *in re* this passage from Virgil.

GUSTO.

PROSECUTIONS UNDER THE PHARMACY ACT.

Sir,—In commenting on my letter, published in the *Pharmaceutical Journal* of October 20, Mr. Fairlie appears to have misunderstood my objection to the prosecutions at Birmingham. If he will refer again to my remarks, he will see that I did not defend the illegal trading of unqualified persons. On the contrary; I said, "Had either of the parties been prosecuted under the 15th section, doubtless a conviction would have resulted." My point was that they had not infringed the provision of the 17th section.

The example I cited, of "Apothecaries' Hall," does, I conceive, very fairly apply to the present case, even according to Mr. Fairlie's description. He says, the manager "is there to represent the company." Just in the same way, "in the event of any accident occurring," consequent on an article sold at the establishment, and bearing the name of "Morris and Co., Chemists, 87, Islington, Birmingham," Anson Edwin Martin was there to represent the company. The question of his qualification was, for the purposes of the 17th section, entirely immaterial.

M.P.S.

The Sale of Food and Drugs Act.

Sir,—Permit me to take exception to the conclusion you draw in your leader in last week's Journal upon the annual report of the Local Government Board on the Sale of Food and Drugs Act.

The readers of the Journal will greatly err if they suppose the examples you quote from the report convey anything like the true state of matters as regards drugs and pharmaceutical preparations. Even your own figures show 33 per cent of adulteration.

It would be a great fallacy to suppose 1 in 3 represents the purity of Liverpool; and although Brighton is the Paradise of England, I do not think it is free from this particular sin. I fear, sir, the innocence of your nature inclines you to believe all men are pure. This is only a consummation devoutly to be wished. I am willing to admit the evil that has been committed under the Act, but the benefit also is great.

Alpha.

[*** We cannot admit the exception taken by our correspondent to the conclusion drawn in the article he refers to. We had no intention of leading our readers to suppose that the data quoted from the report represented the true state of matters as regards drugs and pharmaceutical preparations for that would amount to the assumption that more than 30 per cent. were adulterated. Without raising any question as to analysts' results, we merely took the official figures representing the work done under the Act as showing, so far as they go, that the supply of drugs is not open to serious suspicion, since it must be supposed that the samples examined were obtained from sources where adulteration was thought probable. However, if a greater amount of unrevealed adulteration is practised as our correspondent seems to imply the only conclusion is that the Food and Drugs Act is not doing the work it was intended to do.—Ed. Pharm. Journ.]

Professional Co-operation.

Sir,—The "M.R.C.S." who lowers himself to supply cheap advice at the West End co-operative store will no doubt be snubbed by his professional brethren. Is it not so with the chemist who lends his name to the stores that take away the legitimate profits of his own trade? If he ever commences business for himself he is only blighting his own prospects. Surely he does not hold a very enviable situation.

"Live and Let Live."

Pimlico, October 29, 1877.

Dangerous Coloured Fires.

Sir,—During the past two weeks articles have appeared in the Journal relative to the danger of coloured fires containing sulphur in combination with chlorate of potash; I therefore think a few words on the subject may interest some of your readers. Many of the cases of spontaneous combustion and consequent explosion undoubtedly arise, as Mr. Walters states, from free acid in the sulphur in commerce, and his suggestion to use washed sulphur instead of the ordinary article, although a good one, is not new; as most of the modern treatises on pyrotechny recommend its use in many of the formulæ given. But the non-use of washed sulphur does not arise so much from ignorance as he supposes; another cause, viz., price, being a great consideration with the manufacturer of cheap coloured fires, and the amateur pyrotechnist in many instances wilfully runs the risk of spontaneous combustion rather than pay the higher price of the washed article.

The process adopted by Mr. Walters in washing his sulphur is not a good one for the purpose, on account of the difficulty of washing away the soda employed, and if this is not thoroughly done, there is a great chance of deteriorating the colours of the fires; for from numerous experiments, I have found that a half per cent. of a soda salt, mixed with nitrate of baryta, almost entirely destroys the green colour of its flame, and two per cent. mixed with nitrate of strontia, the red colour.

But even washed sulphur is not infallible, for however thoroughly washed it has a tendency to generate acid, and especially so when in contact with chlorates. I would therefore recommend a method which has been largely employed for some years in the manufacture of an explosive having a similar composition, namely, to intimately mix 120 grains of powdered bicarbonate of potash with each pound of sulphur, before using it in the manufacture of any composition into which chlorates enter.

This method has been found most successful and does not influence the colours of the fires. I have some compositions so prepared four years ago, and although they have been kept in paper for that time and have been alternately exposed to damp and again dried on three occasions, have exhibited no signs of spontaneous combustion; this is a test which I think very few compounds, even if made with washed sulphur, would withstand.

With regard to the formulæ published in this Journal vol. ii. n.s., and again referred to by Mr. G. C. Druce in last week's issue, though they produce excellent results, they are not likely to be generally adopted, on account of cost in production compared with those containing sulphur.

Henry Child, F.C.S.

W. Millington.—The *Journal of Dental Science*, published by J. and A. Churchill.

O. Jones.—Your letter has been forwarded as requested.

W. H. Story.—Your request has been complied with.

G. Evans.—The only explanation that we can furnish is that your letter was considered unsuitable for publication in the Journal.

"*Aderyn.*"—The substitution of one article for another in making up a prescription would be unjustifiable. In the case of an incompatibility the prescriber should be consulted if possible. For your other questions see p. 359.

Student.—See a paper on the preparation of glycerine jelly in vol. v. of the present series of this Journal, p. 401.

"*Ignoramus.*"—(1) In our opinion the label sent would necessitate the use of a stamp. (2) There is nothing illegal in the supply of such articles by wholesale dealers. (3) Oil of nerve is neat's-foot oil; by oil of petre probably petroleum is meant. (4) Such titles are entirely fanciful, and are extended to many preparations, recipes for which are given in the ordinary receipt books.

"*Quœro.*"—Dip white unsized paper into a cooled mixture of strong sulphuric acid with half its volume of water, and afterwards wash the paper with water containing a little ammonia.

R. Jones.—We do not understand why you should have expected effervescence to take place under the circumstances stated.

H. Sparshott.—We are not acquainted with such a preparation.

Chemists' Assistants' Association.—We have received a letter from a Member of this Association who is desirous of making it known that a temporary room has been taken for three nights weekly, in which assistants can meet and discuss topics, play chess, or read papers connected with the trade. He is of opinion, however, that unless the number of members be greatly increased, the Association will inevitably come to an untimely end, the reason given being that chemists' assistants appear to lack courage enough to launch out the requisite subscription. At the same time he appeals to "those chemists in business (both London and provincial), who have half a guinea to spare, and don't know how to put it to a good purpose," to send it to the Hon. Secretary, Mr. E. Cardwell, 92, Kirk Dale, Upper Sydenham, S.E., and become honorary members. We are sorry to say that this betrays a lamentable want of "backbone" in the new association. If it is to depend upon visionary half-guineas that chemists in business do not know what to do with it, is not likely, neither would it deserve, to be permanently successful.

"*Rama*" and "*Chemist by Examination.*"—*Prosecutions under the Pharmacy Act.*—Your letters in reference to the correspondence on this subject having direct personal bearing can only be published with the signatures of the writers.

Communications, Letters, etc., have been received from Mr. Young, Mr. Thirlby, Mr. Elliman, Mr. Kinninmont, Mr. Stoakes, Mr. Bennett, Mr. Oates, Mr. Taylor, Mr. J. W. Lloyd.

THE POISONOUS PROPERTIES OF YEW LEAVES.*

BY PROFESSOR REDWOOD.

Cases not unfrequently occur in which animals are poisoned by eating the leaves of the yew tree. Pereira says, "the poisonous properties of the yew were known to the ancient Greeks and Romans, and have been fully established by modern experience, although some few writers have expressed doubts concerning them." Bentley and Trimen mention, but at the same time discredit, an opinion sometimes entertained that the leaves are not poisonous to animals if eaten off the tree, but become so if cut and allowed to lie on the ground for some time before being eaten. It is sometimes asserted that the leaves are only poisonous at a particular period of the year, an opinion which has probably originated in the circumstance that animals are most likely to browse off the yew, an evergreen, when other vegetation is deficient. Several instances are recorded of human subjects having died from swallowing the leaves and also the fruit of the yew, yet many persons bear testimony to their having eaten the fruit with impunity, and this may be explained by the fact that the part that would be generally eaten, namely, the soft fleshy part of the fruit, which forms the sweetish subacid cup enveloping the hard nuciform seed, is innocuous, while the seed itself is poisonous.

The yew is not used as a therapeutic agent by qualified medical men in this country, but yew leaves are sold by some of the herbalists, and used as an emmenagogue among the lower classes.

Dr. Alfred Taylor says that "infusion of yew leaves, which is popularly called yew-tea, is sometimes used for the purpose of procuring abortion by ignorant midwives." A case in which it was used for this purpose, and in which it proved fatal to the life of the patient, having recently come under my notice, I have thought it desirable that some of the facts should be recorded.

The wife of a railway porter in the neighbourhood of London, being in the family-way, and having had a very difficult delivery at the birth of the previous child, was induced, with the concurrence and aid of her husband, to resort to the use of a decoction of yew. The husband procured some of the leaves and twigs of Irish yew from a neighbouring cemetery, with which a decoction was made, and two or three doses of this were taken by the woman, without, however, producing any perceptible effect. The decoction had been made by boiling about five or six ounces of yew in two quarts of water. Of this half a teacupful was taken on Monday evening, the 13th of last August. Two similar doses were taken the following day, the last being taken at night before going to bed. As no effect had been produced up to that time, some of the chopped-up unboiled leaves were taken with the last dose. At one o'clock in the morning the husband was awoke by his wife, who was retching, and complained of feeling ill. He gave her some cold water, went to sleep, and did not awake again until a quarter past two, when he found his wife breathing very hard. She slightly moved her head but made no reply to his questions, and being now alarmed he went for assistance. Dr. Günther attended soon afterwards and found her dead. The circumstances of the case, which were at once freely explained by the husband, being such as to implicate him in the commission of an illegal if not felonious act, they became subjects for investigation before the coroner, and also before a bench of magistrates.

The medical evidence was to the effect that the deceased when seen about an hour after death had a calm expression; that there was no distortion of the limbs, and no froth before the mouth. At a *post-mortem* examination, made thirty-three hours after death, there were no external marks of violence; the brain and lungs were perfectly healthy; the pericardium was firmly adhering to the heart—probably in consequence of former pericarditis. The heart itself was larger than normal, it was very flabby; on the right side was a large deposit of fat, which extended into the muscular substance; it contained no coagulum, only a small quantity of liquid blood. The liver was healthy. Both kidneys were very much congested; neither the uterus nor the fœtus were in any way affected by what had been taken; the stomach contained about three ounces of half digested food, and pieces of the cut leaves of the Irish yew. There were some red patches on the coats of the stomach, which, however, it was thought might have been caused by incipient decomposition.

Some doubt having arisen as to whether what was stated to have been taken by the deceased was really the cause of her death, I was requested by the magistrates, with the concurrence of the Secretary of State, to make an examination of the decoction, and of the stomach and intestines with their contents.

The decoction, as taken from the saucepan in which it had been made, consisted of three and a half pints of a brown liquid, in which were immersed the leaves and twigs used in making it. The latter bore the well-marked characters of the yew, as also did the former those of a decoction made as described.

The pieces of green leaves found diffused in the contents of the stomach were by comparison identified as portions of yew leaves. The inner surface of the stomach presented an appearance of slight inflammation all over it, and there were two patches more inflamed at the pyloric end. Just beyond the pyloric valve, in the duodenum, there was a compacted mass of digested green leaves, amounting to nearly half an ounce, and the intestine surrounding this mass presented a similarly inflamed condition to that which had been observed in the stomach.

The contents of the stomach and duodenum were tested for mineral and some of the more easily detected organic poisons, but none was found. The digested mass of leaves yielded to spirit and ether a product resembling the oleo-resinous matter similarly obtained from yew leaves.

There could be no doubt of the presence of yew leaves in the stomach, and that some of these had passed in a digested state into the intestines.

With the view of forming an opinion as to whether the quantity of yew leaves which appeared to have been taken by the deceased was sufficient to have caused death, I gave to a strong rabbit about fifty grains of fresh yew leaves. In five hours the animal was dead. It had apparently died without a struggle, for it was found in its natural sitting position with its head on one side on the floor of the hutch, and with no indication of its having suffered pain. The stomach presented the same appearance of slight in-

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, November 7, 1877.

flammation as had been observed in the stomach and intestines of the deceased woman.

The conclusion arrived at was that the deceased died from the effects of the yew leaves, aided probably by the previous condition of her heart.

In connection with this case, it may not be out of place here to allude to the reputed therapeutic effects of yew leaves. Pereira says that, "considered both in a toxicological and therapeutical point of view, the yew appears to hold an intermediate position between savin and foxglove. . . . It is said that when used for medicinal purposes it is unlike digitalis in not being apt to accumulate in the system." The yew appears to contain a volatile oil and also an amorphous alkaloidal substance which has been isolated under the name of taxine. It is probable that the oil gives it the property of savin, and the alkaloidal substance that of foxglove. The effects observed in the cases I have alluded to accord with previous observations, and seem to justify the anticipation that taxine may prove a valuable therapeutic agent. I am having some of it prepared with a view to further investigation of the subject.

[*The discussion on this paper is printed at p.* 375.]

SOME FURTHER REMARKS ON SWEET SPIRIT OF NITRE.*

BY F. M. RIMMINGTON.

In a former paper on this subject,† I stated that a spirit containing 4 or 5 per cent. of nitrite of ethyl is a fair standard of strength for medical uses, and on further reflection there are considerations of some importance why this should be the standard. The process of the Pharmacopœia has not in my hands yielded a spirit of this strength, although the chloride of calcium test implies this amount of ether.

Five per cent. is equal to one ounce by volume, in a pint. An ounce of HNO_3 is required to produce one ounce of nitrite of ethyl, or a pint of sp. æther. nitros.; and in the production of this ether about two ounces of spirit of ·835 specific gravity will be decomposed, and one ounce or more of water formed. These are the quantities that come out in practice, but several conditions may exist to change these results. It follows from the foregoing that there would be three grains (measure) of the nitrite of ethyl in sixty grains of such spirit, and if there be any analogy between the ethylic and the amylic ether, one would conclude that a drachm would be a full dose. It appears to me therefore undesirable, both from a medical and a commercial point of view, to have this preparation either stronger or weaker. How far does the spirit of nitre, which has been in common use amongst us for so long a period, approach this strength? From many samples which I have examined, some from most reliable sources, some contained only a fraction of one per cent., and others none at all; in one instance the spirit appeared to be only a weak solution of aldehyde, and in some instances the small quantity of ether that may at one time have been present had disappeared by decomposition accelerated by an excess of water.

The specific gravity is of some importance and ought not to be higher than ·845, and the question suggests itself to me, how the gravity of ·850 came to be so universally adopted by the trade as the proper strength? I think it may be accounted for in this way. By the old process which was generally followed by manufacturers, it was usual to draw over as much distillate as there had been alcohol put into the still; so that in the latter part of the operation there came over a very weak spirit, and it is my opinion the great proneness of this preparation to change is largely indebted to the presence of this water and some oxidized compounds that accompany it; the contents of the retort being in such a state of hydration as to be unable to form nitrite of ethyl.

We have all of us heard much about "rapid decomposition," the "excess of acidity," etc., of spirit of nitrous ether. The following experiments bear on these two points:

The following two examples had been put away in corked bottles, not quite full, and no particular pains bestowed upon them, and the corks had several times been taken out in the interval.

1st. A sample of spirit of nitre, made in March of this year, after the formula of 1746, contained at that time 18 per cent. of ether. On the 1st of November (being seven months old), I tried it again, to see what changes had taken place. It now yielded me 14 per cent. ether, and the acidity was equal to 0·182 per cent. nitric acid, or about one-half grain per fluid ounce.

2nd. A sample made about the same time after the Pharmacopœia of 1836, but the distillation continued beyond the point directed in the formula. It then contained 3 per cent. of ether—it now yielded 2 per cent. and the acidity was equal to ·367 nitric acid, or 1¼ gr. per fl. oz. So that this tendency to decomposition is not altogether inherent, *per se*, but to a great extent dependent on other conditions.

[*The discussion on this paper is printed at p.* 377.]

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, November 7, 1877.

NOTES ON CASUAL DRUGS.*

BY E. M. HOLMES, F.L.S.

Occasionally drugs which have no recognized value in England are sent over on speculation from foreign countries. These find their way into the dock warehouses at the principal ports, such as London and Liverpool, and if no commercial use is discovered for them, they remain in the warehouses until the expense of housing them necessitates their sale. Such sales are known as "rummage sales" and take place periodically.

Inasmuch as the drugs thus sent to English ports are in most cases of value, or at least are thought to be so in the countries from which they are exported, a short notice of them may perhaps present some points of interest.

At a sale of the kind alluded to, which took place last month, the following articles were noticed:—

Tamarisk Galls.—These small galls came from Mogadore. They vary in size from that of a pea to a horsebean, or more rarely reach the size of a small nut. The taste is powerfully astringent. Internally they are found to be full of small cavities, in which, however, the insect that forms them is very rarely found in a state to be examined. So far as I am aware the name of the insect has not yet been determined. The galls contain about 40 per cent. of a very pure tannin.

In Morocco these galls are known under the name

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, November 7, 1877.

of Tacout, and are produced upon the twigs of *Tamarix articulata*, Vahl. In India similar galls are produced upon *Tamarix Gallica*, L., and *Tamarix orientalis*, Vahl.; those of the former plant are usually rather larger, and are called Bara-mai in Hindostanee; the smaller ones, from *Tamarix orientalis*, being called Chota-mai. The Tamarisk galls of India also occasionally find their way into English commerce, and if better known would probably be largely used for tanning purposes.

A strong infusion of these galls has been recommended in India as an application to foul ulcers, and by the natives they are used in diarrhœa and dysentery.

CALOPHYLLUM INOPHYLLUM, *L.*—The fruits of this plant were imported from the Mauritius under the name of oil seeds. The fruits as imported consist of the hard woody endocarp. They are about the size of an English oak gall, nearly globular, with a small projecting point at one end, and contain a yellowish white oily kernel. According to the official report of the products in the India Museum, the seeds yield sixty per cent. of a fragrant green oil, fluid at ordinary temperatures, but beginning to solidify when cooled below 50° Fahrenheit.

In India it is used as a lamp oil and also as an outward application for rheumatism. Although apparently unknown in the commerce of this country in 1847–8, nearly 4000 gallons of the oil were exported from Madras to Ceylon and the Straits settlements. The tree yielding these seeds bears handsome white fragrant flowers, and it may not be out of place here to remark that there is a wide field for experiment among the native plants of India, for those interested in perfumery.

The following note extracted from Seemann's 'Flora Vitiensis' will show how highly the oil obtained from these nuts is esteemed in Fiji, as well as the method of extraction :—

"The most valuable oil produced in Fiji is that extracted from the seeds of this tree, the dilo of the natives, the tamarind of Eastern Polynesia, and the cashumpa of India. It is the bitter oil or woondel of Indian commerce. The natives use it for polishing arms and greasing their bodies, when cocoa-nut oil is not at hand. But the great reputation this oil enjoys throughout Polynesia and the East Indies rests upon its medicinal properties as a liniment in rheumatism, pains in the joints, and bruises. Its efficacy in this respect can hardly be exaggerated and recommends it to the attention of European practitioners. The oil is kept by the Fijians in gourd flasks, and there being only a limited quantity made I was charged about sixpence per pint for it, paid in calico and cutlery. The tree is one of the most common littoral plants in the group; its round fruits, mixed with the square ones of *Barringtonia speciosa*, the pine cone-like ones of the sago palm, and the flat seeds of the walai (*Entada scandens*, Benth.), densely cover the sandy beaches. Dilo oil never congeals in the lowest temperature of the Fijis, as cocoa-nut oil does during the cool season. It is of a greenish tinge, and very little of it will impart its hue to a whole cask of cocoa-nut oil. Its commercial value is only partially known in the Fijis and was found out accidentally. Amongst the contributions in cocoa-nut oil which the natives furnish toward the support of the Wesleyan missions some dilo oil had been poured, which on arriving at Sydney was rejected by the broker who purchased the other oil, on account of its greenish tinge and strange appearance. On being shown to others a chemist recognizing it as the bitter oil of India purchased it at the rate of £60 per tun, and he must have made a good profit on it as the article fetches £90 a tun.

"In order to extract the oil the round fruit is allowed to drop in its outer fleshy covering and rot on the ground. The remaining portion, consisting of a shell somewhat of the consistency of that of a hen's egg, and enclosing the kernel, is baked on hot stones in the same way that Polynesian meat and vegetables are. The shell is then broken, and the kernels pounded between stones. If the quantity be small the macerated mass is placed in the fibres of the vau (*Hibiscus tiliaceus* and *tricuspis*), and forced by the hand to yield up its oily contents; if large, a rude level press is constructed by placing a boom horizontally between two cocoa-nut trees and appending to this perpendicularly the fibres of the vau. After the macerated kernels have been placed in the midst, a pole is made fast to the lower end of the fibres, and two men taking hold of its end twist the contrivance round and round till the oil collecting into a wooden bowl placed underneath has been extracted. Of course, the pressure thus brought to bear upon the pounded kernels is not sufficiently great to express the whole of the oil and there is still much waste."

BOOMAH NUTS.—These are the fruits of *Pycnocoma macrophylla*, Benth., a small tree belonging to the *Euphorbiaceæ*. These fruits were imported from Natal under the name of galls, probably on account of their bearing a strong resemblance to Aleppo galls in shape and size. Externally they have a black colour, and when broken open exhibit a hard three-celled endocarp, each cell containing a single seed. The seeds in shape and colour are not unlike a castor oil seed, but are less than half the size and have no appreciable taste.

The Boomah nuts are said to be used for tanning in Natal. The tannin is contained in the outer coat or sarcocarp, and must be very small in amount, considering the size of the fruit, since so large a portion is occupied by the woody endocarp. These nuts are not likely, therefore, to be able to compete in this country with other tanning materials.

BAROSMA ERICIFOLIA, *Andr.*—This drug is a species of buchu leaves. The leaves are very small, resembling in size and shape the leaves of the heath, whence the specific name. The odour of the leaves is powerful, but differs somewhat from that of the official species, having a slight resemblance to the odour of caraways. These leaves are used by the Hottentots in the same way as the official kind, and also as a perfume, and in the form of tincture as an application to wounds.

EMPLEURUM SERRULATUM, *Ait.*—The leaves of this plant are mentioned in 'Pharmacographia' as being offered for buchu in this country. The characters pointed out in that work render it an easy matter to distinguish it from the leaves of *Barosma serratifolia*, Willd. the species which it most closely resembles. One feature, however, not noted in that work, is very easily observed. When a leaf of *Barosma serratifolia* is held up to the light the lateral veins are seen to be much straighter, longer, and more strongly developed than in the leaves of *Empleurum serrulatum*.

LOOMOONDERFALL.—The large fruits which bear this name were imported from Zanzibar, and are, I am told, possessed of properties similar those of cocculus indicus. I have not as yet been able to ascertain the name of the tree which produces them.

CASSIA TORA, *L.*—These seeds were imported under ths name of Fantupa seed. They are about the size ot an apple pip, greenish brown, polished, pointed at one end and irregularly angular. The leaves of this plant are used in India for ringworm, and the seed of another species (*Cassia absus*, L.) has been used in purulent ophthalmia, but the object with which the seeds of *C. Tora* were sent to this country, I am not able to conjecture.

[*The discussion on this paper is printed at p.* 378.]

HOANG-NAN BARK.*

BY M. PLANCHON.

Under the name of hoang-nan bark, the missionaries at Tong-King have for some time past spoken highly of a drug which they report to be very valuable in the treatment of hydrophobia and leprosy. It is described as being yielded by a shrub presenting some analogy with the ivy, occurring on the Ngan-Ca mountains in Nghé-An, and in the province of Than-Hoa, particularly on calcareous soil.

A specimen of this bark having come into the author's possession, he submitted it to examination. It consisted of small fragments that had been detached from the tree by clean incisions, which at the lateral edges had been made in the direction of the axis of the tree, but at the top and bottom edges in a very oblique direction, forming parallelograms 1 to 3 centimetres high, 4 to 5 centimetres wide, and 1·5 to 2 millimetres thick. In consequence of the oblique form and the tendency of the bark to curl, the pieces frequently had a spiral form.

The external surface of the bark is more or less verrucous, sometimes blackish-grey, marked with grey and black, or brownish, but more frequently an ochreous red tissue forms the superficial layer. The inner surface varies in colour, being sometimes pale tawny-grey, sometimes darker and approaching a blackish-brown, and always striated longitudinally. The fracture is not fibrous, and shows two distinct layers separated by a clear line that is paler than the rest of the tissue. Nitric acid colours the internal portion blood-red, and the ochreous tissue blackish-green, but when applied to the transverse fracture it scarcely colours the characteristic pale line. The odour of the bark is not marked, but the taste is very bitter.

Examined anatomically from the exterior to the interior, four distinct layers are seen, viz.:—

(1) A suberous layer, formed of radiating lines of thin-walled rectangular cells, flattened from without inwards, reddish externally and paler in the interior. The thickness of this layer is variable; sometimes there are as many as twenty rows of superposed cells, with a mean thickness of 0·3 to 0·4 millimetre.

(2) A parenchyma layer having the same average thickness as the preceding. The cells are elongated tangentially, and the walls are rather thin. Sometimes they contain a yellowish-brown matter, and many of them contain crystals of oxalate of lime. Here and there in the internal portion of this zone are small isolated thick-walled cells that seem to prepare the way for the following one.

(3) The third layer is clearly characterized by the sclerogenous cells of which it is constituted. These cells have very thick walls, yellowish-green by transmitted light, traversed by small canals, and leaving only a small central cavity, which is generally filled with a brownish matter (? resinous). It is this third zone that forms the pale line above referred to; it has a thickness of about 0·015 millimetre.

(4) The fourth, or liber layer, is the thickest of the whole, being twice as thick as the others united. Under the glass it shows a structure rather irregularly striated radially. This is due to the presence of medullary rays, formed of four or five rows of rounded polyhedral cells having thin walls. The remainder of the tissue is formed of two kinds of cells; one kind elongated in the direction of the vertical axis, and containing small (0·003 m.) ovoid, nearly round grains of starch; the other kind much shorter, but placed one above the other so as to border the preceding, and each containing a rhomboidal prism of oxalate of lime. In the outermost rows of this zone are a large number of sclerogenous cells, forming isolated groups; these occur here and there, but less numerously, in the remainder of the zone.

The above, which are the salient characters of the hoang-nan bark, indicate a very close relationship, if not identity, with false angustura bark. The ochreous tissue coloured blackish-green by nitric acid, the red coloration of the inner layer by the same reagent, and the general appearance of the section with its characteristic pale line, are all indications of this affinity. This is confirmed by the anatomical characters, the same structure in the suberous tissue and in the subjacent parenchymatous tissue, the same sclerogenous zone, and the same general disposition of the liber layer. Further, M. Wurtz has obtained, by chemical analysis of the hoang-nan bark, strychnine and brucine, the two alkaloids of false angustura.

The most striking point of difference between the two barks are the following:—The exterior appearance of the hoang-nan bark is much more regular than that of the false angustura. It is more distinctly curled, much thinner, and presents a verrucous exterior surface. In a transverse section the radial striæ of the liber zone are less clearly indicated. Also, in the liber zone of the hoang-nan bark there is a very small number of sclerogenous cells, whilst they abound in the liber zone of the false angustura and are developed longitudinally. In a pamphlet by M. Lesserteur, entitled 'Du traitement de la rage et de la lèpre par le Hoang-Nan,' published at Lyons, it is stated that "the bark is covered by a reddish powder, which contains a subtle poison that constitutes the virtue of the remedy. Only this powder is employed and not the ligneous portion of the bark, which has no efficacy." M. Planchon considers that the powder is evidently analogous to that which is found upon false angustura bark, and remarks that Pelletier in examining that bark found the principles contained in the suberous tissue quite innocuous. He suggests therefore that the above statement is probably incorrect, and that it is the part of the bark containing the strychnine and brucine that would produce the symptoms reported by the missionaries, which would be explained by the presence of those alkaloids.

THE FLORA OF CENTRAL NORTH AMERICA.

Sir J. D. Hooker thus sums up the results of his and Dr. Asa Gray's joint investigation, together with Dr. Gray's previous intimate knowledge, of the elements of the American flora:—The vegetation of the middle latitudes of the continent resolves itself into three principal meridianal flora, incomparably more diverse than those presented by any similar meridian in the old world, being, in fact, as far as the trees, shrubs, and many genera of herbaceous plants are concerned, absolutely distinct. These comprise two humid and one dry intermediate region, each of these three regions being again divisible into three sub-divisions, as follows:—(1) The Atlantic slope plus Mississippi region; sub-divided into (α) an Atlantic, (β) a Mississippi valley, and (γ) an interposed mountain region with a temperate and sub-alpine flora. (2) The Pacific slope, sub-divisible into (α) a very humid cool forest-clad coast range, (β) the great hot drier Californian valley formed by the San Juan river flowing towards the north, and the Sacramento river flowing to the south, both into the bay of San Francisco, and (γ) the Sierra Nevada flora, temperate, sub-alpine, and alpine. (3) The Rocky Mountain region (in its widest sense, extending from the Mississippi beyond its forest region to the Sierra Nevada), sub-divisible into (α) a prairie flora, (β) a desert or saline flora, and (γ) a Rocky Mountain proper flora, temperate, sub-alpine and alpine. The difference between the floras of the first and second of these regions is, specifically and to a great extent generically, absolute; not a pine, oak, elm, maple, plane, or birch of Eastern America extends to Western, and genera of thirty or fifty species are confined to each. The Rocky Mountain region again, though abundantly distinct from both, has a few elements of the eastern region and still more of the western.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 10, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal. MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE AMENDED BENEVOLENT FUND REGULATIONS.

FROM the report which will be found in a subsequent page it appears that at the meeting of the Council, on Wednesday last, the attention of the members was principally devoted to the consideration of two questions, the advisability of allowing ladies the privilege of joining the Pharmaceutical Society, and the amendment of the regulations according to which the Benevolent Fund is administered. As the first of these questions is again remitted to the Annual General Meeting to decide it need not be discussed here, but it may be of service to point out what are the principal alterations in the Benevolent Fund regulations that will come into operation at the commencement of the year now close at hand.

The first amendment occurs in clause 2, relating to the time for deciding the number of annuitants to be elected and the time of election. Hitherto, the consideration of the expediency of electing pensioners, and the decision of the number, if any, to be elected, have come before the Council in June and the elections have taken place in the October following. The consequence has been that a few persons have suffered a disadvantage, as subscriptions and donations given during November and December have been too late to secure to the givers votes for the current year, and have not entitled them to votes in the next year. The election is now to take place in December, or coincident with the close of the financial year of the Fund, so that no votes need be lost in future on that account. Moreover, as the decision of the Council is also to be postponed till October, the interval between that and the election will be decreased from four to two months, which may possibly prove to be a boon to the candidates as shortening the time during which they are tempted to spend ill-afforded money in canvassing.

The next alteration is in the fourth clause, and is a partial realization of the hope expressed by the President at the Dinner in aid of the Fund in May last. In future the annuity paid to each pensioner who is sixty-five years of age and upwards, will be at the rate of £35 per annum; but the annuitants under that age will receive the same as at present, namely £30. As just remarked this is not quite all that was suggested by the President in May, and it would appear to be a considerable modification of the original proposition brought under the notice of the Benevolent Fund Committee, but it will nevertheless involve an increased permanent charge that will require to be borne in mind by the philanthropic contributors to the Fund.

A third alteration is one that has already, to some extent, been anticipated in practice. It empowers the Council in the case of an orphan, not only to provide, as hitherto, but also to "*assist in providing* a home for the child by purchase in one of the public asylums for orphans." On more than one occasion the Council has voted money to be applied in securing the election of a candidate in which it was interested; it is desirable, therefore, that its power to do so should be clearly indicated in the Regulations. It is manifest, however, that considerable discretion will be required, and doubtless it will be exercised, as to the manner of giving this assistance, so that it may never tend to foster the evil of charity-mongering that has more than once been denounced at the Council table.

The next alteration of importance is the introduction of an entirely new clause, which will no doubt receive the unanimous endorsement of the subscribers and donors to the Fund. It is to the effect that should any subscriber or donor, or the widow of any subscriber or donor, become a candidate for an annuity, such number of votes shall be placed to his or her credit, at the succeeding election, as shall be represented by the whole amount of subscriptions or donations to the Benevolent Fund he or she (or in the case of a widow her husband) may have contributed. The justice of such a regulation can hardly be impeached, and its adoption, it may be hoped, will help to secure a still more extended interest in the Fund amongst the whole body of chemists and druggists.

The last alteration that need be referred to is the introduction of a clause giving to persons entitled to vote, but residing abroad, the privilege of voting by proxy. The only conditions are that the person to whom the proxy is entrusted shall himself be a person entitled to vote in his own behalf, and that his name and address shall have been previously communicated to the Secretary.

The above appear to be all the amendments that will practically affect the administration of the Fund, the others consisting chiefly of verbal alterations and rearrangements of the clauses. We think that they may fairly claim to be considered amendments in the true sense of the word, and that it will be admitted they are calculated to promote the interests of the Fund which the Council has so long and so ably administered.

NOTES FROM BRAZIL.

A correspondent who has recently returned from Brazil gives some interesting information respecting the position of the pharmacist in that country, according to which it would appear unlikely that any of those burning questions could arise which are now agitating the minds of certain classes of pharmacists and medical practitioners at home. These things are managed better in Brazil, and with regard to all medical and pharmaceutical matters the Government adopts a rigid system. Medical practitioners are not allowed to dispense, except in special cases, and then only under a licence from the Government. In like manner the pharmacist, whose particular business is to dispense the prescriptions of medical practitioners, is very properly required to pass an examination, and in order to open a "botica" must first obtain a licence from the Government.

The consumption of proprietary medicines in Brazil is said to be very large, many of them being imported from Europe, while a still larger quantity are prepared in the country, and sold with counterfeit English or French labels! This fraudulent practice is ascribed to the excessively high import duties. The Government requires a declaration as to the contents of proprietary articles, to be made, under due guarantee of secrecy, to the sanitary authority at Rio, entitled Junta Central de Hygiene Publica. These regulations contrast strongly with unrestrained practices prevailing in the United States; but as Brazil is in many parts a very scantily populated country, they cannot be very strictly enforced everywhere, and in small towns, no less than in the backwoods, things are done more by natural selection than by Government rules.

A tincture of eucalyptus globulus is prepared on rather a large scale on Brazil, where intermittent and remittent fevers are very prevalent in the low lying districts on the coast and near the rivers, and this tincture is much used by medical men in the treatment of these fevers.

CULTIVATION OF THE IPECACUANHA PLANT.

Upon the first introduction of the ipecacuanha plant into India, great hopes were expressed that it would soon become as successfully established as the species of cinchona. Experience, however, has shown that ipecacuanha is not entirely and absolutely suited for general cultivation in our eastern possessions.

The best and most trustworthy information on this subject, has been obtained from the several annual reports of Dr. King, the Superintendent of the Botanic Garden, Calcutta. It seems that during the year ending June, 1877, plants of the ipecacuanha were distributed from Calcutta to Ceylon, Singapore, Burmah and the Andamans. But Dr. King expresses an opinion that owing to its remarkably slow growth ipecacuanha will not be largely cultivated in India especially by European planters who naturally regard with but little favour crops that yield slow returns. Besides this the unattractive and straggling nature of the plant is not calculated to excite interest among planters. "These facts," Dr. King says, "make it still more a matter for regret that the profitable cultivation of ipecacuanha as a crop at the cinchona plantation seems so hopeless, owing, as I have stated in former reports, to the cold of the winter season, even in the warmest valleys, being too great for a species so thoroughly tropical."

It appears also that the cultivation of vanilla, like that of ipecacuanha, affords but little hope of its general cultivation as a profitable crop. Indeed Dr. King reports thus decidedly:—"I am more than ever confirmed in my opinion that the establishment of vanilla culture as a profitable industry in Bengal is not hopeful."

EXAMINATION RESULTS IN GERMANY.

An official summary of the examinations conducted under the Prussian Ministry of Education, for the licence of general medical practice, either at the Central Board of Berlin or at the Provincial Boards in the University towns, during the examination year of 1876-77, shows the following results: Of 346 candidates who went up for examination, 276 passed, and of these 220 received the character "good," 49 "very good," and 7 "excellent" (vorzueglich gut). 70 candidates failed to acquit themselves satisfactorily or withdrew spontaneously, that is, nearly the third part of the whole number. At the pharmaceutical examinations for the licence of dispensing chemist, 165 candidates presented themselves, of whom 155 passed, viz.; 40 with the character "sufficient," 97 with "good," 18 with "very good." 10 pharmaceutical candidates withdrew, or could not pass. The much larger proportion of failures at the medical examinations might be accounted for by more severe demands, but the lesser proportion in the pharmaceutical test evidently has its cause in the more practical requirements of these candidates and their having, previously to an eighteen months' course of theoretical University lectures, served a three years' apprenticeship in a dispensary and its laboratory.

TEACHING OF PHARMACY IN THE UNIVERSITY OF BERLIN.

It is announced that a pharmaceutical school, in which pharmacological, physiological, and chemical researches on the materia medica will be carried on, is to be commenced in the University of Berlin. The Prussian Government is about to erect a building for the laboratory, and the school is to be under the direction of Professor Oscar Liebreich.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, November 7, 1877.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atherton, Atkins, Betty, Bottle, Churchill, Cracknell, Gostling, Greenish, Hampson, Hanbury, Hills, Owen, Rimmington, Robbins, Sandford, and Shaw.

The minutes of the previous meeting were read and confirmed.

The following being duly registered as Pharmaceutical Chemists were respectively granted a diploma stamped with the seal of the Society :

Bayston, George Coryndon.
Betty, Robert Brown.
Blunt, Thomas Porter.
Cluett, Benjamin.
Dear, Theophilus.
Fell, John James.
Gorrie, Daniel.
Nicholson, Richard.
Peirson, Henry.
Robinson, William Prior.
Savory, Arthur Ledsam.

ELECTIONS.

ASSOCIATE IN BUSINESS.

Samuel Eliott, jun., of Plymouth, having passed the Minor examination, being in business on his own account, and having tendered his subscription for the current year, was elected an "Associate in Business" of the Society.

ASSOCIATES.

The following having passed the Minor examination, and having tendered or paid (as apprentices or students) their subscriptions for the current year, were elected "Associates" of the Society :—

Minor.

Barfoot, John Richard Doughty. Chesterfield.
Bell, John Waller.................Todmorden.
Bessell, James Walter...........Ludlow.
Carter, Henry Ayling ....Winchester.
Clower, John ....Nottingham.
Corden, Frederick W. W. ......Streatham.
Cousens, John Stather...........Hull.
Cridland, Francis E. J. ....Devizes.
Dyer, Edward Henry ....Horncastle.
Godsell, Philip George ....Great Malvern.
Hugill, John Howden...........Edmonton.
Keith, John ....Forres.
Kendrick, Alfred ....Limehouse.
Lakeman, Stephen ....Norwich.
McNaught, Louis A. ....Dumfries.
Matthews, John Henry ....London.
Newbery, Frank ....Lambeth.
Roberts, David Prosser ....Hereford.
Savory, John Field ....London.
Taylor, George ....Brinsley.
Whitlock, Draycott K. ....Southampton.
Wooldridge, Elijah ....Cradley Heath.

Modified.

Bloxham, William Eagleston ...Oxford.

APPRENTICES OR STUDENTS.

The following having passed the Preliminary examination, and tendered their subscription for the current year, were elected "Apprentices or Students" of the Society:—

Crummy, Thomas.................Douglas.
Grieve, Charles Frederick ......Edinburgh.
Pocock, Wm. Fred. Henry......Cape Town.

The names of the following persons were restored to the register of Chemists and Druggists :—

Thomas Hughes ....4, Ogwen Terrace, Bethesda.
Benjamin Johnson.18, Long Causeway, Peterborough.

The names of two ladies who had passed the Minor examination, and had applied to be elected Associates of the Society, were submitted to the Council.

Mr. HAMPSON said he would move that the ladies seeking election be elected, and, not having been present last month when this question was last discussed, he would like to say a word or two upon it. He did not quite understand what took place then, but believed a motion was made and subsequently withdrawn that the subject should be again brought before the annual meeting. The matter was therefore really in the hands of the Council for decision now. As members of Council, it was their duty to elect all eligible persons, irrespective of sex. He could quite understand there might be some delicacy in electing ladies who had not passed the examinations, but who from some accidental circumstances were in business, but the case here was very different. The lady whose case was discussed last month had passed her examination with very great credit, and was now in business, struggling with the world, and he thought they ought to render her every possible assistance the Society could afford. Probably no member of the Council would deny that there was a certain amount of advantage in being connected with the Society, and if they wished to do right they ought to hesitate before refusing admission to the Society, and so far depriving the lady of any advantage she might thus obtain. He understood that the two ladies on whose case they had to decide now had passed their examinations with great credit.

The PRESIDENT said they stood the highest on the day on which they were examined.

Mr. HAMPSON submitted the ladies had a claim on the Society to be elected. The Council might not be legally bound to elect them, because it had the power of refusal, but he thought it was bound in equity to do so, and it was with him a matter of conscience. He felt that if any ladies did embark in the business of pharmacy the Council ought rather to hold out a hand to them than throw any obstacle in their way. The two ladies in question and those who had been refused before were a credit to pharmacy, and it did not seem right that they should be debarred the use of the library and museum except on sufferance, thus denying them facilities for further advance in the occupation they had adopted. But they were told that if they did enter the school and lecture room they should be there as individuals, as it were, outside the pale and not as real pharmacists. He hoped that without further hesitation the members of the Council, feeling their responsibility, would decide to elect them almost, if not quite, unanimously. What was there to fear? He knew that at an annual meeting some years ago, when there were a great many young men in the background, there was a vote, which he denied was a reflection of the Society's opinion, somewhat adverse to the admission of women, but the Council had scarcely any right to consult an annual meeting on such a question. It had a duty to perform as the executive ; any person eligible was admissible, and there was no doubt the ladies in question were eligible and ought to be admitted without any further comment. If the Council refused to do so, it would only show the world that it did not keep pace with the nineteenth century.

Mr. HANBURY, as he had voted against the admission of ladies as members, wished to say that he thought there was a difference in the present case, as they were only seeking admission as associates. He did not want ladies as members of the Council or as office holders, but he could not see any objection to their being associates.

Mr. GREENISH had much pleasure in seconding the motion. On the last occasion he had moved that Miss Clarke be elected, but the feeling seemed to be that the

Council was bound by the decision of the general meeting. He was, on the contrary, decidedly of opinion that that general meeting did not represent the general feeling of the Society on the subject.

The VICE-PRESIDENT said the Council could not go back to the case decided last month, but with respect to the two ladies whose names were now before it, he was present when they passed their examinations, which they did most successfully, and what was very remarkable was that they surpassed all others in chemistry and attained the highest numbers by far of any examined on that day. The minimum number of marks being 600, one obtained upwards of 800. It did seem to him a most extraordinary thing that ladies who had so distinguished themselves should be debarred, not of any real substantial privilege, because they could not be prevented carrying on business, but merely of an honour and distinction which they had fairly earned.

Mr. SHAW said unfortunately he was not present at the debate last month, but he had read the report in the Journal, and was certainly surprised to find that the circumstances of having referred the question to an annual meeting three or four years ago was still one of the barriers to its being reconsidered. He submitted that the Council had no power to delegate any of its duties to an annual meeting under any circumstances. It might as well consult the Society at large with regard to the admission of honorary members, or as to additions to the schedule of poisons, or anything of that kind. He submitted that what was done at that time was simply an act of consultation with the members generally, and did not remove the responsibility of the Council and its right to act afterwards, if it thought proper; most certainly any action or delegation of duty at that time could not bind all future Councils. The bye-laws showed that parties, being eligible, on being proposed and seconded should be elected. He believed that many who voted at the annual meeting referred to were under the impression, though a mistaken one, that they were voting on the question of admitting ladies into the trade, and not membership of the Society. The Solicitor had already stated most positively that a registered chemist and druggist had a right to be elected. He was glad to see the view taken by the President at the last meeting, that the general meeting had no right to over-rule the action of the Council. Mr. Sandford, although he was not favourable to the election of ladies when the Pharmacy Bill was passed, stated that all eligible chemists and druggists would have a right to become members of the Society, and, acting on that principle, he thought ladies had a right to be elected. It had been said that this was a private Society, but he could not admit that that was the case, since it was now performing public functions, receiving fees, appointing examiners, keeping a register, and performing other public duties under the Pharmacy Act. He therefore submitted that the Society was no longer a private one in the same sense as it was formerly.

The PRESIDENT reminded the Council that if it elected these ladies as associates when they came up and passed the Major examination it could hardly refuse them membership.

Mr. ROBBINS thought the question was now becoming an important one. Mr. Shaw said the Council was not bound to act by the decision of a general meeting, but he considered that if the Council had consulted a general meeting it was so bound, and he should like reference to be made to the resolution then passed to see how it was worded. He contended that whatever that resolution was the Council was bound by it until it was rescinded, and then no doubt Miss Clarke and the other ladies would be admitted at once. His view was, that so long as a resolution of the annual meeting stood in the books unrepealed it was equivalent to a decision of the Council.

The PRESIDENT could not agree with that view. The Council appealed to the general meeting for advice and assistance, but it was left to the executive of the Society to do its duty, because it had information which a general meeting never could have. Therefore, although the Council applied to the general meeting for advice,—and that advice might be very valuable and have great weight,—he still must maintain that the Council could not delegate its duties to the general meeting.

Mr. ROBBINS said he must ask that the opinion of the Solicitor be taken on this point, as there was such a difference of opinion existing upon it.

Mr. OWEN said the general meeting elected the Council, which Council was supposed to represent the members as far as their consciences went, and no further. He should be very sorry to be sent to that Council to vote according to any general meeting whatever. Times were altering very much, and though he had always voted against the election of ladies, perhaps without consideration, he had now changed his view altogether, and thought the time had arrived when the Council should look at this question in its true light. He could not conceive what injury would in any way accrue to the Society when two ladies had come forward and distinguished themselves above all the other candidates, if they were elected as associates, and thought it would be a disgrace to the Society to refuse them. He therefore acknowledged openly he was a convert and should vote with all his heart for the election of these ladies.

Mr. BETTY said the Council had heard a great deal lately of the deterioration of commercial morality, and he was very sorry to find at that table an instance which he thought would surpass in extravagance any exhibition of inconsistency and want of faith and political morality which it had been his lot to observe in the columns of any newspaper for the last twenty years. If there was such a thing as political consistency and administrative honesty that Council was as much bound by it as any man was bound to his wife when he had entered into a marriage contract. He would impress on the Council that it was bound in honour, consistency, and morality to carry out its own promise, and he was very sorry to see certain gentlemen because they had changed their opinion change their mode of reasoning. The position in which they stood was this, that they had deliberately, on account of the difficulty they found in deciding this question amongst themselves, placed it for adjudication in the hands of the general meeting; it was not raised by accident, but deliberately put forward by the then Council, a great majority of whom were still members of the same body. It was very well to stand up for the independence and dignity of the Council, but the annual meeting having expressed the sense of the body at large, that ought not to be put on one side. They could not now sit as judges in their own cause and say they would ignore the deliberate action of the meeting because it was now in their power to rescind that vote. He did not argue that that decision was final, but he did say that the only constitutional and right way to arrive at a different conclusion would be to place the matter again before the annual meeting that the members might rescind the vote which they then passed. The argument had always prevailed amongst the members of the Council that they were morally bound to consult their constituents. He had heard gentlemen say in that room that they were not aware of those former proceedings, but now they did know of course they would abide by that decision until it was reversed; and the most straightforward plan would be to give notice to rescind that vote by the members at large. The annual meeting had as much right to have its vote brought before it again as it had to pass it in the first instance, and as the Council had thought it its duty to bring the matter before the annual meeting, it appeared to him equally clear that the annual meeting should have the opportunity of confirming or rescinding its vote.

Mr. ROBBINS referred to the charter of incorporation, page 149, in the Calendar of the Society for the present year, which stated that general meetings of the Society should be held from time to time, and that the said general meetings and the Council should have the entire direction and management of the Society, in the manner and subject to the regulations thereinafter mentioned.

The PRESIDENT said that was to be explained by the bye-laws.

Mr. SANDFORD was very much surprised to find this proposition again before the Council, it having been so much discussed at the last meeting: he did not mean the general question of the merits of ladies, but the power of the Council to elect them as members of this Society. It was quite understood, if not resolved, at the last meeting that the question would be referred to the next general meeting. The members of the Council sat there as the executive and delegates of the Society. This question was not a mere matter of routine work which could not be settled by the Society at large; if there was one point which should be referred to the members it was the constitution of the Society itself—whether it should consist of men alone, or of men and women. The general meeting having expressed such a decided opinion he thought the Council would be behaving most unfaithfully and improperly if it now proceeded to elect ladies without the consent of the general body. The Vice-President had most enthusiastically described the qualification of these ladies, but that was not the point in question. Mr. Shaw said that every man had a right to be elected, and Mr. Hampson said the Council was bound to elect everybody who applied. On the contrary, he (Mr. Sandford) said the Council was bound to consider the application of each person, but was not bound to elect him. Each one had a right to be elected if there were no disqualifying circumstances, but in this case there was a disqualifying circumstance, namely, that of sex. Mr. Hanbury said the Council might elect ladies as associates; but it could not, having done so, refuse to elect them as members; and if they were elected as members he could not see why they should not be members of the Council, or why one of them should not become President. He held that it would be most inconsistent to act in opposition to the determination arrived at last month, which would be running counter to the view of their constituents, to whom he looked for guidance in such a matter. The members of the Council were constantly told they must consider their constituents outside, and in this particular case where they knew that a strong opinion had been expressed that ladies should not be elected, he did not think the Council ought to take the matter in its own hands and elect them even as associates.

Mr. BOTTLE said he believed the general meeting referred to took place in May, 1873.

The PRESIDENT said it would be important to know who brought the subject before the general meeting; whether it was really the act of the Council or a private act. He had almost forgotten the circumstance, although he remembered very well the vote being taken.

Mr. RIMMINGTON said it was a very large meeting.

Mr. SHAW thought it would be well if the resolution of the Council were referred to.

The SECRETARY having referred to the minutes for 1873, said that a resolution was passed in February of that year, "That the question of the election of three ladies as apprentices or students of the Society be deferred until the meeting of the Council in June next," the intention being to refer it to the annual meeting in the meanwhile.

Mr. ATKINS thought the Council was, strictly speaking, an executive and not a legislative body, and he did not know that it had the slightest right to initiate any great organic change without consulting its constituents. It might be said that the annual meeting was not a fair representation of the body of pharmacy, and there was some truth in that, which he regretted, but it was the only means at present existing for testing the sense of the community on any great question. He did not think it was in the power of the Council, however strong the views of its members might be (and he confessed his own were growing stronger every year in favour of admitting ladies), to carry into execution an important organic change without consulting its constituents. He would suggest that distinct attention should be drawn throughout the country to this question, and that the Council should endeavour to elicit a distinct expression of opinion whether ladies were or were not to be introduced into the Society. He felt great reluctance in voting for a proposition which had been rejected at an annual meeting, but it would be better perhaps not to argue the question. It must, however, be distinctly understood that the Council had no power to bar the entrance of ladies to the trade; the simple question was, whether it would or would not admit them to the honours of pharmacy. As had been pointed out by the President, if ladies were elected as associates they could not be refused admittance to full membership hereafter.

The PRESIDENT thought the wisest course would be to refer this matter again to the annual meeting, calling attention to it in the report of the Council, and so elicit an expression of opinion upon it.

Mr. BOTTLE said he must confess that he viewed this question differently now to what he did a few years ago, but he also looked upon the decision of the annual meeting as binding on the Council at present, if anything was to bind it at all. In the earlier part of the year 1873 this matter was discussed at the Council, when opinion was evenly balanced, and the then President gave a casting vote against the admission of ladies, or rather for the purpose of handing it over to the meeting of the June Council, so that the question might go to the annual meeting. When the annual meeting took place the question was most distinctly raised, and there the Society had the benefit of the Solicitor's opinion, when he certainly raised the question as to whether the Society had power to admit ladies; in fact he thought it had not that power, and that if any male member chose to raise the question by *mandamus* the Society would be in a very awkward position. It therefore seemed to him most desirable that further opinion should be taken before attempting to move in the direction in which circumstances no doubt were tending. He must admit himself that he felt flattered that these two ladies had passed such an examination, and that there was great difficulty in excluding such ladies from the Society. But, on the other hand, he felt more strongly bound by the decision of the Society at large as expressed at the annual meeting in 1873. He found that no one had the courage to reopen the question at the June meeting of Council, though he had not time to discover whether or not it was done at the July meeting. On the whole, he hoped this matter would be allowed to stand over until the next annual meeting, when it might be fairly discussed, and, if the Society at large were then prepared to admit ladies, he certainly should not oppose it. But he did hope the Council would be consistent, and that having referred a matter which it felt of grave importance to the members, it would be guided, to some extent, by the decision arrived at.

Mr. GOSTLING said he would move—

"That having referred the question of the admission of ladies to the annual meeting of 1873, and such meeting having decided against such admission, this Council resolves to appeal again to a general meeting before admitting ladies to the privileges of associates or members."

The PRESIDENT said he should not accept an amendment on the question before them, it must be decided one way or the other, but Mr. Gostling's motion might be taken as a resolution afterwards.

Mr. HAMPSON in reply said he should be the last man to do anything unconstitutional. He felt that the annual meeting referred to had a certain weight, expressing a certain conviction or sentiment on the question, but it was now several years ago, and he might also say that the Council at the time did not deliberately send the question to the decision of the annual meeting, it simply waited until the annual meeting was over. He had been told by Mr. Betty and by Mr. Sandford, that it was a deliberate request of the Council to know the views of the annual meeting, but he utterly denied this. There was nothing of the kind. It was simply this, that the Council, strangely enough, could not make up its mind on a simple question like this, and had to wait until the annual meeting had expressed its views. He, of course, should be the last person to undervalue the voice of a general meeting, but since that event there had occurred important elections of members of Council, and he, and those who thought with him, had rendered themselves somewhat obnoxious on this question to certain members, but those views had not proved to be obnoxious to the members at large, since those who held them had been returned more than once, and he felt that they represented the country on this matter. The question had in this way been referred to the constituencies, and if the members at large thought the question so important they would have refused to return a possible or probable majority in favour of this line of action, but they had not done so. He also took exception to the strong language used by Mr. Betty as to the morality of the case. He felt that the morality was on the other side, and that the Council was doing an act of injustice by refusing admission to these persons; that an evil thing was being done, and the sooner it was rectified the better, inasmuch as those female members of the trade who desired to enter the Society were placed at a disadvantage. They knew that in some parts of the country the term "Member of the Pharmaceutical Society" carried more weight than the simple designation of "Pharmaceutical Chemist." And the Council therefore did an injustice in preventing any lady from using that addendum to her name. He hoped that it would act as a faithful executive in this matter. There was no organic change, and no attempt to alter the character of the institution, it was simply a fulfilment of the conditions set forth by the charter. In reply to Mr. Bottle, when he referred to the opinion of the Solicitor, he must take this exception to it, that that gentleman interpreted the Act as being favourable to women having the right to be examined, and he did not think the Solicitor's words would bear the interpretation Mr. Bottle had put upon them. More than that, some four or five years ago when he brought this question before the Society individually, he took the trouble to get counsel's opinion upon it, and he was told most distinctly that it was within the power and functions of the Council, as an executive, to elect such members. If it thought, at any time, that any individual proposed was ineligible from any cause, it did not refer the question to the annual meeting, but simply refused to elect him, and he hoped, therefore, the Council would act as executive, and pass the resolution.

The President suggested that Mr. Hampson should withdraw the motion because he did not think it would be carried, and it was a pity that a vote should be taken against these ladies. It would be much better to let the question stand over until the next annual meeting, when attention should be directed to it, and then the Council would feel justified, perhaps, in electing ladies.

Mr. Hampson said he should like the general meeting to have some idea as to the views of the Council on the matter, because he believed there was a majority in favour of the general question. He would withdraw the motion provided some one would move that the majority of the members of the Council are in favour of the admission of women, but would await the views of the annual meeting.

The President said he did not think anybody would move such a resolution as that.

The motion was then put with the following result.

For—Messrs. Churchill, Greenish, Hampson, Hanbury, Owen, Savage, and Shaw.

Against—Messrs. Atherton, Atkins, Betty, Bottle, Cracknell, Hills, Rimmington, Robbins, and Sandford.

The resolution was therefore lost.

The President and Mr. Gostling did not vote.

Mr. Bottle then moved—

"That the question of admitting ladies to all the privileges of the Pharmaceutical Society (membership or associateship), be referred to the next annual meeting of the Society."

Mr. Atherton seconded the motion.

Mr. Gostling said he would willingly withdraw his proposed motion in favour of this.

Mr. Churchill suggested the following:—

"That this Council regrets that it does not feel able to elect ladies as members of the Society until the matter has been again referred to the annual meeting."

Mr. Betty said if that were carried he should move that the next number of the Journal be printed with a black border.

Mr. Bottle's motion was then put and carried unanimously.

Reports of Committees.

Finance.

The report and recommendations of this Committee were received and adopted, and various accounts were ordered to be paid.

Benevolent Fund.

Two meetings of this Committee had been held during the month. The following grants were recommended.

£20 to the widow of a chemist, an unsuccessful candidate at the late election of annuitants.

£10 to another of the unsuccessful candidates, a widow, whose husband had received three grants of £20, £10, and £10, respectively, during the last eighteen months.

£20 to a member, aged 67, who has been unfortunate in business, and suffers from ill health.

£10 to a registered chemist and druggist, formerly in business for fifteen years.

£52 10*s.* to be placed in the hands of the Secretary, the whole or part to be used at his discretion in securing the election of an orphan child.

£26 5*s.* towards securing the election of the orphan son of a late member to the St. Anne's school.

£5 to the widow of a pharmaceutical chemist who died insane.

£10 to a registered chemist and druggist formerly in business, now suffering from acute disease.

The Committee had also discussed certain alterations in the regulations of the Fund proposed by Mr. Bottle, but no decision was arrived at.

The Committee reported that it had received letters of thanks from each of the newly elected annuitants.

Mr. Atkins desired to express to the Council the gratitude of two of the recently elected annuitants as requested by some of their relatives.

The President said he hoped Mr. Owen would assist the Secretary in the matter of the orphan elections.

Mr. Owen said he would do what he could, but it was a very hard work to be attending to more than one election at one time.

Mr. Shaw suggested that any subscriptions coming in after the election of annuitants should be carried forward to next year so as to give the donor a vote.

The Secretary said there were few or no subscriptions received after the election in each year, and he would remind Mr. Shaw that the election next year, if any, would take place in December.

The report and recommendations were received and adopted.

AMENDED REGULATIONS.

Mr. BOTTLE then moved certain alterations in the regulations of the Benevolent Fund of which he had given notice, but which he said he had somewhat modified in consequence of the discussion that had taken place in the Committee on the previous evening. He would take the two proposals separately, and would first move that:—

Rule 4, as approved and confirmed by the Council, March 7, 1877, to be changed to Rule 3.

Approved Rule 3 to be changed to Rule 4, and also to be altered as follows:—

"The following shall be the scale of pensions:—

£30 per annum to pensioners under 65 years of age;

£35 per annum to pensioners of 65 years of age and upwards.

No pension shall exceed £35 per annum."

He said he brought forward the increase in the annuities partly because he felt that the Council was pledged to it, some of the President's remarks at the dinner having committed them, not only to provide for orphans and to increase the number of annuitants, but also to increase the amount of annuities. Another reason was that £30 at the present time did not represent what it did ten or twenty years ago, and with the increased cost of living additional income was required. It was within his own knowledge that as men advanced in life they required additional means, not for food or clothing, but for attendance. He had at first proposed going still further, but he found the Committee was reluctant to limit the number of annuitants to the extent necessary if his original idea were adopted, and he had therefore limited the charge to an increase of £5 per annum on the annuitant attaining the age of 65. This would only involve an additional expenditure of about £65 per annum.

Mr. HILLS said he had much pleasure in seconding the motion.

The PRESIDENT said the question really was whether the amount given to each annuitant should be increased, or an addition made to the number of annuitants. He should like to see the annuities increased even to £40, but the number of recipients would then of necessity be restricted.

Mr. OWEN said the Society was now doing a great deal more for orphans than it had ever done before, and the question was whether it could also increase the amount expended in annuities.

The PRESIDENT thought there would be no difficulty. It was much better to spend the money in this way than to fund £500 or £600 at 3 per cent., or to give it away in casual relief.

The VICE-PRESIDENT said the question was one of degree, whether it was more desirable to add two more to the number of annuitants on the fund, or spend the same money in the way Mr. Bottle proposed. No doubt the cost of everything had increased, that £35 was not more than an equivalent for £30 some time ago. He therefore saw no objection to the motion.

Mr. HAMPSON would have been better pleased if the Committee had sent this recommendation to the Council and he was rather undecided how to vote. The Committee was in a much better position to judge of the conditions of the fund and the demands made upon it than he could be, and he would therefore suggest that the subject be referred back to the Committee. The proposal would probably receive the sanction of the Committee, but if it came back with that sanction it would be better.

Mr. ATKINS said he understood the Committee had considered the question.

The PRESIDENT said that was so, but it had not come to any decision.

Mr. ATKINS said he understood that Mr. Bottle had amended his proposals in deference to the opinions of the Committee. He should probably vote for the motion, the great argument in favour of which was that last mentioned by that gentleman, that the aged required more attendance. There was no doubt that as persons got into advanced life they required very often skilled and careful nursing, which was very expensive.

Mr. GREENISH would prefer the question being sent back to the Committee. He could not help expressing his opinion as opposed to Mr. Bottle last evening, when he found the amount required annually would be from £130 to £150, which would enable them to put five more annuitants on the list. Mr. Bottle's present views were certainly modified, but he still opposed them and should be much better satisfied to see two further annuitants elected rather than the amount increased.

The PRESIDENT hoped the next Council would see its way to increasing the number of annuitants to thirty, and that the fund would be properly supported by the members at large.

Mr. RIMMINGTON thought there was no fear of the means being too limited to give the increase proposed, also to add two more annuitants, because the subscriptions were increasing.

Mr. ROBBINS supported Mr. Bottle in his very moderate demands. He had for some time given this matter his attention and had intended to include it in his own amendments proposed some time ago, but that he thought it better not to mix up different things. Of course if the money were spent in one way it could not be spent in another, but he thought it would be much better to increase the amount of a certain number of the annuities rather than to multiply the annuities. The number mentioned by the President would cost £900 a year, and he thought it would be well to spend another £100 in the way Mr. Bottle proposed.

Mr. BETTY said Mr. Bottle was perfectly right in saying that, in modifying his resolution, he was virtually expressing the views of the majority of the Benevolent Fund Committee. He thought the present suggestion was a compromise which met the exigencies of the case very effectually. This matter had been referred to by the Chairman at the Benevolent Fund dinner, when the suggestion was very warmly received, and he saw no necessity for referring it back to the Committee.

Mr. BOTTLE said he should be the last man to propose anything that had not been thoroughly discussed by the Committee, but he had modified his proposal to meet the views of the Committee, and the object of agreeing to it at once was that otherwise there would be delay in getting the amended regulations printed.

Mr. HAMPSON moved an amendment—

"That Mr. Bottle's resolution be referred back to the Benevolent Fund Committee for consideration and report."

Mr. GREENISH seconded the amendment.

On a division the amendment was lost, only two members voting for it, and the original motion was put and carried.

Mr. BOTTLE then moved—

"That the clause in the regulations of the Benevolent Fund, empowering the Council to *provide* a home for orphan children should be amended so as to enable the Council to *assist in providing* a home for orphans."

Mr. HILLS seconded the motion. He said that he found that the Council had bought stock to the amount of £1700 from the dinner fund, and £300 from the ordinary receipts. This produced £60 per annum, which would almost cover the extra outlay occasioned by the preceding motion.

The motion was agreed to.

Proxies at Benevolent Fund Elections.

The PRESIDENT read a letter from a gentleman at Shanghai to Mr. Hanbury, requesting him to act as his proxy at elections of Annuitants. This raised the important question of proxy voting, on which Mr. Hanbury intended to have moved a resolution but had had to leave.

Mr. HILLS then moved that the following be added to the regulations:—

"That any person entitled to vote but residing abroad may exercise the privilege of voting by proxy, provided that the person authorized is also entitled to vote on his own behalf, and that his name and address have previously been given to the Secretary."

Mr. CRACKNELL seconded the motion.

Mr. SANDFORD thought it would be extremely unreasonable to object to receive a proxy from any one who was prevented by any reason from signing his own voting paper.

Mr. SHAW and Mr. ATKINS supported the proposal. The latter saw no reason for confining the privilege to those resident abroad.

The PRESIDENT said he could see no objection to this proposal. If it was found necessary it could be enlarged or modified next year.

The motion was then carried unanimously.

Regulations of the Benevolent Fund.

The amended regulations of the Fund which will come into operation on January 1st, of next year, are as follows:—

1. To provide pensions for distressed persons who are or who may have been members or associates of the Society; for pharmaceutical chemists; for chemists and druggists; or for the widows of such persons.

To afford occasional grants of money to distressed persons who are or who may have been members or associates of the Society; or pharmaceutical chemists; or chemists and druggists; or their widows or orphan children.

2. At the meeting of the Council in October, in every year, the expediency (financially) of electing pensioners in the following December shall be considered, and in the event of an election being determined on, the decision of the Council, stating the number of annuitants to be elected, and the date on which the election shall take place, shall be made known by advertisement in the *Pharmaceutical Journal and Transactions*, and such other papers as the Council may direct.

3. Every candidate for election must be at least fifty years of age.

4. The following shall be the scale of pensions:—

£30 per annum to pensioners under 65 years of age.

£35 per annum to pensioners 65 years of age and upwards.

No pension shall exceed £35 per annum.

5. Every petitioner for relief from the fund shall produce a certificate of moral character, and such evidence of his or her age as shall be satisfactory to the Council of the Society; and shall also state the time and place or places in which he or she has been engaged in business, whether on the petitioner's own account or otherwise; how his or her misfortunes originated, and when; the present means of subsistence; the number of persons (if any) dependent upon him or her for support; and any other particulars the Council may require.

6. Every widow who is an applicant for relief shall produce evidence of her age, the *certificate of her marriage*, and the *certificate of the burial of her husband*, or such evidence as shall satisfy the Council on these points; she shall also state the period during which her husband was in business, and where; the cause of misfortune, and the present means of subsistence; the number of children (if any) dependent on her for support; and any other particulars the Council may require.

7. Every application on behalf of an orphan shall state his or her age and afford satisfactory evidence of the marriage of the parents, and burial of the deceased parent or parents; and if any and what provision exists for the maintenance of such orphan; the application to be accompanied by a certificate signed as required by clauses 8 and 9, and any other particulars the Council may require.

In the case of an orphan left under circumstances of urgent distress, the Council may, if it thinks fit, provide, or assist in providing, a home by purchase in one of the public asylums for orphans.

8. In all petitions for assistance from the fund, except those specified in clauses 7 and 9 the truth of the statements therein contained shall be certified by at least four members of the Society, or donors to the fund of five guineas, or persons who have subscribed not less than half-a-guinea per year for the three preceding years, and who are personally acquainted with the facts of the case.

9. In the case of a widow or orphan applying for relief and unable to obtain the required evidence under rule 8, the Council will receive and consider in lieu of such evidence the testimony of four respectable householders, to whom the circumstances of the applicant are known, provided that the persons so certifying are respectively subscribers or donors to the fund of not less than half-a-guinea for the current year.

10. All applications for relief or assistance shall be submitted to a Committee of the Council, to be called the Benevolent Fund Committee, previous to being laid before the Council.

The Council, after due investigation, if satisfied that the case is an eligible one, will decide on the amount and character of the relief to be afforded.

When the Council shall decide that any case is fitting for annual pension, the case shall be recorded in a book, to be kept for that purpose, and immediately after the decision as to the expediency of electing pensioners (but not previously), notice shall be given to the persons whose names are so recorded.

11. Should any subscriber or donor, or the widow of any subscriber or donor, become a candidate for an annuity, such number of votes shall be placed to his or her credit, at the first succeeding election, as shall be represented by the whole amount of subscriptions or donations to the Benevolent Fund he or she (or in the case of a widow, her husband) may have contributed.

12. The votes recorded for any unsuccessful candidate shall be carried to his or her credit at succeeding elections.

13. Pensions will be withheld or terminated by the Council if at any time it shall be evident that the election of any annuitant has been secured by fraud or by false representation; or in case of any misconduct on the part of the recipient; or in the event of his or her forestalling by assignment future payments; or if the improved circumstances of the pensioner at any time shall appear to the Council to disqualify him or her to receive the benefits of this fund. Pensions to widows will cease if they marry again.

14. At each election of annuitants contributors to the fund shall have *one vote* for each half-crown subscribed annually, but the number of votes shall be increased to *five votes* for half-guinea, and in the same proportion for each half-guinea subscribed beyond that sum.

15. Persons contributing five guineas at one time shall have *five votes for life* at each election of annuitants, the right of voting at such elections being increased in the proportion of *one vote* for every guinea contributed.

16. Firms or corporations contributing five guineas at one time shall have *five votes* at each election of annuitants for the period of *ten years* from the date of such contribution, the right of voting at such elections being increased in the proportion of *one vote* for every guinea contributed.

17. Persons or firms giving donations of *less* than five guineas, shall have *five votes* for every half-guinea subscribed at the ensuing election of annuitants.

18. One executor paying a legacy of fifty pounds shall have *five votes for life* at each election of annuitants, and if the legacy amount to one hundred pounds, or upwards, each of the executors shall have the same privilege.

19. Persons subscribing on or before the day of election, will be entitled to vote thereat.

20. Every member of the Society and every associate of the Society in business on his own account, not in the receipt of nor an applicant for relief from the fund, shall have two votes at each election of annuitants, and every associate not in business on his own account, who is not in the receipt of nor an applicant for relief from the fund shall have one vote at each election of annuitants.

21. Every person entitled to vote in more than one class of voters shall be entitled to the votes due to him from each of such sources.

22. The votes shall be taken by the voting papers, which shall be sent prior to the election to every member, associate, donor, and subscriber entitled to votes under clauses 14, 15, 16, 17, 18, 19, 20, and 21.

23. Any person entitled to vote, but residing abroad, may exercise the privilege of voting by proxy, provided that the person authorized is also entitled to vote on his own behalf, and that his name and address have previously been given to the Secretary.

24. The voting papers of members, associates, and subscribers whose payments are in arrear shall be withheld until the subscriptions be paid.

25. At every meeting for the election of annuitants, the chair shall be taken by the President, or Vice-President, or by a member of the Council for the time being, and five or more scrutineers shall be elected from the voters present to examine the voting papers, and report to the chairman the number of votes polled for the respective candidates.

26. Should any voting paper not be properly filled up or signed, the same shall be rejected by the scrutineers.

27. In the event of an equality of votes, the chairman shall have the casting vote.

28. The voting papers and scrutineers' lists shall not be open to the inspection of any person without permission from the Council.

29. Should a second scrutiny be demanded or any complaint made in reference to the result of the poll, the same shall be submitted to the consideration of the Council at its first subsequent meeting, and its decision shall be final.

Form of Bequest to the Benevolent Fund.

"*I give and bequeath the sum of* *unto the* PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, *the same to be paid out of my pure personal estate, and to be applied for the purposes of the* BENEVOLENT FUND *of the said Society.*"

N.B.—Devises of land and bequests of money savouring of realty, or in other words connected in any way with land, will be void.

LIBRARY, MUSEUM AND LABORATORY.

The Librarian's report showed that from July to October, the highest attendance, both during the day and in the evening, was 21. The circulation of books had been, in London, 204; country (to 40 places), 70. A list of books missing from the library was presented, which was directed to be advertized. They are as follows:—

Bentley's 'Manual of Botany,' 3rd ed., 1873.
'British Pharmacopœia,' 1867.
Hoblyn's 'Dictionary of Medical Terms,' 7th ed. 1855.
Mohr and Redwood's 'Practical Pharmacy,' 1849.
Pharmaceutical Journal, vol. vi., 1846-7.

The following books were recommended for purchase:—

General Fund.

Wood and Bache's 'United States Dispensatory,' 14th ed.
De Crespigny's 'New London Flora.'
Miller's 'Chemical Physics,' 6th edition.
Squire's 'Companion to the Pharmacopœia,' 11th ed.
Schlickum's 'Die wissenschaftliche Ausbildung des Apothekerlehrlings.'
Falck's 'Uebersicht der Speciellen Drogenkunde.'

Hanbury Fund.

Hanbury and Flückiger's 'Histoire des Drogues d'Origine Végétale, traduit par De Lanessan.'
Pritzel's 'Thesaurus Literaturæ Botanicæ,' ed. nova.

The Librarian had also presented a report on the conference of librarians recently held in London, and it was resolved that the librarian be authorized to become a member of the "Library Association of the United Kingdom," then initiated, and that the annual subscription of half a guinea be paid by the Society. Also that the Library Journal, containing the proceedings of the Association, be subscribed for.

The Curator's report showed that the average attendance in the Museum had been, in the day, 15; evening, 3, in July. For August and September the totals only were given. He also reported that the index to the catalogue was in the printer's hands, and that the specimens of Indian and other drugs were ready for placing in the museum. Duplicate specimens having accumulated in the museum, it was resolved that a list of such specimens be sent to the North British Branch for selection, and a list of the remainder published in the Journal, so that provincial associations might have an opportunity of applying for the same.

It had also been resolved that a list of additions to the museum be published annually, in the same way, and at the same time as the additions to the library.

Professor ATTFIELD had reported that the laboratory had opened favourably, an unusual number of ten months' pupils having entered.

The other professors attended the Committee, but stated that they were not yet able to give information as to the probable number of students in their classes.

All the professors expressed their willingness to deliver lectures at the evening meetings during the ensuing session.

The PRESIDENT drew attention to what he believed was a common misapprehension as to the value of the Bell Scholarship. It was stated to be of the value of £30 annually, but when to this, which is the money value, was added the value of the laboratory instruction and lectures which were given free, and the present of books from Mr. Hills to each scholar, the value was over £66.

Mr. SHAW suggested that a note to this effect should be inserted in the calendar.

Mr. GREENISH did not see how any misconception could arise. No one reading the Journal could possibly misunderstand the value of the Bell Scholarship. He also wished to remark, in reference to the report of the Committee, on the growing expenditure for the carriage of books into the country, which was very satisfactory, as showing that the country members appreciated the value of the library.

The report and recommendations of the Committee were received and adopted.

THE BOARD OF EXAMINERS.

A resolution was passed that as the Board of Examiners for the ensuing year must be appointed at the next meeting of the Council it is desirable that any member of Council who is desirous of nominating any pharmaceutical chemist as an examiner should send the name of any such person to the Secretary before the 22nd instant. That the Secretary be instructed to communicate with any persons whose names may be suggested as suitable persons for examiners, asking if they will accept office if elected.

HOUSE.

The report of this Committee was received and adopted.

LAW AND PARLIAMENTARY.

The report of this Committee included a report from the Solicitor on cases which had been entrusted to him. In one case the offending party had remitted the amount of penalty, with five shillings toward costs. Several cases of alleged infringement were considered by the Committee. A report had been submitted by the Sub-Committee appointed in February last, to consider if any amendments were desirable in the Pharmacy Act, 1868, which it was decided to present to the Council without adoption. The Committee also recommended that the addition of chloral hydrate and its preparations to part 2 of schedule A of poisons, be submitted to the Privy Council for approval, but that no other poisons be added to the schedule at present.

On the motion for the adoption of the report,

Mr. BETTY moved as an amendment that the report of the Sub-Committee above referred to should be adopted and not merely received.

An animated discussion ensued on this point, the result of which was that the report of the Committee was received and adopted, and it was agreed to adjourn the discussion of the Sub-Committee's suggestions until next month, an abstract of those suggestions to be sent to each member of the Council in the meanwhile.

A formal resolution was also passed, declaring that chloral hydrate and its preparations be deemed poisons within the meaning of the Pharmacy Act, 1868, to be placed in part 2 of schedule A.

REPORT OF EXAMINATIONS.

October, 1877.

1 University of Oxford.

PHARMACEUTICAL MEETING.

Wednesday, November 7, 1877.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting were read and confirmed.

The following donations to the library and museum were announced, and the thanks of the Society were awarded to the donors :—

To the Library.—'Catalogue of Scientific Papers,' vol. vii., from the Royal Society of London ; 'Calendar of the Royal College of Surgeons of England,' 1877, from the College ; Flückiger and Hanbury's 'Pharmaeographia,' and Hanbury's 'Science Papers,' from Thomas Hanbury, Esq., through the British Pharmaceutical Conference ; Walcott's 'Natural History,' 1795, from Mr. J. F. Savory ; MS. Receipt Book, and MS. 'Descriptions and Medical Properties of Plants, with Impressions of their Leaves in Oil,' from Mr. P. L. Simmonds ; 'Inaugural Address delivered at the London School of Medicine for Women,' by Mrs. Garrett Anderson.

To the Museum.—Specimens of fine and coarse powder of the root of *Rheum officinale*; Fine specimen of Crystallized Salicin, from Messrs. Morson and Son ; Specimen of Indian Senna from Madras, consisting of the leaves, etc., of *Cassia obovata*, from Dr. Forbes Watson ; Specimen of Curacoa Aloes and Mafura Seed, from Monsieur C. Chantre ; Specimen of the Pods of *Balsamocarpon brevifolium*, from Thomas Christy and Co. ; Specimens of Boomah Nuts, Loomoonderfall, the seeds of *Cassia Tora*, leaves of *Barosma ericifolia*, and the fruits of *Calophyllum inophyllum*, from the Curator.

The Indian drugs and other donations announced last month were also placed on the table.

Mr. HOLMES said, with regard to the large number of Indian drugs presented by Professor Dymock, in illustration of papers in the *Pharmaceutical Journal*, and which were placed on the table, that each bottle had a label giving a full account of the contents, but one or two of them deserved special notice.

One of these was a kind of aconite root which seemed entirely new ; it had an odour like that of horseradish, was very bitter, but possessed no acridity. There was also a specimen of the ayapana, a plant which grew both in the East and the West Indies, and had been grown for many years in the Mauritius. Concerning the introduction of the plant to the Mauritius, an interesting account was given in the Bouton's 'Plantes Médicinales de Maurice,' which with the permission of the Chairman he would read.

"Captain A. Baudin, brother of the captain who commanded the expedition round the world, brought this plant to the Mauritius in 1797. When at Rio Janeiro, hearing the ayapana spoken of as a panacea, he made all possible efforts to procure slips, but could not succeed, even though he offered its weight in silver. He resolved therefore to carry off surreptitiously during the night a plant which he had seen on a balcony in the town. This was easily effected by a sailor armed with a long pole, and the ship setting sail immediately after, Captain Baudin made off with his treasure. He had hardly arrived in the Mauritius, where the wonderful virtues of this plant had already been published, when each invalid thought himself already cured, and eagerly sought for some of the drug, addressing themselves to the Director of the State Gardens, M. Céré, to whom the cultivation was entrusted. Those who were fortunate enough to grow the plant were soon able to dispose of the leaves at the rate of three sous each in the market. This reputation was maintained for some time, but then a reaction set in, as is usual in such cases, and went from one extreme to another ; and when the plant had been sent to Paris and analysed, many tried to prove that it had no energy whatever. 'Its odour is aromatic,' said one, 'but to a moderate degree ; the same with its bitterness. There is a little astringency, but all its properties are so feeble that it is difficult to believe that it can produce any effect on the animal economy.' Nevertheless, the ayapana continued to enjoy a certain reputation amongst medicinal plants. Every one knows the great use made of it in the outbreaks of cholera in 1855 and 1856, even by prescription of physicians. It is also in every day use in the form of an infusion in cases of difficult digestion, derangement of the stomach, etc. The crushed and macerated leaves mixed with honey and wine also form a valuable application for wounds, contusions, etc., both in the human subject and animals, particularly horses."

There were also specimens of chaulmoogra oil, a plate and description of which plant were given in the present number of Bentley and Trimen's 'Medicinal Plants.' These samples were particularly valuable, because they were prepared by the donor, who is in business as a chemist in the Mauritius, and were therefore known to be pure. M. Loumeau, who sent them, said, in a letter which accompanied the specimens, that the oil imported from India was the only kind which gave satisfaction in the Mauritius for leprosy; these specimens were prepared in his own laboratory, and he should like to know from his old tutor, Professor Attfield, how to detect adulteration in the oil imported from Calcutta, no test being given for it in the Pharmacopœia, in which it was not official.

Another donation he would call attention to was a specimen of Turkey rhubarb grown in England. He doubted himself whether it was the source of East India and Turkey rhubarb, but it was supposed to be so in part by Professor Flückiger and other authorities. The two specimens in coarse and fine powder were equal in colour to the East Indian, but had a slightly different odour. Lastly, he would draw attention to a fine specimen of salicin from Mr. Morson.

The PRESIDENT said there was a time when salicin all came from Germany, but, owing to the great demand, manufacturers in this country were now making it extensively. He desired to call special attention to the value of the collection of Indian drugs sent by Professor Dymock.

Professor BENTLEY also bore strong testimony to the value of the Indian collection. He was at present working, in conjunction with Dr. Trimen, on medicinal plants, and could therefore appreciate the value of such collections. A museum such as theirs should not only represent the materia medica of the present day but to some extent that of the future, and it was only by getting a good collection of specimens from different countries that they could hope to attain this result. He trusted that before long they would have in separate collections in the museum, at all events, the materia medica of the Indian Pharmacopœia and that of the United States. Nothing could be more interesting than such separate groups, and he was sure their energetic Curator would agree with him in this opinion. He perhaps spoke somewhat selfishly, as he was engaged on a work dealing not only with the materia medica of the British Pharmacopœia, but also with that of India and the United States, but still his labours he hoped would be of benefit to others, and it was very important that there should be opportunities of studying specimens of the drugs referred to. The chaulmoogra oil, of which specimens were now on the table, was well known in India, where it was much used for leprosy and scrofula, but up to the present time it had been extremely impure. The seeds were also used both externally and internally, in various cutaneous and other diseases. The specimens, however, now shown did not at all resemble those he had seen from India, which were fluid and of a colour resembling sherry in appearance. He might call the attention of Professor Attfield, if he took up this subject, to a valuable paper by Dr. Dymock, which had appeared in the Journal, wherein he mentioned sulphuric acid as being a good test of its purity. Pure oil would turn, first a burnt sienna colour and then olive-green under the action of sulphuric acid, whilst other oils gave very different reactions. Another plant figured in 'Medicinal Plants,' was *Eupatorium perfoliatum*, which was also in the museum. It was official in the United States Pharmacopœia, and in his opinion, was a medicine well worth a trial in this country. It was much valued in influenza, being called popularly "bone-set," in relation to the effects which a severe attack of influenza often produced.

Professor ATTFIELD felt sure that the confidence which M. Loumeau seemed to feel in the Society and its officials would not be misplaced, and then whatever could be done in the laboratories or other departments towards placing the pharmacopœia of India on a sound footing would be tried; and he hoped this would have a good effect on the materia medica of the future also.

The Chairman then called upon Professor Redwood to read a paper on—

THE POISONOUS PROPERTIES OF YEW LEAVES.

The paper is printed on p. 361, and gave rise to the following discussion.

The PRESIDENT in moving a vote of thanks to Professor Redwood, drew attention to two specimens of yew on the table, one Irish, the other the common variety.

Professor REDWOOD said there were also specimens of the chopped leaves taken from the stomach of the deceased, and also of the digested leaves which had passed into the intestine.

The PRESIDENT said it appeared pretty evident that the mere infusion was practically inert, and as plants of this order generally yielded oleoresins, or bodies of that class, a mere infusion could not be expected to be active. It was well known that the Irish yew was exceedingly dangerous to animals, but it was also consistent with what they knew before, that this woman had to take the plant itself before any ill effect arose, the mischievous quality being probably contained in some oleoresinous body which was not soluble in water. Thus euphorbium was known to be very active although perfectly insoluble in water, but soluble in alkalies and alcohols. The taxine, he observed, was called an amorphous alkaloid.

Professor REDWOOD said it had been called an alkaloid, but he was not prepared to say it was a true alkaloid.

The PRESIDENT said it would probably turn out to be one of those resinous acids which were known to be very active as medicinal agents, such as scammonin and jalapin. He trusted the question would be further investigated, as it was very important. He should like to know if the ordinary yew had the same power, as he had not found that it was poisonous.

Professor ATTFIELD believed there was at least one well recorded instance in which a large quantity of the decoction had proved to have a fatally poisonous effect. He also knew from his own experience that the berries were poisonous when swallowed whole, although it remained to be proved whether the poisonous principle was contained in the fleshy part of the fruit or in the seed, or in both. Some years ago a case of poisoning from eating yew berries occurred in the neighbourhood in which he was then residing, near Finchley, some fifty or sixty being found in the stomach or intestines of the child after death. There were very many instances in which the eating of the leaves had produced strongly marked poisonous effects. It had been stated by Lucas and Maviné that the yew leaves and the fruit contained a poisonous alkaloidal crystalline principle termed taxine, very slightly soluble in water, but freely soluble in dilute acids and in chloroform, petroleum, and spirituous liquids generally. If these observations were correct it would follow that a large quantity of the decoction would have to be taken to produce poisonous effects. They also stated, if he recollected rightly, that taxine was to be found in the fruit, but in a much smaller quantity than in the leaves. It would follow that if the leaves got into the stomach the taxine would be attacked by the acid it there met with, and would be thus absorbed by the system.

Professor BENTLEY said this was an interesting subject, and one upon which a great variety of opinion had been expressed. He had known of undoubted cases of poisoning from yew leaves, and he was glad that Professor Redwood had taken up the subject, because a great many erroneous notions had prevailed upon it. Some said the yew leaves contained a poisonous principle, whilst others denied it altogether, and said their action was simply mechanical. In 'Medicinal Plants' his colleague, Dr. Trimen, and himself had gone into the subject, summing up, as far as they could, the information already obtained. The question was very interesting, not only to pharmacists, but more especially to veterinary surgeons, for there could be no doubt that where animals browsed upon the yew, whether in the green state or lying on the ground dry, it had acted distinctly as a poison. He had no doubt either that the seed was poisonous, but at the same time he was convinced that the fleshy covering around it was was perfectly innocuous. As a boy he had eaten this over and over again, and he did not think Lucas found any poisonous principle in the pulpy parts; in fact he did not remember that he had analysed the fruits, although they had been analysed, and the analysis went to show that the external covering was innocuous though the seeds were poisonous, containing a bitter resinous principle which he had no doubt was the bitter principle found by Lucas in the leaves. It was not, however, described in the older analysis he referred to, as an alkaloid, but as a resinous principle, and he had so described it about a year and a half ago. Since then a paper had been published in the *Journal of the Chemical Society*, by Mavin é, on 'Taxine,' in which he gave a readymethod of obtaining it, and distinctly called it an alkaloid. He was not chemist enough to say whether it was alkaloidal or resinous, but it was evident the subject required further investigation. He believed Maviné was the first who discovered taxine in the seeds though he found it in larger quantity in the leaves. Physiological experiments on the action of this body were also much needed. Dr. Pereira had mentioned the medical action of yew, and there was no question it was a powerful substance, and if it possessed the sedative effect of digitalis which had been ascribed to it, without the cumulative quality which rendered that so dangerous, it would be a most valuable agent.

Professor ATTFIELD said Maviné's paper was published in the early part of the present year, and it stated that the fruit, not distinguishing between the pulp and the seeds, contained less taxine than the leaves. It remained to be ascertained whether the pulp or the seed contained the taxine, which Maviné, if not Lucas, distinctly stated was crystalline and alkaloidal.

Mr. GREENISH remarked that in an old work of great repute on the Continent, 'Kosteletzky's Flora,' it was distinctly stated, that the poisonous property of yew was resident in the leaves, the fruit being used for making a syrup which was given as a sedative in chest complaints. It also stated that the seeds were bitter and poisonous. Peretti found in the leaves a volatile oil, and a bitter principle. According to Lucas the active principle is a white amorphous bitter powder, to which he gave the name "Taxin." In 1859 this matter had been examined by Schroff, who stated that the leaves were exceedingly poisonous, and that they possessed an acrid property and a narcotic property, one of which was soluble in alcohol and ether, and the other in water.

Mr. GERRARD said he had been engaged during the last few weeks in making pharmaceutical preparations of yew, for the use of Dr. Ringer who intended to investigate the subject physiologically. He had exhausted about fourteen pounds of the dry leaves of the common yew with alcohol and then with water, and endeavoured to separate the extracts into their various constituents. He had obtained a body which as far as its external appearance went seemed to be an alkaloid, but chemically it did not appear to be so, it possessed more of the property of a glucoside. This was dissolved out by chloroform, and the mother liquor was then treated with ether. The chloroform residue, although precipitated by phosphomolybdate of soda and nitric acid was not precipitated satisfactorily by any other alkaloidal reagents. It reduced alkaline cupric tartrate, was slightly soluble in water, and did not form, as far as he could tell, salts with acids. If, however, he took ten grains of this residue, and added one drop of dilute nitric acid with water, he obtained at once an acid solution. This he thought was pretty good proof that it was not an alkaloid. He did not say that benzol or bisulphide of carbon might not extract an alkaloid, but he thought it doubtful.

Mr. NAYLOR remarked that while the fruit of the Irish yew could not be eaten with impunity by horses, it could be by those animals which did not crush their food. For instance, pigs had been known to eat these berries to a considerable extent. This would tend to show that the active principle did not reside in the fleshy portion, but in the seed. He had known animals killed by eating the common yew also.

Mr. PRINCEP said he had known the berries of the common yew eaten with impunity, but he could not say whether the seeds were swallowed.

Mr. POSTANS said the subject was a very interesting one. A belief very commonly prevailed that the young shoots might be eaten without harm. It was therefore important that the question should be cleared up.

Mr. G. S. TAYLOR said he had eaten large quantities of the fruit as a boy and had seen others do the same, but never knew any ill effect to follow, but they never chewed the seeds. He should like to ask Professor Redwood whether it was a decoction or an infusion of the yew which was used in the case he had referred to. It was possible that the active principle might be extracted by continued boiling when it would not by ordinary infusion.

Professor REDWOOD said he had employed the term "yew tea," because that was used by Dr. Alfred Taylor, who spoke of its being used as a popular therapeutic agent amongst a certain class of persons he named. The preparation taken by the woman referred to was a decoction which had been boiled for some length of time. It was stated that a large handful had been put into two quarts of water; he found three and a half pints of decoction left, and obtained about three ounces of leaves and twigs after they had been dried, so that he calculated that about six ounces had been employed. It was not, however, until the leaves were swallowed that the poisonous effects were produced.

Professor ATTFIELD asked what was the quantity of leaves taken.

Professor REDWOOD said he had stated that already. There was no evidence to show that anything was thrown off the stomach, though there had been retching; but everything was carefully preserved, and there was no attempt at concealment of any kind. Both the man and his wife were much respected, and he felt that every reliance could be placed on the statements made. He estimated that about twenty grains of the leaves were found in the stomach mixed with about three ounces of half-digested food; but in the duodenum there was a hard compact mass of the leaves which weighed about half an ounce.

Mr. LONG remarked that in the playground of the school he attended in Oxfordshire there were several yew trees, and the boys constantly ate the fruit. Whether they always spat out the seeds he could not say, but he never knew any bad results follow.

Mr. HOLMES briefly described the differences between the common English and the Irish yew, the former being abundant on chalky soils throughout Kent and Surrey. It was the English probably which generally acted as a poison in this country, the former having branches spreading more or less horizontally, and the leaves equally distributed, while the Irish variety had erect branches with leaves more or less tufted, whence its name "fastigiata." The Irish yew was not unfrequently to be seen in gardens and shrubberies, might be easily recognized by its peculiar cypress-like habit. The English yew was common in hedges or chalky soils in Kent and Surrey and occasionally on limestone; in other counties the Irish variety. He knew children frequently ate the berries without harm, and a short time ago he noticed a quantity of the seeds lying under a yew tree, which he imagined had been thrown away by the birds after having eaten the pulp. With reference to the cumulative action of digitalis mentioned by Professor Bentley, he had recently seen it stated in a medical journal that this was due to defective action of the kidneys, which in health would eliminate the poison. With regard to the taxine which Mr. Gerrard spoke of, as far as he could gather, two substances seemed to be obtained, one an amorphous powder and the other a crystalline. It occurred to him that the amorphous powder might be the natural salt and the crystalline one the alkaloid obtained from it. Had Mr. Gerrard tried the action of test paper on taxine?

Mr. GERRARD said he had, but with no result.

The PRESIDENT said he did not believe any harm would arise even if the seeds were swallowed, provided they were not crushed. He would remind the audience that the alkaloids acted mainly on the nervous system, but it was evident that the poison of the yew, which had been fatal in this and many other cases, was of a local character producing local inflammation, which was just the character of the irritant oleoresinous bodies, and he apprehended this would turn out to be the nature of the poisonous principle in this case.

The next paper read was—

SOME FURTHER REMARKS ON SWEET SPIRIT OF NITRE.

BY F. M. RIMMINGTON.

Mr. RIMMINGTON stated that his first paper which appeared in last week's Journal had been intended to be read at the meeting of the Society, but by mistake had first appeared in the Journal. He, however, wished to read the following paper as a supplement to the other:—

The paper is printed at p. 362, and gave rise to the following discussion:—

The PRESIDENT asked Mr. Rimmington how he arrived at the percentages of the ether.

Mr. RIMMINGTON said he took a four ounce flask fitted with a bent tube, and adapted it to a small Liebig's condenser. About 250 grains of fused calcium chloride were introduced into the flask, together with spirit. Distillation was then commenced, and the distillate collected in a 1000 grain flask. The quantity distilled varied according to the quality of the spirit. If it were a strong spirit, such as that of the 1747 Pharmacopœia, it would be necessary to draw over 300 gr. before it all came over, but if it were a weak spirit, such as that usually sold, it would be only necessary to draw over 60 or 70 grains. He used the decem measure, which was easily converted into cubic centimetres if required. It was in fact a fractional distillation. It might be a question whether he got all the ether over, but this was proved by the fact that if distillation was carried further clean spirit was obtained, and sulphate of iron gave no indication of nitrous ether with what was left in the retort. There might be a small loss, but it was very small. He reckoned if he got 4 per cent. of nitrous ether from 100 grains of the pharmaceutical spirit he had lost 1, which would make 5. His results differed considerably from the statements of others as to what different spirits contained or should contain. For instance, Professor Attfield stated 10 per cent., but he had not found anything of the sort. He had found as small a quantity as three or four per cent. of ether.

Professor ATTFIELD wished to ask Mr. Rimmington how he knew that the distillate obtained on heating sweet spirits of nitre in a retort was wholly nitrite of ethyl. He could quite understand that when he tested the residue in the retort, and found no nitrite of ethyl there, he came to the conclusion that it had all passed over, but he did not understand how he satisfied himself that what had passed over was wholly nitrite of ethyl. It had been stated by some experimenters that when the chloride of calcium test was applied to sweet spirit of nitre, if 2 per cent of ethereal liquid was obtained it might be considered that 10 per cent. of that same ethereal liquid, whatever it might be, was present in the sweet spirit of nitre, but he feared that no one knew what the ethereal liquid contained. The statement in his 'Manual,' referred to by Mr. Rimmington, was not taken from his own researches, but was merely given as the statement of others, and he himself had yet to learn what that ethereal fluid was. Experimenting in the way that the author of the paper had stated, and using the term nitrite of ethyl for the liquid which he obtained by his process, he took it Mr. Rimmington wished it to be understood that sweet spirit of nitre was and ought to be a solution of nitrite of ethyl. But he must confess after making scores of experiments with large quantities, both before and after the dilution with spirit of wine, he himself had no conception what sweet spirit of nitre was formerly, what it was now, or what it ought to be in the future. He was casting no slur on the compilers or the able editor of the Pharmacopœia in saying this, because he found it there stated that it was a spirituous solution "containing nitrous ether." This was quite true. Reading further he found it now stated in the paragraph headed "Characters and Tests," that this so-called spirit of nitrous ether, when agitated in a closed tube with chloride of calcium, yielded 2 per cent. of its original volume not of nitrite of ethyl, but of "an ethereal liquid." It seemed from these words that the editor of the Pharmacopœia knew as well as he did that this ethereal liquid was not wholly and solely nitrite of ethyl. What grounds had Mr. Rimmington for regarding his distillates as nitrite of ethyl?

Professor REDWOOD said he felt that Mr. Rimmington had attempted rather too distinctly to define what the ethereal substance contained in sweet spirit of nitre was, and that they had gone as far as it was safe to go in the description given in the Pharmacopœia. He recollected when he brought forward and explained the process which was now adopted in the Pharmacopœia that a gentleman present came up to him afterwards and said he thought it was a very nice process, but there was one defect in his account of it, namely, that he had not clearly explained the nature of the decomposition and reaction that took place, and the composition of the product which was obtained. He was fain to plead guilty to that imputation, and his answer was that he should be very glad to give the explanation if he had possessed the knowledge, but being in ignorance on both those points all he could say was that a sweet spirit of nitre so produced was a product which could be obtained with ease and certainty, for he always made it at his lectures, and the process went on by itself, which was not the case with any of the previously described processes. It always gave a definite result, though what it was had hitherto eluded their investigation. It contained nitrite of ethyl, aldehyd, and probably other compounds, but in what proportion it was extremely difficult to indicate. All they could say was that it always contained the same proportion of the same ingredients. Some said that sweet spirit of nitre was of no medicinal value, but to that he could not agree. It was one of his favourite remedies, and he believed it to be a most valuable therapeutic agent. They knew, moreover, that one at least of the other nitrites, the nitrite of amyl was a very valuable and powerful therapeutic agent, and whatever the efficacy of sweet spirit of nitre, their knowledge must depend upon experimental observation. It was established in the public favour, the public would continue to ask for it, and medical men would continue to prescribe it. It was the duty of the Pharmacopœia, therefore, to supply a process which would enable the manufacturer to produce it in a definite condition.

The PRESIDENT thought Mr. Rimmington's critics had been somewhat unfair to him in their remarks. It was not necessary that he should clearly explain what the oily liquid which floated on the chloride of calcium was. In the Pharmacopœia they were given to understand, at least by inference, that it was looked upon as nitrite of ethyl, and he did not think Mr. Rimington was to blame for assuming that it was so. The real point of his observations was that he took a portion of sweet spirit of nitre, distilled a certain part of it and from that fraction he got a result which, by a slight calculation, gave him the composition of the original liquid This was the really important point which he had brought forward.

Mr. Rimmington wished to ask Professor Attfield what the stuff was if it was not nitrite of ethyl? He knew that Dr. Pereira said such a decomposition took place, but he had not analysed this product to see whether it was true nitrite of ethyl or not. He assumed, as others had done, that it was perhaps not perfectly pure, but tolerably so. He did not believe that aldehyd was separable by chloride of calcium.

Professor Attfield said the only answer he could give to the question was to state again, that he did not know what the product was, but he knew it was not pure nitrite of ethyl although it contained that substance. Mr. Rimmington's distillate probably contained a large quantity of alcohol and, he must add, aldehyd, etc. He, the speaker, and his assistants, had operated on many ounces, he might say pounds of the ethereal fluid separated from spirit of nitrous ether by chloride of calcium, but he did not yet know what the liquid was. It had been assumed to be wholly nitrite of ethyl, but there was no evidence whatever in support of that statement. He was in a position to say that it contained a large proportion of aldehyd, some alcohol and certainly less than half its bulk of nitrite of ethyl; but no one could yet state its exact composition.

The next paper read was entitled—

Notes on Casual Drugs.

BY E. M. HOLMES.

The paper is printed on page 362.

The President drew attention to a small bottle of oil which he had obtained from the seeds of the calophyllum, the process being exhaustion by benzol. He had operated on the kernels of 30 seeds weighing altogether 6 ozs., from which about ½ oz. of oil was obtained.

The Chairman then announced that the next evening meeting would be held on Wednesday, December 5th.

Provincial Transactions.

CHEMISTS AND DRUGGISTS' ASSOCIATION.

Report of Committee Meetings.

A meeting of the Finance Committee of the Association was held at the office, 23, Burlington Chambers, New Street, Birmingham, on November 2, 1877, at 10·30 a.m.

Mr. Thomas Barclay, Vice-President, in the chair.

The Secretary reported that the Association had a balance at its bankers of £869 13*s.* 5*d.*, and that there were about 3450 members on the Register.

A meeting of the Law Committee was held at the office, on November 5, 1877, at 1 p.m. Mr. S. U. Jones, President, in the chair.

The brief of arguments for the appeal in the case of the Apothecaries' Company *v.* Shepperley, drafted by the Solicitor after consultation with counsel, was read and approved. The Solicitor said he had retained three counsel to undertake the argument in the appeal, namely —Sir Henry James, Q.C., Mr. Buszard, Q.C., and Mr. Clement Higgins.

The Solicitor then explained the steps that had been taken in the case of the Apothecaries' Company *v.* Wiggins.

The Secretary reported having received that day a communication from a member residing at Bradford in Yorkshire, stating that proceedings had been commenced against him by the Apothecaries' Company for alleged infringements of the Apothecaries Act, 1815, and that he was summoned to appear at the Bradford County Court, on the 13th inst. The Committee instructed the Secretary to make full inquiries respecting this case.

The Secretary said that in compliance with a resolution passed at the last meeting of the Law Committee, he had taken proceedings under the 17th section of the Pharmacy Act against three unregistered vendors of poisons, and that in each case the offenders were fined by the magistrates.

The case of a firm of chemists, members of the Association, who had been summoned for selling soda water and cayenne pepper said to be adulterated, was then fully discussed, when it was moved by Mr. Jervis, seconded by Mr. Barclay, and unanimously resolved:—"That the Solicitor be instructed to defend members in the summonses taken out against them under the Adulteration Act, 1875, for the sale of soda water and cayenne pepper."

The Secretary said it would be within the recollection of the Committee that a scheme for organization, prepared by him, was submitted to the general meeting of the trade in connection with the Association, held at Glasgow, on September 8, 1876, when a resolution was passed adopting the scheme, subject to such modification as the executive may deem desirable. The portion of the scheme relating to Scotland had been amended by the Scotch Committee, and confirmed by the Executive Committee at its meeting on February 28th last. The remainder of the scheme was submitted to the Executive Committee at its meeting on May 25th last, when a resolution was passed leaving its consideration in the hands of the Law Committee. The scheme for England and Wales, as amended by the Secretary, was then laid before the Committee and approved.

The most suitable time for holding the first election of the General Committee, and the best means of conducting the same was debated, when it was moved by Mr. Southall, seconded by Mr. Jervis, and unanimously resolved:— "That the Secretary be instructed to issue a printed copy of the scheme for organization to each member of the Association, with a circular and voting form, requesting him to nominate and vote for a member of the General Committee (or so many as may be allotted to the district in which he resides), as explained by the scheme; the circulars, etc., to be forwarded to the members not later than the 10th of December next, with instructions that the voting forms must be filled up and returned to the Secretary not later than the 31st of December next.

The Secretary was empowered to engage the services of Messrs. Laundy, Harrison, Harris, and Caldicott, the official auditors of the Association, to superintend the elections, and declare the results of the same.

It was moved by Mr. Holdsworth, seconded by Mr. Barclay, and unanimously resolved:—"That a report of the appeal in the Apothecaries' Company *v.* Shepperley be printed and circulated to all chemists and druggists named on Kelly's 'Chemists' Directory.'"

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, November 1st, Dr. Gladstone, President, in the chair. The minutes of the previous meeting were read and confirmed. The list of presents to the Library was read, and the thanks of the Society given to the respective donors. The following certificates were read for the first time: W. J. Williams, W. D. Harland, A. H. Elliott, H. R. Hind, H. B. Mason.

The following papers were communicated to the Society:—

1. "*a.*" "On some Hydrocarbons obtained from the Homologues of Cinnamic acid," and "*b*" "On Anethol and its Homologues," by W. H. Perkin, F.R.S. "*a.*" Considerable quantities of cinnenylacrylic crotonic angelic and phenylcrotonic and angelic acids were prepared. The

hydrocarbons were at first obtained by decomposing the acids by heat, afterwards the process proposed by F. Binder, viz., treating the hydrobromo acids with bases, was found to yield more satisfactory results. A solution of hydrobromic acid in glacial acetic acid, instead of an aqueous solution answered very well. The following acids were prepared and examined—hydrobromocinnenylacrylic acid, $C_{12}H_{15}BrO_2$, fuses 85° to 87° C.; hydrobromocinnenylcrotonic acid, $C_{13}H_{17}BrO_2$, crystallizes in flat oblique prisms, fuses at 148–150° C., on further heating HBr is evolved; hydrobromocinnenylangelic acid, $C_{14}H_{19}BrO_2$. All these hydrobromo acids when treated with a cold solution of sodium carbonate or potassium hydrate decompose, hydrocarbons being produced as follows:—Isopropylvinylbenzene boils at 203–206° C., sp. gr. at 15° ·8902. Heated for a few hours to 150° C. it solidifies to a transparent glassy mass. This change also takes place slowly at ordinary temperatures in daylight. The properties and chemical reactions of this substance are given. The dibromide was prepared, fusing at 71°. Isopropylallylbenzene, boils at 229° to 230°, sp. gr. at 15° ·890, does not solidify at 15° C.; its formation may be represented thus:—

$$C_6H_4\ (C_3H_7)\ CH{=}CH.\ OH_2\ COOH =$$
Cinnenylcrotonic acid
$$C_6H_4\ (C_3H_7)\ CH{=}CHCH_3 + CO_2$$
Isopropylallylbenzene
$$\text{or } C_6H_4\ (C_3H_7).\ CH_2\ CHBr.\ CH_2\ COOH =$$
Hydrobromocinnenylcrotonic acid
$$C\ H_4\ (C_3H_7)\ CH{=}CHCH_3 + HBr + CO_2.$$

Its dibromide was obtained by shaking the hydrocarbon with bromine. It melts at 59° to a colourless oil, crystallizing beautifully on cooling. Isopropylbutenylbenzene is a colourless oil, boiling at 242–243°, its sp. gr. at 15° is ·8875. It resinifies if kept in contact with air. Its dibromide was prepared, melting at 77°. Allylbenzene boils at 174–175°, sp. gr. at 15° ·9180; when heated between 160°–200° for sixty hours it did not undergo any visible change; its dibromide was obtained as a crystalline mass, fusing at 67°; butenylbenzene, a colourless oil boiling at 186–187° C.; a dibromide was prepared crystallizing in needles melting at 67°. The two last named hydrocarbons have already been obtained: allylbenzene by L. Rügheimer (*Journ. Chem. Soc.*, 1874, p. 894); it has the same constitution as the body prepared by the author. The butenylbenzene; however, prepared by B. Aronheim (*Deut. Chem. Ges. Ber.*, v., 1068), is isomeric with the one now produced. "*b.*" On gently boiling methylparoxyphenylacrylic acid, an oil gradually distils over, having a fennel-like odour. This body, after purification, had the formula $C_9H_{10}O$; the author proposes to call it vinylic-anethol; it boils about 201 to 202°, melts at about 1 to 2°. Its formation may be represented thus $C_6H_4\ (OCH_3).\ CH \underline{\quad} CH\ COOH = C_6H_4(OCH_3).CH \underline{\quad} CH_2 + CO_2$.

An endeavour was made to prepare this substance by Binder's reaction, but without success. On heating methylparoxyphenylcrotonic acid an oil distils over, carbonic acid being evolved; by fractional distillation, freezing, and pressing the mass thus obtained between blotting paper, perfectly pure allylic, or ordinary anethol, was obtained, identical with that obtained from oil of anise. By heating methylparoxyphenylangelic acid butenylic anethol is obtained in an impure state, but by treating the hydrobromo derivative of that acid with sodium carbonate, etc., perfectly pure butenylic anethol is obtained. It is crystalline, fusing at 17° C., boiling at 242–245°; sp. gr. at 30° ·9733; formula, $C_{11}H_{14}O$. In conclusion, the author discusses the formation of the hydrocarbons from the hydrobromo acids by heating with sodium carbonate; he finds that silver nitrate in aqueous solution, sodium acetate, and, in some cases, even water, may be substituted for sodium carbonate, and yet the hydrocarbon be formed, and concludes that the hydrocarbons are formed simply by the separation of hydrobromic acid and carbonic anhydride. The author remarks that only the hydrocarbon and anethol containing vinyl polimerize when heated, and form compounds corresponding to metacinnamene; also their boiling points differ much more from those of the compounds containing allyl than do the latter from those of the butenyl compounds.

Dr. Gladstone said that the Society had rarely listened to a research so productive of new and interesting substances, and pointed out the interesting results which would probably be obtained by an examination of the refraction and dispersion of these new bodies.

The thanks of the Society were then given to the author for the above paper.

Dr. Armstrong then read a paper by M. M. P. Muir, "On Two New Methods for Estimating Bismuth Volumetrically." Chancel has shown ('Jahrber,' 1860, 612) that bismuth is precipitated in the form of phosphate by the addition of a soluble phosphate to a solution of the metal in nitric acid. Both processes are based on this fact. In the first bismuth is thrown down from nitric acid solution, after partial neutralization with ammonia, by addition of a standard solution of sodium phosphate; the final point of the reaction is determined by spotting the supernatant liquid on a slab with warm ammonium-molybdate solution. The results are approximately accurate. In the second process the nitric acid solution of bismuth is mixed with an excess of sodium acetate, a measured volume—excess—of standardized sodium phosphate is added, the liquid boiled and filtered, the precipitate is well washed with hot water, and the excess of phosphoric acid determined in the filtrate by titration with a standard solution of uranium acetate. The results are very accurate. This second method is much to be preferred to the first, and is much more satisfactory than the author's dichromate process (*Chem. Soc. Journ.* i., 1876, 483).

The next paper was also read by Dr. Armstrong "On the Oxidation of Ditolyl," by T. Carnelly, D.Sc. Last year in the production of tolylphenyl the author obtained a quantity of liquid and solid ditolyl as a bye-product, by fractionating solid ditolyl, melting at 121° C.; and two liquid ditolyls boiling about 275 and 285° were obtained. These substances were oxidized with chromic and glacial acetic acids; solid ditolyl gave on oxidation, first, diparatolylphenylcarbonic acid—

$C_{12}H_{18} \begin{cases} CH_3 \\ COOH \end{cases}$ as a white powder melting with blackening at 244°; and secondly, diparadiphenyldicarbonic acid $C_{12}H_{18} \begin{cases} CO{\cdot}OH \\ CO{\cdot}OH \end{cases}$

The two liquid ditolyls gave identical results on oxidation, first, ortho-para-tolyl-phenyl-carbonic acid.

$C_{12}H_{18} \begin{cases} CH_3 \\ COOH \end{cases}$ a white powder melting at 170° C.; and, secondly, orthopara-diphenyl-carbonic acid—

$C_{12}H_{18} \begin{cases} COOH \\ COOH \end{cases}$ a white powder which sublimes before fusing, and finally terephthallic acid. The above experiments show that when sodium acts on a mixture of para and orthobromtoluene, two isomeric ditolyls are produced, the dipara and the orthopara compounds. The author gives graphic formulæ showing the constitution and relations of the above bodies, and concludes by stating that he hopes to be able to prepare the diorthoditolyl from it, obtain by oxidation diphenic acid, and thus confirm the constitution of phenanthrene.

The last paper was entitled, "Note on a New Manganese Reaction," by J. B. Hannay. When a solution of a manganous salt in strong nitric acid is warmed with the addition of crystals of potassic chlorate, the whole of the manganese is precipitated as manganous manganate. If a salt of iron be present a double manganate of iron and manganese, $2\,Fe_2(MnO_4)_3$, MnO, MnO_3, $12\,H_2O$ is precipitated, no other metals seem to be precipitated with manganese under the same conditions. The precipitate is insoluble in nitric and sulphuric acids and unattacked by caustic alkalies. Hydrochloric acid acts on it and reducing agents rapidly decompose it. Sulphurous acid first attacks the iron, setting free manganese dioxide, which rapidly collects into little nodules, having a considerable degree of coherence. The manganese slowly disappears, the final reaction being—

$$Fe_2(MnO_4)_3 + 6 \cdot SO_2 = Fe_2(SO_4)_3 + 3\ MnSO_4.$$

The principal interest in the above reaction is that it furnishes a good method of separating iron from aluminium, etc., without the use of pure caustic soda. The iron compound appears under the microscope as thin flexible plates of a purple-brown colour.

Mr. Groves remarked that nothing was said by the author as to the effect of the presence of phosphoric acid on the reaction.

After the thanks of the Fellows had been given to the authors of the above papers the Society was adjourned to November 15, when the following papers will be read:—

1. "On Gallium," by Professor Odling.
2. "First Report to the Chemical Society on some points in Chemical Dynamics," by Dr. Wright and Mr. Luff.
3. "On the Influence exerted by Time and Mass in Certain Reactions in which Insoluble Salts are Produced," by M. M. Pattison Muir.
4. "On two New Fatty Acids of the series $CnH_{2n}O_2$," by C. T. Kingzett.

Parliamentary and Law Proceedings.

Death from a Narcotic.

On Monday, Oct. 22, an adjourned inquest was held at Weymouth, on the body of Mr. Frank Cole, commercial traveller, who was found dead in his bed. Since the adjournment the stomach, lungs, etc., of the deceased had been in the hands of Mr. Stoddart, analyst, of Bristol, it being the opinion of Dr. Lush that deceased had died from some poison. The day after the inquest, the chemist who sold the draught which the deceased had taken before lying down for the night, made a statement to the Coroner as to what the draught contained, consequently the Coroner decided that the analyst should not proceed with his examination.

The adjourned inquest was held at the Guildhall, and the proceedings lasted several hours, all the medical gentlemen of the town and neighbourhood being present, besides a large number of the inhabitants.

Dr. Moorhead and Dr. Henry Tizard both stated that they had together made a *post-mortem* examination of the body of the deceased, and that they had found the heart in such a state of fat as likely to cause death any day; had heard from Mr. Gregory that he had given a sleeping draught containing a narcotic. They had both known Mr. Gregory for several years, and believed him to be a careful chemist. Dr. Moorhead said he had never known Mr. Gregory to make a mistake.

The inquiry lasted until a quarter after nine o'clock, and very considerable interest was manifested as to the result.

The Coroner very carefully summed up the evidence, alluding particularly to the statements of the medical gentlemen, who were of different opinions, three being of opinion that the deceased died from natural causes, and two that the poison in the draught hastened his death.

The jury retired, and after a short absence, returned with the verdict:—That the deceased died by misadventure: that the draught given by the chemist hastened his death; but that at the time he took the draught he was in a very dangerous state of health." It was the opinion of some of the jurymen that the draught stopped the action of the heart, the deceased being in a sickly state when he took it.—*Western Morning News.*

Prosecution under the Sale of Food and Drugs Act.

At the Pontypridd Petty Sessions, held at the Court House, Pontypridd, on the 31st of October, Mr. John Davies, chemist and druggist, was summoned for two offences under the above Act.

The superintendent of police stated that he went to the shop of Mr. Davies and asked him to supply him with half a drachm of sulphate of quinine and half an ounce of calomel. After the goods were supplied the superintendent informed the vendor that the drugs had been purchased for the purpose of analysis, and that he intended to send one third of the quantity to the county analyst. He also offered to leave one-third part with Mr. Davies. Mr. Davies declined, on the ground that he had enough of the same sort. He wished to put his own label on the samples and did so, putting "quinine" on one packet and "calomel" on the other, delivered both samples to Mr. Scott, the county analyst, and now produced two certificates. The calomel was certified by Mr. Scott to contain traces of bichloride of mercury, and the quinine to contain slightly more than 21 per cent. of cinchonine.

Mr. Davies, on being sworn, said: I am a chemist at Pontypridd. I recollect Mr. Matthews purchasing some quinine of me. I gave it to him out of a bottle, the one produced. I bought it of Howard and Sons, Stratford, London. It is labelled "Sulphate of quinine, prepared by Howard and Sons (late Howard and Kent), Stratford, London." I sold it in precisely the same state as I received it. I never had any cinchonine in my possession. I never mixed anything with the quinine I received from Howard and Sons. The calomel was also sold by me exactly in the same state as I received it in the bottle produced. He (Mr. Davies) stated that, with reference to the calomel, he sold it as he bought it. The perchloride of mercury would be about the same price, and sixteen times the strength, so that there would be no advantage or profit in mixing or adulterating it. He had, however, not sold all the contents of the bottle from which the perchloride had been taken. He had forwarded samples to Professor Attfield, London, and Mr. Thomas, the borough analyst, Cardiff, and both certified that the samples were pure.

The Bench believed that Mr. Davies had not had cinchonine in his possession, so that he could not have mixed it with the quinine; and, further, they were of opinion that a respectable tradesman like Mr. Davies would not be likely to jeopardize his position and prospects by committing the offence with which he was charged. They, therefore, dismissed the case.

Correspondence.

"*Opium.*"—Nothing of importance is left in the marc.

W. N. G. L.—We think the fault must be in the manipulation.

W. P.—Nitric acid is supplied in which nitrous acid would be present as an impurity.

D. Dickinson.—Jenkins'. 'Electricity and Magnetism,' published by Longmans, price 3*s.* 6*d.*

A. F.—Parchment paper made from good sound unsized paper may be used. A parchment paper specially prepared for dialysing purposes is, we are informed, made by Messrs. Rube and Co., Weende, near Gottingen.

J. A.—Numerous recipes for cements, have already appeared in the present series of this Journal, and may be found by referring to the index. A solution of 1 part of aluminium in 10 parts of water, mixed with 80 parts of strong mucilage of gum arabic has been recently recommended.

Communications, Letters, etc., have been received from Dr. Morel, Professor Dymock, Mr. Bateman, Mr. Pooley, Mr. Ackerman, Mr. Stevens, Mr. Thresh, Mr. Laurie, Mr. Cardwell, Mr. Mackay, Mr. Bassett, W. T. T., F. H. B., H. R. M., J. B., A. H., G. H., M. P. S., W. F. F., Tom, Subscriber, Nemo, Omega.

ABNORMAL WATERS.

BY A. J. COWNLEY, F.C.S.

Whilst the condition of the London potable waters, as regards their freedom from impurity, has been very rigidly and ably controlled by the periodical issue of their analyses by the Rivers Commission, there seems to have been no attempt made at any official supervision of a class of waters of not less sanitary importance. I allude to the waters that are used by the public in certain of the metropolitan swimming baths. This investigation was made after having obtained the result of the analysis of the water No. 2, which had been used by an adult subject, who subsequently exhibited symptoms ascribable to the condition of this water.

Samples of the waters were taken from the baths by a competent person, on days at the latter end of the week during the month of August, when the temperature of the air ranged between 68° and 70° Fahrenheit. The earlier publication of this paper has been delayed by unavoidable circumstances.

For the sake of convenience in expressing the results of analysis I have used the terms ammonia α and ammonia β to express the ammonia yielded by sodic carbonate and that yielded by alkaline potassic permanganate respectively.

Water No. 1. This water was inodorous but turbid.

	Parts per 100,000.		Grains per gallon.
Ammonia α	·078	equal to	·054
Ammonia β	·019	„	·0133
Chlorine	1·60	„	1·12
Total Solid Contents	27·50	„	19·25

No. 2. The sample of water was decidedly offensive in smell and was turbid.

	Parts per 100,000.		Grains per gallon.
Ammonia α	·054	equal to	·037
Ammonia β	·030	„	·021
Chlorine	25·72	„	18·00
Total Solid Contents	93·00	„	65·10

No. 3. Inodorous but turbid.

	Parts per 100,000.		Grains per gallon.
Ammonia α	·04	equal to	·028
Ammonia β	·03	„	·021
Chlorine	1·40	„	·98
Total Solid Contents	30·00	„	21·00

No. 4. Very clear and inodorous.

	Parts per 100,000		Grains per gallon.
Ammonia α	·026	equal to	·018
Ammonia β	·027	„	·019
Chlorine	1·23	„	·86
Total Solid Contents	30 00	„	21·00

No. 5. Inodorous and free from turbidity: contained moving organisms.

	Parts per 100,0C0.		Grains per gallon.
Ammonia α	·014	equal to	·0098
Ammonia β	·029	„	·02
Chlorine	12·12	„	8·48
Total Solid Contents	97·00	„	67·90

No. 6. Inodorous: slightly turbid.

	Parts per 100,000.		Grains per gallon.
Ammonia α	·015	equal to	·0105
Ammonia β	·011	„	·0077
Chlorine	3·71	„	2·59
Total Solid Contents	25·00	„	17·50

No. 7. Clear, colourless and inodorous.

	Parts per 100,009.		Grains per gallon.
Ammonia α	·014	equal to	·0098
Ammonia β	·018	„	·0126
Chlorine	1·48	„	1·03
Total Solid Contents	27·00	„	18·90

General Remarks.—In every case the solid residue remaining on evaporation blackened more or less considerably when ignited gently. The large quantity of chlorine in No. 2 and No. 5 points to an impure source of supply. The lesser degree of impurity shown by No. 7 is due to some sort of supervision which is exercised by the parochial authorities.

An opinion may be formed of the condition of the waters under examination from the following analysis of a sample of Thames water collected near the Temple; it was filtered through filter paper before being analysed :—

	Parts per 100,000		Grains per gallon.
Ammonia α	·04	equal to	·028.
Ammonia β	·028	„	·019.

On the supposition that we are justified in demanding that these waters should be equal in purity to a potable water, and should not then contain more than ·002 part ammonia α, and ·007 part ammonia β per 100,000 parts of the water, the proportional amount of impurity in these waters is expressible by the formulæ $\frac{\alpha}{\cdot 002}$ and $\frac{\beta}{\cdot 007}$.

	$\frac{\alpha}{\cdot 002}$	$\frac{\beta}{\cdot 007}$
Potable Water	1·0	1·0
Water No. 1	39·0	2·7
„ „ 2	27·0	4·2
„ „ 3	20·0	4·2
„ „ 4	13·0	3·9
„ „ 5	7·0	4·1
„ „ 6	7·5	1·6
„ „ 7	7·0	2·6
Thames Water (filtered)	20·0	4·0

Whilst recognizing the necessity of not fixing too high a standard of purity for waters of this class, yet these results, showing three and nearly four of them to be more highly polluted than Thames water which had been freed from suspended matter, are so excessively abnormal, when compared with a potable water, that no other conclusion is warranted but that these waters are too impure to be allowed to be used for the purposes to which they are applied. It is to be remarked, further, that as the subsequent experiments prove that by the human pollution of a water the resulting ammonia β is greater than ammonia α, whereas in these waters the contrary is the rule, they must have been exposed in a polluted condition to atmospheric action for a time sufficient to have passed through this change. This deduction of course only holds good for the primarily pure waters and not for those whose source is polluted.

To express these results in a more concrete form would be to ascertain the number of units which represents the human pollution these waters have undergone. The following experiments are to that end.

A water was examined before and after pollution by a human subject who had allowed twelve hours to elapse since a previous matutinal bath.

I.—3·5 gallons taken.

	Ammonia α Grains per gall.	Ammonia β Grains per gall.
After	·0084	·0938
Before	·0014	·0049
Pollution added per gall.	·007	·0889

Total pollution = ·007 × 3·5 = ·0245 grains α
and ·0889 × 3·5 = ·311 grains β.

II.—Twenty-four hours had elapsed since the subject of experiment had passed through experiment I.: there is very nearly a proportional increase in the products obtained. 3·5 gallons of water taken.

	Ammonia α Grains per gall.	Ammonia β Grains per gall.
After	·0161	·1442
Before	·0014	·0049
Pollution added per gall.	·0147	·1393

Total pollution = ·0147 × 3·5 = ·051 grains α
and ·1393 × 3·5 = ·487 grains β.

Under these conditions, therefore, human pollution was eliminated which is expressed by—

·051 grains ammonia α
·487 " " β

III.—This experiment is merely noticed as showing the possibility of obtaining pollution in a more concentrated form.

In this case the same volume of water (viz.: 3·5 gallons) was used twice within a period extending over eighty-four hours, and subsequently to the subject having passed through expt. II.

	Ammonia α Grains per gall.	Ammonia β Grains per gall.
After	·1260	Not ascertained.
Before	·0056	
Pollution per gall.	·1204	

or = ·12 × 3·5 = ·42 grains ammonia α.

It is to be noticed here that the increase in the amount of ammonia α is not in proportion to the increase of II. over I.; partly to be explained by the decomposition which had taken place during the period the water had been exposed to the air as in the case of the waters, No. 1 to No. 7.

As a fair unit to represent the standard of human pollution I have taken twice the sum of ammonia α and ammonia β obtained in expt. II. or $2(\alpha+\beta)$.

Then if x = sum of $\alpha+\beta$ yielded by each water and y = sum of $\alpha+\beta$ yielded by each water when primarily pure;

also if 100,000 gallons be the volume of each water, and they are in most instances above this volume, then

$$\frac{x-y}{2(\alpha+\beta)} \times 100{,}000$$ equals the number of human subjects who eliminating impurity equal to the standard have contributed to its pollution. This number will of course decrease as the amount added by each unit increases; that is to say, the number deducted from the formula $\frac{x-y}{2(\alpha+\beta)}$ × the volume will not represent an absolute number, if the units which have contributed to the pollution of each water be of a higher degree of impurity than the tandard allows for.

On these data the following results are obtained:—

Water No. 1.

Grains per gallon.	Grains per gallon.
·054	·0014
·0133	·0049
x = ·0673	y = ·0063

x − y = (·0673 − ·0063) = ·061 Grains per gallon.

From expt. II., α = ·051
β = ·487

$2(\alpha+\beta)$ = ·538 × 2 = 1·076

then

$$\frac{x-y}{2(\alpha+\beta)} \times 100{,}000 = \frac{.061 \times 100{,}000}{1·076} =$$

nearly 5600 units of pollution

Water No. 2 similarly

$$\frac{·0517}{1·076} \times 100{,}000 = 4800 \text{ nearly.}$$

No. 3.

$$\frac{·0427}{1·076} \times 100{,}000 = 4000 \quad ''$$

No. 4.

$$\frac{·0307}{1·076} \times 100.000 = 2800 \quad ''$$

No. 5.

$$\frac{·0235}{1·076} \times 100{,}000 = 2200 \quad ''$$

No. 6.

$$\frac{·0119}{7·076} \times 100{,}000 = 1100 \quad ''$$

No. 7. The volume of water is taken at 50,000 gallons.

$$\frac{·0161}{1·076} \times 50{,}000 = 750 \text{ nearly.}$$

In the following table the results which I have obtained in this investigation are recapitulated and speak for themselves as to the necessity of requiring that every medical officer of health shall include in his functions the official control of the public swiming baths in his district. Who can say what source of propagating zymotic disease is more easy of development?

Parts per 100,000 parts of the waters.	Ammonia yielded by sodic carbonate.	Ammonia yielded by subsequent treatment with alkaline potassic permanganate.	Chlorine.	Total solid contents.	Proportional amount of impurity taking α in a potable water as being equal to ·002 per 100,000.	Proportional amount of impurity taking β in a potable water as being equal to ·007 per 100,000.	Human pollution per experiment II., et seq.

THE TINCTORIAL POWER OF SOME PHARMACOPŒIA PREPARATIONS.

BY WILLIAM GILMOUR.

(*Continued from page* 181.)

In following out the inquiry into the relation existing between the tinctorial power and the actual strength of some Pharmacopœia preparations, the interest attached to most opium preparations led me to continue the investigation more immediately in this direction. For this purpose a number of commercial samples were obtained and subjected, in the first instance, to an examination colorimetrically, after which, as in previous experiments, the amount which each yielded of dry extractive was determined. This method of procedure was of course here intended only to give an approximate idea of the relation existing between the colour, power, and strength, and not as in any way expressive of an absolute conclusion. This may follow, but in the meantime it is sufficient, as already indicated, that we call attention, in the first place, to the somewhat important general agreement between the two (colour-power and strength in extractive), and in the next place to the sufficiently important variation which both point out as existing in commercial samples of these preparations.

1st.—Tincture of Opium.

Sampl	Transmitted Light.	Dry Extract.
1	46°	5·2 per cent.
2	48°	4·4 „
3	52°	4· „
4	55°	3·2 „
5	57°	3·8 „
6	58°	3·5 „

It should here be noted (and it shows how an investigation frequently widens in the process) that a considerable variation existed in the spirit strength of some of the tinctures, doubtless accounting to some extent for the variation existing in some cases betwixt the amount of transmitted light and dry extract. At least, there was a much closer relation betwixt the two in the case of the liquid extract, and this we think can only be reasonably accounted for on some such supposition. The various samples in table 2 were all made from commercial extract of opium, and with the exception of sample 1, which was made from a dry and nearly hard extract, the samples were all very much alike in appearance, consistence, etc.

2nd.—Liquid Extract of Opium.

Sample.	Transmitted Light.	Dry Extract.
1	46°	4·3 per cent.
2	50°	3·7 „
3	53°	4·4 „
4	53°	4· „
5	58°	3·6 „
6	59°	4· „

The relation betwixt the two columns was still more marked in the case of Battley's solution of opium. Three different samples of this preparation were examined, and in all a very close approximation in strength, both colorimetrically and in extractive, was obtained.

3rd.—Battley's Liquor Opii.

Sample.	Transmitted Light.	Dry Extract.
1	45°	5·8 per cent.
2	46°	5·4 „
3	47°	5·2 „

Now without unnecessarily dwelling on the difference in strength of the foregoing samples it may simply be pointed out that in the case of tincture of opium presumably made by the ordinary chemist and druggist the extreme variation in the six samples was in the case of transmitted light 12° and of dry extract two per cent., but in the case of the liquid extract of opium made from ordinary extract presumably obtained through some wholesale manufacturer, the variation was in the light transmitted 13° and only ·8 of dry extract. Being anxious to test a sample of tincture made under our personal care with the foregoing results, four pints were "set agoing" as an experiment. Filtered, pressed, made up to measure and estimated the result obtained was,—transmitted light 57° and dry extract 4·4 per cent. as against 53·7° transmitted light and 4·01 per cent. dry extract, the average of the six samples. Of more importance, however, was the fact that the marc after being subjected to the ordinary pressure (and which in its damp state weighed only a little over three ounces) on being again re-digested for twenty-four hours with 5 oz. spirit yielded a tincture which gave 65° transmitted light and three per cent. dry extract. The wisdom of the plan pursued by some manufacturers of first digesting the marc of the old preparation in the spirit of the new previous to adding the fresh opium is thus thoroughly demonstrated and commends itself for more general adoption.

As one practical outcome of these experiments let us now take a preparation of opium, the strength of which cannot readily be estimated by any simple process of analysis, and see how it compares with these results. We have seen that the average of transmitted light in the six samples of tincture was nearly 54°, and this was amply confirmed as a fair average by the tincture specially prepared and examined for the purpose. Now if we take for example liniment of opium, we *à priori* assume that it should transmit much more light than this, from the fact that the tincture of opium in this preparation is diluted in equal proportions with a comparatively colourless tincture. This, however, scarcely squares with the actual facts as shown in the following table:—

4th.—Liniment of Opium.

Sample	1	Transmitted Light	47°
„	2	„ „	54°
„	3	„ „	55°
„	4	„ „	57°
„	5	„ „	66°
„	6	„ „	66°
„	7	„ „	71°

As a matter of fact, whatever the remainder may have been, the first two or three liniments in this table could not possibly have been made according to Pharmacopœia instructions. This was more than confirmed by the decidedly alkaline reaction which some of the liniments gave on being tested; and without entering more immediately into the matter, this probably indicates the method of their preparation as well as accounts for the depth of colour which they exhibit.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 162.)

ABUTILON INDICUM.—*Local name*, PETAREE; *the* TUBOCUTY *of Goa.*

The bark of this shrubby plant is used in Goa as a diuretic; it occurs in long, thin, tough, fibrous strips, which are very strong and seem worthy of attention as a fibre. Externally it is striated and covered by a cinnamon-coloured epidermis; internally it is white and striated; the striæ appear to be produced by small interspaces between the fibrous bundles of which the bark is composed. The drug has a feebly astringent taste, and by some is considered to be slightly bitter. The plant is a very common one and appears to flourish in poor soil and require but little water; it is quite distinct from the variety which produces bulbij.

Althæa officinalis.—*Local name of flowers,* Gul Khairo; *root,* Risha i Khitmi; *seeds,* Tukm i Khitmi.

These three articles are imported into Bombay from Persia; the flowers have by some been attributed to *A. rosea,* but the carpels which may be found mixed with them have not the membranaceous margin of those belonging to that plant, and the exterior calyx has from eight to nine divisions instead of six. The greater part of the drug consists of the calyx, which is double, with the half mature petals attached, but some fully developed flowers are to be found, and occasionally a nearly mature fruit. The calyx is thick and covered with simple hairs very closely set, and arranged in star-like tufts; the flower has five petals, which in the dry article are of a bluish-green colour at the base, the blades being purple; both calyx and flowers are mucilaginous. Gul khairo is used in cough mixtures. The root known as khatmi appears to me to be the same as the guimauve of the French, but it is not decorticated, nor is it so plump and free from fibre; it is used for the same purposes as that drug. Tukm i khatmi consists of the carpels, which are dark brown, ear-shaped, about three-tenths of an inch in the longest diameter; their external surface is hairy and furrowed; the flat sides are also studded with white simple hairs, and the margin is plaited. The interior of the carpel is polished and of a grey colour; it contains one dark grey seed, similar in shape to the carpel, with a dull yellow kernel. Tukm i khatmi is mucilaginous.

Malva sylvestris.—*Local name,* Khabazee.

The fruit is a common bazar drug and is imported from Persia. It consists of from ten to twelve glabrous wrinkled carpels, each containing one reniform seed. Some of it is mature, but at least half is in various stages of immaturity. A portion of the thin papery calyx is attached to the fruit. In a good fresh sample a few deep blue flowers may be seen, as well as a number of peduncles of unequal lengths, and occasionally a petiole surmounted by the five-nerved base of the leaf. Although I have not raised the plant from seed I think there can be little doubt that this drug is derived from *M. sylvestris.* Khabazee is mucilaginous.

Viola, Sp. ?—*Local name,* Gul i Banafsha.

The blossoms of a dark blue violet, mixed with a few leaves and fragments of the plant. They have the same appearance as those of the common scented blue violet of Europe.

Viola, Sp. ?—*Local name,* Kishmiri Banafsha.

Consists of small knotted pieces of rhizome, to some of which flowers and leaves are attached; the former appear to have been white originally. I am inclined to think this drug identical with the scented white violet of Europe.

Clerodendron infortunatum.—*Local name,* Kari.

The leaves of this plant are noticed in the 'Pharmacopœia of India,' as a cheap and efficient tonic and antiperiodic. They are also said to be used as a vermifuge. I have not seen them used medicinally in this part of the country, but there is no doubt that they are strongly bitter. The plant may be seen in many of the Bombay gardens, and it grows wild in the Southern Concan. It is an under shrub 3 or 4 feet high. The leaves when fully grown are from 8 to 10 inches long, and from 7 to 8 inches broad at the base, dark green, long petioled, rounded or ovate cordate, edges dentate, hairy on both sides; hairs white, jointed; venation very prominent on the under surface; odour disagreeable, taste bitter. The inflorescence forms large terminal cross-armed panicles, which appear in March; flowers white streaked with pink, sweet-scented; after they have fallen the calyces enlarge and turn red. The plant grows freely and produces a large quantity of leaves.

Papaver Rhœas.—*Local name,* Lala.

This poppy is cultivated in Guzerab as a garden flower, but its petals do not appear to have ever been an article of the Indian Materia Medica. Mr. Law says that the Mahometans of that province believe it to be the Lala of the Persian poets, which is generally translated tulip (*vide* Graham's catalogue of Bombay plants, No. 37). In the Bombay shops the capsules of a poppy, in size and shape just like those of *P. Rhœas,* are sold under the name of Jungli Mudrika. The word mudra means a seal, and mudrika stamped with a seal; under these two names the Hindoos have a metal seal or stamp with which they impress the body after ablution. The impression is made upon the forehead, both temples, both breasts, both shoulders, and the pit of the stomach. The mudra bears various inscriptions peculiar to the sects using it, *e.g.,* followers of Vishnu often engrave upon it Shri Narayen; those of Shiva, Namas Shevaya. The former dip the stamp in a paste made of gopi chandan, a kind of white clay, the latter in a paste made of bhasam (ashes of cow dung). The mudra is also used by Swamis as a branding iron. When these teachers visit a town numbers of their followers flock to them to receive the impression of the hot iron; for this they pay a small fee, and insist upon having a good impression for their money. These poppy capsules somewhat resemble the mudra in shape. As a medicine I should imagine them to be useless.

Polyporus officinalis.—*Local name,* Gharikoon.

This is the white agaric of European medicine, and is imported into Bombay from the Persian gulf. It is commonly kept by native druggists, being an important article in the materia medica of the Mahometans, who prescribe it in a great number of disorders, generally in combination with other drugs. According to their Hakeems it acts principally by expelling cold and bilious humours. A figure and description of this substance will be found in Guibourt's 'History of Drugs,' vol. 2, p. 45. A thin section soaked in glycerine shows under the microscope that the fungus is made up of a branching network of tubular fibres supporting a large quantity of granular and cellular material, amongst which may be seen numerous colourless refractive particles which are probably resinous. White agaric has been analysed by Braconnot, who found in 100 parts 72 of a peculiar white resinous matter, 2 of bitter extractive, and 26 of insoluble fungus.

CONIUM MACULATUM ?—*Local name*, KEERDAMANA.

Under this name a fruit is sold in the shops which resembles English hemlock fruit, with the exception that it is a little larger and of a darker grey colour; sections of both compared under the microscope show a similar structure, viz., that described in the 'Pharmacographia.' Keerdamana when crushed in a mortar and treated with caustic potash has the same offensive smell as the English drug. I suppose the slight difference in colour, and larger size, to be due to climatic influences, our article being probably grown in Persia or Northern India. The occurrence in India of plenty of this seed at a cheap rate enables us to prepare an efficient preparation of hemlock (the extr. conii fructus fluid, U.S.P.) without recourse to Europe.

CINNAMOMUM LOUREIRI ?—*Local name*, KALA NAGKESUR.

Under this name the fruit of a cinnamon is sold. I am informed that it is that of *C. Loureiri*, but I have not seen this tree. Kala (black) nagkesur consists of a small brown mucronate berry, the size of a grain of millet, enclosed in a six-partite calyx half an inch long, and articulated to a slender pedicel; the calyx and pedicel are of the dark brown colour of the clove, and have a strong cinnamon odour and taste. The properties of the drug would appear to be the same as those of cinnamon.

CINNAMOMUM, Sp. ?—*Local name*, DARCHINI.

The darchini, or cinnamon, of Bombay is the Chinese *Cassia lignea* so well known in Europe. Cassia oil obtained from this bark is also largely imported and used as oil of cinnamon. No true cinnamon is obtainable here. The bark of various Indian cinnamons is sold under the name of taj. It is much inferior to the Chinese article, being in short thick pieces and having a coarser flavour.

CORCHORUS TRILOCULARIS.—*Local name*, KARROO CHUNTZ; *Bazar name of seed* RAJA JEERA.

The seeds of this plant are small black and angular, having a diameter of about $\frac{1}{1}$th of an inch. Several seeds may often be seen adhering together, showing how closely they were packed in the trilocular capsule. In all the samples of this drug which I have seen there was a small proportion of the larger seeds of *C. olitorius*. These may easily be distinguished by their shape, which resembles that of a life-buoy. Their length is $\frac{1}{10}$th of an inch. Both seeds are bitter. They are given in fever and bowel complaints, in doses of half a tola (about 80 grains). The plant grows freely in the rainy season, and yields a good fibre.

SISYMBRIUM IRIS.—*Local name*, KHAKSHIR.

Small red oblong seeds, about $\frac{1}{20}$ of an inch long, one surface convex, the other grooved, the grove ending in a notch, interior yellow and oily. They turn rancid if kept for any time. When placed in water they become coated with a transparent mucilage. Khakshir is imported from Persia and is known by various names in different parts of that country. In Fars it is called shafterak, in Khorasan khakshir, in Tabriz soordan, in Turkistan sheewaran, and in Mazenderan shalambee. The Arabs call it khuba. The name placed at the head of this notice is that under which the seed is imported into Bombay; in other parts of India it is better known as khubkalan. Medicinally it is thought to be stimulant and restorative; it is also used externally as a stimulating poultice. A large quantity is imported, as it is in constant demand among the Mahometans.

CERBERA THEVETIA.—*Local name ?*

Common in gardens in Bombay, where it grows very freely, and is usually pollarded a few feet from the ground to make it form a handsome bush, much like an English willow. The fresh bark of the young wood, of from $\frac{1}{2}$—1 inch in diameter, is green, smooth, and covered by a delicate grey epidermis, through which the green colour is apparent. The wood is white and soft, and there is a large central pith. All parts of the plant abound in milky juice, and have an acrid smell when bruised. A section of the bark examined under the microscope shows many large laticiferous vessels arranged in bundles, which form a zone, but is not otherwise remarkable. This plant is the *Thevetia neriifolia* of the Pharmacopœia of India, and is recommended in that work as an antiperiodic; it does not appear to be used medicinally in this neighbourhood. There would be no difficulty in obtaining a good supply of bark, as the trees are frequently cut; if collected from the young wood and dried it forms quills of about the thickness of cinnamon, externally dark grey with brown striæ, internally smooth and black; texture tough, taste bitter, no particular odour.

JUSTICIA GENDARUSSA.—*Local name*, TEO.

The young shoots have a smooth, green, or purple bark; from the joints, which are somewhat tumid, spring secondary shoots. The leaves are opposite, short petioled, lanceolar, obtuse, frequently a little scalloped, smooth; nerve and veins purple, or green according to the variety, from 3—6 inches long, and from $\frac{1}{2}$—1 inch broad. Spikes terminal, erect; flowers dirty white, spotted with purple. The odour of the plant when crushed is ferny, the taste peculiar and not disagreeable; its medicinal properties are noticed in the Pharmacopœia of India. In Bombay it is a well known edging plant for flower beds. When cultivated for this purpose it is stunted and the leaves are seldom more than 3 inches long. I have never known it to be used medicinally.

PISTACIA KHINJUK.—*Local name of Gall*, GUL-I-PISTA.

The galls when old are of a reddish brown colour as stated in the Pharmacopœia of India, but when fresh are bright pink on one side and yellowish white on the other; they vary much in shape and size, some being perfectly fig-shaped, some almost spherical, the majority are ovoid; the apices are pointed or often mucronate; the largest have a diameter of from $\frac{5}{8}$—$\frac{6}{8}$ of an inch; many are no larger than a pea. At the base a portion of leaf often remains attached; here also may be seen an open stoma which communicates with the interior of the sac; the walls are thin, brittle and translucent; the taste acidulous, very astringent, and mildly terebinthinous; the odour terebinthinous. When broken open most of the sacs are seen to contain only a little fecal débris, but in some skeletons of an aphis may be found, consisting of a head, thorax, and abdomen divided into segments, clothed all around with bristles. Gul-i-pista is an astringent medicine; it is also used for tanning leather. The resin of *P. khinjuk* is used in Bombay instead of mastic, to which it is much inferior in perfume.

(*To be continued*).

THE MUTTON WINE OF THE MONGOLIANS, AND ANALOGOUS PREPARATIONS OF THE CHINESE.*

BY DR. D. J. MACGOWAN, OF SHANGHAI.

Chinese medical writers make little distinction between materia medica and materia alimentaria. The *Pun-tsao* ascribes therapeutic properties to all articles that are used as food. Nearly all portions of animals, the human frame included, are supposed to be efficacious in the treatment of disease. In their preparation they are for the most part subjected merely to ordinary culinary treatment. The exceptions consist of animal substances, which are macerated in fermented or distilled liquors. To these they apply the term *chiu*, commonly rendered "wine" by sinologues. Hence we find in the *Pun-tsao*: "Mutton wine, dog wine, deer wine, deer-horn wine, tiger-bone wine, black snake wine, flowery snake wine, *hi* snake wine, and tortoise wine."

Alcohol is designated in the *Pun-tsao* as ah-lih-kih, which indicates the Arabian origin in China of the art of distillation. It is seldom used as a pharmaceutical menstruum, their distilled *chiu* being employed as a solvent for articles used as medicines.

These animalized liquors, if that term be allowable, are for the most part extemporaneously prepared—a few only are to be had in apothecary shops ready made; such are several kind of snake wines. These latter are used in palsy. In Kwang-si the fermenting agent is a species of wild grass. The snake thus employed appears to be peculiar to the mountains of that province. To assure purchasers that the article is genuine, a strip of the skin of the animal is fastened to the top of the containing vessel. This wine is in high esteem as an anthelmintic, and as an antidote to malaria. Wuhu on the Yang-tse produces a snake wine which is in high repute. An adder wine is used in paralysis and insanity. There is a long edible snake spoken of as found in Kiang-si, which, being dried and smoked, is pared off in thin slices, liked smoked beef, and is found a convenient condiment by travellers.

The wine in which tortoise has been macerated is described as useful in chronic bronchitis. Cases of ten and twenty years' standing have, says the *Pun-tsao*, yielded to this remedy.

Dog wine is described as very heating and stimulating.

The officinal *mutton wine* of the Pharmacopœia is in fact made of goat's flesh, the goat and sheep being often confounded; the latter animal does not appear to have been known to the ancient Chinese.

Various species of sheep are described in the *Pun-tsao*, or Chinese Pharmacopœia, which are not recommended for macerating in wine. Among these is the great-tailed sheep of the Kwan-lun mountains, the caudal extremities of which are stated to weigh thirty pounds, rendering locomotion difficult. It is added that these adipose tumours require to be removed annually, else the animal will die. Their tails are cut open, the fat cut out, when the edges are brought together by a suture.

Sheep and goat wines are directed to be prepared in the following manner:—Take ten catties (1 catty = $1\frac{1}{3}$ lb.) of soaked rice, seven catties of goat or sheep flesh, fourteen onions, one Shan-tung cabbage, and a catty of almond kernels. Mix them well together, and let the mixture stand and brew without malt for ten days, at the end of which time a small quantity of liquor is produced; it is a sweet and unctuous liquor, or mutton wine. This is the formula adopted in the preparation of all the animal liquors above named.

"Mutton or goat wine is a great restorer of the constitution; it strengthens the stomach, the kidneys, and testes," according to the *Pun-tsao*.

Having many years ago met with a jar of mutton wine, which its owner, a Mongolian mandarin, greatly prized, I instituted inquiries respecting its mode of preparation and uses among the nomads of the north, but without success until a few months ago, when the Rev. J. Gilmour, in response to a request that I made of him, courteously undertook the investigation of the matter, and was at the pains to have the article prepared under his own supervision.

The following were the ingredients:—one sheep, forty catties of cow's milk wine; one pint of skim milk, soured and curdled; eight ounces of brown sugar; four ounces of honey; four ounces of fruit of dimocarpus (*Euphorbia Litchi*, Desf.); one catty of raisins, and half a dozen other drugs weighing in all about one catty. The sheep must be a castrated male, and two years old, neither more nor less.

Plant necessary for distillation.—One large pot (cast iron), one wooden half-barrel opened at bottom,* one smaller pot (cast iron), one earthenware jar, felt belts, cow-dung, fire.

Process.—Set the boorher on the large pot, calk the joining first with paper, then daub the outside with cow-dung and ashes. Make the boorher air-tight by plastering it all over outside with cow-dung.

Pour in the wine, add half the raisins (*i.e.*, ten ounces), cut or crushed, half the brown sugar, the pint of skim milk, and the bones of the sheep's legs from the knee downward, after breaking them open.

From the other bones strip all the fat and most of the flesh, leaving them fleshy. Hang them, head and all, inside the boorher high enough to be beyond the reach of the wine, and low enough to be out of reach of the pot above. Break up the medicines into small pieces (do not pound them), and put them into the earthenware pot. Into that pot put also the honey, white sugar, dragon's eye, and the remaining half of the brown sugar and raisins; suspend the earthenware pot in the centre of the boorher, put on the pot above, and make the joining air-tight by paper, cloth, and felt bands. Apply fire to the great pot. When the upper pot feels warm to the touch, fill it with cold water and stir it. When the water becomes too hot to touch, ladle it out and fill up with cold water. When this second potful of water becomes too hot for the hand, slacken the fire, take off the upper pot, and the earthenware pot will be seen full of a dirty brown liquor boiling furiously. Take out the earthenware pot, pour off the liquid, replace the earthenware pot, replace the upper pot, fill with cold water. When this potful of water becomes hot the whole thing is over. The earthenware pot is

* From *New Remedies*, for October, 1877. First published in *Journal of the North China Branch of the Royal Asiatic Society*, vol. vii., 1873, p. 235.

* This is about two feet high and tapering. At the bottom it is large enough to sit on the rim of the big pot: at the top it is small enough to let the small pot sit in it without falling through. It is called *Boorher*.

again about half filled, pour it off, and let it cool. When reasonably cold put it up in jars, and close them with the membrane of ox or sheep's bladders.

Remarks.—The great bulk of the flesh of the sheep is not used, nor any of the fat; all the marrow-bones are broken open. The skull is not broken open, nor the tongue extracted from the head. At the end of the process the mutton on the bones is cooked, but tastes badly. The quantity of cow's milk wine in the pot is not much diminished, but the strength is gone, and what remains is good for throwing away only.

Time of making.—"It should not be made before the seventh or eighth Chinese month. This was made on the 12th of the ninth month. It should not be used before the 11th or 12th Chinese month. None but aged people should drink it. It may be taken daily in one, two, or three small Chinese winecupfuls, till finished. The first winter the patient uses it, not more than two or three catties should be drunk. If found to agree with the patient, and if taken a second winter, another catty may be added, *i.e.*, first winter two and a half, second, three and a half, third, four and a half catties. If kept till spring it becomes useless, if not dangerous. Many people use it, but few take it more than one winter. Its use is (seemingly) to repair any manifestations of weakness arising from old age.

"*Case.*—Rev. J. Gilmour's teacher, when fifty years old, was afflicted with a shaking of the head from right to left. He drank two or three catties of mutton wine in the dead of winter, recovered, and is now all right."

The liquor thus prepared has a very strong odour of mutton; it is sweetish and unctuous. Specific gravity, 0·98873. Alcoholic percentage, 9·14.

ADMIXTURE OF STRYCHNIA WITH SANTONIN.

A short time since a statement that the administration of santonin has been occasionally followed by convulsions, and the fact that in one case in this country strychnine crystals were found mixed with santonin, led to some speculation as to how far the convulsions may have been dependent upon a similar admixture. As a contribution to the discussion the following quotation from the *Canadian Pharmaceutical Journal* has considerable interest:—

"Two cases of poisoning by misadventure call for a more particular notice, as showing the necessity of a more careful handling of poisonous drugs on the part of those engaged in their sale. Both resulted from the substitution of strychnine for santonin, and in one case death was only averted by the most prompt and energetic measures. As there is an action at law at present pending in regard to this case, and the details will shortly be made public, we refrain from any extended remarks, and merely give a brief outline of the circumstances. Mr. Lawrason, a druggist of Mitchell, was called upon to furnish a dose or doses of santonin, and for this purpose opened a fresh bottle just received from the wholesale druggists, and from it took directly the quantity required. The patient to whom the medicine was administered soon showed symptoms of poisoning; two medical men were quickly called in, and the stomach pump was at once put into use, fortunately, with the effect of saving the patient's life, for it was afterwards ascertained by analysis that the so-called santonin had been mixed with strychnine. The medical expenses were met by Mr. Lawrason, who in turn falls back on Messrs. Winer and Co., of Hamilton, who furnished the drug, and we understand that a suit for compensation, in which the damages are laid at ten thousand dollars, has been instituted.

"The second case resulted fatally, and is thus stated in the Dundas *True Banner*:—

"'A most unfortunate affair happened in West Flamboro' village, resulting in the death of a child three years and a half old, son of Mr. George Kent, painter, of this place. It appears that the child had been unwell, and Dr. Shaver being called in, prescribed some powders—one to be taken each morning and evening. On Thursday morning one of the powders was administered, and in a few minutes the child was seized with convulsions and died in twenty minutes. An inquest was held on the body by Dr. Biggar, of Lynden, and an analysis of the powders, which were believed to be composed of santonin, established the fact that they contained a quantity of strychnine. Dr. Walker, assisted by Dr. Davidson, held a *post mortem* examination on the body, and they reported that death might have resulted either from the diseased state of the kidneys or from strychnine. Evidence was produced to show that Dr. Shaver had purchased the powder, which he supposed was santonin, from Dr. Stark, druggist, of Hamilton; that Dr. Stark's santonin stock bottle had been examined and its contents analysed, and that it was found to contain a large portion of strychnine; and further, that Dr. Stark had purchased the santonin in question at the wholesale drug store of Winer and Co., Hamilton, where a further examination resulted in the discovery that their stock of santonin was mixed with strychnine. The verdict of the jury was to the effect that the deceased, George Henry Kent, came to his death by taking a powder composed mostly of strychnine, given by Dr. Shaver in mistake for santonin, and that the doctor obtained the same from Dr. Stark, of Hamilton, for santonin, who procured it from Winer and Co., and we hereby attach no blame to Dr. Shaver, but we would hereby advise druggists to be more careful in future.'

"It was extremely fortunate for Dr. Shaver that the inquiry was held, and that the evidence which led to the foregoing verdict was forthcoming, as without such clear proof that he was in no way to blame for carelessness it is just possible that the friends of the child and the public generally might have been forced to conclude that Dr. Shaver was to blame for the death of the child. As it is, however, we are glad to know that he has been thoroughly and completely exonerated. The facts developed at the inquest are of a startling character, however, as it is difficult to say where the mischief will end, as this mixed santonin and strychnine powder may have been distributed all over the country from the wholesale house in Hamilton.

"On the foregoing the Hamilton *Spectator* remarks:—'The fact that the unfortunate affair referred to above had occurred came to our knowledge a few days ago, but in the absence of particulars no mention was made of it at the time. In one or two points the *Banner's* statement is incorrect. Winer and Co.'s stock of santonin was not found to be mixed with strychnine. The portion which became mixed was all contained in a small bottle, and as it is positively known that this has not been "distributed all over the country," we are assured that the fears entertained by our contemporary are groundless.'"

HYDROBROMIC ACID IN PRESCRIPTIONS.*

BY DR. DEWITT C. WADE, MITCHIGAN.

It is not astonishing that hydrobromic acid is suggested so soon after its introduction to the profession as a remedy for many diseases, and in many combinations, for the salts of bromine have been as thoroughly tested by as large a number of physicians as any other known medicine, and have found a place second to few other remedies in value. These salts are undoubtedly generally given for the purpose of obtaining the effects of bromine upon the system; and if hydrobromic acid, in a more exact, scientific and eligible manner, accomplishes this object, it is not unreasonable to suppose that it will rapidly supplant them in the estimation of the intelligent prescriber.

To further call the attention of the profession to the great usefulness of this acid, I am induced to give a few formulæ into which it enters, which I have no doubt will

* From the *Druggists' Circular*, Nov. 1877.

at least have the merit of novelty. It is well known that medicines combined, not chemically, are thus often increased in value, and the convenience of so prescribing hydrobromic acid, if for no other reason, will generally make it preferable to the bromine salts.

I regret that in my paper proposing hydrobromic acid as a medicine, published in the *Peninsular Journal of Medicine* in February, 1875, I did not give a working formula for its preparation. I gave, instead, a theoretical formula, specifying that each fluid drachm of the finished preparation should represent ten grains of bromine, this being the amount of iodine in the same quantity of the officinal dilute hydriodic acid. Since then a formula has been published containing considerably less bromine, the result of which is likely to cause confusion, both with pharmacists and physicians. I think it proper to here give the original formula from which the first preparation was made, and which I shall now take the liberty of denominating dilute hydrobromic acid.

I.	Bromide of potassium	120 grains.
	Crystallized tartaric acid . . .	153 grains.
	Water	1 fl. oz.

Dissolve the salt and then the acid in the water, and place in cold water for several hours, or until precipitation ceases, and decant. The results of the reaction are the formation of bitartrate of potassium (cream of tartar), which is nearly insoluble, and sufficiently pure hydrobromic acid diluted with water, each fluid drachm of which contains ten grains of bromine. By preserving this proportion, any quantity can just as readily be made. For forty fluid ounces the following formula is exact enough for practical purposes:

II.	The bromide. . .	10 troy or 11 avoir. oz.
	The acid	$12\frac{3}{4}$ troy or 14 avoir. oz.
	Water	20 fl. oz.

Proceed as before.

The affinity of hydrobromic acid for bases is between that of hydrochloric and hydriodic acids. I have prescribed it most frequently in half drachm doses well diluted.

III.	Dilute hydrobromic acid,	
	Syrup, of each	1 fluid ounce.

Mix and write—teaspoonful in water.

This is not unpleasant to the taste, and may be given to obtain the constitutional effects of bromine as usually administered in combination with a base. It also acts like other mineral acids in being tonic, refrigerant, solvent, alterative, etc., and is very useful in the "bilious" conditions, including fevers, where the morbid symptoms recede with the coating on the tongue. I use little else in remittent fever.

IV.	Sulphate of quinia	15 to 80 grains.
	Dilute hydrobromic acid,	
	Syrup, of each	1 fluid ounce.

Mix and write—teaspoonful in water.

This is extremely bitter, and in this respect cannot be improved by other additions. Like other acidulous preparations, it is incompatible with licorice. Bromine has the power of modifying, in a marked degree, the cerebral effects of quinine; hence the value of its combination, aside from the alterative and other properties of the acid. In all cases of intermittent fever I continue an antiperiodic from ten to thirteen days after the paroxysm ceases, and for permanent and other satisfactory results, this combination has proved to be far superior in my hands to any other not containing the acid.

V.	Sulphate of cinchonia . .	15 to 45 grains.
	Dilute hydrobromic acid,	
	Syrup, of each	1 fluid ounce.

Mix and write—teaspoonful in water.

I can discover no difference in the effects of cinchonia and quinia, except that the latter is to be preferred as a stimulant. I prescribe cinchonia because of its cheapness.

VI.	Red iodide of mercury . . .	1 grain.
	Dilute hydrobromic acid . .	1 fluid ounce.
	Fluid ex. of orange peel,	
	Syrup, of each	4 fluid drachms.

Mix and write—teaspoonful in water.

The iodide of mercury is decomposed, the bromide being formed with the elimination of the iodine in the form of hydriodic acid. Mercury may be given in this manner for a long time without producing ptyalism, the salt being rapidly excreted.

VII.	Fluid extract of ergot,	
	Syrup, of each	4 fluid drachms.
	Dilute hydrobromic acid . .	1 fluid ounce.

Mix and write—teaspoonful in water.

I do not believe any other combination equals this for efficiency in cases of cerebral hyperæmia. It is not only indicated where venesection would appear beneficial, but it may be administered by enema in a case of intercranial hæmorrhage, with the likelihood of arresting the transfusion, by capillary restriction, when an additional depletion of the arterioles, by artificial abstraction of blood, would still further endanger life without influencing the hæmorrhage, and is consequently positively contra-indicated.

Ergot and hydrobromic acid will be found to be promptly useful in the vertigo of plethora, with confusion of ideas, or where a determination of blood to the brain is prone to occur from other causes.

VIII.	Fluid ext. of stramonium . .	160 drops.
	Dilute hydrobromic acid,	
	Syrup, of each	1 fluid ounce.

Mix and write—one-half teaspoonful in water, the dose to be increased until the specific effects of the stramonium are marked, and there to be maintained.

I offer this combination as a prescription for epilepsy. I will simply say of it that its effects in this disease are remarkable, and I think I have reason to consider it superior to any other plan of medication.

IX.	Tartar emetic	2 grains.
	Denarcotized tincture of opium	2 fluid drachms.
	Dilute hydrobromic acid . .	1 fluid ounce.
	Syrup, to make	2 fluid ounces.

Mix and write—teaspoonful in water.

For acute or chronic bronchitis.

X.	Syrup of bromide of iron . .	4 fluid drachms
	Bromide of quinia	16 grains.
	Dilute hydrobromic acid . .	1 fluid ounce.
	Syrup	4 fluid drachms.

Mix and write—teaspoonful in water.

The wide applicability of this tonic is readily suggested by its composition.

XI.	Subcarbonate of bismuth . .	80 grains.
	Dilute hydrobromic acid . .	1 fluid ounce.

Dissolve and add

	Saccharated pepsine	80 grains.
	Syrup, to make	2 fluid ounces.

Mix, filter and write—teaspoonful in water.

This is preferable to ammoniated citrate of bismuth with pepsine, because it is not only permanent in the bottle, but it is not precipitated in the stomach, as is the citrate. Its indications are evident to the professional reader. To it may be added pancreatine, with or without the pepsine.

I trust I have shown by the foregoing formulæ how readily bromine may be exhibited in a elegant manner, combined with other well known remedies. These formulæ, however, are only intended as skeletons, upon which a great variety of changes may be rung to suit the "notions" of the prescriber.

Elixirs instead of syrups may be substituted, and additions of flavours may be made to render the medicine more palatable. The doses are for adults, and the frequency of their repetition in each case is to be determined in accordance with the circumstances.

Sedation is an indication in almost all diseased conditions, not only as a palliative, but to finally obtain radical results, by the greater curative efforts nature may make in the absence of irritation, aided, if necessary, by artificial means. It is no surprise, then, that the only known mineral sedative, being also a powerful alterative, should have found so prominent a place in the medical art; yet taking into consideration the facts that the salts of this drug are the preparations of it almost universally prescribed, and that they must be decomposed in the stomach and hydrobromic acid produced before the effects of bromine can be obtained in any case, and that these salts cannot conveniently be combined with other medicines, it is an easy matter to gain the impression that, in the light of our present knowledge, there are too many who follow a very clumsy and unscientific method of exhibiting one of our most valuable therapeutic agents.

SCHEME FOR THE RECOGNITION OF THE MORE IMPORTANT RESINS, GUM RESINS, AND BALSAMS.*

BY EDWARD HIRSCHSOHN.

In continuation of the author's researches on ammoniacum, galbanum, sagapenum, and opoponax, an account of which has already appeared in this Journal,† he has made a comparative examination of a large number of the more important resins, gum resins, and balsams. The results have been published in an inaugural dissertation written upon attaining the grade of "magister der pharmacie." This thesis contains a table for the recognition of these substances by their behaviour towards reagents. The following are the reagents used:—

1. Sulphuric acid, sp. gr. 1·820.
2. Alcoholic hydrochloric acid, obtained by saturating 95 per cent. alcohol with dry hydrochloric acid gas.
3. Bromine solution, 1 part of bromine in 20 parts of chloroform.
4. Saturated solution of chloride of lime in distilled water at the ordinary temperature.
5. Alcoholic solution of perchloride of iron, 1 part in 10 parts of 95 per cent. alcohol.
6. Saturated solution of neutral lead acetate in 95 per cent. alcohol.
7. Solution of ammonia, sp. gr, ·980.
8. Solution of pure sodium carbonate crystals in distilled water.
9. Frohde's test: 1 centigram of sodium molybdate in 1 c.c. sulphuric acid.
10. Impure chloral hydrate, containing alcoholate.
11. Saturated solution of iodine in petroleum spirit boiling at 60° C.

Completely soluble in Chloroform.

Completely soluble in Ether.

A. Ethereal solution becomes turbid after addition of alcohol.
- I. Alcoholic solution gives with perchloride of iron a turbidity that disappears on boiling. Chloral reagent colours violet . . . . *Canada Balsam.*
- II. Alcoholic solution gives no turbidity with perchloride of iron.
  - 1. The drug is liquid and forms a clear mixture with petroleum spirit boiling below 40° C.
    - *a.* Bromine solution colours the chloroform solution yellowish, then violet and blue *Maranha Copaiba Balsam.*
    - *b* Bromine solution produces no colour *Peru Copaiba Balsam.*
  - 2. The drug is solid and dissolves only partially in petroleum spirit. Iodine solution colours red violet . . . . *Ordinary Mastic.*

B. Ethereal solution forms clear mixture with alcohol.
- I. Perfectly soluble in alcohol.
  - 1. Perchloride of iron colours the alcoholic solution blue.
    - *a.* Lead acetate gives a precipitate with alcoholic solution. Sulphuric acid dissolves the drug with a cherry red colour . . *Guaiacum Resin.*
    - *b.* Lead acetate gives no precipitate. Sulphuric acid dissolves the drug with a yellow brown colour *Carana Resin (Aceyta americana).*
  - 2. Perchloride of iron colours the alcoholic solution brownish or greenish.
    - *a.* Lead acetate gives with the alcoholic solution a precipitate that is not dissolved by boiling.
      - α. Sodium carbonate solution dissolves parts at the ordinary temperature. Chloral test colours the residue from the evaporation of a petroleum spirit extract gradually red violet with blue streaks. . . *Coniferous Balsams and Resins.*
      - β. Sodium carbonate dissolves none or a very small quantity.
        - † Petroleum spirit extract colourless. Chloral test produces no colour or a very faint greenish *Bombay Mastic.*
        - †† Petroleum extract coloured.
          - ‡ Dark brown. Chloral test colours brown *Mani Resin.*
          - ‡‡ Yellow-brown. Chloral test colours gradually indistinct red violet . . . *Carana Resin.*
          - ‡‡‡ Yellow-brown. Chloral test and bromine solution colour a magnificent violet *Carana hedionda.*
    - *b.* Lead acetate gives with alcoholic solution a precipitate that dissolves on boiling.
      - α. Bromine solution colours red *Peruvian Guaiacum Resin.*
      - β. Bromine solution produces no coloration *Alexandrian Mastic.*
    - *c.* Lead acetate gives no precipitate. Ammonia gives a turbid mixture . . . *Dragon's Blood.*
- II. Imperfectly soluble in alcohol.
  - 1. Lead acetate produces turbidity which disappears upon warming . . *Brazilian Copaiba Balsam.*
  - 2. Lead acetate gives no precipitate. The drug is clearly crystalline. Sodium carbonate does not dissolve it by boiling.
    - *a.* Bromine solution gradually colours green.
      - † Alcoholic hydrochloric acid colours violet, blue, or brown . . . . *Elemi.*
    - *b.* Bromine solution colours violet . . . . *Elemi.*
    - *c.* Bromine solution produces no colour *Elemi (Amyris elemifera).*

Imperfectly soluble in Ether.

A. Perfectly soluble in alcohol.
- I. Sulphuric acid colours the residue from evaporation of a petroleum spirit extract cherry red. The drug is free from cinnamic acid . *Siam Benzoin.*
- II. Sulphuric acid does not colour such residue, or only faintly light brown. Contains cinnamic acid *Sumatra Benzoin* or *Tolu Balsam.*
- III. Sulphuric acid colours such residue yellow-brown passing into violet . . . *Black Peru Balsam,*

B. Imperfectly soluble in alcohol.
- I. Perchloride of iron gives a precipitate, which is neither dissolved by boiling nor soluble in ether *Brazilian Copal.*
- II. Perchloride of iron produces no turbidity or only a slight one that disappears on boiling.
  - 1. The ethereal solution gives with alcohol a turbid mixture.
    - *a.* Alcoholic hydrochloric acid colours it brownish. Chloral test colours evaporation residue of petroleum spirit extract greenish . . . *Dammar.*

---

* *Pharmaceutische Zeitschrift für Russland*, xvi., 81.
† *Pharm. Journ.* [3], vol. vii., p. 369, etc.

b. Alcoholic hydrochloric acid colours it brick red. Chloral test colours the petroleum spirit residue carmine red to violet . . *White Peru Balsam.*

2. Ethereal solution gives with alcohol a clear mixture.

a. Ammonia gives with alcoholic solution a clear mixture. Bromine solution colours blue *Ceradia Resin.*

b. Ammonia gives with the alcoholic solution a turbid mixture. Bromine solution colours greenish *Mecca Balsam.*

Imperfectly Soluble or Insoluble in Chloroform.

Completely soluble in Ether.

A. Ethereal solution red. Ammonia gives with alcoholic solution a clear mixture *Dragon's Blood from Pterocarpus Draco.*

B. Ethereal solution yellowish or colourless.

I. Alcoholic solution gives with lead acetate no precipitate . . . . *Podocarpus Resin.*

II. Alcoholic solution gives with lead acetate a precipitate that is not dissolved by boiling . *Sandarac.*

Imperfectly soluble in Ether.

A. Ethereal solution becomes turbid after addition of alcohol.

I. Alcoholic solution gives with ammonia a clear mixture.

1. The mixture with ammonia is yellow. The solution of the resin in sulphuric acid is yellow brown and gives with alcohol a clear violet mixture *Eryops Resin.*

2. The mixture with ammonia is carmine red *Sonora Lac.*

II. Alcoholic solution gives with ammonia a turbid mixture.

1. Perchloride of iron colours green. The drug contains cinnamic acid. Lead acetate gives a precipitate . . . . *Liquid Storax.*

2. Perchloride of iron colours brownish or not at all.

a. The drug contains cinnamic acid, and gives with lead acetate no precipitate *Liquidambar Balsam.*

b. The drug contains no cinnamic acid, and gives with lead acetate a precipitate *Euphorbia Tirocalli Resin.*

B. Ethereal solution gives with alcohol a clear mixture.

I. Perfectly soluble in alcohol. Perchloride of iron colours dark brown or black.

1. Solution in alcohol is red.

a. Lead acetate gives no precipitate. Chloroform extract colourless *Xanthorrhœa quadrangularis Resin.*

b. Lead acetate produces turbidity. Chloroform extract yellow. . *Xanthorrhœa arborea Resin.*

2. Alcoholic solution yellow. Lead acetate produces a precipitate . . . *Yellow Xanthorrhœa Resin.*

II. Imperfectly insoluble in alcohol.

1. Alcoholic solution gives with ammonia a clear mixture.

a. Ammoniacal mixture is violet. Lead acetate gives a violet precipitate . . . . . . *Lac.*

b. Ammoniacal mixture is yellow or colourless.

α. Perchloride of iron colours the alcoholic extract black. Lead acetate gives no precipitate *Gamboge.*

β. Perchloride of iron gives a precipitate which is neither soluble in ether or by heating. Lead acetate gives a precipitate.

† Readily and completely soluble in ether-alcohol.

‡ Bromine solution precipitates the resin from the chloroform solution . *Australian Copal.*

‡‡ Bromine solution produces no precipitate. *Manilla Copal.*

†† Imperfectly soluble in ether-alcohol *East Indian Copal.* *African Copal.*

2. The alcoholic solution gives with ammonia a turbid mixture.

a. Perchloride of iron gives a precipitate that is neither dissolved by boiling nor in ether *Borneo Copal.*

b. Perchloride of iron gives no precipitate.

α. Completely soluble in ether-alcohol. Chloral test colours residue from evaporation of petroleum spirit extract blue to blue violet *Liquidambar styraciflua Balsam.*

β. Incompletely soluble in ether-alcohol.

† The drug contains sulphur.

§ Yields umbelliferon by dry distillation.

‖ Hydrochloric acid colours the petroleum spirit extract residue reddish yellow; the chloral test colours it green *Persian Sagapenum.*

‖‖ Hydrochloric acid colours the residue blue violet; chloral test colours it rose colour to raspberry red and violet *Levant Sagapenum.*

‖‖‖ Not coloured by hydrochloric acid. The solution of the drug in sulphuric acid is yellow brown with a blue fluorescence. Potassium nitrate colours the gum resin malachite green . *Ordinary Asafœtida.*

§§ Yields no umbelliferon by dry distillation.

‖ Sodium carbonate solution colours the drug light brown, and the extract is not altered by acetic acid or lead acetate *Asafœtida from Ferula alliacea.*

‖‖ Sodium carbonate solution forms an emulsion that cannot be filtered.

° Lead acetate gives no precipitate. Iodine solution is not altered . *Indian Bdellium.*

°° Lead acetate produces immediately or after a short time a precipitate that dissolves upon warming. Iodine solution is not altered . . . . . *African Bdellium.*

‡‡ The drug contains no sulphur.

§ Yields umbelliferon by dry distillation.

‖‖ The petroleum spirit extract residue is coloured by hydrochloric acid and the chloral test.

° Hydrochloric acid colours reddish yellow; the chloral test colours green *Persian Galbanum.*

°° Hydrochloric acid colours red violet; the chloral test colours greenish *Levant Galbanum as at present in commerce.*

°°° Hydrochloric acid colours violet blue; the chloral test carmine red *Older specimens of Levant Galbanum.*

‖‖ Hydrochloric acid gives no colour; the chloral test colours light brown *African Ammoniacum.*

§§ Yields no umbelliferon by dry distillation.

‖ Chloride of lime solution colours the gum resin orange yellow *Persian Ammoniacum.*

‖‖ Chloride of lime solution produces no colour. Lead acetate gives no precipitate.

° Iodine solution is not altered; the chloral test colours greenish . . . *Olibanum.*

°° Iodine solution is not altered; the chloral test gives no colour . *Indian Myrrh.*

‖‖‖ Chloride of lime solution produces no colour. Lead acetate gives a precipitate.

° Bromine solution colours violet red; the chloral test colours violet *Ordinary Myrrh.*

°° Bromine solution produces no colour or only yellowish. Perchloride of iron colours green . . . . *Opoponax.*

°°° Bromine solution produces no colour or only yellowish. Perchloride of iron colours brownish . . *Euphorbium.*

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 17, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal. MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE RESPONSIBILITY FOR PROSECUTIONS UNDER THE SALE OF FOOD AND DRUGS ACT.

ALTHOUGH it is only a month since that attention was called in these columns to some flagrant instances of the misapplication of the Sale of Food and Drugs Act, the cases reported on another page will be seen to fully justify an early reversion to the subject. It is true that our remarks on former occasions have been misconstrued, by ostentatious purists who have been either incapable or unwilling to see the facts of the case, into a defence of the dishonest trader; but we believe that there is no surer way to the Act passed for the protection of the public becoming a dead letter than by its being applied oppressively and without judgment, in such a manner that escape from unjust penalties should be dependent not upon the trader's guilt, but upon his ability to spend money in his defence.

At the Selby Petty Sessions, held on Monday last, a firm of pharmaceutical chemists was charged with two offences under the Act. In the face of known facts, and especially of recent magisterial decisions based upon them, it is astonishing to find that once more respectable tradesmen have had to defend themselves from imputations of fraud because they have sold soda water that did not contain 30 grains of bicarbonate of soda to the pint. Had the soda water been simply the aërated beverage that the public, as a rule, ask for under that name, such a proceeding would be indefensible; but the water did contain equal to about 7 grains of bicarbonate of soda to the pint, and, in the words used by the analyst in his certificate, "Regarded as an effervescent drink the sample was perfectly free from objection." Considering that in a very great majority of cases it is as an effervescent drink that soda water is purchased by the public, it does appear to be the height of absurdity, as well as a gross injustice, to impute fraud to the seller who does not make his soda water according to the formula given for medicinal purposes in the Pharmacopœia. It would only be consistent to attempt to stop all sales of mineral acids that would not pass the tests given in the same work.

The other charge was for selling cayenne pepper adulterated with common salt and red ochre, or some other ferruginous material. The "chemical and microscopical" evidence upon which the imputation of fraud was based was of the flimsiest description. Because oxide of iron equal to 1 part in 1000 was found in the ash, the conclusion was jumped at that the pepper had been "coloured," and the result of an application of a test for chlorides and crystals seen under the microscope was considered a sufficient basis for a charge of an admixture of common salt.

We will do the analyst the justice to quote his assertion that from the result of his "analysis" he would not have recommended a prosecution in this case. But it would be very interesting to know who is responsible for the prosecution. According to the report, a police superintendent, who made the purchases, acted as prosecutor. Although the singular obtuseness manifest in the proceedings might be thus sufficiently accounted for, it can hardly be supposed that he has been acting *en amateur* and without instructions from the local authority. If he has, the sooner his employers relegate him to his proper duties the better it will be. However this may be we cannot altogether acquit the public analyst from responsibility. Although he may not have directed the prosecution he seems to have baited the trap into which somebody else has fallen. When a presumed scientific man reports that he has found common salt in a sample of pepper, and goes on to say that "salt is frequently added to cayenne pepper to increase the brightness of the colour," and further that the sample has been "coloured" by some other substance, it is at least suggestive to the more ignorant mind looking to him for guidance that something wrong has been done; the sequence then is a natural one.

The beer case tried at the Bath Police Court was even worse than those above referred to; for there an attempt was made to prove adulteration not only upon inadequate grounds but in regard to the alleged presence of a material that is allowed to be used as a bitter.

We think the time has arrived for raising the question whether in cases of alleged infringement of the Food and Drugs Act, the power of prosecution should be left in the hands of local bodies, unqualified themselves to decide cases upon the merits of the results certified to by the analyst, and liable to miscontrue, or even to be misled by those to whom they look for advice to an extent in excess of their power of guidance. Fortunately fraudulent adulteration has not proved to be so prevalent as was expected in some quarters, and there would be nothing to preclude the submitting in future of all cases of supposed offences under the Food and Drugs Act to the judgment of some central competent authority before commencing prosecutions. Such a course would have the advantage of relieving public public analysts from the exercise of functions beyond their competence, viz., that of deciding whether an admixture or impurity in any article is injurious to health. Moreover, there are other things to be considered besides the silly fears of a section of the public. It should be remembered that even when the tradesman succeeds in repelling an unjust charge of adulteration, it often, as in the present case, involves a considerable expenditure of time and money, and sometimes a damaged reputation. Too frequently, however, the defendant is incompetent single-handed to offer a proper defence; guilt is then assumed, and conviction follows very often upon the mere *ipse dixit* of the public analyst, a foundation which has been too often proved untrustworthy. We consider that in conducting the defence of Messrs. CUTTING to a successful issue, the Chemists and Druggists' Trade Association has rendered a valuable service not only to chemists and druggists, but to the community.

THE STATE OF THE GASTRIC JUICE IN TYPHOID.

THE *Berliner Klinische Wochenschrift* gives the history of a case in Professor Kussmaul's clinique at Strassburg, which tends to show that during the dyspeptic stage in typhoid fever the gastric juice contains no free hydrochloric acid, though pepsine is abundantly present, as has been already proved by Hoppe-Seyler and Parry. If the juice shows acid reaction this is due to either acetic or lactic acid, but it may, as Kussmaul's case shows, become alkaline from the presence of bile or pancreatic juice after retching or vomiting. The absence of hydrochloric acid lasted as long as the fever, and up to the eighth day after its disappearance, proving the old maxim by which typhoid reconvalescents are forbidden solid food for that period. As Professor Kussmaul's assistant points out, the great advantage of giving hydrochloric acid in fevers is confirmed by this case. He also mentions the experiments made on dogs by Manasseïn in Hoppe-Seyler's laboratory, in which by injecting putrid liquids into their veins and creating fever the quantity of free hydrochloric acid in proportion to the pepsine became diminished. Some old notes, made of similar experiments in Hoppe's laboratory at Berlin nearly twenty years ago, confirm this as far as the reaction of acidity by test paper goes. The gastric juice of dogs is normally always strongly acid and this acidity is mainly due to a normally high proportion of hydrochloric acid. As Rabuteau stated only a few years ago, in the *Comptes rendus*, it amounts on an average to 4 per mille or 0·4 per cent.

EUCALYPTUS AND PHARMACY IN BRAZIL.

IT appears that tincture of *Eucalyptus globulus* is manufactured on rather a large scale in Brazil, where intermittent and remittent fevers prevail extensively in the low coast and river regions, and also in the valleys and backwoods of the uplands. Dr. Senftleben, who has just returned from a twelve months' expedition to the different parts of the southern empire, informs us that the Eucalyptus tincture is used by the native doctors and as a popular medicine mostly in obstinate cases, especially when relapses occur. This tallies with the reports of the Austrian practitioners who treated cases of ague contracted in the swampy river countries of Hungary. In fresh or protracted cases of intermittent fever, where no remarkable enlargement of the spleen has yet taken place, quinine is by far the most reliable febrifuge. But where an "ague cake" has formed and the recurring attacks depend rather on the locally remaining of the diseases, the Eucalyptus in doses of a half or one fluid drachm twice or three times a day for a week or a fortnight proves the more useful drug. The Eucalyptus trees grown in Brazil and the river Plate countries are said to be less fragrant than the Australian and to yield less aromatic oil, which is evidently due to the richer, more clayey soil and the moister climate.

EXPLOSION WHILE PREPARING OXYGEN.

ANOTHER fatal accident while preparing oxygen is reported from Ireland. The information elicited at the inquest does not appear to have thrown much light upon the cause of the explosion. We are informed by a correspondent that a tutor in a school at Moira, who had performed the operation frequently before, wishing to prepare some oxygen, introduced a mixture of 2 lbs. of potassium chlorate and 1 lb. of manganese peroxide into an iron mercury bottle and placed it on a hot fire in a stove. Shortly afterwards an explosion took place, which killed one boy who was present and injured two others. The stove was blown to fragments, carrying away the windows, ceiling, etc., while the detonation was so loud as to be heard at a distance of two miles. Considering the frequency with which oxygen is now prepared under similar circumstances, it would have been interesting to have had it cleared up whether the accident was due to the too rapid evolution of gas, a faulty retort, or to the presence of a foreign ingredient in the mixture similar to that which resulted in an explosion at Irishtown in 1875.

MUNICIPAL HONOURS TO PHARMACISTS.

AMONGST the gentlemen to whom the 9th of November has brought municipal honours we notice the names of several pharmacists. At Bedford Mr. JOHN USHER TAYLOR, Pharmaceutical Chemist, has been elected Mayor. At Haverfordwest, Mr. WILLIAM WILLIAMS, Pharmaceutical Chemist and Local Secretary of the Pharmaceutical Society, has been unanimously chosen Mayor of the borough and "Admiral of the Port." At Lincoln, Mr. WILLIAM COTTINGHAM, Chemist and Druggist, has been elected Mayor. Mr. HENRY DAVID SIMPSON, Chemist and Druggist, has been re-elected Mayor of Louth. Mr. JOHN AVERILL, Pharmaceutical Chemist, also a Local Secretary of the Pharmaceutical Society, has been unanimously elected Mayor of Stafford. Finally, Mr. ALEXANDER BOTTLE, Pharmaceutical Chemist, and a Member of the Council of the Society, has been elected an Alderman at Dover.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of the above Association will be held at 17, Bloomsbury Square, W.C., on Thursday evening, November 22, at 8 o'clock, when a paper will be read by the Secretary, Mr. H. G. GREENISH, on "The Microscope, and its Application in Pharmacy."

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The opening meeting of the new session of the above Association was held in the Manager's Library, Anderson's College, on Friday evening, 9th inst., the President (Mr. Daniel Frazer) occupying the chair. Mr. J. M. Fairlie, Vice-President, acting as Secretary, *pro tem.*, read minutes of the previous meeting, which were approved, and also submitted reports. Letters of resignation from Mr. Jas. L. MacMillan, Secretary, and Mr. Jas. Murdoch, Librarian, were read, both of whom have left the city, and in their stead Mr. John Walker (Glasgow Apothecaries' Company), 34, Virginia Street, was appointed Secretary, and Mr. Wm. McKenzie, 17, Great Western Road, Librarian.

A further donation of books from the Executive of the British Pharmaceutical Conference, comprising Hanbury's 'Science Papers,' and Hanbury and Flückiger's 'Pharmacographia,' was laid on the table, and the Secretary was instructed to acknowledge the receipt of the same, with the Association's best thanks.

The President then made a few introductory remarks, impressing upon members and others the benefit to be derived from mutual association, touching upon the Preliminary examinations, and lamenting the high percentage of failures, and suggested the desirability of approaching the Pharmaceutical Society on the subject. He also submitted the report of the deputation (viz. Mr. Davidson and himself) to the Pharmaceutical Conference held at Plymouth, and spoke in praise of the kindness shown them by the local committee there.

Mr. Fairlie moved, and Mr. Kinninmont seconded:—"That it be remitted to the Council of the Association to consider the desirability of approaching the Council of the Pharmaceutical Society, with reference to the Preliminary examinations."

Dr. J. M. Milne, lecturer on chemistry, etc., who was then introduced to the meeting, read a paper entitled "Some Notes on the Application of Chemical Knowledge" in which he traced the advance and domain of chemistry, and the practical application of the science in the arts and manufactures, impressing on the audience the necessity and advantage of test experiments, and advocating a course of study in practical chemistry. The lecturer also referred at some length to the Adulteration Acts, showing defects in the framing and working of the same, and pointed out that the analyst under the Act should have, besides his analytical experience, a knowledge of the art and manufacture of the article under examination.

On the motion of the chairman, a very hearty vote of thanks was accorded the lecturer for his interesting and instructive paper.

The following classes in connection with the Association were intimated:—1st. Tutorial Class, for Preliminary; 2nd. Theoretical Chemistry Class; 3rd. Practical Pharmaceutical Chemistry Class, particulars of which may be learned from the Secretary.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The first meeting of the above Association for the present session was held at 17, Bloomsbury Square, on Thursday evening, November 8; Professor Attfield, President, in the chair. There were present 29 members and 1 visitor.

The Secretary read the minutes of the previous meeting, including a report of the work of the Association during the past session. The report stated that there had been nineteen meetings, with an average attendance of twenty-five members. In addition to the President's address (already reported in the *Pharmaceutical Journal*), twenty-three papers had been read and discussed, as follows:—"Magnetism," by Mr. Charles Hutchinson; "Arnot's New Test for Potassium," by Dr. A. Senier, F.C.S., and Mr. H. Campbell; "Dispensing Queries," by Mr. Campbell; "The Microscope," by Mr. J. C. Shenstone; "Emulsions," Mr. W. B. Tuck; "The Signs used to Decorate the Show Bottles of the Pharmacist," by Mr. J. H. Hugill; "Faraday," by Mr. W. R. Atkins; "Diagnosis of the Principal Natural Orders," by Mr. E. M. Holmes, F.L.S.; "Radiometer," by Mr. C. J. Mead; "Fermentation," by Mr. G. F. Gutheridge; "The Common Metals and their Chief Uses," by Mr. A. P. Luff, F.C.S.; "The Starches," by Mr. G. Bullen; "The Occurrence of Cinchonidine in Quinine," by Mr. R. W. Parker; "Oxalate of Cerium," by Mr. H. G. Greenish; "Analysis of Scale Compounds and Alkaloids," by Dr. A. Senier, F.C.S.; "Luminosity of Flame," by Mr. H. Senier, F.C.S.; "Practical Dispensing," by Mr. C. Shapley; "Methods of Flower Fertilization," by Mr. J. Savory; "Poisons," by Mr. Rickarby; "Iles's New Test for Boracic Acid," by Mr. S. Hardwick; "Method of Producing Voltaic Electricity," by Mr. E. Richardson; "Atomic Theory," by Mr. C. Hutchinson; "Theories of Darwin concerning Evolution," by Mr. E. Richardson.

The election of officers was next proceeded with; Mr. Ashweek and Mr. Dunstan being appointed a committee to examine the voting papers.

During this examination a discussion was introduced by the President on the management of the Association, in which Messrs. Gadd, Naylor, and Atkins took part.

The report of the committee on elections was then read, and the following gentlemen were declared officers for the session 1877–78:—

Vice-Presidents, Mr. John F. Savory and Mr. W. R. Atkins; Committee, Mr. R. H. Parker, Mr. William B. Mason, Mr. Henry Allen, Mr. J. Graham Sangster; Secretary and Treasurer, Mr. H. G. Greenish, 17, Bloomsbury Square, W.C.

The President then addressed the members on the subject of education generally, more especially on the modes by which the knowledge acquired by pupils in the primary, secondary, and other schools throughout England is commonly gauged, urging the value of knowledge for its own sake, and particularly the kind and quality of knowledge which was too deep and subtle to be probed by examinations as ordinarily conducted.

The Secretary then announced that a paper would be read at the next meeting, November 22, and with a vote of thanks to the President the proceedings terminated.

Parliamentary and Law Proceedings.

Quassia in Beer.

At the Bath police court, on Monday, Nov. 5, Mr. Henry Arnold, brewer, was summoned for unlawfully selling a certain article of food, to wit, a half-gallon of beer, which was not of the nature, substance and quality of an article of food demanded of him. Mr. F. H. Moger supported the prosecution on behalf of the Sanitary Committee of the Urban Sanitary Authority, and Mr. Bartrum for the defendant.

Mr. Montagu, inspector, was called and deposed to purchasing the beer in question on the 8th of October. Mr. Arnold declined his offer to return him part of the beer. He handed it to Mr. Gatehouse, city analyst, and from him received a certificate of analysis which he handed in. The certificate stated that the component parts of the beer were, water 87·42, extractive matter 7·38, and alcohol 5·20 parts, and stated as the opinion of the analyst that the sample contained the foreign ingredient quassia. Mr. Moger asked upon the certificate for the imposition of a penalty.

Mr. Payne said that for some purposes quassia was legal. It might be used as a substitute for hops.

Mr. Moger: Under an Act of George III. the brewers were liable to a heavy penalty if quassia was found on their premises. That Act, however, had been repealed.

Mr. Bartrum said it was for the prosecution to prove that quassia had been introduced into the beer, which was a compound article.

Mr. Moger observed that he treated it entirely as an article of food. He further stated that the certificate of the analyst was the proof required by the Act, but after some discussion called Mr. Gatehouse, who deposed to the accuracy of the certificate.

Mr. Gatehouse was cross-examined at length by Mr. Bartrum as to the methods by which he tested the beer. He said there was great difficulty in distinguishing between the bitters in beer. The chemical results obtained from wormwood and quassia were very similar. Was not aware that a premium of 1000 francs was offered by the Academy of Sciences in France to any chemist who could distinguish between the bitters in beer. By the Bench: I should not like to swear there is no other bitter in the world besides quassia that would produce the results obtained by my tests.

Mr. Bartrum then addressed the Bench, saying that although Mr. Gatehouse might be a good chemist, he had not the practical experience which was desirable in a public analyst. The trade in Bath had much reason to complain of a young man being placed in a position where his analysis might affect the trade in a most signal way. Here was a most respectable brewer liable to be deprived of his business by a dash of the pen upon the idea of an analyst. He should be able to show that Mr. Gatehouse had made a gross and palpable mistake.

Mr. Arnold was called and said his beer was composed entirely of malt, hops, saccharine and Bath City water. He denied absolutely that any other ingredient had been used. He did not know what quassia was. A sample of hop substitute from Wolverhampton had been sent him, but he ordered it to be destroyed.

Defendant's son and a brewer in his employment were called to substantiate this evidence.

Mr. W. W. Stoddart, public analyst for the county of Somerset and city of Bristol, was next called. He said he had examined over 200 samples of beer this year by order of the county magistrates, and had a large analytical practice among brewers. He did not believe there was any reliable test for quassia in beer. Had heard Mr. Gatehouse's evidence and would not have given a certificate upon the tests he had used. Had found quassia mixed with hops in numerous samples of beer but never dreamt of giving a certificate on them, as the instructions issued to the Government officers stated that any bitter might now be legally used in brewing. If quassia was used to any extent it would make the beer intolerably bitter. It would give only three or four ounces of extract from a hundredweight, and the only test he should rely on would be actually to see the dregs among the spent hops. Quassia was very frequently used by respectable brewers. It was an ingredient of hop substitutes which are openly sold. He never regarded quassia as an adulteration of beer because he did not know what beer was really. Quassia would not be deleterious, but if much of it was used the beer could not be drunk, it would be so bitter. Other substances besides quassia would produce the results Mr. Gatehouse had given. As a public analyst he should not consider that an to be adulteration which is allowed by the Excise.

The Magistrates retired to consider the case and on their return after a few minutes' absence, Mr. Blaine said it was the opinion of the Bench that the prosecution had failed, and the case was therefore dismissed. They wished to express their opinion that Mr. Arnold left the court without a stain upon his character as an honest tradesman. The costs of Mr. Bartrum and Mr. Stoddart would be allowed.—*Bath Herald.*

Prosecutions under the Sale of Food and Drugs Act.

At the Selby Petty Sessions on Monday, the 12th inst., before C. M. Weddall, Esq., and W. T. Smith, Esq., Messrs. Cutting and Son, Pharmaceutical Chemists, Finkle Street, Selby, were summoned under the Sale of Food and Drugs Act, 1875, for selling on the 11th September last, three bottles of soda water which were not of the quality required by the Act. Police Superintendent Gill prosecuted, and Messrs. Cutting and Son were defended by Mr. Henry Glaisyer, LL.B., under instructions from the Chemists and Druggists' Trade Association.

Mr. Gill stated that on the 11th of September, he purchased of Mr. T. J. Cutting three bottles of soda water, for which he paid ninepence. He told Mr. Cutting they were required for analysis. They were sealed, and one was sent to Mr. Alfred N. Allen, the public analyst for the West Riding of Yorkshire, one he retained in his own possession, and the third he left with Mr. Cutting. The analyst certified as follows:—"The sample of soda water was quite free from lead and other poisonous metals. The sample contained an amount of bicarbonate of soda, not exceeding about seven grains to the pint. Regarded as an effervescent drink the sample was perfectly free from objection; as a remedy it was deficient in soda, the amount of bicarbonate of soda in the soda water of the Pharmacopœia being thirty grains to the pint."

Mr. Glaisyer having called Mr. Gill's attention to that portion of the certificate which stated that as a beverage it was perfectly free from objection, inquired if he was aware there were two kinds of soda water.

Mr. Gill replied in the affirmative, but said he asked simply for soda water.

Mr. Gill then called Mr. Alfred Henry Allen, the public analyst for the West Riding of Yorkshire, North Derbyshire, and Sheffield.

Mr. Allen having explained the result of his analysis of the soda water as given in his certificate, he was cross-examined by Mr. Glaisyer as to the different qualities of soda water, their constituent properties, and their uses.

Mr. Allen said as a beverage Mr. Cutting's soda water was free from objection. He, however, drew a distinction between soda water as a beverage and soda water as a remedy; if he went to a druggist's shop and asked for a bottle of soda water he should expect to get the B. P. preparation, that was soda water made according to the standard prescribed by the British Pharmacopœia, which required that there should be thirty grains of soda to the pint, or fifteen grains to the bottle. If he asked for soda water at an hotel, or place of refreshment, he should expect to get an article prepared as a beverage with less soda in it. He had at different times examined one or two dozen samples; of these one contained no soda, some had a small quantity, while others had the full amount.

Mr. Glaisyer: Is soda water prepared according to the Pharmacopœia adopted as a beverage?—As a beverage only it contains too much soda.

Is the Pharmacopœia soda water such as a person would ordinarily take?—It is very nasty and would not agree with one.

As a beverage do you consider this a fair sample?—As a beverage it is unobjectionable.

And as a remedy?—That is a question for the magistrates to settle.

You tested it for lead?—Yes, but I found none. The total alkalinity of the water was equal to nearly seven and a half grains to the pint, this would give about three and a half grains to the bottle.

Mr. W. T. Smith: There was not in the sample a sufficient quantity of bicarbonate of soda as required in the official article, and if a medical man sent a patient for soda water it was important the article supplied should possess the proper quantity of soda.

Mr. Glaisyer: The summons does not treat this soda water as a "remedy," but as an "article of food," and I contend that as such it is unobjectionable, and contains a sufficient quantity of bicarbonate of soda. If Mr. Gill had asked for the Pharmacopœia preparation, *liquor sodæ effervescens*, he would have been supplied with it; but he asked for soda water, and he got soda water as it is usually prepared. There were two distinct kinds of soda water manufactured—one for medicinal purposes and the other to be consumed as a beverage. What was sold to Mr. Gill was soda water proper, and was an entirely distinct article from the soda water of the Pharmacopœia.

Mr. Glaisyer then called Mr. Thomas John Cutting, who said that he had sold soda water for twenty-eight years, during which time he had no complaints and his trade had increased. Dr. Todd was one of his customers, and he had expressed great satisfaction with it. He kept the Pharmacopœia or medicinal soda water, but he did not sell it unless it was specially asked for; he should not like to drink it regularly as it left a disagreeable soapy taste in the mouth.

Dr. John Attfield, Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, and a member of the Council of the Chemical Society, was examined by Mr. Glaisyer. He said that from his experience of soda water there were three articles sold under that name. There was aërated water, which contained no soda at all; there was a second kind which was a mixture of aërated water, bicarbonate of soda in quantity varying from two to eight grains to the bottle; and there was a third kind known as the medicinal article or *liquor sodæ effervescens*, also known as the B. P. soda water. This was introduced into the Pharmacopœia that physicians might have a medicinal article of constant strength. The official variety had a disagreeable soapy or alkaline taste, from the quantity of soda which was introduced into it. No. 2 was more or less soapy, and it was within his knowledge that the public objected even to this. What the public generally required was simply aërated water without even the two or three grains of bicarbonate of soda to the bottle. That aërated water should be called soda water was the fault, if fault it was, of the public. The vendor was helpless in the matter. When there was an excess of acid in the stomach, No. 3 was the very thing that was wanted, but it could only be taken as a medicine, Of the three bottles of soda water which Mr. Cutting sent him, under the seal of the police, one contained seven grains, and the other two somewhat more of bicarbonate of soda per pint. There was a little difficulty in mixing the bicarbonate of soda, so that it frequently happened the quantity would vary in a few bottles. He never found thirty grains per pint in any but medicinal soda water. He quite agreed with what Mr. Allen had said that the medicinal soda water would be very deleterious if taken constantly, weakening the action of the gastric juice.

The Chairman, after deliberating some time with Mr. Smith, said they had fully considered the case. They thought there had been less soda than there ought to have been, but having regard to the professional evidence they had decided to dismiss the case.

Alleged Adulteration of Pepper.—The same defendants were then charged with having sold two ounces of cayenne pepper adulterated with common salt and coloured with red ochre or some similar ferruginous material. The pepper was bought by Mr. Gill, on the 11th September, and Mr. Cutting was told for what purpose it was required. It was divided into three portions, one being sent to Mr. Allen in a registered letter, one kept by Mr. Gill, and the other was left with Mr. Cutting, The following was a copy of Mr. Allen's certificate:—

"The sample contained about $1\frac{1}{2}$ per cent. of common salt. Common salt is often added to cayenne pepper to increase the brightness of the colour and to prevent it from fading in the light. The sample was also coloured with a small proportion of red ochre, or some similar ferruginous material. The above additions are not injurious to health. No other adulterations or admixtures were detected."

Mr. Allen having repeated the result of his analysis was cross-examined by Mr. Glaisyer.

What test did you apply in analysing the pepper?—I applied the microscope; and then burnt the pepper, and I saw from the ash that it was not pure.

What did you find?—I detected salt. The solution of the ash showed the presence of salt, and I detected the crystals through the microscope.

Might not those crystals have been chloride of potassium?—My test did not distinguish between chloride of sodium and chloride of potassium, but the latter does not so readily form into crystals.

You say you found red ochre in the pepper; what test did you apply for that?—I said I found red ochre or some similar ferruginous matter. The ash of the pepper was red, and cayenne does not burn red. I also found in the ash traces of oxide of iron.

In what proportion did you find the oxide of iron?—About ·1 per cent.

What, only 1 in 1000! Might not the presence of this minute particle of oxide of iron be due to the rust from the mill in grinding the pepper?—I scarcely think so; for then it would have been brown, and what I detected was red. There was some matter in the pepper foreign to its true condition; but I am not here to say how it got in.

Can you be certain whether it was chloride of sodium or chloride of potassium that was found in the pepper?—I would not be positive, but I adhere to the belief that it was chloride of sodium.

And as to the ochre, it might be oxide of iron or rust from iron in grinding?—It might be, but I do not think it was rust.

I will ask you one question more. From the result of your analysis would you have recommended a prosecution in this case?—I should not.

Mr. Glaisyer, addressing the Bench inquired if they considered it necessary to go on with the case. He had Professsor Attfield at his elbow and other witnesses and he was prepared to tender their evidence.

Mr. Smith said that after the admission made by Mr. Allen they could not do otherwise than dismiss the summons.

The Chairman having concurred, the summons was dismissed.

Mr. Glaisyer applied for costs, but his application was refused.

Mr. Francis Taylor, chemist, of Selby, was also summoned for selling as soda water, water aërated with carbonic acid gas containing no soda.

Mr. James Grayson, solicitor, of York, appeared for the defendant and urged that aërated water was well known to the public and constantly sold as soda water.

The Bench fined the defendant 2*s.* 6*d.* and costs.

Review.

ETUDES SUR LA BIÈRE, SES MALADIES, CAUSES QUI LES PROVOQUENT, PROCÉDÉ POUR LA RENDRE INALTÉRABLE, AVEC UNE THÉORIE NOUVELLE DE LA FERMENTATION. Par M. L. PASTEUR. Paris: Gauthier-Villars. 1876.

It is part of the creed of the average English beer-drinker, that the brewers of this country practise their art with an admitted superiority over the brewers of all other lands. Here and there one better informed might admit that something in the way of beer brewing was done in Germany, but the popular conception of the relation of Frenchmen to the calling is manifest in the partiality of the typical Gaul of the comic prints for English "*portaire*." Those who share this belief may be surprised to learn that the book which is the subject of this notice is the work of a Frenchman and is one of the most important that has yet been written on beer brewing, being one which by the scientific light it throws upon difficulties that have hitherto been dealt with empirically cannot fail to exercise eventually a wide-spread influence on brewing operations.

The readers of this Journal are not unacquainted with M. Pasteur's views on fermentation, and in March 1874 an account was given of the manner in which he proposed to practically apply his theories in the brewing of beer. In his new volume M. Pasteur has gone into the subject more fully, and considering its importance and interest it may be desirable to recapitulate here the principal points of M. Pasteur's arguments and observations.

It is practically admitted that there is a close connection between the keeping properties of beer wort and the finished beer and the processes adopted for their production. Thus after the wort has been boiled it remains sound whilst at a high temperature, but when the temperature falls below 70° C. it becomes liable to lactic and butyric fermentation, and between 25° and 35° C. especially so. Hence the practice of reducing the temperature of the wort as rapidly as possible by the use of ice and other means to a point where the wort is comparatively safe from alteration.

The changes that take place in beer are various; it may become tart, flat, putrid, ropy, or otherwise unfitted for drinking. Simultaneously with each of these changes there is a development of characteristic organisms and these, which are beautifully figured in the book, M. Pasteur holds to be the cause of the changes. In putrid beer the organism is a vibrio, but in the other commoner varieties of deteriorated beer the organisms, although differing in each case, have more or less a filamentary outline of less diameter and are very different from the spherical granules of true beer yeast. So uniformly is this the case that the author recommends the regular use of the microscope in a brewery, as the detection of these filamentary organisms may be taken as a sure sign of actual or impending deterioration of the liquor. For this reason he terms them *ferments de maladie.*

As to the source of these organisms of course, M. Pasteur will not admit their spontaneous generation, neither will he admit that they are modifications of a common organism brought about by the conditions in which they are placed. But he looks upon each as a separate vegetation, the germs of which have been deposited in the liquor, or on the apparatus from the atmosphere, or directly introduced as a contamination of the yeast. But although *ferments de maladie* are not transformed one into another through the conditions surrounding them, these conditions exercise a selective influence on their development. Thus the spores of mucedines, and the germs of bacteria, leptotrix, vibrios, etc., may fall simultaneously into an acid liquid, such as grape must, but whilst moulds would flourish there. bacteria and vibrios would be retarded in their growth if not killed by the acidity of the liquor.

If, however, the must were previously saturated with carbonate of lime, the opposite of these conditions would obtain; bacteria, lactic ferments and butyric vibrios would invade the liquor long before the moulds had time to establish themselves, their germination being very sluggish in an alkaline or neutral liquid. When once an infusion becomes covered with one vigorous growth it does not for the time readily support another, as all the available nutriment, and especially the oxygen, are seized by the first comer. But as the special nutriment of this growth becomes exhausted from the liquor its development gradually flags, until a point is reached when it may give way to the development of a hitherto dormant ferment more suitable to the altered condition of the liquid.

This selective action of liquids M. Pasteur turns to account in the cultivation of particular ferments in suitable media, where they will grow to the exclusion of the development of any other fungi with which the orignal spores may be mixed. But as long as there exists the smallest admixture of a foreign ferment there is a possibility under altered conditions of the admixture becoming the predominant growth. Thus, if beer yeast apparently pure, but containing the least trace of lactic ferment, be introduced into an alkaline mixture of milk and sugar, the fermentation that takes place is not the ordinary alcoholic fermentation but the lactic fermentation. In this way the author explains the hypothesis that has been put forward that one ferment is transformed into another by a variation of surrounding circumstances.

But although one of these fungoid growths is not transformed into another—as, for instance, the *Penicillium glaucum* or *Aspergillus glaucus* into beer yeast—some interesting facts were observed in the course of the investigation by which that result was established. When a mould that ordinarily vegetates in contact with atmospheric air, and draws from thence the oxygen necessary for its existence, is deprived of that source of supply, it may still continue to live, although with difficulty; but in this case the form of its sporic or mycelium development undergoes a change. Generally it may be stated that the tubes of the mycelium become shorter and thicker, approaching a globular form, and at the same time the plant shows a great tendency to act as an alcoholic ferment; that is to say, when plunged beneath the surface of a saccharine liquid it decomposes sugar with formation of carbonic anhydride, alcohol, and other undetermined substances, probably varying with the different moulds. The explanation given by Dr. Fitz, of Berlin, and endorsed by the author, is, that a fermentation fungus requires oxygen for its development; if it finds this in a free state it uses the oxygen in burning up a part of the sugar to assist it in assimilating another part; if there be no free oxygen the plant obtains from the sugar itself the oxygen it requires. This is in accord with what is observed in the development of even superficial beer yeast; for although it grows most luxuriantly when freely in contact with the air, it does not induce the formation of alcohol so rapidly as a less luxuriant growth submerged beneath the surface of the liquor.

It may be remarked that, whether right or wrong, the views propounded by the author are not mere speculations, but are inferences drawn from numberless experiments, many of which are described and beautifully illustrated in the volume, but cannot be more than alluded to here.

The chapter on the alcoholic ferments is intensely interesting and is almost bewildering in its suggestiveness. Take beer yeast, for instance. It is usual to speak of this as of two kinds—superficial yeast and bottom yeast; the former being almost exclusively used in this country and the latter on the continent. By some these two have been looked upon as two forms of one ferment, modified by its development, in the one case submerged in the liquor at the bottom of the vat, and in the other by its development at the surface of the liquor in the presence of atmospheric air. But M. Pasteur is evidently doubtful of this. In fact he quotes evidence to show that each may be a mixture of several distinct ferments. Thus, superficial yeast, obtained absolutely pure by cultivation, is killed by a temperature of 50° C., and is no longer capable of provoking fermentation. But one commercial sample of superficial yeast submitted to that temperature still remainedcapable of producing fermentation, due to the survival of a previously unnoticed form, to which in consequence of its physical appearance the name of *levûre caséeuse* has been given. This ferment was afterwards separated in the same way from other samples of superficial yeast, and further investigation and comparison led the author to believe that this hitherto unnoticed yeast plays an important *rôle* in some breweries, especially in the production of the famous pale ales manufactured at Burton-on-Trent by Messrs. Bass and Allsopp! Another superficial ferment accidentally met with was cultivated and yielded a beer unlike any at present known. Moreover all these forms can, by a special treatment, be made to undergo modifications; the products can in their turn be modified indefinitely; and each is said then to yield its special beer, the aroma of which in some cases is easily distinguishable.

It has been attributed to M. Pasteur that in his opposition to the theory of spontaneous generation, and also of the transmutation of species, he has accounted for the setting up of fermentation in fermentescible liquids, by supposing the air everywhere to be full of germs of all kinds of ferments, which are deposited on the surface of any such liquid whenever exposed. This, however, is not in accord with the result of M. Pasteur's experiments, for they went to show that although such germs do exist in suspension in the air, they are relatively few in number, except in localities where fermentation operations are carried on. The question therefore arises, whence do these remarkable bodies, such as the vinous ferment, take their origin? It has been found that the juice of a crushed grape does not ferment if it be preserved from contact with the powder occurring on the skin of the grape or on the wood of the vine; whilst the powder from a single cluster, or even a single grape, is sufficient to set a whole vat of juice into fermentation. This powder, collected by washing twelve grapes successively in 3 c.c. of water, was sufficient to render the water turbid, and when examined under the microscope was seen to consist of small organized bodies, associated occasionally with crystalline needles. A still larger relative quantity was obtained by washing the wood of the peduncle, and the washing of gooseberries, plums, peas, etc., gave similar results. The liquor so obtained when added to grape juice previously boiled, induced fermentation under conditions that led the author to the conclusion that the yeast cells have their origin in small brown organized bodies, which can be seen in great abundance by the aid of the microscope in the powder that covers the surface of fruits. Other experiments indicated that these bodies are only met with about the time of the maturity of the fruit, and that they disappear during the winter.

The foregoing may explain the origin of ferments which cause what may be called spontaneous fermentation, such as the fermentation of wine, where the process of crushing the grapes impregnates the juice with so many of these germs that it is left to ferment without further treatment. The case is different, however, with the fermentation of beer, where the material for inducing fermentation has to be added in the form of beer-yeast. Where the yeast for the first brewing came from, and whether it was superficial or bottom yeast, is an open question. As a matter of fact, beer wort abandoned to spontaneous fermentation may yield yeasts akin to that of the vine, but never the true beer yeast of either kind. Whether the ears of corn in its primeval wild form were covered by their appropriate organized pulverulent ferment, or whether beer yeast has been derived from another source and has become modified by prolonged cultivation in a particular manner, cannot now be decided.

Long as this notice has become only a few of the topics discussed in M. Pasteur's book have been alluded to. It will be seen, however, that it is not a book for criticism, the author's statements being supported by a plethora of experimental results that would have to be disproved before his inferences could be well impugned. The subject is one of extremely wide interest. The practical result of the author's researches, however, specially set forth in the present work is, that by the proper cultivation of beer yeast in suitable media, the so-called *ferments de maladie* can be eliminated, and with the pure yeast so obtained beer, or beers, can be prepared that will remain perfectly unalterable. How this is to be done is too long a story to be transferred to these pages, but must be read in M. Pasteur's handsome volume, which promises to inaugurate a new era in the history of beer brewing.

Obituary.

Notice has been received of the death of the following:—

On the 17th of September, 1877, Mr. Robert Hargreaves, Chemist and Druggist, Castle Street, Clitheroe. Aged 58 years.

On the 20th of October, 1877, Mr. Charles Tovey, Chemist and Druggist, Cairo. Mr. Tovey was pharmacist in the establishment of His Highness the Khedive of Egypt.

On the 2nd of November, 1877, Mr. William Charles Hayland, Chemist and Druggist, Ousegate, York. Aged 57 years. Mr. Hayland had been a member of the Pharmaceutical Society since 1869, and under a *nom de plume* frequently contributed to the Correspondence columns of this Journal.

On the 3rd of November, 1877, Mr. James Byron Burt Shenstone, Pharmaceutical Chemist, High Street, Colchester. Mr. Shenstone was a native of Bath and in 1839 was apprenticed to Mr. Smith of Colchester. After the expiry of his apprenticeship he was in business for several years at Wells, Norfolk, but in 1854 he entered into partnership with his former master, Mr. Smith, and since 1865 he has carried on the same business on his own account. Mr. Shenstone was Local Secretary of the Pharmaceutical Society, having been a member since 1853, and was the President of the Colchester Chemists' Association.

On the 5th of November, 1877, Mr. William Laird, Pharmaceutical Chemist, West Port, Dundee. Aged 52 years. Mr. Laird had been a member of the Pharmaceutical Society since 1853, and was an occasional contributor of papers to this Journal. He was also President of the Dundee Chemists' Association.

Dispensing Memoranda.

[21]. Apothecaries' or Avoirdupois?—It seems to me that Mr. Symes and P. B. are both very positive on this matter without any very good reason. In the P. L., 1851, we find the sign ℥ used to indicate one ounce of 480 grs.; and that being the latest authoritative interpretation of the sign I consider that it is still in force, and will continue so until altered by a competent authority.

The omission of any reference to it in the B. P. does not, I imagine, alter its value or prove that when used 437·5 grs. are intended. No one, I imagine, would dispense Liq. Sodæ Borac. ʒij, P. Sacch. ʒiv, Pot. Supertart. ℥j with 437·5 of Cr. Tart. and 120 and 240 grs. of the other two ingredients.

No doubt, if any one, customer or physician, sent to me for a number of articles, and wrote ℥j, ℥ij, ℥iv, and so on, I should supply the articles by avoirdupois weight, because that would be a commercial transaction; but when ℥j is written in a prescription I conceive it is used as a multiple of ʒj, and should be so interpreted.

Manchester. W. Wilkinson.

[21]. Apothecaries' *versus* Avoirdupois Weights.—I have often observed the conflicting opinions with regard to the correctness of dispensing with the apothecaries' weights when compounding medicines according to prescriptions, and attention having been recently called to the matter through the columns of the Journal, I venture to express my opinion on the subject, and, in doing so, I would unhesitatingly bear you out in the legitimacy of rendering the sign of "℥j" as equivalent to 480 grains. The following are some of my reasons for deciding in favour of your injunction:—

1. There is a wide difference between the buying or vending of drugs and the dispensing of medicines, although your correspondents seem to confuse the nature of simple purchase with the more difficult and important duty of dispensing with accuracy; so I hold that the comparison does not apply in this case.

2. The introduction of the avoirdupois system of weights into the Pharmacopœia in lieu of the other was (I fancy), more as a matter of convenience than necessity, so that large quantities of preparations (galenical or chemical) might be made by manufacturers without the trouble of converting the one scale into the other, since there are no large troy weights met with in commerce.

3. The physician knows the strength of such preparations (it being stated in the B. P. under each crude drug the number of grains the fluid ounce of its tincture is equal to), and prescribes accordingly, whereas when he orders solid ingredients he employs in preference the more readily divisible quantity, wishing the sign "℥j" to be understood as indicating the multiple of ʒj.

4. In selling over the counter we must conform to the established rule of selling by the avoirdupois ounce like other traders, when the price charged for the article bears a simple relation to its prime cost per pound. Further, customers want to know what weight they are getting.

5. It seems to me as clear as noonday that ℥j cannot possibly imply 437·5 grs., but an example or two will possibly afford better proof of the truth of my premises: (1) A physician orders a mixture containing Potass. Brom. ʒj, Aquam ad ℥viij, along with some adjunct dose ℥ss! Does he mean to give a dose of 27·33 grains, or does he intend ʒss to be administered periodically? Certainly the latter. In many instances the prescriber, after diagnosing the disease, ascertains the proper proportion to exhibit, and by simple calculation converts it into a multiple; at other times he specifies the quantity for one dose and adds "Mitte ℥viij." In the last case the dispenser would use troy weight, while in the former the majority would use avoirdupois weight, and, with the same original intention, the results would be different.

6. Another case in point, which has frequently come under my notice, is the following: ℞ Potass. Chlor. ℥j, divide in chart. viij. Sig.: One to be dissolved in a glassful of water and taken in three portions. Here, one scruple is meant to be given at a time.

7. Again, suppose we have an effervescing mixture prescribed with Potass. Bicarb. ℥ss in a twelve-ounce bottle, and, in conjunction with it, separate powders, each containing the requisite amount of citric acid to produce Pot. Cit. at the time of taking. In this instance there should be no dubiety as to what course to pursue; but those who fail to see the propriety of employing the troy weight would weigh the acid powders rightly, or according to the apothecaries' scale, and yet use another kind of weight for the alkali; hence the salts would not saturate each other as was intended. Such a mode of procedure is not only extremely inconsistent but, as I have endeavoured to show, unquestionably erroneous. Unfortunately there are many dispensers who rigidly adhere to the wrong way, which human nature appears almost persistently to follow.

"B. P." remarks that the troy weights ℥i, etc., are "practically obsolete;" this is not so, however, for they are used in many pharmacies throughout the kingdom (from ʒii to ℥viij, cup shaped). Of course, when the quantity is one ounce (*sic*) there need be no difficulty; or, again, if the drug or chemical be sent out in bulk, it is immaterial what weight is used (although it is better to employ the right one) so long as the dose remains the same; this is obvious, for, "as much as will lie on a shilling, etc.," may be taken from either 437½ or 480 grs., and practically there will be no difference in the absolute weight.

Another source of error, and one which is too prevalent, is the same confounding of weights in making solutions of salts for convenience in dispensing, *e.g.*, Chloral Hydrate one ounce, Water to two ounces; the solution is then labelled, and the strength marked as "one in one." I need not comment upon the blunder. I hope the time is not far distant when no ambiguity shall arise about the interpretation of signs, but that ℥j shall infallibly imply the recognized equivalent of 480 grs. I fear, under existing circumstances, it would not be policy to introduce the metrical system of weights and measures, as it would only cause more confusion and mistakes.

JAMES B. L. MACKAY.

Newcastle-on-Tyne.

---

[27]. AQ. CAMPH. CONC.—During the discussion on the subject it has been repeatedly stated that Aq. Camph. contains ½ gr. camphor in each ℥j; this is not quite correct. Wishing some time ago to make an Aq. Camph. Conc., and not having the least idea to what extent camphor was soluble in water, I put a weighed lump in ℥xx of water and allowed it to remain seven days; at the end of that time I found it had lost 12½ grs., and therefore concluded the pint of water had dissolved that quantity, and calculated my Aq. Camph. Conc. accordingly.

℞ ʒj Camph., ℥iij Sp. Vin. Ten. ʒj of the above added to ℥iv of water forms a clear solution in the course of a short time, which contains 2½ grs. camphor in the ℥iv.

W. W.

---

[27]. AQ. CAMPH. CONC., 1 to 7.—I have been in the habit of employing a solution of camphor in rectified spirit, *e.g.*:—

Camphoræ . . . . gr. xvj.
Sp. V. R. . . . . fl. ℥j.

This diluted with fl. ℥iij. of proof spirit will contain 4 grains of camphor in each fluid ounce, or ½ grain in each fluid drachm; fl. ʒj., therefore, of the diluted solution added to fl. ʒvij of water will form Aq. Camph., B. P., gr. ½ in each fluid ounce, perfectly clear. In cases where the employment of the diluted solution containing as it would a large proportion of spirit might interfere with the intentions of the prescriber, I employ the more concentrated, in the proportion of 15 minims to the fluid ounce, the proportions of camphor being equal, the spirit is reduced to a minimum. R. W. CARTER.

---

[31]. To be of any service as an liniment the following are evidently the proportions intended by the prescriber.

Chloral Hydrate,
Camphoræ . . . . āā ʒj.
Glycerini ad . . . . ʒvj.

Just powder the camphor, using as usual a few drops S. V. R., then mix with chloral, and allow to stand in mortar until the mixture becomes liquid. Having poured this into bottle, add glyc. and shake.

W. F. TOCHER.

---

[39]. Can any one suggest a method for mixing the following prescription, without separation taking place?—

℞ Tinct. Canthar.,
Liq. Ammon. Fort.,
Vaseline . . . . āā ℥ij
Aquæ . . . . ad ℥xxx.
Misce. Fiat Lotio.

F. H. B.

---

[40]. Could some one inform me the best way of dispensing the following prescription, so as to make a good mass for rolling and for the pills to keep a uniform shape?—

℞ Ferri Redacti . . . . . gr. iij
Ext. Belladonnæ . . . . gr. ⅙
Bals. Peru . . . . . . ♏j
Ft. Pil. Mitte xij.

H. R. M.

Notes and Queries.

[556]. DRUG MILLS.—The Enterprize Manufacturing Co., Philadelphia, to whom I wrote for information about the American drug mill, informed me that Messrs. Kenrick and Sons of West Bromwich were manufacturing their American coffee, drug and spice mill here, and on application to Messrs. Kenrick, I was glad to find they had a supply on sale at their agent's, Mr. Geo. Burton, 232, St. John Street, E.C. Mr. Greenish and I have each had a No. 4a with enamelled and iron hopper, both of which work well. I tried mine with linseed; it ground it to a nice powder, but I think an hour on the treadmill would be gentle exercise compared with that of producing two pounds of linseed meal. It grinds most drugs which do not contain much resin or fixed oil sufficiently fine fine for percolation.

WM. MARTINDALE.

[561]. PULV. SULPH. ET POTASS. BITART.—Can any one give me the formula Pulv. Sulph. et Potass. Bitart? F. STEVENS.

[562]. BRILLIANTINE.—Will any correspondent oblige by giving a good formula for Brilliantine; one that will separate into two parts, each part remaining perfectly bright? "TOM."

Correspondence.

THE PROPOSED ADMISSION OF WOMEN TO THE PHARMACEUTICAL SOCIETY.

Sir,—As many of the members of the Society, like myself, live in the provinces, and are generally unable to attend the annual meetings, it is well that such an important matter as has been lately referred by the Council to the decision of the coming conclave should be fully ventilated; and I can think of no likelier way than discussing it in your columns, if you will kindly grant the required space. The proposition may be briefly stated thus: Is the female sex a sufficient disqualification in an individual for admission within the borders of our Society? This question I, for one, venture to answer in the affirmative. What is the purpose in nature of the distinction of sex if there are not distinct duties and privileges belonging to each? The male is therefore generally formed of sterner stuff to fit him for his rougher work, but he looks to the female sex to provide for his welfare in the household duties and comforts of home. In consideration of her weaker frame, woman has always been allowed certain privileges among civilized nations, such as exemption from military service and other onerous duties, so that even as far back as the middle ages we find furious knights and proud cavaliers invariably respectful to ladies, so that the very word chivalrous was coined out of this circumstance. It becomes, then, a serious question whether we are prepared to see distinctions which have been kept up by a long period of natural selection ruthlessly overthrown and set aside, and woman lowered to the level of the arena of competition with man. If so, good-bye to all chivalry and every other privilege which the female sex has enjoyed, and let us have a fair fight and no favour. But this is impossible at present, as the traditions of centuries are not easily overthrown; and, meanwhile, ladies, by exercising their charms over examiners, will have an unfair advantage over gentlemen in the competition. If any one doubt this, let them compare the reports of the various teachers in a school of young ladies partly taught by masters and partly by mistresses, and they will find those of the former usually much more flattering than the latter.

But it may be urged that all this is not to the point, as our regulations already permit ladies to present themselves for examination. I am not about to discuss the wisdom or unwisdom of the present *régime*, but what I wish to impress upon those who are interested in the subject is the extreme folly of taking away any remaining barriers to the entry of a profession for which ladies are by their sex eminently disqualified. It was urged by Mr. Hampson, in his late speech at the Council board, as a special reason for electing two ladies as associates of the Society, that they had passed their examination with great credit; and our worthy President chimed in with the declaration that they were the highest on the list on the examination day; and at the end of the discussion it is worthy of note that the same gentleman appealed to Mr. Hampson, in a most pitiful strain, to spare him and some of his colleagues the alternative of having to violate their convictions or vote against the ladies. Well, all this proves my argument that there is likely to be an unfair bias in favour of the female sex.

The reasons why it seems to me we should do well to discourage the entrance of ladies into our profession are briefly these:—

1. It is an onerous business at best, with scant remuneration for the amount of time given to the accommodation of the public.
2. There is a considerable amount of drudgery connected with it, which must be repugnant to ladies, and which I should seriously be disposed to think their constitution would not be adapted to endure.
3. The market is already crowded; as you can go to very few towns but you will find druggists' establishments in far greater proportion than the wants of the population for their special commodities.
4. Though I can conceive that a young lady might perform the office of a dispenser pure and simple, yet there are many cases brought to the notice of an ordinary chemist which would be exceedingly undesirable to bring her in contact with; and hence the mixture of sexes in a pharmacy of the ordinary description would be an unmitigated evil.

For these reasons I must beg most respectfully to differ from the conclusion of Mr. Hampson, that "if any ladies did embark in the business of pharmacy the Council ought rather to hold out a hand to them than throw any obstacle in their way." I believe the only right way, and the kindest one in the long run, towards those who are taking a course which we believe to be adverse to their best interests, is to throw as many obstacles in their way as possible, and then if some still persist, why they must accept the consequences. But to throw the door of entrance into our Society open to all—indiscriminate of sex and other disqualifications—would, I believe, be a great mistake. It would be a direct invitation to ladies to come and compete with us, of which I fear that many would not be slow to avail themselves, and these would find themselves, when it was too late to withdraw, in a false position. As to the hardship of the fate of those unfortunate ladies who may seem really qualified to fill the arduous posts to which they aspire, I believe and trust they will always be exceptions, and must submit to the only sound policy in legislation—the greatest good to the greatest number; and whilst the dreadful doors of the examination rooms are not closed against them, they really have very little reasonable ground for dissatisfaction or complaint.

CHARLES FRYER.

12, *St. Nicholas Street, Scarborough,*
Nov. 12, 1877.

[*** We have received another letter on this subject from "*A Moral Pharmacist*," which like the foregoing travels beyond the record, and to a greater extent. We would remind our correspondents that the question to be brought before the annual general meeting is not whether women may practise pharmacy—that has been decided by Parliament—but, whether having become qualified and registered as pharmaceutical chemists or chemists and druggists, they should be elected as Members or Associates of the Pharmaceutical Society.—ED. PHARM. JOURN.]

THE SALE OF FOOD AND DRUGS ACT.

Sir,—Allow me to suggest that the results given in the report referred to are on too limited a basis to ground any opinion upon. What can be said about three draughts of one article, probably, or six of another. Supposing a person purchased laudanum at twenty places in any provincial town, what would be the proportion that would be equal to the B. P.; or, to take another example, vin. ipecacuan. or tinct. rhei co. Our trade or any other trade dealing in articles that come under the cognizance of the Act would act very foolishly were they to continue selling such articles as have been condemned under its operation.

All the rubbish that was formerly sold has had to be destroyed or sent abroad for the heathens. But the stomachs of Englishmen are relieved of the trouble of digesting plaster of paris, excepting when they take lac sulphuris.

ALPHA.

November 4, 1877.

The Poisonous Properties of Yew Leaves.

Sir,—During the discussion on "The Poisonous Properties of Yew Leaves," at the last evening meeting, the President expressed some doubt as to whether the common yew possessed equally poisonous properties with the Irish variety.

In 'Withering's British Plants' (1830), in addition to a reference to the case of three children being poisoned by a spoonful of the green leaves, although they had taken a similar quantity of the dried leaves on the previous day without effect, he states that "sheep and goats eat it; horses and cows refuse it (Linn.). . . But there are instances of both having been killed by eating it. . . Sheep are said to have been killed by browsing upon the bark. . . In August, 1822, Mr. E. Nicholls, of Ringmer, Sussex, turned a horse into a field in which there were some sprigs of yew tree, which had been clipped off in the course of the day. The horse ate of these afterwards drank at a pond and quickly died. In January, 1823, in a deep snow, Messrs. Woodward, of Chelmsford, in Kent, turned out three healthy horses into a small close, adjoining which was a yew tree. In three hours they were found dead with yew in their stomachs. It is believed to be equally fatal in sheep." The editor also states that "Four ounces of sweet oil, taken at two doses, in warm ale, and after that a pint of salt and water, have been found to relieve cattle thus poisoned." That, however, the leaves of the yew can be used in times of scarcity as a food for cattle, provided always that great care is taken with them, is evident from the following extract taken from 'Cattle; their Breeds, Management and Diseases,' by Youatt:

"The yew is probably the most destructive (vegetable) poison, especially when a quantity of it is taken unmixed with other food. M. Husard, however, relates that in Hanover and Hesse the cattle are partly fed on the leaves of the yew. He examined the trees as they grew on the mountains of those countries, and found them to be the tree yew. In winter, and especially when fodder is more than usually scarce, a portion of yew leaves and branches is mingled with the other food. The quantity of the yew is small at first, but it is gradually increased until it constitutes the greater part of the food; and it has the reputation of materially contributing to the fattening of the beast. The inhabitants of Hanover and Hesse are, nevertheless, perfectly aware of the poisonous property of the leaves of this tree, and are sometimes taught, by dear experience, that it will destroy their cattle, unless it is managed with this degree of caution.

"M. Husard adds, that on his return to France he determined to put this matter to the test, but he selected the horse instead of cattle as the subject of his experiment. He gave the yew mixed with oats in the proportion of half a pound of the former to a pound and a half of the latter, and the horse did not appear to be in the slightest degree inconvenienced by what he had eaten.

"This animal, however, was enfeebled and emaciated previous to the experiment; and it occurred to M. Husard that there might be a deficiency of sensibility in the stomach and in the frame generally, and that in consequence of this the poison might not produce its fatal effects: he, therefore, selected a mare in good health and condition as the subject of a second experiment. She ate the mingled yew and oats, and suffered no inconvenience.

"He selected another horse as the subject of a third and decisive experiment. He took seven ounces of the yew, and bruised and mixed it with twelve ounces of water, so as to make a kind of electuary, which he gave to a horse which had fasted for hours; an hour afterwards it fell and died."

Youatt, however, goes on to warn persons against using yew without the greatest caution, as he has himself known several instances to occur in which the presence of a considerable quantity of other food in the rumen has not preserved the beast from the fatal effects of the yew.

I am aware all the above cases possess veterinary rather than pharmaceutical interest, but I imagine it may be rather difficult to obtain information on the action of this plant when given to human subjects, and have therefore forwarded these extracts.

Yew leaves are stated to have the power of "stealing away life speedily, without raising convulsions or commotion" in the horse; and although, of course, very many drugs and herbs act in a totally different manner on human beings, I think it highly probable that in this case the action may be the same in both.

F. H. Storey.

W. F. F.—You will find many recipes for colours for show bottles in the recent volumes of this Journal; if you had specified the colours we would have provided a reference. Recipes may also be found in Cooley's 'Cyclopœdia,' or Beasley's 'Druggist's Receipt Book.'

"*Compositor.*"—We cannot say what kind of printing press would be "suitable for a country chemist;" so much would depend upon what he wanted to do with it. If you explained your want to Messrs. Ulmer and Co., printers' brokers, Farringdon Road, probably they would advise you.

Student.—Barber's 'Pocket Companion to the Pharmacopœia' is published by Philip and Son, Fleet Street.

C. Williams.—We cannot give you the information, but it could probably be obtained from a respectable scholastic agent.

E. Cardwell.—We differ from you as to there not being any foundation for the opinion expressed, which we still think was justified by the fact that the appeal to the employers was accompanied by a statement that the assistants were not themselves supporting the Association as might be expected. We do not think we can be fairly charged with acting adversely to the interests of the Association, its promoters having on several occasions been allowed to make known their projects in these columns, and we shall be happy to give the Association such further assistance as lies in our power, as soon as the signs of "life and good" of which you speak are more manifest.

W. J. Doe.—The strawberry tree, *Arbutus Unedo* (Ericaceæ).

E. Jerrett.—The explanation is to be found in the fact that the peas were dry.

J. C. Thresh.—(1) Microscopic drawings of the structure of capsicum fruit and seed are given by Hassal in his work on Food, and by Berg in the Anatomische Atlas. (2) We cannot.

Nemo.—Apply to the Registrar of the University of London.

A. H.—We do not known; consult a solicitor.

G. H.—The cause of the decomposition which takes place occasionally in mixtures containing subnitrate of bismuth and an alkaline carbonate, has been recently discussed in this Journal. See vol. vii., pp. 1053 and 1073, and present vol., p. 66.

A Subscriber (Ashton-under-Lyne).—The envelope was open and contained no sample when it arrived.

C. H. K.—Try solution of salicylic or carbolic acid.

W. S. Harris.—(1) The third edition of Bentley's 'Manual of Botany' was published in 1873. (2) The Pharmaceutical Latin Grammar is published by Groombridge and Co.

W. D.—We believe the article can be obtained from any manufacturing chemist.

W. V. Lewis.—A formula for Composition Powder was given in vol. vii., p. 308 (Oct. 7, 1876).

J. A. Floyd.—Your specimens consist of four fungi and one lichen. (1) *Corticum læve*; (2) *Stereum purpureum*, young state; (3) Too fragmentary to name; (4) *Nectria cinnabarina*; (5) *Physcia stellaris*.

R. S. T.—A separation of quinine sulphate in consequence of its slight solubility.

Inquirer.—See Mr. Warington's paper on "The Manufacture of Citric Acid," vol. vii., p. 767.

Communications, Letters, etc., have been received from Mr. Jackson, Mr. Brend, Mr. Maltby, Mr. Hurst, Chemist, A.P.S., D.D.

"THE MONTH."

In the country, bare trees, fallen leaves, and naked hedgerows meet the eye everywhere, and even the gardens present a desolate and bedraggled aspect, with little to brighten them except, perhaps, a few scattered chrysanthemums or a late blossom of the dahlia or African marigold. One extremely pretty object, however, may be seen occasionally in the hedgerows, which when seen is almost sure to be gathered for its beauty. This is the fruit of the spindle tree, of a most lovely rose-pink colour and coral-like appearance, and which splits open and discloses to view four seeds covered with a brilliant orange-coloured arillus. The leaves, flowers, and fruit of this shrub are commonly reported to be poisonous, but probably this idea is erroneous, since the wood has been used for skewers on account of its freedom from bitterness; the fruits also were found by Grundner to have only a diuretic effect. A bark of a nearly allied species, *Euonymus atropurpureus*, which from its equally bright coloured berries is known in the United States under the name of the "burning bush," is used as a tonic and diuretic in that country.

A very noticeable object in gardens at this time of year is the winter cherry, *Physalis alkekengi*. To botanists it is interesting as affording an example of an accrescent calyx. The calyx, at first green, and not by any means conspicuous, increases in size more rapidly than the fruit, so that by the time the fruit is mature the calyx, which is then of a bright orange-red colour, is several times larger than the globular fruit which it encloses. The fruit contains citric acid and a bitter principle, physalin, to which its properties are most likely due. The fruit is said to form a principal ingredient in a well-known nostrum for gout, and the leaves have been used in the south of Europe as a substitute for quinine. The bitter principle when dry has the curious property of becoming strongly electric when rubbed. Another species of the same genus, *Physalis viscosa*, is used in America as a diuretic in various urinary complaints. The winter cherry probably deserves more attention than it has hitherto received. The fruits of the winter cherry form one of the objects used for groups of skeleton leaves.

Few medicinal plants are as yet to be seen in blossom. At Kew, *Cinchona officinalis* is now coming into bud, and *Olea fragrans*, *Ricinus communis*, and a few varieties of tobacco and of orange are sparingly in flower, while different forms of *Capsicum annuum* relieve the mass of green foliage with their bright coloured and variously shaped fruits. The ripe capsules of the cotton plant are now in good condition for observation.

At the Edinburgh Botanical Gardens the cinnamon and contrayerva are in blossom, as well as the colchicum and the Christmas rose (*Helleborus niger*). *Cassia corymbosa*, also blossoming in the hothouses, affords an example of the structure of flower characterizing the sub-order Cæsalpiniæ of the Leguminosæ; and the curious arrangement of the stamens in different lengths, the porous anthers and the single gland at the base of the lowest pair of leaflets are worthy of notice. At the Regent's Park Gardens this plant has nearly ceased flowering, while the *Helleborus niger* has not yet made its appearance. *Helleborus fœtidus* is however now in flower in the open ground. The time of flowering seems to depend somewhat upon the time of year that the plants have been moved.

The November number of 'Medicinal Plants' contains figures of the following plants:—*Gynocardia odorata* (a double plate), *Galipea Cusparia*, *Arctostaphylos Uva-ursi*, *Solenostemma Argel*, *Capsicum annuum*, *Veronica virginica* and *Nectandra Rodiœi*. Of these plants *Nectandra Rodiœi* has not been previously figured; *Veronica*, better known as *Leptandra virginica*, only once before in an obscure work; and *Gynocardia odorata* only by Roxburgh.

Gynocardia odorata is official in the Indian Pharmacopœia as the plant yielding chaulmoogra oil, used in leprosy, and *Veronica virginica* in the United States Pharmacopœia as a stimulant in hepatic affections, while *Solenostemma Argel* owes its presence in the work solely to the fact of its being an adulteration of Alexandria senna.

The failure of ipecacuanha in India as a profitable crop, as reported by Dr. King of Calcutta, and the utter want of success with cinchona in Australia recorded by the director of the Botanical Gardens at Melbourne, in his recent report, are much to be deplored. It is always a wise policy not to be dependent upon one country for a supply of any drug, and it is to be hoped that an endeavour will now be made by the Government to introduce both these plants, not forgetting also the *Eucalyptus globulus*, into tropical Africa, in some parts of the region so recently laid open to English enterprise by the great American explorer, Stanley.

Every month seems to bring with it new remedies for trial, and while some few, like *Sophora speciosa* and curari, possess very powerful properties, many others are either almost inactive or require accident, as in the case of salicin, to discover their special properties. *A propos* of curari, which has long been known, comes its application to that frightful disease hydrophobia, of which both the medical journals and the daily papers are so full. Amidst all the talk of the learned and the twaddle of the ignorant, it is refreshing to find that some steps have been taken to investigate the true nature and treatment of the disease, for it is obvious that unless the seat of the disease and the structural lesions produced by it be discovered, it will be impossible to suggest a remedy, or to find one except by accident. The names of Dr. T. Lauder Brunton, F.R.S., Dr. J. Burdon Sanderson, F.R.S., Mr. Callender, F.R.S. and the energetic editor of the *British Medical Journal*, Mr. Ernest Hart, appear as members of the committee which has been appointed for this investigation. It is to be feared, however, that the best which can be done will only amount to a collation of the most carefully observed facts regarding cases of the disease. It will be many years hence before a definite knowledge of the causes and scientific treatment of this complaint can be attained.

Of course a number of methods for the treatment of hydrophobia have been already described. Thus the *Lancet*, of a recent date,* contains a note setting forth Buisson's treatment, which is as follows:—M. Buisson, of Paris, while attending a patient who was affected with hydrophobia, took the disease, and experienced its symptoms, such, for instance, as constriction of the pharyngeal muscles, and in despair of his life he determined to anticipate inevitable death by suicide. He therefore entered a Russian vapour bath at 107° F., when the symptoms subsided, and he in time completely recovered. He claims to have since then treated eighty cases of hydro-

* *Lancet*, Sept. 29.

phobia successfully in this way, supplementing the vapour bath by induced night perspiration and administration of decoction of sarsaparilla. The old journal from which this was extracted states that so convinced was M. Buisson of the efficacy of his treatment that he would allow himself to be innoculated with the virus.

Up to the present time curari, chloral and pilocarpine are the only new remedies suggested which present any chance of success in the treatment of this horrible disease. There is, however, one mode of treatment known to have proved successful, but which does not appear to have been recommended to any extent, probably on account of its requiring considerable courage, and that is the immediate excision with a sharp knife of the spot bitten, the subsequent bleeding tending to prevent the absorption of the virus, which lunar caustic or the actual cautery must tend to keep in the wound.

It is not a little instructive to outsiders to observe the difficulty that medical men have in coming to scientific conclusions from their results. Thus in one medical journal a case is given in which poisoning by ten grains of morphia was cured by the subcutaneous administration of sulphate of atropine and the internal use of tincture of belladonna, while in a contemporary almost of the same date another doctor gives his experience as tending to the conclusion that atropia "intensifies rather than counteracts the sedative effects of morphia."

There does not, however, appear to be any want of agreement among medical practitioners as to the opinion that chemists should never prescribe under any circumstances. Even in distant Chicago and still more distant New Zealand the same course is being pursued as in this country, and any case of injury arising from the careless prescribing of a chemist is eagerly pounced upon and held up to public gaze for the severest denunciation. In common fairness it might be demanded that accidents happening in the practice of medical men should receive equally rigorous advertisement and castigation, for the medical profession will scarcely lay claim to infallibity of judgment. Thus while the Weymouth chemist is made an object for caustic remarks, the apparent neglect of the use of antidotes in the case of the poisoning of Mr. Ellis, of Leicester, by prussic acid is allowed to pass without remark. Well known antidotes, such as the affusion of cold water on the spine and the administration of the hydrated peroxide of iron, do not seem to have been tried, or even recommended in this case, although there would appear from the newspaper reports to have been ample time for the use of the one first mentioned. A little more generosity is desirable on the part of those who hold up these incidents for public condemnation.

There are probably few chemists who could not call to mind cases in which had the prescriptions been dispensed as written disastrous consequences must inevitably have resulted, and in which the tact or presence of mind of the dispenser alone averted the suspicion of the patient. It is not improbable that if a well attested register of such cases were kept it would be found to quite counterbalance in point of numbers the cases in which dangerous or fatal results have attended the indiscretion of prescribing chemists. But it is to be hoped that it will never be necessary for dispensing chemists to keep such a record for self-defence or to rake up such cases for exposure to the reprobation of the public.

The *American Journal of Pharmacy* gives an interesting account, by Mr. E. G. Bissell, of hop-culture in New York, an amusing description of drug stores in the Far West, and a paper, by Mr. W. C. A. Busch, on the constituents of *Podophyllum peltatum*, in which he gives the amount of officially prepared resin soluble in ether as 60 per cent., a quantity which is intermediate between the amounts stated in different text-books. In spite of the numerous papers which have been published upon this drug, the numbers of active constituents and the proportions in which they exist in the rhizome have not yet been satisfactorily cleared up.

A new remedy, in the shape of a prophylactic against abortion, is being used in some of the United States. It consists of a fluid extract from the bark and young twigs of the black haw (*Viburnum prunifolium*, L.), given in doses of half to one drachm.

The Philadelphia College of Pharmacy is exhibiting considerable signs of vitality, and bids fair to make its museum excel that of our own Society. Having selected nearly two hundred drugs more or less used in the United States, and derived from plants indigeneous or naturalized in that country, but not found in Europe, for exhibition at the International Exposition at Paris next year, the committee propose further to send similar collections for the purpose of exchange to the various pharmaceutical institutions at London, Berlin, Vienna, Strassburg, Dorpat, Japan, and Mexico, and to enter into correspondence with well-known writers on medicinal plants at Rio Janeiro, Cairo, Athens, Bombay, Melbourne, and Buenos Ayres, with a view to obtaining from them collections of drugs indigenous in those countries. The growing desire to know more of the medicinal plants of all nations and to sift the good from the bad, is still further exemplified in the list of proposed additions to the next edition of the United States Pharmacopœia. With a liberality which is rare in this country, the work done by homœopaths is recognized in the proposed introduction of such drugs as *Calendula officinalis*, *Anemone pulsatilla*, *Thuja occidentalis* and *Hamamelis;* while old remedies such as *Rhamnus Frangula* and *Menyanthes trifoliata* are by no means despised because they had fallen for a time into desuetude. *Eucalyptus globulus*, *Eriodictyon Californicum*, *Grindelia robusta* and *Viburnum prunifolium* appear to be already sufficiently esteemed to deserve a place in the list.

Recent investigation and analysis seem to show that there are subjects close at hand waiting for some master-hand to clear up. No reliable test for quassia in beer, or for adulteration of balsam of copaiba, seems to have as yet presented itself.

An interesting paper will be found in the *Journal de Pharmacie*, upon the constituents of bitter almonds, in which the writer shows that even in the youngest state there is a chemical difference between the bitter and sweet varieties; and that while the emulsin appears in the embryo, the amygdalin localizes itself at first in the integument of the seed, and afterwards gradually penetrates the cotyledons through the radicle. Another paper in the same journal points out that a solution of pepsine in glycerine possesses greater digestive power than a solution in alcohol, and that the presence of more than 10 per cent. of alcohol in an aqueous solution of pepsine deteriorates its digestive power.

Pilocarpine seems likely to emulate, if not to supersede, calabar bean for contracting the pupil of the eye, it having been found to possess powers in this respect as active as those of eserine, while it does not excite irritation like that substance.

At the drug sales this month there have appeared, under the name of bush leaves or bush tea, from the Cape of Good Hope, the leaves of *Cyclopia latifolia*, DC., which have a rather pleasant flavour and a somewhat tea-like odour.

The leaves of another species, *C. Vogelii*, Harv., have been received from Port Elizabeth under the same name; both are used by the natives in the form of tea as a restorative drink. It is rather singular that the leaves of *C. latifolia* should form an article of import, since the plant is considered by botanists to be a rare species. Another species, *C. genistoides*, R. Br., with narrowly linear revolute leaves, is well-known at the Cape under the name of Honigthee, where it is used as an expectorant and tonic in catarrh, etc. The leaves of *C. Vogelii* are similar in shape to those of *C. latifolia*, but the latter has smooth leaves and the former minutely wrinkled leaves tapering towards the base. Both are easily distinguished by their elliptical outline from the leaves of *C. genistoides*. One or two cases of Caraccas sarsaparilla were also offered for sale this month. The bright pale brown colour and very thick root-bark of this kind and the absence of rootlets readily distinguish this variety, which is not of common occurrence.

London is scientific London once more; the November fogs have gathered round us; the scientific clubs and meeting-houses are full of activity; the lecture theatres are crowded with workers and students; and the learned societies are almost in full swing again. It is true that—contrary to anticipation—the advent of the fogs was not simultaneous with the enlivenment of Burlington House with the radiometer, but—in *Nature*—that instrument has served the same purpose and in a wider sphere. The lessons there taught are not merely scientific, but social. It appears that Dr. W. B. Carpenter wrote an article in the *Nineteenth Century* for April, on "The Radiometer and its Lessons," which in the opinion of Professor G. Carey Foster manifested an unmistakable tendency, whether intentional or unintentional, to depreciate the value of Mr. Crookes' discovery. This opinion was embodied in a communication made at the Plymouth meeting of the British Association, and in *Nature* of October 25, Dr. Carpenter defends himself against this charge of Professor Foster by professing the highest opinion of Mr. Crookes the physicist, but a very low opinion of Mr. Crookes the spiritualist, whilst incidentally he charges Mr. Crookes with having lent himself with facility to the support of wicked and mischievous frauds. He goes on to give the grounds for the charges brought against Mr. Crookes by himself, and seeks to substantiate the view that Mr. Crookes at an earlier period entertained erroneous ideas regarding the radiometer. Thus it is shown from Mr. Crookes' own papers that at one time he conceived the action to be at least mainly due to the impact of waves of light and that there was an evident inclination on the part of the discoverer to identify the cause of motion with a new force or mode of force. In reconciliation of the double mental state of Mr. Crookes, Dr. Carpenter says it is owing to an imperfect mental and bodily training, and he insists on the importance of a proper cultivation of the whole mind.

Of course Mr. Crookes replies to Dr. Carpenter in a subsequent number of *Nature*, and the discussion also entangles Professor Foster, Professor Osborne Reynolds, and Mr. Wallace, who is charged with an attempt to rehabilitate, in the July number of the *Quarterly Journal of Science*, the well known Odyle-doctrine of Reichenbach. Again and again the combatants return to the charge; Mr. Crookes becomes allotropic, being at one time Ortho-Crookes and at another time Pseudo-Crookes, and as others join in the fray "the damning with faint praise" intensifies and the *malus animus* emerges; men "have to choose between being fools and knaves," and altogether the quarrel is not pretty. It appears that Dr. Carpenter once addressed Mr. Crookes thus:—"Let us bury the hatchet; why should scientific men quarrel?" Why, indeed, should they? Whatever may be the explanation, it is to be feared that among scientific men there is more than enough of the Ishmaelite character.

Even chemists quarrel sometimes. For instance, J. H. van't Hoff recently wrote a *brochure* on "the Position of Atoms in Space," which Professor Kolbe has attacked* with zealous meaning. He writes "that trivial, fatuous, natural philosophy, with its profound intellectual air, which fifty years ago was thrown to one side by exact investigators, is at present rescued by pseudo-philosophers from the lumber room harbouring the hallucinations of the human mind, and the attempt is made to smuggle it—like a painted and bedizened courtezan—into society where it has no right."

To day the Institute of Chemistry of Great Britain and Ireland exists as a corporate body limited by guarantee under the 30 and 31 Vic., chap. 132, sec. 23. Its objects are as follows:—

(*a*) To promote and encourage a thorough study of chemistry and all branches of science allied thereto in their application to the arts, to agriculture, to public health, and to technical industry.

(*b*) To adopt such measures as may be necessary for the advancement of the profession of chemistry, and particularly for the maintenance of the profession of the consulting and analytical chemist on a sound and satisfactory basis.

(*c*) The doing of all such other lawful things as are incidental or conducive to the attainment of the above objects.

The members of the Institute comprise fellows and associates, for each of which classes a standard of proficiency and qualification is adopted, while the Institute is possessed of, and will exercise, where and if necessary, powers of censorship over alleged misconduct of the members and infringement of the regulations.

The *Analyst* was warned some time since that a certain sort of opposition to the incorporation of the Institute, with which it was acquainted, would be futile, and so it has proved. This excellent contemporary, however, although it has ceased to rail, still whines. The Institute is large enough for all who are qualified to become members thereof, and while it will embrace "the aspiring gentlemen of limited practice" to whom our excellent contemporary refers, it will also welcome those other gentlemen of unlimited practice if their fitness and qualifications prove not to be too limited. It is a day of

* *Journ. für. praktische Chemie*, Nos. 9 to 13, 1877.

conciliation and peace, therefore, and now that the turmoil of the waves has vanished it is to be hoped that the scientific barque will float more happily along its professional roads. It would not be matter of surprise if some day the world were to awake from its night's slumber and find on its breakfast table a work entiled, 'The Acts of the Analysts.' What stamping and raving, weeping and gnashing of teeth there would be! Pseudonyms protect the man who may dare to write that treatise! Let us hope that the chemical lion will lie down with the analytical lamb in the new sheepfold which is now provided for their common benefit. Leaving these altitudes with some regret, it is now necessary to recur to other matters of interest during the past month.

In a communication to the Akademie der Wissenschaften, Vienna, M. G. Ciamician details the results of some spectroscopic observations, from which he concludes, with Mr. Lockyer, that the spectra of compounds, as well as those of the first order of elements, consist exclusively of bands; and, further, that the bands are produced by molecules and the lines by free atoms.

The same chemist also submitted the results obtained in the distillation of resinous bodies with zinc dust. Abietic acid and colophony both yielded toluene, ethyl-methyl-benzine, naphthalene, ethyl-naphthalene, and methyl-anthracene; while gum benzoin gave rise to toluene, accompanied by smaller quantities of xylene, naphthalene, and methyl-naphthalene.

At the same time H. Skraup submitted a paper on "Cinchonine," in which he revives the old formula of Laurent, $C_{19}H_{22}N_2O$, and rejects the one now commonly adopted of $C_{20}H_{24}N_2O$, on the grounds that the former represents a number of carefully conducted analyses made by the author, and, further, because the amount of potassic permanganate required for oxidation into cinchotenin and formic acid is expressed in the equation—

$$C_{19}H_{22}N_2O + O_4 = C_{18}H_{20}N_2O_3 + CH_2O_2.$$

The author appears also to have obtained the base—hydrocinchonin $C_{19}H_{24}N_2O$.

Cazeneuve and Caillol* have extracted the piperine from various kinds of pepper by grinding these with twice their weight of slaked lime and a little water, then heating the mixture to boiling, filtering, and evaporating the extract to dryness. From the residues the piperine is extracted by ether, and on concentration the piperine is deposited from the ethereal solutions in large crystals of a light straw colour. It may be recrystallized from alcohol—

M. J. Béchamp† has studied the action of some anhydrous organic acids upon anhydrous mineral bases by heating them in contact at about 130° for some few hours. Acetic, butyric, and caproic acids thus combine directly with bases, and when excess of the acids is used, the quantities of the obtained salts are almost theoretical in regard to lime when that is the base employed. Anhydrous acetic acid combines directly with anhydrous baryta at 100° C.; it also combines with the oxides of lead and mercury.

* *Bull. Soc. Chem.* (2), xxvii., 290.

† *Comptes Rendus*, No. 18, October 29, 1877.

M. Bussy had previously shown that sulphate of barium is produced when anhydrous sulphuric acid and anhydrous baryta are brought into contact, and several instances are known where anhydrous mineral acids form compounds with the anhydrous oxides of organic radicles—sulphate of methyl, for example. Moreover, compounds of anhydrous organic acids with such bases may be obtained, although with difficulty. The author regards these results as fully confirmative of the views held by Lavoisier regarding the acid nature of so-called anhydrides.

O. Loew* describes a number of additive compounds producible by the passage of cyanogen gas through albuminous solutions. He claims to have obtained compounds of $2\,CN\,3\,H_2O$; $4\,CN\,8\,H_2O$; $8\,CN\,16\,H_2O$, with albumin ($C_{72}H_{112}N_{18}SO_{22}$). These compounds give up part of their cyanogen to alkalies.

In an article on "Iridescent Glass," the *Chemical News*† states that the principle observed in its manufacture consists in submitting the glass articles to the action of dilute hydrochloric, sulphuric, or other acid, under a pressure of from two to six atmospheres. The inventor of the process is M. Clémandot, who claims to be able to imitate the nacreous films which are seen on ancient glass which has been exposed to combined atmospheric influences for thousands of years. It must be admitted that the articles fabricated by M. Clémandot's process are exceedingly beautiful and from their rapid appearance in shop windows may be deemed a success in spite of the high price asked for them.

Mr. G. E. Davies‡ has examined the various processes which have been suggested and used for the estimation of the available sulphur contained in the spent oxides of iron from gas works containing from 62 to 67 per cent. of free sulphur. After enumerating the various advantages and disadvantages of each of these, he describes experiments which show that the best method consists in drying at 100° C., and burning in a current of air; passing the sulphurous anhydride into a decinormal solution of iodine and titrating the excess of the latter reagent by standard solution of hyposulphite of sodium.

In this Journal for October 27, there appeared a note by Mr. J. B. Barnes, calling attention to the dangerous nature of an arsenical magenta-coloured paper used by pharmacists for capping purposes. Since then the arsenic contained in this paper has been estimated and it was found to amount to no less than 6·65 per cent. metallic arsenic, a fact which is not surprising in view of the statement made by Mr. Barnes, who says "the colour is evidently the product of the oxidation of aniline by arsenic acid." As Mr. Barnes has seen an improperly corked bottle coloured pink by its means dispensers will do well to avoid this paper, and also to cork their bottles better. The subject is, however, by no means new. Some time ago, in the *Archiv der Pharmacie*, there was a paper by Christel, on the red aniline glazed paper which he had examined, and he there gave the quantity of arsenic found in a ream of the paper. As a ready means for detecting its presence in a sample of paper, he recommends Reinsch's test. At the present time this subject deserves more than a passing notice, when certain public analysts—who whilst aiming at celebrity have attained notoriety—are busying them-

* *Journ. für. Praktische Chemie*, Nos. 9-13, 1877.

‡ *Chemical News*, October 26, 1877.

selves in sniffing about chemists' shops, like the truffle-hunter's pig grubbing with his nose in any soil likely to yield him the much coveted fungus.

Professor Church* has also called attention to the presence of arsenic in coloured tapers, and from an estimation which he made of its amount, he concludes that they contain 1·48 per cent. reckoned as metal upon the original tapers. In this case the presence of the arsenic is readily revealed by the colour which it imparts to the flame in burning, as well as by the odour of the smoke when the flame is blown out.

Dr. Dupré has evidently been in a state of mental restraint for some time; at last when the internal pressure can be no longer supported he pours out his grievances to the *Analyst* in a lengthy epistle in which he covers ground ranging from castor-oil pills on the one hand, to the salt contained in Burton beer on the other hand. Intermediately he refers to preserved peas containing copper and confesses that he had hoped the authors of a paper which has been more than once mentioned in these columns would have withdrawn what, in his opinion (whatever that may be worth) constitute their hasty conclusions. Dr. Dupré commands our pity for his ill-cherished hope; those same authors may possibly entertain still more defined opinions regarding Dr. Dupré's hopes and prejudices. However, "it is never too late to mend;" and let us hope for the best.

The October number of the *Druggists' Circular* contained a remarkable article entitled "Glycerite of Kephaline," by Dr. Chas. G. Polk. Of this name he writes, "I employ (it) to designate a solution of cerebrates or brain hypophosphites;" he says further, "Cerebric acid may be obtained after Frémy's method. It will thus be seen that the glycerite of kephaline does not contain the phosphates or phosphites of the brain and is not identical in its constituents with protagon which embodies these."

Glycerite of kephaline exists only in the brain of Dr. C. G. Polk, and being an utterly abnormal constituent, in it is to be found the explanation of that learned gentleman's ignorance of the literature of brain chemistry, and his even more alarming original statements regarding that somewhat useful nervous tissue. May the shadow of glycerite of kephaline never grow less!

Writing of the brain calls to mind the physiological tables† just published by Dr. E. B. Aveling. He states that nervous tissue contains 15 per cent. of fats, which he classifies thus:—

$$\begin{matrix}\text{Fats 15 per cent. in white} \\ \text{5 per cent. in grey}\end{matrix} \begin{cases}\text{Oleophosphoric acid;} \\ \text{Olein; Margarin;} \\ \text{Palmitin; Cholesterine.}\end{cases}$$

Now the truth is (and it may surprise Dr. Aveling to learn it), that cholesterine is not a fat, and none of the other matters named occur in nervous tissue at all; oleophosphoric acid indeed has no existence.

Both Dr. Polk and Dr. Aveling may be set right by a short statement.

The phosphorized constituents of the brain are all derivatives of glycerine, and thus far they resemble fat, a resemblance which gains support from the fact that when decomposed they yield various fatty acids. In the case of one principle (lecithine), oleic and margaric or palmitic acids are thus obtained; in another stearic and a second unknown acid; in a third palmitic and a second unknown acid. But all are embraced in the following general formula:—

$$C_3H_9 \begin{cases}\text{HO substituted by fatty acid radicle.} \\ \text{HO} \quad ,, \quad ,, \quad ,, \\ \text{HO (OPO)}\ C_5H_{13}NO.\end{cases}$$

At the International Medical Congress recently held at Geneva, Professor Schiff, of that town, read an important paper* on the functions of the spleen, a subject which till then had received practically no explanation. The author found that extirpation of the spleen has no lasting influence upon the absolute or relative quantity of the white or red blood globules. During full stomachic digestion the spleen increases in volume from the fourth to the seventh hour, and during that digestion prepares for the same a ferment which enters the pancreas with the blood and transforms albumenoid substances there present into pancreatopepsine or trypsine. That this is so, seems more than probable, from the fact that after extirpation of the spleen the pancreatic juice loses its digestive power over albuminous matters while retaining other digestive properties.

Nitrate of pilocarpine (from jaborandi) is again receiving considerable study in the hands of medical men. Among others Dr. Dowse and Mr. Edes have found this agent to be possessed of considerable diaphoretic and sialogogue effects, when administered subcutaneously.

Mr. Alexander Morison, M.B., writing to a contemporary† calls attention to a case of chylous urine containing as he thinks sugar. In other respects the urine had the usual properties exhibited by the lixivium in such disorders; that is to say, it was milky from contained fatty matter in suspension and admitted of the isolation of this fat. Mr. Morison has not isolated his sugar, but considers this substance to be present, by reason of the chemical reactions he has obtained. When evaporated the urine deposited crystals which under the microscope looked like those of grape sugar; this appearance, however, does not go for much, as these crystals may have been composed of uric acid or its salts. Moreover, one might rather expect to find uncrystallizable glucose than crystallizable grape sugar, if sugar be present at all.

Now that the public have been awakened to the liability of infection being conveyed by water supplies, bad drains, tainted linen from the laundry, etc., another source of danger is pointed out,‡ and supported by a number of cases. The danger alluded to has its origin in the pawn-shops; infected articles are often left at these shops, and these contaminate other articles, which when redeemed, too often communicate small-pox or other disease to the owner, and hence the spread of disease is assisted. Those same pawnbrokers will, by and by, have to go in for ovens heated to such a temperature as may be deemed requisite for the destruction of the disease-matter, without harming the articles bearing it. In short, things are becoming decidedly hot for them.

The chemical waters are again troubled by analytical disturbances, and several journals have rather gone out of their way to describe the matter in question as "analytical discrepancies." This is scarcely a fair designation, as will be seen from the

* *Analyst*, November, 1877.

† 'Physiological Tables for the Use of Students.' Compiled by Edward B. Aveling, B.Sc., F.L.S. Hamilton, Adams and Co. London, 1877.

† *British Med. Journ.*, Nov. 17, 1877.

‡ *Sanitary Record*, Nov. 16, 1877.

facts, which may be thus briefly set forth. Mr. Gatehouse found in a sample of Burton beer 68 grains of common salt to the gallon, while the report from the laboratory at Somerset House shows the presence of 66·5 grains to the gallon, but goes on to say that "the strong Burton beers contain about 60 grains of common salt per gallon, solely derived from the water, malt, and hops used." Now, as regards the analyses the discrepancy is not very dreadful, but objection may and has been taken against the additional statement which is quoted above. It is not probable that the water, malt, and hops would furnish so much salt, and this has been placed beyond doubt by subsequent work conducted by Mr. Gatehouse. The Licensing Act allows the presence of 50 grains of common salt to the gallon of beer, to cover the quantities introduced into beer from the sources stated; hence anything above that amount is fairly viewed as evidence of adulteration. The squabble to which allusion has been made would have been avoided had the Somerset House analysts restricted themselves to the bare analysis. It was an act of supererogation to make the additional statement which caused the grievance.

If analytical and consulting chemists generally, in giving certificates confined themselves more particularly to the facts of their investigations, and abstained from going into hypothetical reasons and expressing opinions of qualities and things, and instituting comparisons, such certificates would be less offensive to a healthy professional mind, and admit less of malconstruction or abuse.

Before proceeding to reply to dispensing queries, it may not be amiss, in reviewing the events of the past month, to direct attention to one or two subjects of interest to dispensing chemists. In last month's Journal a case is recorded of poisoning by eye water containing atropine, which had been given to a child in mistake for a mixture. At the inquest the mother stated that "she administered to deceased a dose from the lotion bottle believing it to be the mixture bottle, there being a similarity in the bottles," and that "the bottle was not labelled 'poison.'" Although the medicines in question were procured from a dispensary, the unfortunate circumstance brings into relief a very careless and objectionable practice which prevails in some establishments, that of using the same kind of bottle for both mixtures and external applications, relying only on the difference of label. Probably to this cannot be added the habit of sending out bottles without labels, but very commonly labels are not sufficiently distinctive for external medicines; there should be no exception to the use of the blue "poison bottles" for all external applications, and when these bottles are used the label should be in red type, or a red ground with black type; the public would then learn gradually to associate the red label with the danger signal. In addition to this a red slip label, "liniment," "embrocation," or whatever the contents of the bottle may be, should be pasted over the cork or cap, and finally all blue bottles should be sent out wrapped in paper of a different colour to that of those containing mixtures for internal administration. Careful habits on the part of the dispenser are appreciated by the public and become remunerative; they serve also to distinguish between a pharmacy and those other places called "open shops." In the case above quoted, the jury were of opinion that carelessness was shown by the dispenser in not affixing to the bottle a label with *poison* written or printed upon it, and that the bottle was not a proper one for a small quantity of lotion as prescribed.

The discussion that has been provoked by an opinion expressed in these columns last month respecting the use of the ℥ sign discloses a diversity of practice that was hardly to be suspected. At present it would be premature to treat the discussion as at an end, and before it does close it would be very interesting to have an expression of opinion from one or more members of the Pharmacopœia Committee, as to what was the meaning intended to be conveyed by the passage in the Preface to the British Pharmacopœia that has been quoted as decisive on both sides of the argument.

And now to deal with the "Memoranda," according to their consecutive numbers.

No. 29. A formula is required for Tinct. chinæ nit. This is evidently a preparation of China nit. or *Cinchona nitida*, one of the South American quill barks usually imported from Huanuco. The bark is figured by Howard and also by Berg, but it is evident from the figures differing that they had not before them the same kind of bark. As there is no formula for a tincture of this bark it might be made as Tr. cinchon., B. P. If convenient, it would be well to refer to the writer as the bark is rarely found in commerce.

No. 30. The doses of hyd. bichlor., ergotine and ext. bellad., as combined in this prescription are those commonly prescribed, and there is no difficulty in making a satisfactory pill by first evaporating the ergotine to a pilular consistence. A pill with ergotine in its composition should be sent out in a bottle, as it readily absorbs moisture. Under the same number there is a prescription ordering pepsina porci, acid. carbolic., etc. A very satisfactory mass may be obtained by using the carbolic acid in crystal and adding from one-half to two-thirds of a grain of bread crumb to each pill. The mass should be well kneaded and the pills quickly rolled out, when they may easily be silvered. Bread crumb is a good excipient when there is more moisture prescribed than is convenient.

No. 31. This formula of chloral hydrate and camphor is most probably an error of the writer, and was intended to be either ʒj of camphor or ℥j of chloral hydrate. Equal proportions of pulv. camph., and chloral hydrate after being mixed a short time liquefy, and to this product may be added any quantity of glycerine. The mixture made according to the formula in question leaves a large portion of the camphor undissolved, and is not a presentable compound. If the inquirer is a reader of pharmaceutical literature he must have observed frequent reference in this Journal to a mixture of equal parts of camphor and chloral hydrate becoming liquid, and also to the value of the mixture as an external application in some forms of neuralgia.

No. 32. Lin. saponis, B. P., made with sapo animalis becomes solid. Sapo animalis is a soda soap made with purified animal fat, consisting principally of stearin, and this forms a stearate of soda, nearly insoluble in spirit, whereas Sapo durus, B. P., is made with olive oil and soda and forms an oleate of soda, soluble in rectified spirit. Sapo animalis cannot be substituted for sapo durus in the lin. saponis, B. P., or where a fluid preparation is required, but is well adapted for a solid preparation.

No. 33. An ℥viij mixture containing ℨiij sp. camph. This quantity of sp. camph. is equivalent to eighteen grains camphor, which is more than the fluid will take up ; it cannot be made a clear mixture, and should not be filtered. It is not unusual for medical men to order such a quantity of sp. camph. in a mixture of this size, and as the dose is not mentioned, it is difficult to determine the intention of the prescriber in this case.

No. 34 is a pill containing hyd. bichlor. gr. ij., with the same quantity of ext. opii in each pill. There is evidently a mistake of the writer of this prescription ; it is the proportion usual for about thirty pills. The inquirer has made no observation on the excessive dose. Had he been passing his Minor, and overlooked the evident error, the chances are that he would have been "spun" for it.

No. 35. The inquiry is whether where ferri cit. is ordered in a prescription ferri am. cit. should be used? It would be justifiable. Ferri am. cit. is a recognized preparation, and is not unfrequently written ferri cit. when ferri am. cit. is evidently intended.

No. 36 is the old and well-known Locock's lotion formula with perhaps a very slight variation. It may be made by melting together the mace and olive oils, pouring the product into a mortar, and then emulsifying it with the ammonia, adding gradually the water, and finally the spirit of rosemary. But a better result is obtained by rubbing up the oil of mace with the ammonia and oil alternately, then adding the water, and finally the spirit of rosmary. In either case there will after some time be a certain amount of separation.

No. 37. Aluminæ sulph. being ordered in a prescription, the question is, should the double sulphate of the B. P. be used? It is probable that the double sulphate was intended, but as the aluminæ sulph. is known in commerce, it would be better when practicable to refer to the writer. If that cannot be done the dispenser must rely on his own judgment. A knowledge of the prescriber's habit of writing his prescriptions will sometimes materially assist the dispenser.

No. 38. In this instance, the same rule will apply as in the preceding, No. 36. The addition of spirit to this and other similar emulsions will cause more or less separation; and the amount of separation and the time at which it occurs will mainly depend on the relative proportion of the spirit to the water.

No 39. This prescription cannot be mixed without separation. The best method, but one that would require the sanction of the writer, would be to add a quantity of sapo mollis, B. P., about equal to that of vaseline, rub them together, then add the ammonia, afterwards the water, and lastly, the tincture. Even then a certain amount of separation will take place. Vaseline is a substance of indefinite composition, and the usual rules will not apply here.

No. 40 is a pill containing bals. peru with other ingredients. It may be satisfactorily made by the use of a little bread crumb, as in the preceding prescription, No. 30.

Correspondents who have communicated formulæ for aq. camph. conc. may be reminded that a concentrated preparation was required that when diluted one part to seven of water should represent aq. camph., B. P., which contains on an average half a grain of camphor in the ounce. Any formulæ that would make a camphor water stronger than the official form would not be admissible, and the same may be said with regard to the addition of tr. myrrh. said to promote the solubility of the camphor.

LABORATORY NOTES ON QUININE. *

BY ALBERT B. PRESCOTT.

I. *Solubility of Quinia Precipitate in Water-washing.*—On precipitating quinia sulphate acidulate solution with sodium or with ammonium hydrate, and washing on the filter with water until the washings gave no cloudiness with solution of barium salt, Mr. W. J. Holloway found a loss of 11·6 per cent. of the quinia. The weight of quinia sulphate taken was 0·250 gram, two operations, one with each alkali, giving the same result. Two other operations were made, the precipitates respectively by sodium hydrate and by ammonium hydrate being set aside for twenty hours before filtering, and then each washed with 18·4 c.c. of water. The precipitate by soda had wasted 2·9 per cent. of the alkaloid, that by ammonia 10·6 per cent. The filtrate from one of the precipitates by ammonia (added in very slight excess) was made turbid by adding soda, and the dilute washings of this same precipitate were made turbid by ammonia (though the first filtrate was not so affected). Apparently the solvent power of water upon the alkaloid was diminished by presence of a very small proportion of ammonia, though it is increased, as is well known, by presence of more ammonia. A change in the proportion of the same solvent reverses its effect, just as dilute sulphuric acid dissolves less lead sulphate than either water or concentrated sulphuric acid.

Mr. A. S. Lobb washed 0·280 gram of dried quinia on the filter with a half liter of water, dropped from a burette, at about 87° F., and found the alkaloid had lost 50 per cent. of its weight, each c.c. of the water having dissolved 0·000216 gram of quinia. In all these cases the filtrates gave a precipitate with potassium mercuric iodide.

The solubility of quinia precipitate in sodium sulphate solution becomes of interest, because this solution is the filtrate, in the use of the best precipitant, with the common salt of the alkaloid. From an experiment by Mr. Lobb it appears that solution of sodium sulphate has practically neither more nor less solvent power than pure water. A precipitate of 0·280 gram of the alkaloid was washed with 500 c.c. of a half-saturated solution of sodium sulphate, dropped from a burette on the filter during $2\frac{1}{2}$ hours, and then washed with pure water (214 c.c.) until free from sulphate, when 0·1375 gram of alkaloid remained. Therefore, of the 714 c.c. of sodium sulphate solution and pure water, averaged together, each c.c. dissolved 0·0002 gram of alkaloid, a result practically the same as the 0·000216 gram dissolved by a c.c. of pure water.

Of course, solubility in washing precipitates must fall below *solubility of saturation.* The latter is given for quinia, at 1667 parts of water of 68° F. (Sestini), in which proportion 1 c.c. of water dissolves 0·0006 gram of the alkaloid, nearly. J. Regnault found 2024 parts of water at 15° C. to dissolve one part of pure quinia.

Evidently, the precipitation of quinia as a free alkaloid is inaccurate in quantitative work, under any circumstances, and, if there is much dissolved matter in the filtrate to be washed away, the operation gives no result of even approximate quantity. By measuring the filtrate with the washings, some notion of the loss may be gained, but this loss is varied by proportion of the precipitant, and may be varied by other dissolved bodies in the filtrate. Moreover, the precipitation of quinia by alkali,

---

* From the *American Journal of Pharmacy* for October, 1877.

in the preparation of citrate of iron and quinia, is wasteful and inaccurate.

II. *Gravimetric Determination of Quinia, as a Precipitate by Potassium Mercuric Iodide.*—The value of this precipitate, washed and dried at 212° F., was found to be 2·900 grams for 1 gram of quinia, dried at the same temperature. This finding was the mean of three determinations, using Mayer's solution upon an acidulated sulphate solution of alkaloid, the results being respectively 0·801, 0·824, and 0·812 of precipitate from 0·280 of alkaloid. Just 26 c.c. of Mayer's solution were required for the full precipitation of each portion $(26 \times 0{\cdot}0108 = 0{\cdot}2808)$, after which 4 c.c. of the standard solution were added in each portion, to represent an excess of the reagent, as convenient in a gravimetric operation. The quinia taken was Powers and Weightman's "pure quinia," which was found to lose 6⅝ per cent. at 212° F., so 0·300 gram was weighed in each portion to represent the 0·280 gram as dried at 212° F. The volume of Mayer's solution required for each, as given above, very nearly coincides with 0·280 of Mayer's quinia. Farther investigation is desirable as to presence and proportion of combined water in the residue of quinia at 212° F. Mr. A. H. Allen* has reported the residue from ether solution to retain constant, at 212° F., 4·28 per cent. of combined water, a little less than that of a monohydrate. From this report Mr. A. N. Palmer† dissents, stating that a residue of constant weight can only be obtained at 260° to 270° F. See IV.

The precipitate by potassium mercuric iodide is very close, and bears water washing without weighable loss. The reagent need not be of standard strength for gravimetric results; it can be prepared simply by treating solution of corrosive chloride of mercury with solution of iodide of potassium until the precipitate at first formed is just all dissolved. (For the execution of the determinations given in this note I am indebted to Messrs. J. J. Johnston and A. S. Lobb.)

III. *Gravimetric Determination of Quinia as a Precipitate by Phosphomolybdate.*—This precipitate is exceedingly close in the case of quinia, and bears washing without loss, but does not bear a temperature above 158° F. (70° C.) without reduction of molybdenum, shown by a blue colour. The value of the precipitate, dried below 158° F. to a constant weight, was found by Mr. Lobb to be 3·665 grams for 1 gram of quinia as dried at 212° F. This result was the mean of two nearly identical determinations, 0·280 gram of the alkaloid giving respectively 1·026 and 1·0265 gram precipitate. The reagent, the acidulate solution of sodium phosphomolybdate, is added in slight excess, when the precipitate separates admirably.

IV. *Solubility of Quinia Precipitate in Washed Ether.*—This was found by Mr. Lobb to be 20 parts of the ether for 1 part of quinia (monohydrate), after twenty-four hours' digestion in a stoppered jar. A portion of the saturated ether solution was drawn into a specific gravity bottle and its weight obtained, then poured, with the ether rinsing, into a thin glass evaporating dish (tared), the ether evaporated, the residue dried at 212° F. A constant weight was believed to be obtained, notwithstanding the difficulty of gain by hygroscopic water while weighing. The last four weighings were, for dish and contents, 26·895, 26·894, 26·893, 26·895. (See reference to Mr. Palmer in Note II.) The residue of quinia from ether solution is amorphous and does not yield a perfectly crystallizable sulphate. Taking this residue as a monohydrate, nearly 21 parts of the *washed ether* are required to dissolve a precipitate of quinia containing 1 part of anhydrous alkaloid.

The solubility of quinia in *ether* is given by van der Burg at 23 parts (ether of sp. gr. 0·72 and 18° C.), by Merck at 60 parts, Flückiger and Hanbury 21 parts, by Hesse—for quinia trihydrate—at about an equal weight of ether, by J. Regnault at 22·6 parts (15° C.).

V. *Valuation of Six Samples of the Citrate of Iron and Quinia in the Trade.*—The samples were obtained indiscriminately from different dispensing drug stores in Michigan. Only *the total alkaloid* was determined. This was done by extraction with chloroform, as follows: a weighed portion of the scales was dissolved in water in a wide tube with a stopper, a small amount of tartaric acid was added (to prevent precipitation of ferric hydrate, a hindrance to the separation of chloroform), solution of sodium hydrate was added to alkaline reaction, and the liquid repeatedly shaken with successive portions of chloroform, the chloroform being drawn off into a weighed beaker and evaporated until a portion of the chloroform caused less than one milligram increase of weight to the beaker. The total residue in the beaker was now dissolved in water acidulated with sulphuric acid, the solution treated with a slight excess of sodium hydrate solution, then extracted with successive portions of chloroform, as before, and the residue from this solution was dried at 212° F. to a constant weight. This residue is given as the alkaloid, containing, according to Allen, 4·28 per cent. water. The determinations were done by W. J. Holloway, in June, 1876, with the following results:—The samples gave

5·2 12·2 8·7 9·0 11·4 8·3 per cent. of alkaloid.

VI. *The Presence of Sulphates in Citrate of Iron and Quinia.*—In each of the six samples, numbered above, Mr. Holloway found sulphates present. In three of them the quantities of sulphuric anhydride were found to be less than 1 per cent. of the preparations; in the other three the quantities were found to be respectively 6·5 3·5, and 1·8 per cent. of the preparations. A sample of citrate of iron and ammonium, from the same manufacturer who furnished the sample of quinia iron citrate which had the 6·5 per cent of sulphuric anhydride (above given), was found to contain 4·9 per cent. of sulphuric anhydride. A few ounces of solution of tersulphate of iron were precipitated by ammonia water, and the precipitate washed "with water until the washings are nearly tasteless," as the Pharmacopœia directs in the preparation of solution of citrate of iron, from which the three scale iron citrates are made. In this washed ferric hydrate, sulphate was found present, amounting, as sulphuric anhydride, to 14·8 per cent. of the drained moist precipitate. A sample of citrate of iron and quinia was made by the pharmacopœial process, except that the quinia sulphate was added, as such, without precipitating the alkaloid, and the scales were found to contain 4·3 per cent. of sulphuric anhydride. By calculation (if I am correct) all the sulphuric anhydride of the quinia sulphate cannot form over 1·8 per cent. of the scales of quinia iron citrate. If 10 per cent. of water be assumed in the scales, their per cent. of sulphuric anhydride would be about 1·6. It will be remembered that the British Pharmacopœia, for preparation of the iron citrates, directs to "wash the precipitate (ferric hydrate) with distilled water until that which passes through the filter ceases to give a precipitate with chloride of barium." Such is the well-known adhesion of ferric hydrate for alkali salts, that to wholly remove them requires persistence and wash-water, in a sufficient quantity of each; but it is farcical to wash away the sulphate from the quinia, wasting from 2 to 11 per cent. of the alkaloid and making the preparation uncertain in strength within the same limits, while taking a greater quantity of sulphate in the hydrated oxide of iron. Of course, after the solution takes place, any quantity of combined sulphuric acid present, if derived from the iron precipitate, will be *just as much* in combination with the quinia as though it had been introduced in quinia salt.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 24, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal. MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE COMMERCIAL HISTORY OF A CINCHONA PLANTATION.

Now that the cultivation of cinchona trees in other countries than those where they are indigenous is likely to become more general, some information in reference to a variety of cinchona yielding bark that contains from 6 to 9 or 10, and even 13 per cent. of quinine, will not be without interest. The variety to which we refer is that known as *Cinchona Calisaya Ledgeriana*, which has been cultivated with success in Java, and to some extent also in British India.

The seeds with which these experiments have been made were obtained by Mr. C. LEDGER, through the medium of a native of Peru, named MANUEL, who travelled with him between the years 1841 and 1858. This man had been a collector of cinchona bark, and had the repute of being intimately acquainted with the value of the different kinds, and notwithstanding the obstacles thrown in the way of obtaining cinchona plants or seeds by the Peruvian authorities, MANUEL undertook to obtain for Mr. LEDGER a quantity of seeds of the best kind. Early in the year 1865, Mr. LEDGER returned to Peru, and some months afterwards MANUEL hearing of his return brought him a quantity of seeds which he had collected in the Bolivian province of Caupolican. These seeds were sent from Arica to England and placed in the hands of Mr. GEORGE LEDGER for disposal. The original intention was to offer them to Sir WILLIAM HOOKER, but in consequence of his death about that time, this project was not carried out. Sir JOSEPH (then Dr.) HOOKER was absent through ill health, and Mr. MARKHAM had shortly before left for India, so that Mr. LEDGER was in some difficulty as to the disposal of the seeds, and fearing that if kept they might spoil he offered a portion of them to the Dutch Government. Upon the recommendation of Professor MIQUEL, LEDGER's offer was accepted and he received as a preliminary payment a sum of about £8 10*s.*, under the condition that he should receive further remuneration if it should turn out that the seeds arrived in Java in a condition capable of growth and that the plants belonged to a good variety. In 1866 VAN GORKOM reported that from these seeds about 20,000 plants had been raised, and a further sum of about £42 10*s.* was then paid to Mr. LEDGER. The rest of the seeds were purchased by Mr. MONEY, on the recommendation of Mr. J. E. HOWARD, and sent to India.

At first the plants grown in Java were considered to be but slightly different from the *Cinchona Calisaya* already in cultivation there, but fortunately the new plants were kept separate. The plantations situated chiefly at Tjiniruan suffered considerably from sickliness, which hindered the growth of the trees without killing them entirely. A small quantity of the bark was collected in 1872 amounting to about 500 lbs., and samples were sent for analysis to Mr. MOENS, who soon found that it was very rich in quinine. Further samples were collected from other plantations in order to test the accuracy of the result obtained, and from their examination it was established to a certainty that the Javan plantations contained a variety of cinchona yielding bark that contained twice as much quinine as the best kinds of American bark. This result was still further confirmed by the sale of the 500 lbs., which took in May, 1873, at Amsterdam, when it fetched the price of 7*s.* 9*d.* per lb., or twice as as much as that of Bolivian calisaya. As a natural result of this experience special care was directed to the cultivation of this tree. Originally the trees had been too thickly planted; they were thinned by removing or cutting down some of them, and in this way a quantity of bark was obtained annually, amounting up to the end of 1876 to about 16,000 lbs. The extent of the plantations where these trees were grown is 59½ square roods, but some portions of it are still occupied by forest trees that have been cut down to make room for the plantation, so that the extent of cultivated ground is less than the area given. The cost of clearing the land and planting 7 roods of each is estimated at £12 10*s.* The cultivation and supervision, including various other expenses amounted to £3 6*s.* 8*d* per 7 roods, and according to a report recently published by Mr. MOENS, the nett profit arising from the above-mentioned area amounted at the end of 1876 to £4070 10*s.* In the year 1874 not only had the expenses of the plantation, commenced in the year 1866, been covered, but there was even then a profit of more than 100 per cent. upon the whole capital sunk in the undertaking, and the nett profit of the eleventh year amounted to about £479 per 7 roods.

But these facts do not complete the history of the plantations. There still remain 3320 the original trees and 4085 living stumps, from many of which new stems have grown up from 6 to 10 feet high. Amongst these trees are some that would yield more than 20 lbs. of bark if they were cut down at the present time, and Mr. MOENS estimates that if the whole of the plantations, including the roots and stems, were to be cleared they would yield about 16,000 lbs. of bark, which would have a value of £4600. Consequently it would have been possible at the end of 1876, or ten years after the trees were planted out, to have realized from this piece of ground a profit of upwards of £8000.

These calculations were made by Mr. MOENS a a time when he was unacquainted with the recent high price of cinchona bark, amounting to about 50 per cent. in excess of that which he has adopted in his calculations, so that really a very much more favourable result might have been obtained if the sale of bark had taken place so as to share in the rise in price since the last sales.

According to the account given by Mr. MOENS, cultivation and the use of manure have had the effect of increasing to a very considerable extent the amount of quinine. Referring to the fear entertained in British India that the attempt to cultivate *Cinchona Calisaya* from seeds would not be successful, on account of the possibility that the plants might deteriorate, Mr. MOENS expresses the opinion that this would be equivalent to abandoning the cultivation, since the cultivation from cuttings is so difficult in the case of *Cinchona Calisaya* generally, and especially of the variety *Ledgeriana*. He considers this fear to be exaggerated, for although there always are among the seedlings from one and the same tree some which are distinguished by the peculiar form or colour of the leaves, still the greater number of of them resemble the mother plant, a circumstance which obtains also with *Cinchona officinalis*, and to a less extent with *Cinchona succirubra*. Experience, however, has shown that both these plants, as compared with the American mother plants, are as a rule rather richer in alkaloids than poorer. The trees of these varieties in Java are again seedlings from British Indian plants, and it is beyond doubt that the bark obtained from them in Java is not poorer in alkaloids than that from the mother plant in Ceylon and Madras. The plants raised from seeds of *Ledgeriana* vary amongst themselves considerably in the form of the leaf and even in the colour and shape of the flowers and fruit, but nevertheless they all yield bark which is very rich in quinine. Guided by the experience of several years Mr. MOENS expresses the opinion that the average amount of quinine in the bark from trees raised from seeds of *Cinchona Ledgeriana* will be found to correspond with the amount existing in the mother plants; and that although in such a plantation there may be some trees yielding poorer bark, there would also be as many that would yield much richer bark than that of the mother plant. He is therefore of opinion that there is no reason to fear that the contents of alkaloid will either diminish or deteriorate.

In reference to the facts above stated we cannot do better than reproduce the following passage from one of the papers on cinchona cultivation by Mr. JOHN ELIOT HOWARD: "My advice to all cultivators of cinchona bark is to plant none but the very best species, and to go in for high cultivation. In so doing they will be quite independent of all courtly favour and of all foreign competition. Success must be won by strenuous persevering exertion, for (as SCHILLER says of the flowers of German poetry), the cinchona blossoms 'do not expand under the sunshine of princely favour.'" It would seem that Mr. MOENS has given a practical exemplification of the value of this precept.

CHEMISTS ASSISTANTS' ASSOCIATION.

WE are glad to learn that the Chemists' Assistants' Association, in reference to which some correspondence has lately appeared in the Journal, is beginning to manifest some sign of vitality. From a notice which appears in this week's advertising pages, we learn that a place of meeting has been secured, and that a General Meeting will be held on the 28th inst., at 8 p.m., when the following papers will be read:—"Pill Making and Excipients," by Mr. MARSHALL; and "A Botanical Ramble in Cumberland," by Mr. STUART, both of which will be followed by discussion. There is also to be an exhibition of microscopes and other subjects of interest. We are glad to express our wishes for the successful progress of this Association, which if wisely managed and earnestly supported may become very serviceable to many, if not all, of its members, and contribute to remove the too general belief in the necessity of "cramming" as a preparation for attendance in the examination room.

THE SOCIETY OF ARTS LECTURES.

THE three courses of CANTOR lectures to be delivered before the Society of Arts in the course of the present session are announced as follows:—The first is to be a course of six lectures on "The Manufacture of Paper," to be delivered by W. ARNOTT, F.C.S., commencing Monday, November 26. The subject of the second course is to be "The Application of Photography to the Production of Printing Surfaces and Pictures in Pigment," to be delivered by T. BOLAS, F.C.S., and commencing February 18. The last course will commence on the 8th of April and is to be on "Some Researches on Putrefactive Changes and their Results in Relation to the Preservation of Animal Substances," by B. W. RICHARDSON, M.D., F.R.S. There will also be a course of three special lectures on "Explosions in Coal Mines," to be delivered by T. WILLS, F.C.S., on Monday, January 28, and two following Monday evenings, at eight o'clock.

THE COUNTER PRACTICE APPEAL CASE.

IT will be seen from a report on page 413 that the hearing of the appeal against the decision of the judge in the case of the *Apothecaries' Society* versus *Shepperley* was commenced in the Exchequer Court on Wednesday last, before the Lord Chief Baron and Baron CLEASBY. Sir HENRY JAMES, however, began his opening argument only half an hour before the rising of the Court, and the further hearing was adjourned to Friday morning.

MUNICIPAL HONOURS TO PHARMACISTS.

WE are enabled by the courtesy of correspondents to add to the list given under this heading last week. Mr. FRANK BAKER, Chemist and Druggist, has been re-elected Mayor of Sandwich. Also, Mr. HENRY GOODALL, Pharmaceutical Chemist, has been elected a Common Councilman at Derby.

Provincial Transactions.

DOVER CHEMISTS' ASSOCIATION.

The annual meeting of this Association was held on the 14th inst., at the Apollonian Hall.

The balance sheet was presented and passed, and an opinion was expressed by the chairman and others that the working of the Association, especially with regard to the maintenance of uniform prices, had been satisfactory and beneficial.

Messrs. W. H. Cotterell and J. F. Brown were re-appointed as chairman and secretary, respectively, for the forthcoming year.

After the business had been despatched the members present sat down to an excellent supper.

In proposing the health of the Mayor and Corporation, coupled with the name of Alderman Bottle, the Secretary remarked that whatever success had been attained by their Association was very largely due to that gentleman's kind advice and assistance, which he had always placed at their disposal.

Other toasts were drunk and a very pleasant evening was spent.

HULL CHEMISTS' ASSOCIATION.

The first meeting for the present year, of the above Association, was held at the Cross Keys Hotel, on Thursday evening, November 15. The President, Mr. C. B. Bell, in the chair.

After the ordinary business had been concluded, the President delivered an inaugural address, in the course of which he reviewed the history of the Pharmaceutical Society and the various Acts of Parliament passed in connection with it from its formation to the present time, and then proceeded to notice the Chemists' Trade Association and its doings. In conclusion, he expressed his regret at the apathy shown by the junior members of the trade with regard to the various facilities for study and advancement now provided for them, and urged all chemists to stand together for the common good.

Mr. J. F. Smith proposed and Mr. Thyar seconded a vote of thanks to the President for his very able address.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

Erratum.—In the abstract of Mr. Perkins's paper, read before the Chemical Society on the 1st inst., which appeared on p. 379, the word "cumenyl" was by mistake written "cinnenyl" throughout the report.

A meeting of this Society was held on Thursday, November 15, Dr. Gladstone, President, in the chair. After the announcement of visitors and presents to the library, and confirmation of minutes, the following certificates were read for the first time:—T. C. Cloud, G. F. Dowdeswell, A. Ginders, A. Linnell, D. A. Louis, S. P. Pickering, and J. Woodland.

The President then announced that Professor Odling being unable to attend, his paper on "Gallium" would be postponed till the next meeting of the Society.

The following papers were read:—

(1). *First Report to the Chemical Society on Some Points in Chemical Dynamics.* By Dr. WRIGHT and Mr. LUFF.—From certain theoretical considerations the authors thought it probable that the temperature at which a body A begins to act on a compound B C, in accordance with the reaction A + B C = A B + C, is a function of (*a*) the physical condition of the substances, (*b*) the heat disturbance (evolution or absorption), taking place during the change, and (*c*) the chemical habitudes of the bodies, possibly expressible as numerical values constant for each substance. An elaborate series of experiments has, therefore, been made to find out the temperatures at which the actions of carbonic oxide, hydrogen, and free amorphous carbon on oxide of iron or oxide of copper are first perceptible. Various specimens of oxides in different states of physical aggregation were prepared, in some instances by special devices so as to obtain products free from all traces of organic matters derived from washing water, filters, etc. The temperatures at which carbonic oxide begins to act on these bodies were determined by keeping portions of them in a tube at various temperatures, passing pure carbonic oxide (carefully freed from admixed oxygen—from air) over them, and noting the temperature at which the issuing gases first rendered baryta water turbid. The temperatures of initial action of hydrogen were obtained by dissolving the substances after exposure to its action in hydrochloric acid or hydrochloric acid and ferric chloride, and testing by permanganate or ferricyanide. The temperatures at which carbon begins to act were found by observing when gas began to be evolved on heating in a Sprengel vacuum, due corrections being made for small quantities of carbonic oxide and carbonic acid occluded by the carbon, and gradually given off by it during the heating. Two kinds of carbon were used, one a dense sugar charcoal, well washed, ignited in a current of chlorine, and again treated in a closed platinum crucible till no more hydrochloric acid came off; the other a light pulverulent carbon, obtained by acting on ferric oxide with carbonic oxide at about 400° C., and dissolving out the reduced iron by hydrochloric acid. The general results of these experiments are as follows:—(1) The temperature at which the action of a given reducing agent on a given metallic oxide is first perceptible depends on the physical condition of the metallic oxide, and if carbon be the reducing agent also on the physical condition of the carbon. (2) Hydrogen uniformly begins to act on a given oxide, in a given physical state, at a lower temperature than carbon, and carbonic oxide begins to act at a lower temperature than hydrogen. (3) When the physical state is about the same, a given reducing agent begins to act on copper oxide at a lower temperature than on iron oxide. (4) The two last conclusions are special cases of the general rule that *the greater the algebraic value of the heat disturbance* (*i.e.*, the more heat evolution or the less heat absorption) *the lower the temperature at which the action is first noticeable.* (This rule is, however, not general for all metallic oxides, as it does not apply in the case of iron and tin oxides.) Thus in the case of the reactions: 1. $CuO + CO_2 = Cu + CO_3$; 2. $CuO + H_2 = Cu + H_2O$; 3. $2\,CuO + C = 2\,Cu + CO_2$; there is respectively an evolution of heat to the extent of $+30{\cdot}05$, $+19{\cdot}52$, and $+9{\cdot}48$ kilogram heat units per sixteen grams of oxygen transferred from metallic oxide to reducing agent. In the corresponding action of these agents on Fe_2O_3 the heat disturbances are $+1{\cdot}90$, $-8{\cdot}63$, and $-18{\cdot}67$. In the reduction of cuprous oxide there is almost the same heat disturbance as in that of cupric oxide (by the same reducing agent). Hence the temperature of initial action on Cu_2O of each agent lies very close to that found for CuO, in fact within the limits afforded by variations in physical state. The action of carbonic oxide on precipitated cupric oxide is noticeable at a temperature much lower than 100°; at 100° carbonic oxide is wholly converted into carbonic acid by heating it in sealed tubes with some oxide. By passing carbonic oxide over cupric oxide at 100° pyrophoric copper is soon obtained almost free from oxide. If the carbonic oxide contain a trace of air the partially reduced oxide serves as a conveyer of oxygen to the carbonic oxide, thus producing much more carbonic acid than that due to the cupric oxide acted on. The actual temperature values obtained with chief specimens examined are given in the following table:—

Substance.	Initial temperature of action with—			
	CO	H	Sugar C	C from CO
Copper oxide by precipitation	60°	85	390	350
Copper oxide by ignition of nitrate	125	175	430	390
Copper oxide by prolonged heating of metal	146	172	440	430
Cuprous oxide . . .	110	155	380	345
Ferric oxide by calcining $FeSO_4$	202	260	450	430
Ferric oxide precipitated	90	195	450	—
Ferric oxide precipitated and gently ignited .	220	245	450	430

Dr. Gladstone pointed out that the above paper was the first fruits of the research fund, and was therefore of special interest to the Society. He complimented the authors on opening out a new region of thought and experiment, and on the success with which they had overcome the great difficulties they had met with in obtaining substances sufficiently pure for their experiments.

Mr. Vernon Harcourt asked if any experiments had been made as to the effect of time on the reactions; whether, for instance, given an unlimited time, a reaction would not go on to the end at a comparatively low temperature. He would also like some further explanation of the term "algebraic value of the heat disturbance."

Mr. Wills inquired whether after heating, cooling and reheating a substance several times, a rising of the initial temperature of reaction did not take place, also how it was possible to compare the action of a solid body such as carbon with the action of gases such as hydrogen.

After some remarks by Messrs. Kingzett, Neison and Drs. Dupré and Armstrong, Dr. Wright briefly replied to Mr. Harcourt, that experiments of the kind indicated were in progress; that the above term was used simply to express the production of heat, whether it was a positive or a minus quantity, and that "heat disturbance" was simply a translation of the German word Wärmetönung. In reply to Mr. Wills, Dr. Wright said that the temperature did rise, and so care was taken always to have fresh samples for each experiment; that as regards the relative action of a solid and a gas, the solid would no doubt act very much less rapidly, but this would not affect the temperature at which the action commenced.

The next paper was communicated by Mr. C. T. Kingzett.—

(2.) *On the Chemistry of Cocoa Butter*, Part I. *Two New Fatty Acids*.—The specimen of cocoa butter examined was hard, imperfectly transparent, slightly yellowish, melting at about 30° C., and when once melted remaining liquid for some time at a lower temperature. It contained no volatile or soluble fatty acids. The acids were prepared by saponifying the butter, and decomposing the soaps with dilute sulphuric or hydrochloric acid; they were purified by recrystallization from alcohol, fractionating, etc. Many analyses and melting points of products obtained are given. The extreme acids found were represented by the formulæ $C_{12}H_{26}O_2$ and $C_{64}H_{128}O_2$. The first is the formula of lauric acid, but it melts at 57·5° (lauric acid melting at 43° C.), so it must contain some acid of a higher melting point than lauric acid, and therefore the acid itself must be lower in the series $C_nH_{2n}O_2$ than lauric acid. The highest known acid in this series is melissic acid $C_{30}H_{60}O_2$. The new acid has a formula not lower than $C_{64}H_{128}O_2$. Many salts of these acids were prepared, but details as to their composition are reserved for a future communication. The lower acid crystallizes in pearly plates or fine long needles. The higher acid, for which the author proposes the name of "theobromic acid," crystallizes in microscopic needles or granules, melts at 72·2° C., at a high temperature distils apparently unchanged, is somewhat electric when dry, a property which is possessed in a high degree by its silver salt. The total fatty acids of cocoa butter contain about 20 per cent. oleic acid. The author, in conclusion, points out that text books state "that cocoa butter yields, almost exclusively, stearic acid." From the present investigations it is clear that this statement is entirely incorrect; it is based entirely on determinations of the melting point of the fatty acids obtained.

Mr. Duffy said that from the proportion of carbon he should have expected a higher melting point, observing that a very small quantity of a fatty acid containing a low percentage of carbon had an enormous effect on the melting point of a high acid, perhaps from some kind of solvent action.

The next paper was read by Dr. Armstrong—

"*On the Influence Exerted by Time and Mass in Certain Reactions in which Insoluble Salts are Produced.* By M. M. P. Muir.—In this paper the author has worked out in detail a suggestion given by Dr. Gladstone (*Chem. Soc. Journ.*, ix., 54), to the following effect:—"It is easily conceivable that where the affinity for each other of two substances that produce an insoluble compound is very weak the action may last some time, and become evident to our senses. Is not this actually the case when carbonate of soda in solution is added to chloride of calcium?" The author has taken solutions containing known quantities of calcium chloride and potassium or sodium carbonate, allowed them to stand for a certain number of minutes after mixing, collected the precipitate formed, and thus has obtained approximate results, which are, however, strictly comparable among themselves. These results the author has represented graphically in curves. The greater portion of the chemical change takes place during the first five minutes, afterwards the reaction decreases very much in rapidity. The relative masses of the salts exert an important influence; thus, if the mass of alkaline carbonate be four times that required by the equation $CaCl_2 + M_2CO_3 = 2MCl + CaCO_3$, the action is completed in five minutes, but if the salts are in mixed equivalent quantities, the action is not completed in forty-six hours. For short periods of time potassium carbonate yields more calcium carbonate than sodium carbonate. An increase of the temperature produces in every case an increase in the amount of calcium carbonate formed in a given time, whilst dilution causes a marked decrease. Dilution with sodium or potassium chloride solution gives a still more marked decrease. A discontinuous addition of one of the solutions to the other causes the action to reach a maximum more quickly than when the solutions are mixed at one time, but the maximum so reached is no greater than that which is finally attained under the latter conditions. In conclusion, the author gives the results obtained by mixing solutions of calcium sulphate and sodium chloride, allowing them to remain for four weeks, and then estimating the calcium sulphate decomposed, when 14·2 molecules of sodium chloride were used to one of calcium sulphate, 32·9 per cent. of the latter was decomposed. Further experiments on this subject are promised (see Graham, *Chem. Soc. Journ.*, iii., 60). Graham has shown that sulphates of potassium and sodium are decomposed by lime water yielding diffusates containing caustic potash and soda respectively. The above experiments show how the chlorides of the alkalies may yield sulphates, and these in turn may furnish the alkaline carbonates required by plants.

The Society then adjourned to Dec. 6th, when the following papers will be read:—

1. "Gallium," by Professor Odling. 2. "The Constitution of the Terpenes and of Camphor," by Dr. Armstrong. 3. "Potable Waters," by Dr. Mills.

Parliamentary and Law Proceedings.

PROSECUTION BY THE APOTHECARIES' SOCIETY.

At the Bradford County Court on Tuesday, Nov. 13, John Faull, chemist and druggist, White Abbey Road, Bradford, was the defendant in an action brought by the Master and Wardens of the Society of Apothecaries of the City of London, by whom he was charged with having acted as an apothecary without being lawfully entitled to do so. Mr. Gane (instructed by Mr. C. L. Atkinson, on behalf of the Bradford Medical Ethical Society) appeared for the Apothecaries' Society; and Mr. West (instructed by Messrs. Lancaster and Wright) appeared for the defendant.

Mr. Gane said that action was brought for an infringement of the Apothecaries Act, 55 George III., chapter 194, section 20, which imposed a penalty of £20 on every person who infringed the Act by acting as apothecary without having passed the requisite examination. The question for the Court to decide was not whether defendant had acted as a chemist—for he was entitled to do so—but whether he had acted as an apothecary. The distinction between the two was laid down by Mr. Justice Cresswell in Moody and Robinson *v.* the Apothecaries' Company, where it was said that a chemist was one who supplied drugs which were asked for; an apothecary was one who judged of the symptoms of the persons who came to him, and used his judgment in determining what medicines he should give them. In that case it was not a question as to whether the medicines given by Mr. Faull were beneficial or not, but whether the provisions of the Act of Parliament had been observed. The cases which would be sworn to in evidence were not surgical cases, but cases of disease, and two of them were very serious. In one of them the child, who was suffering from bronchitis and pleurisy, died two or three days after Mr. Faull had mixed up medicine for it. In another case a young woman was suffering from diarrhœa; she went to Mr. Faull—who did not recommend her to go to a doctor—and died within a day or two afterwards. He therefore submitted that Mr. Faull had brought himself under the penal section of the Act.

After referring to a case at Nottingham brought by the Apothecaries' Society (*Law Times Reports*, vol. xxxiv., page 76), Mr. Gane called Leah Hayhirst, a married woman, living in Queen Street, Bradford, who said that on the 29th May last her child, eleven months old, named Ann, was very unwell, and she took the child to Mr. Faull. She asked him if the child was dangerously ill, and he replied that she was not, but that she had a "snatch" of the bronchitis. He gave her a bottle of medicine, for which she paid 9*d.*, and a plaster, and told her to give the child a spoonful of the medicine three times a day.

Mr. West here observed that, as it was not suggested that anything like malpractice had taken place, or that what was given to the child was not suited to her, there was no need going into what took place subsequent to the medicine being given. It was not suggested that any subsequent illness was occasioned by the medicines Mr. Faull gave; the question was, had Mr. Faull infringed that section of the Act which had been referred to.

Mr. Gane agreed with Mr. West, and observed that the offence would remain even if the child had not taken the medicine, because defendant's act was complete in itself.

Elizabeth Page, 40, Raven Street, Bradford, said that on the 28th July she and her daughter, Mary Ann, went to Mr. Faull's shop. They asked for medicine for diarrhœa, and defendant told her daughter to go home and take a dose of the medicine. He also gave her two powders, and charged 8*d.* for the bottle of medicine and 2*d.* for the powders.

Samuel Hibbert, King Street, Bradford, stated that on the 25th May he went to the defendant's shop and asked for a bottle of medicine, as he had got the sick headache and felt a little bit dizzy. Defendant made up a bottle of medicine, and said if that did not put him right he was to call again.—By Mr. West: I did not call again, for it did me good. I have not got the bottle. I went into the Durham Ox public-house to get a draught, and there was a party in who, when he heard that I had got a bottle of medicine from the defendant's, asked to see it, and when he got hold of it said he would keep it. I told him he might do so.

Charlotte Sykes, of Manningham, said that on July 25th she took her child, Martha, to Mr. Faull, and told him her baby was very ill. She asked if he could give her anything that would do her child good, and he said "Yes." He then made her up a bottle of medicine and gave her a powder and a plaster. On a subsequent day she took the child, who had become worse, to the defendant: he then gave her another bottle of medicine and two powders.

Mr. West then addressed the Court some length, contending that Mr. Faull had done nothing more than was customary on the part of druggists, and nothing more than he had a perfect right to do.

His Honour observed that if he were directing a jury in such a matter he should certainly tell them that a druggist who mixed up and dispensed medicines on his own judgment was liable under the Act. He should not, however, give judgment in the case at present, but would wait until the appeal in a similar case from the decision of the Nottingham County Court Judge had been disposed of. He fully believed the case then before the Court was not by any means an isolated one, and that many besides Mr. Faull would be interested in the decision which was ultimately arrived at.—*Bradford Observer*.

APOTHECARIES' SOCIETY *v.* SHEPPERLEY.

This case, which is an appeal from the decision of the Judge of the Nottingham County Court, came on for hearing in the High Court of Justice, Exchequer Division, on November 20, before the Lord Chief Baron Kelly and Mr. Baron Cleasby.

Sir Henry James: My Lords, this is a special case stated by the learned county court judge, and raises a question of considerable practical importance as to how far persons carrying on the business of chemists and druggists may exercise a discretion in the sale of medicines across the counter. That, my Lords, is the main point to be determined.

The Lord Chief Baron: For whom do you appear?

Sir Henry James: My Lord, I appear for the appellant, who was the defendant.

The Lord Chief Baron: Who is the appellant; is he convicted?

Sir Henry James: Yes, my Lord, in penalties under the Act of George III. The learned judge felt it was a case for the determination of a superior court, and on the case stated by him the appeal comes before your lordships. My Lords, to direct your attention to what is the matter for your determination, I may say generally the question is whether the chemist and druggist who in his shop, dealing across the counter, sells certain drugs and wares in his business and to a certain extent exercises his discretion in the sale of those wares—how far he practises as an apothecary so as to bring him within the penal clauses of the Act of George III. My Lords, the case is stated as follows:—

"This action was brought by the Master, Wardens, and Society of the Art and Mystery of Apothecaries of the City of London against the appellant, the defendant, who is a chemist and druggist, carrying on business at Nottingham, within the jurisdiction of the Nottingham County Court, to recover from him the sum of £20, under and by virtue of the 55 George III., chap. 194, sec. 20, for that he, not being a person who on the first day of August, 1815, was actually practising as an apothecary, did, on the 22nd August, 1876, and on divers days within six months next before the commencement of this action, act and practise as an apothecary, in the town and county of the town of Nottingham, by then and there as such apothecary attending and advising and furnishing and supplying medicines to Thomas Jolly Death, one Daniel Hubbard, and divers other persons, without having obtained such certificate as by the said Act is directed, contrary to the form of the statute in such case made and provided. Upon the evidence set forth in my notes hereunto annexed I find that in one instance the defendant in his shop heard a patient state his complaint, examined him medically, and supplied the said patient with medicine of his, the said defendant's, own prescription, and in another instance supplied medicine to a patient for an eruption on his face. The question for the Court is whether these facts brought the defendant within the provisions of 55 George III. chap. 194, and made him liable to the penalty therein provided and sought to be recovered in this action."

Although these findings are in the terms mentioned, your lordships see the learned judge there leaves it to the Court to determine whether those facts brought the defendant within the provisions of the 55 George III. My Lords, the notes are rather long because they refer to some cases on which the learned judge seems to have found in favour of the chemist's conduct, but the only evidence which applies to the determination of the judge in favour of the Apothecaries' Company is the evidence that has relation to the cases of two persons, Thomas Jolly Death and Daniel Hubbard. Those are the two cases to which he refers. Now, my Lords, the evidence as to those cases occurs at page 3.

The Lord Chief Baron: Then you pass by George Shepperley's evidence—that is not one of the two cases.

Sir Henry James: Shepperley, my Lord, is the defendant himself. I shall have to refer to it, but the formal evidence with respect to the two cases I have mentioned had better commence with the persons referred to, and Thomas Jolly Death's commences at page 3. He says:—

"On 22nd August, last year, I went to defendant's shop. I saw him behind the general counter. I said, 'I want some medicine for sore throat, cold, tightness of chest.' Defendant came between the two counters and told me to face the light and open my throat. He looked down my throat. He said, 'a tightness there,' touching my chest. He said, 'I think I can give you something to relieve you. I do not think there is much amiss with you.' He gave me a bottle of medicine, to be taken internally and I paid him 1s. I said, 'How much?' and he said, '1s., please. I think you will find relief from that; if not, come again.' I did not specify the medicine I required."

What follows is simply what took place after the cause of action arose, and does not affect the case. Mr. Shepperley himself says as to Death's case:—

"I believe Death called and asked me to look at his throat. If he asked me I should. I believe I gave him medicine. I don't think he brought a prescription. I do not recollect what I charged him. I have several times refused to prescribe."

Then, my Lords, as to Hubbard's case, the evidence of Mr. Shepperley himself, which is the only evidence, is at page 2.

"I believe I saw Daniel Hubbard in my shop. He asked for something for some pimples he had on his face. I saw that he had pimples. I did not examine him at all. We have a dispensing counter, which has a screen in front of it. I did not take him behind the screen. I don't think he went there. I think I gave him some medicine. This (bottle put in) has my writing on it."

The Lord Chief Baron: Is that the bottle which came from this man, Hubbard?

Sir Henry James: I am told so.

Mr. Baron Cleasby: How did the county court judge decide this?

Sir Henry James: He found, leaving it to your Lordships' further judgment, that this case is a case coming within the 20th section.

Mr. Baron Cleasby: I did not collect that.

The Lord Chief Baron: No; he puts it as a mere question as if it were a special case without any decision. However, you say he decided to convict.

Sir Henry James: Certainly, my Lord, *pro formâ;* that is the way I read it, leaving it to your Lordships to say whether if you had been in his position you would have held that he had committed an offence within the 20th section of the Act of 55 George III. Now, my Lords, the better way will be perhaps to call attention to the Act, and then to place before you the position of an apothecary, and to see whether this is acting or prescribing as an apothecary. My Lords, the Act under which these proceedings are taken is the Act which first really recognized the status of an apothecary in this country. It is the Act of 1815, 55 George III. chap. 194. The Act recites the original charter of James I. under which the apothecaries were incorporated. My Lords, probably at that time, the time of James I., the principal object of that incorporation was to give power to certain persons to search in the shops or warehouses where drugs were sold so as to see that no spurious articles were sold. The status of apothecaries at that time was scarcely recognized other than as vendors or sellers of drugs. You will find this expressed all through the Act, I think, and I shall trace the history of the time, to show that they afterwards became of much more importance than they formerly were, and this is a portion of that recognition and legislation which placed them in that position. Your Lordships will see, if you have the Act, the first section recites the charter of James I. Then, my Lords, it repeals that charter to a certain extent, and the first material section is the 5th section. That section says:—

"And whereas it is the duty of every person using or exercising the art and mystery of an apothecary to prepare with exactness, and to dispense such medicines as may be directed for the sick by any physician lawfully licensed to practise physic by the President and Commonalty of the Faculty of Physic in London, or by either of the two Universities of Oxford or Cambridge; therefore, for the further protection, security and benefit of his Majesty's subjects and for the better regulation of the practice of physic throughout England and Wales, be it enacted that if any person using or exercising the art and mystery of an apothecary shall at any time knowingly, wilfully and contumaciously refuse to make, mix, compound, prepare, give, apply or administer, or any way to sell, set on sale, put forth, or put to sale to any person or persons whatever, any medicines, compound medicines, or medicinal compositions, or shall deliberately or negligently, falsely, unfaithfully, fraudulently, or unduly make, mix, compound, prepare, give, apply, or administer, or any way sell, set on sale, put forth or put to sale to any person or persons whatever, any medicines, compound medicines, or medicinal compositions as directed by any prescription order or receipt signed with the initials in his own handwriting of any physician so lawfully licensed to practise physic, such person or persons so offending shall be guilty of an offence."

My Lords, the only material part there is, that this is dealing with that which at this time could only have been one portion of the apothecary's duty, namely, that of making up prescriptions or of compounding that which formed the subject of the prescription in selling the medicine; but the art and mystery could not be confined to that, because at this time druggists were equally with apothecaries selling drugs and making up prescriptions of physicians. Now, my Lords, the next section which is important is the 14th, and this deals with the practising of apothecaries, and allowing them to do so without examination. This was the first time apothecaries had been subjected to any examination.

"And to prevent any person or persons from practising as an apothecary without being properly qualified to practise as such, be it further enacted that from and after the 1st day of August, 1815, it shall not be lawful for any person or persons (except persons already in practice as such), to practise as an apothecary in any part of England or Wales, unless he or they shall have been examined by the said Court of Examiners, or the major part of them, and have received a certificate of his or their being duly qualified to practise as such from the said Court of Examiners, or the major part of them, as aforesaid, who are hereby authorized and required to examine all person and persons applying to them for the purpose of ascertaining the skill and abilities of such person or persons in the science and practice of medicine and his or their fitness and qualification to practise as an apothecary; and the said Court of Examiners, or the major part of them, are hereby empowered either to reject such person or persons, or to grant a certificate of such examination, and of his or their qualification to practise as an apothecary as aforesaid: Provided always that no person shall be admitted to such examination until he shall have attained the full age of twenty-one years."

Your Lordships will see the examination was to deal with that which would be a matter of science and of skill, not as formerly that which had been one of the principal duties of an apothecary, namely, to sell medicines and drugs; but the examiners had to ascertain "the skill and abilities of such person or persons in the science and practice of medicine." Of course, my Lord, that is distinct from the certificate granted by the College of Physicians for those who practise as such, but this was as to their skill in dealing with all medical cases, such as fevers and other internal disorders. This is the science and practice of medicine, which was perfectly distinct of course from the practice of an apothecary to sell the drugs and medicines in the shops which frequently before it had been their habit to wholly carry on their business in. Now, my Lords, we come to the section under which these proceedings are taken; but perhaps I should mention that by section 15—

"No person shall be admitted to any such examination for a certificate to practise as an apothecary, unless he shall have served an apprenticeship of not less than five years to an apothecary and unless he shall produce testimonials to the satisfaction of the said Court of Examiners of a sufficient medical education."

Then, my Lords, section 20 is the section under which these proceedings have been taken, and upon the words of this section much turns. It is enacted—

"That if any person (except such as are then actually practising as such), shall, after the said 1st day of August, 1815, act or practise as an apothecary in any part of England or Wales, without having obtained such certificate as aforesaid, every person so offending shall for every such offence forfeit and pay the sum of £20; and if any person (except such as are then acting as such and excepting persons who have actually served an apprenticeship as aforesaid), shall after the said 1st day of August, 1815, act as an assistant to any apothecary, to compound and dispense medicines without having obtained such certificate as aforesaid, every person so offending shall for every such offence forfeit and pay the sum of £5."

Then, my Lords, there is a section to which many of the authorities in these cases have had reference, section 21, which enacts—

"That no apothecary shall be allowed to recover any charges claimed by him in any court of law unless such apothecary shall prove on the trial that he was in practice as an apothecary prior to or on the said 1st day of August, 1815, or that he has obtained a certificate to practise as an apothecary under the provisions of this Act."

Then, my Lords, as far as I know there is only one other section which bears much on the matter, and that is section 28, by which a distinct question in this case arises.

The learned judges here conferred for a short time.

By such section, my Lords, it is provided as follows :- -

Mr. Baron Cleasby: You have not Wilcox's Medical Acts in court, have you?

Sir Henry James: No, my Lord, I have not.

Mr. Baron Cleasby: They are all collected together there, I think.

Sir Henry James: My Lords, I think I have most of the Acts. There are very few Acts which I think affect this question, and I will mention them as I go on.

The learned judges again conferred.

Sir Henry James: My Lords, I was calling attention to section 28, that reserves the rights of chemists and druggists, not then at the time of passing this Act, living, but to any person who at any future time shall carry on the business of a chemist and druggist, to carry on that business. The section is this:—

"That nothing in this Act contained shall extend or be construed to extend, to prejudice, or in any way to affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing, and vending drugs, medicines, and medicinable compounds, wholesale and retail; but all persons using or exercising the said trade or business, or who shall or may hereafter use or exercise the same shall and may use, exercise, and carry on the same trade or business in such manner and as fully and amply to all intents and purposes as the same trade or business was used, exercised or carried on by chemists and druggists before the passing of this Act."

My Lords, as I have said, a distinct and separate point arises on that section 28.

The Lord Chief Baron: You defer dealing with that point at present. You say there is a separate point which arises on that, but you do not propose to deal with that at present. You are going back now to the first point?

Sir Henry James: My Lords, I will go back to the first point; I call that the second point, and I have mentioned it in calling attention to the sections, and I will deal with the points as they occur in order. Now, my Lords, I have to ask your Lordships to determine whether upon the facts to which we shall have to apply certain considerations, the appellant here has, under the 20th section of this Act 1815, 55 George III, acted or practised as an apothecary. And, my Lords, what I have to submit to your Lordships is that, inasmuch as those words "acting or practising as an apothecary" must have a certain meaning attached to them, it must mean that the person is holding himself out and carrying on business as an apothecary, and it is not enough for one person who, for charity's sake or for any other reason, does one isolated act, or one thing that an apothecary would do as a portion of his profession, in order to bring him within this clause and to render him subject to penalties.

Mr. Baron Cleasby: You are on the 20th section now.

Sir Henry James: Yes, my Lord. A chemist and druggist from the very nature of his business, if he never opens his mouth, exercises no discretion, takes no notice of anything that a person who applies to him as a customer is suffering from, but simply sells him a medicine, is in one sense doing that which an apothecary also does. An apothecary sells his medicine, obtains a price for it, and can sue for it as for goods sold and delivered. An apothecary can do that, and therefore, my Lords, if it is to be said that a chemist and druggist who, without doubt, as not only the ostensible but the real purpose and the object of his business is selling his wares, and if for the sale of his wares he does a certain thing which equally an apothecary in carrying on his business as an apothecary does, that, with submission, is not enough to bring the chemist and druggist within the section of the Act. The words must be looked at in a broader view, namely, "acting or practising as an apothecary," meaning thereby, that he generally and substantially carries on his business so as to come upon equal lines with the carrying on of the profession of an apothecary.

The Lord Chief Baron: You are contending that one act is not sufficient.

Sir Henry James: My Lord, I am contending not that one act may not in some cases be evidence that he is generally carrying on or acting as an apothecary, but what I am contending is that one act, when it is only one act, or portion of what an apothecary does to carry on his business, and when I show to your Lordships that that act is what a chemist and druggist would do to carry on his business, then that is not acting as an apothecary.

The Lord Chief Baron: It is the entire act, because you know the act which the defendant has done is a compound act; there are two acts, in fact there are three acts.

Sir Henry James: I have a little more to say before we come to the evidence, if you will allow me.

The Lord Chief Baron: There is one act with this person of the name of Death, and there is another with a person of the name of Hubbard. I wish to ask you whether you mean to contend that there must be more than one act, or possibly more than two acts, to constitute an "acting or practising" within the meaning of the section?

Sir Henry James: I did not mean one act in that sense.

The Lord Chief Baron: Because you used the term "holding out." I wished distinctly to understand what your argument was.

Sir Henry James: My Lord, nothing was further from my mind than to use the words "one act" in the sense of selling to one person. I was dealing with a general act away from the facts before your Lordships, in the sense of one portion of the profession of an apothecary. I am speaking of things in their generic sense, not particularly in relation to what is before you. What I wish to convey to your Lordships is that whereas an apothecary in the practice of his profession has to do, as I will show your Lordships, naturally a great many things which require the exercise of skill and knowledge (as we have found in the Act of 55 George III. "science and skill" are the words used) that whilst and when he practises his profession generally he will have to attend to many classes of cases and diseases requiring skill and knowledge, and in the course of carrying on that profession will have to sell his drugs to the person he may attend; it is not sufficient to bring a chemist and druggist within this section of this Act to show that he, equally with the apothecary, does one of those acts of which the apothecary does many, in order to carry on his profession. I hope I am making myself understood in the sense I am using the words "one act." I am not speaking of selling across the counter, but merely of a chemist and druggist generally, every day of his life, doing one of those things which I shall have to admit that an apothecary equally does, namely, selling his drugs.

The Lord Chief Baron: Is there any doubt that that is so?

Sir Henry James: I hope not, my Lord; but I must go by steps.

The Lord Chief Baron: There is no doubt that every chemist and druggist in London compounds certain medicines.

Sir Henry James: Quite so, my Lord.

The Lord Chief Baron: An apothecary does the same.

Sir Henry James: And he must dispense them?

The Lord Chief Baron: Dispense them; by that you mean sell them?

Sir Henry James: Well, my Lord, of course, he takes money for them; but probably dispensing will have rather a different meaning from the word selling.

The Lord Chief Baron: What is the meaning you give to it?

Sir Henry James: I rather want your Lordships to define that because it is important you should. Perhaps "selling" would apply to a patent medicine, a thing that is of known constituents, like a box of matches, which a chemist might sell across his shop counter; but I should think dispensing had rather a different meaning.

The Lord Chief Baron: It may; therefore I ask what you mean by it? You may call it dispensing physicians' prescriptions. When a prescription is laid before the chemist he prepares it and supplies it for money. It is selling, but you may also call it by the grander name of dispensing.

Sir Henry James: I should have thought selling a very much narrower word.

The Lord Chief Baron: Suppose it is; I only want to know in what sense you use the word?

Sir Henry James: I use selling in the same sense in which any ware is sold requiring no skill.

Mr. Baron Cleasby: Merely selling; "dispensed" would be sold for a purpose.

Sir Henry James: Certainly, my Lord; dispense may include the making up of medicine; it may include the mixing together several chemical substances in order to produce one result, and it must be subject to the skill of the chemist and to the qualities of those different substances and the proportionate quantities in which they are to be placed together, as they may be poisons if not properly compounded.

Mr. Baron Cleasby: And as to the mode of mixing them?

Sir Henry James: And as to the mode of mixing them. That is, as I was endeavouring to show, if not properly mixed they may be poisonous.

The Lord Chief Baron: I know but two modes in which a chemist and druggist sells or dispenses his medicines, and it is very immaterial, as it strikes me, whether you call one or the other, or both, by the terms selling or dispensing. If a man goes into a shop and asks for a bottle of Godfrey's Cordial the thing is handed to him. That is a very well known patent medicine, or once was a well known preparation; the chemist hands it to him and receives the money. Another mode in which the chemist carries on his business is where a physician's prescription is brought to him and laid before him and he then compounds a medicine, which perhaps he had never seen or heard of in all its ingredients before, according to the prescription placed before him. Then he returns the prescription at the same time as he delivers the medicine which is compounded, mentioning the price he charges, and receives the money for it. You may call either of those modes selling or dispensing.

Sir Henry James: Is there not another class of dispensing medicine? The second is the case where the chemist has a prescription which may be written by a physician; he makes that up and dispenses it, but there he would only have to use that skill which Baron Cleasby has referred to, the skill of mixing that which he is directed to use.

The Lord Chief Baron: What is the third, if there be a third mode?

Sir Henry James: Suppose a person goes to a shop without any prescription, and says, give me a dose of epsom salts. The chemist sells those epsom salts to him, but he must look at the nature of the person who asks him for it, a strong man or a weak child. He must give a proper, fair dose of epsom salts. He cannot say "Do you want two ounces?" and see the person take treble what he ought to take.

The Lord Chief Baron: There you know; I am not saying it is not a part of his business, but if he is asked for a dose of epsom salts, and inasmuch as a dose for a full grown strong man and a dose for a child of six years old would be a very different quantity, he must ask for whom it is wanted and for what purpose.

Sir Henry James: I am putting the case of a person being drugged on the premises, if I may use the expression, supposing it is a harmless thing to do. You go into a chemist's shop and say to him, "Give me an effervescing draught." He dispenses that to the person who asks him.

You do not carry it away in a bottle, you drink it on the spot.

The Lord Chief Baron: No; I see no objection to that, you may subdivide the business of a chemist and druggist into twenty such operations if you please.

Sir Henry James: That is dispensing surely in one sense if we are treating him. Take the case I put of the salts. There he acts not upon a prescription, which is directory, which he has to obey; but not giving the mode in which that which is asked for has to be taken, he must in dispensing that, bring to bear some skill, because of course the customer does not know how it is to be mixed, and what quantity of water corresponds to a proportionate quantity of salts. That kind of dispensing by the chemist is the result of his skill and knowledge of his business.

The Lord Chief Baron: You will be able to tell us, when we resume this argument, into how many subdivisions you say a chemist's business is to be divided.

The further hearing of this case was then adjourned until Friday next.

Dispensing Memoranda.

[21]. ℥ VERSUS OUNCE.—I quite agree with the writer of the article "The Month," p. 323, that when ℥j of powder (or any solid) is ordered in prescription, 480 grains should be used, and further, I contend that this is intended by the prescriber; therefore I cannot accept the conclusions arrived at by your two correspondents on this subject in the Journal of November 3.

Previous to 1864 there was a certain weight in use in the Pharmacopœia, distinguished by the sign ℥ and whose value was 480 grains; when the first edition of the British Pharmacopœia appeared in 1864, the old familiar ℥ had disappeared, and the ounce with a value of 437·5 grains assigned to it was substituted, just in the same way that many old preparations were omitted and new ones took their places. Bear in mind, the actual value of the ℥ was not altered, but simply omitted altogether; I suppose no one would question the right of a medical man to order any preparation of the Pharmacopœia of 1851, if he felt so disposed, or if it suited his convenience to do so. The same argument I contend applies to the use of the signs ℥ and ounce; so long as the present anomalous systems of weights and measures remain in use, so long will medical men continue to use the sign ℥, because it represents a value conveniently sub-divisible without fractions, which the ounce cannot be said to do. When magnes. sulph. ℥j is prescribed in an eight ounce mixture, the dose of which is ordered to be an eighth part, does the prescriber intend the dose of magnes. sulph. to be 54·6875 grains or 60 grains? Common sense points to the latter I think. The signs ℥ and ounce represent two distinct values, and cannot in any way be considered synonymous. The majority of the instances quoted by "P. B." refer to the sale of articles, and therefore are entirely beside the question at issue. To call a thing in every day use obsolete is, to say the least of it, a perversion of terms; as well might beefsteaks, tea, sugar, etc., be considered obsolete. To the question asked by "P. B," "How do you know that when a physician writes in a prescription for ℥j he intends 480 grains to be dispensed?" I answer, because he has used a sign which never had, and is never likely to have any other value; and therefore conversancy with the "latent" intention of prescribers is not needed.

That Dr. Symes, usually so clear and precise in his argument, should have been led into the same error (the synonymous values of the ℥ and ounce) is a matter of some astonishment to me. Had he quoted the whole of the paragraph instead of half of it, I think he and most others would have seen the fallacy of the argument based upon it. It is as follows:—"It is strongly urged upon all medical men to avoid the use of the terms ounce and pound with reference to any other than the avoirdupois or imperial standard weights; but it will be optional with the physician in prescribing to use the symbols ℈ and ʒ (and I imagine ℥ too if he feels inclined to do so) the former representing twenty and the latter sixty grains, if such should be found to conduce to accuracy or convenience." This to my mind clearly indicates that when a physician wishes to order ℥j or 480 grains, he must do so and not use the term ounce which, as a matter of fact, they do. I cannot commend the writer of "The Month" for the way in which he subsequently confuses the signs ℥ and ounce. However clear the advice given to No. 21, the same cannot be said of the answer to No. 26, in which the querist is told that there is a formula in the British Pharmacopœia for ung. belladonnæ, eighty grains ext. to ℥j (*sic*) of lard. My copy reads:—Extract of belladonna eighty grains; prepared lard one ounce. I regard the whole system (or rather no-system) of weights and measures in use in this country as an unmitigated evil, and a disgrace to our boasted civilization. Let us then be unanimous in our efforts to rid ourselves of this incubus and to do all in our power to hasten the adoption of that which is admitted by all scientific men to be the only complete perfect and philosophic system, I mean the metric, which based as it is on the eternal harmonies, may be expected to last

"Not for an age, but for all time."

Fairfield, Liverpool. ALFRED E. TANNER.

[21]. AVOIRDUPOIS VERSUS APOTHECARIES' WEIGHT.—The chief argument of Mr. Wilkinson is based on the ground that ℥j means an apothecaries' ounce = 480 grains and nothing else, and on a desire for uniformity, in illustration of which he quotes a very unusual prescription that to my mind tells more against than for his argument. I cannot of course determine the nature of the prescriptions received by these gentlemen, but I do know as a fact that of those dispensed at our own pharmacies at least ninety-nine out of every hundred containing the sign ℥ do so with unmistakable evidence that 437½ grains (or a bulk equivalent to that weight of distilled water), and not 480 grains are intended.

℞ Ung. Cetacei . . . . ℥j

Would any dispenser send 480 grains? If he weighed it at all he would give an avoirdupois ounce, but most probably he would fill a pot of that capacity, which according to Maw's list, p. 50, should be accurate water measure. If the ointment ordered be a compound one, thus—

℞ Hydr. Iodi Rub. . . . . . gr. xxxij
Ung. Simplicis . . . . . . ℥j.

Would a tyro dispenser commit such an error as to translate this ℥j as an apothecaries'? Clearly, the intention of the medical man would be to prescribe an ointment double in strength to that of the B. P., or about one half that of the Dub. Pharm.

Again

℞ Potassæ Bicarb. . . . . ℥j
Aquæ Destil. . . . . ℥x.
M.

Whatever doubt may exist as to the intended value of the former ℥ no one can entertain any as to that of the latter; why then (for the sake of uniformity) (?) will people advocate putting two different values on the same sign, in the same prescription?

Mr. Mackay commences by "unhesitatingly bearing you out in rendering the sign of ℥j as equivalent to 480 grains." He of course refers to the article "The Month," in your Journal of October 27 and to number 21 of that article. May I ask him to read number 26, where the writer states that "in the British Pharmacopœia there is a formula for Ung. Belladonnæ, 80 grains, extr. to ℥j lard"? Of course he will unhesitatingly endorse the value here set on the sign ℥j also. He then renders seven reasons why he advocates the apothecaries' ounce in dispensing.

1. States that a wide difference exists as regards accuracy in buying, selling, and dispensing medicines. I fail to see the application.

2. Apologizes on behalf of the B. P. for the introduction of avoirdupois weight. No apology is necessary, it was simply consistent with common sense and with the progressive requirements of the age.

3. Assumes that the physician when prescribing remembers the exact number of grains of solid ingredients per ounce of each tincture in the B. B. "because it is there stated," whilst he is incapable of remembering that the avoirdupois ounce contains 437½ grains. This requires no answer; but I may say, however, that in many instances the B. P. does not give the number of grains of crude drug per ounce of tincture but the number of ounces per pint. Ginger, gentian, columba, and senna, are examples.

4. Is irrelevant.

5, 6, and 7. Are formulæ and surmises, with some moralizing on the perversity of human nature. Finally we are pointed to "an error which is too prevalent in making solutions for dispensing, *e.g.*, chloral hydrate one ounce, water to two ounces; the solution is then labelled and the strength marked one in one."

This very discussion tends to prove that even pharmacists cannot lay claim to infallibility. But may I ask, sir, did such an absurd blunder as this ever really occur, or is it not rather the result of a creative imagination on the part of the writer?

The apothecary and his ounce are both things of the past; it is true the former has an Act and the latter a name, but the sooner both are repealed the better.

Liverpool. CHARLES SYMES.

---

[21]. TROY OR AVOIRDUPOIS WEIGHT?—Your correspondent, Mr. Wilkinson, in the issue of October 17, quotes the now obsolete London Pharmacopœia of 1851, on this question, thus appearing altogether to ignore the more certain, precise, and simple definitions which have been adopted in the later, and now the only legally recognized standard, viz., the British Pharmacopœia of 1867. Any one thoughtfully reading the preface which is attached to that work surely can never so stultify himself as to uphold that the troy system of weights and measures has now any official sanction. In order to illustrate the following remarks I may be allowed to requote some portions; italicizing those which have a direct bearing upon the subject:—

"The grain weight established by law in this country is well known and well defined. It has been in use from a very remote period, and forms a convenient unit for estimating the weight of many medicines. The avoirdupois *ounce and pound, being the weights practically used in the sale of medicines*, and generally in commercial transactions, *were adopted in the edition of* 1864, *and are still retained in preference to troy weights of the same denominations.*"

"*It is strongly urged upon all medical men* to avoid the use of the terms *ounce* and *pound*, with reference *to any other* than the *avoirdupois or imperial standard weight.*"

If the above quotation has any meaning, it is that the symbol ℥ ought *never* to be used, or that, if it should be used, "*it is strongly urged*" that it be translatable into the avoirdupois ounce of 437·5 grains. But, to all rules, however rigidly laid down, there must be exceptions. Doubtless it was never intended by a dogmatic fiat to sweep away all vestiges of the troy system, but rather, (from the language employed) we would infer that the compilers of the B. P. intended that the troy system (like many other old relics which had served their day and generation) should be allowed to die a painless death. The exception therefore, in all cases where the symbol ℥ is used, will be the *intention* of the prescriber in using it. If the dispenser should happen to know that it *represents in the prescriber's mind* 480 grains by weight, then he has no option but to honestly dispense that quantity. If he does not know the prescriber's intention, then he has the above official sanction for dispensing 437·5 grains. In these days of high pressure, physicians have not the time to write their prescriptions as a logician would lay down a proposition, or a mathematician a theorem, and therefore, particularly under the present transitional system of weights and measures, a dispenser must exercise his judgment in dispensing some prescriptions.

In the following a consistent adherent to the troy system would be placed in a quandary:—

℞ Sodæ Bicarb. . . . . ℥ss.
Ammon. Carb. . . . . ʒj.
Tinct. Gent. Co. . . . . ℥j.
Spt. Chlorof. . . . . ʒss.
Aquæ, ad . . . . ℔j.

Doubtless he would dispense a troy half-ounce of sodic carbonate, but would probably for the nonce break faith with his pet system, and send out a *sixteen-ounce* mixture. Again:—

Acid. Hydrocyan. Dil. . . . . . ℈j.
Sodæ Bicarb. . . . . ʒij.
Spt. Amm. Arom. . . . . . . ʒij.
Liq. Bismuth. . . . . ℥j.
Aquæ, ad . . . . Oss.

Would this consistent adherent send twenty grains (by weight) of hydrocyanic acid, or only twenty minims (by measure), which would only weigh 18·174? Would he dispense an eight or a ten-ounce mixture? These are doubtless frivolous questions, but they serve to show up the present anomalous state of dispensing weights and measures. The above examples also show that there is something besides mere official sanction influencing the dispenser in his daily routine. Time-honoured customs and the prescriber's intentions must not be rudely interfered with.

In sending out liquid medicines, however, a dispenser disregards and ignores the troy system. For in all graduated measures as now used, every fluid ounce represents only 437·5 grains by weight of distilled water at 60° Fahrenheit, and 30 inches barometric pressure. If the troy system must be adopted in dispensing solids, why have measures graduated by that of avoirdupois?

In conclusion we may be permitted to hope, that (in the words—though not in the spirit of Mr. J. B. L. Mackay) "the time is not far distant, when no ambiguity shall arise about the interpretation of signs"—a time, in which the old complex and heterogeneous order of weights and measures with their empiric units, the grain, inch and yard, shall give place to that of the stabler and homogeneous new, having the metre as its sole unit of weight and measurement.

Worcester. G. S.

[21.] AVOIRDUPOIS OR APOTHECARIES'.—In "The Month," October 27, you state that the apothecaries' ounce of 480 grains should be used, when ℥j occurs in a prescription.

Three of your correspondents hold the same opinion, but three others think the avoirdupois ounce of 437·5 grains is meant. I have always used the avoirdupois ounce myself, and never doubted but that I was fulfilling the intention of the prescriber.

I believe a doctor would write ʒviij if he meant 480 grains; I know at least one who does so, and who intends 437·5 grains when he writes ℥j, and was no more aware that it was used with any other intention than I was myself. J. S. W.

	Ol. Bergam.	♏xvj.
	Ess. Mosch.	♏xxx.

"TENENS."

[563]. GINGER BEER SYRUP.—Will any one kindly give me a good formula for Ginger Beer Syrup for aerated waters that will produce a good frothy head when poured into the glass?

I have tried albumen, but it causes the drink to become turbid in a few days.

Also should be glad to know the address of a maker of refrigerators. S. R.

Obituary.

Notice has been received of the death of the following:—

On the 12th of November, 1877, Mr. William Battle Maltby, Chemist and Druggist, Bail Gate, Lincoln. Aged 50 years.

On the 15th of November, 1877, Mr. William Henry Mackereth, Pharmaceutical Chemist, Ulverston, Lancashire. Aged 50 years. Mr. Mackereth had been a Member of the Pharmaceutical Society since 1870.

We regret also to announce the death of Mr. Francis George Warrick, late of the firm of Warrick Brothers, Old Swan Lane. Mr. Warrick died at the Vice-Consulate, Nice, on the 20th November. Aged 53 years.

Correspondence.

ADMISSION OF WOMEN TO MEMBERSHIP.

Sir,—As you very necessarily remark the question the Council reserved for the next annual meeting is not whether women may practise pharmacy—that happily, if Mr. Fryer represents the general opinion, is beyond the Society's control—but whether, having obtained the requisite qualifications, they ought to be refused the privileges of membership. It is well that in any discussion this should be distinctly borne in mind. The first paragraph of Mr. Fryer's letter travels over the old ground as to the right of women to compete with men in the business of life, and as such is outside the issue, so I refrain from commenting upon it, though the way in which fact, fiction, argument, and sentiment have been mixed up, is simply delightful. So, again, the reasons which Mr. Fryer has given us are simply those which have been used times out of number on the general question—he uses them merely with more or less reference to his own trade.

Granting, for one moment, that pharmacy is a business in which women are not fitted to engage, I would ask, does the experience of the last few years entitle Mr. Fryer and those who think with him to the belief that throwing as many obstacles as possible in the way, will have any deterrent influence? I think not. Instance the medical profession where the argument of unfitness would seem to have especial force. For the last eight or ten years women have been "pegging away,"—and with what result? One by one the numerous barriers existing and carefully created by their wiser male friends have been overcome till at length, though it has been all fight and little favour—to paraphrase Mr. Fryer,—complete success has attended their efforts and practically women can now study and enter the profession on the same terms as men. Everywhere it is beginning to be felt that it is impossible to draw any arbitrary line as to what women may or may not do. Witness the recent act of the University of London and the tendency of the Cambridge University during the past three or four years. Men have a right to judge and act for themselves, and women equally have this right and will undoubtedly exert it in the future. Surely, then, if women are not qualified for the pharmaceutical profession, the only way of convincing them is to let them find it out for themselves, even to the "bitter end." An "obstructive policy" will only increase their exertions and have a contrary effect to that intended. Viewed as a question of expediency it will be wiser to open unreservedly our doors, and allow women to compete on equal terms with ourselves.

I would remind Mr. Fryer that after all it is only a very few women who are ever likely to enter into competition with us in this or any other profession, and that "mixture of the sexes in a pharmacy," of which he has so evident a horror, is not likely to occur to any extent, if at all.

I am sorry to see the old argument cropping up about "the market being already crowded;" at the best, this is but a selfish motive, and as such can have little weight, and we might equally apply the same reasoning amongst ourselves, and attempt to limit the number of chemists in the country at large.

Whatever conclusion the annual meeting may arrive at, eventually there can be but one result. It will be felt that in fairness and consistency women must be admitted unreservedly to all the privileges of the Society equally with ourselves.

REES PRICE.

54, *Loftus Road, Shepherd's Bush, W.*

Sir,—With a view of obtaining the feeling of the members on this subject, could not our local secretaries issue papers for voting, and send them up to Bloomsbury Square before the annual meeting?

If this could be managed, I think we should have a fair representation of the general opinion of the Society, and this would tend to strengthen the action of the Council.

The attendance at the annual meeting in May next will represent the London members chiefly, and therefore cannot be a fair test of the views of country subscribers.

The time has certainly gone by for entering into the subject of the desirability, or otherwise, of women becoming pharmacists, and it is only now a question of their joining the Society as members or associates.

I think we cannot in justice deny the examined women membership, although we may not legally be obliged to admit them; and as a matter of fair play, as well as of policy, it would be better to do so. Let us consider the question of the admission of women to practise medicine or pharmacy together, as the subjects to be taught are so nearly allied that they may be regarded as different branches of the healing art.

If women have made up their minds to enter upon either sphere of labour, let the medical schools and the Pharmaceutical Society open their doors to them, on an equal footing with men, and give them all the advantages possible.

If, by our adverse votes, we refuse the ladies membership, we shall find them entering on the practice of medicine and pharmacy by irregular channels, and we shall be contributing to the increase of the various classes of unqualified practitioners and chemists. Taking, for a moment, the broader view of the alleviation of human suffering and distress, it will be generally acknowledged that women are particularly adopted for nurses and attendants on the sick, and it cannot be doubted that there are women of sufficient skill and ability to act in any emergency.

Why should a woman be debarred from rising higher than a subservient help to the physician?

Medical and pharmaceutical knowledge is not for one sex only, but for all. There are now in this country many women, suffering from various diseases, who would gladly consult one of their own sex, but linger on, afraid to tell their symptoms to a man.

Although there is much in the practice of medicine and pharmacy to shock the sensibility and refinement of many educated ladies, there are undoubtedly some of sufficient nerve and energy to conquer all such difficulties, and instead of giving way under their first trials, struggle on bravely and devotedly to cure and heal.

Looked at in a commercial point of view I am afraid lady pharmacists would find many obstacles in their way, and think it would only be in dispensing and the higher class businesses where they would succeed. However, that remains to be proved, and there is no valid reason why a woman who is qualified should not employ male assistants to help her.

As to first entering to learn the business, it would not be desirable to have young ladies of eighteen or twenty behind the counter with young men, but there are lots of businesses conducted by a principal only, where ladies might be employed as pupils. Let us cast aside trade prejudices, and consider well the question on its merits.

We cannot deny that the ladies pass first-class examinations, and have proved themselves well qualified to practise pharmacy. By all means let us give them a fair chance of showing their practical ability and usefulness; but as competitors in business they must not expect any favours.

I can testify to the truth of Mr. Hampson's remark that some people think more of M.P.S. and the Society's arms than the title pharmaceutical chemist on prescription envelopes, etc.

FRATER.

SHALL LADIES REGISTERED AS PHARMACEUTICAL CHEMISTS OR CHEMISTS AND DRUGGISTS BE REFUSED ADMISSION INTO THE PHARMACEUTICAL SOCIETY?

Sir,—In order to obtain a correct view of this question which is to be submitted to the next annual meeting it is well that we should consider what are the privileges involved in the membership or associateship of the Pharmaceutical Society, and whether lady pharmacists are capable of using these privileges equally with gentlemen.

In the first place there is the privilege of attending the meetings of the Society, scientific and political; of voting and being voted for; of reading papers and discussing those read by others. No one will deny to the ladies who have embarked or may embark in pharmacy the same intellectual standing enjoyed by their sisters throughout the world. Are they then capable of taking part in our meetings? Our general or political meetings are but councils where each member has less responsibility. To decide whether ladies are capable of exercising this responsibility affirmatively, I have but to point to the great school boards with their illustrious ladies—indeed, to the greatest councils of the empire.

Are ladies qualified to read papers, etc.? Upon this point, although I might find abundant affirmative evidence in this country, I prefer to speak of what I know concerning the valuable work done by lady classmates of mine in societies, which were but smaller pharmaceutical societies, notably in the society which originally suggested the formation of the School of Pharmacy Students' Association. This work has appeared in the American and English journals, and its worth has been acknowledged by eminent men of science.

In the next place must be mentioned the privilege of securing the *Pharmaceutical Journal*, and of using the museum and library in the same way as gentlemen. These are truly valuable privileges, but are so purely educational that no one, I think, would wish to refuse them to lady pharmacists. I may be told, however, that beneath these lie concealed such dreadful things as the admission of ladies into the Society's laboratories—they are already permitted to attend the lectures of Professors Redwood and Bentley. Though this, of course, does not necessarily and may not follow from their admission into the Society, it is a result which I should view with satisfaction. I do not say so from theoretical reasons, but from knowledge, having worked side by side with ladies in the laboratories of the University of Michigan. I may say also that most favourable reports reach me from time to time of the results of co-education throughout the various departments of that advanced institution.

What privileges remain to be mentioned? The privilege of contributing to the Society's funds, and of using a distinction said to be of greater value in some cases than the title pharmaceutical chemist. I need not discuss the first of these privileges, and the last might have been passed over almost as briefly, were it not the only privilege which the Society can refuse that could possibly be an "obstacle" to ladies entering pharmacy. For this reason and because Mr. Fryer of Scarborough, in his letter in last week's Journal, advocates the opinion that it is extreme folly to take away any remaining barriers to the entry of ladies into pharmacy, I must dwell somewhat upon it. Will the refusal of this distinction have the effect desired by Mr. Fryer? I think not. It may, however, in certain cases reduce somewhat the income of the lady pharmacist—this I commend to Mr. Fryer and those who wish for a "fair fight," for I can assure him a "fair fight" is all lady pharmacists desire.

But Mr. Fryer tells us that under the present examination system a "fair fight" is impossible. He says that "ladies by exercising their charms over examiners will have an unfair advantage over gentlemen." Well, Mr. Editor, in institutions where this whole question has become one of the past no such difficulty has been met with. But even if it should prove true in the case of our examiners, the remedy is clear and easy. Let us have ladies on the examining board.

Mr. Fryer goes farther. He says in effect that not only the examiners but the Council, even our distinguished President himself, has become affected by this dreaded feminine influence, so that in matters pertaining to lady pharmacists he cannot pass unbiassed judgment. Well, if this be so, which I deny, our remedy is likewise clear. Let us have ladies on the Council — let us find places for the Helen Taylors of pharmacy.

Mr. Fryer then, seeming to fear the competition of ladies who pass first in the list, tells us what a dreadful business pharmacy is. One is forced to ask, if pharmacy be so poor an occupation, why grudge it to the ladies?

In conclusion, Mr. Editor, I submit that while there may be, and doubtless are, two opinions upon the question of the desirability of ladies entering pharmacy—a question which may be well left to the ladies themselves—there is little room for but one opinion concerning the admission of qualified ladies into the Pharmaceutical Society.

The Pharmaceutical Society is and should be in the widest sense an educational society, and as such we shall have to say at the next annual meeting whether we shall associate with ourselves in our educational advancement these lady pharmacists of admitted attainments, or whether we shall deny them that advantage. CURARA, THE PROPOSED REMEDY FOR RABIES.

SYNONYMS: *Ourari, Urari, Wourara, Wourali, Wouraly.*

BY JOHN MOSS, F.C.S. LONDON AND BERLIN.

A few remarks on this drug cannot fail to be of interest at a time when hydrophobia, against which it has been again proposed as a remedy, is more rife amongst us than at any previous period of our history; and notes taken from various sources for personal information may be the means of saving time and labour to those who have felt disposed to look up the matter with a similar object, or, what is still more important, may give information to those who have not the opportunity of informing themselves.

Historical: Source and Preparation.—Curara is the name of a poison used by all the South American savages between the Amazon and the Orinoco to arm the points of their arrows. Most authorities say that it is made by the Macoushi Indians, but the Acaaway tribe is also mentioned.

Perhaps the first account of the wourali poison is given by Waterton in his 'Wanderings in South America.'* Waterton was a Yorkshire gentleman of independent means with a passion for travel and the study of nature. When in Guiana, in 1812, he travelled 800 miles into the interior for the two purposes of collecting a quantity of the strongest wourali poison and of reaching the inland frontier post of Portuguese Guiana. He succeeded in obtaining a sufficient quantity of the poison from the Indians of Macoushia, a district far away in the wilds of Essequibo and Demerara. This tribe has a reputation above all others for preparing wourali of the utmost potency, and Waterton gives their mode of preparing it as related to him. He does not seem to have made any inquiry respecting the plant yielding the principal ingredient, or to have obtained a specimen of it, and hence he left the subject obscured in gloom, which, though pierced here and there by subsequent explorers, has not yet been entirely dissipated. The process is briefly this:—Thin scrapings of the wourali vine and of a bitter root are percolated with water in a crude fashion into an earthern pot, and into the percolate the green and glutinous juice of two kinds of bulbous plants is squeezed with the hands; two kinds of ants, the one large and black, the other small and red, are bruised up with the fangs of two kinds of snakes and a quantity of the strongest Indian pepper, and all is thrown into the pot, which is then placed over a fire, and the contents boiled down to a thick syrup of a deep brown colour. If on trial it is found to be satisfactory, the syrup is poured into a calabash and carefully covered with leaves and deerskin and set aside in a dry place.

Two accounts subsequently given by different Indians to Dr. Hancock, who resided for many years in British Guiana, agreed very well with each other. "They called the plant *mavacuri*, and say it is of the gourd kind, or one of the cucurbitaceæ, of the size of a large orange, round, and having a hard shell or pericarp, which is used at times to contain the poison. In regard to the manufacture of the poison they in general add nothing, though some to thicken it add the bark. They merely peel or scrape off the bark and bruise it well in a mortar. The mass is then put into a funnel or cartocho made with wild plantain leaves, and having a little cotton at the bottom to strain it; plenty of cold water is thrown over it, and they proceed in the same manner as in drawing the lixivium of ashes. This infusion is put into an earthern pot and boiled down to a proper consistence. Neither had any idea of the addition of other substances." Another account given to Dr. Hancock by Mr. J. Forsyth states, "I send you a small branch of the wourari vine and two other vines, called *woorarybally* and *courampoey*, which the Indians use as auxiliaries to strengthen the former. . . . The inner bark or rind of the root (for it is the root only that is used) is scraped off into some vessel. The wooraybally root undergoes the same process, but it is the vine itself of the courampoey that is used. To these, mixed together and well boiled down with some water, the Indians add some peppers, and further boil the whole mass to a thick syrup. This account of the process I have had from the Indians." Dr. Hancock, in 1837,* added to his previous statements that in the preparation of the poison by the Macoushis, the slimy barks of the *kyheri* and *quasima* are added to give tenacity to the extract; and that it is considered of such importance that it gives names to several mountains and rivers, as *Oorariquera* and *Oorarimetsa*. He has also remarked "the most efficient poison is prepared from the worari vine alone." Subsequent writers have accepted the results of Schomburgk's inquiries as conclusive that the poison is furnished chiefly or entirely by *Strychnos toxifera* (Loganiaceæ), viz., Redwood,† Wormley,‡ Bentley,§ and the authors of the 'Imperial Dictionary,' who also mention *Lasiostoma Curare*. Gregory|| says, "from some plant of the family *Strychneæ*," whilst Watts¶ says that it is a "resinous substance consisting of the aqueous extract of a climbing plant (genus *Strychneæ*)." Taylor** states that the poison is called "curara from the plant *curari* from which it is obtained." Those who are agreed upon the identity of the plant yielding the poison are yet at variance as regards the relation of the two. Whilst Wormley avers "Schomburgk states that it consists alone of vegetable matter and chiefly of an *extract of the bark of Strychnos toxifera*," Bentley says "The *juice of Strychnos toxifera* is the basis of the celebrated wourali poison of Guiana." It is probable that both statements are correct, and that the *modus operandi* of the savage varies with the materials at his command in the changing seasons of the year.

Description.—As to the poison itself the descriptions do not always tally. Waterton speaks of it as "a thick syrup of a deep brown colour," and afterwards (1838), in an autobiograpy which forms the introduction to his 'Essays on Natural History,' he says, "on opening the wax in which it is enclosed, I found it quite soft and ready for use, although it had not been looked at for above twenty years." Hancock's Indian informants merely state that "it is boiled down to a proper consistence;" and Forsyth says "the Indians boil the whole mass to a thick

syrup." The syrupy form would be the most convenient for smearing arrows. Wormley, Watts, and Taylor have a general agreement in their description of the poison, which, according to Watts, is a brown-black, shining, brittle, resinous mass, almost wholly soluble in water, either cold or warm; sparingly soluble in absolute, easily in aqueous alcohol, partially soluble in ether; bitter taste, neutral reaction. This description applies to the curara which is at the present time found in commerce.

Even as regards the stability of curara the authorities are not in accord. Professor Redwood in a very comprehensive paper on this poison* says "it is necessary to keep the wourali in a perfectly dry state and when thus preserved it appears to preserve its properties for a considerable number of years." Bernard (Taylor on Poisons) found that some which had been loosely kept on the tip of an arrow for fifteen years killed an animal very quickly. He preserved it in a state of solution in water for fifteen years without any loss of its power. It is obvious that the syrupy preparations spoken of by Waterton and others cannot be preserved in a perfectly dry state, and possibly the presence of pepper in these enables them to bear damp and exposure.

Properties and Antidotes.—For the poisonous effects of curara to be produced it must be introduced directly into the circulation by puncture. Gregory says that it may be swallowed with impunity; probably he meant in the mininum doses which will produce death by inoculation.

Dr. Hancock says, "Its operation on the animal frame is most mysterious. It extinguishes the vital spark without a pang or struggle if prepared without any other substance being added; for the most efficient poison is prepared from the worari vine alone. The sensation and effect it produces are extremely analogous to those which arise from excessive bleeding—the animal under its influence sinking from existence in the most placid swoon." Compare this with Pereira's statement that "it produces paralysis with convulsive movements, death from apparently suspended respiration." Waterton, in Guiana, inoculated several animals with the poison for the purpose of trying the efficacy of the antidotes recommended by the Indians, viz., holding the animal for a considerable time up to the mouth in water, pouring the juice of the sugar cane down the throat, and rum. All were ineffectual. He says, "it is supposed by some that wind introduced into the lungs by means of a small pair of bellows would revive the poisoned patient, provided the operation be continued for a sufficient length of time." On his return to England this method was tried upon an ass which lay apparently dead from the effects of the poison, and in four hours she rose up and walked about, but was not well for more than a year. She survived the operation twenty-five years. Waterton did not believe that the Indians had a sure antidote; if they had "it is likely they would carry it about with them, or resort to it immediately after being wounded, if at hand, and their confidence in its efficacy would greatly diminish the horror they betray when you point a poisoned arrow at them. . . . Should the part affected admit of it let a ligature be tied tight round the wound, and have immediate recourse to the knife." It is stated in the paper by Professor Redwood, previously quoted, and to which I am indebted for numerous references, that "it appears that the Indians are acquainted with some means of recovering animals from the effects of the poison, and are in the habit of shooting monkeys, birds, etc., with the poisoned arrows, and after bringing them to the ground, resuscitating them." It may be that the means referred to consisted in simply allowing nature to assert herself and throw off the effects of a quantity of poison too minute to produce death, for Waterton observed that to kill a bulky animal, such as a hog, several large arrows were used by the Indians, though one small arrow was sufficient for a monkey or a bird, and it would frequently happen that the wounded animal was only weakened to such an extent that its capture was easy, and its recovery a matter of time. In Mayo's 'Outlines of Physiology' a case is described in which a horse was recovered from an attack of tetanus and locked-jaw by means of wourali, death from the latter being prevented by artificial respiration continued for four hours. Artificial respiration was the method employed to overcome arrest of respiration in a woman, aged twenty-four, who was under treatment for hydrophobia, and cured by subcutaneous injection of curara.*

Active Principle.—The supposition entertained some time ago that the poisonous properties of curara were due to the presence of strychnia was doubtless based upon the fact that curara contains a body which greatly resembles strychnia in its chemical behaviour, notably in its reaction with chromic acid. It is remarkable that such a supposition should be entertained in face of the fact that curara does not produce poisonous effects when administered by the mouth in quantities which have been known to produce death when introduced directly into the circulation.

So far from curara containing strychnia, Vella† has shown that each is an antidote to the other. His experiments were of two kinds: first, those in which animals poisoned by the introduction of strychnia into the stomach received into the blood successive doses of ourari, in such a manner as to exactly subdue the manifestations of tetanic convulsions; secondly, those in which a mixture of strychnia and ourari was injected into the blood of animals. In a dog weighing 5½ kilos., two centigrammes of hydrochlorate of strychnia administered by the mouth were neutralized in three hours by three centigrammes of ourari injected into the blood. Three days after the dog was killed by two centigrammes of strychnia alone. In another experiment two milligrammes of strychnia and fifteen milligrammes of ourari in water were injected into the jugular vein of a dog weighing 8·7 kilos. without effect. Eight hours afterwards the same dose of strychnia produced death in ten minutes.

Roulin and Boussingault‡ were the first to attribute the poisonous action of curara to *curarine.* They obtained the latter as an amorphous, horny mass of a yellowish colour. Preyer§ was the first to isolate curarine in the crystalline form; according to him it has the formula $C_{10}H_{15}N$. It is very hygroscopic; has a very bitter taste; crystallizes in colourless four-sided prisms; dissolves freely in water and alcohol, less easily in chloroform and amyl al-

§ *Bull. Soc. Chim.*, 2, iv., 238. 1865.

cohol; and is insoluble in anhydrous ether, benzol, turpentine, and carbon disulphide. It blues litmus very slightly, acquires a splendid and permanent blue colour in contact with sulphuric acid, purple red with nitric acid, and violet with potassium dichromate and sulphuric acid (like that of strychnia, but more permanent). Its hydrochloride, nitrate, sulphate, and acetate are crystallizable. Dragendorff* also finds that curarine is quite distinct from strychnine, and that a very active curara occurs in commerce in which neither strychnine nor brucine can be detected. His 'Manual de Toxicologie' contains an excellent chapter on curarine.

If Taylor's† statement that the properties of curara are due to the presence of this alkaloid be accepted, it explains and supports Hancock's statement that the most efficient poison is prepared from the wourari vine alone; for it will be observed that in the modes of preparation either the wourari vine alone is used or it is mentioned as the chief ingredient, the additional ones spoken of being used for superstitious reasons or others more useful. For example, the juice of the bulbous plants of Waterton, or the slimy barks of Hancock, would give adhesiveness to the poisonous extract and so prevent it rubbing or chipping off the arrow heads before they were required for use, and the pepper would have a certain antiseptic value. In Forsyth's account, the phrase, to "strengthen the former," should be understood rather in the sense of "to give it consistency" than that of "to increase its lethal power," for it is not conceivable that a poison owing its properties to a definite alkaloidal principle whose salts have the same power, could be rendered more poisonous by the addition of any substance which would not itself be weakened by the admixture. In the account first obtained by Dr. Hancock the mother-plant of the poison is called *mavacuri*. This is probably only another name for the wourari vine in a different locality, for from the description given to Dr. Hancock he concluded it to be one of the cucurbitaceæ, a family which includes many climbers. Even if the names refer to the same plant, that fact would not preclude the possibility of curarine existing in other species of the same order, whichever that may be.

Microscopical examination.—None of the students of curara appear to have submitted it to microscopical examination with a view to testing the statements relative to the addition of pepper and other matters possessing organized structure, such as barks, fangs, or ants. My own experiments in this direction, though very incomplete, are not without a certain interest. A minute fragment of curara corresponding to the description already given, was placed with a drop of alcohol (not the best solvent of curarine) on a slide, and well crushed by pressure on the cover. The central mass of curara was seen to be of a rich brown colour, and copiously studded with quadrilateral prisms. Outside this were numerous isolated crystals of the same shape, from which the cementing material had been dissolved by the alcohol, leaving them colourless. Scattered with tolerable evenness over the field were myriads of dusty particles having a faint tinge of yellow, and moving freely when the slide was rotated. The particles were subsequently found to be oxalate of calcium; the crystals were taken to be curarine. The cementing material was apparently amorphous.

Some curara which had been treated with water till it imparted only a faint tinge to the menstruum was, after drying, placed in a very dilute solution of potash, warmed and filtered. Some of the residue on the filter was placed on a glass slide and examined with water under the microscope; it resembled the dusty material previously seen. The filter was washed with acetic acid; oxalate of ammonium when added to the washings produced no change, nor did the washings give a yellow precipitate with nitric acid solution of molybdate of ammonium. Phosphate of calcium was therefore absent. The filter was further washed with very dilute hydrochloric acid and the washings similarly tested with oxalate of ammonium, when a copious precipitate was at once obtained. The matter insoluble in potash and in acetic acid was thus found to consist chiefly of oxalate of calcium; the proportion of this to the entire quantity of curara originally employed was such as to lead to the conclusion that either the stem or root used in the preparation of the poison was of no great thickness, or the bark was chiefly used in the preparation. The hydrochloric acid washings also were tested for phosphates; the result was negative, and it was therefore concluded that no bony material, such as serpents' fangs, could have been present in the curara. What remained after treatment with hydrochloric acid was so minute that it was regarded as of no account. The results of the examination are such as favour the opinion that curara as now met with is an aqueous extract of a bark, root or stem.

Solution of Curara for Hypodermic Injection.—The properties of curara preclude its medicinal use in any other form than that of a solution for hypodermic injection. For such a solution, to be ready for use at all times, certain characteristics are essential, or at least highly desirable. It must be of convenient strength, so that the dose fixed upon may bear a simple relation to the number of minims, yet not so strong that the injection of a quantity slightly in excess of what was intended may be of too great importance, and not so diluted that the maximum dose is inconveniently large. The solution should produce as little pain as possible when injected; having regard to the fact that rabies patients have an intensified dread of pain, this characteristic is perhaps more important in the particular solution now under consideration than in any other. The solution should not only be at all times prepared of the strength that it professes to be, but should keep well, and remain of that strength. To prepare a uniform solution of a drug so deadly and various as curara, one should always have recourse to the same parcel, of which the strength has been proved. Curarine or one of its salts might be used, but independently of the grave risks incurred in preparing them, we are as yet without trustworthy data upon which to frame a formula.

The keeping powers of a solution will depend in great measure on the menstruum. Water would produce a solution giving the minimum of pain when injected, and Taylor's statement that Bernard preserved curara in solution in water for two years without any loss of its power is confirmed by the experience of Dr. Lauder Brunton, who informs me that he has kept a very weak solution (1 in 1000) for the same period without change. I have prepared

* *Zeitschrift f. Chem.*, 2, iii., 28.
† 'On Poisons,' 3rd edition, 787.

solutions of curara in the following menstrua, viz., water, water with 0·2 per cent. of salicylic acid, diluted spirit of wine (1 to 3), and diluted glycerine (1 to 3). The last forms by far the best looking solution and is also the best solvent. It dissolves 85·2 per cent. of curara when left in contact with it for twenty-four hours and filtered; the dried residue hardly imparts any tinge to water. Water dissolves 83 per cent. and diluted spirit 79 per cent. of curara, and the dried residue in each case gives a decided tinge to water; both solutions are iridescent on the surface and at the side when examined in a glass vessel, and commence to deposit soon after being filtered. The glycerine solution deposits to a much smaller extent.

It appears, however, from observations kindly communicated to me by Dr. Ashburton Thompson, that even so weak a solution of glycerine as that indicated above, viz., 25 per cent., is productive of great pain when injected; and seeing that the aqueous solution keeps very well, I would propose the following formula as best meeting the requirements of the case:—

Hypodermic Injection of Curara.

Curara	gr. j.
Water.	min. xij.

Dissolve; let the solution stand forty-eight hours and filter.

Using this solution two-thirds, a half, third, or quarter of a grain may be given in a whole number of minims. Of the other strengths likely to suggest themselves, viz., one in ten and one in fifteen, the first would only allow of a tenth, and half a grain; and the second, of a fifteenth, a third, and two thirds of a grain being given in the same way. The accounts of the use of curara seem to indicate that the dose is from a quarter to half a grain.

CAUTION.—Curara requires to be handled with the utmost care. It should not be allowed to come into contact with a fresh cut or scratch. Two good rules would be—never to powder it in the dry condition, and never to touch it with the naked fingers.

THE CONSTITUENTS OF PODOPHYLLUM PELTATUM.*

BY WILLIAM CHARLES A. BUSCH, PH.G.

Abstract from an Inaugural Essay.

The resin was prepared by mixing the concentrated incture—

1. *With water.*—A turbid liquid was obtained, which after a time produced a light-grey precipitate, completely soluble in ether and alkalies. On being again set aside the turbid liquid settled very slowly, but on the addition of a little muriatic acid it became clear, and the dark-grey precipitate was found to be nearly insoluble in ether, but readily soluble in alkalies.

2. *With acidulated water.*—A greyish precipitate was readily obtained which retained its colour if dried at the ordinary temperature; a higher temperature deepened the colour very perceptibly, and caused the resin to fuse to a blackish-brown mass, which on being dissolved in alcohol and precipitated by cold acidulated water was again obtained as a greyish powder. It was completely soluble in alcohol and alkalies, and partly in ether. On incineration a little ash was left. With hot water a solution was obtained which precipitated on cooling; cold water dissolved a little of the resin, the yellowish colour of the solution being discharged by an acid and reproduced with a darker shade by alkalies.

3. *With alum solution.*—A bright-yellow pulverulent precipitate was obtained, which darkened somewhat by hot water, but did not fuse to a brown mass. On incineration an ash was left, consisting mainly of alumina; boiling with dilute hydrochloric acid removed most of it from the resin, which afterwards left but very little ash.

Resin soluble in ether.—The officinal resin, obtained by precipitation with water acidulated with muriatic acid, yielded to ether sixty per cent. of its weight. This portion dissolved in alcohol with a light-brown colour; the solution had a bitterish taste, and was precipitated light-greyish by water, bright-yellow by alum solution and orange-yellow by alcoholic solution of lead acetate. All the precipitates dissolve to some extent in hot water, most of the dissolved portion being reprecipitated on cooling. The alum precipitate left 1·25 per cent. of ash, consisting of alumina; the resin obtained by evaporating the ether left no fixed residue.

Resin insoluble in ether.—It was found to have a bitter taste and to be soluble in alcohol and alkalies, and slightly so in water. The alcoholic solution became turbid on the addition of water, and very gradually yielded a greyish precipitate; acidulated water produced a similar precipitate, solutions of alum and of acetate of lead somewhat darker, but not yellow precipitates. The bright-yellow colour of the resin prepared with alum solution is therefore due only to the resin soluble in ether.

The aqueous solutions of both resins gave no reaction with Mayer's solution, except in one instance; their alkaline solutions were of a yellowish-brown colour, when sufficiently diluted with water were not precipitated by acids, and after having been boiled with dilute hydrochloric acid gave no indication of sugar with Trommer's test.

Principles soluble in water.—The tincture precipitated with acidulated water yielded a reddish filtrate, of a very bitter taste, and containing sugar, as indicated by Trommer's test. On concentrating the solution, an amorphous bitter mass separated, which dissolved in alcohol, but could not be obtained in a crystalline state.

The filtrate obtained by precipitating with alum solution was likewise bitter, and on being concentrated changed to ruby-red and separated crystals of alum; a blackish, semi-fluid, bitter substance was likewise separated, which was insoluble in ether, carbon bisulphide and petroleum benzin, but dissolved in alcohol and warm water. It was not obtained in a crystallized state.

On mixing the tincture of the rhizome of podophyllum with ether a dark-coloured mass separated, which had a very bitter taste, but contained sugar, as indicated by Trommer's test.

THE MANUFACTURE OF EXTRACTUM CARNIS.

According to a report by Mr. Consul Munro, on the trade and commerce of Monte Video, the establishments upon the River Uruguay for making the "extractum carnis," and the general conversion of cattle and sheep with their skins and offal into money, produce items of increasing consequence in the list of exportation. For instance, the Liebig's Extractum Carnis works at Fray Bentos have exported in twelve months 16,500 tons of animal produce, representing a value of upwards 2,000,000 dollars, shipped in thirty-five vessels, and another establishment, on more or less the same principle, belonging to Don Incas Herrera, has shipped to the value of 470,000 dollars. There are other works also in the same line, but Mr. Consul Munro has not been able to obtain a report of their exports.

Another application of meat, smoked, and made into what is called "charque dulce," has been tried, and has been shipped in small quantities for the west coast; the success and value of the experiment has yet to be decided.

THE RIGHT TO PRESCRIBE.

THE inconclusive position in which the case between the Apothecaries' Company and chemists and druggists has been left by the result arrived at by the judges before whom the hearing of the appeal came on last week must, we think, be so far a matter of regret to all concerned, that it necessarily postpones for some considerable period the settlement of a question having much importance for the public, no less than for the contending parties.

In order that our readers might be fully informed in respect to what took place in the Court of Appeal, we have considered it desirable to give a full report of the proceedings, which will be found on a subsequent page, and though it would be premature now to enter upon any minute discussion of the points at issue we venture to suggest that the remarks of the judges point to the necessity of considering one aspect of the case in a more extended and thorough manner than was done in the trial at the Nottingham County Court. We refer to the provision of the Apothecaries Act, which provides that it is not to affect chemists and druggists. This section of the Act was evidently held by the judges to be one of very great importance, though they expressed no opinion with regard to its effect, and they considered a new trial in the Superior Court to be requisite for obtaining material upon which to come to a conclusion, whether or not the defendant in the case was entitled to the privilege of that section.

The Lord Chief Baron put the matter very clearly when he said that as regards the making up of prescriptions and vending medicines across the counter the chemist and druggist has power to act as an apothecary, and whether or not he has an apothecary's certificate, so far at least he may act as an apothecary. But the question at issue involved something more than merely selling drugs or medicines across the counter, viz., the fact of his being consulted and giving something to a man who tells him that he has a pain in his chest or a sore throat, and is thereupon supplied with medicine by the chemist and druggist. If, said the Lord Chief Baron, it can be shown that this is also within the privilege of a chemist and druggist, although it may be within the privilege of an apothecary, it could not be held that the defendant in this case was liable.

By reference to the report of the proceedings it will be seen that this point was repeatedly brought forward in connection with the twenty-eighth section of the Apothecaries Act, and as such prominent importance has thus been given to the scope and bearing of this section we think it desirable to quote its exact words, which are as follows:—

"Provided always, and be it further enacted, That nothing in this Act contained shall extend, or be construed to extend, to prejudice or in any way to affect the Trade or Business of a Chemist and Druggist, in the *buying, preparing, compounding, dispensing,* and *vending Drugs, Medicines, and Medicinable Compounds,* wholesale and retail; but all Persons using or exercising the said Trade or Business, or who *shall or may hereafter use or exercise the same,* shall, and may use, exercise, and carry on the same Trade or Business in such Manner, and *as fully and amply to all Intents and Purposes, as the same Trade or Business was used, exercised, or carried on by Chemists and Druggists before the passing of this Act.*"

The italics are our own, and we may add that the wording of the section is remarkable inasmuch as it appears to draw a distinction between "compounding" and "dispensing." The reservation of rights, moreover, is not limited to those chemists and druggists who had exercised their business prior to the passing of the Act, but is extended to all who may thereafter exercise that business and it secures to them the future right to do so as fully and amply as had been done before the passing of the Act.

The decision of the question raised by the Apothecaries' Company appears, therefore, to turn very much upon the evidence which it may be possible to produce as to the habitual practice of the chemist and druggist prior to 1815.

With these remarks we leave the more immediate point in dispute, and will pass on to consider some other points which have already been referred to in these pages on several occasions, with the object of showing that the present action of the Apothecaries' Company, under the instigation of the Medical Defence Association, is ill-advised and more likely to lead to an extension of the counter-practice which they deprecate than to promote that good feeling between medical practitioners and pharmacists which might safely be looked to as a means of mitigating grievances on both sides.

In the first place it appears to us that, even setting aside the exemption of the rights of chemists and druggists by the 28th section of the Apothecaries Act, there is in the attempt of the apothecaries to claim a prescriptive right to the practice of medicine too much disregard of the history of the class to which they belong. The Act of 1815, upon which they rest in the present crusade against chemists and druggists does not in any part of it confer upon the apothecary the right to practise medicine; the very utmost that it does express in that direction is—

"That from and after the First Day of *August*, One thousand eight hundred and fifteen, it shall not be lawful for any Person or Persons (except Persons already in Practice as such) to practise as an Apothecary in any Part of *England* or *Wales*, unless he or they shall have been examined by the said Court of Examiners, or the major Part of them, and have received a Certificate of his or their being duly qualified to practise as such from the said Court of Examiners or the major Part of them as aforesaid, who are hereby authorized and required to examine all Persons and Persons applying to them, for the Purpose of ascertaining the Skill and Abilities of such Person or Persons in the Science and Practice of Medicine, and his or their Fitness and Qualification to practise as an Apothecary."

And if we inquire what were the recognized functions of the apothecary prior to 1815 little will be found to justify his modern representative in putting himself forward to repress what he regards as the improper if not illegal practice of medicine. In fact the position of the apothecary prior to that period, in regard to the practice of medicine, was merely one of encroachment upon the province of the recognized medical practitioner. We need not go further than the Act which the apothecaries now seek to make an engine of oppression to learn what were the recognized duties and functions of the apothecary. They are amply set forth in the fifth section, as follows:—

"And whereas it is the Duty of every Person useing or exercising the Art and Mystery of an Apothecary, to prepare with Exactness, and to dispense such Medicines as may be directed for the Sick by any Physician lawfully licensed to practise Physic by the President and Commonalty of the Faculty of Physic in *London*, or by either of the two Universities of *Oxford* or *Cambridge*; therefore, for the further Protection, Security, and Benefit of His Majesty's Subjects, and for the better Regulations of the Practice of Physic throughout *England* and *Wales*, be it enacted, That if any Person using or exercising the Art and Mystery of an Apothecary, shall at any Time knowingly, wilfully, and contumaciously refuse to make, mix, compound, prepare, give, apply, or administer, or any way to sell, set on Sale, put forth, or put to Sale to any Person or Persons whatever, any Medicines, compound Medicines, or medicinable Compositions, or shall deliberately or negligently, falsely, unfaithfully, fraudulently, or unduly make, mix, compound, prepare, give, apply or administer, or any way sell, set on Sale, put forth, or put to Sale to any Person or Persons whatever, any Medicines, Compound Medicines, or Medicinable Compositions as directed by any Prescription, Order, or Receipt, signed with the Initials in his own Hand-writing, of any Physician so lawfully licensed to practise Physic, such Person or Persons so offending shall," etc.

Here is not a word of the practice of medicine, neither is there anything more, if there be so much as is specified in the twenty-eighth section as being comprised in the exercise of the business of a chemist and druggist, and even the function of dispensing medicines for the sick is mentioned as belonging to the apothecary only under the condition that such medicines were directed by a physician lawfully licensed to practise physic.

We do not pretend to question the fact that prior to 1815 apothecaries did practise medicine, as no doubt many chemists and druggists did, but they did so without any special privilege, with no greater right to do so than appertains to any other persons or class of persons, and by the recognized medical practitioners of the day they were not only looked upon as interlopers, but were actually prosecuted for so doing by the College of Physicians. In fact, the apothecary of that time was merely the chemist and druggist of the present, and the Act by which he was slipped into the position of a qualified medical practitioner upon condition of his passing an examination for the purpose of ascertaining his skill and ability in the science and practice of medicine was passed, not as protection of his rights, but in the interests of the public, as a means of furnishing greater facilities for obtaining medical relief.

At the present time the apothecaries having abandoned the practice of all those duties and functions which originally belonged to them, and having exclusively developed the medical branch of the business they carried on prior to 1815, are now seeking to assume, in regard to the chemist and druggist, the position of the physicians who then endeavoured to prevent apothecaries from practising medicine. There is an exact parallel between the two cases and we should not be surprised to see that parallel become still closer. The decision of the contest between the physician and the extinct apothecary was made conducive to the public interest; is there any reason to expect that interest will be disregarded in the present contest between the modern apothecary and the chemist and druggist?

Whatever may be the result arrived at, however, we think it right to say that the Pharmaceutical Society as a body has always sought to develop the opinion that the business of the pharmacist should not comprise the prescribing of medicine; this, however, is a matter of principle and of ethics, quite apart from the question as to rights and privileges, and since the right to practise medicine is not barred even by the Medical Act, we cannot perceive that the chemist and druggist is less entitled to do so, if he pleases, than any other member of the community.

THE EVENING MEETING.

The next Evening Meeting of the Pharmaceutical Society will be held at 17, Bloomsbury Square, on Wednesday, December 5th, when the following papers will be read:—"The Colour of Podophyllum Resin," by Dr. A. SENIER, F.C.S., and Mr. A. J. G. LOWE; "*Rheum officinale* Root grown in England," by Mr. HAROLD SENIER, F.C.S.; "False Angostura Bark and Strychnia," by Mr. W. A. SHENSTONE, F.C.S.; and "Nitrite of Ethyl," by Mr. JOHN WILLIAMS, F.C.S. The Chair will be taken at half-past eight o'clock precisely.

DEATH OF AN ANNUITANT.

WE regret to have to announce the death of another annuitant on the Benevolent Fund of the Pharmaceutical Society in the person of Mrs. SOPHIA PEDLEY HENSON, who was elected in 1872. Mrs. HENSON is the fourth annuitant who has died during the present year, and the second since the election last month.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of the above Association will be held at 17, Bloomsbury Square, on Thursday evening, December 6, when a paper will be read by Mr. R. H. PARKER on "Coal Gas; its History and Manufacture." The Chair at eight o'clock.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The second general meeting was held in the lecture theatre of the Royal Institution, October 26, 1877; the President, Mr. T. Fell Abraham, in the chair.

The minutes of the previous meeting were read and confirmed.

Messrs. W. H. Leatham and B. Adams were unanimously elected members. After some miscellaneous communications, Mr. Edward Davies, F.C.S., read a paper on "The Influence of the Nascent State on Chemical Action." The paper was listened to with a considerable interest, and numerous experiments were performed to illustrate the subject. At the close the President expressed his high appreciation of Mr. Davies' able lecture. The lecture will be printed in an early number of this Journal.

Dr. Symes endorsed the President's remarks upon the lecture and moved a vote of thanks to Mr. Davies for his very interesting and able paper. The motion was seconded by Mr. Haddock, and being put to the meeting was carried by acclamation. The attendance of ladies had been invited and several were present on the occasion.

The third general meeting was held at the Royal Institution, November 8, 1877. The President, Mr. T. Fell Abraham, in the chair.

The minutes of the previous meeting were read and signed.

Various donations to the library and museum were announced, and a vote of thanks accorded the donors.

Mr. T. H. Melmore was duly elected a member, and Mr. Capper, jun., an associate.

The President called attention to the approaching associated science and art soirée to be held in St. George's Hall, on December 14, the arrangements for which were under the control of an executive committee, and the Association represented by its President.

Mr. John Abraham having made the sign ℥ on the black board, said he supposed that most of the company were acquainted with it. As long as he could remember, and he believed for ages before, it signified 480 grains, but by a correspondence in the *Pharmaceutical Journal* he found that some persons supposed that it now represented 437½ grains. He thought it was to be regretted that any doubt or difference of opinion should prevail as to its precise significance. The United States Pharmacopœia defined it as a troy ounce, which is 480 grains. The British Pharmacopœia did not mention it, but uses the avoirdupois ounce of 437½ grains, and applies to that the sign oz. He had no reason to think that the old sign had changed its meaning, and did not know of any authority for supposing that it had.

Dr. Symes said, as the writer of one of the letters in the Journal, he felt bound to defend the position he had taken. The sign ℥ was every day used to represent an avoirdupois ounce. The writer of the article called "The Month," who gave rise to this discussion by first recommending that where the sign ℥ was written an apothecaries' ounce should be used, also stated a few paragraphs further on that the "British Pharmacopœia gave a formula for belladonna ointment 80 grains of the extract to ℥j of lard." Here obviously he used this sign to represent 437½ grains. To retain the apothecaries' ounce would tend to destroy the uniformity which the British Pharmacopœia had endeavoured to establish, and that merely for the sake of retaining an old custom and a weight that had practically become obsolete.

Mr. A. H. Mason, F.C.S., called attention to the statement in the *Lancet*, that a quantity of adulterated morphia was being offered for sale in London. He said the investigation published in the *Pharmaceutical Journal* of the preceding Saturday would show that there was not much ground for the statement, which he believed had probably arisen from the fact, that a German agent in London had shipped a large quantity of morphia to Japan. This was found to be adulterated with 30 per cent. of sulphate of soda, and was consequently not passed by the authorities. It was returned to England and offered for sale on the market, but as the whole was purchased by a manufacturer and reworked, it is not probable that medical men have anything to fear.

A paper was then read on "Antiseptics and Disinfectants," by Mr. A. H. Mason, F.C.S.

At the close of the paper, a lengthy discussion took place in which the President, Messrs. Abraham, Armstrong, Jones, Tanner, Drs. Hall and Symes, and others took part. On the motion of Dr. Symes, seconded by Mr. J. T. Armsrong, F.C.S., a cordial vote of thanks was given to Mr. Mason for his paper.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The quarterly meeting of this Association was held at Burlington Chambers, New Street, on Friday, November 16th; the President, Mr. W. Jones, in the chair. There was a good attendance of members and associates.

Mr. Dewson was called upon to read the quarterly *résumé* of pharmaceutical news. Some discussion ensued and doubts were expressed whether for sweet nitre the spt. ætheris nitrosi of B. P. strength must necessarily be sold; the question was decided, however, in the affirmative.

The President then called upon Mr. H. W. Jones for his paper on "Some Remedies Recently Introduced."

The following remedies among others were referred to:—

Acid. Hydrobromic. Dil.—This was stated to be a somewhat unsatisfactory preparation when made according to the original formula of Dr. Wade, as it invariably deposits on keeping. A better process was that of C. Rice, which had appeared in *New Remedies*, in which alcohol was added to precipitate more completely the acid tartrate of potash, the alcohol being afterwards removed by distillation and the acid brought to the s p. gr. of 1·075, containing 10 per cent. of HBr. The sample exhibited had been made from recently distilled acid, prepared by the action of bromine upon phosphorus, the portion being used that distilled over nearly colourless. It was remarked that a perfectly colourless acid could be easily prepared from the distilled acid, and when the strong acid had become discoloured it could be decolorized by a little sulphuretted hydrogen; heat would remove excess of gas, and filtration the deposited sulphur.

Liq. Ferri Dialysat.—The sample shown had been from 300 parts of liq. ferri perchlor., and 100 parts of liq. ammoniæ, of sp. gr. ·92, as proposed by Dragendorff. Highly basic chlorides of iron had been prepared previous to 1861, when Graham obtained a solution containing ninety-five molecules of oxide to one molecule of chloride; a solution containing the oxide in this proportion, as that experimentalist had shown, would not keep, so that for pharmaceutical purposes a decided, though relatively small amount of chloride would have to be present; this, however, should not be looked upon as an excuse for using a bad preparation, or such a solution as would, without the iron being first precipitated, show the presence of a chloride with a solution of silver.

Salicylic Acid, although classed among the less recently introduced articles, was noted from its important uses in medicines. The three kinds were shown; the precipitated acid, the crystalline, and the acid chemically pure obtained by dialysis.

Guarana.—Specimens were shown in the roll and in the powder. A number of specimens had been examined by the speaker, but none found adulterated. In one case, a number of minute metallic fragments were visible by means of a lens, which on examination proved to be metallic lead; the total amount was small, and its presence seemed to be accidental, and not added with a view to adulterate. This sample was in fine powder, not in rolls, as usually imported.

Monobromated Camphor was then exhibited, and the mode of manufacture explained, and the dispensing difficulty was referred to. The speaker thought that an *emulsion syrup* could be prepared by dissolving the camphor compound in spirit, precipitating with water, collecting the finely divided monobromide, and mixing it with cold syrup. By this means a sort of emulsion could be made, and although it separated, the camphor compound floating to the surface, still it could readily be diffused again by shaking.

In treating of *chrysophanic acid*, it was said that, whilst the method of heating was greatly to be preferred to the use of benzine in making an ointment, still a smooth ointment was not obtained by dissolving the acid in the hot fat, but by rubbing down after cooling a satisfactory preparation resulted.

Nitrate of Bismuth and its Glycerole and a few other references brought the paper to a close.

Mr Dewson then explained a ready method by which the absence of alum as an adulterant of cream of tartar can be ascertained. He said that since alum, if present as an adulterant, is always found in considerable quantity, it could be detected by the simple process of agitating forty grains of the cream of tartar with ℥iij of cold distilled water, filtering off the fluid, and evaporating it to dryness. In consequence of the sparing solubility of the acid tartrate, the dry residue will weigh less than one grain if the cream of tartar be free from this adulterant, but much more* if it be present; thus, if the residue weigh less than one grain, the absence of soluble salts as *adulterants* may be inferred, though they may be present in small quantities as impurities.

A vote of thanks to Mr. H. W. Jones, for his interesting paper, brought the meeting to a close.

* This residue of course being examined for alumina.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

Assistants' Section.

The opening meeting of the session, 1877–8, of the above Association was held in Anderson's College, on Wednesday, 14th ult.; Mr. Peter Boa, President, in the chair.

After the minutes of last meeting were read and confirmed,

The President read a letter from Mr. J. S. Whyte, Secretary, intimating that he could no longer hold office on account of his having left the city.

On the motion of Mr. W. Simpson, seconded by Mr. McLeish, Mr. W. Paris was unanimously elected to the office for the session.

The President, in a few introductory remarks, said that he hoped the session now opened would be a successful one, and that all that was required to make it so was in the power of the members to give, viz., good attendance at the meetings and a few useful papers; good audiences and useful papers reciprocally encouraged each other.

The President then read a paper on "Salicylic Acid." He described the method of its manufacture by Kolbe's process, and explained, by equations, the reactions that take place in the several stages, and showed its relation to carbolic and benzoic acids and salicin. He also explained the old method of obtaining the acid from wintergreen oil. Referring to its use in preserving infusions he said that concentrated infusions might as well be used as infusions preserved by it, and that if they were to be used at all they ought to be freshly made. For the suspension of the acid in water, powdered tragacanth answered admirably. Pills could also be formed with the acid and tragacanth, using a small quantity of glycerine, but, owing to the solvent power of glycerine on the acid, excess should be carefully avoided.

After some remarks by a few of the members, a hearty vote of thanks was awarded to Mr. Boa for his instructive paper.

Mr. Simpson then read the report of the Early Closing Committee, which showed that their efforts to obtain a reduction of the hours of Sunday had been only partially successful.

The Secretary intimated that he had received a communication from Mr. Fairlie regarding the classes, stating that a few more members were required to make it worth while for the teachers to carry them on, and recommended all who were intending to go in for examination to take advantage of them.

Mr. Boa intimated that being about to leave Glasgow he would require to resign the office of President. It was agreed to accept his resignation, and appoint a successor at the next meeting.

After a few new members were enrolled, the meeting was brought to a close.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

A meeting of Executive Committee of the above Association was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on November 26th, 1877, at 1 p.m. Mr. S. U. Jones (Leamington), President.

After the usual formal business, the report of the Law Committee, and that of the Finance Committee were received and adopted.

A discussion then followed upon the bearing of the decision in the appeal in the case of the Apothecaries' Company *v.* Shepperley, a full report of which proceedings will be found on the following pages.

Mr. Greenish inquired if the Solicitor knew of any persons able and willing to give evidence as to the practice of chemists and druggists prior to the passing of the Apothecaries Act in 1815.

The Solicitor said four or five gentlemen were willing to give evidence as to the custom of the trade before, or about, 1815. It would be well to seek for additions, but no doubt others would come forward before the new trial, and volunteer evidence. He further said, in reply to questions, that he had written to the clerk of the Apothecaries' Company several months since, requesting him to refrain from taking proceedings against other chemists and druggists until the case of the Apothecaries' Company *v.* Shepperley had been decided. The reply he received was to the effect that the Apothecaries' Company would give no such undertaking, each case stood on its own merits.

Mr. Southall said, that in his opinion, there was no doubt the county court judges would postpone the decision in any case coming before them under the Apothecaries Act, pending the new trial in Shepperley's case.

The Solicitor was instructed to take all necessary steps to obtain a definite decision in the Apothecaries' Company *v.* Shepperley.

The Secretary inquired if he should cause a report of the appeal to be printed and circulated to the trade, and whether he might pledge the Association to fight the case through the highest possible tribunals.

The President said the Secretary might so pledge the Association, and in his opinion a report of the case should be printed and circulated to the trade.

The Secretary was also instructed to prepare a circular, appealing to the trade for support in deciding the question; to be forwarded with a report of the hearing of the case to each chemist and druggist named in Kelly's 'Chemists' Directory.'

A report of the proceedings of the Scotch Committee was read by Mr. Fairlie, and it was decided on the recommendation of that committee to postpone the whole of the elections of the general committee for England, Wales, and Scotland, until March, 1878.

Moved by Mr. Greenish, seconded by Mr. Shaw, and unanimously resolved:—"That Mr. James Colquhoun (of the firm of Messrs. H. J. and D. T. Colquhoun), 158, St. Vincent Street, Glasgow, be appointed solicitor to the Scotch Branch of the Association."

Some considerable discussion took place on sections 14 and 15 of "The Sale of Food and Drugs Act, 1875." The Secretary said that as a rule chemists refused to accept the duly sealed official sample of articles purchased by inspectors appointed under the Act, and that on more than one occasion the Association had been put to considerable expense in endeavouring to obtain sealed samples from the authorities after proceedings had been commenced for alleged adulteration of articles sold; it would be advisable to take steps to so amend the 14th section that it should be compulsory for the official making the purchase to leave a third portion duly sealed in the hands of the vendor.

A resolution was passed to the effect that such an amendment of the Act was desirable, and the subject was referred to the Law Committee with instructions to take action when a suitable occasion shall arise.

It was resolved that the second annual general meeting of the Association should be held in London, on the third Tuesday in May, 1878.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held at 17, Bloomsbury Square, on Thurday, November 22, when a paper was read by the Secretary, Mr. H. G. Greenish, on "The Microscope and its Application in Pharmacy." The author having first alluded to the simple microscope consisting of a single lens, and to its convergent effect upon rays of light, proceeded to describe the compound microscope and the lenses of which it was composed, showing their effect upon rays of light reflected from an object. He next directed his remarks to the use that might be made of the microscope in pharmacy, first noticing the starches and the means by which starches from different plants might be distinguished from each other. Vegetable histology was the next branch, and the importance of the microscope was here illustrated by sections of roots exhibited under the microscope, notably aconite and the root sometimes found mixed with it—imperatoria or masterwort. Brief allusion was also made to the importance of a knowledge of this branch of the subject in cases of poisoning by vegetable substances. Micro-sublimation received some attention, being well illustrated by the tea-leaf, from a fragment of which a sublimate of theine could easily be obtained. The few instruments for microscopic manipulation required by the pharmacist were next described, and the author concluded with some practical remarks on the choice of a student's microscope.

The paper gave rise to a considerable discussion, and a vote of thanks unanimously awarded to the author.

Parliamentary and Law Proceedings.

Apothecaries' Society *v.* Shepperley.

The hearing of this case was resumed on Friday, November 22nd, before the Lord Chief Baron Kelly and Mr. Baron Cleasby.

Sir Henry James: I remind your Lordships that the question turns upon the construction of the 20th section of 55 George III., chapter 194, and then when your Lordships determine what is the proper construction to be put upon that section, whether the facts of the case and the notes of the learned county court judge bring the appellant within that section. My Lords, I remind you that the words of the section are—

"That if any person shall act or practise as an apothecary in any part of England or Wales without a certificate he shall be liable to a penalty."

The Lord Chief Baron: Yes.

Sir Henry James: I have to ask your Lordships to be good enough to consider, first, what is the meaning of "acting or practising as an apothecary," and when that is determined, probably the duty of applying that determination to the facts of this case will not be so very difficult. My contention in relation to the words "acting or practising as an apothecary" substantially is, that a person to act or practise as an apothecary must not only do some particular act identical with one that an apothecary does, but that in substance the person complained of must hold himself out, and in fact act as an apothecary, substantially performing the same acts that an apothecary in the course of the practice of his profession does. Now, my Lords, to determine whether there has been any acting or practising as an apothecary, in the sense which I submit to you the words should be used, it is necessary, first of all, very shortly to consider what an apothecary is, and to trace how an apothecary has sprung into an existence, both at the time when this Act was passed, and also to see what an apothecary is now that this Act (almost obsolete, as, I think, I can show your Lordships) is sought to be put in force. An apothecary appears to have been originally a mere shopkeeper, and at the time when the physician's existence in the art of surgery was first recognized by the charter of the 10th of Henry VIII., probably an apothecary was unknown as a person who required to possess any skill in relation to the art of medicine. Perhaps, my Lords, I may give to you the date of the charter—the 10th Henry VIII. The 10th of Henry VIII. seems to have been the first recognition, at least as far as I know, of the existence of any persons practising medicine in requiring skill in relation to its practice, and that charter is set out and is confirmed by the statute of 14 and 15 Henry VIII., cap. 5. No doubt that charter and that statute were intended only to apply to physicians and surgeons. The words are general. They protect all persons who shall exercise medicine; but there is no doubt that at that time the persons intended to be protected were physicians, and it may be, surgeons. I cannot find the charter in which the Royal College of Surgeons exists as distinct from the charter of the College of Physicians, but the persons who at that time were apothecaries were persons simply who carried on their business in shops, and probably, my Lords, found a common business with grocery; but without doubt the apothecary never attended any patient—never brought to bear any skill in relation to the art and practice of medicine, and was a mere dispenser in the sense of a seller of drugs. Now, my Lords, by degrees that position of an apothecary became altered, and in the reign of 6 James I. there was a charter which is recited in the case before your Lordships—the Act of 55 Geo. III.

The Lord Chief Baron: What is the chapter?

Sir Henry James: The chapter, my Lord, is 194. The charter is recited in the preamble to the Act, and your Lordships see there that reciting charter 6 of King James I. In that charter the apothecaries are spoken of in these terms:—

"And to all and singular other persons whomsoever, brought up and skilful in the art, mystery, or faculty of apothecaries, and exercising the same art, mystery, or faculty, then being freemen of the mystery of grocers of the city of London, or being freeman of any other art, mystery, or faculty, in the said city of London."

And what appears by that charter to have been its object is that they should be subject to supervision and that certain persons should have power to inquire into the nature of the drugs and wares sold by persons who, no doubt at that time, were so selling them in shops as a grocer would sell his wares. Now, my Lords, that was the condition of things in the time of James I., but an apothecary from that time—and probably before that time—must have been growing into a person who required to show skill in his profession, and was a person, no doubt, at that time, to some extent other than a grocer or a seller of wares and drugs, because in the 6 and 7 William III., cap. 4, it recites that—

"Whereas, the art of the apothecary is of great and general use and benefit by reason of their constant and necessary assistance to His Majesty's subjects which should oblige them solely to attend the duty of their professions, yet by reason that they are compelled to serve several parish wards and leet offices in the places where they live and are frequently summoned to serve on juries in inquests, which take up great part of their time, they cannot perform the trust reposed in them as they ought, nor attend the sick with such diligence as is required; and whereas King James I., by his letters patents under the great seal of England, did incorporate the apothecaries exercising that art within London and seven miles compass by the name of the Master, Wardens, and Society of the Art and Mystery of the Apothecaries of the City of London. Be it therefore enacted: That apothecaries shall be exempt from," performing certain duties—attending juries, ward courts, and so forth.

The exemptions are set out in sections 2 and 3 of the Act. The point is that apothecaries must have had duties other (at that time) than those of mere sellers of wares in shops as shown and recited in that statute; but, my Lord, still their position was undefined as to whether they were entitled as against physicians and surgeons to practise the art of medicine, and the point was raised in a case of Rose against the College of Physicians, which is reported in 6 'Modern Reports,' p. 44. An action was brought upon the statute to which I have referred your Lordships—the physicians' statute, 14 and 15 Henry VIII.—"for practising physic within seven miles of London without licence."

The Lord Chief Baron: Practising as a physician?

Sir Henry James: No, practising physic, which, my Lord, would no doubt include both a surgeon's and a physician's practice. The words here are "practising physic;" "for practising physic within seven miles of London without licence. The case upon a special verdict was that the defendant being an apothecary by trade was sent to by John Scale, then sick of a certain distemper, and he, having seen and being informed of the said distemper did, without prescription or advice of a doctor, and without any fee advise, compound, and send to the said John Scale several parcels of physic as proper for his said distemper, only taking the price of his drugs. The question was whether this is a practising of physic such as is prohibited by the statute, and after several arguments the Court at last unanimously agreed that practising of physic within this statute consists, first, in judging of the disease and its nature from the constitution of the patient, and many other circumstances; secondly, in judging of the fittest and properest remedy for the disease; thirdly, in directing or ordering the application of the remedy to the disease, and that the proper business of an apothecary is to make, compound, or prepare the prescriptions of the doctor pursuant to his directions, and it was agreed that the defendant, taking upon himself to send physic to a patient as proper for his distemper without taking aught for his pains, is plainly taking upon himself to judge of the disease and fitness of remedy, as also the executive or directing part;" and the plaintiff had judgment. But, my Lord, that judgment was wrong, because in 5 Brown's 'Cases in Parliament,' p. 553, that judgment is overruled. I am sorry that no light is thrown upon the reason of the judgment in the House of Lords. As is usual in these reports, the arguments of counsel are always given as if they were important, but the judgment of the Court is treated with apparent contempt, because it simply says that the arguments being given the House of Lords reversed the judgment.

The Lord Chief Baron: What was the decision that was afterwards overruled?

Sir Henry James; My Lord, the decision was overruled.

The Lord Chief Baron: What was the decision?

Sir Henry James: The decision is that which I have just read to you.

The Lord Chief Baron: Yes, you have read the special verdict, but what I did not catch was the decision.

Sir Henry James: The decision was for the plaintiff, my Lord. That was under the statute of the 14th and 15th Henry VIII.

The Lord Chief Baron: That he had practised as a physician?

Sir Henry James: He had practised physic.

The Lord Chief Baron: As a physician I think you said. It must be.

Sir Henry James: My Lord, the decision in the Court below, as reported 6 'Modern,' was that upon the action brought to recover penalties within the 14th and 15th Henry VIII. The practice I have read to your Lordships was the practising of physic within seven miles of London, which rendered the defendant liable to penalties.

The Lord Chief Baron: The practising of physic?

Sir Henry James: The "practising of physic" are the words of the charter. The words are very general.

The Lord Chief Baron: And the judgment was for the plaintiff—that he had practised physic?

Sir Henry James: That the defendant had.

The Lord Chief Baron: That the defendant, who was an apothecary, had practised physic?

Sir Henry James: Yes, my Lord.

The Lord Chief Baron: In other words, I suppose he had done the business of a physician.

Sir Henry James: Yes, it is upon the special facts. He had attended at the house of the patient, he had been sent for to the house of the patient, and then, having examined him, no doubt he had returned to his own shop, which was at that time, an apothecary's, and sent him drugs and charged for those drugs; then your Lordship will recollect the three resolutions that the Court arrived at, as to what constituted a practice of physic.

The Lord Chief Baron: Very well, and that was overruled.

Sir Henry James: Then, my Lord, the whole report is, that after hearing counsel on this writ of error, the judgment being set out at great length, it was ordered and adjudged that the judgment given in the Queen's Bench for the President and College or Commonalty of the Faculty of Physic, London, against the said William Rose, should be reserved.

The Lord Chief Baron: Does not the report in Brown give you the arguments or show what the points were?

Sir Henry James: Yes, my Lord, it gives the whole of the arguments.

The Lord Chief Baron: You say it gives no reason.

Sir Henry James: It gives the arguments of counsel, but they do not seem to me to touch the point at all, my Lord.

The Lord Chief Baron: That may be; but you say the judgment which overrules the judgment of the Queen's Bench gives no reasons.

Sir Henry James: No, my Lord; none.

The Lord Chief Baron: Well, if it be necessary we must refer to the case and see if we cannot collect what must have been the reasons from the arguments and the points made. However, there it is.

Sir Henry James: I think the case in 6 'Modern' did show something of the principle on which the Court there proceeded. I have read these arguments and I will read them to your Lordships if you like, but they do not seem to me to be much to the point.

The Lord Chief Baron: I do not wish anything to be read that you do not wish to bring under the attention of the Court.

Sir Henry James: The argument, my Lord, is stated to be this—first, the facts are set out as set out in 'Modern'—"The plaintiff, who was an apothecary and freeman of London, attended one Scale, a butcher, in the parish of St. Martin-in-the-Fields, and made up and administered proper medicines to him but without any licence from the faculty, and also without the direction of any physician, and without taking or demanding any fee for his advice. The defendants, apprehending this conduct to be an infringement of their privileges, brought their action against the plaintiff to recover the penalty of £5 per month, under the above clause in their charter, and on the trial the jury found a special verdict, stating the charter, the confirmatory statute, and the facts of the case, and submitted to the Court whether the defendant Rose did practise physic within the intent of the letters patent and Act of Parliament. And after this verdict had been three several times argued in the Court of Queen's Bench, the judges were unanimously of opinion that the facts found did amount to the practising of physic within the meaning of the Acts of Parliament, and gave judgment accordingly. Hereupon a writ of error in Parliament was brought to reverse this judgment, and on behalf of the plaintiff in error it was argued that the consequences of it would not only ruin him but all other apothecaries, as in case of the affirmance of this judgment they could not exercise their profession without the licence of a physician, that the constant usage and practise which had always been that the apothecary was conceived to be the best expounder of this charter, and that therefore the selling a few lozenges or a small electuary to any person asking a remedy for a cold, or any other ordinary or common case where the medicines had a known and certain effect, could not be deemed unlawful, or practising as a physician when no fee was taken or demanded for the same; that the physicians by straining an Act made so long ago endeavoured to monopolise all manner of physic solely to themselves, and if they should succeed in this attempt it would be attended with many mischievous consequences; for in the first place, it would be laying a heavy tax on the nobility and gentry, who in the slightest cases, and even for their common servants, could not have any kind of medicine without consulting and giving a fee to a member of the college; it would also be a great oppression upon poor families, who, not being able to bear the charge of a fee, would be deprived of all kind of assistance in their necessities, and it would prove extremely prejudicial to all sick persons who, in case of sudden accidents or new symptons happening in the night time, generally send for the apothecary" [your Lordships see the weight of these arguments I think] "but who should not dare to apply the least remedy without running the hazard of being ruined." [These are Mr. Brown's own arguments.] "On the other side it was contended that by several orders of the college its members were enjoined to give their advice to the poor gratis, and that not only to such as could come to them for it, but every physician in his neighbourhood was obliged to visit the sick poor at their own lodgings, and therefore the objection that if the apothecaries could not administer physic, but by the prescript of a physician, the poorer sort of people would be lost for want of proper remedies, had not the slightest foundation. And when these orders were observed not to have their full intended effect, on account of the high prices which the apothecaries generally demanded for the remedies prescribed, whereby the poor were deterred from consulting the physician for fear of the charge of the physic, the college, by a joint stock, erected several dispensaries in town, where after the physicians had given their advice gratis the patients might have the physic prescribed for a third, and generally less, of what the apothecaries used to exact for it."

Your Lordships wished me to read the arguments, but they are all of this general nature. They do not seem to me to touch any point that is before your Lordships now; they were put forward apparently as popular arguments. That is the whole gist really of what is stated here, on what is the policy of the Act rather than any question of construction upon the charter. Mr. Rose by that judgment certainly established this right, that apothecaries under the charter of James I. had a right to attend patients, in the sense in which we use the term now, at their own houses, bringing skill to bear upon the diseases from which those patients were suffering, and, my Lords, that seems to have been in addition to and distinct from what had been the primary office of an apothecary, viz., making up, dispensing, and selling the prescription that the physician wrote. That portion of the apothecary's duty, your Lordships see, is pointed out very fully in the 5th section of the Act which we are discussing—the Act of George III.—

"And whereas it is the duty of every person using or exercising the art and mystery of an apothecary, to prepare with exactness and to dispense such medicines as may be directed for the sick by any physician lawfully licensed to practise by the President and Commonalty of the Faculty of Physic in London."

Then the offence is created in these words:—"That if any person using or exercising the art and mystery of an apothecary shall at any time knowingly, wilfully, and contumaciously, refuse to make, mix, compound," and so forth, then he shall be liable to a penalty. You see that even in 1815, so far as that section is concerned, the duty of an apothecary, and the only duty mentioned in that section, is, that of compounding medicines which a physician may prescribe; but, my Lords, it is clear that those duties there set out were not the only duties that an apothecary in the practice of his profession would fulfil. My Lords, there is a case reported in 4 'Barnewell and Adolphus,' page 625, a case of the Apothecaries' Company against Allen. I shall have to refer to it again, but I quote it at this moment for the dictum of Justice Park, afterwards Lord Wensleydale. Mr. Justice Park was then sitting in the Court of Queen's Bench. He says this: "The preamble to section 5 does not profess to recite all the duties of an apothecary, but only those referred to by the penal enactments which follow." So your Lordships see that although in 1815 it was contemplated that an apothecary was a person who did make up and sell without bringing to bear any skill upon the subject, the prescriptions which the physician wrote, yet no doubt at that time the apothecary had grown into existence as a profession. The apothecary's profession existed where skill other than that of selling medicine is required. Now, my Lords, of course practically, as your Lordships have to determine and apply this Act, now, that portion of an apothecary's business which is mentioned in the 5th section of the Act of 1815 is substantially gone. No apothecary now of course keeps a shop. It may be that, sometimes acting, as I shall show your Lordships when I come to it, under the Pharmacy Act, a person who is also a chemist and druggist may have a diploma from the Apothecaries' Hall, but *quâ* apothecary and apothecary only of course he ceased to carry on business as selling drugs, and I presume, my Lords, the fact is that if anybody were to go with a prescription to a gentleman who was practising as an apothecary now, as a practitioner, and ask him to make up the prescription of any eminent physician he would not do it. If he did do it and did not see the patient he would simply act as a chemist and druggist in making up that prescription, charging the mere price of 2*s.* or 3*s.* 6*d.*, or whatever the price of the drug might be that he was selling.

The Lord Chief Baron: Why?

Sir Henry James: Because they do not do it any more than if you ask a barrister to endorse a writ.

The Lord Chief Baron: You say so; but why, if this statute be unrepealed?

Sir Henry James: I do not know, my Lord, why people do a great many things.

The Lord Chief Baron: But you are making an assertion, as it appear to me.

Sir Henry James: I do make that.

The Lord Chief Baron: You are making the assertion of a fact or usage that if any gentleman were to go with a prescription of Sir William Gull's to an apothecary the apothecary would object to make it up—you state that as a fact—but why?

Sir Henry James: My Lord, I must put it as argument to your Lordship. It is a fact that the making up of the physician's prescription now no doubt falls into the hands of the chemist and druggist.

The Lord Chief Baron: There is no doubt about that, but I want to know why do you say—with this provision in the statute-book as far as I know unrepealed—that if a gentleman who has consulted Sir William Gull and obtained a prescription from him, that then if instead of going in the ordinary way to a mere chemist and druggist he should go to an apothecary and call upon him to make up the medicine prescribed, that he would object to do it. You say that he would not do it. I want to know why?

Sir Henry James: I'll tell your Lordship why I think so; because now the fact is that almost every apothecary has a diploma from the College of Surgeons. Your Lordship sees that the general practitioner who exists now—the apothecary—according to common knowledge, does not exist separately and distinct as an apothecary selling drugs, but he exists as a person bringing skill to bear upon all diseases.

Mr. Baron Cleasby: What you say is true generally, but not universally, I should suggest.

Sir Henry James: Well, I leave it to your Lordships' knowledge. I won't put it to your Lordships as being universal; it may be that it would be done under certain circumstances, but it is not so done. The practice is that an apothecary now practising as a general practitioner in the first place *quâ* apothecary has no shop. In the next place, he does not hold out that it is his business to simply sell the drugs that another person writes on a piece of paper is to be made up, but the apothecary practises as a general practitioner in almost all cases with a diploma from the College of Surgeons and also with a diploma from the Apothecaries' Hall. He is not a seller of drugs, a bare dispenser, he is a person who brings skill to bear in attending his patients; and, my Lords, to show that that is so, as your Lordships are aware, now an apothecary may attend as an apothecary and not charge for any sale of the drug at all. He is entitled to charge for his bare skill and the knowledge of the art and mystery that he brings to bear and not charge for any drug at all. My Lords, that was determined in Town and Lady Gresley, reported in 3 'Carrington and Paine,' page 581; it being an action of assumpsit for work and labour as an apothecary and for medicines furnished. The plaintiff had charged both for medicines and attendance. Serjeant Wild submitted that the charge for attendances must be taken off as an apothecary had no right to make such a charge. Chief Justice Best said, "I am inclined to think that there is something in some of the Acts of Parliament upon the subject of attendances; but if there is not any express provision, yet the practice is so inveterate that I cannot allow the plaintiff to charge in both ways. An apothecary may charge for attendances if he pleases and then the jury will say what is reasonable for those attendances, or he may charge for the medicine he sends, but he cannot be permitted to make a charge for both. I shall recommend the jury in the present case to strike off the charges for attendance and make an allowance for the medicines only."

The Lord Chief Baron: There there is a claim then for attendances and also for the supplying of medicines.

Sir Henry James: Yes, of medicines.

The Lord Chief Baron: Whether in prescriptions or merely his own?

Sir Henry James. My Lord, he seems to have supplied them himself from his own surgery.

The Lord Chief Baron: What Chief Justice Best held was, that he might charge for attendances if he pleased and recover, but he could not charge for attendances and for the medicine supplied pursuant to whatever may have been the necessities of the occasion.

Sir Henry James: Yes, my Lord. There is a note, I quote it as a note of the editor's, but it puts the position of an apothecary somewhat strongly. Perhaps you will allow me to read it. The note to the case is—"This is the first case which has decided that an apothecary may charge for attendances provided he makes no charge for the medicine he furnishes. There has long existed in the profession a vague and undefined notion that an apothecary cannot charge for attendances. This may have arisen from the fact that an apothecary originally was only a compounder of medicines prescribed by a physician. There does not appear to be any express provision in any of the Acts of Parliament upon the subject of attendances, and there is no doubt that the rule laid down by the learned Chief Justice is, in the present state of the medical profession, the most reasonable and the best that could be adopted both for the practitioner and the patient. There are many cases which require both skill and attendance, but which do not require the administering of much medicine, and it is well known in point of fact, that when attendances are not charged for, much more medicine is often sent than the case actually requires, and also that the charge for medicines generally bears no proportion to the cost price of the drugs. By giving the apothecary the option of charging for medicines or attendance, according to the nature of the case, one of those inconveniences will be removed and the other considerably diminished."

The Lord Chief Baron: Does it appear in that case whether the attendances for which part of the claim was made were attendances at the apothecary's own house or his own premises, or did he go out to visit the patient? Does it appear one way or the other?

Sir Henry James: It does not; but I should draw the inference that it is attending at the patient's house, because it says here, "the plaintiff lived near Waterloo Bridge and the defendant in Conduit Street," and the plaintiff had charged for both medicines and attendance, but it does not directly appear.

The Lord Chief Baron: I suppose that is so.

Sir Henry James: I suppose, my Lord, it was probably attending at the house. There are other cases in which they are attended. There is also mention made of an apothecary in the case of Alison against Haydon, reported in 4 'Bingham,' page 619. It was an action of "assumpsit for work and labour as a surgeon and apothecary," with counts for medicines sold and delivered. At the trial it appeared that the plaintiff had a certificate from the College of Surgeons, but none from the Master and Wardens of the Apothecaries' Company. There the defendant disputed certain charges for attending him in a typhus fever; and it was objected that he could not recover for these attendances, the 55 G. III. c. 194, s. 21, having enacted that "no apothecary shall be allowed to recover any charges claimed by him in a Court of Law unless he shall prove at the trial that he was in practice prior to or on the 1st of August 1815, or that he has obtained a certificate from the Court of Examiners by the said Act constituted." There the plaintiff was nonsuited for those charges upon the defendant for attendances upon him and giving him advice in relation to this typhus fever. Chief Justice Best says, "I think this is a useful law, intended to put apothecaries upon a more respectable footing and to exclude low and ignorant persons from the practice of medicine. But the words of the Act prevent all persons from recovering for attendance, except such as have duly qualified themselves as apothecaries." Then the Chief Justice read the section. "No one therefore can recover unless he were practising as an apothecary before 1815 or has a certificate from the Court of Examiners of the Master and Warden of the Apothecaries' Company. If indeed the plaintiff had been practising as a surgeon and had administered medicine as ancillary to a surgical case his claim could not have been resisted, but he was lowering a typhus fever, which is the province of the physician or apothecary." Then, my Lord, although this does not bear upon the express point, the Chief Justice says, "a surgeon formerly was a mere operator who joined his practice to that of a barber. In latter times all that has been changed and the profession has risen into great and deserved eminence. But the business of a surgeon is properly speaking with external ailments and injuries of the limbs, with a view to the recovery of a patient. In a case of that description he may perhaps prescribe and dispense medicine." Then he concludes and says, "we think the plaintiff has interfered with the province of the apothecary, and that therefore this rule must be discharged." Now, my Lords, I have quoted these cases to show your Lordships that the art of an apothecary is quite distinct from that of vending drugs, and of course if you are going to hold that because apothecaries formerly sold drugs in their shops, a chemist by selling drugs in his shop is acting and practising as an apothecary, of course no physician's prescription can ever be made up by a chemist and druggist again, and of course the whole trade of a chemist and druggist would be gone, because that is the principal part of his business.

The Lord Chief Baron: What is the meaning of what you are now contending for? Because if this were a mere case of a person going in and asking for a particular medicine and the medicine being sold over the counter as by the defendant in this case, that would be acting, it may be merely as a chemist and druggist; but here the patient, if there is a patient, goes and consults him and upon that consultation he recommends a certain medicine, or thinking that a certain medicine would be appropriate and useful he supplies that medicine.

Sir Henry James: My Lord, that is not sufficient.

Mr. Baron Cleasby: Allow me to make an additional interruption. I understand what you say is this—undoubtedly it was part of the business of an apothecary to make up the prescriptions of physicians.

Sir Henry James: Certainly.

Mr. Baron Cleasby: You say if you are to construe the Act of Parliament in the way that is contended for, every chemist who makes up a prescription presented to him with the initials of a physician is liable to a penalty.

Sir Henry James: That is so. If the Lord Chief Baron will forgive me, I am most anxious to follow his view of the argument, but if he would allow me to proceed with the view of the case I was taking, I think we shall shorten the argument when we came to apply the principle, which I wish to submit to your Lordships, ought to govern the construction of this statute to the particular facts of this case, and it is rather difficult before we quite determine what this statute means to spring at once into the particular facts of the case. Now, my Lords, I am still upon the question of what was "acting and practising as an apothecary," and it is in order to know what is the meaning of this statute that it is neccessary to know what an apothecary was—in what sense he acted and practised his business; and I am showing to your Lordships that there was first, in former times, but one act that was done by an apothecary, viz., that he sold wares; that afterwards and by degrees he had attached to his existence as an apothecary the performances of other duties and he practised and acted in a different manner, viz., that he brought skill to bear upon attending diseases other than those cases which were called surgical cases, or organic diseases where the ordinary functions did not act. Every disease, except those diseases and injuries, it was the province of the apothecary to attend upon and give advice, and that although he sold no drugs, although there was no medicine administered, and therefore no drug could have been sold, he had a right to charge for his attendances, viz., for the advice he gave to the patient, without selling anything at all. I am now pointing out to your Lordships, if you will allow me, that you cannot construe the Act literally, because if you say that a chemist by selling a drug is acting and practising as an apothecary, we reduce the Act to an absurdity. It is true that in selling a drug he acts an an apothecary would act, and perhaps did act to some extent in 1815, because an apothecary may have sold drugs then, and he may have practised as an apothecary in that sense; but still your Lordships are not going to convict him for that, of course. Therefore, so far as anything is done in relation to the selling of a drug that does not come within the 20th section of the Act of George III., and it must be something other and different than the performance of a duty of an apothecary *quâ* the selling of a drug. Now, my Lords, there are some cases that throw light upon this question, when it was necessary to construe the 21st section of this Act. Your Lordships will recollect that by the 21st section of the Act,

"No apothecary shall be allowed to recover any charges claimed by him in any court of law unless such apothecary shall prove on the trial that he was in practice as an apothecary prior to the 1st day of August, 1815."

The Lord Chief Baron: He shall not recover for what?

Sir Henry James: Any charges, my Lord.

The Lord Chief Baron: What section are you reading?

Sir Henry James: Section 21, my Lord. He shall not be allowed to recover any charges claimed by him in any court of law. Now, your Lordships see that after the passing of this Act there were many questions that arose when an apothecary brought his action upon his bill, because all the apothecaries who had been practising before 1815 did not apply again for a certificate. They did not subject themselves to an examination, and in order to prove their right to recover they had to prove that being without a certificate under section 21 they had practised "As an apothecary before the 1st of August, 1815." Then, my Lords, the judges had to determine whether they had or had not practised.

The Lord Chief Baron: Of course, this man, the defendant, did not practise before 1815.

Sir Henry James: Oh no, my Lord, of course he did not. I am afraid I have not made myself understood for the moment. Your Lordships will see on section 20 we are discussing the words "act or practise as an apothecary."

The Lord Chief Baron: Yes.

Sir Henry James: Now, will your Lordship be good enough to look at section 21, where you see the words are not quite the same, but that a person might practise after 1815 if he was in practice as an apothecary before.

The Lord Chief Baron: Yes.

Sir Henry James: Well, my Lord, I thought it was of some value to see what was the meaning of the words in section 21, "In practice as an apothecary," as bearing upon the proper construction to be put upon the words, "act or practise as an apothecary" in section 20. In that view it was advisable to look at the cases where a construction had been put upon the words "in practice" in section 21.

The Lord Chief Baron: Yes.

Sir Henry James: That was the point, my Lord. That has nothing to do with this gentleman, who I hope was not in practice before 1815; he must be a very old man if he was.

The Lord Chief Baron: Well?

Sir Henry James: The question that had to be determined under section 21, if I may explain it again, arose always in actions for penalties.

(Their Lordships conferred together).

Mr. Baron Cleasby: My Lord does not object to my saying that regarding this as a most important question, as I think it is, I myself feel very great difficulty in dealing with it as the case stands, because I cannot help looking on section 28 as a most important one.

Sir Henry James: Yes, my Lord, it is.

Mr. Baron Cleasby: There are four branches of the medical profession, namely, physicians, surgeons, apothecaries, and chemists. You will find it is laid down so that chemists form one branch of the medical profession. Well, consider what a chemist is entitled to do after the passing of the Act of 1815, and referring to the rights reserved by the 28th section. That section recognizes chemists as a branch of the profession, and reserves to them all the rights which they were in the habit of exercising (right or wrong) before 1815.

Sir Henry James: Yes, my Lord.

Mr. Baron Cleasby: What materials have we before us upon which we can come to any conclusion upon the point as to the present defendant being entitled to the privilege of that section?

Sir Henry James: My Lord, it is a question not only of great importance to every chemist and druggist, but to every poor person who frequents a chemist and druggist's shop. As regards the point of the 28th section, that is entirely distinct from the point we are now discussing. I should have to take, if I may say respectfully, the same view that your Lordship has expressed, when I come to the point that the learned county court judge has found no fact whatever upon the evidence. There is the evidence of the two witnesses for the defence—Parsons and Glaisyer.

Mr. Baron Cleasby: That is hardly sufficient. If you show going back as far as living memory does that chemists have been in the habit of dispensing across the counter, giving all the evidence you can on the point, that now and for a considerable time it has been part of the business of a chemist to do that, it would be very important.

The Lord Chief Baron: Of course, if it should appear that in this case the defendant has done nothing more than every chemist and druggist in the kingdom has a right to do—if he has not acted as an apothecary—then the judgment is wrong altogether.

Mr. Baron Cleasby: If he has acted not as an apothecary but in a manner that he is justified in doing.

The Lord Chief Baron: Acted as an apothecary.

Mr. Baron Cleasby: He has acted as an apothecary; because, of course, an apothecary has to make up prescriptions.

Sir Henry James: Certainly, my Lord; I may apparently have gone over some ground which, at first sight, may not have appeared to bear on the statute, but with submission it seems to me it is most relevant, and almost crucial to this case to show your Lordships that what an apothecary was is now the common business of a chemist and druggist, and that he is bound to fulfil that business. I will show your Lordships, under the Pharmacy Act, that so far as the apothecary, who until lately did nothing else but sell drugs, the chemist, of course, is entitled to sell drugs apart from giving advice; and therefore it is important to see whether what the chemist has always done does not came within one construction of the words "act or practise as an apothecary," and I am endeavouring to show your Lordships that that one construction of acting or practising as an apothecary, viz., selling drugs which of course was the act and practice of an apothecary—that that cannot be the construction to be put upon these words. Do I gather from what the learned Baron says that he thinks there ought to be some more clear finding by the learned county court judge upon the evidence of the two witnesses?

The Lord Chief Baron: You may put it in what language you like. The apothecary has power to do what a chemist and druggist also has power to do, that is, to make up prescriptions and vend medicines across the counter, and, therefore, so far he may act as an apothecary if he happens to have an apothecary's certificate, or it may be done by a chemist and druggist who has no such certificate, and is not an apothecary. But the question here is whether upon what the defendant has done, which is something more than merely selling drugs or medicines across the counter, because it is his being consulted and giving something in fact to a man who tells him that he has a pain in his chest or a sore throat, or one thing or another, he thereupon supplies him with medicine. If you can show that that also is within the privilege of a chemist and druggist, although it may be within the privilege of an apothecary also, to hold that this man is liable to this action and subject to the penalty, would be to hold that every chemist and druggist is liable.

Sir Henry James: My Lord, we must argue the case by steps.

Mr. Baron Cleasby: It will be a very long argument in this case, and it may turn out at last to be futile.

Sir Henry James: Certainly.

Mr. Baron Cleasby: It seems to me to be a case of so much importance that if I were to say what my view of it would be—I do not think we ought to do that now; but what I should recommend would be this, that a new trial should be ordered, and that a *certiorari* should be applied for to have this question argued in the court.

Sir Henry James: As I have endeavoured to put myself into possession of this case, directly we come to take the view which the Lord Chief Baron has pointed out, and to apply it to this case, we shall place before your Lordships the gravest possible difficulty to determine where the duties or the rights of a chemist and druggist cease, and those of medical men begin. I am using the term in its ordinary sense. I may say at once that every chemist and druggist in this country is interested in this matter, and, no doubt, to some extent they are taking a practical interest in this litigation and, therefore, as your Lordship suggests, if the Apothecaries' Company wish to bring this matter to a solemn decision in that way, I accept it most readily, and ask that that should be done.

The Lord Chief Baron: I have no objection to that course.

Sir Henry James: I must readily accept what has been said upon this point of the 28th section, there being no judicial decision at all given. If a new trial is ordered we will undertake to ask for the removal of this case to a Superior Court, in order that we may, if necessary, take it to the highest Appeal Court to which we can take it.

The Lord Chief Baron: I have no objection to the course suggested by my brother Cleasby, quite the contrary. What does the other side say to it?

Sir Henry James: My friend, Mr. Day, is thinking over it, my Lord; he will give your Lordship an answer in a moment. He is in consultation.

Mr. Day: If I may be allowed, my Lord, to make a suggestion, I am told that there is another case involving precisely the same point, now in course of progress, if I may use that expression, in your Lordship's Court. I do not know whether it is yet set down for trial.

The Lord Chief Baron: Do you mean an action to be tried in this Court?

Mr. Day: An action of the Apothecaries' Company *v.* Wiggins. In fact I am told there are two such cases pending, and those cases of course are in train for solemn decision. What I would respectfully suggest to your Lordships is this, that if your Lordships have any doubt as to what the finding of the learned county court judge is that this case may be sent down for him to give his finding upon it, and that the matter should not be argued until after the decision of the cases in your Lordship's Court.

The Lord Chief Baron: That it shall be sent down for what?

Mr. Day: Sent down, my Lord, to be restated, because I am assured that the learned county court judge did find the fact on which the discussion has arisen, viz.

whether there had been a practising as an apothecary. I am assured that he actually did find it as a fact.

(Their Lordships conferred.)

The Lord Chief Baron: I see no objection to its being sent down again to be restated. In that event no consent will be necessary. We may at once say, and I daresay you would not hesitate to agree, even if we were not to exercise the power which we possess, but which we are slow to direct—that this case should stand over altogether until after the decision of one or more of the cases to which you have referred.

Sir Henry James: My Lord, my friend mentioned the case of the Apothecaries' Hall *v.* Wiggins. I know nothing about Mr. Wiggins, but one of my learned friends who assists me says he does.

The Lord Chief Baron: What?

Sir Henry James: This case my friend has mentioned, of the Apothecaries' Company *v.* Wiggins. One of my learned friends, whose assistance I have, is counsel in this case, and he informs me that Mr. Wiggins has not acted quite in the same way as this gentleman.

The Lord Chief Baron: That does not matter; if there be a case which will raise anything like the questions we have to determine here, we should like to have that case tried before a judge and jury in one of the Superior Courts before we proceed to decide finally upon this case.

Sir Henry James: I have no objection to this case standing over; but may I point out, supposing in the case which is now in your Lordship's Court it should be proved that the defendant has been in the habit of attending patients at their houses and has been giving advice perfectly distinct and independent of the selling of drugs, of course I am not going to be bound in this case by that decision.

The Lord Chief Baron: Oh no; you would not be bound. Neither party would be bound by anything that may hereafter take place; it is only that we may be a little enlightened by what may take place in those cases in this court, or any one of them, before pronouncing our decision upon the case which is now before us.

Mr. Day: Wiggins's case is in this court.

The Lord Chief Baron: I think it is extremely probable—do not imagine that I am throwing out anything like a decision—but I think it is extremely probable that if we were to consume the day in hearing this case argued, the end would be that we should, without giving any reasons or any judgment at all upon the law, direct a new trial. I think it is extremely probable, but do not think I am so adjudging. Therefore, if instead of that, which would be condemning the parties to go before the county court judge again, whose decision after all may be wrong, you would agree to have a new trial in this court.

Sir Henry James: That was Mr. Baron Cleasby's suggestion, with which I readily fell in. If your Lordships will direct a new trial in this case we will undertake to apply to your Lordships for leave to remove the case for decision to the Superior Court. But my client is personally interested in this decision and he wants a decision upon his own case and not upon Mr. Wiggins's case, and if your Lordship will take that course we will bring this case up.

The Lord Chief Baron: You say that if we direct a new trial it shall be agreed at once that the case shall be transferred from the county court to this court.

Sir Henry James: Certainly; we will take that course.

Mr. Day: I should submit respectfully that there is no ground on which your Lordships can direct a new trial. I submit that the facts have been before the county court judge and that he has given his decision. If your Lordships think the case does not sufficiently set out the facts and your Lordships wish to ascertain what the learned judge's finding was, I suggest the better course and the only proper course is to send the case down to be restated. On behalf of my client, I must say we prefer to stand upon the trial.

Mr. Baron Cleasby: We have power by the Act of Parliament to direct a new trial.

Mr. Day: Yes my Lord.

Mr. Baron Cleasby: If it appears that a material issue or a material question is not disposed of one way or the other by the decision, to direct a new trial would be the proper course.

Mr. Day: Undoubtedly.

The Lord Chief Baron: The better way will be to have a new trial and then if it be brought before this Court in the meantime either party will give whatever evidence he thinks fit. Then we shall be in full possession of all the facts and the law which can be proved, to enable us to judge whether the defendant has committed a breach of law or not.

Mr. Day: What I submit is that no issue has been left undetermined; that the trial was complete so far as it goes, and your Lordships have nothing but the case before you. I submit that if the case is not sufficiently stated the course that should be taken is that it should go back to the county court judge to restate the case. That I can have no objection to, but I do protest against a new trial being ordered where there is no evidence of any issue being left untried by the learned judge or any improper direction, or improper finding on the issue.

The Lord Chief Baron: I think, considering that you appear for the great Apothecaries' Company, who can be interested only in seeing that the law is conformed to and obeyed, if we think that upon such a case as this, where a penalty is claimed in the action, that it ought to be fully considered and that either party should have full liberty to have all the evidence of which the case is susceptible, you ought to agree to it.

Sir Henry James: My Lord, I would also join in the appeal which your Lordship has made to my learned friend. He appears for the Apothecaries' Hall. My client is in this position that he might go and do the same thing to morrow, and have a fresh action brought against him, and this ought not to be treated as a question of the costs of the old action.

Mr. Day: Oh, no; it is no question of costs. I never suggested it, but we desire to get a decision at the earliest possible moment.

The Lord Chief Baron: You will have a decision, if, instead of sending it down to be restated, we direct a new trial and it is agreed at once that the case shall be transferred into this Court.

Sir Henry James: If your Lordship pleases.

Quinine Pills.

At the Wednesbury Police Court on the 20th inst., before Mr. I. Spooner (Stipendiary), Henry V. Jessop, chemist and druggist, Market Street, Willenhall, was summoned by J. G. Horder, inspector under the Food and Drugs Act for the South Staffordshire district, for having sold, on the 10th of September, to Henry Constable a certain compounded drug—to wit, quinine pills, which were not composed of ingredients in accordance with the demand made.

The defendant said he did not sell the pills; his assistant sold them.

Mr. Spooner: You are responsible for the goods sold in your shop.

Henry Constable said he was in the employment of Mr. Horder, the inspector, and on the 10th of September he visited the defendant's shop and tendered a piece of paper to the asssistant, on which was written "Twelve quinine pills." He received a box containing the pills, and he afterwards gave them to Mr. Toy, a senior assistant to Mr. Horder, who stood outside the shop whilst he purchased them.

Defendant said the pills were made in accordance with the orders of the Pharmacopœia, and it was also understood that some quinine pills should be so made as to enable the maker to sell them at a reduced rate so that poor people might be in a position to purchase them.

Mr. Spooner: But the pills did not contain as much quinine as they ought to have done.

Isaac Fry deposed that he received the pills from the last witness, and he went into the shop and informed the assistant that the pills had been purchased for the purpose of being analysed. He then returned to him part of the pills.

Mr. Horder having proved that he forwarded the remainder of the pills to Mr. Jones, the county analyst,

Mr. Jones stated that the pills were forwarded to him on the 18th of September, and after analysing them he gave the following certificate:—"I am of opinion that the said sample, if intended as four grain pills, contains 1·21 grain of sulphate of quinine too little, and in each pill, viz., 1·79 instead of three grains, but the pills averaged 4·65 grains, and therefore the percentage of sulphate of quinine in the mass is 38·55 instead of 75, as ordered in the Pharmacopœia."—In answer to the Stipendiary, witness said there were but six grains [so reported] in two pills, whereas there should have been a grain more in each pill.

Mr. Spooner said he did not see how he could convict in the present case.

Witness said the messenger was sent to defendant's shop in accordance with his instructions, and on the note was written "B. P.," which meant that the pills were to be such as those ordered by the Pharmacopœia.

Mr. Spooner said that the private mark referred to was liable to various constructions.—After further remarks had been made by Mr. Jones, the Stipendiary said the case would have to be dismissed, but he would advise the defendant not to sell such pills again. If Mr. Horder wished he would grant him a case for a higher Court.—*Birmingham Daily Gazette.*

Prosecution under the Pharmacy Act.

At the Petty Sessions held in the Corn Hall, Stradbroke, Suffolk, on Thursday, November 22, 1877, before the Rev. W. R. Colbeck (chairman), the Rev. F. French, and the Rev. H. S. Marriott, Ephraim Cullingford, grocer, etc., was charged by Hart, P.C., with selling poison; he not being a chemist. He was fined 4*l.* 17*s.*, including costs. He was further charged with selling poison without having the word on the wrapper, and without making a proper entry. These informations were withdrawn.—*Sussex Chronicle.*

[*** According to the 15th clause of the Pharmacy Act, 1868, an unregistered person selling poison becomes liable to pay a penalty of *five pounds* to be "sued for, recovered, and dealt with in the manner provided by the Pharmacy Act [1852] for the recovery of penalties under that Act," where the Registrar under the Act is specified as the person who is to recover the penalty "under the provisions of any Act in force for the easy recovery of small debts and demands." It follows, therefore, that if the above report is correct, the decision of the Stradbroke magistrates was illegal, as they had no power either to reduce the penalty below £5, or to enforce it on the application of a police constable. The offence of insufficiently or improperly labelling a poison is quite distinct from the breach of the law as regards the Register, and in such a case any person may act as prosecutor.—Ed. Ph. J.]

Conviction for Administering Laudanum to a Child.

In the Paisley Sheriff Court, Monday, November 26, before Sheriff Cowan and a jury, Jane M'Kean or Corbett, was indicted on a charge of culpable homicide, or, alternately, of having recklessly administered laudanum or other deleterious drug on the 15th ult. to a child seven months old. It appeared that the child was put out to nurse at a house where the prisoner was staying, and that it died with symptoms of opium poisoning.

James M'Ginn, aged ten, said prisoner sent him for a halfpennyworth of laudanun. He did not know what the laudanum was for. Corbett (the prisoner) poured the laudanum out of the cup into the child's mouth. She afterwards gave the child to witness and went to bed. The child was "greeting" when Corbett sent for the laudanum.

By a juryman: Corbett did not state the object for which she had given the laudanum.

Mary M'Kie or M'Ginn gave corroborative evidence.

Eliza Robertson, barmaid with Mr. T. Arrol, publican, recollected the boy M'Ginn getting two imperial gills of whisky on Monday the 15th ult.

John Paterson, detective officer, said the boy M'Ginn pointed out Mr. Wilson's, druggist's shop, as the place he had got the laudanum.

Wm. Wilson, druggist, 36, Ferguslie, deponed that he did not recollect the transaction referred to. He sold laudanum at the rate of one drachm of 60 drops for halfpenny. He manufactured the laudanum himself. He sold laudanum as often as any other medicine in the shop, and quite frequently to boys of ten. He sometimes refused children who came for it.

By the Sheriff: It was nothing unusual for him to sell laudanum to children even although a drachm was two doses for a healthy man. He manufactured the laudanum in accordance with instructions in the British Pharmacopœia, allowing two-and-a-half ounces of opium to a pint of alcohol.

Prisoner's declaration was then read. She sometimes took laudanum, she said, for a nervous wind on the stomach. She recollected going to M'Kie's house on the day specified. She sent the boy for only one gill of whisky, having previously sent him for halfpennyworth of laudanum, of which she gave the child a small quantity and drank the rest herself. She was not aware that a few drops of laudanum would kill a young child, and had drank as much as one pennyworth herself at a dose.

The medical report of Drs. Richmond and Graham was then read. The immediate cause of the child's death was congestion of the brain, the *post mortem* experiences corresponding with those which might be expected from an overdose of laudanum. Dr. Richmond, after reading the report, deposed that a half drop of laudanum was sufficient for a child seven months of age. Laudanum had to be administered with the greatest caution to young children and old people. For a healthy man the dose averaged from 20 to 30 drops. He had no doubt that laudanum was the cause of death.

The jury unanimously found the prisoner guilty of the culpable and reckless administration of laudanum to an infant child, whereby it was deprived of life, as libelled, and recommended her to the leniency of the Court.

Sentence of three months' imprisonment was then passed.—*From the Glasgow Herald.*

The Right to Sell "Condy's Fluid."

In the Court of Appeal, November 27, before Lords Justices James, Baggallay, and Thesiger, the case of Condy *v.* Mitchell was heard.

This was an appeal from an order of Vice-Chancellor Bacon, refusing to restrain the defendant, a former partner with the plaintiff, from carrying on the business of a manufacturer of disinfecting fluid under the style of Condy's Fluid Company, though his Lordship at the same time declared that the defendant had no right to use the plaintiff's full name of Henry Bollmann Condy, under which title the partnership business had been carried on. It was admitted by the plaintiff at the bar that, in face of the recent decisions in the Singer sewing-machine case, it could not be contended that a manufacturer has not a right to call the article he makes by the name it has acquired; but it was contended that the defendant's rival articles being of different composition to those made by the plaintiff, he had no right to carry on business under the style of the Condy's Fluid Company, so as to deceive the public, and leave them to believe that the former were made under the management and superintendence of the plaintiff. Patents obtained by the plaintiff for his fluids had expired. He had carried on business alone in their manufacture from 1856 to 1870, when he took the defendant in as a partner, and the business was then carried on under the name of Bollmann Condy and Co. The partnership was dissolved in 1873, and for some years the business was carried on by a receiver appointed in a suit instituted by the defendant, that official, of course, using the trade name and labels. The plaintiff commenced another business in the meantime in his own name, and the defendant took the same course, using the style of Condy's Fluid Company. This the plaintiff complained of, and sought to restrain, on the ground that the name could only have been adopted for purposes of deception, and to represent to the public that the defendant's fluids were made under the superintendence of the plaintiff as inventor. Evidence was adduced in support of the plaintiff's case, for the purpose of showing that people had actually been deceived. It was further alleged that while the plaintiff's fluids were made from permanganates of soda and lime—both expensive and special products—the defendant's were obtained from permanganates of potash, a cheap and objectionable article, common in the market. The defendant simply claimed the right to trade as a maker of an article which anybody might manufacture, and which could only be described by its name.

Mr. Hemming, Q.C., and Mr. Bradford appeared for the appellant; Mr. Kay, Q.C., and Mr. Woodroffe for the respondent.

Their Lordships strongly disapproved of the course of employing detectives to procure evidence of the sales of defendant's articles which had been pursued by the plaintiff, those emissaries having handed to the shopkeepers slips of paper bearing the plaintiff's name, to particularize the purchases, a proceeding which might easily operate to prevent the sale of the defendant's fluids. The Vice-Chancellor had made the proper order. The defendant had made no misrepresentation, and was entitled to sell disinfecting fluids which he had formerly made in partnership with the plaintiff under the names by which they were known. Accordingly the appeal must be dismissed, with costs.—*Daily Telegraph.*

Dispensing Memoranda.

[21]. Troy or Avoirdupois?—I have noticed with, I may say, no small amount of interest, the discussion for the last few weeks on the dispensing of prescriptions, as to whether when a physician writes the sign ℥, he means the *old* apothecaries' (as some of our chemists style it) or the avoirdupois. The former is the only one (except the metric system) capable of being divided up without any chance of mistake.

It would no doubt have been much better for the Medical Council when they did away with the one to have done the same for the other, substituting the metric system for them.

Since the discussion has been going on I have had the opportunity of asking three or four medical men, when they write, say Sodæ Bicarb. ℥ss, if they mean the avoirdupois. In each instance the answer has been most emphatically no, they mean ʒiv apothecaries'.

I have been always accustomed to dispense a prescription according to the apothecaries weight, feeling perfectly certain in my own mind I am carrying out the wishes of the physician.

I should not think if a chemist received a prescription like the following, he would make it up weighing the two first ingredients by the avoirdupois, and the other by the apothecaries' weight.

℞ Sodæ Carb. . . . . ℥jss.
Pulv. Zingib. . . . . ℥ss.
Pulv. Rhei . . . . ʒvj.
M. ft. pulv.

Would he be justified in using two different kinds of weights? It would, I think, be evident to men of reason that it was meant by the physician to be 480 grains to the ounce, not 437·5.

I wish some of our brother chemists who are so much in favour of doing away with the apothecaries' weight, would do as I have done, take the trouble to ask a few medical men what they meant by the sign ℥. They would find nineteen out of every twenty of the same opinion as myself.

I will undertake to say if a vote were taken of all the chemists in the kingdom three-fourths of them would think the same.

It seems a very strange thing that after a lapse of thirteen years this controversy should spring up. It would have been much better had the Council not abolished it and recommended physicians when they meant the troy ℥, that a T should be placed after it; this I think would have suited all parties concerned and would not be a difficult thing for the doctor to remember.

Chas. Smale.

[21]. Troy or Avoirdupois?—Is it allowable to translate ℥j into one ounce avoirdupois?

Two other questions, fairly considered and candidly answered, ought to throw a light sufficient for our guidance on the above subject, which if obscure in any degree has been made so only by the collateral issues raised by certain correspondents.

1. Is there any recognized authority which has ever defined, or would ever define ℥j as being the equivalent of $437\frac{1}{2}$ grains?

℥j = ʒvij gr. $17\frac{1}{2}$. At first view the equation does not look well.

2. When a physician writes ℥j has he in his mind's eye the sixteenth part of an avoirdupois pound, or does he not certainly intend eight times the value of the apothecaries' drachm, to be dispensed? Until we get some Vatican decree which shall be final in this matter, we had as well retain practically in our weighings the old belief that

1 oz. = $437\frac{1}{2}$ grains.
℥j = 480 „

Truro. Samuel Feaver.

[21]. Avoirdupois *v.* Apothecaries.—Whilst there can be no doubt but that the British Medical Council decreed that the sign ℥j should be used to indicate one ounce avoirdupois, and that only (that they do not leave it optional with the physician may be inferred from the fact that they allow it to "be optional with the physician in prescribing to use the symbols ℈ and ʒ"); yet I have been surprised that the majority of medical men with whom I come in contact, invariably mean an ounce troy in using the symbol ℥j. This variance with official decrees places the chemist in an awkward position. It seems to me that this discussion has already been somewhat too prolonged without any probability of a satisfactory settlement. Would it not be better to call a special meeting, or allow it to be discussed at next week's meeting at Bloomsbury Square?

Wm. Hy. Symons.

[21]. ℥ *versus* Ounce.—I am surprised there should be so much correspondence on this subject, for I cannot imagine that much difficulty ever occurs in actual practice, for although ℥ is an obsolete sign still in use (if such is not a contradiction of terms) and so open to two constructions, still the nature of a prescription will generally give us a clue to the prescriber's intention. Common sense tells us that when used in a formula for

internal remedies where the amount is arrived at by multiplying a single dose that it means 480 grs., and I contend that as that was its value in the P.L., and as it is omitted from the B.P., that literally that is its true significance, although probably the same prescriber who uses ℥i to represent 480 grs. in a mixture, in writing Ung. Cetacei, ℥i, would mean the B.P. ounce (if the difference occurred to him at all); but to be strictly correct a physician ought not to use the symbol ℥ to represent 437·5 grs. as it is a sign not mentioned in the B.P. But as medical men, like other mortals, are not infallible, until the much needed metric system is universally established we must not be guided by any arbitrary interpretation of a doubtful sign, but use our judgment and common sense in the faithful discharge of our duty.

Cambridge. M.P.S.

---

[21]. ℥ *v.* Ounce.—The prescription I quoted, through some blunder either of mine or the printers, had no doubt a very unusual appearance. It was one dispensed by me, and was written by an old practitioner as a cooling drink for a patient of his, and ought to have been—

℞ Ol. Limonis . . . . . . gtt ij
Sodæ Biborat. . . . . . ʒij
Sacc. Alb. . . . . . . ʒiv
Potass. Bitart. . . . . ʒj.

To be mixed in a pint of water for a drink.

I think a few grains of common sense would help us far more in any difficulty in this and some other matters than some people seem to suppose. No one, I imagine, would think of weighing a troy ounce of water if ℥j aq. were ordered. Mr. Symes knows that long before the B.P. was invented the sign ℥ was used to denote a fluid ounce of any liquid as well as 480 grs. of any solid, and I should draw exactly the opposite conclusion from the potass. bicarb. prescription and say there is no doubt that the prescriber intended the solution to contain 48 grs. to the T℥j, and not 43·75 grs.

"G. S." speaks of the London Pharmacopœia as being obsolete. He may think so, but there is at least one eminent medical man in this city, with no small practice, who almost invariably writes on the head of his prescriptions "P.L. 1851."

Manchester. W. Wilkinson.

---

[24]. Pill Coating.—Among the varied correspondence on coating pills I have not seen, to my remembrance, any thing written about the following process, which I tried on a few pills, with satisfaction as to result:—

The materials needed to furnish the coating are, albumen, such as white of egg, and very finely powdered white sugar. Pills sufficiently firm and dry may be thinly enveloped in the albumen by rolling between the fingers and thumbs with just sufficient albumen to cause cohesion of the sugar, and no more; they are then placed in a suitable vessel containing the sugar, in which a rotary or suitable agitation will secure pills of pleasant taste; but I do not know how long the coating would last.

The suggestion naturally occurs that a more conveniently obtained form of albumen than white of egg would obtain favour where such a practice existed; probably also the mode of application may be much improved.

East Dean. Edward Jerrett, A.P.S.

---

[29]. Tinct. Chin. Nit.—May I criticize your remarks on the "Dispensing Memoranda" of the month?

In 29 a formula is required for Tinct. Chin. Nit. You state "this is evidently a preparation of China Nit. or Cinchona Nitida, etc."

Please excuse me for saying it is nothing of the sort, but a common preparation in homœopathic pharmacies as prescribed by Dr. Kidd. The formula is:—

Quiniæ Disulph. . . . . ʒij.
Aquæ Dest. . . . . ℥x.
Acid. Nitrici . . . . ʒiv.

Mix and add

Spt. Vini Rect. . . . . ℥vj.

I am not a homœopath, but meeting with the preparation in a prescription I referred it to a neighbour who kindly supplied the formula as given to him by the prescriber. J. Whitfield.

---

[29]. Tinct. Chinæ Nit. is a homœopathic preparation by Dr. Kidd, and is a preparation of nit. quinine. Probably "A Country Dispenser" will find affixed to it on the prescription 1 dec. or 1-100 or 2 dec. 2-200, signifying the potency. I occasionally dispense it and other homœopathic preparations which I procure from a homœopathic chemist.

Hadleigh. R. E. Read.

---

[40]. Where Balsam of Peru is ordered in pills, it answers well to combine it with a little bees' wax.

I think I gathered this some time ago from the Journal and have found it practically useful. J. Whitfield.

---

[41]. SALICYLIC ACID LOTION.—Will any one inform me if a dispenser is justified in straining or filtering out the undissolved acid in the following prescription?—

℞ Acid. Salicyl. . . . . ʒij.
Aquæ, ad . . . . ℥viij.
M. ft. lotio.

A sufficient quantity mixed with an equal quantity of warm water to be used in the manner directed. F. P.

---

[42]. I should be glad to know the chemical change which takes place in the enclosed prescription. Before adding the tr. opii, the mixture is of course perfectly clear, but on this addition being made a semi-opaque milky compound is produced, which on standing throws down a brownish flocculent deposit, and therefore forms a very inelegant mixture. Is it the intention of the prescriber that the mixture should be "shaken before taken"?

Tr. Opii . . . . ʒij.
Pot. Iodidi . . . . ℈ij.
Liq. Hyd. Bichlor . . . . . . ℥ij.
Aq. M. P. ad . . . . ℥vj.

M. ft. M. ʒij ex aq. ter die sumd. Qy., can this mixture be prepared so as to form a bright solution?

A Tyro.

---

[43]. Would some one inform me how to dispense the following prescription, which I had to make up?—

℞ Ung. Zinci . . . . . . ℥j.
Sp. Vini Rect. . . . . . ʒj.
M. ft. Unguent. An Assistant.

---

[44]. Will you be good enough to insert in the *Pharmaceutical Journal* the translation of the following?—

℥j bis 7 mane. S. H.

Notes and Queries.

[564]. COMPOSITION POWDER.—Can any of your readers oblige with a formula for "Composition Powder" (Coffin's)? It should contain "cayenne, ginger, and cloves, etc.;" the formula, October, 7, 1876, is not the one sold here.

Kidderminster. Vaseline.

---

[565]. WHITE FULLERS' EARTH.—Can any reader inform me where I can obtain some White Fullers' Earth that is sold by some chemists, or is it merely the ordinary fullers' earth mixed with starch powder?

Tenens.

DEODORIZATION OF IODOFORM.—Dr. Cole (*New Remedies*, vi., 307) states that iodoform may be deodorized by the addition of tannin. He uses a compound of equal parts of iodoform and tannin as an application to chanchroids and old offensive ulcers.

Obituary.

Notice has been received of the death of the following:—

On the 26th of July, 1877, Mr. Edward George Jones, Chemist and Druggist, Staines. Aged 45 years.

On the 28th of July, 1877, Mr. Edward Pitt Tate, Chemist and Druggist, Eastbourne. Aged 40 years.

On the 27th of August, 1877, Mr. Frederick Augustus Williams, Chemist and Druggist, Wellington, Somerset. Aged 65 years.

On the 21st of September, 1877, Mr. William Knight, Chemist and Druggist, Tewkesbury. Aged 69 years.

On the 23rd of October, 1877, Mr. Richardson Wilson, Chemist and Druggist, Hessle Road, Hull. Aged 49 years.

On the 5th of November, 1877, Mr. Urban Parminter, Chemist and Druggist, Exeter. Aged 56 years.

On the 13th of November, 1877, Mr. Thomas Hornsby, Chemist and Druggist, of the London Hospital. Aged 46 years.

On the 18th of November, 1877, Mr. John Steward, Pharmaceutical Chemist, Kingswinford. Aged 61 years. Mr. Steward had been a Member of the Pharmaceutical Society since 1853.

On the 23rd of November, 1877, Mr. Thomas Davys Manning, Pharmaceutical Chemist, Yeovil. Aged 44 years. Mr. Manning had been a member of the Pharmaceutical Society since 1869.

Correspondence.

ADMISSION OF WOMEN TO MEMBERSHIP.

Sir,—The letter of Mr. Fryer (as you pointed out at the time) was so foreign to the subject that I was not surprised at the way in which your correspondent Mr. Price treated it, his able exposition of the point at issue, supported by "Frater" and Mr. Senier, leaves little more to be said; however, as the subject has to be further considered at the next annual meeting, it is well that the members in the country should give expression to their opinion. The Council were evidently so divided in opinion that four years ago they remitted the subject to the annual meeting, and Mr. Hampson then proposed a motion and very ably supported it. Leaving out the preamble it ran thus:—

"This meeting is of opinion that it is contrary to the plain intention of the statutes to refuse admission to female persons who, having conformed to the legal tests of the examiners and the regulations of the Society, may desire to become connected with the Pharmaceutical Society in the capacity of apprentices or students, or associates, or members."

This was negatived and will now assume another form, inasmuch as the progress of events has clearly shown a better and more liberal feeling towards females, and that a course of obstructiveness only tends to further the object opposed, so that that which is now only a request may become a demand. Certain ladies having distinguished themselves and complied with the requirements of an Act of Parliament ask for the reward of their industry, and certain influential members of the Council oppose on the only plea that they can urge, viz., that they are women. And the most remarkable fact in connection with the opposition is that the opponents are chiefly composed of the bachelors of the Council—men distinguished for benevolence and strenuous supporters of the widow and orphan. This seems an unaccountable anomaly. The limited number of females ever likely to enter the Society is not of sufficient magnitude to excite jealousy of their becoming members of Council or possible Presidents of the Society.

I have carefully examined our Acts of Parliament for 1852 and 1868, and also our bye-laws, but I can find nothing to justify the action of the Council. Every person passing the respective examinations shall be eligible to be elected a member or associate, as the case may be. Surely "every person" does not imply males only? If any doubt is felt about the decision of the next annual meeting, let the suggestion of your correspondent "Frater" be adopted, that country members may be enabled to express through the local secretaries their wishes on the matter.

PATER.

Sir,—As I was one of the first that took up this subject after the last meeting of the Council, and holding a contrary opinion to those gentleman that have so fully expressed theirs in last week's *Pharmaceutical Journal*, I have deemed it expedient to offer some comments on the principal points which they have urged in their letters as being in favour of the admission of women as members of the Pharmaceutical Society. I shall endeavour to deal in as brief a manner as I can with each letter in the order in which they appear in the Journal.

In the first letter, written by Mr. Price, the first point which I deem worthy of commenting upon, is his very profound mode of arguing. after naming a few points; then coming to the grand and happy conclusion that the reasons employed by his opponent are old and have been used times without number. Such a futile effort of refutation as this is not worthy of the name, for his opponent can say just as much of what he says. In passing I may refer him to that wise saying that says "That there is nothing new under the sun," consequently every thing is old. Next he instances the medical profession and the universities of London and Cambridge. I do not consider that the latter have any relevancy whatever to the point in question, and as regards the medical profession we know that females have been admitted into it, but against the desires and wishes of many of the wise members of that body. Although they have been allowed to practise for some time, I do not think that either Mr. Price or any other pharmaceutist can enumerate any particular benefits that have as yet accrued from it; and surely we do not know what good these ladies might have achieved if they had used both their money and their irrevocable time in a more becoming field of labour, perhaps they might have found an office whose duties they would be far more adapted by nature to fulfil. From what follows I would gather from Mr. Price's words that if he had a daughter that walked not within the limits of propriety, as a mode of convincing her of her folly, he would let her find it out for herself, even to the "bitter end." I need not expatiate upon this point, as every one can see that such a notion is worse than ridiculous. Again, he informs his opponent in an affirmative manner that not many women will ever be likely to enter the profession of pharmacy. I do not pretend to be a prophet or the son of a prophet, consequently I do not know how far Mr. Price is endowed with this spirit, but I think this much, that if he had left it untouched he would not have lost much.

"Frater" at the commencement of his letter gives what I consider to be a very valuable suggestion, viz., to try and get our local secretaries to issue voting papers, and send them to 17, Bloomsbury Square before the annual meeting, for I am afraid that we shall not be able to have anything like an approximation to a fair representation of the general opinion of the Society unless we do so. In this letter there are a few more points which require to be considered. In the first place, he thinks we cannot in justice deny the examined women membership. If we confined ourselves to look only on one side of the question their admission would be inevitable. But since many of us believe with minds unbiased that when women embark in the profession of pharmacy they embark in a profession whose duties by nature they are not destined to fulfil, as they lack in point of fitness, etc., then it follows in congruity with a clear conscience that we can no more vote for their procedure further in such a calling than we could vote for women qualified for the army to be leaders of our regiments in time of battle, however gloriously they might have figured in their respective examinations. Next he asks why should a woman be debarred from rising higher than a subservient to the physician. It might as well be asked why a female tractarian should not be raised to the position of a clergyman. I think that the answer that I have given to the previous question would be applicable to either of these. Further he admits that there is much in the practice of medicine and pharmacy to shock the sensibility and refinement of many educated ladies, and that only few would possess a sufficient nerve. I think that here he plainly but perhaps unwittingly acknowledges the weakness of his position. For if those that are educated and who can be deemed no less competent judges for themselves will be shocked, would it be advisable for us to encourage the more gynandrous species that are less educated and, as I think, should be no better judges. For does not the shock, and the acquisition by degrees of a better nerve, speak plainer than words could put it that the profession which they aspire to has not been intended for them, being something similar to a boy that begins to tell falsehoods, who feels nervous at first but by frequent repetition of the dose hardens his heart and renders it impermeable to the dictates of conscience. Lastly, he remarks, that some people think more of M.P.S. and the Society's arms than the title pharmaceutical chemist. I must say that I respectfully beg to differ with him on this point, as I can testify within my own knowledge, many of the best country businesses use neither the title M.P.S. nor pharmaceutical chemist, but simply chemist, chemist and druggist, and such like, and it is comparatively few of those businesses that are conducted by pharmaceutical chemists that exhibit the title of M.P.S. on their prescription envelopes. Again, if we look on the best businesses in London I think that you will find that many of them use neither the title M.P.S., nor hardly any other, and I may say that I feel fully convinced that in the localities where they are used they are thought of far less by the general public than the pompous chemist thinks; so as regards this honour I do not believe that the ladies' remuneration will be one atom lessened for not obtaining it. But pharmacists in reserving their votes will have clean hands for not being guilty of abetting them in taking a course which is universally admitted as being of questionable propriety. As the greater part of the third letter has been already dealt with whilst treating of the other two there are but a few points worthy of notice. In the first place, Mr. Senier endeavours to show the wonderful loss ladies have to sustain by not being permitted to attend the scientific and political meetings of the Society, etc. As I consider that I have already given answers to these questions or questions of a similar nature when referring to the female physicians, etc., it will be unadvisable for me to occupy any more of your valuable space than I can help. Mr. Senier informs us that he has attended classes in which females were taught and that he can speak very favourably of the general issue. As I am not able to speak as to the satisfactory or unsatisfactory demeanour of females in their various departments of labour on the other side of the Atlantic, I can direct his attention to women in this country that have achieved quite as high intellectual attainments as those in the advanced institution of Michigan; let him look at the actresses in our theatres of whom it may be said that the moral and religious character is lower than that of most ladies in other professions. The same may be observed in the gin palace and, more or less, in all places where there is an indiscriminate admixture of young men and maidens. THOMAS REECE.

48, *Great Marylebone Street, London, W., Nov.* 26.

ERRORS IN PRESCRIBING.

Sir,—The writer of the article "The Month," in the *Pharmaceutical Journal* of this date, remarks—

"There are probably few chemists who could not call to mind cases in which had the prescriptions been dispensed as written, disastrous consequences must inevitably have resulted."

I can fully endorse the justice of these remarks, and numerous cases of the kind have come under my own observation. I enclose you a copy of prescription, ordered for a young man in a delicate state of health, and imagine that had the chemist not exercised his knowledge and vigilance, the services of the undertaker would soon have been required.

Copy of prescription brought to be dispensed October 15:—

℞ Acid. Nitrici Dil.		ʒj
Tinct. Cascarillæ,		
Tinct. Zingiber,		
Tinct. Lupuli	āā	ʒiij
Aq. Laurocerasi ad		℥vj

M. Capt. pars 6tam. ter in die ante cibum.

EXPLOSION OF OXYGEN GAS.

Sir,—Reading the account of the late explosion of oxygen gas at Moira I am reminded of what occurred to me many years ago when preparing this gas from a mixture of oxide of manganese and chlorate of potassium in a glass bolt head cased with copper.

For some time after heat was applied there was no sign of evolution of gas and then suddenly the cork and delivery tube were expelled with a loud explosion, accompanied, as I thought, with a flash of light. I picked up the cork and delivery tube and re-inserted them into the uninjured flask when a perfect torrent of gas came off as fast as I could collect it.

I was sure, in this case, that the elastic delivery tube was pervious on commencing the experiment, and the only way I could explain the violence of the reaction was on the theory that suddenly a large volume of gas was set free from the chlorate and hence the explosion.

JOHN C. THOROWGOOD, M.D., F.R.C.P.

Welbeck Street, November 21, 1877.

TINCTURE OF QUININE.

Sir,—May I suggest that in the preparation of tincture of quinine the hydrochlorate of quinine is in every respect superior to the sulphate? It dissolves *at once* in the tinct. of orange peel and is immediately ready for use without even filtering, making a permanently clear solution. A reduction of one tenth should be made in the quantity used as it contains a larger proportion of alkaloid.

I think the hydrochlorate of quinine might with advantage have a place in our next Pharmacopœia; it is fairly soluble in cold water and for many purposes a more convenient salt than the sulphate.

As "soluble quinine" I supply it to my customers and find it is appreciated.

Scarbro', November 24, 1877. JOHN WHITFIELD.

Wholesale.—Try ordinary flour paste, with as much dilute sulphuric acid added as will give it a strongly sour taste.

F. Y. R.—(1) Brilliantine: a solution of castor oil in eau de Cologne, 1 in 4 (Beasley). (2) Syr. ferri et calcis lactophosphatis: see vol. vi. of present series, p. 883.

"*Ignoramus.*"—The green colouring matter is soluble in spirit, and therefore should not be absent.

J. H.—The proportion of potash contained in wood ashes varies very considerably, according to the plant from which they are obtained and other circumstances. A series of tables is given in Richardson and Watt's 'Chemical Technology,' vol. i., part 3, p. 447.

Omega.—Rub the powder with a little of the water first, so as to form a paste, and then add the remainder.

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Bate, Mr. Price, Dr. Symes, Professor Prescott, Mr. Mackay, Mr. Kinninmont, Mr. Burgess, Mr. Edwards, Mr. Phillipps, Mr. Stokoe, Occidens, Soft, L. J. R., J. C. H.

NITRITE OF ETHYL.*

BY JOHN WILLIAMS, F.C.S.

At the last Evening Meeting of this Society, Mr. Rimmington made an interesting communication upon the subject of Sweet Spirit of Nitre. Still, more interesting perhaps was the discussion which ensued; at any rate, I was much struck by the remark of Professor Attfield, that the oily liquid separated by a saturated solution of chloride of calcium from spirit of nitre, as directed in the Pharmacopœia, did not represent simply nitrite of ethyl, as might be inferred from the Pharmacopœia, but was a liquid of a very composite character, the nature of which he declared his inability to define. His remarks also tended, I thought, to disparage the value of spirit of nitre altogether as a medicine. Professor Redwood, on the contrary, remarked that as nitrite of amyl was known to possess great medicinal power it was fair to infer that the nitrite of ethyl was also a body of considerable power, and that the old remedy of sweet spirit of nitre had not gained its popular reputation without a cause.

It struck me that a short paper upon nitrite of ethyl, and its mode of preparation in a pure state, might prove of interest and tend to clear up some of the contradictory statements frequently made regarding the nature and properties of sweet spirit of nitre. Nitrite of ethyl can be prepared by the Pharmacopœia process, but is best made by passing nitrous acid gas into alcohol. The nitrous acid gas is prepared by acting upon such bodies as starch, copper, mercury or arsenious acid with nitric acid. I need not dwell upon that part of the process. The alcohol is generally recommended in the text books to be diluted with half its bulk of water; this, however, is I consider a decided mistake. The alcohol should be as concentrated as possible, even absolute alcohol is preferable. The main points to be attended to are that the current of nitrous acid gas should be slow and steady so as to give time for the reaction to proceed properly, and that the vessel containing the alcohol should be kept as cool as possible; in this way much of the production of bye-products will be avoided, and the gas can be passed through the alcohol as long as it continues to be absorbed.

The resulting liquid (of which a sample is on the table) is anything but pure; it contains much nitrite of ethyl, some aldehyde, acid,—it is even stated to contain malic acid. In fact, it is well known that the reaction between the nitrous acid and such products as alcohol, however pure, is not sharp, but is always accompanied by secondary products.

Thus amyl alcohol, even when as pure as can be made, yields under like circumstances in addition to nitrite of amyl a number of substances, some boiling up to 200° Cent., and it appears some cyanogen compounds. This subject is, however, being investigated by Mr. Miles Smith, and will probably form the subject of an interesting communication.

It may be remembered that in a former edition of the 'Edinburgh Pharmacopœia,' sweet spirit of nitre was ordered to be prepared by passing the gas evolved from a given quantity of starch and nitric acid into a known quantity of spirit of wine. The product was not however found satisfactory as a medicine, and must have been a very impure preparation.

From the crude alcoholic solution obtained by the method I have described, the pure nitrite of ethyl can be obtained without difficulty. Nitrite of ethyl is an extremely volatile liquid; it boils at about 61° F., whereas aldehyde boils at 90° F., and alcohol at 180° F. Taking advantage of this fact we are able to separate it from the crude liquid by distillation. Some precautions, however, are necessary to ensure the purity of the product. The flask containing crude product is placed in a water-bath, and connected by bent tubes with several other flasks and bottles. The first tube should be passed into a small empty flask, this will condense most of the alcohol which may pass over during the operation. Then a second bent tube passes into a second flask containing a little water; this condenses any alcohol which may not have been stopped in the first flask, together with free acid and nearly all the aldehyde. From this wash bottle a third tube proceeds into a somewhat shallow flask, containing a strong solution of caustic potash; the gas is, however, not allowed to pass through this alkaline liquid, but simply over the surface. In this way the last portion of aldehyde is absorbed, and the potash solution gradually assumes an amber colour. From this vessel the gas (for such at the ordinary temperature of the laboratory the nitrite of ethyl is—in very cold weather it would be necessary to gently warm the different flasks) is passed through a tube charged with anhydrous chloride of calcium to absorb moisture, and the pure and dry nitrite of ethyl thus produced finally passes into alcohol, which readily absorbs it. It is only necessary to note the weight of the alcohol used for absorbing the gas and its weight at the end of the operation to know the strength or percentage of nitrite of ethyl which must be in solution. Thus if 9 oz. alcohol becomes 10 oz. it is evident we have a solution of 10 per cent.; if it becomes 12 oz., then the strength must be 25 per cent. and so on. Specimens are on the table of 5, 10, 25, and 50 per cent. solutions thus obtained. Ordinary spirit will answer for condensing the nitrite of ethyl, but it is better to use absolute alcohol, as it is very desirable to avoid the presence of water in any form. The solutions made with weaker spirit soon turn acid; those made with absolute alcohol, on the other hand, keep a long time. It is true the very strong solutions of 50 and 25 per cent. show traces of acidity when tested with moistened litmus paper, but the 10 per cent. solution is quite neutral.

One point I have not mentioned; it is that the distillation must be conducted at the very lowest possible temperature; in fact, the water in the water-bath should only be kept gently warm, and the process should be continued only so long as the conducting tubes feel cool to the touch; when they become warm the distillation should be discontinued. By passing the gas into a tube in a freezing mixture, instead of into alcohol, the pure nitrite of ethyl is readily obtained in a liquid form; it is, however, necessary to seal the tube, otherwise the very volatile liquid would soon be lost.

These solutions of nitrite of ethyl in absolute alcohol possess the following characters:—The 50 and 25 per cent. solutions as already mentioned are slightly acid, the 10 and 5 per cent. are neutral. They are not coloured brown by caustic potash, even when boiled. The sp. gr. is as follows:—

At 60° F.	10 per cent.	·810
	25 „	·824
	50 „	·850

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, Dec. 5, 1877.

When treated with saturated solution of chloride of calcium, as sweet spirit of nitre is ordered to be tested in the Pharmacopœia, the following results are obtained:—

The 50 per cent. gives a separation of 48 per cent. of oily liquid by measure.
The 25 per cent. gives quite 23 per cent.
The 10 per cent. gives only 5 per cent.
The 5 per cent. gives a thin but decided oily film, not quite sufficient to measure, but quite tangible.

Now when we consider that the nitrite of ethyl is a heavier body than the alcoholic solution tested, it having a specific gravity of ·947, it appears that the stronger solutions yield very nearly, if not quite, the whole of the nitrite in a free state, but the 10 per cent. solution suffers a loss apparently of about 40 per cent., and the 5 per cent. solution of nearly the whole of the nitrite.

This 5 per cent. solution appears to represent (supposing the active medicinal ingredient of sweet spirit of nitre is nitrite of ethyl) the strength of the best samples of sweet nitre obtainable in the shops of London. I need hardly remind the meeting that many samples, even when obtained from first-class houses, yield no trace of oily stratum, and only a few yield sufficient to indicate its existence, and so clearly is this fact recognized that it has had much to do with giving rise to the doubt as to the nitrite of ethyl being indeed the active ingredient of spirit of nitre.

As some precautions are necessary in applying the test of the chloride of calcium solution, it may not be out of place if I here give my experience of the matter. It must be remembered that when the solutions of nitrite of ethyl and chloride of calcium are mixed considerable elevation of temperature takes place, and unless care be taken some of the very volatile nitrite of ethyl will certainly be lost. Even under the best conditions it is probable some loss occurs. I employ a tube of 27 inches long and about $\frac{5}{8}$ in. in diameter, sealed at one end and divided into two unequal portions; one, the lower division, being of twice the capacity of the upper and containing 400 grains; the upper division containing 200 grains is also graduated into 2-grains divisions—thus each graduation represents one per cent. of the oily liquid which may separate. The solution of chloride of calcium is poured into the tube until the proper mark is reached; the solution of nitrite of ethyl (or spirit of nitre as the case may be) is then gently poured on the top to the proper point; the tube is then corked, but not too tightly, for fear of its bursting. The tube should now be placed under a tap of running cold water and gently inverted, and then in about a minute reversed, and this repeated very slowly and with the stream of water constantly passing over the tube several times; in about three minutes the two liquids will have been sufficiently mixed and the nitrite of ethyl separated as an oily liquid floating in the upper part of the tube; but even when this operation is most carefully conducted it is probable some loss of the volatile liquid is incurred.

The principle I have explained in this paper of distilling pure dry ethyl nitrite into a known weight of alcohol, noting the increase in weight and so obtaining solutions of definite strength, is very applicable to other substances. Thus nitrite of methyl, a body boiling at −12° Cent. or 17° Fahr., and therefore a permanent gas in our climate, can readily be prepared in the same manner and in the same apparatus as I have described in this paper, substituting methyl for vinic alcohol; the gas is very soluble and easily absorbed by alcohol. A solution is on the table of 10 per cent. strength. Chloride of ethyl also, another highly volatile liquid, boiling at 12·5° C., can be absorbed. A solution of this substance of 20 per cent strength is also on the table.

Aldehyde also by taking suitable precautions, which I need not here describe, is easily procured as a pure dry gas, and can be condensed in alcohol. A solution thus made of 25 per cent. is on the table. When this solution of aldehyde is shaken with twice its weight of concentrated solution of chloride of calcium no separation of any oily liquid takes place, but the two liquids mix without change; in this differing materially from the nitrite of ethyl.

In this paper it will be observed I have only incidentally alluded to sweet spirits of nitre, and the process for making it as given in the Pharmacopœia. I think it must be apparent that we never can hope to obtain a perfectly definite and constant product by any such process as that hitherto recognized for producing that article. Mixing certain ingredients in a retort and distilling something out is not exactly a process which modern chemistry can recognize as a proper one if a definite product is desired. The product will vary, even if the proportion of ingredients be kept exact, by many circumstances—the quantity acted upon, the temperature at which the process is carried on, even shape and kind of apparatus would all have an effect in altering the nature of the product.

Perhaps the day may come when pharmacists will be required to produce active medicines in a pure and definite form; then some such process as the one I describe may be employed for such bodies as compounds of ethyl, etc. I think there is good evidence that even now medical science requires more exact pharmaceutical preparations than heretofore. The great use made of the vegetable alkaloids in preference to the raw drugs from whence they are obtained, and the increased use of definite chemical products in place of the uncertain vegetable infusions and extracts of past times, is I think a proof of the change to which I allude.

It may be objected that such preparations would be more expensive; that would probably be the case, but I do not think such a circumstance should be allowed to have weight in considering this question. When life or health is concerned it is surely not too much to use our best and utmost power to produce the medicine which will most certainly produce the desired effect. And again, should the time ever arrive when such preparations are demanded on a large scale for medicinal use, or even become officinal, competition may be trusted to reduce the cost of producing such products to a fair and reasonable level.

I cannot conclude without expressing my thanks to Mr. Miles Smith, to whose suggestions I am much indebted, and who has most carefully prepared the various solutions I have been able to place on the table this evening.

THE COLOUR OF PODOPHYLLUM RESIN.*

BY DR. A. SENIER, F.C.S., AND A. J. G. LOWE,

Assistants in the Laboratories of the Pharmaceutical Society.

Resin of podophyllum is described in the British Pharmacopœia as "a pale greenish-brown amorphous powder." In commerce it is found to vary much in colour, from different shades of yellow to brown and green. The question from a pharmaceutical point of view is, Does the colour indicate difference of composition or of strength and is it admissible to use specimens different in colour to that described in the Pharmacopœia?

In the case of three commercial specimens, which we will call *a*, *b*, and *c*, *a* was of a deep orange-brown colour, *b* a yellow-chrome, and *c* a bright lemon-yellow. It was noticed as significant that the dark *a* was about twice the density of the light *b*. This difference in density led to an examination of physical differences. The microscope showed that the particles of resin constituting the dark and heavy *a* were decidedly larger than those of the pale yellow and light *b*. By trituration, the dark *a* was obtained of a much lighter colour, approximating the pale yellow *b*. By fusing *a* in water and coarsely powdering the deep brown mass a darker colour was obtained. Fused and treated in the same manner, pale yellow *b* gave a resin like that from *a*. By further triturating the dark powders obtained, colours successively lighter were produced until pale yellow *b* was again approximated. Commercial specimen *c* was subjected to the same treatment, the results agreeing with those from *a* and *b*.

A was next dissolved in rectified spirit and the concentrated tincture dropped rapidly into water well agitated. Volumes of water, varying from two to twenty, were employed. The resins washed and dried over sulphuric acid were all of a light yellow colour. That from twenty volumes was the lightest, and was identical in appearance with commercial specimen *b*. A solution of *b* in rectified spirit was then precipitated by means of water acidulated with hydrochloric acid—the strength ordered by the British Pharmacopœia. Using two volumes of acidulated water, a resin was obtained darker than *a* and about the same colour as that produced by fusion and slight trituration from either *a* or *b*. All the dark specimens were found to be heavy and all the pale specimens light.

It is well known that water precipitates the resin slowly and imperfectly, while acidulated water precipitates it rapidly and completely. We may add that small proportions of water precipitate the resin in a much finer state of division and of a much paler colour than the same proportions of acidulated water. It is stated by several writers that washing with hot water deepens the colour of the resin. We can confirm this, and find it to be due to partial fusion and agglomeration of the particles.

We found then that dark specimens of resin might be made darker or lighter, and light specimens darker by suitable physical treatment. These facts led us to conclude that the sizes of the resin particles and consequent variation in density of the powder was probably the whole cause of the difference in shade observed in commercial resin; and that in this respect resin of podophyllum was analogous to common resin, which may be obtained of shades varying from deep red to nearly white by different degrees of comminution. We speak of shade as distinct from colour because difference of comminution does not account for variations in colour, which in commercial specimens is a matter less noticeable and of much less importance to the pharmacist.

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, Dec. 5, 1877.

It was next decided to make synthetical experiments with tincture of may-apple rhizome itself, to try the effect of different proportions of water or acidulated water in the precipitation and also to try the effect of varying the strength of the tincture employed. For the preparation of the tincture of may-apple rhizome of commerce we are indebted to the kindness of Messrs. Godfrey and Cooke. The directions of the Pharmacopœia were followed and the tincture obtained was concentrated—every 2500 c.c. being reduced to 365 c.c. In the following experiments the resin was collected, washed, and dried, either by simple exposure to the air or over sulphuric acid. Distilled water was used throughout.

No. 1.

Concentrated Tincture	1 part.
Acidulated Water	2 parts.

No. 2.

Concentrated Tincture	1 part.
Water	2 parts.

No. 1 gave a dark brown resin, somewhat darker than the dark commercial specimen *a*. No. 2 was pale buff, a trifle denser than commercial specimen, *b*.

No. 3.

Concentrated Tincture	1 part.
Acidulated Water	10 parts.

No. 4.

Concentrated Tincture	1 part.
Water	10 parts.

No. 3 was a shade lighter than No. 2 and almost white compared with No. 1. No. 4 was lighter than No. 2, and pale yellow.

No. 5.

Concentrated Tincture	1 part.
Acidulated Water	20 parts.

No. 6.

Concentrated Tincture	1 part.
Water	20 parts.

No. 5 corresponded in colour with No. 3, and No. 6 with No. 4. The density of each was found to be decidedly less than that of light commercial specimen *b*.

No. 7.

Concentrated Tincture	1 part.
Acidulated Water	3 parts.

No. 8.

Very Dilute Tincture	1 part.
Acidulated Water	3 parts.

No. 7 is the form directed by the British Pharmacopœia. It produces a mass, which when coarsely powdered gave a heavy deep brown resin. A lighter colour was obtained by further trituration, but we never succeeded in obtaining the colour described in the British Pharmacopœia. No. 8 was only a shade lighter in colour. Solutions of Nos. 1 and 5 were then made in rectified spirit (1 to 10), and precipitated by small and large quantities of acidulated water. The resins obtained from both tinctures, so far as shade was concerned, were the same; that is one from each was light like No. 5, and one from each was dark like No. 1. These synthetical experiments go to confirm the previous ones that difference in shade depends upon the state of comminution,—that the pale coloured resins are light in density and are composed of small particles, while the dark coloured resins are heavy and composed of larger particles.

Concerning the colour of the resins as distinct from shade the above experiments furnish a few points to be noticed. Using large quantities of water or acidulated water as in Nos. 3—6, no difference in shade was noticeable and the state of division was about the same. In Nos. 4 and 6, where water alone was employed, there was a distinct yellow colour, which was more or less transformed into a buff in Nos. 3 and 5 where large proportions of hydrochloric acid water were used. This was most evident where Nos. 1 and 5 were redissolved and again precipitated from a large quantity of acidulated water; in the last case a green tint appeared. The distinct yellow tint in Nos. 4 and 6 was most evident in those portions which were the last to subside and was due probably to the slow separation of the natural compound of the yellow colouring matter which exists in the rhizome. It is not due, as will presently appear, to the separation of a salt of berberina, as some have supposed. In regard to the presence of berberina, Wood* says that muriate of berberina imparts its colour to the resin of the British Pharmacopœia. Maisch† says that berberina which had been stated by Mayer‡ to exist in may-apple rhizome may occur in the resin, especially when it is precipitated from water acidulated with hydrochloric acid. In view of these statements we examined resins *a*, *b* and *c* for berberina by washing them with hot water, concentrating the filtrates and treating separate portions with hydrochloric acid (Maisch), potassium mercuric iodide and other alkaloidal reagents. In every case the result was negative even after standing. The same result was obtained from resins of our own manufacture and from large quantities of concentrated filtrate after removal of resin.

In a paper before the last meeting of the American Pharmaceutical Association, at Toronto, an abstract of which has lately appeared, Mr. Power reports the absence of berberina in the rhizome. Professor Maisch in the discussion which followed is reported to have said that only in some cases were traces of alkaloid found. In the case of three samples of resin examined by Beach,§ two were found to contain traces of alkaloid. The probability is that the presence or absence of berberina in the rhizome is variable and that it never occurs in large quantity. Traces only may, therefore, sometimes be expected in the resin. At all events we are justified in saying that the yellow colour of some specimens of resin is not due to berberina. It is due doubtless to the acid colouring matters of the rhizome, and may be heightened by the use of certain solutions instead of water or acidulated water. Alum water gives a bright yellow resin, as was pointed out by Professor Maisch at Toronto. The use of alum, however, increases the ash. In one experiment we found the ash to be ·8 per cent.,‖ whereas the resin made by us with water or acidulated water never gave more than ·1 per cent.; this small proportion of ash always contained phosphates. We have examined the ash of several commercial samples, with the following results, expressed in percentages:—2·4, 2·5, 1·, 1·2, 1·6, ·5, ·2, and 4·1.

Some of these ashes point to the use of solutions of alum or other substances, whilst the rest are probably due to different sources of contamination. We have now pointed out some of the possible causes of the variations in colour observed in podophyllum resin. That these changes of tint do not affect the activity of the resin may be taken as certain. With the exception of the alum water experiment, the processes producing them are covered essentially by the official processes of the United States Pharmacopœias of 1860 and 1870, and that of the British of 1867. We have, however, obtained confirmatory physiological evidence in the case of experiments made upon ourselves. The bright yellow resin obtained by the use of alum water was also tried physiologically and found to be equally active.

It appears, then, that the variations of shade and colour seen in commercial podophyllum resin do not affect its physiological activity. There would be no disadvantage to the patient therefore if these various coloured commercial resins were substituted for the particular coloured resin ordered by the Pharmacopœia, provided, of course, that they answered in other respect the official requirements.

In conclusion, we have to express our obligation to Mr. E. M. Holmes for suggesting this investigation, and for several of the specimens examined; to Messrs. J. Moss, C. Umney, H. G. Greenish, and H. Senier, for other specimens; and to Professor Attfield for permitting the experiments to be conducted in the laboratories of the Pharmaceutical Society.

NOTE ON RHEUM OFFICINALE GROWN IN ENGLAND.*

BY HAROLD SENIER, F.C.S.

In the *Pharmaceutical Journal* (series iii., vol. vii., No. 364), Mr. Holmes has described the history and mode of cultivation of some plants of *Rheum officinale*, grown by Mr. Usher of Banbury, pointing out their botanical characteristics, and comparing the physical appearance of the root with that produced by the East Indian plant. Since, by the more rapid growth of this species, the yield is much larger than that of the *Rheum rhaponticum*, as grown in this country, it becomes a matter of interest to know whether it can replace this latter species commercially, and also how it varies in medicinal properties from the East Indian root, supposed to be derived from the same species.

In order to attain these objects, I first compared the powdered roots and the two simple official preparations of them, the infusion and extract.

The powders, when prepared quite dry and passed through sieves of the same fineness, show a marked difference in colour, the English *Rheum officinale* being the brightest, the East Indian coming next, and lastly *Rheum rhaponticum*.

The infusions, when prepared according to the

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, Dec. 5, 1877.

British Pharmacopœia, vary but little in colour, that from the English *officinale* being a little darker than the other two.

The extracts.—The amounts of extract derived from the three varieties were estimated first by manipulating in the manner directed in the British Pharmacopœia, and, secondly, by using rectified spirit in place of the weak spirit ordered in the preparation of the official extract. In each case average portions of the roots were reduced to an equal state of comminution and the greatest care taken that each sample should be acted upon by the solvent in the same degree. Operating in this way I obtained by the official process from the East Indian root 45 per cent., from *Rheum rhaponticum* 29 per cent., and from the English *Rheum officinale* 25 per cent. of dry extract.

By using rectified spirit as the solvent, I obtained from the East Indian root 38 per cent., from *Rheum rhaponticum* 21 per cent., and from English *Rheum officinale* 17 per cent. of dry extract. This latter extract I believe to be a more reliable basis of comparison than that obtained by the process of the British Pharmacopœia, insomuch as it contains all the supposed active principles of the rhubarb (notably chrysophanic acid, emodin, rheotannic acid, and a resinous body, phœoretin), minus a certain quantity of albuminous matter.

The ash was estimated in order to obtain an idea of the quantity of oxalate of calcium present in the root, and gave the following results:—East Indian 12·72 per cent., *Rheum rhaponticum* 7·9 per cent., and English *Rheum officinale* 4·66 per cent. These results point to the conclusion that the root of *Rheum officinale* is of less commercial value than that of *Rheum rhaponticum*, and are what one might expect from the rapid growth of the root—this particular sample being produced in about three years; so that if this species does produce any of the foreign rhubarb of commerce, its growth must become much less rapid after a certain age. But it does not necessarily follow that because the root yields less extract, that it is of less medicinal activity than the East Indian root, and in my own experience, I have found a ten grain dose of its extract produce a very decided cathartic effect. This, however, is a point which can only be decided by experiments on a large number of patients, and must be left to the medical profession to determine.

In conclusion I must express my thanks to Mr. Holmes, who has kindly provided me with the necessary specimens of rhubarb, and to Messrs. Godfrey and Cooke for permission to make the experiments in their laboratories.

St. George's Place, London.

[*The discussion on this paper is printed at p.* 456.]

FALSE ANGOSTURA BARK AND BRUCIA.*

BY W. A. SHENSTONE, F.C.S.

I. In the course of the work described in this paper it has frequently been necessary to repeat the fundamental experiment employed in my investigation upon the action of nitric acid on brucia. All my results have been concordant with those formerly obtained; invariably when brucia from ordinary sources is treated with 5 per cent. nitric acid, and the product rendered alkaline and extracted with chloroform, a residue is obtained on evaporating the chloroform, which consists of nearly pure strychnia; with equal regularity I find that after careful purification of the brucia the amount of strychnia obtained is very small, though to attain absolute purity is a matter of considerable difficulty. As strychnia is destroyed by rough treatment with even so weak an acid as the above, these statements only hold provided the operation is performed with due care; on the other hand, by the exercise of this care the process becomes an excellent method of detecting, and even of estimating strychnia in brucia; indeed, I have been unable after many efforts to devise any plan equally satisfactory, and I now habitually use it in the examination of brucia, though, as I am not unconscious of the objections to it, I only adopt it provisionally as the most delicate method I am at present acquainted with.

My exact method of working is as follows: about ·5 gram of brucia is placed in a test-tube with 3 or 4 c.c. of the dilute acid, and warmed rather gradually by immersion in a beaker of hot water, effervescence occurs, and presently yellow crystals of cacotheline are deposited. Directly these make their appearance solution of potassium hydrate is added in excess, and the mixture is cooled by placing the test-tube in cold water; it is then extracted by agitation with chloroform, and the residue obtained by evaporating the chloroform is tested in the usual way. When the amount of strychnia is small, it is necessary to char the residue with sulphuric acid before testing it, as the chloroform usually extracts a small quantity of a resinous substance which masks the reaction of the strychnia. I find this interfering substance is, to a great extent, removed by washing the chloroform with a small quantity of water, to which a drop of solution of ammonia has been added.

I have employed the above method in examining quantitatively four specimens of brucia, obtained from sources of high character, with the following results, which may be regarded as indicating the condition of the best brucia ever employed in pharmacy:—

In cases II. and IV. two experiments were made on two portions of the same sample.

I. Reported in a former paper contained 1 to 1·5 per cent.

II. (*a*) ·687 gram of brucia gave ·003 gram = ·43 per cent. of strychnia.

(*b*) ·860 gram of brucia gave ·004 gram = ·46 per cent. of strychnia.

III. ·859 gram of brucia gave ·009 gram = 1·05 per cent. of strychnia.

IV. (*a*) ·629 gram of brucia gave too little to be worth weighing, apparently under ·25 per cent. of strychnia.

(*b*) ·538 gram of brucia gave too little to be worth weighing, apparently under ·25 per cent. of strychnia.

In all the above cases the strychnia obtained was of a pale straw colour, and free from brucia,

II. It will be observed that in only one of the four samples examined was the amount of strychnia sufficiently small to be at all unimportant, when we consider its great activity. This induces me to mention my present method of purifying brucia, the method indeed by which I propose to purify a supply for experiments upon its physiological action; it has several advantages over the process of frac-

* Read at an Evening Meeting of the Phaamaceutical Society of Great Britain, Dec. 5, 1877.

tional precipitation I have previously suggested and employed, though in principle the two plans are alike. I now crystallize the brucia by cooling a solution of it in boiling water to which a few drops of acetic acid have been added, and I find that one crystallization has considerably more effect in removing strychnia than a single precipitation; it also entails less loss (at any rate on a small scale), is less troublesome, and yields the alkaloid in a much better condition. It is, however, imperative, for reasons given later on, to avoid applying prolonged heat to a solution containing brucia, in this or in any other part of its manufacture or purification.

In connection with this process, I may mention that the relative solubilities of brucia in hot and cold water are generally inaccurately stated; usually it is said to dissolve in 850 parts of cold, or 500 parts of hot water. This is very far from being correct. Hanbury, in 'Pharmacographia,' states that one part dissolves in 150 parts of boiling water, which, as far as my experience goes, is much nearer to the truth; I have not attempted an exact verification, however, on account of the difficulty of obtaining a really saturated solution, and of the rapid alteration to more soluble bodies which brucia undergoes when heated with water. I have alluded to this, because the convenience of my process of purification depends upon Hanbury's expression of the solubility being more nearly correct than the general one.

III. In the discussion on a paper of mine, read at an evening meeting in February, 1877, some curiosity was expressed as to the presence of strychnia in false angostura bark. This same question had for some time been interesting me; I had, indeed (through the kindness of Messrs. P. W. Squire and Son), a small supply of the bark in my possession, which I had reserved from a large quantity that had been used in an unsuccessful attempt to prepare pure brucia for my examination of the "conversion into strychnia" question, and which I had decided to devote to an examination for strychnia.

It is impossible to detect strychnia by its ordinary reaction with bichromate and sulphuric acid in the presence of any quantity of brucia, even if other organic substances are absent. I have, however, succeeded in isolating strychnia from strychnos bark, by the following modification of the process employed by Pelletier and Caventou, in the research by which they discovered the, then new, active principle, brucia. These investigators commenced their examination of strychnos bark with the expectation of extracting strychnia from it; that they failed to do so is not surprising, for they had themselves quite recently discovered strychnia, and were only aware of its more obvious properties, and consequently had not the necessary knowledge for separating it when in very small quantity.

Three and a-half ounces of the bark was exhausted by roughly powdering and repeatedly boiling with fresh portions of rectified spirit; the various alcoholic decoctions so obtained were united and the spirit distilled off, the residue was diluted with water, and evaporated to a small bulk to remove the last traces of spirit, again diluted, warmed and after cooling filtered; to the filtered solution excess of subacetate of lead was added to precipitate colouring matter, which was filtered off, and lead removed from the filtrate by a current of sulphuretted hydrogen; after boiling to expel excess of this gas, the liquid was boiled with magnesia, filtered, and the residual magnesia well washed with boiling water, the washings being added to the filtrate; the mixed filtrate and washings were evaporated to dryness,* the residue dissolved in acidulated water, and the acid solution, rendered alkaline by ammonia, was repeatedly washed with ether; the ethereal solutions were combined and distilled, and the extract which remained after distillation was treated for some hours with sulphuric acid on a water-bath, then diluted, and after addition of excess of ammonia again extracted by agitation with ether; this ether on evaporation yielded a residue, which though not colourless gave ample indication of consisting largely of strychnia. The impurities appear to be, a trace of brucia, and a resinous body, difficult of destruction, which at first prevented the strychnia from crystallizing, though I afterwards succeeded in obtaining the hydrochloride in the crystalline form. These impurities might probably have been removed by treatment with weak nitric acid, but when I did the above work I was not so well acquainted as I am now with that method, and I adopted the safer, though less delicate, process of extracting with ether from an alkaline solution, in consequence of having previously observed that this solvent will to a considerable extent separate the two alkaloids if there is as much as one or two per cent. of strychnia in a mixture of them; generally the strychnia is accompanied by a small quantity of brucia.

False angostura bark does therefore contain strychnia, though only in small quantity. The statements to the contrary in Watt's 'Dictionary' and elsewhere are doubtless due to the unsuccessful attempt to extract it of Pelletier and Caventou.

The brucia whose physiological action was examined by Pelletier and Caventou was prepared from this source, and therefore probably contained strychnia, and, from the results of my examinations of commercial brucia, and the varying reports of the degree of its activity given by investigators, I have come to consider it very doubtful if the physiological effects of *really pure* brucia have ever been studied, and to think it not impossible that the strong resemblance of its action to that of strychnia may even be due to the proportion of strychnia which it contains. I have reason to hope that this interesting question will before long be thoroughly investigated.

IV. When purifying brucia by crystallization from boiling water to which a few drops of acetic acid had been added, I was not at first aware of the extent of its solubility, and I hoped to avoid the loss, which otherwise seemed unavoidable, by employing the mother liquor from each crop of crystals for a fresh crystallization. Operating in this way I obtained two yields of nicely pure brucia; but subsequent products were somewhat dark coloured, and the loss was greater than I anticipated from the solubility of the alkaloid in cold water. Hoping to recover some of this loss I left the mother liquors, which had now

* During an unavoidably prolonged absence at this point the water-bath employed for the operation went dry, and the part of the residue nearest the bottom of the dish was a little charred. Whether any serious loss of strychnia resulted I am unable to say. I state the circumstance as it may be that the amount obtained at the end of the experiment is not even the greater part of the total quantity in the bark, though considering the difficulty of destroying strychnia by treating with sulphuric acid, and the degree of the charring, I am of opinion that the loss was not considerable.

rather a dark colour, to spontaneous evaporation during a period of eight weeks in the warm weather of the summer, and, meanwhile, met with the investigations of the "Aconitine Committee" on the saponification of that alkaloid, and of Buchheim on similar operations with atropia. Consequently, I was not surprised to find after this interval that the fluid, which I now first noticed to have a strongly acid reaction, had deposited fine crystals of a brown colour. I obtained a further quantity of the same substance in smaller crystals by evaporating to a small volume; and finally by evaporating to dryness I got a mass of a darkish yellow deliquescent solid.

As far as I have examined them these bodies have the following properties:—

The brown crystals.—Soluble in hot, less so in cold water, freely soluble in alcohol, insoluble in ether, contain nitrogen, reddened by nitric acid; an aqueous solution gives with ammonia a white precipitate, which also is reddened by nitric acid. Probably, therefore, this is a new salt of brucia, though the base is not necessarily brucia, as other bodies, viz., the igasurines, are affected like brucia by nitric acid.

The yellow substance.—Chiefly soluble in water and spirit, not reddened by nitric acid, had an acid reaction,* is precipitated in crystals from solution in spirit by the addition of an equal volume of ether, slowly changes colour on exposure. In some respects, but not in all, it resembles Ludwig's igasuric acid.

When brucia is boiled for some hours with a solution containing rather more than 1 per cent. of caustic potash, the solution gradually becomes yellow, and after filtering and evaporating over sulphuric acid *in vacuo* yields some bright, pale yellow crystals, soluble in alcohol, reddened by nitric acid, and which on crystallizing from weak spirit are more or less completely changed to white silky crystals, an alteration which may be due to an altered state of hydration. After removing this body, I have not yet succeeded in separating any other satisfactory substance from the mother liquor.

By boiling with distilled water brucia rapidly becomes much more soluble. Fifteen grams, after boiling with rather more than a litre of water for forty-eight hours ceased to crystallize on cooling, and after continuing the ebullition for twenty hours longer was still strongly alkaline, and gave on evaporation a mass of a dirty brown substance, reddened by nitric acid, and apparently readily soluble in alcohol and rather less so in water. I have not further examined it at present.

I have given an account of these, so far, very incomplete experiments, which I have been compelled to put aside during the past two months, on account of their interest from a manufacturer's point of view. The readiness with which brucia seems to undergo alteration by heating with pure, slightly acid, or slightly alkaline water, rendering it very important to perform all operations of this nature in its preparation with as little heat and as much speed as may be.

I shall proceed very shortly with the examination of these reactions and their products, and of some analogous ones which I have reason to think strychnia takes part in.

[*The discussion on this paper is printed at p.* 456.]

* May have been due to acetic acid which was set free during the latter part of the evaporation of the solution which yielded this.

OBSERVATIONS ON RUSSIAN TURPENTINE OIL, AND ON OLEUM FOLIORUM PINI SYLVESTRIS.*

BY WILLIAM A. TILDEN, D. SC.

I have lately had an opportunity of examining a specimen of Russian turpentine oil, and inasmuch as it differs materially from ordinary American, as well as from the French oil, it occurred to me that the attention of pharmacists should be directed to the matter.

The crude oil possesses an odour which is quite distinct from that of ordinary turpentine oils, and is strongly suggestive of "pitch-pine" wood and sawdust.

Its specific gravity at 15° is ·8682, and it turns the plane of polarization of a ray of polarized light to the right. After shaking up with solution of soda to remove acetic acid and empyreumatic products, a quantity of the oil was submitted to distillation. The following products were received separately:—

	ozs.
(*a*) Came over at 160° C. to 171° and was rather turbid from presence of water	1
(*b*) At 171°—172°	$6\frac{2}{3}$
(*c*) At 172°—185°	$2\frac{1}{2}$
(*d*) Residue boiling at 185° and upwards, bright yellow, and rather viscid when cold	$\frac{1}{2}$
	$10\frac{2}{3}$

By far the greater part is thus found to pass over at a temperature from 14° to 15° higher than the boiling point of ordinary turpentine oil.

By careful fractional distillation and examination of the products the constituents of this oil are found to be:—

a. A liquid having the same composition and nearly the same properties as common turpentine oil, but having a stronger action on polarized light.

b. A liquid having the same composition as turpentine oil, but boiling at 171-5°, or thereabouts.

c. High boiling hydrocarbons, polymeric with turpentine oil; a small quantity only.

Complete details as to the chemical composition and properties of the new hydrocarbons will shortly be published elsewhere.

For the present it is sufficient to say that they are probably identical with the compounds recently extracted from Swedish turpentine oil by Atterberg (*Deut. chem. Gesell. Ber.*, x., 1202); but that the properties assigned to them by that chemist do not quite agree with those observed by myself as belonging to the Russian oil.

In order to render Russian turpentine oil available for pharmaceutical purposes, to which its fragrant odour specially commends it, it is only necessary to shake it up with solution of soda, to separate it, and then re-distill either alone or perhaps better in a current of steam.

From the presence of empyreumatic products in the crude oil, there can be no doubt that this oil is not procured by exudation from the living trees, but is a product obtained in the distillation of tar from the wood of various coniferæ. According to Hanbury and Flückiger the *Pinus sylvestris*, or so-called Scotch pine, is chiefly employed for this pur-

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, Dec. 5, 1877.

pose in the north of Europe. I am informed that comparatively little of this oil reaches the English market; but since its production in Russia is carried out upon a very large scale, I believe there would be no difficulty in procuring the importation of any desired quantity should a demand for it arise.

Since this matter was in my hands I have thought it worth while to examine the oil distilled from the leaves of the *Pinus sylvestris* which has lately been introduced into pharmacy, and with this object I applied to Mr. A. W. Postans, of Baker Street, who very generously sent me a supply. The examination of this oil is not quite finished, but I may venture to refer to the few facts I have established thus far. To me they are rather interesting, for on the assumption that the Russian turpentine is obtained from *Pinus sylvestris*, I expected to find that the chief constituents at least would be the same in the two oils. But this is not the case.

Ol. Fol. Pini Sylvestris, as I received it, has a specific gravity = ·8756 at 12° C. It is dextrorotatory.

$$[\alpha]_D = +6{\cdot}2^\circ \ (\lambda = \text{decim.})$$

When distilled it began to boil below 100°, but the temperature went up rapidly to 165°. The first fractions obtained were as follows:—

	Fl. oz.
(*a*) Below 165°	1
(*b*) 165° to 175°	$2\frac{1}{8}$
(*c*) 175° to 195°	$\frac{3}{8}$
195° and upwards	$\frac{1}{4}$
	$3\frac{3}{4}$

After careful fractionation two chief products were obtained—

(*a*) Boiling at 156° to 159°; dextrorotatory; almost certainly identical with common turpentine.

(*b*) Boiling between 171° and 176°.

The small quantity of material at my command has not been sufficient to enable me to get a product of perfectly constant boiling point. But this fraction has nearly the same odour as the chief terpene from Russian turpentine, and I have little doubt it possesses the same composition. It is, however, *lævo-rotatory* in its action on polarized light. It thus seems to bear the same kind of relation to the oil from the wood of the *Pinus sylvestris* that French oil (terebenthene) bears to American (australene).

From a pharmaceutical point of view, the chief result of these observations is to indicate that neither Russian nor any other turpentine oil of commerce can be said fairly to represent the ol. foliorum pini sylv., or to be a proper substitute for it. But I believe that a preparation of Russian oil might be obtained by a single distillation, which would be found very suitable and agreeable for medicinal purposes. This, however, is a question which can only be settled by pharmacists and medical men.

[*The discussion on this paper is printed at p.* 456.]

THE USE OF RUSSIAN TURPENTINE IN PHARMACY AND MEDICINE.*

BY A. W. POSTANS.

Following up Dr. Tilden's suggestion, that the use or otherwise of Russian turpentine in medicine must now be settled by pharmacists and medical men, I turned to the Pharmacopœia of India, because it seemed to me to contain a very comprehensive account of the properties and therapeutic uses of turpentine, and there I find it stated (p. 219) that the properties of turpentine are—"Primarily—stimulant, especially increasing the quantity of urine, to which it communicates a peculiar violet odour. Secondarily—sedative, antispasmodic and astringent. In large doses, purgative and anthelmintic. Locally or externally applied, a valuable rubefacient and counter-irritant."

Therapeutic uses.—In typhus, typhoid fevers, and inflammation of the lungs. In puerperal fever it has been vaunted as a specific. It is useful also in hysteria and epilepsy, also in tetanus; and in flatulent colic it proves valuable as an antispasmodic. Amongst the other diseases in which it has been used with advantage may be mentioned the advanced stages of dysentery, gonorrhœa, dropsy, and diseases of the eye.

Dose.—As a diuretic and astringent, from eight to thirty minims; as a stimulant and antispasmodic, from ʒss to ʒj; as a purgative and anthelmintic, from ℥ss to ℥j; as a rubefacient or counter-irritant it may be applied in the form of liniment or ointment.

With this evidence before us, showing something of the value of commercial turpentine in medicine, we are led to inquire how it is that the oil of turpentine preparations have not found greater favour with the profession, and the reply I think is quite easily found from the fact that all the official preparations of turpentine (owing to the turpentine itself), are nauseating, and possessed of a most unpleasant paint-like odour, which is much objected to.

Under these circumstances, and finding on examination of the Russian turpentine that far from being unpleasant it is on the contrary possessed of a most agreeable, attractive, and aromatic odour, and by no means unpleasant taste, I have been induced to make the following preparations of the British Pharmacopœia, substituting in each case the Russian turpentine, and the result has, I think, fully justified, pharmaceutically, what Dr. Tilden has stated regarding it.

Preparations.—Linimentum Terebinthinæ; Linimentum Terebinthinæ Aceticum, known as St. John Long's Liniment; Confectio Terebinthinæ.

The paint-like odour of common turpentine oil is entirely absent in preparations made with this new Russian oil. The preparations themselves resemble in appearance the old ones, but are free from the objection before mentioned, and are indeed quite agreeable.

Before concluding I would beg to be allowed to suggest a formula for its administration internally, assuming that it may be desirable to give thirty drop doses:—

℞. Russian Turpentine	ʒij.
Mucil. Tragacanth.	ʒiv.
Pulv. Amygdalæ Co.	ʒiv.
Aq. Chloroformi . . . . . ad	℥vj.

Misce secundum artem. Ft. Emulsio.

Quarter part a dose.

This seems to be a good form for its introduction.

[*The discussion on this paper is printed at p.* 456.]

THE PRELIMINARY EXAMINATION AND ITS SUPPOSED DIFFICULTIES.

IT will be seen from the report of the proceedings at the Council meeting last Wednesday, that there is still an impression in some parts of Scotland that the Preliminary examination which candidates are required to pass is too severe, and that on this account great difficulty is to be anticipated in securing apprentices. The fact that there is a large proportion of failures among those who present themselves for the Preliminary examination appears to have been regarded by the Glasgow Chemists and Druggists' Association as indicating the possibility that the candidates at recent examinations may be inferior in education to those at former examinations, or that the examination itself is more difficult than it formerly was. But in both respects an erroneous opinion appears to have prevailed, for according to the statistics furnished by the Registrar, the average percentage of failures has been less during the present year than it was from 1873 to 1876, as shown by the following figures:—

PERCENTAGE OF FAILURES.

	England.	Scotland.	Great Britain.
1872	38·019	44·961	...
1873	48·14	41·35	...
1874	52·18	42·1	...
1875	51·81	33·64	...
1876	...	...	42·4
1877	...	...	46·

From these data it is evident that the Glasgow Chemists and Druggists' Association has been misled, and that there is no real foundation either for the belief that the standard of the examinations is too severe or for the supposition that the candidates at the present time are inferior to those of previous years. The facts indicated by the foregoing statistics constitute indeed the best and most complete answer to the questions that are put to the Council, and they are calculated, not only to allay the regret expressed by the Glasgow Chemists and Druggists' Association, but also to encourage the hope that when the necessity of the Preliminary examination as a test of educational fitness for entering upon the career of a chemist and druggist becomes more generally recognized, candidates will present themselves while still fresh from school; there will then be little fear of failing in such a commonplace ordeal.

THE RIGHT TO PRESCRIBE.

WE have been informed that an opinion is entertained by some country members of the trade that in writing the concluding paragraph of the article which appeared in last week's issue upon the Right to Prescribe we failed to understand or appreciate how much country chemists and druggists are affected by the question that has been raised in regard to that subject. We do not think it necessary to acknowledge any deficiency in that direction, or to admit that the remarks contained in the concluding paragraph of the article are in any degree speculative. The tendency of the Pharmaceutical Society as a body in regard to "counter practice" is a fact beyond question, and as a justification of our remarks we cannot do better than refer to the following passage in a paper read by Mr. T. N. MORSON, in 1841, upon "The Rise and Progress of Pharmacy":—

"It is not the wish of chemists and druggists as a body to become medical practitioners. From the nature of our elementary studies we are not likely to attain excellence in the other sphere, and by grasping at a shadow we may lose the substance. At the same time, the restrictions which some persons are anxious to place upon us in regard to recommending simple medicines are more severe than judicious, and are, in fact, impracticable."

NEW POTASH FIELDS.

THE discovery of another immense bed of potash salts near Stassfurth is announced by *Iron*. It appears that the Continental Diamond Rockboring Company, having some of its machinery unemployed, made some speculative borings at Aschersleben to ascertain the limits of the Strassfurth deposits. The borings proved the existence of thick beds of potash and soda salts, supposed to be the residue of the evaporation of an inland sea, lying within the triangle formed by the three towns of Magdeburg, Halle, and Nordhausen.

Ten kinds of minerals were met with in the borings. The first found, after passing through the salt clay, was a variety of common salt and kieserit containing 18 to 20 per cent. of chloride of potassium. This was followed in succession by carnallite (upwards of 100 feet thick in many parts), a double chloride of potassium and magnesium ($KCl \cdot MgCl_2 + 6H_2O$) and kainit, a double sulphate of potash and magnesia, combined with chloride of magnesium, ($K_2SO_4 \cdot MgSO_4 \cdot MgCl_2 + 6H_2O$). Then kieserit, a monohydrated sulphate of magnesia ($MgSO_4 + H_2O$), was found in considerable quantities, forming about 17 per cent. of all the minerals extracted; polyhalit, which is a triple sulphate of lime, magnesia and potash, ($2CaSO_4 . MgSO_4 . K_2SO_4 + 2H_2O$), was found both at the top and bottom of the potash layers: in the former in the kieserit; in the latter in the salt. Common rock salt was found below the potash layers, to a depth of more than 2000 feet, and then was not exhausted. In the carnallite and kainit layers were found sylvin, nearly pure chloride of potassium; tachydrit ($CaCl_2 . 2MgCl_2 + 12H_2O$); astrakainit, a double sulphate of soda and magnesia; ($Na_2SO_4 . MgSO_4 + 4 H_2O$), and boracit ($2Mg_3B_8O_{15}MgCl_2$).

Very liberal terms are granted under the Prussian laws to mineral explorers, and the managing director is said to have secured for the prospecting company the concession of an area of nearly twenty-four million square metres of land. It is intended to commence operations for working the beds forthwith.

A NEW CHEMISTS' ASSOCIATION IN WARWICKSHIRE.

On Monday last a well-attended meeting of chemists and druggists was held in the Mayor's Parlour, Coventry, and it was resolved to form a new Society under the name of the Coventry and Warwickshire Pharmaceutical Association, which it is hoped may "prove to be the nucleus of a local centre of pharmaceutical education." An influential council was appointed, presided over by Mr. Councillor Wyley, and the new Society has been so fortunate as to secure the services of Mr. Frederick Barrett as its first Honorary Secretary.

APOTHECARIES' OR AVOIRDUPOIS.

Several more letters upon the subject of the disputed value of the ounce sign have been received, the publication of which is necessarily deferred until next week. Amongst them is one from the Editor of the British Pharmacopœia, giving his own opinion and that of a member of the Committee as to the manner in which the instructions given in the Preface to the Pharmacopœia are to be construed. As this must be held to be fairly decisive at least of what may be called the official portion of the discussion, and a considerable latitude has already been given to the expression of individual opinion, it is not intended to publish any further correspondence upon the subject beyond what has already been received.

CHEMISTS' ASSISTANTS' ASSOCIATION.

We are glad to learn that at the meeting of the above Association, held on the 28th ult., in its new room, 29, Brewer Street, Air Street, W., there was a good attendance of members and visitors. The Honorary Secretary reported that the Association now numbered 66 members, and that the funds were in a satisfactory condition, after which a paper on "Pill Making and Excipients," by Mr. Marshall, was read. Another meeting is announced for Wednesday next, when a paper is to be read by Mr. Stuart, on "A Botanical Ramble in Cumberland."

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, December 5, 1877.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Atherton, Atkins, Betty, Bottle, Churchill, Gostling, Greenish, Hills, Mackay, Robbins, Sandford, Schacht, and Shaw.

The minutes of the previous meeting were read and confirmed.

Appointment of Examiners for 1878.

The President suggested that the Council should go into Committee for the appointment of Examiners, in order that if necessary the merits of the various gentlemen whose names had been suggested might be freely discussed. This was unanimously agreed to.

The Council having resumed, and a ballot having been taken, the President declared the following Pharmaceutical Chemists to be appointed Examiners for the ensuing year, subject to the approval of the Privy Council:—

England and Wales.

Allchin, Alfred, England House, Primrose Hill Road, N.W.

Barnes, James Benjamin, Trevor Terrace, Knightsbridge, S.W.

Benger, Frederick Baden, 7, Exchange Street, Manchester.

Brady, Henry Bowman, 29, Mosley Street, Newcastle-on-Tyne.

Carteighe, Michael, 180, New Bond Street, W.

Corder, Octavius, 2, London Street, Norwich.

Gale, Samuel, 338, Oxford Street, W.

Hanbury, Frederick Janson, Plough Court, Lombard Street, E.C.

Linford, John Samuel, The Quabbs, Drybrook, Gloucestershire.

Martindale, William, 10, New Cavendish Street, W.

Moss, John, 300, High Holborn, W.C.

Southall, William, 17, Bull Street, Birmingham.

Taylor, George Spratt, 13, Queen's Terrace, St. John's Wood, N.W.

Umney, Charles, 50, Southwark Street, S.E.

Scotland.

Ainslie, William, 58, George Street, Edinburgh.

Borland, John, 7, King Street, Kilmarnock.

Kemp, David, High Street, Portobello.

Kinninmont, Alexander, 69, South Portland Street, Glasgow.

Gilmour, William, 11, Elm Row, Edinburgh.

Noble, Alexander, 139, Princes Street, Edinburgh.

Stephenson, John Bertram, 71, George Street, Edinburgh.

Young, James Robertson, 17, North Bridge, Edinburgh.

Retirement of Mr. Haselden.

The President said he could not allow the opportunity to pass without saying a word on the resignation from the Board of Examiners of Mr. Haselden from ill-health. The members of the Council were all aware that Mr. Haselden had been much affected by the death of his wife last year, and he had since suffered so much in health that he had felt unable to continue his services as examiner beyond the close of the present year. Mr. Haselden having been President of the Society, and for many years a member of the Council, nothing more need be said with regard to his good qualities. He would therefore move—

"That this Council desires to express great sympathy with Mr. Haselden in his present inability to continue his connection with the Board of Examiners, and earnestly trusts that he will shortly be entirely restored to health."

The motion, having been seconded by the Vice-President, was carried unanimously.

MEETINGS OF THE BOARD OF EXAMINERS IN 1878.

It was resolved that the examinations should be held during 1878, in February, April, June, July, October, and December in England, and in February, April, July, October, and December, in Scotland.

Mr. HILLS said he hoped the President would not forget to make arrangements for a deputation to visit the examination of the North British Branch.

Mr. CHURCHILL asked if it was proper that a young man who failed to pass in London should be allowed to go to Scotland and try.

The SECRETARY did not see that any one had any right to prevent a candidate choosing where he would be examined, provided the due interval had elapsed since his failure.

Mr. BETTY suggested that it would be well to have a return prepared next year showing the number of candidates who, having failed to pass in London, had afterwards passed in Scotland, and *vice versâ*.

The VICE-PRESIDENT said he had been informed by a young man who went from Brighton to Edinburgh with an idea that the examination was much easier there than in London, that he found this was quite a mistake.

Mr. BOTTLE, while he agreed with the plan of deputations from the two Boards visiting one another occasionally, also thought it would be well if the two Boards kept themselves a little better posted as to their own arrangements, and that no alteration should be made in the regulations without communicating from one Board to the other. He understood that the English Board had recently made a regulation not to inform a candidate who failed what subjects he had failed in. The Scotch Board, on the other hand, had still gone on in the accustomed mode of giving this information to rejected candidates.

Mr. MACKAY said he had not expected this subject to be brought forward; but as it had been mentioned he must express how much the Board in Scotland felt at such a regulation having been decided on without any communication to it on the subject. The Board in Edinburgh felt that it was unfair to a candidate who failed in certain subjects that he should not be told where his weakness lay, and that there was an inconsistency in refusing this information when at the same time a man who failed hopelessly in the first subject he attempted, was told so, and rejected at once. He believed it had been said that this rule was adopted in order to prevent unsuccessful candidates sticking very closely to those subjects in which they were low to the exclusion of the others; but he did not see any force in this objection, because the candidate knew he must pass in every subject, and the experience in Scotland was that those who had failed in certain subjects and had been told so, came up again better prepared in those points, but still kept ahead in the others. He believed that some two years ago it was an understood thing that there should be such an interchange of views as Mr. Bottle had referred to, and that deputations should go from one Board to the other. He hoped this plan would be carried out, and that opportunity would be taken of such meetings to discuss any alterations which were in contemplation, so that the two Boards might work unanimously.

The PRESIDENT said the resolution referred to was passed when the Vice-President was in the chair, and he himself was not aware of it until his attention was called to it by a letter from the chairman of the North British Branch. He had been in the habit of telling young men who had hopelessly failed those subjects in which they had been most conspicuously deficient, and he could not see that he had done wrong. But he could well understand that when a young man who went through all his subjects and failed, came next day to the office and wanted to know in what subjects he had so failed, it was not quite reasonable that the clerks in the office should have the books of the Examiners open before them and state what numbers the candidates had obtained in each subject. He did not wish any hard and fast line to be drawn, and he agreed that the resolution ought not to have been passed without communicating with the Scotch Board of Examiners.

Mr. SANDFORD thought this was a matter which should be remitted to the Board of Examiners. There were reasons given for this resolution at the time it was passed, and the Council should not prejudice the matter by discussion.

Mr. SCHACHT was exceedingly glad to hear of anything which would lead to the result of making the examinations in the two localities as nearly as possible identical. It was very desirable that every member of the Council should make himself familiar with the interior of the examination rooms, as it would tend to assist them in the future choice of examiners, and perhaps some gentlemen who might not feel quite satisfied as to the way in which the examinations were conducted might thus have their opinions modified, as he confessed his own had been.

The PRESIDENT said members of the Board of Examiners were always happy to see members of the Council.

Mr. ATKINS was glad this point had been mentioned. Hitherto he should have considered himself an intruder in the examination room.

The PRESIDENT said it would of course be impossible to have all the Council present at once; it was a matter of courtesy.

Mr. MACKAY said the Board in Scotland would be very glad to welcome any deputation of the Council which should accompany the deputation from the Board of Examiners when it visited Edinburgh in the course of the ensuing year.

THE PRELIMINARY EXAMINATION.

The PRESIDENT read the following letter from the Secretary of the Glasgow Chemists and Druggists' Association:—

"Glasgow, Nov. 30th, 1877.

"The President and Council
of the Pharmaceutical Society of Great Britain.

"Gentlemen.—At a meeting of Council of the 'Glasgow Chemists and Druggists' Association,' held on Wednesday, 21st instant, there came up for consideration 'the large percentage of failures in recent Preliminary examinations throughout the country,' remitted them by the Association, when it was unanimously resolved that your Council be approached on the subject.

"The Council have noticed with regret the very large percentage of failures, and naturally ask, why is it so? are the candidates at recent examinations inferior in education to candidates at former, or, are the questions in examination papers more difficult now than formerly?

"This Council think the reason will be found in the last-named cause; they also think that the questions are too severe as an entrance qualification to our trade, and that if such a standard be continued, great difficulty will be felt in securing apprentices. They therefore respectfully ask that your Council take into their consideration the Preliminary examinations, and that you instruct the framers of the examination papers as to the standard to be adopted by them.

"In name of the Council.

"We are, yours respectfully,

"DANIEL FRAZER, *President*,

"JOHN WALKER, *Secretary*."

The PRESIDENT said he need hardly remind the Council that the examination papers were set by the College of Preceptors, of course under general instructions from the Council or Board of Examiners. He thought the matter might be referred to the Board of Examiners.

The SECRETARY said he had prepared a table showing the percentage of failures from 1872 to the present time. In 1872 the percentage of failures was, in England, 38·019; in Scotland, 44·961. In 1873, England, 48·14; Scotland, 41·35. In 1874, England, 52·18; Scotland, 42·1. In 1875, England, 51·88; Scotland, 33·64. In 1876, when the examination papers were all set by the College of Preceptors, and all the answers came to that body, the percentage of failures was 42·4. In 1877 the percentage had been nearly 46.

Mr. ATKINS was surprised to find the position which Scotland held in this matter, from his general knowledge of the state of education in that part of the kingdom. He felt that the great cause of failure was that young men put off coming up for examination too late. The examination was intended to be preliminary to entering the business, and he was satisfied that many lads could pass the examinations on leaving school, when they might have a difficulty in doing so after three or four years. There was a case within his own experience of a young man who was really well informed, but who had failed once, and he feared he had failed in his second attempt very recently.

Mr. ATHERTON said the statistics prepared by the Secretary had answered the questions put by their Scotch friends. Having moved the resolution transferring the examinations from their own Board to the College of Preceptors, it was a matter of satisfaction to him to know that the percentage of failures had been on the whole less since this change was effected than before.

Mr. MACKAY agreed with Mr. Atkins's remarks, but he thought the cure lay rather with the masters than the young men. For some time past the leading pharmacists in Edinburgh had set their faces against binding any young man who had not passed the Preliminary examination. If all masters would follow the same rule they would very soon get rid of the objection.

Mr. GOSTLING was convinced that the Preliminary examination was not at all more severe than it ought to be. The questions were very few and simple, and he thought their friends in Scotland ought to be informed that the Preliminary examination was not in any degree too severe.

The PRESIDENT said the object of the Preliminary examination was to see whether a young man had received such an education in early life as would fit him to undergo his future examinations and to carry on the business afterwards. Perhaps their friends in Glasgow were taking their apprentices from a lower grade in society than had been the practice before.

Mr. CHURCHILL said he knew there was a feeling amongst some members of the trade, that it was more difficult to get apprentices than it used to be; he had no experience in the matter himself, but he knew the feeling existed, and he hoped the Council would consider the matter. It was a well known fact that at many schools where what was called a classical education was given English subjects were very greatly neglected, and he believed there were many who could really speak and write good English who would yet find a difficulty in answering questions on the technicalities of English grammar.

Mr. SCHACHT thought the question before them was very simple. A section of their body had memorialized the Council on the basis of certain supposed facts which on examination turned out to be imaginary, and he thought the simplest answer would be to place before those gentlemen the true state of the case.

The PRESIDENT agreeing with this suggestion, it was adopted accordingly.

ELECTIONS.

ASSOCIATES.

The following having passed their respective examinations, and having tendered or paid, as Apprentices or Students, their subscriptions for the current year, were elected Associates of the Society:—

Cowgill, Benjamin Rangdale ...Bingley.
Macdonald, Ewen..................Inverness.
Phillips, Evan ....St. Clears.

An Associate was restored to his former status in the Society on payment of a fine.

The following person was restored to the Register of Chemists and Druggists:—

George Pickrell, Burnham Westgate, Norfolk.

CHLORAL HYDRATE.

The SECRETARY read a letter received from the Privy Council, stating that the proposal of the Council to place chloral hydrate and its preparations in the schedule of poisons was still under consideration.

ST. THOMAS'S HOSPITAL.

The SECRETARY read a letter from Mr. Sydney Plowman, asking for the loan of some specimens from the museum for exhibition at the ensuing *soirée* of the St. Thomas's Hospital Physical Society, on the 13th inst.

The request was unanimously agreed to.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was read and adopted, and sundry payments ordered to be made. The report also included the recommendation to purchase £2000 stock New 3 per Cents. to the account of the General Fund.

Mr. SANDFORD proposed as an amendment, that £500 should be transferred to the Benevolent Fund.

Mr. BETTY thought such a proposal ought not to be entertained without notice having been given.

The PRESIDENT said it was important in his view that they should look to increasing the invested capital of the Society, because he hoped the day would some day come when the Society might be able to become its own landlord and have a permanent freehold home of its own.

Mr. BOTTLE asked Mr. Sandford to withdraw his resolution, because he did not think the Benevolent Fund would be really benefitted by such a grant, but would be rather damaged than otherwise. The Council was now distributing a large portion of the Benevolent Fund to those who did not contribute to the funds of the Society, or to the Benevolent Fund itself, and if the Council allowed these men to infer that their subscriptions were not wanted, it would much cramp the action of the Secretary in getting in those small subscriptions which he was so anxious to obtain. He also endorsed the argument put forward by the President for keeping the funds of the Society intact.

Mr. SANDFORD said he would for this day withdraw the motion, but would give notice of it for next month.

LAW AND PARLIAMENTARY.

The report of this Committee included the usual monthly report from the Society's Solicitor, giving particulars of the progress of those cases which had been placed in his hands, in one of which the person proceeded against had consented to the payment of a penalty and costs. Other cases were standing over for want of clear evidence.

The report was received and adopted.

The Council had under consideration, in committee, the question now pending between the Society of Apothecaries and chemists and druggists respecting counter practice, and after some discussion it was adjourned to a future meeting.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£15 to the widow of a registered chemist and druggist, who had been 18 years in business.

£15 to a registered chemist and druggist, aged 66, in feeble health and out of employment.

The Secretary had reported that there being no chance of securing the election of the child for which a grant was made at the last meeting into an orphan asylum, he had not expended any portion of the money.

The death of one of the annuitants was also announced. The Committee recommended that a portion of the balance in the Treasurer's hands be invested in the purchase of £104 14*s.* 9*d.* stock in Consols, making the total amount invested on the Benevolent Fund Account £17,800.

The report and recommendations were received and adopted.

LIBRARY, MUSEUM AND LABORATORY.

The report of this Committee was read.

Mr. SCHACHT said amongst the recommendations for the purchase of books, there were often seen that of new editions. He wished to ask what was done with the old ones.

The PRESIDENT said some of them were sent to Edinburgh.

Mr. SHAW asked if the list of museum duplicates had been published. They were re-arranging their museum in Liverpool, and would be glad to see this list.

The PRESIDENT said the list was not yet made; but the Leicester Society having sent up a list of what they wanted, the Committee thought it as well to send at once such specimens as the Society had in duplicate.

Mr. GREENISH said the list would be prepared as soon as possible, and when it was done the provincial societies would do well to send up their requirements promptly.

Mr. MACKAY remarked that a complete list of the duplicate specimens sent to Edinburgh had been prepared, and he believed would have been published in the Journal last week, but for a pressure of other matter.

The PRESIDENT added that new editions were purchased only of books for which there was a constant demand.

The report and recommendations were unanimously adopted.

NEW ASSOCIATION AT COVENTRY.

The PRESIDENT said he knew it would please the Council to hear that a new Chemists and Druggists' Association was in process of being formed at Coventry.

HOUSE.

The report of this Committee was read and adopted.

PHARMACEUTICAL MEETING.

Wednesday, December 5, 1877.

MR. JOHN WILLIAMS, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting having been read and confirmed—

The CURATOR called attention to various specimens on the table. Among them was one of *Grindelia robusta*, which he said was coming into use in this country. It had been employed for some time in America as a remedy for asthma. It was first introduced in that country into notice as an antidote to the poison *Rhus Toxicodendron*, which in some persons caused an inflammation like that of erysipelas. It afterwards came into use in spasmodic asthma, in relieving which it seemed to have very much the same effect as lobelia. The small pot on the table was one of the original pots in which the curari poison was imported. The specimen of cinnabar came from a recently discovered mine in California, the New Almaiden mine, which was said to be very rich. The specimen of ndilo oil had been, he believed, prepared by pressure, and that Mr. Moss would be able to give its history.

Mr. MOSS said he believed that the sample of ndilo oil had been veritably prepared by the natives of Polynesia by pressure. It had some reference to an oil which the President showed at the last meeting of the Society, and which was obtained by benzole from the kernels of *Calophyllum inophyllum*. At the last meeting Mr. Holmes read an extract from Seemann's 'Flora Vitiensis,' to the effect that the oil was used by the natives of the South Sea Islands in cases of rheumatism, bruises, sprains, and so on, and was obtained by pressure. The sample now on the table had a green tint, whilst that shown by the President at the last meeting was brownish yellow. He (Mr. Moss) thought that the difference might possibly be due to chlorophyll extracted in the process of expression, but from Seemann's account it appeared that that idea could hardly be correct. However, perhaps Seemann's account was not the only one which might be given of the mode of getting the oil, for the colour was after all probably due to chlorophyll. If the oil was shaken up with a little strong rectified spirit the green colour was removed, and the liquid became the same colour as that shown by the president.

The PRESIDENT said that before proceeding to the proper business of the evening he ought to mention that they had amongst them a very old friend and member, and, in fact, a former practical instructor and student in the school of that society—Mr. C. H. Wood. That gentleman had just returned from India for a short holiday trip, and he was sure the Society would welcome him. Mr. Wood proposed to give them a paper at the next meeting, on the 6th February, on the "Progress of Cinchona and Alkaloid Production in Bengal." He need hardly remind them that Mr. Wood was the Government Quinologist in India, and therefore was the best authority they could have on a subject of that description.

The PRESIDENT said that before calling upon the authors of the six papers to be read that evening, he would invite the attention of the meeting to a circumstance which seemed to him to be of particular interest—namely, that they were all written by former students in the Society's School of Pharmacy.

A paper was then read on—

NITRITE OF ETHYL.

BY J. WILLIAMS, F.C.S.

During the reading of this paper, and the discussion which followed it, the chair was occupied by Mr. Sandford. The paper is printed at p. 441.

The CHAIRMAN (Mr. Sandford), in thanking the President for the paper on a subject so nearly allied to a question which had of late exercised the minds of so many of them, remarked that the latter part of the paper drew particular attention to the increasing use of the active principles of drugs, instead of the drugs themselves, and the necessity of having those active principles carefully prepared. That was a matter to which pharmacists ought to take great heed, and he felt very thankful that they had a President who would be so good a guide, always keeping himself abreast of the science of the day.

Mr. RIMMINGTON said that personally he thanked the President for having introduced this matter to the Society. In many respects the paper confirmed the conclusions which he had himself arrived at, and stated in the paper read at the last meeting, and he intended to make a further contribution on the subject. He also had found that strong alcohol was necessary for the production of a proper article. The object of his former papers was to show the necessity as well as the possibility of producing a very much better article than had been generally produced. Sweet spirit of nitre had acquired rather an ill name among the profession, as well as amongst the public, and if it was not to be driven out of pharmacy some improvement must be made in it.

Professor ATTFIELD said that it was gratifying to him that such an eminently practical paper should, to some extent, have arisen out of the remarks that he made at the last meeting. Those remarks were not made without good foundation. During the last four or five years they had made a large number of experiments in the laboratories of the School of Pharmacy on this question, both synthetically and analytically. They had failed to find any process which would enable them to assay a sample of sweet spirit of nitre accurately. In estimating the value of a sample they had consequently been driven to isolate the pure nitrite of ethyl. Many fractional distillations had to be made, the examination of one sample often involving a dozen or twenty of such processes. With reference to the impression upon Mr. Williams' mind that he (Professor Attfield) had disparaged the value of sweet spirit of nitre as a medicine, he could say that he did not intend to state anything of the sort, and he did not think that the record of his speech would warrant Mr. Williams in coming to that conclusion. However, he might say once for all, that he did not disparage the use of so ancient and excellent a medicine when properly prepared. At the same time it was well known that many medical men had considered that sweet spirit of nitre was altogether valueless. The reason was, doubtless, that some samples of the article sent into pharmacy for the use of medical practitioners had been little else than spirit of wine. A remedy so largely used with such obvious and often rapid results must have some good in it, but whether that good was due to nitrite of ethyl or to aldehyde, to alcohol or to other bodies, was open to question. He himself was under the impression that the active principle of sweet spirit of nitre was the nitrite of ethyl, and he was led to that conclusion mainly by the researches of Dr. Richardson, who had experimented largely upon the nitrites. He might refer to what Dr. Richardson had said about the nitrites of methyl, ethyl, butyl, and amyl. In a paper read before the British Association, Dr. Richardson, after speaking of nitrite of butyl, the third member of the series said—"We may, I think, consider that the physiological properties of the nitrites are, in an elementary sense at least, understood. They all present a beautiful unity of action, varied only in increasing force and persistency of action as the weight of each representative in the series increases with and from increase of carbon. The summary of their action is briefly as follows: they act instantaneously on the nervous system of organic life, reducing the power or force of that system, and reducing, as a result, the vascular tension; thus they cause relaxation of extreme vessels, and that suffusion of blood which is the most prominent visible sign of their effect; thus they cause intense action of the heart, followed by quickened respiration, due to the liberation of the heart from the tension to which it is normally subject; thus, administered internally, they cause (and this is specially the case with nitrite of ethyl or nitric ether) free secretion of organs, such as the kidneys, which are under the control of the organic nervous centres." But whatever opinion might be held as to nitrite of ethyl being the active principle in sweet spirit of nitre, Mr. Williams had given to therapeutists the means of using definite solutions of definite chemical substances, and he did hope that more than one therapeutist would be led to experiment with these substances. It was quite clear that nitrite of ethyl, for instance, was a most useful medicinal agent. Hitherto the medical profession had only had sweet spirit of nitre to look to for a solution of that agent; and as the proportion in which nitrite of ethyl occurred in sweet spirit of nitre was most variable, medical men might be pardoned for viewing that medicine with halting confidence. Let medicine plainly tell pharmacy whether she needed a solution of nitrite of ethyl, of aldehyd, of a mixture in definite proportions of those substances, or what not, and medicine would find pharmacy to be an able as well as willing handmaid equal to the occasion. As he understood Mr. Williams' process, it was mainly Liebig's process improved. His late assistant, Mr. Davies, had also prepared nitrite of ethyl in the laboratory by Liebig's process and rectified it. There was on the table a pure sample which had very much the character of the sample which Mr. Williams had brought before the meeting. As to the strength which Mr. Williams recommended, namely, 5 per cent., he (Professor Attfield) thought it was suitable. With reference to the present official process, he should say that the article prepared by it contained less than 5 per cent. If the whole of the nitric acid which was ordered there was converted into nitrite of ethyl, it would be impossible that it could yield more than 7 or 7½ per cent., and he knew that the whole of the nitric acid was not converted into nitrite of ethyl. In the laboratory they had succeeded in getting the official spirit to contain from 3 to 4 per cent., so that, probably, 5 per cent. might be regarded as a fair and full strength. As to the mode of testing the solution he believed that most persons employed such a tube as that which had been alluded to by Mr. Williams. The speaker was interested in knowing that chloride of calcium solution added to a spirituous solution of aldehyde did not cause any separation of the aldehyde. A recent experiment of his own seemed to show the same thing. At the same time, it would be readily understood by chemists that when a body like nitrite of ethyl was separated from its alcoholic solution containing aldehyde by a saturated solution of chloride of calcium it took the aldehyde with it, and that the liquid separated was a mixture of nitrite of ethyl and aldehyde, notwithstanding the fact that the chloride of calcium would not alone cause the separation of the aldehyde from the spirit. He believed that in this fact they had another instance of the phenomenon which might be called molecular adhesion, by which one body would take another body into or out of solution with it, although the body so taken into or out of solution would not be dissolved or separated if the other body were absent. He agreed with all that Mr. Williams had said respecting the importance of preparing definite substances in pharmacy for presentation to medical men or therapeutists. He should like to read two sentences which Dr. Richardson had uttered at the Exeter meeting of the British Association, as bearing on that part of the subject, and because they were of great general interest to pharmacists. Dr. Richardson had been referring to a report on the physiological action of the very substances of which they were now speaking, and he said, "The leading idea of the report is that which I brought forward at the Birmingham meeting—the idea of studying the action of substances which are to become remedies, not by the old and faulty method of so-called experience, but by proving physiological action and the relation of chemical constitution to physiological action. I am certain the time must soon come when the books we call 'Pharmacopœias' will be everywhere re-constructed on this basis of thought, and when the chemist and physician will become one and one." Respecting Mr. Williams' remarks on the parallelism of action of single active principles of drugs, and of infusions, decoctions, and extracts of those drugs, pharmacists and chemists had been told over and over again by therapeutists that they must not consider the action of the single active principle of the drugs and the action of the galenical preparations of those drugs as identical, but that they must consider that the action of the single so-called active principle of an infusion, or decoction, or extract, was either toned down, enhanced, possibly partially neutralized, or otherwise altered by the other substances which were present. One word more. He hoped that such a substance as pure nitrite of ethyl would not be demanded of pharmacists, for he thought that it was extremely undesirable that the public should have undiluted chemical principles of such great activity placed in their hands. Such substances were frequently very deadly poisons, and sometimes, as in the case of ethyl nitrite, physically dangerous.

Mr. R. H. Davies said he thought that Liebig's process which had been adopted in the laboratory was, perhaps, a little simpler, at any rate with regard to the apparatus employed, than that which Mr. Williams had used, although, doubtless, the latter would yield a purer product. He had used arsenic and nitric acid as being the best means of getting nitrous gas evolved, and he had used dilute alcohol instead of strong. The alcohol and water in which the nitrous gas was passed were immersed in a mixture in which ice was permitted to melt. By this process a large quantity of nitrite of ethyl had been collected on the water. This crude nitrite of ethyl mixed with alcohol had been mixed with a solution of bicarbonate of soda, and then decanted, or, rather, the heavier liquids had been allowed to run away by a separating funnel, and the purer nitrite of ethyl was distilled from the chloride of calcium. This had yielded a product of which five-sixths had distilled over under a temperature of 63·5 and as 62·5 was the boiling-point given by Schorlemmer, it would appear necessarily to be a very pure product. It was perfectly easy to mix that product with alcohol. He had made 5 or 10 per cent. solutions with great ease. The 10 per cent. solution had given 7 per cent. upon separation, instead of the 5 per cent. obtained by Mr. Williams. This might point to the former being a little less pure than Mr. Williams's. On one other point he differed from the results obtained by Mr. Williams. Mr. Williams had said that a solution of aldehyde mixed with a concentrated solution of chloride of calcium did not yield any separation. He (Mr. Davies) was inclined to think that it did. At any rate, a solution of pure aldehyde, so-called, produced by some celebrated manufacturers, yielded a separation when mixed with alcohol to form a 10 per cent. solution. He believed that about 5 per cent. separated. In the laboratory they had prepared nitrite of amyl very satisfactorily by the same method.

Mr. Umney said that, as a manufacturer of sweet spirit of nitre by the Pharmacopœia process, he felt bound to say that he had for years prepared, with the greatest ease, a concentrated solution of hyponitrous ether by the process there described. He had dealt with large quantities, having never less than four gallons of spirit in the still, and this generally produced eighty pounds of the official sweet spirit of nitre when completed. The process must not be carried on in the ordinary way, without extra attention, for sometimes the action was so violent that in the summer months he had seen the head of the still lifted off. He had been compelled to lay on cold water to the jacket of the steam still to moderate the action. With these precautions there was no difficulty in making a preparation which, when diluted as directed, would give 2 per cent. of that ethereal liquid by the chloride calcium test, whatever it might be. He was positive that it could be made of double or treble the strength, if necessary. There would be no difficulty in doing this if, instead of conducting the distillate into an open carboy, the adapter was connected with a piece of glass tube passing to the bottom of the vessel and dipping into alcohol. The nitrite of ethyl coming over in a gaseous form was then rapidly absorbed, and a solution was produced containing at least 20 per cent. of hyponitrous ether. He had for years prepared concentrated spirit of nitre in that way. He believed that the statement in the Pharmacopœia led to the inference that the separation of 2 per cent. would leave 8 per cent. absorbed by the chloride of calcium solution. As far as he could gather from Mr. Williams' paper, 5 per cent. was absorbed by the chloride of calcium, and not 8 per cent. If so, then the Pharmacopœia solution would be more accurately put down as containing 7 per cent.; but that the process could be carried on on the largest scale he himself could bear testimony from experience during the last five or six years.

Professor Redwood said that he should not have thought it necessary to make any remarks if it had not been for what had just been stated by Mr. Umney. He gathered from what Mr. Umney had said that he had found that the process could be very easily conducted, with some little modifications, but that it was liable to some danger without further precautions than were indicated in the Pharmacopœia, and that on some occasions the head of the still had been blown off and caused danger to the operator. He (Professor Redwood) wished to observe that he also had seen that process worked for many years in quantities quite as large as those mentioned by Mr. Umney, and in no instance in which the instructions of the Pharmacopœia had been obeyed had there been any approach to a violent action. In the cases he alluded to, certainly not less than four gallons of spirit had been operated upon at once, and the process had been carried on with a thermometer to indicate the temperature as directed by the Pharmacopœia, although that was hardly necessary, because the process went on with perfect regularity without any other precaution than that of taking care that there was the required heat, and no more, to get up that evolution of gas which caused a froth upon the surface of the liquid, amounting to a thickness of one or two inches. The spirit was distilled over, containing a large amount of ethereal liquid. It was true that in a former issue of the Pharmacopœia the liquid which separated was represented as nitrous ether, that term being used in a popular sense; but when the recent reprint came out he changed that term to the more correct term of "ethereal liquid." The amount of this ethereal liquid would usually be from 38 to 40 per cent., that is to say, such a quantity of the distillate would separate upon mixing the spirit with a concentrated solution of chloride of calcium. It was perfectly obvious that the ethereal liquid was not entirely nitrite of ethyl, and while the sweet spirit of nitre would contain about 10 per cent. of that liquid, it would contain probably about 5 per cent. of the nitrite of ethyl. A solution made in that way would, as Mr. Umney had admitted, cause a separation of about 2 per cent. when the spirit was mixed with the concentrated solution of chloride of calcium. He was anxious not to allow the subject to pass over without saying so much in vindication of the Pharmacopœia process, which he had always felt some little gratification in having been the means of introducing. He still felt that it was the only known process of producing sweet spirit of nitre of a tolerably definite composition.

Mr. Williams, in reply, said that his paper was not on sweet spirit of nitre, but upon nitrite of ethyl, and he did not wish to deal with the former body, but as Mr. Umney had introduced it he (Mr. Williams) trusted that his observations might not be misunderstood as applying to sweet spirit of nitre. He did not know what that compound was. He only wished to speak of a pure chemical of indicated and definite strength, and he had placed before the meeting a method of making that body in a definite way. Mr. Umney had made a remark as to the percentage of oily liquid yielded by the chloride of calcium test, but he (Mr. Williams) would remind him that the paper was speaking of absolute alcohol solutions, while Mr. Umney was not. In dealing with solutions of nitrite of ethyl in absolute alcohol, he (Mr. Williams) had a liquid when mixed with chloride of calcium which would dissolve a great deal more nitrite of ethyl than that which Mr. Umney used, and therefore the results could not be compared.* Something had been said about the boiling point. He (Mr. Williams) maintained that the boiling point of a liquid which would boil at 61° or 62° could not be taken as an indication of its purity at the temperature prevalent in this country. If they were living at the

* If in making this test of the strength of a solution of nitrite of ethyl in absolute alcohol the solution containing 50 per cent. be tested, it is evident that the 400 grain measures of solution of CaCl have united with 100 grain measures of alcohol, but if the test is applied to the 5 per cent. solution, the same quantity of chloride of calcium solution has united to 195 grain measures of alcohol. Consequently the latter solution has a much greater solvent power over the nitrite of ethyl than the first, in fact experiment shows that whereas the 50 per cent. solution only loses 2 grain measures of the nitrite, the 5 per cent. solution loses nearly the whole.

North Pole, where mercury was, normally, in a frozen state, then he should consider that a liquid boiling at something like 61° or 62° was a very tangible thing, and should be able to calculate its purity accordingly. But under existing circumstances the boiling point of 61° or 62° could not be taken as much evidence of purity. He would remind Mr. Davies that a pure aldehyde was not easily obtained. Aldehyde, as ordinarily met with, contained a certain quantity of acetic ether and acetone, and thus there was a separation; but if they had a pure aldehyde they would find that there would be no separation with chloride of calcium.

The President then resumed the chair.

A paper was read on the

Colour of Podophyllum Resin.

BY DR. A. SENIER, F.C.S., AND A. J. G. LOWE.

The paper is printed on p. 443, and gave rise to the following discussion:—

Mr. Martindale said that the explanation given in the paper was not entirely what he agreed with. It was a well-known fact that there were two resins easily separated from one another in the commercial podophyllum resin of the Pharmacopœia. Some years ago he tried experiments with regard to this substance, and he had two different samples. The resin which was soluble in ether was quite of a bright yellow colour; and the other, which was insoluble in ether, but soluble in spirit of wine, was of a pale stone-brown colour. With regard to the difference of colour, he believed that a great deal of it was due to the proportion in which the resins existed in the commercial resin, and when the yellow resin was present to a greater extent it gave a deeper tint than when it was present to a lesser extent. From notes which he made at the time of his experiments he found the commercial article was very variable. It was curious that the Pharmacopœia stated the resin of podophyllum was entirely soluble, or nearly so, in ether.

Professor Redwood: Not entirely.

Mr. Martindale thought that the part insoluble in ether, at any rate, accounted partly for the difference of colour, although the degree of comminution might account for some of the difference. The two resins which he had exhibited to-night were prepared by Mr. Morson, junior, eleven years ago. With regard to the action of the two there was very little difference, but the brown resin, which was insoluble in ether, had a quicker action than the yellow resin which was soluble in ether. The yellow resin had a much stronger odour than the brown resin, the latter having scarcely any smell. He had an idea that the brown resin was crystallizable, though he had not pursued his experiments far enough to be able to state this with certainty.

Professor Attfield said that he did not see that the observations of Mr. Martindale in any way conflicted with those of the authors of the paper. Might not Mr. Martindale's observations account for the slight differences in colour, as distinguished from shade, met with in commercial samples? That the state of comminution explained the differences of shade was, he thought, amply proved by the experiments of Dr. Senier and Mr. Lowe.

Mr. Martindale said that he had been speaking of the brightness of the yellow colour which was visible in some samples.

The President said that as Mr. Martindale's specimens were obtained eleven years ago, he thought that it was hardly fair to bring such specimens forward in contradiction to a paper which had just been written. They had advanced, and knew more about podophyllum since Mr. Martindale's experiments were made.

The next paper read was—

A Note on Rheum Officinale Grown in England.

BY HAROLD SENIER, F.C.S.

The paper is printed on p. 444, and gave rise to the following discussion:—

The President said that he noticed that the paper described the root as yielding only one-third the quantity of extract yielded by the East Indian root, and it stated that that extract, taken in ten grain doses, was about as active as that which the author obtained from other rhubarbs. Then he said that one was of equal medicinal value with the other. He (the President) supposed that the writer meant that it had only one-third the value.

Professor Attfield said that he was about to ask a somewhat similar question of Mr. Harold Senier, seeing that he had subjected himself to the action of this extract. By the way, it seemed to be getting quite the fashion amongst pharmacists to make such experiments on themselves, and thus do the work of therapeutists. They were getting quite famous for their martyrdom. He heard a conversation the other day between some medical friends as to the effect of some drug, and one gentleman said to another, "If you want to know its effect, send it to the Pharmaceutical Society, '*Fiat experimentum in vili corpore.*'" He was going to ask Mr. Harold Senier whether he really thought that the colour of the powder or of the infusion, or the amount of the extract or ash, really afforded any indication of the therapeutical value of the substance.

Mr. W. Hills said that Mr. Usher brought him about three years since a specimen of English grown rhubarb, he believed from the *Rheum officinale*. He made an extract with it according to the B. P. process, and compared the result with an extract similarly prepared from an East Indian rhubarb. He obtained 28 grains of extract from the former and 31 grains from the latter per 100 grains of root, and there was a marked difference in the physical characters of the extracts—the English being almost entirely devoid of the characteristic odour of extractum rhei, and of a much more sticky and mucilaginous nature.

The President said that he had no doubt they were not only very different in those qualities which had been mentioned, but totally different in their nature.

Mr. Harold Senier, in reply, said that his statement referred to the extract and not to the root. With respect to Professor Attfield's question, he could not say positively, but he thought that these differences afforded an indication of the value of the root; but that point, of course, could be only tested by the medical profession.

The next paper read was—

On False Angostura Bark and Brucia.

BY W. A. SHENSTONE, F.C.S.

The paper is printed on p. 445.

The President observed that this paper was one of a very important series, which was intended to clear up a subject which had been a mystery for fifty years. The present paper was a most important step in the matter. He wished that the author could show them more clearly how to purify brucia from strychnia. Still, the subject was progressing, and he had no doubt that the next paper would be in advance upon this.

A paper was then read, entitled—

Observations on Russian Turpentine Oil, and Oleum Foliorum Pini Sylvestris.

BY DR. TILDEN.

Mr. Postans also read a short communication on the same subject. These papers are printed on pp. 447 and 448.

The President had no doubt that the turpentine that had been described was very much more aromatic and pleasant in smell than the ordinary turpentine which was used in pharmacy. From its smell he should almost suppose that it had some terebene in it.

Mr. Moss asked whether he understood that this turpentine was the ordinary Russian oil of turpentine. He seemed to gather that idea from the paper which had been laid before the meeting, and he also understood that the variety was spoken of as new. He (Mr. Moss) did not know about Russian turpentine being new, but it had been quoted in the lists of the brokers for some time, and it had all the appearance of being a very old stager. It was indeed sold at a price of £2 or £3 a ton below American turpentine, and he should not be surprised if much of the turpentine now, or up to a late period, in commerce was Russian turpentine.

The PRESIDENT said that the smell of this purified turpentine would show that it was very different from the ordinary turpentine oil. It was much more like *oleum pini sylvestris*.

Mr. POSTANS said that he believed, from what Dr. Tilden had said, that it was comparatively new, notwithstanding the facts which Mr. Moss had stated. He believed that the advantages of the redistilled Russian oil were so great, compared with all other kinds of turpentine, and especially with regard to its fragrant odour, that when it was better known it could not fail to come into considerable use.

The meeting was then adjourned till February 6th.

NORTH BRITISH BRANCH.

The first meeting of the twenty-fourth session took place in the Society's rooms, 119A, George Street, Edinburgh, on Wednesday evening, 21st November. Mr. J. B. Stephenson, President of the Branch, in the chair.

The following opening address was delivered by Mr. Stephenson:—

"Gentlemen,—My first utterance from this chair must be the hearty acknowledgment of the great honour you have done me in placing me in it, and it would be mere affectation did I not add that I have accepted it with great diffidence. Especially do I feel this when I recall the honoured names of my predecessors in it—many of them, alas! no longer with us, and most of them standing to myself, and I believe to most of you, in the relation of fathers in the profession. I can only promise my best endeavours to advance the interests of our Society and to maintain the dignity of the chair, and I rely not so much on myself, as on your kind indulgence and forbearance, and on the well-known ability and willingness of our valued Secretary and his indefatigable assistant to keep me right.

"Gladly passing at once from things personal, I have to congratulate you on the continued prosperity of this, our North British Branch. During the past year our museum and library have been taken advantage of more largely than ever, which is certainly the very best evidence we could have of our prosperity.

"The Benevolent Fund of the Society had a benefit in the form of a dinner on its behalf last May. I am not sure that it proved quite such a success as its more sanguine friends had expected from the result of a similar appeal ten years ago. Still, it gave a great lift to the Fund. It is gratifying to find that this Fund advances year by year. We have now between twenty and thirty annuitants at £30 per annum which I see is to be raised in some cases to £35, and temporary relief, was given during last year to the amount of about £500. This shows a yearly revenue of about £1100. It is only when we take into account the large number of chemists in the country that these provisions appear insignificant and inadequate. Many other corporate bodies have widows' fund schemes on the principle of a mutual assurance company, but this involves a compulsory payment, and any such arrangement would be impossible in our present circumstances. Let us hope, however, that by and by when our Society becomes more consolidated, some such plan may be devised, and meantime, and indeed even in such a case as I have supposed, there will always be ample scope for benevolence; and allow me to suggest as a duty we all owe to the Fund, the making such provision as may tend to keep ourselves and our families from coming upon it. By so doing, you will mark that a poor man who can contribute perhaps little or nothing to the Fund, may still by the exercise of self-denial in insuring his life, become one of its most munificent benefactors.

"I wish I could congratulate you on the falling of the percentage of failures at our examinations. I have often felt quite depressed observing how high this percentage was. However, I must tell you that I have been making special inquiries, and I find that in more than one examining body in the city the rate is not at all unlike our own, and more than this I must mention that although my own limited experience as an examiner hardly warrants my speaking, I have the testimony of my colleagues that the style and class of candidates have improved very much within these few years, and we have Dr. Maclagan's emphatic opinion to the same effect in his last report as Privy Council Inspector. This is very gratifying and satisfactory, yet it is just what we might expect. We are yet only a very young society; our charter of incorporation dates 1843—just a generation ago—and up till 1868 we had no compulsory powers. Up till that year we were a voluntary association, and no doubt comprised all the best men, but since then we are only entering on our real mission, which is to raise the status of the whole body, and according to the evidence I have quoted we are already beginning to reap the fruit of the seed which has been diligently sown ever since our foundation. We are still quite a young society, and in an essentially transition state, but I have a firm faith in our *future*, and it is founded in great measure on our *past*, for who will say in looking back since 1843 that we have not accomplished much? We have now on our Register little short of 14,000 names—we have a school of pharmacy—in its organization and equipment, perfect—we have our examining boards in London and Edinburgh in constant operation and doing their work in a manner of which I leave Dr. Greenhow and Dr. Maclagan, who attend them on behalf of the Privy Council, to speak—we have scholarships and medals—we have on our roll of departed celebrities such names as Jacob Bell, Pereira, Fownes, Hanbury, and many more—names already household words. And let me point also to the speaking likenesses on our walls in this room of Mr. Brown and Mr. Tait, men who by their character and attainments would ennoble any association to which they belonged. Not the least hopeful promise of our future lies in the irresistible conviction that the memory and the example of such men are ours, and must be powerful in its influence on their successors. I have referred to our progress as a body, but in estimating it there is one thing specially that we should take into account. On the Continent they lay down a constitution on paper, and legislate on all the details at once, the qualification, the relation to the physician, the tariff of prices even, etc. In this country we can do no such thing. Look how long we were in getting any legislative sanction at all, and how grudgingly, and piecemeal as it were, it came. Our institutions *grow*, they are *not made*; they are the product of public opinion brought to bear on wants which must be long felt and agitated for till they are supplied. Thus it comes that our institutions are of slow growth, but then in the very process they acquire practicalness and stability. The essential condition of all our progress, indeed of our very existence as a body, is knowledge—in the most liberal sense. Our charter of incorporation in 1843 begins with the declaration that it is granted 'for the purpose of advancing chemistry and pharmacy, and promoting a uniform system of education of those who should practise the same,' and the Society has loyally acted up to this principle. Her agency extends to the general as well as to the technical education of her members. We have our Preliminary examination, which is in many respects the most important of them all, for on the educated character of the entrants to the profession depends the staple of the material of the whole body, and if the youth be not grounded in his general knowledge before entering on his pharmaceutical career he will be heavily handicapped in his future progress. While, however, I have no desire to minimize the stringency of this examination, I am bound to express my own personal opinion that the tendency lately has been to err in the opposite direction. Our agency for technical education has hitherto been confined to our school of pharmacy in London, but I think the time is rapidly approaching when it must be extended. Of course wherever there is a medical school there are opportunities for our students attending courses of lectures on materia medica, chemistry and botany, and in Edinburgh they have peculiarly advantageous means of doing so; but I believe the great majority of them get up their knowledge in scraps and patches, perhaps attending a course of lectures on a single subject when practicable, and eking out their knowledge by means of books, and perhaps that wonderful postal system that we hear of,—but altogether in a fragmentary and unsystematic manner. Now, except in very rare and exceptional cases, the acquiring of knowledge without a competent teacher or guide, is sure to be a wasteful and unsatisfactory process,—wasteful of time and energy, and productive of an inferior result. There can be no doubt of the perfection of our London school. It has done good work and will ever continue to do so. Even as a model and ideal of a school of pharmacy—something to go by, and aim at—it serves a valuable purpose. Let as many as can, take advantage of it, but these will ever be a limited class. Our great desideratum I think is a curriculum with special reference to pharmaceutical requirements, on the Bloomsbury Square plan, but shorn of its proportions, and established in various centres both in England and Scotland. Such schools would, I believe, be self-supporting, but at first I would have them under the auspices of the Society. The subject excited considerable interest some time ago, and gave rise to a good deal of discussion, and various communications appeared in the Journal, all showing that the want is being generally realized, and this being so, we may hope that the problem (for problem it assuredly is) is in course of being solved.

"Many years ago I heard Dr. George Wilson, of gentle memory, within a month of his lamented death, deliver a lecture on pharmaceutical education at one of our evening meetings. There were many memorable points in his address, but one especially I would reproduce. He told us in the outset that Pharmacy was not only an *art* but a *science*, or at least an art requiring a scientific knowledge for the proper prosecution of it; and in this connection I would like to quote a few sentences from the prospectus of the session in Bloomsbury Square by the Professors: 'Examination,' they say, 'even by the most highly skilled board with ample time at its disposal, and a wide area from which to select questions, is admitted by all authorities on education to be but a partial test of knowledge and an extremely imperfect test of education. Not alone the knowledge which can be tested by examination, but that which cannot be so gauged, should in all honour and in the highest self-interest be the knowledge ever assiduously sought. The one desire should be education, that is, knowledge accompanied by enlightenment of the understanding, mental training, mental discipline, and general elevation of the intellect.' I am glad to be able to quote two such competent authorities on the scientific character of Pharmacy, and it can hardly be superfluous to insist on it, when we have one of the leading medical journals some time ago, describing Dispensing as a nice, genteel, clean, and easy employment, essentially mechanical, and well adapted for females, and denouncing our whole tariff of charges as exorbitant, which could hardly be done if knowledge or responsibility, or even skilled labour, are to count as of any value at all. If there be an excellency in knowledge which ennobles, then is ours certainly not a mere trade to make money by, but a profession that we may well glory in belonging to. It must partake of the commercial character of other businesses, but I for one, repudiate the sordid idea that this is its main aspect, and that knowledge is to be sought only for the purpose of, as it were, floating us into it. Rather—the scientific is the main aspect, and I would urge you all, the young especially, to cherish this idea of it, and to let your aspirations and endeavours be ever towards realizing it. The result will be, as in cherishing a lofty principle and aim, to elevate the character, to ennoble the commonplaces of every-day life, and to brighten the inevitable anxieties and drudgeries of business. I have a practical end in view in this whole line of remark. I have no faith in the *science* which neglects the *art* of pharmacy. Let us never forget that for the successful prosecution of our business the same homely qualifications are indispensable as in any other business—moral integrity, devotion to business, diligence, punctuality, perseverance—and then, seeing we have a profession that ennobles us, let us take care that we adorn it, do nothing unworthy of it, take an intelligent interest in all that concerns it. There are our scientific meetings. We are certainly much indebted to our friends from without, who contribute to our edification, and to none more than to our friend Dr. Macadam, who is here again this session and is only waiting till I have done to begin. None of these friends will think that I speak in disparagement of their services when I complain that we should be so almost exclusively dependent on them. I know there are few amongst us who can give us an exhaustive scientific disquisition like my gifted predecessor in this chair, Mr. Gilmour; or who can lead us into the flowery fields of philosophy, like our friend Mr. Baildon, and there let us witness him measure swords (not unsuccessfully in my judgment) with Professor Tyndall himself; but are there any who could not, except from want of will, or excess of diffidence, give us some result of their observation and experience, some remarks which might provoke discussion and elicit similar results of experience, and so benefit the entire body? '*Verbum sat sapienti.*'

"The subject of counter prescribing has again come to the front in consequence of several cases of prosecutions of chemists by Medical Associations in England, and—as affecting our understanding with the medical profession, it is a most important and interesting one. Now, no one can deprecate more than myself anything like an encroachment on the medical man's province, or would be more willing to waive anything like an abstract right in the matter, yet I am bound to say, as the result of my experience, that I cannot see how we are to carry on our legitimate business as pharmacists in an intelligent and satisfactory manner, without constantly bringing into requisition in the service of the public our knowledge and experience; nor how any hard and fast line could be laid down, defining the boundaries of our respective provinces. Let me offer one or two considerations. First, as mere vendors of goods we ought to be able to recommend them, to speak of the advantages and disadvantages attending their use,—our education in our profession should have enabled us to do so much, as well as to give, when applied to, such remedies as a cough mixture, a gargle, a liniment, a dose of aperient or astringent medicine, and even to vary them according to circumstances. But further, we may be supposed to have some personal experience of ailments and their treatment, like everybody else. Why should we alone of all men be restricted from giving our neighbour the benefit of it; for I would never think of prescribing over the counter, except on the same footing that I would advise a friend or neighbour away and apart from my shop altogether? Only I would add as a rider to these, that an accomplished chemist ought to know at once, when the case is one for the physician and not for him, and to keep the public right in this matter also, and I believe that the man who is most competent for his other duties will be the most ready to perceive this one too. I wish, however, I could add that all chemists confine their prescribing to these lines. In England I constantly see dispensing and *prescribing* businesses for sale, and I believe that in Scotland also many of our brethren go to a quite unjustifiable extent in prescribing. No doubt it is largely practised as a retaliatory measure against doctors dispensing medicines, but however this be, we ought to have no hesitation in condemning it; it is not our business, nor have we any right to look for any remuneration from it; indeed I have long looked on this as the principle which ought to guide us in the whole matter, viz., that we should give our advice exclusively in the interests of the public, and make no profit by it either directly or indirectly.

"There is another subject allied to this, which I think fairly falls within the scope of these remarks—I mean the system of patent and proprietary medicines. You are all aware how large, how increasingly large, this department of our business becomes. I confess it is with a feeling of humiliation I observe how large a proportion of my business it is, and that I see the long list of articles of that description advertised in the daily prints. I am very far from grudging the reward either of fame or money to any one who, by his knowledge or skill, succeeds in introducing some new compound or preparation (and I could easily mention such cases), but I am sure it will be at once conceded that the great majority of the authors of these articles are not men distinguished for their attainments, either pharmaceutical or scientific. Their chief characteristic appears to me to be their universal habit of audacious and persistent assertion of the excellencies of their productions. Let me, by way of illustration, refer you to the class of preparations which are put forward under a fancy name, as curing sea-sickness and bilious headache, vitalizing the blood, and being eminently beneficial in cholera, typhus, yellow and other fevers. Now a very little consideration of the circumstances attending some instances where the composition of the article is known will lead to the conclusion that either the advertisers are ignorant of the nature of the hypothecally active ingredient, or they are not, in which case I leave you to draw the inference. *Ab uno disce omnes!* I think we should discountenance the whole system, as well from motives of loyalty to our profession as from self interest. Observe how it works. It is my business to compound medicines—to make my living by so doing—but when these gentlemen assume the compounding and delegate to me the selling, I must do so with a seller's instead of a dispenser's remuneration, and besides, I am degraded to the position of something like a huckster. It is difficult to indicate any practical course to take in the matter. It has been suggested that Government should withdraw what may be construed as their sanction in the requirement of the stamp, and no doubt the tendency of this is to give a certain official importance to the article, more especially when we see it stated that Her Majesty's Commissioners of Stamps have ordered the maker's name to be engraved on the stamp in white letters on a red ground or otherwise: yet this would meet only part of the case, for many of these articles are not subject to stamp duty, and besides, there can be no doubt that this whole class presents a very legitimate object for taxation. Of course I do not moot the question of our declining to deal in the articles: as the case stands, this would be quite impracticable or even suicidal; but short of this I think we can do much. Only let the conviction be wrought generally in our minds, that the system is an excrescence on our profession, and that it is likely if encouraged to drain the life blood from it; and that it is our duty—our mission, if you like—to educate the public on the matter, and I can imagine at least one practical outcome of it. We should take measures that the authors of the system did not get the advantage either of our names or of our profession to bolster up their productions. Our opinion goes for much with the public, and I believe is likely to become more and more powerful. We should let them know how we hold the whole system of quackery in contempt, that the articles are made like the razors of old *only to sell*, and that in using them they do so on the authority of the fabulous legends attached to them—not on ours. By so doing we shall win the respect not only of the medical profession, but also of the more intelligent of the public who will be able to appreciate our motives. But, better than either, we shall preserve our own self-respect, for it is quite certain to me that it is only in dispensing remedies, when we have an intelligent apprehension of their nature and properties and uses, that we can vindicate our claim to be an integral part of the old healing profession, whose glorious appellation we have adopted as our own motto, 'Opifer, or Help-bringer, over the Whole World.'"

Mr. Ainslie proposed and Mr. Mackay seconded a vote of thanks to Mr. Stephenson for his interesting address, which was most cordially responded to.

The Chairman then introduced to the meeting Dr. Stevenson Macadam, who expressed the pleasure he had in again appearing before the Pharmaceutical Society.

Dr. Macadam then read a paper "Paraffin Oils and their Action upon Metals." This lecture will be printed in the next number of this Journal.

At the conclusion of his lecture, the doctor was awarded a very hearty vote of thanks, proposed by the chairman and seconded by Mr. H. C. Baildon.

The Honorary Secretary announced the following donations and contributions:—

Museum.—A Musk Deer, from Mr. Robert Howden, London. Specimens of *Gymnina sylvestre; Polypodium quercifolium;* Strip Catechu; *Mimusops Elengi; Monarda punctata; Hygrophila spinosa; Cassia auriculata;* Opaque Bdellium; Bonduc Nuts; Boomah Nuts; Native Calamine; White Olibanum; Kaur Gum; Dead Bark; *Boerhavia diffusa; Eupatoria Ayapana;* Carnauba Root; *Ulmus fulva;* Seeds of the Poonwood tree; Safflower seeds; Bark of *Abutilon Indicum; Tiaridum Indicum;* Goa Ipecacuanha; *Aucklandia Costus; Eclepta erecta;* Japanese Isinglass, made from seaweed: from the Society in London.

Library.—'Pharmaceutical Journal,' 1st series, 1841-59, 18 vols.; 'American Journal of Pharmacy,' 8 vols.; Bloxam's 'Chemistry;' Faraday's 'Chemical Manipulations;' 'Throat Hospital Pharmacopœia;' Sutton's 'Volumetric Analysis;' 'Calendar of the Yorkshire College;' Mrs. Garrett Anderson's Inaugural Address, London School of Medicine for Women: from the Society in London. Hanbury's 'Pharmacographia' Hanbury's 'Science Papers:' from the British Pharmaceutical Conference, *per* the Hon. General Secretaries. A small collection of Autograph Prescriptions, from Mr. E. Coates, Edinburgh.

In proposing a vote of thanks to the donors, Mr. Mackay said that it should be a special one to Mr. Howden, for his kindness in sending such a rare and interesting contribution. This was carried unanimously. The Honorary Secretary then intimated that, through the kindness of Professor Archer, the next meeting would be held in the Museum of Science and Art.

Parliamentary and Law Proceedings.

Alleged Death of a Child from Opium.

An inquest was held on the 23rd November in the Devonport Guildhall by the Coroner, Mr. J. Vaughan, upon a child eight months old, who had been found dead in bed. The mother of the deceased said that the deceased was "teething," and that on the previous Wednesday evening about 8 o'clock she gave it part of a powder that she had obtained some two months previously, or more, from Mr. Codd, chemist, Duke Street, Devonport. This powder was not supplied to her by Mr. Codd for the deceased, but for another of her children who was much older than the deceased. She had on one occasion before administered half of a similar powder to the deceased, and at that time it appeared to do the child good. When she gave the deceased the powder it went to sleep, and continued in that sleep, without any movement that she observed, until about 1 o'clock in the night, when it was seized with a convulsive fit. It recovered from that, however, and again went to sleep. About 7 o'clock the next (Thursday) morning, the deceased had another convulsive fit. She gave the deceased only half the powder, because the deceased was very much younger than the child for whom she obtained the powder. The directions for use were printed on the label on the paper in which it was wrapped.

The paper was produced, and the Coroner stated that by the directions the whole powder might be given to any child between the ages of three and eight months old. The powders were called "Codd's teething and soothing powders."

Mr. F. Codd, chemist, said that after an experience and use of the powders extending over ten years he was perfectly satisfied that they were quite suitable for children of the ages mentioned on the directions, whatever might be their constitutions. Amongst other things the powders contained opium. When any one came to him for these powders, if they had never had any before, he always told them that they must not administer more than two a week.

Mr. Horton, surgeon, stated that he was first sent for at 8 o'clock, but was then in bed and when he reached the house before ten the child was dead; he ascertained that it had had slight colvulsions and that its mother had administered to it half of a powder which she had ob-from Mr. Codd. Under those circumstances he refused to give a certificate of death. Mr. Horton then proceeded to relate the result of the *post-mortem* examination of the body. He stated that the brain and its membranes were congested, and then described the internal appearance of the chest and abdomen. The right lung was congested very much; the left was unusually small, the lower part of it never having been inflated, thus proving that the child had never breathed properly from its birth; the liver was unusually large, and the child was of a delicate constitution. In his opinion the cause of death was attributable to the general disturbance of the system during the period of "teething," to the imperfect condition of the left lung and the other organs, and to the utter inability of the child to bear the dose of opium given. In answer to the Coroner, Mr. Horton replied, "My opinion is that if the child had not had that dose of opium, it would have been living now." The Coroner further asked Mr. Horton whether he would not consider a child having a very large liver, and having one part of its lung so defective that it had never been able to breathe through it, in a very precarious condition; and Mr. Horton said that he should not very willingly give a dose of opium of the strength of that administered to the deceased to a child five times as old. No medical man would ever give opium to a child in a similar condition to that in which the deceased was at the time this powder was administered. Children's constitutions were very susceptible to the effects of opium. There would be one-tenth of a grain of opium in the half powder administered to the deceased; he believed all chemists sold powders of the description of those sold by Mr. Codd. A juror inquired whether the opium would have occasioned the convulsions, and Mr. Horton replied that the occurrence of convulsions would be one of the most convincing symptoms for believing that opium had been administered. The Coroner inquired whether Mr. Horton, without having had a previous knowledge of opium having been administered, would from what he observed, when making the *post mortem* examination, have attributed death, bearing in mind the defects in the child's constitution, particularly to opium as he had done. Mr. Horton said the symptoms he saw would have caused him to suspect that opium had been administered, and hence he should have made inquiries, and in all porbibility arrived at the same conclusion as he had done.

Mr. Codd said he wished to explain how the powders were prepared, pointing out that it was impossible for the components parts not to be thoroughly mixed. The powders would act differently upon different constitutions.

The Coroner asked Mr. Codd whether he still adhered to his former statement relative to the administration of the powders and Mr. Codd said, "After hearing what Mr. Horton said, I shall endeavour to curtail, if not to stop the sale of them—or I shall diminish most certainly the quantity of opium they contain."

The Coroner: I think you would thus do well, because they are liable to get into the hands of persons who will give them to children whose constitutions are not suited to receive them.

Mr. Codd said: If I don't stop the sale of them I shall certainly diminish the opium, because of the effect it has, which I was not aware of before.

The Coroner, in summing up, pointed out that the deceased's constitution was such that it was clearly more dangerous to administer opium to him than it would be to children of healthy constitutions, and expressed the hope that the effect of the inquiry would be to cause chemists to be more careful in administering opium to children, which was clearly a dangerous thing to do except under the strictest medical supervision. He did not consider that any one could be said to be responsible for the deceased's death.

The jury ultimately returned a verdict of "Death from natural causes," and recommended generally that opium should not be given to children so young.—*From the Devonport Independent.*

Obituary.

Notice has been received of the death of the following:—

On the 11th of October, 1877, Mr. Henry Thomas Judd, Chemist and Druggist, Market Place, Warwick. Aged 48 years.

On the 18th of November, 1877, Mr. James Dresser, Chemist and Druggist, second son of Mr. Richard Dresser, Pharmaceutical Chemist, York. Aged 29 years.

On the 24th of November, 1877, Mr. Thomas Potts, Pharmaceutical Chemist, Grainger Street, Newcastle-on-Tyne. Aged 63 years. Mr. Potts had been a Member of the Pharmaceutical Society since 1853.

On the 2nd of December, 1877, Mr. John Sterriker, Pharmaceutical Chemist, Great Driffield, York. Aged 61 years. Mr. Sterriker had been a Member of the Pharmaceutical Society since 1852.

Erratum.—In the obituary notice of Mr. Hornsby, on p. 439, it should have been stated that deceased was late of Gateshead, and not of the London Hospital.

Correspondence.

F. Hollingsworth.—The book is published by Messrs. Groombridge.

C. Crook.—Probably iodide of bismuth is formed. You are recommended to analyse the precipitate.

Erratum.—On p. 422, col. i., line 21, *for* "fifteen" *read* "two."

A. K.—See vol. vii. of the present series, p. 850.

Carnifex.—A suitable quantity of any blue pigment ground fine in a mixture of 3 parts of balsam of copaiba and 1 part of hard soap.

Communications, Letters, etc., have been received from Dr. Symes, Mr. Williams, Mr. Davies, Mr. Rayner, Mr. Slipper, Mr. Proctor, Mr. Raynor, Mr. Macintosh, Mr. Stock, Mr. Barnes, Mr. Dixon, Mr. Tibbs, Mr. Lewis, Mr. Kimber, Mr. Rickaby, Mr. Linford, Mr. Lines, Mr. Hickisson, Mr. Laitram, Mr. Arblaster, Mr. Siebold, Experientia docet, Antipater, Hyacinth, Young Pharmacist, W. PILLS AND PILL COATINGS.*

BY CHARLES SYMES, PH.D.

The pilular form of medicine is one which has received considerable attention at the hands of pharmacists, and so much has already been written and said concerning it that a difficulty presents itself to me in bringing the subject forward to offer much that is really original; I can however give some of the results of my experience, record and estimate certain known facts as they appear to me of more or less value, and thus submit my views of the matter which might not be uninteresting, inasmuch as we know by daily experience that just as the same ray of light falling on different bodies is either absorbed, transmitted, or reflected, and these in different degrees, so the same phenomenon impinging on different minds is differently received and produces a different impression, or, as we commonly say, is seen from different points of view.

The pill is a concentrated and portable form of medicine and often contains ingredients which would be exceedingly nauseous if taken in a liquid state; it requires no measuring out of dose and is thus exceedingly convenient; we cannot therefore be surprised that it has become very popular, and that the skill of the pharmacist has been taxed to its utmost to bring into this form a large variety of substances, to enhance its keeping qualities by every conceivable means, and to cover it in a manner which at once renders it both elegant and tasteless. The first operation in the production of pills is of course that of weighing out the ingredients. I mention this because I fear it is not always as carefully done as it might be; often the same balances are used to weigh one grain and one hundred Now as the knife edges will necessarily become somewhat blunted by these heavier weights, their delicacy wil become impaired and they will thus be rendered unsuitable for weighing small quantities of active substances. For these I prefer the German balances with graduated beam and sliding weight or rider, capable of weighing from one-tenth to five or ten grains *and not more;* then for larger quantities or less potent substances the ordinary dispensing balance weighing from a few grains to one hundred; and for anything above this quantity a small well made pair of counter scales should be used. These latter will of course only be required when the patient wants a large supply, or for the manufacture of stock pills.

Sometimes the ingredients of a formula will when mixed, themselves form a mass suitable for dividing into pills; but usually an excipient has to be added, and the proper selection of a suitable one constitutes the chief art in pill making. The list of excipients is somewhat lengthy in detail, but they may be summarized as follows:—Glycerine of tragacanth, glycerine, treacle, syrup, mucilage, tinctures, spirit, water, confections, extracts; powders of tragacanth, gum arabic, taraxacum root, bees'-wax, almond meal, soap, bread crumb, etc. Mr. Martindale has recommended a mixture of starch and glycerine, and Mr. Walter Searle a solution of soluble cream of tartar and citrate of potassa, to which is added syrup and mucilage. Whatever be the ingredients or the excipients, it should be borne in mind that to attain satisfactory results a pill must resemble a building and contain constituents possessing the physical characteristics of both bricks and mortar; these too, if possible, in such proportions as to produce a substantial structure.

Of the soft or plastic excipients in the foregoing list, glycerine of tragacanth is probably the most generally useful, as by means of it in small quantity we are enabled to get sufficient adhesiveness to bring solid particles, themselves devoid of that property, into a compact mass, and cause them to cohere firmly together without imparting undue hardness or insolubility. Metallic oxides and salts are by it rendered most tractable and a pill which would otherwise be very large is by it rendered quite within the average size. I produce samples of pills containing five grains bromide of potassium, and ten grains of subnitrate of bismuth respectively, neither of which are larger then a five grain colocynth pill. Glycerine itself, except in very small quantity, is not a good excipient though frequently prescribed; pills containing it are liable to absorb moisture and become sticky; they also do not take silver well when required so to do. Pills prepared with mucilage are liable to become very hard when kept for any length of time; with spirit they require to be rolled off quickly or will become brittle and crumble on the machine. Spirit should never be used when there is much resin in the pill, indeed with this, as with the other liquid excipients named, most pharmacists will have ascertained the special cases to which they are best adapted as the result of experience. Of the extracts that of liquorice is about the most useful, as it possesses no active medicinal properties; confection of roses and that of hips usually tend to increase the bulk of the mass rather more than is desirable, otherwise they possess good combining properties. It not unfrequently happens that the ingredients of a prescription, instead of requiring moisture, have in themselves too little solidity to form or retain the pilular consistence; we have as it were all mortar and no bricks wherewith to build. In such cases Mr. Proctor strongly recommends the addition of powdered wood; he compares a pill to an animal, and says this substance is real bone to it, which, doubtless is the case; but in the face of the satire on the apothecary and his sawdust pills, I have never been able to reconcile my mind to its use.

If the mass require but a small addition in the way of solidity and some elasticity, then a little powdered tragracanth answers admirably, but if the quantity be too great then the elasticity is also excessive and it becomes somewhat difficult to round off the angles under the pill finisher. If the mass is much too soft, and consists chiefly of moist extracts, the first thing to be done is to dispel some of the moisture by the judicious application of heat (for this purpose a very small hot-water plate is an acquisition to the dispensing counter), a little of some powder, such as tragacanth, gum arabic, liquorice root, or taraxacum might then be worked in and the mass be rolled out quickly before it has thoroughly cooled. If the extract possess a hygroscopic nature, such as that of dandelion, then tragacanth, which tends to dryness, answers well. But what I believe to be still better in the case of extracts which are not injured by drying is to use them in powder.

Pills containing much essential oil are best manipulated by the addition of a few shreds of

* Read before the Liverpool Chemists' Association, November 22, 1877.

wax and a little powdered soap where not incompatible; this combination enables the operator to get in more oil, carbolic acid, creasote, etc., in a satisfactory manner than any other means I am acquainted with. Almond meal has also been recommended for causing oily and watery substances to unite; it does so by its emulsifying properties and would be very valuable but, unfortunately, it gives an insoluble character to the pill and thus impairs its activity. An excipient formerly much prescribed, but about the worst I know of, is crumb of bread.

Some substances require special excipients. I will only mention two of these—sulphate of quinine might be made into pills with confection of hips; better, because smaller, with glycerine of tragacanth; but, best and smallest with tartaric acid (about two grains to twenty) and a single drop of water. Camphor and extract of henbane usually form a very refractory mass, breaking and crumbling on the machine; if, however, the camphor is powdered by the addition of a little *water* instead of *spirit*, all difficulty disappears, the mass retains its plastic condition for some time, and might be rolled out with perfect ease.

Whatever means are used for the formation of pills, they should when finished be perfectly spherical and present a smooth, firm surface; this is essential, not only for the sake of appearance, but for the proper performance of the second operation, viz., that of coating them.

Reading a short extract from the 'United States Dispensatory,' of 1833, will prove that even America, which has gone ahead so rapidly in pill coating as in most other things, contemplated nothing of the kind in those days. The method of covering pills with powders as there described was that which obtained in this country during my early initiation into the art and science of pharmacy some twenty years or more ago; indeed it is still practised in many, if not most pharmacies in the present day, a little of the powder also being placed in the box to keep the pills at a respectful distance from each other. The first improvement on this with which I became acquainted was that adopted by myself in 1860; possibly the same or similar methods might have been in use at the same time by others, but as far as myself was concerned it was original (at least as original as ideas ever are), and very simple too. It consisted in utilizing a waste product, viz., the resin left after preparing syrup of tolu; this, dissolved in ether, preferably with a sp. gr. of ·717 or ·720, formed a varnish in which the pills were rolled and whilst still moist were transferred to a box containing finely powdered french chalk, then turned on to a warm pill tray and kept rotating for a short time; finally they were polished *with slight* pressure under the pill finisher. Pills so prepared possess a steel grey appearance and smooth surface, though not the egg-shell white character now given them; but this method of procedure or some modification of it is the first part of the process adopted for accomplishing the latter.

The pills are now placed in a covered pot as at first, and are moistened with syrup, mucilage, or a mixture of the two; when evenly covered they are transferred to a box containing french chalk, or a mixture of it and finely powdered sugar, well shaken and again transferred to a warm pill tray, kept rapidly rotating until dry and smooth; the operation taking but a comparatively short time. Well covered in this way they will keep good for years. I have a specimen of some pills thus coated more than four years since; on cutting them open they will be found less hard than they would have become in as many weeks if left exposed as these have been and uncoated.

There is a drawback to this covering in the case of pills containing essential oils; the oil dissolves some of the colouring matter of the pill, and takes it through the coating which then becomes yellow or brown and unsightly. Manufacturers of these pills on the large scale usually get over this difficulty by substituting gingerine for any essential oil in the formula, but such a procedure is inadmissible in dispensing.

Under these circumstances the covering recommended by M. Calloud (*Journal de Pharmacie*, xxiii, 310) might be used with advantage; it consists of a powder prepared as follows:—

One part of powdered tragacanth mixed with two of water is pressed through muslin; this is then mixed with twenty parts powdered sugar of milk and spread on a porcelain slab in a thin layer to dry; lastly, it is reduced to a fine powder. This is not easily accomplished, but I have found by experience that the excellence of this coating largely depends on the fineness of the powder. The pills are merely moistened with water and rolled in the powder, keeping up a rotary motion till dry, and repeating the operation if necessary.

Pills of this kind also do well with gelatine coating, one of the oldest methods, and one which is now seldom used in this country, but the Americans still adopt it to some extent, and one house in New York advertises somewhat extensively a full line of gelatine-coated pills. The process is exceedingly simple, but like all others requires some amount of practice and dexterity for its successful accomplishment. The only necessary apparatus consists of a pin board, *i. e.*, a piece of wood into which pins have been pressed, so as to allow the points to project a good distance above the surface, and a small vessel of melted gelatine. I generally use the French sheet gelatine,—say four parts, water sixteen, glycerine one. The points of the pins should be slightly greased before placing the pills on them, and any scum or skin should be removed from the solution before dipping them; when removed a rotary motion with occasional inversion is kept up till the gelatine has set, they are then put aside to dry. In the *Pharmacist* (March, 1877) Mr. Charles B. Allaire describes an ingenious little apparatus, which can be readily constructed for coating pills with gelatine. A second piece of wood, the same size as the pin board, is so hollowed out in small hemispherical depressions as that one pill in each hollow corresponds with each pin in the pin board; this is for the convenience of picking up a quantity at once. When dry the whole are removed at once by a kind of comb with long teeth made to slide between the pins.

According to the tabulated results of a number of experiments by Mr. J. P. Remington (*Amer. Journ. Pharm.*) gelatine coating is not readily soluble, but the solvent used was only water, and even so could not apply to the coating containing glycerine. By a similar means Hawker's patent jujubes are covered, and I have never heard a customer complain of any difficulty in removing the coating; it appears to be readily soluble in the mouth.

Mr. E. K. Durden proposes (in the journal just quoted) to cover pills with collodion having a sp. gr. ·810; two dippings in this are said to give an elegant appearance; it is readily put on and completely conceals the taste of the medicine. Valerianate of zinc pills so coated,—which is about as severe a test as we can apply,—stand it moderately well. It remains, however, to be proved how far this coating is soluble in the stomach.

We now come to sugar coating. This process is conducted by manufacturers, especially in America, on an extensive scale, and seems daily to be gaining favour from the profession, the pharmacist, and the public. It possesses the advantages of a pleasant taste and ready solubility, and whilst there might be some doubt on the part of the patient as to the prudence of frequently swallowing pearl coating there certainly could be none on the part of the most fastidious as to taking a small quantity of sugar. This coating varies somewhat, however, and the purest sugar is not always used to produce the whitest coating; still it might be done without any admixture.

Numerous inquiries have been made of late as to the exact process to be adopted for satisfactorily accomplishing this object, the usual reply being, "Follow the practice of the confectioner in the production of his comfits," about which I may add there is but one secret. The process is simply this: pills well dried on the surface are introduced into a tinned copper bowl with a flat bottom, or enamelled iron dish, the surface of which has been moistened with syrup or with syrup and gum, they are then rotated and gently heated, very finely powdered sugar is dusted on, and the motion kept up until a perfectly dry, hard, and whitish coating is obtained, the operation being repeated till the desired result is accomplished—which with the pharmacist in his first attempt *is usually not the case.*

But now for the secret. We have followed the method of the confectioner in its outline; but what about his skill and experience? These are just the things wanting; the confectioner would be a very clumsy hand at producing the pill, the pharmacist is usually equally so at sugar-coating it; the confectioner could be educated to make the pill and the pharmacist to coat it with sugar if he would only apply his ability, gain experience by perseverance, and keep up by practice his acquired knowledge. A gentleman writing to the *Pharmaceutical Journal* a short time since, complained of what he considered to be want of courtesy on the part of certain Americans respecting a little apparatus for sugar-coating small quantities of pills. The truth is, I believe, that the said apparatus is to be found in every pharmacy; it is simply the knowledge of how to use it that is not.*

Lastly, we have silvering as an elegant coating readily applied. It is mentioned in the old 'United States Dispensatory' as a thing of the past, but is frequently used in the present day. I need say little or nothing about its application. Avoid the use of glycerine as an excipient in the pill, put as little moisture on the surface as will enable the silver to adhere, and burnish by rotating in a covered pot containing a little cotton wool to remove any loosely attached fragments of silver leaf.

* In the *Amer. Journ. Pharm.*, May, 1867, there is an article by Mr. H. C. Archibald, on "Sugar Coating Pills."

PARAFFIN OILS AND THEIR ACTION UPON METALS.*

BY DR. STEVENSON MACADAM, F.R.S.E.

During a lengthened series of experimental observations on different paraffin oils it was found that certain oils burned somewhat imperfectly in different lamps, and an examination of these oils led to the discovery that they were contaminated so largely with lead compound, as to lead to the choking up of the wicks, and ultimately to the lessening and practical extinguishment of the light. In the case of one of the oils the wick of the lamp had to be changed several times during a single night and the examination of these wicks proved that they contained so much lead compound as to leave, when charred, a fine net work of metallic lead. The oil in question had been stored in a cistern or tank lined with sheet lead, and notwithstanding the absence of affinity between paraffin oil and other substances, as indeed its own name indicates, the oil had apparently acted upon the metal and held the lead in solution.

In order to determine how far paraffin oil could act upon lead, a series of experiments was instituted in which oils of various qualities, originally free from lead, were allowed to remain in contact with the metal for different periods of time. These experiments proved that all the samples of paraffin oil which were experimented upon had more or less action upon metallic lead; that mere contact of the oil with the lead was sufficient to communicate traces of lead to the oil, and that in a week's time the oil invariably became so highly charged with lead that it was rendered unsuitable for combustion in ordinary lamps, owing to the encrusting of the wicks, and the consequent lowering of the luminosity of the flame. In order to render the experimental observations more complete similar trials with paraffin oil and other metals were carried on, and to enable the various experiments to be compared with each other the same quality of oil was employed in the principal investigations with the different metals.

Twelve series of experiments were made with the highest quality of burning oil and the metals—lead was employed in three of the trials because this metal is more liable to be acted upon when the surface is bright than when the surface possesses the ordinary skin or coating of oxide and carbonate, and the results obtained with bright lead might not apply to tarnished lead. This difference in action is well known in the case of the chemical influence of different natural waters upon lead.

1. *Bright Lead.*—When paraffin oil is brought in contact with scraped lead where the surface is quite bright, the chemical action begins instantly, and a few moments are alone required to communicate the metal to the oil. In a day the action is so decided that the oil begins to present rather a cloudy appearance, owing to the presence of the lead compound, and on washing the oil with water the latter on settling retains a milky appearance from the lead compound, which is apparently a basic salt, and has an alkaline action on test papers.

2. *Tarnished lead with unprotected edges.*—Lead cut into small sheets and placed in the paraffin oil without any protection to the fresh cut edges necessarily exposes a large surface of tarnished metal with the natural skin of oxycarbonate, and a comparatively small surface of bright metal, where the fresh cut edges are visible. The investigation showed that under these circumstances, the lead is not so readily acted upon by the oil, but in a couple of days the oil gets impregnated with lead compound and becomes unsuitable for illuminating purposes.

3. *Tarnished lead with protected edges.*—In this case the lead was taken with its natural skin and the fresh cut edges were protected by wax. Under those circum-

* Read at an Evening Meeting of the North British Branch, November 21, 1877.

stances, the paraffin oil acts even less energetically, and though traces of the metal may be found in the oil in an hour from the commencement of the experiment, yet it takes about a week before the oil becomes largely impregnated with the metal.

4. *Tin.*—This metal is very slightly acted upon by the oil, and in a month's time the amount of metal dissolved in and diffused through the oil is very small, and is not sufficient to impede the combustion of the oil in lamps.

5. *Copper.*—A very slight action is apparent after a month's exposure, and practically the oil is not affected thereby as a luminant.

6. *Iron* is slightly affected by the paraffin oil, and on ten day's contact the oil becomes deeper in colour and throws down a fine ferruginous sediment. The oil itself is, however, not materially injured as an illuminating agent.

7. *Zinc.*—This metal is sensibly acted upon by the paraffin oil, and the latter retains the zinc compound in solution and suspension. The oil is decidedly injured as a luminant.

8. *Tin solder* of the best quality, containing two parts of tin and one part of lead, is acted upon by the paraffin oil, and the latter is injuriously affected as an illuminating agent.

9. *Tin soldered with tin solder* is also acted upon, and lead is dissolved out from the solder by the paraffin oil. The quantity of metal dissolved out is not large, but is sufficient to influence the oil as a luminant.

10. *Tinned copper* is not practically affected by the paraffin oil so far as the combustion of the oil is concerned, but traces of both the tin and the copper are found in the oil after a month's exposure.

11. *Tinned iron* is acted upon very slightly, but the oil does not suffer as an illuminating agent.

12. *Galvanized iron* is readily acted upon by the oil, and the quality of the oil for burning with wicks is sensibly injured.

These experimental observations demonstrate that the metals lead and zinc should not be employed in the construction of or in the lining of cisterns or other vessels intended for the storage or reception of paraffin oils; that the metals, tin, copper and iron, as well as tinned copper and tinned iron, may be safely employed in the fabrication of the cisterns or other vessels, and that ordinary tin solder, containing lead, should not be used in the soldering of such cisterns or vessels. Galvanized iron should likewise be avoided. Whilst stating that the cisterns or vessels for the retention of paraffin oil may be safely constructed of or be lined with tin, copper or iron, it would be preferable to use cisterns or vessels lined with enamel in the interior, provided such could be obtained of sufficient size for the purpose. The ordinary enamelled iron pots present absolutely no surface upon which the paraffin oil can act, and cisterns or vessels constructed in a similar way with an interior lining of enamel would retain the paraffin oil for any time without affecting in the slightest degree the purity of the oil or its entire suitability for illuminating purposes.

In cases where lead cisterns or vessels have been in use for the retention of the paraffin oil there can be no doubt that the inferior illuminating power of the oil may be fairly attributed to the lead impregnation. The action is lessened much by washing over the surface of the lead with dilute sulphuric acid which forms a coating of the insoluble sulphate of lead, in or through which the paraffin oil has comparatively a feeble action. The oil, however, does take up a little lead and hence the impurity still continues to pass to the wick. A better protective coating is obtained by brushing over the surface of the lead with solution of sulphuretted hydrogen, and still better with sulphide of ammonium, when a coating of insoluble sulphide of lead is formed, on or through which the paraffin oil has still less action than on or through the sulphate of lead. The impregnation of the oil, however, still goes on, though in a minimum degree.

The paraffin oil employed in the principal trials was of excellent quality and was free from acid or alkali. The action, therefore, of the oil upon the metals was not due to the presence of any impurity in the oil. In other experiments made with different samples of paraffin oils upon the metal lead, it was found that the power of action differed materially in the various oils, but such difference in degree of action was not traceable to impurities in the oils. It is probable, however, that the various proportions of the hydrocarbons present may have an influence in aiding or arresting the action of the oil upon the metal.

TEST FOR SANTONIN.*

BY DAVID LINDO.

Place the santonin in a small deep porcelain dish, and dissolve it (without heat) in concentrated sulphuric acid. Rubbing the crystals down with a glass rod greatly facilitates solution. Add highly dilute solution of perchloride in small quantities at a time, and between each addition give the dish a pretty quick rotatory motion while it is supported on a table. A fine red colour is first developed, which changes to a magnificent purple, and then to a splendid violet as the sulphuric acid becomes more dilute. The heat produced by mixing the fluids is necessary to develop the colours.

When applying the test to small quantities of santonin a somewhat different method of proceeding must be adopted. The experiment in this case is best performed in a 1-inch shallow porcelain capsule, with a thick flat bottom. Mix the highly dilute solution of perchloride of iron with an equal bulk of concentrated sulphuric acid, and add the mixture to the santonin. Heat must then be cautiously applied. The crystals of santonin will slowly dissolve, and the colour will be developed.

The capsule is conveniently supported on the blade of a spatula, and heated by a spirit lamp.

One drop of a solution of 1 grain of santonin in 1 fluid ounce of chloroform was evaporated to dryness in a small capsule, and the residue heated with a drop of the perchloride of iron and sulphuric acid mixture. A very fine reaction was obtained.

The separation of santonin, however, from other organic matters would in most cases be a very difficult—and in many instances an impossible—thing to accomplish, owing to the facility with which it suffers decomposition.

In trying the experiment of separating santonin, by means of chloroform, from a powder containing rhubarb and santonin, I noticed a thing which I have not seen mentioned before. The chloroform separated from the powder by filtration was evaporated to dryness, and the residue tested for santonin. The violet colour was obtained very distinctly. I then tried the effect of the test-fluid on the colouring-matter of rhubarb alone, as I noticed this is disolved by chloroform. The test produced a reddish colour, not the violet or purple colour of santonin.

Thinking that in the case of rhubarb the iron had nothing to do with the reaction, I next tried the effect of *concentrated sulphuric acid alone* on the colouring-matter of rhubarb. I found it produced a beautiful scarlet colour: this is much the same effect (as is very well known) produced by alkalies on the colouring-matter; and when the latter has been turned red by an alkali an acid restores it to yellow.

Falmouth, Jamaica.

* From the *Chemical News*, Nov. 16, 1877.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 15, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal· MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE MEANING OF SYMBOLS USED IN PRESCRIPTIONS.

THE plan of setting apart a special section of the Journal to the discussion of questions connected with dispensing appears to have been an appropriate and welcome means of intercommunication, if we may judge from the number of queries sent in, and from the number of prominent pharmacists who have come forward to render information and express their opinions. If no other result had been attained than that of deciding the question raised by the memorandum No. 21, which appeared last August, there would still be much ground for satisfaction, and we hope that it is not the only instance in which service has been rendered by the column for Dispensing Memoranda.

The question we refer to, concerning the propriety of interpreting the ounce symbol ℥ as indicating apothecaries' weight or the avoirdupois weight, is one in reference to which it appears, from the correspondence that has been published, a much greater difference of opinion prevailed than might have been expected. The first two answers to the query were diametrically opposite, and in commenting upon the subject in the October monthly article we seconded the view expressed by Mr. E. SAMSON, that the symbol ℥ is simply a mode of representing the old apothecaries' ounce of 480 grains, just in the same way that the symbol ʒ represents the eight part of that weight, or the drachm.

This opinion was speedily called in question by Dr. SYMES, under the impression that some ten years since the matter had been finally settled in the opposite direction; and his argument in favour of the ℥ symbol being understood to signify the avoirdupois ounce is based upon the fact that there is no specific mention of this sign in the preface to the British Pharmacopœia, where it is stated that physicians are to have the option of using the symbols ʒ and ℈ as representing sixty and twenty grains. But why that omission of the sign ℥ in the reference to apothecaries' weight should place its use in any more ineligible position than the use of the correlative symbols ʒ and ℈, or why it should attach to the ℥ symbol a significance which it never possessed, we have all along failed to comprehend, and from that point of view we still regard Dr. SYMES' argument as fallacious.

Our Glasgow correspondent, though conspicuously positive, was in our judgment not less entirely in error, and he also confuses the symbol of the troy pound with that properly belonging to the avoirdupois pound, which resembles it but is without the bar across the lb. His inference from the recommendation to avoid the use of the terms ounce and pound in reference to any other than the avoirdupois ounce and pound is not justified when he says that if a physician writes ℥j, meaning 480 grains, he has no business to do so, for this is merely begging the question, and his statement involves the assumption that the symbol ℥ represents the avoirdupois ounce. If he had said that the term ounce used to indicate 480 grains was improper he would have been so far right and in accordance with the British Pharmacopœia.

It is, however, unnecessary to follow out in further detail the arguments of the several writers on this subject, since we are enabled, through the kindness of Professor REDWOOD, to place before our readers a minute exposition of the facts to be taken into consideration in dealing with this question. In the letter which Professor REDWOOD has written (see p. 477), he gives in the first place a historical *résumé* of the legal position of the question, showing that out of four systems of weights and measures which have been legalized, two, viz., the troy and avoirdupois, are accurately defined on scientific principles, while the other two are made up of integers taken from them, and in one case having intermediate integers introduced for the purpose of making the system more suitable for use in prescribing and dispensing medicine, this constituting the apothecaries' weight in which the pound, ounce, and grain of the troy system are supplemented with the drachm and scruple; the ounce like its subdivisions being represented by the symbol ℥, while the avoirdupois ounce, as ordered to be used in medicine, is represented by the symbol oz.

The authority with which Professor REDWOOD writes upon this subject, as the editor of the British Pharmacopœia, is further strengthened by the concurrence of one of the members of the Pharmacopœia Committee, whom he has consulted, with the result that he entirely approves of the views expressed by Professor REDWOOD. We may, therefore, regard this question as being practically and definitively settled, and we recommend our readers to the careful consideration of the letter which appears under the head of Dispensing Memoranda in this number of the Journal.

Before concluding, however, it may be well to point out that the misconception under which some of our correspondents have laboured seems to have arisen in great measure from an impression that the apothecaries' weight is obsolete. That, indeed, seems to be the only real foundation for the opinion that the avoirdupois ounce should be understood as being indicated by the use of the symbol ℥. In regard to this point, however, it is explained by Professor Redwood that the intention of introducing avoirdupois weights into the British Pharmacopœia, and recommending their use by medical men, was to facilitate the ultimate substitution of these weights for the old apothecaries' weights. It was not reasonable to expect that this change could be effected suddenly and it is for this reason that the recommendation to use avoirdupois weights was accompanied by the sanction to use the symbols ʒ and ℈ in place of writing gr. 60 or gr. 20 in their prescriptions. This sanction, however, does not furnish any justification for confounding the weights of the avoirdupois system with the apothecaries' weights.

THE UNITED STATES PHARMACOPŒIA COMMITTEE.

The proceedings of this Committee, to whose first report reference was recently made in these columns, appears to be attracting considerable attention amongst United States pharmacists. The suggestion that has raised most discussion is the one to abandon all measures of capacity and to express quantities only in parts by weight. Professor Diehl points out that though this may be comparatively easy with the majority of preparations, yet, in dealing with one important class—the liquid extracts—it will be a problem involving much thought and labour to solve. One difficulty raised by this gentleman is not very complimentary, though probably it cannot safely be ignored in the United States any more than it could be in this country. Professor Diehl asks, evidently doubtingly, whether, in the event of the change being made, the average American pharmacist could be entrusted with the production of preparations the eventual strength of which would be so dependent upon the careful determination of the specific gravities of the menstrua employed and judgment as to the complete exhaustion of the drug. He manifests an evident fear that the supposed simplification may result in throwing the production of certain galenical preparations into the hands of manufacturers more than it is at present.

It is also noteworthy that there are signs that the use of glycerine as a menstruum, which constituted such an important feature in the last edition of the United States Pharmacopœia, is now looked upon in some quarters with disfavour, and an opinion has been expressed that in respect to the menstrua generally too much has been sacrificed to uniformity. Professor Remington believes that glycerine is too freely used, and that it is objectionable on account of its powerful solvent properties. The professor compares glycerine to an over-enthusiastic friend, who gets the pharmacist into more difficulty than he well knows how to get out of, and expresses his opinion that the proper plan is to use as little of either alcohol or glycerine as possible, or, in other words, that it is necessary to determine the smallest amount of these liquids that would be sufficient to exhaust the drug and to preserve the product.

There is no doubt ground for congratulation to be found in this discussion, for if but a portion of the work shadowed forth in the various suggestions be satisfactorily performed, the pharmacy, not only of the United States, but of the whole world, must be the gainer.

CONGRESS OF THE ITALIAN PHARMACEUTICAL ASSOCIATION.

Our Roman Correspondent writes:—On Monday, the 3rd inst., the representatives of the Italian Pharmaceutical Association closed their sitting at Florence, under the presidency of the Hon. Signor Asperti, Deputy in the Parliament of Italy. The question for deliberation was:—The bases on which to organize the "Associazione Federale Farmaceutica Italiana" (Italian Federal Pharmaceutical Association). These were ultimately settled and the Congress proceeded to the election of office bearers. Professor Luigi Guerri was elected President; Signor Cesare Pratesi, Director of the Pharmacy of the Ospedale Maggiore, Florence, Vice-President; and Drs. Enrico Pegna and Guglielmo Romei, Secretaries. The Congress then commissioned Professor Luigi Guerri as President, and Dr. Pegna as Reporter, to compile a report to be presented to the Senate of the Kingdom on the labours of the Congress relative to the new sanitary code.

In the evening the members of the Congress met in the Cornelis Restaurant at a sumptuous banquet given by the Florentine Pharmaceutical Association, which was represented by its most distinguished office-bearers. Much cordiality prevailed, and among the toasts that of the "Pharmacists of Great Britain" was not forgotten.

THE SALE OF SPIRIT OF WINE.—EXCISE PROSECUTION.

The fact that the question is not unfrequently asked whether a chemist and druggist is allowed to sell spirit of wine would appear to indicate that there exists here and there some uncertainty as to the law on this point. It may be useful, therefore, to quote somewhat prominently an announcement from the *Scotsman* to the effect that on Tuesday last, at the Justice of Peace Court held at Dunblane, three chemists and druggists were fined £12 10*s.* each for selling spirit of wine without a licence, and that a second penalty of a like amount was imposed upon one of them for the offence of selling methylated spirit without a licence. The magistrates recommended, however, that the Excise authorities should if possible make some remission of the penalty in each case.

A DANGEROUS ADDITION TO A QUININE MIXTURE.

A Correspondent of the *Indian Daily News* records a remarkable case of poisoning at Peshawur. A native, having to make up a quinine mixture for the wife of an officer on the station, added hydrocyanic acid as a solvent of the quinine. The mixture was taken and death was instantaneous.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fourth general meeting was held at the Royal Institution, Nov. 22nd, 1877. The President, Mr. T. Fell Abraham in the chair.

The minutes of the previous meeting were read and confirmed. The donations to the library were acknowledged.

Mr. Michael Conroy, F.C.S., said there appeared in the *Pharmaceutical Journal* of Nov. 3rd, an article relative to a recent prosecution for selling adulterated cream of tartar, which stated that out of six samples obtained from different sources and submitted to analysis, two were found adulterated with barium sulphate. Being curious to know how Liverpool samples would turn out, he procured nine samples from various sources, which he analysed with the result of finding one adulterated, and that only to the amount of 1·3 per cent. The others were all good commercial quality, the tartrate of lime varying from 4 to 6 per cent. He would offer a few remarks on a means of detecting this adulterant, especially as the pharmacopœia gives no qualitative test for its detection. The easiest and most readily applied method depends on the solubility of cream of tartar in solution of potassium hydrate, or in other words its conversion into the neutral soluble tartrate. The Pharmacopœia of the United States gives this test in the following words :—"Bitartrate of potash is dissolved sparingly in water, but freely by hot solution of potass ; whatever remains undissolved by the alkaline solution is impurity." He would recommend this test for its simplicity to those who have not the time to go further into the matter ; but it would of course not do to conclude that any matter left undissolved is barium sulphate, but sufficient would be known to prevent anyone from selling such an article. The plan he adopted for the barium sulphate was to incinerate a weighed quantity, whereby any sulphate of barium present was converted into the soluble sulphide at the expense of the carbon of the tartrate, and this, on the addition of water to the incinerated mass, is further converted into carbonate of barium by the action of the carbonate of potassium in solution. The carbonate of barium, together with the carbonate of lime produced by the decomposition of the tartrate of lime, was then collected on a filter, washed and dissolved in hydrocloric acid, and from this solution the barium was precipitated as sulphate by the addition of dilute sulphuric acid, the usual precaution rendered necessary by the presence of lime being observed.

Mr. Alfred E. Tanner stated that he had also recently examined eight samples of cream of tartar, with the result that all contained tartrate of lime, some to a very large extent; two samples were in addition adulterated with barium sulphate. In view of a case recently reported in the *Pharmaceutical Journal* in which a chemist of Huddersfield was fined on the report of the public analyst, who stated that he found 2 per cent. sulphate of barium in the sample of cream of tartar sold, he would recommend all chemists to examine their stocks of this article, and for this purpose he would propose a very simple test which needed no more special appliance than he hoped was to be found in every pharmacy, viz.—a test tube. One part of the suspected sample should be shaken with ten parts liquor potassa of the Pharmacopœia strength, when if pure it will entirely dissolve; the same result will be attained if the sample contain tartrate of lime ; but if the solution be now heated to boiling, tartrate of lime will be precipitated ; this is owing to the curious property it possesses of being soluble in cold liquor potassa, but not in hot. Barium sulphate, if present, will of course remain undissolved in the first part of the process, and may be distinguished from most other substances by its insolubility in strong nitric acid. There is one caution, however, to be observed in this process. The liquor potassa itself must be ascertained to be free from lime, and as this is not an improbable impurity, he would just state that its absence may be assured by adding a few drops of solution of oxalate of ammonium to the liquor potassa, when the lime, if present, will be shown by a formation of white precipitate. Mr. Conroy had rather questioned whether the presence of tartrate of lime in any sample could be considered an impurity, but he (Mr. Tanner) would remind the meeting that the Pharmacopœia had clearly defined what acid tartrate of potash, or cream of tartar (for they are synonymous), should be, and had provided tests which entirely excluded the presence of more than a trace of lime salt, and he contended that tartrate of lime to the extent of 5 per cent. or more could not in any sense be considered a trace, and further, the last test given, viz., the quantitative one, assumed the absolute purity of the article in question, for it ordered 188 grains of the sample to be incinerated and the alkaline residue to be titrated with volumetric solution of oxalic acid, of which 1000 grains measure should be required for exact saturation. The 188 is the molecular weight of acid tartrate of potash, and this requires one half the molecular weight of oxalic acid in grams, viz., 63 for exact saturation, which is the quantity contained in 1000 grain measures of the solution ; consequently, 100 per cent., or absolute purity, is indicated. Of course we all know whence the tartrate of lime is derived, being contained in the argol or crude tartar ; insufficient purification of this will account for its presence in the finished product. Its separation, however, may be effected by treating the crude tartar with very dilute HCl, which removes the lime salt, and then washing with cold water to remove the acid. His opinion was that the presence of 5 per cent. or more tartrate of lime was quite as much an impurity as was the presence of sulphate of lime in precipitated sulphur. He only wondered that the marvellous zeal in detecting adulteration displayed by public analysts had not before been directed towards such a commonly used and commonly impure article as cream of tartar, and he strongly urged pharmacists to examine this article by the simple test mentioned above before taking it into stock, lest they should find themselves placed in the unfortunate position of the chemist in the Huddersfield case before alluded to.

Mr. Conroy did not think with Mr. Tanner that public analysts would treat tartrate of lime as an adulteration, because it existed in tartar as a natural impurity, and an impurity for which the Pharmacopœia made allowance by stating that the solution "neutralized by ammonia was rendered slightly turbid by oxalic acid." Pereira also states that tartrate of lime exists in cream of tartar to the extent of from 2 to 5 per cent.

Other members having taken part in the discussion of the above subject,

Dr. Charles Symes read a paper on "Pills and Pill Coatings," which is printed on p. 461. In a discussion which followed,

Mr. Conroy said he considered the practice of covering pills with a resinous varnish previous to coating as most objectionable, because the pills were by that means rendered almost insoluble, and that such a practice was unnecessary was evident by the fact that the finest pearl-coated pills in the market are guaranteed free from resinous coating. The gelatine pills made and exhibited by Dr. Symes he considered were very neatly coated, and superior to some of American manufacture which he had seen and which he had heard were sold to a large extent in the United States. They were elliptical in shape, and it was claimed by the manufacturers that pills of this shape were more readily swallowed than the ordinary spherical pills.

The President and Mr. Tanner did not think with Mr. Conroy that resin coating of pills was objectionable, because the influence brought to act upon it when in the stomach immediately removed it.

Dr. Symes replied to the points of discussion of his paper, and a cordial vote of thanks to the author brought the meeting to a close.

THE COVENTRY AND WARWICKSHIRE PHARMACEUTICAL ASSOCIATION.

A well attended meeting of the chemists of Coventry and neighbourhood, with their assistants and apprentices, took place on the 3rd inst., in the Mayoress's Parlour, St. Mary's Hall, Coventry, to consider the advisability of establishing "an Association having for its object the better scientific education of its associates, and the general advancement and mutual improvement of its members."

After the circular convening the meeting had been read, the chairman (Mr. Councillor Wyley) dilated on the great benefits which must accrue from the establishment of a local Pharmaceutical Association. He was desirous of seeing established in Coventry facilities which would afford to the assistants and apprentices of the district better opportunities for the study of the science and practice of pharmacy. He held in his hand, and had pleasure in reading to them, a telegram, received from Professor Attfield, expressing his entire sympathy with the objects of the meeting, and his good wishes for the satisfactory carrying out its intentions. He also read letters of apology, from Messrs. John Wyley, Councillor Phillips, Dudgeon, etc., all of whom heartily supported the movement. He had every reason to hope that the Association would prove not only beneficial to the students, but would serve as a means for the promotion of good feeling amongst the members of the trade.

Mr. G. Walker (Wyley's and Co.) then proposed the first resolution:—"That a society be formed by the chemists of Coventry and district, having for its object the promotion of brotherly feeling amongst its members and their mutual improvement, and the better scientific education of its associates." Mr. Walker observed that the best augury of the success of the movement they had met to establish was the unanimity with which the proposal had been received by the members of the trade. It was reasonable to expect some "cold water" would attend the launching of such a project, but they must contrive by the fire of energy to convert the water thrown into "steam," and thus propel the movement to a useful and prosperous issue.

Mr. W. Litchfield had pleasure in seconding the proposition, inasmuch as any agency for the scientific advancement of their younger brethren must redound to the credit of their employers.

Mr. Stokes Dewson (Hon. Sec., Midland Counties Chemists' Association), in supporting the resolution, remarked that such societies afforded the means of reunion and better acquaintance between those whose interests were identical, and the mutual interchange of ideas on scientific and general topics affecting the trade. Local pharmaceutical classes, properly organized and conducted, were of inestimable benefit to apprentices and assistants, affording the best specific against the evils of superficial knowledge attained by the "cram" system.

The resolution being unanimously carried, Mr. Councillor Sellors then proposed that the society should be called "The Coventry and Warwickshire Pharmaceutical Association." He contrasted the present meeting with one he had attended prior to the passing of the Pharmacy Act, and observed that as their present objects were purely educational it must command the sympathy and support of all connected with the business.

Mr. Whiting, in seconding the resolution, stated that a personal canvass of the district led him to believe that the Association would prove to be the nucleus of a local centre of pharmaceutical education.

This resolution having been carried the meeting elected the following officers for the ensuing year:—President, Mr. Councillor Wyley; Vice-President, Mr. Councillor Sellors; Treasurer, Mr. Alderman Wyley, J. P.; Members of Council, Mr. G. Walker, Mr. Councillor Bird, Mr. Councillor Phillips, Mr. Hodgkinson, Mr. Hinds; Hon. Secretary, Mr. Frederick Barrett, F.C.S.

The President then called upon their newly elected Secretary to suggest a programme for their consideration.

Mr. Barrett, after reviewing the proposed objects of the Association, stated that in towns where such societies existed, it was found that frequent social or scientific gatherings greatly tended to promote better feeling and more harmonious working amongst members of the same trade. He suggested monthly meetings at which scientific and popular lectures should be delivered, papers read on various subjects connected with pharmacy, new drugs, apparatus, etc., exhibited, and their merits discussed. Possibly once a year an extra entertainment might be arranged, to which ladies could be invited, and he would even suggest, as an extra attraction, a dance; being convinced from the mercantile, municipal, and social position of the chemists of the city that such an entertainment would prove not only a matter of enjoyment but a financial success. The society's most important object, however, should be to provide suitable *practical* instruction for its apprentices and assistants. It was too frequently the case that *practical* instruction was either wanting or altogether unsuited for the requirements of the pharmaceutical student. Chemistry could only be taught in the laboratory, botany in the field and by the hedge side, and a knowledge of materia medica and pharmacy amongst the drugs and preparations themselves. For the purposes of the society a room should be engaged where chemical appliances, a library, and the current pharmaceutical periodicals might be placed at the disposal of the students, and he had reason to hope that Messrs. Wyleys and Co. would contribute a valuable collection of materia medica specimens. He hoped to announce at the meeting in January, at which their President (Mr. Councillor Wyley) would deliver the introductory address, an outline of the proceedings for 1878, and a long list of donations towards the funds of the Association.

After a general discussion a cordial vote of thanks to the President brought this highly successful meeting to a close.

SUNDERLAND CHEMISTS' ASSOCIATION.

The annual dinner of the above society was held at the Palatine Hotel, on Wednesday evening, December 5. The chair was taken by the President of the society, Alderman Thompson, and Mr. Harrison Thompson occupied the vice-chair. It was numerously attended by the chemists of the town and several visitors, and all the loyal and professional toasts were duly honoured and responded to.

EDINBURGH CHEMISTS' ASSISTANTS' SUPPER.

The chemists' assistants of Edinburgh held a supper (which they propose shall be annual), on the evening of Thursday, the 6th inst., in the Windsor Hotel, Princes Street; covers were laid for upwards of 100. Mr. John Young (Messrs. Macfarlan and Co.) occupied the chair, and was supported by Dr. Taylor, Dr. Aitchison, and Dr. Linton, Messrs. Taylor and Simpson, a deputation from the Glasgow Chemists' Assistants' Association, and Mr. James Johnstone Taylor. Messrs. Cairncross and Welsh acted as croupiers. After supper the Chairman gave the usual loyal and patriotic toasts which were enthusiastically responded to, that of the Army, Navy, and Volunteers being acknowledged by Captain Watson.

In proposing "Success to our Annual Gathering," the Chairman referred to an attempt to inaugurate an annual social meeting such as the present, made in 1873, but the movement at that time either from apathy or want of support fell through. On the present occasion, however, all this was changed; the preliminary meeting was so enthusiastic and the call so cordially responded to that had it not been that arrangements for the present room had been made and the accommodation thus limited, double the number of tickets might have been sold. In alluding to the present condition of the chemists' assistants of Edinburgh, he stated that as a body they were not only far behind those of London and the larger provincial English towns, but also those of Glasgow and the West of Scotland. He hoped that now they would "gird up their loins and put their armour on," and waking out of their lethargy organize a permanent association, which he trusted would, by bringing them into contact, make them a more united body. Before concluding he welcomed the deputation from Glasgow and acknowledged the kind support given by the medical gentlemen present.

Mr. Welsh, in proposing "The University and Royal Colleges of Physicians and Surgeons," referred to the many illustrious names which had been connected with these institutions. Such men as Simpson and Sime had given to the Edinburgh University a name that would last for ever; such a man also was the late Dr. J. Warburton Begbie. Within the last few months several names had been taken from the roll. Sir Robert Christison had retired from his chair, and Professor Lister and Dr. Matthew Duncan had been removed to another sphere; but they could yet rejoice that among those who are left are found the names of Professor Spence, Dr. Taylor, and Dr. Aitchison.

Dr. Taylor, in replying, said that an overworked doctor was the worst speech maker. He had no command of language, his usual vocabulary consisted of about forty words. His favourite phrases were something like "What do you complain of?" "How long have you been ill?" and so on, all day and every day repeating the same list. Again, it had been said that the less a doctor said the more he was thought of; this made him taciturn. He therefore apologized for any disappointment his speech might cause. He would like to ask the Chairman to explain how he considered the Edinburgh assistants were so much behind others. He had always thought that the Edinburgh chemists and their assistants were unequalled for intelligence and accuracy in this country and in the world, and whatever it might be elsewhere he knew that in this city a physician writes a prescription with the faith that his instructions will be carried out to the letter, and if it should happen that he makes a slip, a nice polite young man calls to point out the error and get it rectified, and meantime the customer is told that the prescription will take some time to make up. He concluded in referring to the University by wishing peace and prosperity within her walls, and expressed a hope that her present prestige would not be lost, but that she should go on and flourish continually.

Dr. Aitchison, in acknowledging the toast on behalf of the Royal College of Physicians and Surgeons, said that he represented what in England was looked upon as a person who did not exist, namely, a Scotchman who had lived in England and had found his way back to Scotland again, and so having some experience of English practice he would like to say a word on that subject. The general practice in England, at least in the provinces, was that every doctor should be his own druggist. He while there kept his own drugs, and might say so without much shame. He did his own dispensing, but he owned that he did it badly. In the town in which he was located there were thirteen practitioners, the leading man was a gold medallist of the London University, a B.A. and M.D., and had been a member of Parliament, and this doctor also sold his own drugs. From his (Dr. Aitchison's) experience of the system, he must say that it was thoroughly bad, both for the doctor and for the general public, and he was very pleased to find that this practice did not prevail in Edinburgh. It was a retrograde movement. At the same time he must say that the Edinburgh chemists got as much for their medicine alone, as did the English prescribing druggist with his advice, or for that part as much as the doctors in most cases got for the same.

Mr. William Inglis Clark (Messrs. Duncan, Flockhart and Co.), in proposing "The North British Branch of the Pharmaceutical Society," said that he regretted that such a young man as himself had been selected to give this most important toast; he would have preferred to hear some one speak who had witnessed its growth and progress. He could not speak of the founders except so far as he had been made familiar with them from books or from hearsay. Among those founders was the late Mr. Duncan, to whom they all owed much; he had revolutionized the practice of dispensing. At the time when Mr. Duncan went to the business ointments were sent out in mussel shells, and pills and powders in odd scraps of paper; he inaugurated a new system, and though by many it was considered a dangerous experiment, yet the experiment turned out a success, and showed the master mind. This was not Mr. Duncan's only improvement; among his formulæ should be mentioned that for citrine ointment, which was retained in the present pharmacopœia. Among founders and contemporaries of Mr. Duncan he would mention Mr. Robertson of George Street and the late Mr. Flockhart. The year 1843 witnessed the formation of the North British Branch, and at that time and since Mr. John Mackay had spared neither time nor trouble in organizing the chemists into a harmonious and influential body, who when the time came were not behind in expressing approval of the compulsory Act, which has proved such a benefit to chemists and druggists at large. Regarding the examinations, it has been said that those of Edinburgh were easy compared to London, but deputations and light thrown on the subject from other sources had proved this to be a mistake. As far as papers contributed to the evening meetings were concerned, Edinburgh was behind, being dependent on outside medical and professional aid to a large extent. This should not be. It was to the young men the Society must look for papers, and in dispensing and daily routine many little things must be met with, which if brought forward would be useful to the Society, besides the personal benefit derived by the essayist, the mind being enlarged, and advantage in the way of association and correspondence were sure to result. Edinburgh chemists had a good museum and a good curator, yet more might be done for it by providing specimens. In London, remarkable specimens and fine crystals are constantly being handed over to the museum, and something more like that might be done there. Among the contributors to whom the museum was indebted were Mr. Brown, of Messrs. Macfarlan and Co., as well as T. and H. Smith, firms which have made Edinburgh the centre of the manufacture of morphia and alkaloids. Chloroform was also an important product, of which there were several makers in the city. Referring to early closing, Mr. Clark said that it was to be regretted that some men who were leaders of the movement as assistants, when they became masters were the greatest offenders. He advised each assistant to speak to his own master on the subject as well as to bring general influence to bear, and also urged upon medical men to ask their patients to come early.

Mr. Robert Stenhouse acknowledged the toast.

Mr. Cairncross, in proposing the Glasgow Chemists' Assistants' Association, welcomed the deputation, and expressed a hope that this meeting would not be their last, and wished that in Edinburgh they could boast of such an Association as Glasgow possessed—it would be better for both masters and men.

Mr. Simpson in replying, said that Edinburgh assistants had much greater facilities for education than they enjoyed in Glasgow, but the Glasgow Society hoped soon to have a museum of their own, and they already had a small library. They never had any difficulty in getting papers for their evening meeting, of which they had six each session, and though they might not be of a very high class, yet he was sure the members all derived benefit from the discussion of the subjects. He thanked the Edinburgh assistants for their hospitality, and hoped that before the end of the session his Glasgow friends would be able to return the compliment.

Among the other toasts proposed were "The Strangers," by Mr. Coates; "The Press," by Mr. McLaren"; "The Ladies," by Mr. F. Clark; "The Chairman," by Mr. Thompson; "The Croupiers," by Mr. R. T. Linton, and "The Committee," by Mr. Chislett.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The first meeting of the session of this Association was held on Friday, November 9, 1877, at the rooms, Britannia Chambers, Pelham Street. The chair was occupied by the President, Mr. J. H. Atherton, F.C.S., and there was a very small attendance of members and associates. After reading the minutes of the last meeting the Hon. Secretary, Mr. Roberts Jackson, announced that the *Pharmaceutical Journal* had been regularly received, and also that he had received a handsome donation of £5 to the funds of the Association from Mr. Edward Harvey, of Giltspur Street, London; also splendidly bound copies of 'Science Papers,' and 'Pharmacographia,' from Mr. Thomas Hanbury (through Professor Attfield), in memory of his brother, the late Mr. Daniel Hanbury. On the motion of the President a hearty vote of thanks was awarded to the donors.

Five gentlemen were elected associates.

The President then presented the prizes in the pharmaceutical chemistry class to the successful associates and complimented the recipients on the excellence of their papers at the examination—Mr. J. Clower obtaining the first prize and Mr. J. Cox the second.

The President then said there being so few members present he should decline to give his inaugural address, and his decision was supported and endorsed by Messrs. Fitzhugh, Bolton, Humphreys, Warriner, and Jackson, who all regretted the apathy shown to the work of the Association and the want of personal support to the officers.

After some discussion it was decided to adjourn the meeting, and a deputation, consisting of Messrs. Bolton and Warriner, was appointed to wait on all members not present, and ask them to attend the adjourned meeting to discuss the position and decide on the future conduct of the Association.

The adjourned meeting was held on the 29th ult., and was the largest meeting of Nottingham chemists ever held.

The chair was occupied by the President, Mr. Atherton, who delivered a most able and telling address, in which he alluded to the large amount of apathy and indifference in the work of such associations, by both members and associates, not only in Nottingham, but in nearly all kindred societies in the country. Being determined to get at the root of the disinclination, at the first meeting of the session, he declined to give his usual address to so few members, and urged the adjournment until a canvass had been made to ascertain the general feeling. The suggestions from members were very various, but the necessity of such societies was a principle unanimously agreed upon, and he called upon the meeting to decide, first, whether the society should be carried on; secondly, in what way to command the sympathy and support of all the members; and thirdly, if it were decided to carry on the society, whether the members would pledge themselves to support it by their presence and sympathy at all its meetings. The President then urged the claims of the society on the support of the members at some length, referred to the work which had been done, and impressed upon the members the moral obligations which bound them to carry on the work of local associations. Educationally he maintained that the passing of the Pharmacy Act of 1868, and compulsory examination for business qualification, rendered necessary in large centres the institution of classes and educational facilities for the young men, and that it was the bounden duty of masters, who by apprenticeship undertook to teach the art, mystery and science of pharmacy, that they should either do so themselves, or provide a means by which such education could be obtained. Socially, he believed that such associations were of enormous value for the good of the trade, a value far beyond direct estimation. The *esprit de corps* thus established, and fostered by intercommunion, and the friendship formed did insensibly but surely raise the moral tone of the trade, and made them carry on their business with due regard to the feelings of others as a trade. Association was invaluable, and the President instanced the many occasions in which great advantage has accrued; and made an earnest appeal to the meeting to show more interest in the work of the society.

The President alluded to some important matters affecting the interest of the trade, and in reference to the prosecution of one of their members (Mr. Shepperley) for prescribing over the counter, confessed his consciousness of the difficulty of discussing the question in a mixed company of chemists, as opinions would vary a little according to circumstances and position. He, however, assumed that on one point they were agreed, and that was, to defend their right to give simple medicines for simple ailments when called upon to do so by the public; the only point on which they might differ was the question of degree. He urged that by indiscriminate prescribing they did the public, the medical profession, and themselves a wrong—they were not qualified for it—and thereby risked the public safety. He felt very strongly that if chemists cultivated this indiscriminate prescribing, and if, by visiting, by private consultation, by the use of instruments, they led the public to suppose that they were qualified to give relief in all cases, they not only evaded the law, but did a material and moral wrong. If, on the other hand, they avoided such matters, he maintained that they were perfectly justified in conducting their business as it had been carried on before the apothecaries existed. To refuse relief would be an injustice to themselves, a great inconvenience to the public, and no advantage to the medical men. By such refusal they would act churlishly to their customers and confess themselves ignorant of the properties of the drugs they were called upon to sell. The medical laws were not instituted for the good of the medical men but for the safety of the public, and as such they would receive the support of all right thinking persons; but if a portion of the medical profession overstrained the law—by injudicious action, for their own monopoly—they would not only have the better part of their own body and the chemists, but also the general public against them. He did not wish to foster or sanction a spirit of retaliation, but if medical men would persist in dispensing medicines, for which duty the chemists and druggists of the land were specially educated, they could not be surprised at some counter practice to enable chemists to eke out a living, impoverished by their own action.

The President then referred to the enormous increase of the sale of patent medicines, and to the illicit competition the chemists of Nottingham were subject to at the present time by a barber and a herbalist, and strongly urged the meeting not to reduce the published price in competition, and gave financial reasons and statistics in favour of his views. He further urged that it seemed a most unjust thing that for the safety of the public chemists should be compelled to educate and pass examinations in order to fit them for the sale of poisons and dispensing medicines, and yet the most ignorant persons may sell the most deadly poisons by means of a government stamp. The Patent Medicine Act should in all fairness be subject to the operation of the Pharmacy Act, and when the time came for a new act, such a scheme would no doubt receive consideration. After referring to the vexatious prosecutions under the Food and Drugs Act, the President alluded to the proposed visit of the British Pharmaceutical Conference to the town in 1879, and expressed a hope that the chemists would give a downright hearty welcome to that body, whose previous visit, in 1866, had called the Nottingham and Notts Chemists' Association into existence.

The address was listened to with great attention, and frequently elicited loud and hearty applause.

Mr. C. W. Dixon, in a short speech, proposed: "That the Association should be carried on."

This was seconded by Mr. James Beardsley, who thought that all the members should assist the council in both educational and trade work, and the resolution was carried unanimously.

Mr. Reuben Widdowson proposed "That the educational work for the associates be carried on as usual." Mr. W. Widdowson seconded and offered to lend the Association a set of botanical specimens, mounted; his offer was thankfully accepted and the resolution was carried.

The President then invited suggestions as to the evening meetings, saying the council were necessarily silent on the matter, but were prepared to carry out the wishes of the members.

A general discussion then ensued in which Mr. Bolton, Mr. Warriner, Mr. Beardsley, and other gentlemen took part, all urging upon members the necessity of working with the council, as well as paying their subscriptions, in order to make the Association a thorough success. Eventually Mr. James Beardsley proposed and Mr. Cowley seconded—"That three social meetings and three educational meetings be held during the session, with special meetings when necessary."

This was carried unanimously, the President remarking that he hoped every member would make it a point of honour to attend the educational meetings as well as the social ones.

Mr. Warriner next proposed a vote of confidence in the officers and council. He thought such a public expression necessary as the want of interest exhibited by the members in the past might seem like want of confidence in the executive.

Mr. C. Fletcher seconded and Mr. J. Beardsley supported the vote, which was carried unanimously.

The President returned thanks on behalf of himself and colleagues.

A very pleasing incident occurred during the evening, three members of the Association, formerly students (Mr. James Beardsley, Mr. Reuben Widdowson, and Mr. W. Widdowson), kindly offered to assist the associates in their studies at the improvement class on Monday evenings. They all warmly acknowledged the benefit the Association had been to them when students, and it is is almost unnecessary to say their generous offer was heartily accepted and thoroughly appreciated by the meeting. It was arranged for Mr. Reuben Widdowson to assist the class in chemistry; Mr. W. Widdowson in botany, and Mr. Beardsley in pharmacy on alternate Monday evenings during the session, and the Hon. Secretary was requested to issue a circular to that effect, with a request that each member would make an effort to allow his apprentices to attend regularly.

Three new members were elected.

A hearty vote of thanks to the President for his conduct in the chair, and for his eloquent address, proposed by Mr. Inger and seconded by Mr. Moore, brought a most successful meeting to a conclusion.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The second monthly meeting of the session of this association was held in the Manager's Library of Anderson's College, the President, Mr. D. Frazer, in the chair. Mr. James M. Fairlie, Vice-President, read the following paper on—

The Pharmaceutical Society and Provincial Education.

Mr. Chairman and Gentlemen,—It seems to me that the question of provincial education, having now been in abeyance for a few years, should be brought to the front and dealt with in a statesmanlike manner by the Council of the Pharmaceutical Society, and as our esteemed chairman has requested me to read to you a paper in lieu of his inaugural address, I have thought I could not take up a better topic. It will be necessary that we should take a brief glance at the past in order that we can realize our present position and make our calculations for the future. First, then, the Pharmaceutical Society in its original programme had the education of its apprentices or students as one of its chief objects, and to that end a School of Pharmacy has been in existence for many years, and no one denies but that through its able professors it has done good service to the cause of pharmaceutical education. Some say that it has been at too great expense that it has been kept up, but I am disposed to think that all the money that has been spent upon it has been well spent, and I believe that if the same amount was spent again, in a similar direction, far more good would result in the future than has been done in the past. I am aware that some of our leading pharmacists hold the view that the time has almost come when the Society should cease to have any control over the education of the students at all, and they look upon it as an anomaly that the Society should both be a teaching and an examining body. I hold that this view should not be entertained for a single moment in present circumstances. If such a step is taken, it will be to my mind a retrograde one and opposed to the principles adopted and carried out by most other bodies having duties and responsibilities placed upon them of a nature similar to those of the Pharmaceutical Society, aye, even and carried out by the Government itself; for what is our present system of national education? Is it not controlled by the State? Are the teachers and taught alike not examined and inspected by the State? Yes, and the State also pays a large share of the expense! Why, then, should there be an outcry against the Society exercising some control over this important matter? I suppose it is almost wholly on the ground of expense. This, I think, is short-sighted policy. Some people do not know how to spend a shilling that they may receive eighteen-pence. Others, again, spend eighteen-pence, and scarcely receive a shilling's-worth of value in return. Looking at the past of the Pharmaceutical Society, I am not disposed to criticize too severely the conduct of the old leaders at Bloomsbury Square, many of whom are now lying in honoured graves; and I do not know that had I been placed in the same cirumstances I would have acted otherwise than they did; but standing as we are now on a higher platform, we can survey the past from a different standpoint, and while I give all honour to the Bells and the Allens, the Hanburys and the Morsons, for their life-long efforts in the advancement of pharmacy, yet I cannot but think that had all the time and money and effort that was put forth year after year in endeavouring to obtain an Act of Parliament been spent in spreading useful knowledge amongst chemists in the country districts, and by establishing in all the large centres schools of pharmacy on the model of that at Bloomsbury, much more good would have resulted. There would, I am sure, have been less jealousy and distrust amongst the different sections of the trade, and a better Act of Parliament would have been obtained, when not only the trade but the country would have been ripe for the kind of legislation necessary. But there is no use looking at the past unless to conserve those good and useful legacies that have been handed down to us by our predecessors, and to improve upon that which we are convinced needs improving. And I look upon the School of Pharmacy at Bloomsbury Square, and its scheme of education as conducted there, as one of the most important of those legacies. But it is well known that all students cannot reach London to obtain the necessary tuition, and at present it is impossible, even in our own city, with all our educational advantages, for any young man to receive the systematic course of training necessary to equip him properly for the work he should pursue in after years in connection with his business. I have already hinted that I think that in the past the provinces have been neglected by the authorities in connection with our Society at London. I am aware that a scheme exists whereby local associations may obtain grants of money and loans of books and apparatus under certain conditions and restrictions; but I am disposed to think that the restrictions are either too severe, or the grants that have been given have been so paltry on the whole, and given with such a grudging hand, that local committees think twice before they make any application at all. The members of Council of late have thought they had nothing to do in this matter but promulgate a scheme, and let it work itself; they passed, so to speak, a permissive bill, but they hemmed it round with so many whys and wherefores that it has practically become a dead letter. What would the people have said of our Government, when they passed the Education Bill, had they left out the provision for the appointment of School Boards in the various parishes and burghs throughout the country? Would education have been any further advanced to-day? I am sure not, and this is just what our Council did a few years ago. They, in effect, said, "We will lay aside a moderate sum for provincial educational purposes, for we acknowledge that we must do something in this matter. We obtain a good deal of money from provincial members of the Society, and we must keep them on and get others to join, to send up their guineas also; and although we send them seventeen shillings' worth of Journals every year, yet we get a profit, and we cannot keep it all in London. But we know our country cousins well enough; they are very slow to move, very conservative, so we will not make this money too easy to get at, for they may, after all, make a bad use of it, and it is far better that we should buy a few more 3 per Cents. than that it should be sent to Birmingham, or Leeds, or Glasgow, to be squandered there, when we would never see it more." This, though a little strained, is practically what they said and have carried out. No local committee would be troubled in the way that is laid down in the scheme. What is required is some simple plan, something that we have been accustomed to in other departments of life, not a new-fangled, intricate scheme, that will take a man half a lifetime to master. It seems to me that there are many plans that should commend themselves to us for their very simplicity. When the hero of the Scottish Reformation accomplished his purpose by overthrowing the tyrant power which tried to crush the Scottish people, he did not attempt to dazzle the inhabitants by promulgating some perplexing scheme for keeping down the old powers, and improving the habits of the people, but he adopted the very simplest plan he could, and in doing so he carried the people with him. He established a school in every parish alongside of the church, and for 300 years Scotland has stood a monument of John Knox's sagacity and forethought. The plan I would propose is perhaps not new. Something like it has certainly been suggested by some one, but if simplicity is a recommendation I think it possesses that element:—First, let the country be divided into, say, twelve districts; second, let the members of the Society in each district elect, every three years, an education board; third, let the Council, at the commencement of each year, set apart a certain sum of money for aids to education, say £600 the first year, thus giving a grant of £50 to each of the twelve districts, which ought to be supplemented by at least an equal sum subscribed locally. By this means the education board would be able to secure two lecturers who would willingly accept the fees obtainable from the classes set agoing, and the bonus of £50 each might go in providing either room accommodation, apparatus, or some other necessary matters that would occur to the board. This plan, I think, has several points in its favour. The issuing of the ballot papers every three years would add an interest on the part of the members of the Society which they could not otherwise take in this matter. The board, once elected, would require to do something in the furtherance of education, or of course the grant would not be paid. The fact of classes existing in a district regularly from year to year, and not in the spasmodic way in which some local associations find it necessary to carry them on at present, would become known to all young men within each radius who would naturally strive to attend one or two sessions. The objection, of course, would come in, where is the £600 to come from? So far as I can calculate of the income and expenditure during the past few years I think the Society might well afford £600 or £700 annually for educational purposes, apart from its endowments at Bloomsbury Square. If we take Scotland alone, as an example, two districts in addition to the North British Branch might answer for the present. We find that during the past year the Scotch examining board made a clear profit of £100 to the Society, apart, no doubt, from those who would become annual subscribers as members afterwards. Thus we, in Scotland, would be but receiving back for educational purposes the excess of income on the examinations, which I hold to be but fair and just, as I do not think the Society should make a single penny of profit out of the hard-earned fees that are paid by the students who present themselves for examination. I am not aware whether the English examining board is as profitable to the Society as the Scotch one. I should fancy it ought to be much more so, as a larger number of students must present themselves at London in proportion. The money difficulty might come in, however, apart from this; but there seem to me to be other ways and means of raising the necessary sum, for as the old saying has it: "Where there's a will there's a way." I would like, for instance, to know whether it is absolutely necessary that all members and associates, subscribing on an average, I presume, about 15*s.* per head per annum to the Society, should receive 17*s.* 4*d.* worth of Journals every year in return. It seems to me that the Society pays heavily for this practically gratis distribution of the Journal. If the Journal was put upon an independent basis, I am strongly of opinion that it would, in the first place, pay better than it does even at present; and in the next, I am certain its editorials and leaders would more fairly represent the opinion of the majority of the trade, and have more independence about them, while its articles generally would be more in keeping with the stage of progress attained by the great bulk of its readers. We need the Journal; we must have at least one highly scientific publication, and no doubt we would get one or more whether it was continued to be sent out by the Society to its members or not, and the trade would willingly pay for it or any other journal, and I do not see why the Society should care to monopolize this particular department. I therefore think that if it is necessary to make any sacrifice for the sake of the funds of the Society, that the education of our youths should not be neglected or left to itself, but that if a "Jonah" must be thrown overboard, let the Journal go to fight its own battle with other enterprises of a similar character. This, no doubt, will sound in the ears of some of our friends as a terrible proposal. I think I hear them say, "We can't do without our official organ; we must have some means of reporting our Council meetings, and we can only allow our own trusted editor and reporter to sit at our side, for it does not do to let the whole world know all that is going on inside." What would the country say if the Houses of Parliament and our town councils were to close their doors against the representatives of the press, and only permit a trusted servant to provide the reports to the nation? It would not be tolerated a single day, and why the members of the Pharmaceutical Society have submitted to this indignity so long is more than I can understand? There is another common objection often raised against the adoption of a thorough scheme of provincial education, namely, that of the smaller towns. If, say, a grant of £50 was made to Glasgow, why should the pharmacists in Greenock or Perth not also establish a little school and get a share of the grant? Looking at the question as a matter of common fairness, one naturally would say, "They are entitled to it, and if they can get up a school, let them elect a board and give them a share of the grant." But I have no great fears of the smaller towns interfering with the grant in this way. Throughout the country there are certain recognized centres, just as London is looked upon as the leading city in the empire. There are always inducements to young men to go from the smaller towns to the larger and more attractive ones, and while a system of teaching would be an additional attraction to the larger towns, I do not think it would militate one iota against the interests of the pharmacist in those outlying towns. I rather think that the advantages are all the other way; each district would be placed upon an equal footing. They would elect their own board, which would superintend the arrangements in its own way. The Pharmaceutical Society could have a check upon the board by having the power to place the local secretary *ex officio* a member of the board, at the same time a guarantee would be required to be given by the board that the grant should only be used for educational purposes. Thus the Pharmaceutical Society having laid the foundation, and placed the edifice of provincial education on a fair basis, it might rest on its oars in that department and watch results for a time with perfect safety, but only, I should say, for a time, for a higher power may step in and re-arrange matters. And I fondly look forward to the time when no youth shall be apprenticed until he has passed his "Preliminary" examination, when the "Minor" examination shall be the test for assistantships alone, and the "Major" the only portal by which a pharmacist shall be able to commence business on his own account. Then our young men shall be looking for their education within the walls of some of our local universities and science colleges, and by that time, I trust, that in each of these halls of learning a chair of pharmacy may be established and endowed, partially by the Government, partially by the Pharmaceutical Society, and partially by local effort.

And now, in conclusion, let us look at our own position as a local association. Are we prepared to enter upon some such plan as I have here sketched out? We are certainly more peculiarly situated here than in any other district, and there is the more necessity for something being done, and that quickly. Our spasmodic efforts have been quite as successful as might be expected in the circumstances, but we have had no system, and where there is no system there is not that thoroughness without which our efforts are practically worthless. I know from my intercourse with the young men that they are anxious for something being done. I know also that there are teachers in the city able and willing to give their services if the smallest encouragement, such as a grant from London, would give, were forthcoming; and I believe, further that the employers have but to be appealed to to giyewhat assistance is needed in furtherance of such a scheme. I do not see why in a city like Glasgow at least £100 should not be subscribed annually for the upkeep of a set of classes in conjunction with a library and museum. I know what our young men can do when they make up their minds. But for them no library, I believe, would yet have been in existence in connection with our Association. But for them the business hours would have been kept stretched out much longer than they are. And I am convinced that in this matter they have it pretty much in their own hands; also, and as it is the young men who will mainly benefit by such a reform, I would say let them keep steadily in view the ideas associated with three words, namely, Educate! Unite! Progress!

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, December 6th, Dr. Gladstone, President, in the chair. After the confirmation of the minutes, the list of presents to the library was read, and the thanks of the Society voted to the respective donors. The following certificates were read for the first time:—Messrs. R. Bodmer, T. F. Harris, A. Jamieson, G. E. Stodart, W. Watson.

The President then announced that Professor Odling was again unfortunately prevented from reading his paper on Gallium, but that his assistant, Mr. Fisher, was present, and would give an abstract of it to the Society.

Mr. Fisher apologized for the absence of Professor Odling, stating that the lecture would have been deferred but for the fact that the specimens had to be returned shortly; he hoped, however, that Professor Odling would give to the Society some theoretical considerations on the new metal at a future date. The following is a summary of the facts stated:—Gallium was discovered by Boisbaudran 27–29th August, 1875; it was first obtained in the metallic state in November, 1875. The spectrum consists of two bands in the violet, one brilliant, of wave length 417, and a feeble band of wave length 403·3. It was extracted in the first instance from zinc blende of Pierrefitte, a mine in the Pyrenees, afterwards from a black blende of Bensberg on the Rhine; the latter contains one part in 100000, the former one in 400000; 0·65 grams of gallium being obtained from 430 kilogrammes of Pierrefitte blende. In appearance it resembles lead, but is less blue, tarnishing slightly on exposure to moist air; it is slightly harder than lead, flexible, malleable and can be cut with a knife. It is not appreciably volatile at a red heat, and is but slightly attacked by oxygen at that temperature. Its sp. gr. is 5·9; when fused 6·08. It melts at 30·15 C., presenting a brilliantly white appearance; when once fused it remains liquid even for several months at 0° C., but is immediately solidified when in this condition by contact with solid gallium. In consequence of this curious phenomenon of surfusion, the element was at first described as a liquid metal. It crystallizes in square octohedra. In properties it is more or less intermediate between aluminum and indium. The solutions of its salts give the following reactions:—With ammonia a white gelatinous precipitate, soluble, but not freely, in excess; potash a similar precipitate, soluble in excess; acetate of ammonia on boiling, in a solution free from excess of acid, precipitates a basic compound; carbonate of baryta easily precipitates salts of gallium in the cold. The salts already prepared are the sulphate, which is very soluble but not deliquescent; the chloride very soluble and very deliquescent, decomposed by a large excess of water; and the alum. A solution of the latter on heating deposits a basic sulphate, which dissoves again on cooling.

In reply to some questions by the President and Mr. Groves, Mr. Fisher stated that no satisfactory determinations of the atomic weight or specific heat of the new metal had yet been made, and pointed out that the small quantity (0·65 gram) had prevented M. Boisbaudran from fully investigating some other reactions. Specimens of the metal and the alum were exhibited.

The next paper was "*On Nitrification: a Report of Experiments conducted in the Rothamstead Laboratory*," by R. Warington.—After pointing out the technical importance of the above process, and the want of knowledge as to the production of nitric acid from nitrogenous organic bodies the author states that it has been generally assumed when such bodies decay in a porous medium offering a sufficiently large surface for oxidation that nitrates must necessarily be formed. This view has, however, never been confirmed by exact experiments. In February last, Schloessing and Müntz (*C. Rend.*, lxxxiv., 301) laid before the French Academy a paper proving, in their opinion, that nitrification was due to the action of an organized ferment. Their fundamental experiment is the following:—A glass tube, one metre long, was filled with a mixture of 5 kilos of ignited sand and 100 grm. of powdered limestone; through this mixture a slow stream of sewage filtered, so that it occupied eight days in passing down the tube. During the first twenty days no nitrates appeared in the exit water; after this period they could be detected, the quantity rapidly increased until no ammonia could be found in the exit water; this continued for four months. A small vessel of chloroform was now placed on the top of the tube, so that the vapour passed down through the soil (this reagent effectually suspends the action of organized ferments, whilst it has but little effect on soluble ferments [*C. Rend.*, lxxx., 1250]). In ten days all nitrates disappeared, and the ammonia salts passed through unchanged. After fifteen days the chloroform was withdrawn, but no nitrification took place during seven weeks. 10 grms. of a soil which was known to nitrify were now treated with water and the washings poured on the column of sand, so as, if possible, to seed the soil anew. Eight days after, nitrates again appeared as before. The importance of this new theory is clearly very great, so the author has tested it by further experiments in two distinct lines of proof:—(1) The action of antiseptic vapours in preventing nitrification. Four tubes were filled with moist kitchen garden soil; through the first moist ammonia—free air was drawn by an aspirator; through the second moist air as before, but passed previously through a bottle containing sponge moistened with carbolic acid; the air drawn through the third tube was similarly charged with a little bisulphide of carbon; that through the fourth with chloroform. Two series of experiments were made. At the end of the experiments the nitrates formed in the soil were determined by the method of Crum and Frankland. The results are given in the following table, the experiments lasting thirty-nine and forty-six days respectively:—

Nitrogen as nitrates and nitrites per million of air-dried soil.

History of Soil.	First experiment.	Second experiment.
Original soil	6·12	8·91
Air passed	40·87	50·86
,, ,, with carbolic acid .	17·20	40·77
,, ,, ,, carbon bisulphide	6·70	9·75
Air passed with chloroform .	9·48	7·86

The results of these experiments prove that chloroform and bisulphide of carbon effectually prevent nitrification; that carbolic acid is probably effective to the extent in which it comes in contact with the soil. So antiseptics as a class are inimical to nitrification. The second line of proof investigated was the possibility of inducing nitrification by seeding with a substance already nitrifying. After several unsuccessful attempts the author succeeded in nitrifying practically the whole of an ammonium salt. Four stoppered pint bottles were taken and nearly filled with a solution of ammonic chloride (1 c.c. = 0·000025 gram ammonia) to which a small quantity of acid phosphate of potassium was added; two of the bottles were seeded with about 1 gram of surface soil from a "fairy ring;" one unseeded and one seeded bottle were kept in the light, the other two in the dark. In three months time the seeded bottle in the dark contained abundance of nitric acid and no ammonia, the other three contained plenty of ammonia but no nitric acid. 1 c.c. of the liquid which had undergone nitrification was now added to each of the unseeded bottles, one in the light and one in the dark; 0·005 gram of acid tartrate of potassium to supply organic carbon was also added to each bottle; in a month the bottle in the dark contained abundance of nitric acid, the one in the light was unnitrified. The conclusions of Schloessing and Müntz have thus been completely confirmed with the addition of the important fact that darkness is apparently essential to the action of the nitrifying germs.

After the thanks of the meeting had been given to the author for his important communication, Dr. Gilbert said that it now seemed strange, having the parallel of the acetic acid fermentation, that this important process had remained so long uninvestigated; in his opinion the experiments of Schloessing and Warington left no doubt as to the correctness of their explanation of the process. Dr. Gilbert then drew attention to the great variety which had been found to exist in the power possessed by soils and plants to nitrify in different degrees; thus one soil would nitrify four to five times as much as another under similar conditions.

Mr. Howard said that the value of old nitre beds as compared with new ones had long been appreciated but not understood, the paper of Mr. Warington afforded a satisfactory explanation of their value. He would like to ask if any substances, such as spongy platinum, besides the ferment, possessed the power of nitrification.

Mr. Tidy did not quite understand the relative action of light and darkness on the process, as the bottles exposed to the light were for such a long time, *i.e.*, during the night, in darkness.

Mr. Kingzett inquired whether the presence of oxygen was necessary.

Dr. Frankland could but express his admiration of the paper; the subject was one of the greatest importance. He would suggest that some experiments should be made to try and assist the action of these industrious, inoffensive mycoderms. For instance, an acre of soil, six feet deep, will dispose of the sewage of three thousand people, it would be very desirable to increase this nitrifying power five or even one hundred fold, and in his opinion it was quite probable that the rate might be much increased.

Mr. Hartley thought that the strongest evidence of the presence of an organism was the fact that the process would not go on without the presence of organic carbon.

Dr. Armstrong pointed out that all known instances of the action of unorganized ferments could be resolved into simple effects of hydration; in every case there was a splitting up of a complex molecule. With organized ferments, however, a complication in structure was often produced. The absence of nitrification in the bottles exposed to light might be due to the presence of chlorophyll containing organisms.

Mr. Warington, in reply, stated that it was by no means asserted that nitrification could not take place without an organism, but that for the process to go on in soil in this rapid way the presence of the organism was requisite. In answer to Mr. Tidy he could throw no light on the fact that darkness was necessary for the process. No attempt had been made to specially aërate the liquids in the bottles. He would not like to say without further experiment that the presence of organic carbon was essential for nitrification; but from analogy he should conclude that it would be necessary.

The next paper—

On Potable Waters by E. J. Mills, D.Sc., was read by Mr. Perkin. After a consideration of the processes for determining the organic constituents of water the author concludes that the process of Frankland and Armstrong must form the philosophical starting point in an endeavour to solve the problems of water analysis and refers to it exclusively throughout his paper. He first considers in an elaborate manner the errors incidental to this process, and compares them with those found in Gmelin in determinations brought forward as evidence of the composition of various bodies, and finds that the accuracy of the process compares favourably with that of the ordinary combustion process and may be safely used as a basis of inference. As regards errors, the author discriminates in blank experiments "a" the chemical error due to the introduction of sulphites, and "b" the volume error from the addition of n cubic centimetres of purified water. The size of the dish used to evaporate the water has a perceptible effect, thus, with a three-inch dish the organic carbon =·323, organic nitrogen =·024, with a six-inch dish $C=0·307$, $N=0·034$, the carbon diminishing and the nitrogen increasing with the size of the dish. The author then describes a new evaporator which consists of a cylindrical copper water-bath with a hemispherical copper cover cooled by a flow of water; the water is contained in a three-inch glass dish underneath the cover and is supplied by a constant, convectionless feed; a stream of purified heated air is drawn across the top of the glass dish by an aspirator. In an hour, with a current of 1062 litres 100 c.c. will be evaporated. From a consideration of the analyses in the Sixth Report of the Rivers Commission the author has arrived at three natural constants or ratios of organic carbon to organic nitrogen in potable waters, α $3·067\ C_{12} \div N_3 = 3·429$; β $2·521\ C_{12} \div N_4 = 2·571$; γ $2·056\ C_{12} \div N_5 = 2·057$.

In conclusion the author makes some interesting suggestions as to the origin of the constancy of the composition of the air, the effect of an alteration in the mass of atmospheric oxygen, etc.

The next paper was—

On Some Derivatives of Allylacetone. By J. R. Crow.—The acetone was prepared according to Zeidler's method, diluted with an equal volume of ether, and transferred to a flask surrounded by cold water, and containing a volume of water twice as great as the ethereal solution. The flask was connected with a reversed condenser, and an excess of sodium gradually added. The ethereal solution was separated, and distilled after drying with potassium carbonate. After the ether had distilled over, the remaining liquid came over chiefly at 135–140°. After repeated fractional distillations it yielded the pure substance, boiling at 138–139°, having the composition $C_6H_{12}O$, sp. gr. 1·842 at 16·2°. It appears to be a secondary alcohol, and a homologue of allyl alcohol. Its acetate was prepared as a colourless liquid, boiling at 147°–149°. A dibromide was also formed by the action of bromine as a slightly brown thick mass, which did not crystallize; it has the composition $C_6H_{12}Br_2O$.

The next communication was—

On a Fourth Method for Estimating Bismuth Volumetrically. By M. M. P. Muir.—It has been shown by Sonchay and Lenssen (*Ann. Chem. Pharm.*, cv., 245), that normal bismuth oxalate on boiling splits up into a basic oxalate of the composition $Bi_2O_3 2C_2O_3$+aq., but slightly soluble in nitric acid; the author has utilized this reaction for estimating bismuth. An excess of saturated solution of oxalic acid is added to the solution containing bismuth, the precipitate allowed to settle, the supernatant liquid poured off, the precipitate boiled with water until free from acid. The residue is now dissolved in dilute hydrochloric acid and titrated with permanganate. The absence of free hydrochloric acid must be secured before precipitating. The results are accurate, and the method is generally applicable.

The next paper was—

The Gas of the Grotto del Cane. By T. G. Young.—The author has analysed the gas, which contains 61·5 to 71·0 per cent. of carbonic acid. The residual air having the composition, oxygen, 20·25, nitrogen, 79·75. Finot (*Chem. News*, 35, 21) states that in the residual air there is more oxygen than in ordinary atmospheric air. The author cannot confirm this statement. The temperature of the cave in some places is as high as 40°.

The last paper was entitled—

Note on Tetrabromide of Tin. By T. Carnelly, D.Sc., and L. T. O'Shea.—A piece of combustion tubing was bent into the shape of a capital V and W joined together; in the middle bend some tin was kept melted; bromine was dropped from a tap funnel into one of the other bends. The metal burns in the bromine vapour, and the tin bromide condenses in the third bend. By distillation the body was obtained pure as a colourless liquid, solidifying to a mass of colourless crystals. Melts at 30° C. Boils without decomposition 201°. Does not fume, and is very slowly decomposed in air; dissolves in cold water without immediate decomposition. It gave on analysis Sn 27·11 Br 72·78. The vapour density was found to be 229.

The Society then adjourned to Dec. 20th, when the following papers will be read:—

1. "The Constitution of the Terpenes and of Camphor." by Dr. Armstrong. 2. "Communications from the Laboratory of the London Institution," by Dr. Armstrong. 3. "Hydrocarbons obtained from *Pinus sylvestris*, with Some Remarks on the Constitution of the Terpenes," by Dr. Tilden. 4. "Cuprous Chloride and the Absorption of Carbonic Oxide and Hydrochloric Acid," by J. W. Thomas. 5. "The Action of Reducing Agents on Potassium Permanganate," by F. Jones. 6. "On Citric Acid as a Constituent of Unripe Mulberry Juice," by Dr. Wright and Mr. Patterson.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting of Executive Committee, on December 5, 1877, at 10.30 a.m., at 17, Bloomsbury Square, London.

Present—G. F. Schacht, Esq., President, in the chair, Professors Redwood and Attfield, Williams and Thresh.

The minutes of the previous meeting were read and confirmed.

The late Treasurer (Mr. Schacht) reported that, in accordance with the instructions given him at the previous committee, he had disposed of the Russian securities of the Bell and Hills Fund, and had re-invested the proceeds in consols. Also that there had been transferred from the General Fund to the Bell and Hills Fund the sum necessary to raise the income of the latter fund, from consols, to a clear ten pounds a year. The Treasurer's books and documents had been handed to his successor, Mr. Ekin.

The Hanbury Books.—Professor Attfield reported that in accordance with the wishes of Mr. Thomas Hanbury and with the instructions of the Committee he had sent a copy of 'Pharmacographia" and of the late Daniel Hanbury's "Science Papers" to the libraries of the pharmaceutical associations of Bath, Birmingham, Nottingham, Exeter, Liverpool, Edinburgh, Brighton, Bradford, London, Bristol, Glasgow, and Plymouth, and that he had received very hearty acknowledgments from the officers of the respective societies. A printed copy of the following statement had been placed inside the cover of each book:—

"In 1877, Thomas Hanbury, Esq., in memory of his late brother, Daniel Hanbury, F.R.S., presented thirty copies of each of these books to the Executive Committee of the British Pharmaceutical Conference, with the request that a copy of the 'Science Papers' and of the 'Pharmacographia' should be given to the library of the pharmaceutical association of every one of the fifteen towns in which the Conference had already met or where it would assemble during the succeeding fifteen years."

Dr. Alfred Senier was appointed Assistant-Secretary, at a salary of £40 per annum, to commence from Nov. 1, 1877.

The Senior Secretary was instructed to write to Mr. Siebold as soon as the editorial work of the current year was quite completed, offering him the editorship for the year 1877-8, on the following terms:—

1. That the salary be £150, payable when the completed volume is issued by the printers.

2. That the manuscript of the Year-Book be placed on the table at the annual meeting at Dublin in August, 1878, complete in every respect excepting the introduction.

3. That the introduction be completed and forwarded to the printers on or before Oct. 1, 1878.

4. That no manuscript be interpolated in the printed proofs without the permission of the President or one of the General Secretaries.

Professor Redwood proposed and Mr. Thresh seconded a resolution in accordance with the five previous paragraphs.

Professor Attfield submitted a proof of a circular of invitation to membership, proposed to be sent to all persons interested in pharmacy in Ireland, provided such action met with the approbation of the Irish Committee now being formed to promote the success of the meeting in Ireland in August, 1878. The Committee accepted the proof and ordered copies to be printed and circulated, subject to the wishes of the Irish Committee.

The Secretaries submitted an account of receipts and disbursements since the previous meeting of Committee.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held at 17, Bloomsbury Square, on Thursday last, December 6, when a paper was read by Mr. R. H. Parker, on "Coal Gas, its History and Manufacture."

The author divided his subject into four heads:—I. History. II. Composition. III. Manufacture. IV. Details of Apparatus. Under the first head was given a description of naturally-formed inflammable gases, and the notice they attracted in early ages, followed by a detailment of the many steps by which the manufacture of gas from coal attained its present dimensions. Composition included tables showing the principal gases evolved from coal by its destructive distillation, and the proportion they bear to one another. The bodies upon which the illuminative power of the gas depends were next considered, and the statement that the illuminative power of gaseous bodies depends upon the percentage of carbon contained in them was shown to be incorrect, inasmuch as a mixture of gases could be obtained containing less carbon than marsh gas, but burning with a more luminous flame. Under manufacture was given the qualities which coal must possess to yield a good product, the heat best suited, and the method of determining the value of coal for the production of gas. The process of manufacture was followed from the introduction of coal into the retort, the formation of gas, its passage through the hydraulic main, condenser, exhauster, washer, and scrubber to the holder. Each separate piece of apparatus was fully detailed, and was illustrated by means of diagrams. The purifier received considerable attention, the action of the various deleterious gases upon the lime and oxide of iron contained in them was described, and the description was supplemented by numerous equations showing the decompositions. The construction of the station-meter, tell-tale, and consumer's meter, was explained, and the author concluded his most interesting paper by noticing two methods for the production of gas other than by the distillation of coal.

A vote of thanks to Mr. Parker was unanimously agreed to, and the meeting adjourned till Friday, January 4th.

Parliamentary and Law Proceedings.

Adulterated Sweet Spirit of Nitre.

At the Ryedale Petty Sessions, on the 23rd Nov., John Kneeshaw, grocer, of Farndale, was charged under the Food and Drug Acts, with selling sweet spirit of nitre not according to quality required. The inspector deposed that on the 24th September he purchased at defendant's shop six ounces of sweet spirit of nitre, which he divided into three parts, sending one portion to Mr. Fairley, county analyst, of Leeds. The certificate of that gentleman showed that the mixture corresponded to 34 parts water added to 100 parts sweet spirit of nitre, and that the liquor did not contain any "nitrous ether," the substance upon which the medicinal virtue of sweet spirit of nitre entirely depends. The mixture was, in fact, 16 degrees under proof, whilst genuine sweet spirit of nitre is 53 degrees over proof. The bench ordered defendant to pay £1 fine and costs.

A similar charge was also preferred by Inspector Milner against Charles Frank, grocer, of Hutton-le-Hole, but in this case the analyst certified that the mixture corresponded to 33 parts of water added to 100 parts of sweet nitre, and that it did contain "nitrous ether," though less in proportion than would be in the genuine article, which is 53 degrees over proof, whilst that sold by Frank was only 2 degrees over proof. The defendant was ordered to pay 12*s.* 6*d.* fine and costs.—*Selby Times.*

Important Decision upon the Law of Trade Marks.

In the Common Pleas Division (sittings at *Nisi Prius*, before Mr. Justice Lopes and a common jury, whose services were, however, dispensed with after the case had proceeded a short time), the case of Hickisson and another *v.* Murphy has been heard. It was an action for the alleged piracy and infringement of the plaintiffs' trade marks—that for Bond's marking ink.

The defendant pleaded that the plaintiffs had no exclusive right to the trade marks, and that he was the legal successor and representative of one of the original inventors.

Mr. Collins, Q.C., Mr. Yeatman, and Mr. E. C. Willoughby appeared for the plaintiffs; Mr. H. Matthews, Q.C., and Mr. Finlay for the defendant.

Mr. Collins, Q.C., in stating the case, said the original inventor of "Bond's marking ink" was one John Bond, who died in 1848. At his death three persons became entitled to use it, viz., John Bond's widow, who traded under the name of Bond, and who was known in the trade as the "Widow Bond," the plaintiff, Mr. Hickisson, who married in 1849 a daughter of John Bond (he traded under the name of "the daughter of John Bond"), and Henry Bond, brother of the original inventor. The two first were still alive. Henry Bond gave up his business to his son Edwin, who died in April, 1867, leaving a widow Arabella, who carried on the business of a chemist as well as a marking ink manufacturer. In February, 1870, Arabella sold the business of a chemist to the defendant's husband, but reserved to herself the right of manufacturing the marking ink. She married a man named Christian shortly after, and died in June of the same year. Christian continued to carry on the marking ink business. The employment of the name by another person for the purpose of describing an imitation of their article was an invasion of the right of the original manufacturer. This the defendant had done. He purchased the chemist's business only, and yet he was selling marking ink with the name of "Bond" on the cases and wrappers, advertising that he was the real successor, and inducing people to believe he had a right to do so. He had imitated as closely as possible the pedestals, wrappers, labels, and words on them. Evidence bearing out the opening statement having been given by Ann Christian, William Christian, James Hickisson (who said he was "the daughter of John Bond"), Peter Simmonds, and others, Mr. Matthews, Q.C., contended that the defendant having purchased the right of the chemist's business had the right of manufacturing the ink in question, and there was sufficient distinction between the colours of the wrappers and the wording of the labels to prevent the public being misled into the belief that the inks were identical.

Mrs. Murphy, who admitted she had never registered Bond's name, but only her own, and several other witnesses were called, who admitted that people generally asked for "Bond's" ink. The trade, of course, knew the difference, and would not be deceived.

After a long legal argument, especially on the question of whether fraud was necessary on defendant's part,

Mr. Justice Lopes, in giving judgment, said he was of opinion that the defendant had made the representation that the ink was "Bond's;" that there was no right either under the agreement or by licence to do so; that there was in addition a general resemblance calculated to deceive an unwary purchaser; and that the defendant had fraudulently acted. He found £15 by way of damages for Hickisson and £10 for Christian (the plaintiffs not asking for damages), and he also granted a perpetual injunction against the defendant, his agents, and servants, with costs.

The case, which lasted three days, was then concluded.

Dispensing Memoranda.

The Meaning of Symbols used in Prescriptions.

It appears from the discussion which has been carried on through the medium of the Journal, that much difference of opinion exists with reference to the meaning of signs used for representing quantities in medical prescriptions. The question first raised in these pages had reference only to the symbol (℥) for the ounce apothecaries' weight, but the discussion has since taken a wider range and other signs have been referred to by correspondents, who seem to be in doubt as to their meaning. It is to be regretted that any uncertainty should exist on this subject in the minds of those in the performance of whose duties it is of the utmost importance that they should use weights and measures with exactness. Some complication has undoubtedly been caused by changes which have been made in the weights and measures ordered for use in medicine, but I cannot think there is any substantial difficulty in understanding what the correct interpretation is of the terms or symbols referred to in this discussion.

It may perhaps contribute to the clearing up of any still existing doubts if reference be made to the legal position of the question.

By a law passed in 1824, the meaning and value of the terms used for expressing the integers of weight according to the troy and also the avoirdupois weights were explained and established; and by a law passed in 1835 it was enacted that after that date "all articles sold by weight shall be sold by avoirdupois weight, except gold, silver, platina, diamonds, or other precious stones, which may be sold by troy weight; and drugs, which, when sold by retail, may be sold by apothecaries' weight." In 1858 the Medical Act authorized the General Council of Medical Education to describe in the British Pharmacopœia "the true weights and measures by which medicines are to be prepared and mixed."

We thus have, as the result of modern legislation, four systems of weights which have been legalized, two of which—namely, the troy and avoirdupois—are accurately described and defined on sound scientific principles, while the other two are made up of integers taken from the preceding, in one case with intermediate integers introduced for the purpose of making it more suitable for use in prescribing and dispensing medicines. The law indicates the purposes for which these weights may be respectively used. All other weights are illegal if used in the sale of goods in this country, and penalties are incurred by their use.

With reference to measures of capacity, the case is more simple. The Acts already referred to specify only one system of measures of capacity, of which the imperial gallon is the integer. The value of this has been accurately defined with its multiples and sub-multiples, which are the only measures that can be legally used in the sale of articles in this country. A slight modification of this system has been adopted by the Medical Council in ordering the measures to be used in preparing and dispensing medicines, which consists in adding to the gallon and pint, a fluid ounce, fluid drachm, and minim. These had previously been introduced as medicine-measures, and they have become familiar from long established use.

At the time of the publication of the British Pharmacopœia, apothecaries' weights were exclusively used in the formulæ given in the London and Edinburgh Pharmacopœias, and also in medical prescriptions throughout Great Britain. But since 1850 the Dublin Pharmacopœia had adopted a different system, in which the avoirdupois ounce was divided into drachms, scruples and grains, all of which had different values from those used in England and Scotland.

The reasons which induced the Medical Council to follow the example of the Dublin College of Physicians in taking the avoirdupois pound and ounce as integers of weight, and to avoid their example in dividing the ounce into parts having the same names and symbols as those of apothecaries' weights but with entirely different values, are fully explained in the preface to the first edition of the British Pharmacopœia. There were strong grounds of objection to such a division of the avoirdupois ounce as the Dublin College proposed, but it is sufficient to say that the College had no legal authority for introducing such a system, and the question need not therefore be complicated by further reference to it.

We have only two systems of weights specially designed for use in medicine and legally authorized: namely, the apothecaries' weight, in which the troy pound, ounce, and grain are supplemented with the drachm and scruple, and the weights of the British Pharmacopœia, consisting of the avoirdupois pound and ounce with the troy grain. The integers in each of these systems have their distinctive signs or symbols which are intended for use in prescriptions, and it is important to observe that where integers of the same name have different ponderable values they are distinguished by having different symbols. Thus, for example, the symbol for the troy or apothecaries' pound is ℔, whilet he symbol for the avoirdupois pound is lb., the absence of the bar across the letters serving to distinguish the latter. The troy or apothecaries' ounce has its characteristic symbol ℥, while the avoirdupois ounce, as ordered for use in medicine, is represented by the symbol oz. The grain being the same in both systems, no difference in the symbols was required.

It was obviously intended or desired, in introducing avoirdupois weights with the troy grain (for there is really no avoirdupois grain) into the British Pharmacopœia, and recommending them for use by medical men in prescribing, that these weights should ultimately supersede the use of the old apothecaries' weights, and thus simplify the practice of pharmacists by making one system of weights applicable for all their requirements; but it could not have been expected that practitioners would at once or for many years completely adopt the new arrangement, and hence the necessity that each weight should have its distinctive sign. The sanction given by the Medical Council in the last edition of the Pharmacopœia to the use in prescriptions of the symbols ℈ and ʒ in place of writing gr. 20 or gr. 60, was intended, as there stated, for the purpose of promoting convenience and accuracy in prescribing and dispensing. How this sanction could be construed into an authority to use or interpret the symbol ℥ as having any other meaning than that of the troy or apothecaries' ounce of 480 grains, I am at a loss to understand. The only excuse I know of for opinions which have been expressed to that effect is, that physicians sometimes use the symbols referred to in a way in which they were not intended to be used. This is a part of the subject, however, which I do not purpose discussing, my object being to endeavour to explain the strict meaning of the terms or symbols used for indicating quantities in medical prescriptions, in reference to which I may add that I have consulted one of the members of the Pharmacopœia Committee of the Medical Council, who entirely approves of the views herein expressed.

T. REDWOOD.

[21]. AVOIRDUPOIS *versus* TROY OUNCE.—I consider that the adherents of the troy ounce are scarcely consistent in their practice, however virtuous they may be in theory. Mr. Wilkinson says, "In the P. L., 1851, we find the sign ℥ used to indicate one ounce of 480 grains, and that being the latest authoritative interpretation of the sign, I consider that it is still in force." He then gives a formula containing ℥j by way of illustrating his mode of procedure in his adherence to the troy ounce. However, he says again, "No doubt, if any one customer or physician sent to me for a number of articles and wrote ℥j, ℥ij, ℥iv, and so on, I should supply the articles by avoirdupois weight, because that would be a commercial transaction; but, when ℥j is written in a prescription, I conceive it is used as a multiple of ʒj, and should be so interpreted." This is inconsistent; it is scarcely likely that a physician attaches a different value to each case. Why does not Mr. Wilkinson follow out his troy ounce in both cases? Physicians *may* write ℥j to represent 480 grains; from the examples given by Mr. Mackay one may gather some evidence that they do, but I believe that in the majority of cases in which ℥j is written the ounce of 437½ grains is meant. How to know when one or the other is meant is the puzzle. For example, I take two *bonâ fide* formulæ from recent dispensing experience:—

No. 1.

℞. Veratriæ . . . . gr. xv.
Adipis . . . . ℥j.

Fiat Unguent.

No. 2.

Potass. Bromid. . . . . . ℥j.
Infus. Calumb . . . . ad ℥viii.

Sig.: A tablespoonful a dose.

No. 1 is from the pen of a physician who frequently orders veratria ointment of Pharmacopœia strength, but at times wishing it stronger in veratria, writes it as given above, and it is very evident that he means the Pharmacopœia ounce of lard; at any rate it is as evident as that in No. 2, the prescriber's intention was to give 30 grains of bromide in each dose, supposing ℥j to mean 480 grains. My experience of prescribers is in accord with that of J. S. W., in that when they wish to be accurate, they either write grs. or drs. For example:—

℞. Citrat. Potass. . . . . gr. 180
Tr. Digitalis . . . . . . ʒj.
Inf. Calumbæ . . . ad ℥vj.

Sig.: A tablespoonful; and

℞. Pot. Iodid. . . . . . . ʒxij.
Tinct. Aconite . . . . . ʒiss.
Inf. Chiratæ . . . . ad ℥vj.

Sig.: A tablespoonful.

These I do not manufacture for the occasion.

In my former letter I asked the question, "How do you know that when a physician writes a prescription for ℥j he intends 480 grains to be dispensed?" Neither Mr. Wilkinson nor Mr. Mackay answered this question. Mr. Mackay gave a few (?) reasons for his adherence to the troy ounce; none of his reasons, however, contain satisfactory evidence in favour of it. Mr. Tanner, in reply to this question says, "Because he has used a sign which never had, and is never likely to have, any other value; and, therefore, conversancy with the 'latent' intention of prescribers is not needed." Mr. Tanner here overlooks the fact that the important point is not what value the ℥ has of itself, but the value that is by the writer assigned to it; consequently it seems to me that conversancy with the "latent" intention of prescribers is very much needed. Mr. Mackay and Mr. Tanner say that my statement that troy weight is practically obsolete is incorrect. Mr. Tanner adds, "as well might beef-steaks, tea, sugar, etc., be considered obsolete." I withdraw my statement at their instance. This discussion will have shown Mr. Tanner that troy weight is not of quite such general adoption as the articles of which he makes mention.

It is beyond question that the ℥ sign is used to represent the avoirdupois ounce more frequently than it is used to represent the troy ounce. Physicians know this very well and they are not justified in using it to represent 480 grains when they have their choice of expressing their quantities in grains or drachms.

The use of any but the avoirdupois ounce is not countenanced by the Pharmacopœia. The fluid ounce for which the symbol ℥ is used regularly, is the measure of 437½ grains of distilled water at the standard temperature and pressure. I consider, therefore, that when ℥j of a powder or any solid is ordered in a prescription, it is perfectly justifiable, in the absence of positive knowledge that the writer means the troy ounce, to dispense the avoirdupois ounce; it is, moreover, consistent, which is more than can be said for the use, in such a case, of the troy ounce.

I agree with Mr. Tanner and G. S. that the earlier the metric system is made official the sooner we shall be free from any anxiety with regard to the interpretation of signs.

P. B.

Glasgow, November 27, 1877.

[21]. APOTHECARIES' OR AVOIRDUPOIS?—With regard to the above question, the compilers of the British Pharmcopœia, 1864, speak very plainly, and to my mind leave no room for doubt.

In the preface, page xviii, the following occurs:—"The council in resolving to adopt for pharmacy the imperial ounce and pound, could not assimilate the sub-division of the ounce to that of the fluid ounce, without substituting a new medical grain, hitherto the medical as well as the standard grain of the kingdom."

This alteration they did not consider advisable; it has therefore appeared to them a necessary consequence that the drachm and the scruple, the old denomination of weights "between the ounce and the grain of pharmacy, must be abandoned since they can no longer exist as both simple multiples of the latter and integral parts of the former; accordingly, all who prescribe and dispense medicines are strongly recommended to discontinue henceforth the use of the drachm and scruple weights."

In the B. P. 1867, the avoirdupois ounce is specially mentioned as "still retained in preference to troy weight of the same denomination."

From this I learn that the ounce adopted by the council is the avoirdupois ounce (437·5 grains), and should always be used, whether in dispensing or in the sale of medicines, there being no authority for the use of the troy ounce.

---

[21]. AVOIRDUPOIS *v.* APOTHECARIES'.—When first writing on this subject, I had no idea that the discussion would reach its present length; the interest in it, however, appears to be increasing rather than diminishing. I am always willing to learn from others and to respect the opinions of those who differ from me, but up to the present time I fail to gather from anything adduced a single reason which should cause me to alter my views.

It seems to me that appealing to the wishes of any one or half a dozen medical men helps the matter very little; what we must have is a principle to go on applicable alike in the small or large establishment, near and known to, or distant from and unknown to the prescriber; exercising judgment by all means, but in so doing leaving that principle unaltered.

The U. S. Pharmacopœia still retains troy weight and the old wine measure, whilst the buying and selling is done by avoirdupois weight; the result being that in any one drug store, three ounces, each possessing different values are still in use, viz. 480, 455·7, and 437·5 grains respectively.

Exactly the same state of things obtained in England at one time, but we have been freed from this yoke, and although all that could be desired has not yet been accomplished, every one will surely acknowledge that the abolition of the apothecaries' weight and the adoption of a single unit for both weight and measure in the British Pharmacopœia is a step in the right direction. The unit adopted was the grain recognized by law in this country possessing the same value as, but not a troy grain; and knowing how diffiult it is to eliminate from the minds of even enlightened men the impression placed there as the results of usage, the signs ℈ and ʒ are permitted (not recommended) as representing, or rather as a convenient mode of expressing, twenty and sixty grains avoirdupois not scruple and drachm as formerly; there was no necessity for mentioning the ounce in this part of the preface of the B. P., because a definite value is given to it elsewhere.

Many prescriptions have been quoted. I will just take the one as corrected by Mr. Wilkinson, and in the absence of any special instructions to the contrary should dispense it (or indeed any other prescription) with the weights and measures of the British Pharmacopœia.

				Avoirdupois.
℞.	Ol. Limonis . . .	gtt ij	=	♏ij.
	Sodæ Bibor. . . .	ʒij	=	grs. 120.
	Sacch. Alb. . . .	ʒiv	=	grs. 240.
	Potass. Bitart. . .	℥j	=	1 ounce.

To be mixed in a pint of water for a drink.

Then the dispenser compounds the prescription by avoirdupois weight and measure, the patient dissolves it in a pint or twenty avoirdupois ounces, and takes it by the same measure also. Why so far the metric system itself could scarcely furnish greater uniformity!

It might be objected that by weighing thus, I have introduced fractions of grains in the divided dose, say an ounce of the liquid. True, but this will occur any way. That quantity will contain essence of lemons one-tenth of a minim, borax six grains, sugar twelve grains, cream of tartar twenty-two grains practically; if the prescriber intended to give twenty-four grains in each ounce the fault rests with himself, not with the dispenser. It is quite possible, however, that no special dose would be intended at any one time. Many medical men do not under ordinary circumstances give special doses, but estimate the amount of any medicine that they are prescribing that the patient will bear or require in a given time, say twenty-four hours, and then order that quantity to be given in divided quantities, small and frequent, or larger and less frequent, according as they wish the effect to be constant or intermittent. At the worst the discrepancy would be less than eight per cent., whilst if the instructions of the prescription were implicitly followed, the difference in dispensing the oil of lemons at any two establishments might be fifty per cent.

In the case of the medical man quoted, who continues after ten years have elapsed to write P. L. 1851 at the head of his prescription, there is no ambiguity most assuredly; but had he spent one-fourth the time thus occupied in perusing the B. P., he would doubtless ere this have discontinued the practice, and have unhesitatingly acknowledged the superiority of the latter work.

CHARLES SYMES.

December, 1877.

[No 21]. If the present correspondence be in any way the means of bringing the metrical system into general use great good will be accomplished thereby.

G. S. in his remarks upon the following quotation from B. P.: "It is strongly urged upon all medical men to avoid the use of the terms ounce and pound with reference to any other than the avoirdupois or imperial standard weight," confounds the word terms with symbols which, I take it, has quite a different meaning. He should have quoted the whole of the sentence, which continues thus :—"but it will be optional with the physician, in prescribing, to use the symbols ℈ and ʒ, the former representing 20, and the latter 60 grs., if such should be found to conduce to accuracy or convenience."

Now the symbols ℈, ʒ, and ℥ have always been used in connection with troy and apothecaries' weight, but never with avoirdupois. I therefore venture to assert that we are fully entitled to, and justified in infering that if a physician uses the sign ℥ we are to interpret it as representing 480 grs. or ʒviij, and not 437·5 grs.

Further, if we reduce a mixture or powder, from, say the six or twelve doses as written for, to one dose, we shall find that 99 per cent. of such cases will give an equal number of grains per dose, to which the sign ℥ may be appended (reckoning 480 grs. to the ℥j).

From this, if from no other reason, the dispenser would be justified in using ℥j troy, and not 1 oz. avoirdupois. I would call Dr. Symes' attention to the fact that in the B. P. the sign or symbol ℥ is carefully abstained from and the word ounce always used.

G. S. is not to the point in his sample prescriptions, inasmuch as the question in dispute is the use of the symbol ℥ as regards solids, and not liquids. He "may be surprised to hear" that in sending out liquid medicines a dispenser does not disregard or ignore the troy system, as there is no troy measure to ignore.

Dr. Symes (Nov. 24) no doubt disposes of Mr. Mackay's seven reasons entirely to his own satisfaction, but hardly so, I imagine, to that of the majority of your readers. With regard to the prescription for ung. hyd. iodid. rubr., which he mentions, I should be rather inclined to think that the medical man meant an ointment with 4 grs. to the ʒj than one double the strength, B. P.

Looking at the, in many cases, odd and inexpressible proportion in parts (*i. e.*, 1 part active ingredient in so many parts of the bulk), may not the compilers of the B. P. have overlooked their preface, and reckoned according to the old, and to them more familiar, apothecaries' weight?

Medical men generally are in the habit of mentioning the strength of different preparations as being one in so and so, rather than so many grains to the oz.

Islington. A. LAITRAM.

[21]. TROY *versus* AVOIRDUPOIS.—Believing that the wishes of the prescriber should guide us in reference to the above, I have, during the last fortnight, taken the opportunity of inquiring from some of our best men here which weight was intended when the sign ℥ was written, and I find without exception all for troy, and in some cases they quite ridiculed the idea of any other being used. I fancy this will be found pretty general throughout the kingdom. J. ARBLASTER.

New Street, Birmingham.

[43]. "An Assistant" will find, that by slightly warming the pestle and mortar (or slab and spatula), he will be able to blend the ung. zinci and S.V.R. without any difficulty.

BOOKS, PAMPHLETS, ETC., RECEIVED.

THE CHEMISTS AND DRUGGISTS' DIARY. 1878. London: 44a, Cannon Street.

The 'Chemists and Druggists' Diary' for the present year, which we learn from the Introduction is the tenth of the series, has been received, and we are glad to note that it presents no signs of falling off from the high standard of excellence attained by its predecessors. The value of the 'Diary' proper and skeleton pages has no doubt, in former years, been proved by our readers, and we feel sure that the "literary matter" in the present volume will be extremely serviceable. One feature in it is worth special notice, the "Dictionary of Synonyms," which numbers upwards of one thousand articles, and no doubt will be the means of removing many perplexities arising from the advent of unfamiliar names into different pharmacies.

HISTOIRE DES DROGUES D'ORIGINE VÉGÉTALE. Par F. A. FLUCKIGER et DANIEL HANBURY. Traduction de l'ouvrage anglaise 'Pharmacographia,' augmentée de très-nombreuses Notes, par le Dr. J. L. DE LANESSON. Avec une Préface par H. BAILLON et 320 figures. Paris: O. Doin. 1878. From the Translator and Publisher.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

AN EXPLANATION.

Sir,—Judging from the fact that my name has appeared with unenviable prominence in the advertisement columns of the Journal, I am led to suppose that there has been some dispute between Messrs. Muter and Wills as to whom should be the credit, or otherwise, of having coached me for the Major. Will you, therefore, allow me space in the Journal to give a plain statement of the facts of the case, which I hope will effectually put a stop to a most unwarrantable use of my name?

Towards the end of 1876, I commenced to study privately for the Major examination, being then and up to the date of passing it, senior in a London business, and feeling the want of some help in the matter, amongst other things I applied to Mr. Wills for his postal lectures. The result was that I paid him a guinea for two lectures a week; but when I came to look into them and the sequence between them I found that they were not in any way suited to my purpose, so transferred them to a friend who believed he could derive some benefit from their perusal. The lectures were, I believe, not half finished when I received my certificate. During the time I was studying, having a fortnightly day off duty, and wishing to employ it usefully, I entered into an arrangement with Dr. Muter, who allowed me to spend that day in practical analysis with the Major students at laboratory, this being towards the end of my studies. I spent, I believe, not more than two or three days in this manner, and to that extent only may I be considered his pupil.

In conclusion, I may add that absence from England prevented my sooner making this explanation.

A. H. BALDWIN, PH.C.

Byculla, Bombay, November 11, 1877.

G. Lines.—The first specimen sent was a fragment of a *Juniper*, but the materials were not sufficient for the determination of the species. The second is *Teucrium Scorodosma*, used by herbalists in the treatment of dyspepsia.

H. A.—We presume the Inland Revenue authorities would not interfere if the spirit were obviously used for medical purposes; but see p. 466.

W. D. W.—We do not think that any good purpose will be served by the publication of your question. Previous experience has shown, as might be expected, that opinions expressed from different localities have been very diverse.

B. T. Kimber.—The mistake may have been made either by the witness or by the reporter of the newspaper from which the report was quoted; it would not do always to alter reports of evidence in accordance with our ideas of correctness. We do not think the danger you hint at is very great.

PHYSIC MASS AND BALLS.

BY ELLIMAN, SONS AND CO.

In July 1875, with a view to the introduction of a physic ball as a *spécialité*, we made a number of experiments on physic mass. We were desirous of finding a mass which should have the following properties:—

First.—Contain a large proportion of aloes.

Secondly.—Which though firm should yet be plastic and ductile.

Thirdly.—Which should be readily dissolved in the horse's stomach.

Fourthly.—Which would keep, retaining its plasticity, ductility, and solubility, for any length of time, and could be made into balls with ease, being worked cold.

Fifthly.—That when made into balls, the balls would not lose shape or fall.

We searched in vain for a formula giving a product which would fulfil these requirements. The formulæ given by Morton and others produce a ball falling far short of this ideal, as those who have had experience with physic mass well know.

Glycerine soon proved to be the best solvent of aloes, and made a mass both plastic and ductile, but so hygroscopic that it was perfectly useless, especially in an English climate. We then thought—was it possible whilst retaining the glycerine as a solvent for the aloes, to combat the tendency of the mass to absorb moisture?

We found that by using less glycerine and adding castor oil, the hygroscopic nature of the product was so much lessened that the mass approached the ideal standard. We will briefly give the formula and *modus operandi* which we found most successful.

Take of

Best Barbadoes Aloes	10 lbs.
Glycerine	1 lb.
Castor Oil	1 lb.
Powdered Unbleached Ginger	$\frac{1}{2}$ lb.

Dissolve the aloes in the glycerine by means of a water-bath, then add the castor oil, and lastly stir in the ginger previously resifted through a coarse sieve. When operating upon 50 pounds of aloes we have found that it would dissolve in five pounds of glycerine in about one and a-half hours, so that the mass of over 60 pounds could be made in a little more than two hours.

The mass possessed the first four properties we were seeking.

It contained a large proportion of aloes, the aloes forming nearly $\frac{5}{6}$ of the mass. It was firm, plastic, and ductile. It was readily dissolved in the horse's stomach. It would retain these properties for any length of time, and could be readily made into balls, being worked cold. But our fifth requirement was not satisfied; when made into balls they would not retain their cylindrical form: like pitch they fell.

Could this tendency of the balls to fall be in any way removed? Not in any way that we could discover except at the expense of the other necessary qualities of the mass. It was therefore requisite to give the balls a support, and for this purpose we had white cardboard boxes made of the same shape as marking-ink cases. Into these the balls, wrapped in waxed paper, were placed as soon as made.

Division of the mass into balls.—If a *specialtié* prove a success, not many dozens but many grosses are sold daily; it was therefore necessary to devise a method by which the mass could be very rapidly divided into balls; for the ordinary process of weighing each one separately, and rounding with the hand is slow and tedious. The following is the method we employed for the division into balls:—

The plate of a 7lb. Pindar's piping press is perforated with six holes, $\frac{3}{4}$-inch in diameter, placed hexagon fashion. The press being filled with the ductile mass, pressure is applied; pipes of mass are produced which when from 8 to 10 inches in length are rapidly cut off, placed on a table, and rolled all six together with a weighted board to remove unevenness in them. No powder is required to prevent adhesion of the pipes. The pipes are then placed into semicylindrical zinc gutters to prevent falling, till their turn arrives to be cut up.

For cutting up a number of knife edges are fixed at equal distances in a board. The pipe is placed on these knife edges and rolled gently backwards and forwards by means of a light board, very gentle pressure being applied. The balls are immediately placed in other zinc gutters till their turn arrives to be wrapped in waxed paper and placed in boxes.

By this method a man and boy can make, wrap, and place in boxes, over a gross an hour.

No scales are used; the boxes being made to contain a certain volume of mass. If the balls are too large they will not go into the boxes, if too small they fit loosely; but with a little practice the pipes can be cut with ease into balls which have very nearly the same weight and which accurately fit the boxes.

For balls of different strengths, pipes of the same diameter are cut into balls of different lengths, and of course placed into boxes of same diameter but of different lengths. A separate cutter is therefore required for each strength ball, but balls containing 4, 5 and 6 drachms of aloes are sufficient for all ordinary purposes.

This mass shares with all other ductile masses the property of falling, but the boxes add very little to the cost of the balls and enable them to retain a perfectly cylindrical form, which is a step in the direction of elegant veterinary pharmacy.

A NEW PROCESS FOR MAKING PHOSPHATE SYRUPS.

BY JOHN LAURIE.

So much has already been published upon the production of these syrups, that the writer feels a delicacy in again introducing the subject; but the fact that by no published formula can a satisfactory product be obtained is his apology, and he therefore wishes to bring under the notice of pharmacists a process which in his hands has been eminently successful.

In the following formula the method adopted for the production of the ferrous phosphate is that proposed by Mr. Borland.*

The author is not aware that the process employed by him for obtaining the calcic phosphate has before been applied to the manufacture of these syrups; he proposes it as an easy way of obtaining a pure tricalcic phosphate, the varying composition of the commercial phosphates of lime being in his opinion a very frequent cause of the precipitates which have been found so troublesome; besides, the ordinary

* *Pharm. Journ.* Sept. 30, 1876, p. 280; Trans. Brit. Pharm. Conf., 1876, p. 593.

phosphate of lime, as is well-known, always contains a large percentage of water, hence the finished syrup is frequently deficient in the lime constituent.

The strength adopted for Parrish's syrup, viz., half a grain ferrous phosphate and two grains calcic phosphate in the fluid drachm, is the same as would result in making a syrup from Parrish's published formula; and agrees with the best commercial samples of syrup, as shown by Mr. Howie (*Pharm. Journ.*, 3rd series, vol. 6, p. 808).

A syrup of the full strength stated on the labels of "Parrish's Chemical Food" may easily be obtained by the process now described, but the large quantity of acid necessary to dissolve and retain the phosphates in solution renders the syrup disagreeably acid.

A saccharated solution of lime is prepared by shaking together during several hours—

Freshly Slaked Lime	8 ounces
Refined Sugar, in powder . .	16 ounces
Water	40 ounces

The clear solution is estimated volumetrically for hydrate of lime, and will be found a little over four times the strength of the similar solution of the British Pharmacopœia.

Parrish's Chemical Food.

Take of

Saccharated Sol. of Lime, sufficient to yield	670 grains hydrate of lime
Sulphate of Iron, pure . . .	448 grains
Phosphoric Acid, sp. gr. 1·75 .	3 fluid ounces, or q. s.
Carbonate of Soda, crystallized	50 grains
Carbonate of Potash	75 grains
Cochineal, in fine powder . .	2 drachms
Orange Flower Water . . .	1½ fluid ounces
Refined Sugar, coarsely powdered	30 ounces
Distilled Water q. s.	

Dilute the solution of lime with distilled water to a pint, put into a quart bottle, gradually add the phosphoric acid, frequently shaking, till the precipitate is dissolved, then carefully add the carbonates dissolved in one ounce of distilled water, shake till clear, then add the orange flower water and enough distilled water to make the whole measure 32 fluid ounces; to 26 fluid ounces of this solution add the cochineal, digest for several hours, and filter into the sugar; shake occasionally till dissolved.

Put the sulphate of iron, with the rest of the phosphate solution, into a bottle of about seven fluid ounces capacity; cork tightly, shake occasionally for half an hour, squeeze strongly through moistened calico, and mix the clear liquor with the syrup; the product measures 48 fluid ounces.

It is necessary strictly to follow the direction of first dissolving the sugar in a portion of the phosphate of lime solution, and afterwards adding the ferrous phosphate; if an attempt be made to dissolve the sugar in the mixed lime and iron solutions a precipitate of iron salt will certainly result—

Syrupus Ferri Phosphatis, B.P.

Take of

Saccharated Sol. of Lime, sufficient to yield	120 grains hydrate of lime
Sulphate of Iron, pure . . .	448 grains
Phosphoric Acid, sp. gr. 1·75 .	10½ fluid drachms
Refined Sugar, coarsely powdered	17 ounces
Distilled Water, q.s.	

Dissolve the sugar in eight fluid ounces of distilled water with the aid of heat; prepare a solution of ferrous phosphate, as above directed (diluting the solution of phosphate of lime to five fluid ounces before adding the sulphate of iron), add this to the syrup, and enough distilled water to make the whole measure 24 fluid ounces.

This syrup will contain approximately the same quantity of acid as the Pharmacopœia syrup, but six fluid drachms of acid, sp. gr. 1·75, will be found amply sufficient to dissolve and retain the iron; the formation of precipitates in these syrups not being retarded by a large excess of acid.

A larger proportion of the carbonates of soda and potash added to "chemical food," will make the syrup less acid—or phosphate of soda may be substituted for the same purpose.

Syrups prepared according to the process just described will contain, as an impurity, a trace of sulphate of lime, and, in the case of the Pharmacopœia syrup, of phosphate of lime also, but the very small quantities present can hardly be considered an objection.

Samples of "chemical food," Syr. Ferri Phosph., B.P., and Syr. Ferri Phosph. c. Strychnia, prepared as above, have been kept for six months without undergoing any visible change. All are entirely free from deposit. The chemical food has been kept in a Winchester quart three-fourths filled, the other two in stoppered bottles, full, and exposed to strong light.

SYRUPUS FERRI PHOSPHATIS C. QUINIA ET STRYCHNIA.

BY GEORGE MASSON.

Having to prepare some Easton's syrup, the attention of the writer was arrested by the variation exhibited by the different formulæ. It was found that three methods for the preparation of this syrup had been proposed, each varying alike in the process employed, and in the strength of the finished product.

First may be mentioned the formula of Mr. M. Carteighe,* which directs dried phosphate of iron to be mixed with a small quantity of water and dissolved in syrupy phosphoric acid, to which has been added an appropriate quantity of strychnia and quiniæ phosph., the whole being finally mixed with syrupus B.P. Each fluid drachm of this preparation contains two grains phosphate of iron. This form offers some advantages with regard to facility of preparation, but is open to the serious objection, that dried ferrous phosphate has always undergone oxidation, the amount varying with the age of the sample and the care exercised in manufacture and storage.

The second process was suggested by Mr. E. C. Saunders,† and is an adaptation of the method originally introduced by Mr. H. W. Jones,‡ a modification of which was published by Mr. W. L. Howie,§ in his excellent and exhaustive paper on phosphate syrups. Prepared thus, the ferrous phosphate is formed by direct combination, metallic iron being employed and syrupy phosphoric acid; certain precautions being observed to prevent atmospheric contact, both during and after solution. For obtaining a syrup tolerably free from ferric contamination this is doubtless superior to the ordinary method of dissolving the precipitated phosphate.

* *Pharm. Journ.*, March 25, 1871.
† *Pharm. Journ.*, July 15, 1876.
‡ *Pharm. Journ.*, 3rd series, vol. 5, page 541.
§ *Pharm. Journ.*, April 8th, 1876.

Leaving aside, however, the question as to whether the product is identical with that formed by the action of sodic phosphate or ferrous sulphate, the process is rather a tedious one, and moreover the use of syrupy phosphoric acid is objectionable, unless care be first taken to ascertain its purity. Should the acid employed happen to contain the smallest proportion of either pyrophosphoric acid, $H_4P_2O_7$, or metaphosphoric acid, HPO_3, the result is a most unstable syrup, which causes considerable trouble. This preparation contains one grain phosphate of iron in the fluid drachm.

The third process is given in Squire's 'Companion' to the B. P. (10th edition). In its details the *modus operandi* is very similar to that described in the latter work for syr. ferri phosph., and it is probably the form most generally employed. Here ferri sulph. 2½ ounces and sodæ phosph. 3 ounces are directed to be dissolved in a sufficiency of water, the solutions mixed, the precipitated ferrous phosphate collected, washed, and finally dissolved in 56 ounces acid. phosph. dil., together with quiniæ sulphas 1½ ounces and forty-eight grains, and strychnia twenty-four grains; this mixture to be added to 56 ounces of sugar so as to produce 96 fluid ounces of syrup. Being doubtful whether the above weights were the troy or avoirdupois a calculation was made on the quantity of quinine, which converted into grains gave 768 grains troy and 704 grains avoirdupois; it was, therefore, concluded that the former was intended, although this fact is nowhere stated. Were the avoirdupois weights employed it would further impoverish a formula already deficient in active ingredient. A very little further consideration soon makes it apparent that even when troy weights are used the quantities ordered are insufficient to form a syrup containing as stated 1 grain phosphate of iron and 1 grain phosphate of quinia in the fluid drachm. For instance, 2½ ounces (troy) ferri sulph. is only capable of yielding on decomposition 515 grains $Fe''_3P_2O_8$; hence each drachm of syrup could only contain 0·670 grain phosphate of iron. This is assuming that complete decomposition really took place; such, however is not the case for, according to the researches of Mr. R. Price,* a loss through imperfect precipitation of no less than 28·2 per cent. occurs in the nearly identical process for syr. ferri phosph., B. P. Taking it for granted that there would be a corresponding loss it is evident that the proportion of ferrous phosphate would suffer a very serious further diminution. A deficiency also occurs in the quinine, no allowance having been made for the loss of weight consequent upon conversion of the sulphate into phosphate, the quantity ordered being capable of producing a syrup containing only 0·891 grain of quinic phosphate $(C_{20}H_{24}N_2O_2)_3 2H_3PO_4$ per fluid drachm.

The following is the formula I would propose; by it a colourless syrup may be readily obtained of full strength and possessed of good keeping qualities. The syrup should be preserved from the air in bottles, well filled, and securely stoppered:

℞ Strychniæ . . .		24 grs.	
Quiniæ Sulph. .		860 ,,	
Ferri Sulph. . .	4 ozs.	40 ,,	Avoirdupois.
Sodæ Phosph. . .	12 ,,		
Sacchari Purif. Contus. . .	60 ,,		
Acid. Phosph. Dil.	48 ,,		

* *Pharm. Journ.*, March 4, 1876.

Dissolve the quiniæ sulph. in aq. dest., with a sufficiency of acid. sulph. dil., precipitate with liq. ammon. q.s., collect on a filter, wash carefully, avoiding the use of too much water, and add to the acid. phosph. dil. in which the strychnia has been previously dissolved. Dissolve the ferri sulph. in Oij, and the sodæ phosph. in Ov of recently boiled distilled water, filter the iron solution if necessary to remove any oxidation, allow the solutions to cool to 130 F., and then add very gradually with constant stirring the solution of soda to the iron; allow the precipitate to subside, remove the supernatant fluid and wash the ferrous phosphate by decantation with recently boiled distilled water, then transfer to a calico filter, express quickly the remaining liquid and dissolve in the dilute phosphoric acid; finally add the sugar, dissolve without heat and subsequently add a sufficiency of distilled water to make the product measure ninety-six fluid ounces, each fluid drachm of which will contain one grain phosphate of iron, one grain phosphate of quinia and $\frac{1}{32}$ of a grain of strychnia.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 386.)

HYSSOPUS, Sp. ?—*Local name*, ZOOFAI YABIS.

From an examination of the drug this appears to be a small plant 6—8 inches high; stem not thicker than a crow quill, 4-angled, purplish, branched from the base, which is woody; root woody, seldom branched; flower heads numerous, oblong; calyx striated, hairy, purple, with five sharp teeth; seeds naked, four in number, oblong, 3-angled, of a pale brown, studded with rows of small round tubercles; on one side of the hilum there is a fringe of smaller tubercles very closely set, and on the other two elongated white prominences. In the drug the plant is much broken up; it has a pleasant odour like sweet hay; there are no leaves to be seen. Taste bitter; properties, stimulant, anthelmintic and deobstruent. This drug has often been attributed to *Hyssopus officinalis*, but this cannot be correct, as the flowers are in oblong spikes. It is imported from Persia.

——— ?—*Local name*, BADRUNJBOYA.

Calyx striated, hairy, 5-fid; not so long as that of Zoofai Yabis, and not coloured; seeds four, naked, brown, 3-angled, nearly smooth, a white patch on each side of the hilum; flowers in axillary clusters of about six, upon a short peduncle; leaves ovate, margin deeply dentate, somewhat hairy. The drug is always much broken, and consists chiefly of stem and fruit; the former is quadrangular, much larger than that of zoofai, of a purplish tint. Taste bitter, odour faintly aromatic; properties stimulant and deobstruent. Imported from Persia. By some attributed to *Napeta ruderalis*, but I do not know upon what authority.

CUSCUTA Sp. ?—*Local name*, KASUS.

What is sold in the shops is a species of cuscuta, and is mixed with the small oblong leaves and spines of the plant upon which it has grown; most of it is in seed, but the flowers are also present. The seeds are four in number, light brown, convex on one side, concave on the other, enclosed in a round capsule; taste bitter. Imported from Persia. Sometimes called Tukm i Kasus.

Cuscuta Sp. ?—*Local name*, Afteemun.

Also a dodder, but a rather larger plant than the last; the fruit and seeds are nearly double the size. Taste bitter. Imported from Persia. This article is described in Arabic and Persian works as the afteemun of the Greeks, which had so great a reputation in melancholy madness; it is still a medicine of importance with the Hakeems of India, who follow in the footsteps of Jalenus (Galen).

Cuscuta reflexa.—*Local name*, Akasweli.

Another of the dodders, very common in India upon bushes; it bears small white bell-shaped flowers, and is used for the same purposes as afteemun.

Picrorrhiza Kurroa.—*Local names*, Kutki *and* Kurroo.

The drug consists of a rhizome, generally about the size of a goose quill, but often no larger than a crow quill, the lower portion of which is covered by a shrivelled greyish-brown corky bark, and marked by prominent scars, the remains of rootlets; towards the upper end it becomes larger ($\frac{1}{4}$ inch in diameter) and is thickly set with dark greyish-brown scales, and terminates in a scaly leaf bud or stem. The rhizome is generally broken into short pieces, from 1—2 inches long; the fracture is short, the root very fragile and light, and black internally; it has no odour, and a very bitter taste. Examined under the microscope the corky bark is seen to be made up of numerous rows of empty brick-shaped cells; within this is a cellular parenchyma of oblong brown cells containing a little granular matter; next a dark brown line composed of wood cells, forming the boundary of the inner column of the root; within this several very large bundles of dotted cells arranged so as to form a broken ring, which surrounds a central cellular parenchyma. Kutki has been found to be a valuable tonic in doses of from 10—20 grains three times a day; it has also been used in larger doses as an antiperiodic. It has little or no purgative action. It has been sometimes confounded with black hellebore, owing to the name kali kutki being given in books as the Hindee for kharbuk aswad, the Arabic name of that drug. Ainslie remarks of kutki that it is not at all like black hellebore. Picrorrhiza grows in Gosainkhan, Kumaon and Cashmere; it is described as having sessile deep blue flowers in dense spikes (*vide* Royle's Illust.). It is noticed in the Pharmacopœia of India and its Supplement, and seems worthy of a further trial.

Echium Sp. ?—*Local names: The herb*, Gaozaban; *The flowers*, Gul i Gaozaban.

Gaozaban consists of the leaves more or less broken and mixed with pieces of stem; it cannot be mistaken for any other drug as the leaf is remarkably thick, and studded on both sides with large white calcareous glands, from which simple calcareous hairs one-eighth of an inch long arise; the latter generally get broken off, but where protection from friction has been afforded by a bend in the leaf the perfect gland and hair will be found. When fresh the dried leaves are of a greyish-green colour, and have a rather pleasant tea-like odour; the taste is mucilaginous and saline; placed in water they give out a large quantity of mucilage. Mr. Moodeen Sheriff has raised the plant from seed, but as it did not blossom he was unable to determine the species. Gul i gaozaban are of a deep blue colour, 1—1$\frac{1}{4}$ inches long, tubular, with a wide mouth, and have the same tea-like odour as the leaves. The calyx is 5-partite and thickly set with calcareous hairs; stamens 5, attached to the corolla; the bulk of the drug is deprived of the calyx. If long kept it loses its deep blue colour and turns reddish. Both drugs are imported from Persia; they are much used in native practice, especially for bilious affections. Their properties are described in the Pharmacopœia of India.

Withania coagulans.—*Local name of fruit*, Kaknuj.

A description of the plant and its uses will be found in the Pharmacopœia of India. The fruit is sold in the Bombay shops; it is about the size, shape, and colour of a dried cherry; skin smooth and shining, reddish-brown, much shrivelled. It contains a large number of flattened reniform seeds of a light reddish-brown colour, and about one-eighth of an inch long; these are sticky, from the presence of a small quantity of brown pulp; the testa is reticulated. Kaknuj has a fruity odour and hardly any taste.

Valeriana Hardwickii ?—*Local name*, Tugger gauthoda.

This valerian has crooked roots about two inches long, and from a quarter to half an inch in diameter, of a dull brown colour, marked with transverse ridges, and thickly studded with circular prominent tubercles, to a few of which thick rootlets still remain attached. The crown of the root is marked by a number of bracts; the lower end is blunt; the root is very hard and tough, and the fractured surface greenish-brown. Odour like valerian but much more powerful. Examined under the microscope the outer bark is seen to be composed of ten or twelve layers of compressed cells; within this is a starchy parenchyma, and next to it a cambium layer; within the cambium layer is a broken ring of vascular bundles, and lastly, a starchy parenchyma thickly studded with conglomerate masses of large cells, having greenish-yellow contents of a resinous appearance. The drug is mostly used in Bombay as a perfume, but there can be little doubt that it would prove an efficient substitute for valerian.

Labiatæ, Gen. ? Sp. ?—*Local name*, Mishk-i-Trayamana.

Imported from Persia. It is a very small plant, two to three inches high; root as long as the plant, single, woody, with a few small fibres. The stems, which are two to five in number, are also woody, and branch from the ground; they are thickly set with leaves and flowers which reach to the apex and form a spike. The leaves are linear-lanceolate and have several prominent straight veins on each side of the midrib. The calyx, which is purple, encloses four oblong seeds of a brown colour, and is marked with numerous ribs, and ends in five sharply cut claws; it is studded with simple hairs, and is three-tenths of an inch long. The odour and taste of the drug is pleasant, like peppermint, but sweeter. Properties stimulant and carminative.

GRISLEA TOMENTOSA.—*Local name*, DHAITEE OR DHAWREE.

This shrub is common in Khandesh, also along the Ghauts, and in the Concon. The flowers and their calices are red; the latter are permanent and retain their colour after the flower has faded. As met with in commerce the calices generally contain the nearly mature capsule, which is two-celled and two-valved, and completely enclosed. The seeds are light brown, very minute, oblong, and very numerous. The calyx is twelve-toothed. In ordinary samples of dhaitee some of the flowers are in small racemes, and a good many lanceolate leaves, with a whitish under-surface studded with black dots, are mixed with them. The enlarged calices are very astringent and contain much tannin. They are used medicinally by the natives; commercially they are of considerable importance, being used in dyeing and tanning.

(*To be continued.*)

THE NASCENT STATE AS AFFECTING CHEMICAL ACTION.*

BY EDWARD DAVIES, F.C.S.

The discovery that at the moment of being set free from one state of combination, elements and compounds have a more powerful chemical action than in their free state, is one which has placed in the hands of chemists a means of effecting decompositions and producing new compounds, which has already yielded most valuable results, and bids fair in the future to be second to none in the inroads which it will enable us to make on the regions of the unknown. As any help to research must be valuable to those who desire to extend the domain of knowledge, I feel sure of a favourable reception for my endeavour to collect the facts and theories which, so far as I know, have hitherto been scattered as isolated items in chemical works, and to set them out in a connected form.

I must first ask careful attention to the theory relating to the state in which elements exist when free—that is, when uncombined with any other elements. The atomic theory has of late years been the subject of attack, but as I am unable to imagine any rational explanations of the nascent state without admitting that theory, I shall assume its truth. Shortly it is that all elements are composed of almost inconceivably small particles, which are incapable of further division by chemical means, and are the smallest particles which exist in compounds, so that, for example, if the smallest possble portion of hydrochloric acid were to be the subject of further division, the result would be one atom of hydrogen and one of chlorine. Of late years there has been added to this theory, that of molecules of elements as well as compounds, which is that an atom of at least most of the elements cannot exist for any appreciable time free and uncombined, and that when set free from a combination, in default of any atom of another kind, it will combine with another atom of the same element; for example, H will unite with H to form H_2, O with O to form O_2. The smallest particles of many of the elements existing in the free state will therefore be two atoms; this is the case with H, O, N, Cl, Br, I, F, S, Se, Fe; the monad metals P and As, and probably Sb and Bi, have four atoms in the molecule, while Hg and Zn, and probably many of the dyad metals have only one, their two combining powers uniting in a sort of self saturation.

That this view has much to recommend it is clear when we consider that all gases, simple and compound, expand alike for equal increments of heat. Now the molecules of compound gases and vapours all occupy equal spaces, and the action of heat consists in causing the molecules to recede to a greater distance and so occupy greater spaces. As equal effects are produced by heat on compound and simple gases, the probability is that as the compound bodies acted on are molecules, so the simple bodies are also in the state of molecules. Also, suppose two equal vessels, one containing 1000 atoms of Cl and the other 1000 atoms of H; a certain pressure will be exerted on the sides of each vessel. Now suppose these two vessels brought together, and the gases combined to form HCl, of which there will be 1000 molecules, 500 in each vessel; the pressure will be unaltered, although there are now 500 molecules in each vessel instead of 1000 atoms, whence we conclude that the 1000 atoms of H were combined in twos, so as to make 500 molecules, and that the same was the case with the 1000 atoms of Cl. Another proof is shown in the tendency of O to unite with O in the action of hydroxyl, H_2O_2 on Ag_2O. Both bodies lose O, and the simplest way of explaining this is, that one atom of oxygen in the hydroxyl unites with the atom of oxygen in the oxide of silver, both being loosely united, to form a molecule of oxygen, or O_2 leaving water and metallic silver, $H_2O_2 + Ag_2O = H_2O + Ag_2 + O_2$.

The bearing of this on our present subject is, that we can well conceive that if we could get an atom to act chemically before it had united itself to another atom of the same kind, it would act more powerfully than it would do if it had to be torn away from combination with another atom. The union of H with H must present some amount of resistance to be overcome before the hydrogen can be united with something else, whilst if we can present the hydrogen atom not yet united, this resistance will not exist and the union of the hydrogen with oxygen, for example, much facilitated.

This condition we realize in the various reactions which depend on the application of the nascent state, and as a matter of fact elements can thus be made to exert a power which is totally absent from them when they are fairly set free. Of course the element or compound which is to act in the nascent state, must be formed in the solution containing the body so acted on, or be in actual contact with it, for the slightest appreciable distance would give the opportunity for the union of atom with atom, and the element or compound would then be in the free, and not in the nascent state. Examples of the action of elements in the nascent state may now be mentioned. Reduction of oxygenated bodies by nascent hydrogen gives some of the most striking examples: free hydrogen may be passed through a solution of a nitrate for any length of time without formation of water by union of the oxygen of the nitrate, or of ammonia by the union of hydrogen with nitrogen. If, however, the hydrogen be nascent, both of these actions will take place, and an analytical method for the determination of small quantities of nitrates has been founded on this. Again, free hydrogen is without action on ferric sulphate, but if nascent hydrogen be used the salt is soon brought to the ferrous state.

Sulphurous acid, by the action of nascent hydrogen, loses its oxygen, and the sulphur unites with the hydrogen to form H_2S.

Direct combination of hydrogen with bodies, both organic and inorganic. Aldehyde can thus be brought back to the original alcohol. Nascent hydrogen will form H_2S with precipitated sulphur, and remarkably in the case of the action on insoluble sulphides, such as PbS and CuS, will even remove it from the state of combination. It exerts both the actions spoken of when it acts on As_2O_3, first removing the oxygen and reducing the arsenic to the elementary condition, and then uniting with the arsenic, also nascent to form AsH_3.

Nascent hydrogen is produced in various ways, amongst which may be named the action of H_2SO_4 or HCl on zinc, sodium, amalgam, or zinc amalgam, the copper zinc couple, and the action of alkalies on zinc, aluminum, or iron.

---

* Read at the evening meeting of the Liverpool Chemists' Association, held October 27, 1877.

Oxidation.—By means of bichromate of potassium, peroxide of manganese, or permanganate of potassium, and sulphuric acid, nascent oxygen can be produced and reactions obtained, impossible, or at least difficult, for free oxygen.

Alcohol is thus transformed into aldehyde, and acetic acid; and amyl alcohol into valerianic acid. Of reactions, which are slow when free oxygen is used, but immediate with nascent oxygen, the oxidation of ferrous salts may furnish an example.

Oxidation is also brought about indirectly by the action of chlorine. For example, in bleaching we find that dry chlorine produces no effect, water must be present, and the destruction of the colour is really due to the combination of chlorine with the hydrogen of water, and the evolution of nascent oxygen. Nickel hydrate is not affected by free oxygen, but if chlorine be passed into a strongly alkaline solution in which the hydrate is suspended, sesquioxide of nickel is formed.

The oxidizing action of peroxide of hydrogen is explained when we remember the readiness, with which it decomposes into water and nascent oxygen. Also, ozone, which contains three atoms of oxygen in the molecule, is more powerful than ordinary oxygen, because of its tendency to form the ordinary molecule of two atoms, and set free an atom in the nascent state. That this is so is shown by the fact that in oxidation by ozone only one third of the oxygen acts, the other two thirds remaining as ordinary oxygen.

Chlorine also acts more powerfully in the nascent state. Thus in aqua regia we have a powerful solvent of metals owing to the formation of nascent chlorine.

Substitution in organic compounds is also, in my opinion, largely due to the action of elements in the nascent state. Each stage in a substitution requires a molecule of, say, chlorine or Cl_2. Take CH_4: the first step is to form HCl by the affinity of H for Cl. The other atom of Cl is thus rendered nascent, and immediately unites with the residue CH_3. This is repeated until four molecules of chlorine have been employed, and, as a final result, CCl_4 is produced, although free chlorine is absolutely without action on free carbon. A similar action takes place in the case of iodide of nitrogen. A molecule of iodine or I_2 acts with formation of HI and NH_2I. Three molecules act thus until NI_3 remains, although nitrogen and iodine have such a slight affinity that the disturbance produced by the touch of a feather is sufficient to cause their separation.

Another chemical action in which the effects of the nascent state may be traced is double decomposition. Here, from two compounds, one new one is formed, probably from a more powerful attraction existing between the basylous radical of the one and the acidulous radical of the other than between the basylous and acidulous radicals of either of the original compounds, or because an insoluble or a volatile compound can be formed. The formation of one new compound leaves the other radicals in the nascent state and thus favours their combination. Thus we can form the sulphides of gold and platinum easily, although free sulphur and gold or platinum have little power of combining, by adding H_2S to their chlorides, where the attraction of hydrogen for chlorine leaves gold or platinum and sulphur in the nascent state.

The nascent state of compounds has not excited so much attention as that of elements, but we may in this fact get the explanation of many analytical difficulties and some analytical processes.

The simple method of estimating tin in alloys by acting on the alloy with nitric acid and filtering off the stannic hydrate is rendered inaccurate by the tendency of the nascent stannic hydrate to combine with CuO, and especially with Fe_2O_3. The former metal appears to be almost entirely removed by evaporation almost to dryness with excess of nitric acid and re-treating with dilute nitric acid, but Fe_2O_3 cannot be thus removed. Chromic hydrate is precipitated by cold caustic potash, and is freely soluble in excess, but in presence of excess of ferric hydrate not a trace is dissolved, and methods of qualitative analysis founded on this reaction are useless. Chromic hydrate and zinc hydrate are also retained, but not so completely, by ferric hydrate in the nascent state. Perhaps in nothing is this so remarkable as in the formation of those compounds of saturated molecules with one another which are the puzzle of theoretical chemistry to represent in graphic formulæ, such as have $PlCl_4 2KCl$ for a type. These bodies are generally double salts, and it is to the influence of the nascent state in forming these that we may trace some of the difficulties of analysis. Such are the carrying down of ZnS by CuS in acid solutions, and of oxalate of magnesia by oxalate of lime when neither zinc nor magnesia would have been precipitated but for the other metals.

A case in which this tendency of compound bodies to unite with others when in the nascent state is utilized for analytical purposes is the separation of phosphoric acid from nitric acid solutions by means of tin. Here stannic hydrate is formed, and at the moment of its formation it combines with phosphoric acid, completely removing it from the solution. I have tried a variation of this process, in which the stannic hydrate was precipitated from solution by adding $SnCl_4$ to the acid solution of phosphates, and boiling with sodium sulphate, but the co-precipitation of ferric oxide was so complete that the object was entirely defeated.

The principal applications of the nascent state have been in scientific chemistry, but there are many practical processes depending on it. Nitrobenzene is reduced and hydrogen substituted for oxygen by means of nascent hydrogen, and aniline is obtained, the starting point for the brilliant and lovely tints derived from coal tar.

The application of chlorine as an indirect oxidizer has rendered bleaching an affair of hours instead of weeks, has economized land, so valuable in manufacturing districts, and has even diminished crime by removing the temptation to theft which the calico spread out in the bleach croft so strongly offered; whilst as applied to old rags, esparto grass, and other paper making materials, cheap paper making cheap books and newspapers, knowledge itself must acknowledge its indebtedness to the nascent state. Nascent oxygen, as evolved by sulphuric acid acting on potassium bichromate, is employed to bleach palm oil, and thus enables us to use a dark coloured material in the manufacture of white soap and candles. Many other cases might be cited, and in the future we may expect to find many applications of this state which so mightily increases chemical energy.

A DRUG STORE IN THE FAR WEST.*

BY LOUIS WEISS, PH.G.

The particular location of the store I am about to speak of is in a small, but by no means insignificant town, named Pueblo (after a tribe of Indians who first located there), on the Arkansas, in Colorado; the time from 1869 to 1872. The proprietor was a physician, a graduate of a western medical college.

Previous to this time, the store was in the hands of two physicians, both carrying on business outside of the store and practice. One was notary public and somewhat of a politician, the other was postmaster, while a brother of his was telegraph operator or drug clerk, as occasion required. All these different branches were carried on in the store, a room about twenty-three feet by forty, in a one-story building, built of adobes (sun-dried brick). On the right hand side on entering the store was a case of glass front boxes; this was called the post-office department. On the left hand side was the telegraph office; back of these on each side, next the walls, was the stock of

* From the *American Journal of Pharmacy*, November, 1877.

drugs, etc. These were in a dilapidated condition; no regard was taken to keep them protected from light, heat, dust or moisture. Patent medicines were there an unknown luxury (!) at that time. Back of the store was a small room, termed the consultation room, into which the wily politician lured his victim, poured into his ears such floods of promises and into his glass such quantities of the enthusiastic beverage as none but the firmest could resist. This was about the state of affairs when my preceptor purchased the store and stock, in the year 1868. The post-office with the telegraph office were removed, and in order to make the store pay, the stock had to be enlarged and other goods added which properly did not belong to the drug business. On my introduction to the store as an apprentice, I found a young man in charge from New York, the doctor having his time pretty well occupied in visiting patients, some of them living a distance of sixty miles from the store, in other small settlements. These trips were generally made on horseback, or per ambulance, and were of frequent occurrence, and on occasions would require his constant attendance for several days, the prevailing troubles being caused by six-shooters, wild bronchos, and last, but not least, cases of confinement. The first three months of my time were spent in learning the names of the different drugs and medicines, and in getting acquainted with the stock, which I found consisted of an innumerable variety of things, such as drugs, patent medicines, wines, liquors, cigars, tobacco, garden seed, paints, oils, varnishes, glass and other painters' material, fixed ammunition, fishing tackle, picture frames, moulding, cord and tassel, clocks, wall paper and trimming, window shades, coal oil, lamps, chimneys, brackets and chandeliers, stationery, playing cards, field glasses, and a variety of minor articles, some of which are, and most others are not, generally to be had in a drug store. The dispensing department was not so well stocked, but was up to the demand, which was generally confined to calomel, blue mass, sulphate of morphia, chloroform, copaiba, spirit of nitre, iodide of potassium and caustic. Valerian, bromide of potassium, sulphate of quinia, and chloral hydrate were sometimes called into use. Elixirs, bitter wine of iron and like preparations were occasionally prescribed, but more frequently called for and sold over the counter. Many of the drugs that are in daily demand in Philadelphia never came into the store in my time. The stock was always bought in large quantities, as the goods were either bought in St. Louis, Chicago or New York—more frequently in New York when drugs proper, and in St. Louis when heavy goods—for the reason that it took from six weeks to two months from the time goods were sent for until they were received, as they had to be carried by wagon a distance of from two to three hundred miles, which was generally accomplished by Mexican bull trains; these were not always at hand, then the goods would lie in the warehouse until transportation could be procured. These trains consisted of from three to thirty wagons, each of which would load from two to four tons. Two of these wagons were coupled together, to the front one were hitched from ten to fifteen yoke of Texan or Mexican steers; these would be driven from eight to twenty miles a day or night, according to load, pasturage or water. This mode of transportation was quite expensive, which, in connection with the charges on the railroad made freight come high, at times footing up eight dollars per hundred pounds gross, delivered at the door from New York.

New York would never receive more than two orders for goods, amounting to from eight to twelve hundred dollars each, in one year, while St. Louis would not receive more than three in the same length of time. The price for medicines was not considered so extraordinary, though a prescription always brought four bits (fifty cents.) at the lowest, no matter how small or for what purpose; a four-ounce mixture, a dozen and a half of blue mass and colocynth pills, or a box of seidlitz powders were considered settled for with six bits (seventy-five cents.) Patent medicines, such as Ayer's pills, pain-killer (small), gargling oil (small) brought four bits, while the dollar preparations were paid for with one dollar and a half without grumbling. Coal oil sold for one dollar per gallon. Onion seeds were worth their weight in gold; the mountaineer put his gold dust on one side of the scale, whatever he wanted to invest, and when it was counterpoised with onion seed it was considered he had value received. Even exchange was no robbery. The people were all very liberal in their dealings; ten cent. customers were as scarce there as one dollar customers are here; less than ten cents.' worth was not sold—ten cents or no charge was the rule.

The druggist and physician was looked upon as a somewhat superior being; his will was done, his word was law. Whenever there was a public meeting or a social gathering, it was not considered complete until the doctor was identified with it in some way. Many a meeting—political or for the organization of a fire company, base-ball club, dancing club or church festival—was started in the store, subscriptions and donations received, and tickets sold for one or all, as the case might be. The doctor's name was always on the ticket for coroner; his services in that capacity were frequently called into use after there had been what they called a neck-tie festival. These were generally held after horses had been stolen and the aggressors caught by the Vigilantes.

In all the time that I was in the Far West I do not remember a single instance of a person asking for simply a dose of oil, as it is called here, the article not being put to use in that way.

Strychnia, arsenic, laudanum, or any other poisonous drugs were sold to any one that pleased to buy, and no questions asked. A friend of the doctor's at one time sent him a case of strawberries; these he was to sell for him merely as an experiment. They sold readily at one dollar per quart, and the individuals considered themselves favoured at having the chance to buy, there not being enough for all. After that we had California grapes, pears, and peaches for sale in their season, which brought six bits and one dollar per pound.

Everything is sold by the pound in that country, excepting eggs, liquids, and dry goods. Water was sold at that time at two bits (twenty-five cents.) per barrel, and was delivered from a tank on wheels, or by placing a barrel on the forked branches of a tree, drawing it to the river by horse, filling and drawing back to the place. This water was generally very muddy, and had to be allowed to settle, or else be clarified by adding alum before it could be used for ordinary purposes; the water obtained from wells was entirely unfit for use, it being very alkaline.

The class of people we had to deal with were as various as were their wants, they coming from all parts of the country, Texas, New Mexico, or the Colony, passing through our town on their way to the mines, and as a matter of necessity stopping and replenishing their stock of medicines, this being the only drug store within seventy-five miles or more around. All owners of sheep, horse, and cattle ranches were purchasers of large quantities of medicines for both man and beast. The Indians and Mexicans would come, complaining of being muncho mala (very sick). If we took pity on poor Lo, and gave him a seidlitz powder in separate doses until the froth came out of his mouth, he thought it a good joke, and would go off and return with another buck, who would likewise complain of being sick, and when treated in the same way would go and do likewise; and so on until the thing became monotonous. The Indians also frequently come to swap (trade) furs, pelts, skins and robes for paint; these in return we would sell for cash. The Mexicans' wants were generally limited to blue ointment, agua dienta (whiskey), medicena per granis (medicine for itch), or pietra infernal (nitrate of silver). The arrival of a soda fountain and generator for the drug store created quite an excitement, and on the day the charging of the fountain for the first time took place there were a considerable number of spectators standing around the back of the store where the performance was going on. As none of us had ever charged a fountain before, we made quite an awkward piece of business of it, and when the pipes got choked up with marble dust, necessitating our taking off one of the nuts, the marble dust and water were blown out with such violence that an alarm was given that the place had blown up, and a general stampede resulted. After we succeeded in making the soda water, we for several reasons found ready sale for it at fifteen cents. per glass, or two bits a glass with a stick in it. The ice for our use we had stored ourselves, or, when such was not the case, bought and paid at the rate of three dollars per hundred pounds for the same.

Things were not alone in this shape in Pueblo, but Denver, the largest city in Colorado, had but little to boast of. With the coming of the railroad, things changed; goods could be had on quicker time and much cheaper, and a gradual improvement in the conducting of the drug business was noticeable. Whereas heretofore the proprietor's formula book had ruled supreme, it was now replaced by the United States Pharmacopœia, and preparations that were heretofore bought in the East we now prepared according to its directions. Prescriptions began to take the place of patent medicines, other physicians having located in the meantime. Goods not proper to the drug store were discarded as opportunities would permit, and replaced by a more complete stock of drugs. At the present time the drug business is carried on in a more legitimate manner in Colorado than in many of the Eastern States. Druggists get a good price for what they sell, and can afford to sell a good and pure article at the price, and such is the intention of the average druggist; when he fails to do so, it is in ignorance and not knowingly that the fraud is committed.

In no other part of the country can a thorough druggist and pharmacist apply his knowledge and ability to so good an advantage as in the Far West. There he has no wholesale stores at hand to send to, where he can get whatever he happens to want on the spur of the moment, but is thrown on his own resources and ability to manufacture,

NOTE ON THE "SAPONIN" OF SARSAPARILLA.

BY PROFESSOR FLÜCKIGER.*

Galileo Pallotta was the first chemist who attempted the separation of an active principle from sarsaparilla. His work appears to have been done early in the present century, shortly after the discovery of the first alkaloids. By treating the aqueous extract of the root with milk of lime, drying the precipitate, and boiling with alcohol he obtained a substance that he claimed to be an alkaloid and named "pariglina," or "parillina;" it is difficult however from Pallotta's meagre description† to form an idea of the properties of this body. According to a note in the *Pharmaceutische Zeitung*, of the 2nd of May last, Dr. Pallotta, who is a Professor of Natural Science at Naples, is still of opinion that in his pariglina he discovered an alkaloid. Whether or not it was a more or less pure form of the constituent of sarsaparilla hereafter referred to, Professor Flückiger considers that Pallotta's name, parillin, should be retained for the special crystallizable body found in that root. Subsequent investigators called this body "smilacin," by which name it has gradually become generally known. That both alkaline and acid properties should have been attributed to this substance by various authors was due probably to the presence of impurities, which however are easily removed by recrystallization. Parillin is decidedly a neutral body. Strangely it is occasionally confused with a body yet uninvestigated, probably a stearoptene, said to occur in the root of *Hemidesmus indicus*, R. B., which has been called Indian sarsaparilla, although it does not resemble the *Smilax* root.

In 1859, O. Gmelin stated that parillin is decomposed by acids into sugar and a substance insoluble in water, a statement that has been questioned by others. Some experiments carried out in the author's laboratory by Klunge also pointed to the glucoside nature of parillin; but doubt was not altogether dispelled, because the unaltered parillin itself reduces alkaline cupric tartrate, though very slightly. For these reasons Professor Flückiger considered an examination of parillin desirable in order at least to ascertain whether it was a glucoside. Meanwhile, this point was decided last year by Otten,* who however looks to Professor Flückiger to carry on the investigation. Professor Flückiger suggests that in order to facilitate a comparison of the nearly allied, if not identical, substances, saponin and parillin, a more exact investigation of the former, prepared from cheaper materials, should be undertaken by others, he himself dealing with the sarsaparilla "saponin" or parillin.

The following method of preparation is recommended as preferable to that given in Pharmacographia. The chopped and bruised sarsaparilla root is heated at least twice with alcohol of about 0·835 sp. gr., the liquid poured off and the marc pressed, and the product distilled until the residue in the retort equals one-sixth, or rather less, of the weight of root used. The liquid, which is strongly coloured but not particularly thick, is diluted gradually with one and a-half times its weight of water, which causes the formation of a light yellowish loamy precipitate of crude parillin. The liquor is allowed to stand some days in the cold, after which the very dark-brown clear liquor can be decanted off. With the deposit is then mixed about half its volume of alcohol, and the mixture is filtered, then precipitated, and the precipitate washed with very dilute spirit, containing about 20 to 30 per cent. by weight of alcohol. This operation depends upon parillin being less soluble in dilute spirit than in ordinary alcohol or in water, it being precipitated from an alcoholic solution by the addition of water, or from an aqueous solution by the addition of spirit. In alcohol of sp. gr. 0·835 it is freely soluble. Although freely soluble in boiling water and very slightly soluble in cold water, it crystallizes best from alcohol. Prepared in this way, after treatment with animal charcoal, the parillin is obtained pure white, either in thin scales or prisms, showing a double refraction in polarized light.

In several experiments with different kinds of sarsaparilla, working with about 4 kilograms of root, the author obtained about 0·18 to 0·19 per cent. of pure white crystallized parillin. Some more parillin can be obtained by concentrating the mother-liquor and precipitating with a little water, or boiling it with alcohol. This second yield, however, is less readily purified, it becoming mixed with sodium chloride, which occurs plentifully in all aqueous extracts of sarsaparilla. The author failed to obtain parillin from the root stock of *Smilax aspera* or from China root, but the quantity operated on was small.

* Abstract of article in the *Archiv der Pharmacie*, 3rd series, vol. vii., p. 532.

† *Journal de Pharmacie*, x. 543.

* "Vergleichend histiologische Untersuchung der Sarsaparillen aus der pharmacognostischen Sammlung des pharmaceutischen Institutes zu Dorpat, nebst einem Beitrage zur chemischen Kentniss dieser Drogue." Dorpat, 1876. In the latter part of this exhaustive treatise, which is too long for insertion entire in this Journal, and unsuited for abstraction, Herr Otten identifies a second substance present in sarsaparilla with saponin, and from his experiments arrives at the conclusion that parillin has an action similar to, but not so strong as that of saponin, and that it is sapogenin *plus* sugar. Dragendorff has already pointed out that saponin and senegin affect the heart's action more energetically when impure than pure, and Otten suggests that the action of these allied bodies, as well as of parillin, is dependent upon another body always occurring together with them.—ED. PHARM. JOURN.

Marquis reports (*Archiv d. Pharm.*, ccvi., 342), that he obtained 1·75 per cent. from sarsaparilla, 5·12 per cent. from *Smilax aspera*, and over 0·60 per cent. from China root.

Air-dried parillin contains water of crystallization, which it loses at 100° C.; but different experiments gave results varying from 6 to 12 per cent. At about 140° it cakes together, melts with partial decomposition at about 210°, and acquires a strong brown colour by further heating. Melted parillin readily takes fire, and burns quietly after the removal of the flame, but it is difficult to effect a perfect combustion of the light charcoal at first produced. Pure crystallized parillin is almost insoluble (about 1 in 10,000) in cold water, but a solution prepared with boiling water remains supersaturated after it has become cold. It dissolves at 25° C. in 25 parts of alcohol, sp. gr. 0·814, and much more freely in boiling alcohol, crystals separating from the latter on cooling. Parillin dissolves in warm chloroform to a thin liquid which cannot be filtered, and yields upon evaporation no crystals, but only an amorphous varnish, which, however, can be recrystallized from hot alcohol.

Parillin does not seem to be provocative of sneezing, like saponin from quillaia, cyclamen, and other sources is. Solid parillin has not an acrid taste; an alcoholic solution has more acridity than an aqueous solution, but incomparably less than saponin solution. No effects were observed to follow the use of such solutions of parillin. Parillin in alcoholic solution has no rotatory action and does not colour litmus paper.

Parillin gives with strong sulphuric acid a pure yellow solution that becomes of a beautiful cherry-red at the edges, due to dehydration. With dilute sulphuric acid (10 per cent.) it becomes greenish when heated; kept in a water-bath it gradually becomes a beautiful red and finally brown. Phosphoric acid acts similarly, but gives more of a yellow-green colour. The addition of nitric acid, nitrates, or bromine to the sulphuric acid solution produces no special colour.

An aqueous solution of parillin gives with an alcoholic, but not with an aqueous, solution of acetate of lead, a precipitate again soluble in excess of the lead salt or of alcohol. No precipitate is produced by subacetate of lead or tannic acid. In the cold a solution of parillin does not reduce alkaline cupric tartrate, but at 80° or 90° a separation of cuprous oxide takes place in a few hours. But it produces no separation of metallic bismuth from a solution of bismuth tartrate in caustic alkali even after prolonged heating in a water-bath. Boiled with dilute sulphuric or hydrochloric acid, and the filtrate neutralized, it freely reduces cupric tartrate in the cold after a short time, and with the least warmth immediately. It is therefore evident that parillin is a glucoside.

The parigenin produced by the decomposition of parillin with dilute mineral acids is perfectly insoluble in boiling water, so that it can be readily separated and washed. It is probable that the sugar separated is at least partially crystallizable.

During the decomposition of the parillin by dilute mineral acids the liquid acquires a strong green fluorescence. The fluorescence is still more marked when parillin in solution in chloroform containing alcohol is decomposed with dry hydrochloric acid gas. This liquid is at first colourless, and does not develop heat, but suddenly becomes brown by transmitted light and full green by reflected light. Upon the addition of water, or evaporation of the alcohol and chloroform, white flocks of parigenin are formed whilst sugar remains in the solution. As in similar cases the fluorescence of parillin is very persistent. An unweighable quantity heated with a few drops of strong sulphuric acid in a water-bath gives a liquid that can be diluted with 100 c.c. of acid without losing its fluorescence, but dilution with water causes its immediate disappearance. After saturation with ammonia the liquid does not again show the green shade. In this behaviour and the colour parillin gives with a little sulphuric acid in the cold lie the best means at present known for its detection. It is noticeable that the "saponin" of digitalis, to be presently mentioned, Schmiedeberg's digitonin, also gives this fluorescence, but not cyclamin.

Three analyses of parillin (smilacin) given in Gmelin on the authority of Henry, Peterson, and Poggiale, agree fairly well with the figures obtained by Klunge in two analyses. But Professor Flückiger believes that these specimens were contaminated with parigenin. Parillin dissolved in warm water, which does not take up parigenin, filtered, and reprecipitated by alcohol, gave between 2 and 3 per cent. less carbon, or as a mean of three analyses, C = 60·4; H = 9. Three other analyses of another sample gave the following figures, showing still less carbon:—

C	57·66	56·80	56·4
H	—	8·27	8.3

These figures appear to show a remarkable relation between parillin and the saponin prepared by Rochleder, Schwarz, and von Payr from the "soap root" erroneously attributed to *Gysophila Struthium*, which had the formula $C_{64}H_{106}O_{36}$. If this formula be written $C_{32}H_{53}O_{18}$, the next lower in a homologous series of "saponins" would have the formula $C_{31}H_{51}O_{18}$. Possibly this is the place of the "saponin" found by Schmiedeberg in commercial digitalin, and named "digitonin;" he, however, attributed to it the formula $C_{31}H_{52}O_{17}$. Should there really be a homologous series of "saponins," the eighth step upwards from Rochleder's saponin would be the compound $C_{32}H_{53}O_{18} + 8CH_2 = C_{40}H_{69}O_{18}$. This would require 57·3 per cent. of carbon, and 8·2 per cent. of hydrogen, figures not irreconcilable with those obtained in the last three analyses of parillin, whilst the mean of the previous three analyses would agree with the formula of a saponin $C_{32}H_{53}O_{18} + 16CH_2 = C_{48}H_{85}O_{18}$, which would require 60·7 per cent. of carbon and 9 per cent. of hydrogen. Subsequently, however, Rochleder has published the formula $C_{32}H_{54}O_{18}$ for his saponin, which agrees better with the results of its decomposition, and also pretty closely with the saponin prepared by Cristopherson from Levant soap root, quillai bark, *Saponaria officinalis* and *Agrostemma* seeds, which he believes to be identical as obtained from all four sources. As, however, this would only slightly alter the hydrogen it is not inconsistent with the homologous nature of the "saponins." From these and other considerations it appears probable that there exists a series of saponins with the general formula $C_nH_{n2-10}O_{18}$.

Sapogenin and parigenin produced, with sugar, when saponin and parillin are split up under the influence of acids, are closely allied, as is also cyclamiretin resulting from the decomposition of cyclamin, and possibly they are also homologous.

GARRYA FREMONTI.*

BY DAVID WILLIAM ROSS, PH.G.

From an Inaugural Essay.

Having obtained from Professor Maisch a small quantity of the branches and root of the above plant, I endeavoured to procure a larger supply from California, but without success; my experiments were therefore not as satisfactory as I could have wished, but I have nevertheless succeeding in isolating a bitter principle, which, from the tests, seems to be an alkaloid, for which I propose the name of *Garryina*. It was obtained by the following process:—Two troy ounces of the dried leaves were exhausted with alcohol, and about two pints of a dark green tincture obtained. It was concentrated to about two fluid ounces, and an equal bulk of water was added, which precipitated the resinous matter. The

* From the *American Journal of Pharmacy*, December, 1877.

filtrate had a dark brown colour, a very bitter taste, and an acid reaction to litmus paper. The precipitated resin, when washed with water until tasteless, was of a light yellow colour. Part of the filtrate was acidulated with muriatic acid and iodo-hydrargyrate of potassium added, which gave a white precipitate. Ammonia water added in excess changed the colour to a dark greenish-yellow. Petroleum benzin or ether, agitated with the solution, did not extract any of the bitterness. Chloroform was agitated with the ammoniacal solution in six separate portions, being allowed to remain in contact each time for twenty-four hours, with frequent agitation, then separated and evaporated spontaneously: a light brown very bitter substance was left, having an alkaline reaction, and being soluble in alcohol, slightly in water. It was dissolved in water acidulated with muriatic acid, digested with animal charcoal, and filtered. The filtrate was very bitter; after being evaporated over a water-bath and set aside for a few days, a few cubical crystals were obtained, which had a bitter taste, were soluble in alcohol and water, and gave the following reactions:—With sulphuric acid, after a few minutes, a purple colour; with chromate of potassium and sulphuric acid first a red, then a yellow, and lastly a green colour. Its aqueous solution was precipitated by iodo-hydrargyrate of potassium.

Besides the garryina, the leaves contain resin, chlorophyll, tannin and sugar. They yielded 5 per cent. of ash, containing salts of potassium, calcium, iron and magnesium. The root contains the same alkaloid, answering to the same tests, and obtainable by the same process, except that digestion with alcohol was found to be advantageous. The root contains also resin, starch and sugar, and yielded two and one-half per cent. of ash, in which the same bases were found as in the ash of the leaves.

ADDITION OF CHLORAL HYDRATE TO THE POISON SCHEDULE.*

At the *Council Chamber, Whitehall*, the 13th day of *December*, 1877.

By a Committee of the Lords of Her Majesty's Most Honourable Privy Council.

PRESENT:

Lord President.
Viscount Sandon.
Mr. Sclater-Booth.

WHEREAS by "The Pharmacy Act, 1868," section 2, it is enacted that the Council of the Pharmaceutical Society of Great Britain may from time to time, by Resolution, declare that any Article in such Resolution named ought to be deemed a poison within the meaning of that Act; and thereupon the said Society shall submit the same for the approval of the Privy Council, and that if such approval shall be given, then such Resolution and approval shall be advertised in the *London Gazette*, and on the expiration of one month from such advertisement the Article named in such Resolution shall be deemed to be a poison within the meaning of that Act:

And whereas the Council of the Pharmaceutical Society of Great Britain did, on the 7th day of November, 1877, resolve and declare in the words following:—

"That by virtue and in exercise of the powers vested "in the Council of the Pharmaceutical Society of "Great Britain, the said Council does hereby resolve "and declare that *Chloral Hydrate and its preparations* "ought to be deemed poisons within the meaning of "the Pharmacy Act, 1868, and ought to be deemed "poisons in the Second Part of the Schedule A of the "said Pharmacy Act, 1868."

And whereas the said Society have submitted the said Resolution for the approval of the Privy Council, and the Lords of the Privy Council are of opinion that the said Resolution should be approved:

Now, therefore, their Lordships are hereby pleased to signify their approval of the said Resolution.

C. L. Peel.

* From the *London Gazette*, Dec. 14, 1877.

THE BOARD OF EXAMINERS FOR 1878.*

At the *Council Chamber, Whitehall*, the 13th day of *December*, 1877.

By a Committee of the Lords of Her Majesty's Most Honourable Privy Council.

PRESENT:

Lord President.
Viscount Sandon.
Mr. Sclater-Booth.

WHEREAS there was this day read at the Board a letter to the Clerk of the Council from the Secretary and Registrar of the Pharmaceutical Society of Great Britain, dated the 5th day of December, 1877, in the words following:—

"I have to acquaint you that at a meeting of the "Council of this Society held to-day the Pharma- "ceutical Chemists whose names appear on the other "side were appointed Examiners for the ensuing year, "and I am requested to submit their names to the "Privy Council for approval, in accordance with the "Bye-laws of the Society.

"Neither of the persons appointed has held office as a "Member of the Council of the Society during the "year preceding the date hereof."

"ENGLAND AND WALES.

"Alfred Allchin.
"James Benjamin Barnes.
"Frederick Baden Benger.
"Henry Bowman Brady.
"Michael Carteighe.
"Octavius Corder.
"Samuel Gale.
"Frederick Janson Hanbury.
"John Samuel Linford.
"William Martindale.
"John Moss.
"William Southall.
"George Spratt Taylor.
"Charles Umney.

"SCOTLAND.

"William Ainslie.
"John Borland.
"David Kemp.
"Alexander Kinninmont.
"William Gilmour.
"Alexander Noble.
"John Bertram Stephenson.
"James Robertson Young."

And whereas by the sixth section of "The Pharmacy Act, 1868" (31 and 32 Victoria, cap. cxxi.), it is provided that no person shall conduct any examination for the purposes of that Act until his appointment has been approved by the Privy Council:

And whereas it appears that the persons appointed are as required by the Bye-laws of the Society, under the age of 65 years, that none of them have held office as Members of the Council during the preceding twelve months, and that no objection exists to the approval of the Lords of the Council being given to such appointments:

Now, therefore, their Lordships are pleased to approve the appointments of the said persons as Examiners for the year 1878, for the purposes of the Pharmacy Act, 1868.

C. L. Peel.

* From the *London Gazette*, Dec. 14, 1877.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 22, 1877.

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE REPORT OF THE EARLY CLOSING ASSOCIATION.

SOME of our readers who may receive a copy of the new report of the Early Closing Association will naturally open it with some curiosity as to the outcome of the passing of certain resolutions at the meeting in the Society's Theatre, Bloomsbury Square, last April; but, we are sorry to say, they will find little beyond an account of the meetings referred to. There was considerable talk then of local meetings to be held and individual efforts to be made, and an influential committee was formed to lend its co-operation; but the Report confirms a previous impression that up to the present time nothing more has been done, and that the Committee's services have not yet been once applied for, if indeed it has met. The Association is able to report decided advances with respect to the hours of business of drapers, grocers, tailors, and bootmakers; but there is nothing to show that the apathy of chemists and druggists was more than temporarily disturbed by the eloquence of Mr. LONG and his coadjutors.

The Report, however, illustrates in the experience of the Association the great difficulty that awaits any attempt to take united action for securing earlier closing. It is found that in seeking to obtain an agreement for earlier closing among a large number, especially of the smaller class of shopkeepers, it is very difficult to secure the requisite amount of unanimity. Two or three stand out in opposition to the proposed arrangement, and deter a much larger number from acting according to their better judgment. Sometimes the refusal of even a single employer to close at a given hour has been fatal to the prospects of early closing in an entire neighbourhood. Of course in these days of keen competition such a result is quite a natural sequence to the cause, and probably such an explanation might very frequently take the place of the euphemism, "the public convenience," which has so frequently been seriously discussed as a reason for the chemist and druggist vieing with the publican in respect to late hours.

The disappointment attending the breakdown, through the obstinacy or fears of individuals, of well conceived efforts for securing earlier closing in a district, has naturally suggested to some minds an appeal to Parliament, and the Association has been more than once requested to promote a Bill in Parliament for making compulsory the closing of places of business at a certain hour. But such a proposition is evidently impracticable, and there can be no doubt that the Board of Management is right in its conclusion that the closing of shops in the evening will never be undertaken by the Legislature. The Report points out, however, that the absence of any decided effort on the part of shopkeepers to throw off this incubus of late hours is very provocative of an attempt on the part of shop-assistants to seek the relief they need through the medium of trades' unions.

We are far from suggesting that the business of a chemist and druggist can be arbitrarily confined within certain specified hours, in the same sense as many other businesses can. Neither do we deny that in some districts a great improvement with respect to the hours during which chemists and druggists shops are kept open has taken place during the last twenty years. Our complaint is that all is not done that could be done, and that those who at the risk of loss have volunteered to act as leaders in the movement have not yet received the general support they were entitled to reckon upon. Eight months ago it was agreed at a meeting which was fairly representative of the chemists and druggists of at least an important section of this metropolis, that, Saturdays excepted, the window shutters on week days might be closed at 8 o'clock, and the doors at 8·30 without inconvenience to the public, and that even on Saturdays an abridgment of the hours of labour might be effected. We have not heard it even whispered since that there was anything Quixotic or unreasonable in such an arrangement, and yet to what a large extent it is still ignored! We appeal to all those who concur in the spirit of the resolution passed last April, and who have at present not acted upon it, not to be deterred any longer by fear of want of unanimity, but to determine at once to do all that in them lies by individual, if not by associated effort to secure so desirable an end.

CHLORAL HYDRATE AND THE POISON SCHEDULE.

IT will be seen by the extract from the *London Gazette*, quoted on another page, that the resolution passed by the Council of the Pharmaceutical Society at its meeting in November, to the effect that Chloral Hydrate and its preparations ought to be deemed poisons within the meaning of the Pharmacy Act and included in the second part of the Schedule A of that Act, has received the approval of the Lords of the Privy Council. After the 14th of January, 1878, therefore, it will be illegal for unregistered persons to sell chloral hydrate or its preparations, and it will be unlawful for any person to sell them unless the box, bottle, vessel, wrapper, or cover containing them are distinctly labelled with the name of the article, the word "poison," and the name and address of the seller. The reason for this step is very obvious. The enormous consumption of chloral hydrate, and its frequent administration by unskilled hands have led to several fatal accidents, and in placing its sale under the same regulations as that of laudanum the Council has acted in accordance with the recommendations of several coroners and the medical press generally. In Ireland, chloral hydrate has been included in the schedule of poisons for some time past.

A WORD OF CAUTION.

We should be very sorry at any time, and especially at this season of the year, to say a word that would have a tendency towards checking the full gratification of the generous impulses of pharmacists. But it is desirable to secure as far as possible that the recipients of their benevolence should be deserving of it. We have reason to believe that this is not always the case, and that, even recently, pharmacists who have thought they were relieving the necessities of some poorer members of the craft or their families, have been made the victims of plausible tales. We would suggest that the very best way of giving such alms, especially to strangers, is through the medium of the Benevolent Fund, the organization in connection with which so facilitates the making of proper inquiries, whilst cases of urgency can be relieved at once from the Secretary's Casual Fund. But should the donors prefer to relieve unknown persons themselves, it would be as well to delay doing so until they have communicated with the Secretary, Mr. Bremridge, who, it is needless to say, would willingly and at once communicate to them any information he may possess respecting the applicants.

DEATH OF M. CAP.

French pharmacy has lost one of her veteran members, M. Paul Antoine Cap having died in Paris on the 12th ult., at the age of ninety years. He was a correspondent of the French Academy of Medicine, and during the last forty-two acted as one of the associated editors of the *Journal de Pharmacie et de Chimie*. He was also an Honorary Member of the Pharmaceutical Society of Great Britain, having been elected in 1856.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

A soirée in connection with this Association is to be held in the Town Hall, Birmingham, on the 23rd of January, 1878. A large number of objects of interest are to be shown, and amongst them the telephone. There will also be practical illustrations of the mode of carrying on various operations in chemistry and pharmacy, perfumery, etc.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

December 12, 1877.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, Taylor, and Umney.

MAJOR EXAMINATION.

Seven candidates were examined. *Three* failed. The following *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Duncalf, Jas. Mills Woolfenden Congleton.
Mortlock, William John.........Peckham.
Tamplin, Charles Edward ......Kingston-on-Thames.
Turner, George Thomas ....London.

MINOR EXAMINATION.

Eighteen candidates were examined. *Six* failed. The following *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bascombe, William ....Nottingham.
Brown, Francis Arthur ....Liverpool.
Cooper, Frederick Ashley ......Cockermouth.
Eardley, James Furnival ......Hulme.
Heywood, John Henry ....Lincoln.
Hutton, Harry ....Warwick.
McConnal, Alan ....Dudley.
Martin, William Lee ....Derby.
Martlew, Thomas..................Carlisle.
Mather, John Henry ....Newcastle-on-Tyne.
Pursell, John Rushton ....Liverpool.
Sanders, William Josiah.........Cardiff.

MODIFIED EXAMINATION.

Three candidates were examined. *Two* failed. The following passed, and was declared qualified to be registered as a Chemist and Druggist:—

Mills, William Drew ....London.

December 13, 1877.

Present—Mr. Williams, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, Taylor, and Umney.

MAJOR EXAMINATION.

Seven candidates were examined. *Six* failed. The following passed, and was declared qualified to be registered as a Pharmaceutical Chemist:—

Phillips, Evan ....St. Clears.

MINOR EXAMINATION.

Twenty candidates were examined. *Eleven* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bowden, Thomas Lemon ......Barnstaple.
Collinson, Frederick William...Alnwick.
Finney, Arthur Cook ....Gainsborough.
Green, Arthur ....Halifax.
Holmes, James William ....Norton, Malton.
Huband, Alfred Edward.........Birmingham.
Lakeman, Jasper James.........London.
Tritton, Charles Edmund ......Bristol.
Warrell, Edmund...................London.

December 19, 1877.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, Taylor and Umney.

Dr. Greenhow was present on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-five candidates were examined. *Fifteen* failed. The following *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Mansergh, William ....Burton-in-Lonsdale.
Metcalfe, John......................Bedale.
Morgan, David.....................Llandilo.
Pass, William John Warhurst..Bury.
Peet, Henry ....Gosberton Hall.
Richardson, Alfred ....Manchester.
Roberts, Morgan ....Cardiff.
Skelton, Thomas ....Maryport.
Wood, Frederic Percy...........Bolton.
Wray, Edward ....Bishop Auckland.

December 20, 1877.

Present—Mr. Savage, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Hanbury, Linford, Martindale, Moss, Southall, Taylor, and Umney.

MINOR EXAMINATION.

Twenty-six candidates were examined. *Fifteen* failed. The following *eleven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Allison, Joseph William ....Sunderland.
Dingle, James Hender............Penzance.
Gourd, William ....Stoke, Devonport.
Hunt, George ....Landport.
Massey, Richard Francis ....Lower Tooting.
Powell, Walter......................Cleveland.
Smith, Joseph ....Sneinton.
Smith, Morgan......................Trecynon.
Will, William Watson............Montrose.
Winter, Harry ....Cambridge.
Wordsworth, George ....York.

Provincial Transactions.

HULL CHEMISTS' ASSOCIATION.

The annual supper of the members of this Association took place at the Cross Keys Hotel, on Wednesday evening, December 12. The chair was occupied by Mr. C. B. Bell (President), and the vice-chair by Mr. J. F. Smith. There were also present the Mayor (Alderman R. Waller), Dr. A. K. Rollit, and Councillors Gibson, Leak, Toogood, Smith, and Fryer, Mr. R. Micks, and other gentlemen. Letters of apology were read from the Rev. J. M'Cormick and Alderman Seaton. The usual loyal and patriotic toasts were given from the chair. "The Archbishop and Clergy of the Diocese, and Ministers of all Denominations" was suitably acknowledged by the Rev. J. Gilmour. "The Mayor and Corporation" was responded to by the Mayor.

Mr. E. Allison gave "The Town and Trade of Hull," and, referring to the trade of the majority of the gentlemen present, expressed the opinion that that trade had been a little over legislated for.

Councillor T. J. Smith responded, and touched upon the recent visit of the Associated Chambers to this town. He then went on to refer to the evils with which the chemists and druggists had to contend, and alluded particularly to the prosecutions at Selby. He was glad that it had been agreed that no prosecution for adulteration should be instituted in Hull without the consent of the Sanitary Committee, as this would prevent those vexatious prosecutions which had taken place in other towns.

The Mayor submitted the toast of "The Hull Chemists' Association," referring to the various qualifications which he considered must be necessary to make a chemist and druggist.

The President, in responding, thanked the members of the Association for re-electing him as President for the third year. The Association was formed for no aggrandisement on the part of chemists and druggists, but for two objects solely, viz., the protection of the trade and the education of the apprentices, and he considered those were two worthy objects for any association to have in view. The President went on to allude to the difficulties which chemists and druggists had to overcome in the course of business, and alluded especially to the progress made by the students who attended the lectures given under the auspices of the Association.

Mr. Wokes gave "The Honorary Solicitor to the Association" (Dr. A. K. Rollit), which toast was warmly honoured.

Dr. Rollit humorously responded, and afterwards spoke of the advantages of education to the younger members of the trade especially.

Mr. Thyar proposed "The Officers of the Association," which was acknowledged by the Vice-Chairman.

The Vice-Chairman then gave "The Medical Profession," observing that the chemists were extremely desirous of working in amity with that profession.

Dr. Gibson, in acknowledging the toast, remarked that he knew there was a desire amongst medical men to be in good fellowship with the chemists and druggists. He hoped that the time would come when no medical man would dispense his own drugs, and although there were many difficulties in the way, those difficulties had been overcome in France and Germany, and he did not see why they could not he overcome in England.

Mr. Woodruffe briefly gave "The Pharmaceutical Society," which was acknowledged by the Chairman.

Mr. Stoakes (Hon. Sec.) proposed "The Lecturers," for whom Mr. J. C. Niven responded, and dwelt upon the fact that the number of students was not in proportion to the size of the town and number of chemists and druggists there.

Dr. Gibson suggested that the apprentices had scarcely sufficient leisure during which to study, and he thought this was worthy of consideration by the masters.

Mr. Oldham submitted "The Health of the Visitors," who found a respondent in Mr. R. Micks.

Councillor Leak gave "The Health of the Chairman." "The Press," and other toasts followed.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The following discussion followed reading of the paper by Mr. Fairlie, printed in last week's Journal, p. 471:—

Mr. Kinninmont believed that if the trade were more remunerative to assistants and employers, the scheme advocated by Mr. Fairlie would follow, but as matters are at present he failed to see how it could be accomplished, and where the necessary funds would come from.

Mr. J. A. Clarke pointed out that in Glasgow there are already numerous advantages for study if assistants could only manage the time; but he also stated that in two cases where he had given his apprentices time to attend classes they ultimately went into the medical profession for no other reason than that it is much more remunerative.

The President (Mr. Daniel Frazer) took exception to some of Mr. Fairlie's proposals and also defended the course pursued by the Pharmaceutical Society, in admitting to its meetings one reporter only, holding that the Society being a business or a private Society, could make what rules it chose, nor did he (the President) think it advisable that the proceedings should be open to all reporters.

One or two other members having taken part in the discussion, Mr. Fairlie replied briefly, stating that he had found that by letting apprentices or assistants away to classes where they came in contact with medical students, there was a great temptation to go into the medical profession, but that was not what was wanted, they desired that these young men should remain in the trade, and he believed this would be best accomplished by classes arranged apart from the medical students.

The President moved a hearty vote of thanks to Mr. Fairlie for his paper, to which (the President remarked) he was *fairly* entitled.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The first ordinary evening meeting of the session was held on Tuesday, December 11, in the Memorial Hall. The President, Mr. W. S. Brown, occupying the chair.

Mr. Benger being prevented from reading his paper on the "Telephone,"

Mr. Louis Siebold delivered a short lecture, illustrated by experiments, on—

Poisonous Wall Papers.

Alluding to the popular impression that green wall papers alone were to be suspected, the lecturer stated that blue, red, brown, pink, etc., in fact, papers of every colour except grey and white, were seldom free from arsenic. Out of sixty or seventy wall papers of various colours analysed by him only ten were harmless, the rest contained arsenic.

Of the various tests for arsenic one of the most convenient and delicate consisted in the production, in the presence of zinc and hydrochloric acid, of arseniuretted hydrogen, which could at once be detected by holding over the mouth of the test-tube containing the reagents a piece of paper moistened with nitrate of silver solution. By this method one five-hundredth of a grain of arsenious acid almost instantly gave a distinct dark stain of metallic silver.

This test, however, had not hitherto been much applied in the examination of wall papers, since the latter often containing sulphur compounds, the sulphuretted hydrogen evolved also blackened the nitrate of silver paper, and so interfered with the reaction. The difficulty could be surmounted by placing in the test-tube a plug of cotton wool soaked in acetate of lead solution, which absorbed and removed the SH_2 and permitted the AsH_3 to pass through; but to preclude the possibility of error from traces of SH_2 escaping, Mr. Siebold made use of the following modification of the test:—To the pure hydrochloric acid containing the sample of paper add weak iodine solution till it is in slight excess (starch may be used, if necessary, to indicate this point), then add the zinc. The iodine decomposes any sulphur compounds capable of evolving sulphuretted hydrogen, and any blackening of the nitrate of silver paper is then due to the presence of arsenic.

Mr. Siebold also read a paper on—

Tests for the Indication of Acidity and Alkalinity.

The lecturer first referred to litmus, which, though very delicate, was open to the objection that it was difficult to determine the exact point at which neutrality was reached, especially by gas light. This drawback disappeared with the use of a sodium flame, as by its light red litmus solutions appeared colourless, and blue litmus of an inky black, the transition from an acid to an alkaline solution being thus well marked.

The following five substitutes for litmus were then considered:—

1. *Cochineal*, giving with acids a pale yellow solution, instantly turned by alkalies to purple or pink, the change being well marked by day light or gas light.

2. *Logwood.*—Acid solutions pale yellow, changed by alkalies to purple.

3. *Brazilwood.*—Acid solutions greenish-yellow, giving a distinct transition on the addition of alkalies to deep red; a test preferred by the lecturer to logwood and useful for the titration of calcium carbonate in potable waters.

4. *Alizarine.*—Alkaline solutions of a deep purple colour changed by acids to yellow and restored by alkalies; this is far superior to litmus, as an acid so weak as not to affect the latter will react distinctly on alizarine solution.

5. *Salicylate of Iron.*—Salicylic acid solution on addition of perchloride of iron becomes purple owing to the formation of salicylate of iron. In weak acid solutions this colour is less striking than in neutral ones, but is gradually heightened by the addition of alkalies, being most intense when the point of neutrality is reached. Directly this point is passed and the solution becomes akaline, the colour instantly vanishes.

At the conclusion of this paper, which was also accompanied by experiments, Mr. J. T. Slugg proposed a vote of thanks to Mr. Siebold for his exceedingly interesting lectures. The motion was seconded by Mr. Westmacott and cordially passed.

Proceedings of Scientific Societies.

PHILADELPHIA COLLEGE OF PHARMACY.

The first pharmaceutical meeting of this Society for the session was held on Tuesday, October 16. Mr. Charles Bullock, Vice-President, took the chair.

Professor Maisch presented on behalf of Mr. J. J. Brown, of Oakland, California, a pair of bulbs of the *Chlorogalum pomeridianum*, Amolia, the California soap-root, remarkable for the large percentage of saponin which it is said to contain, as also for a peculiar mucilage. These two constituents caused the Indians and early Spanish settlers to esteem it very highly as a detergent; and it is so efficient and harmless that it is still preferred for washing laces, embroideries, and such like fabrics, to any soap attainable. A cold infusion of the bulb may be used in place of soap as a dentifrice, a shampoo liquid, and a valuable lotion for both face and hands. But little use has been made of it in medicine, although it is claimed to have some virtue when employed as a lotion to ulcers and in skin diseases; the fibres have been separated from the bulbs by the Chinese, washed, dried and put in the market for making *hair* mattresses. The plant grows abundantly upon the dry hill-sides of the Pacific coast, from Oregon to Central America, and perhaps further south; but as its flowers open at night time Mr. Brown has not been able to obtain them.

Mr. L. R. Carbonel presented specimens of a plant which Professor Maisch stated to be a eupatorium, and which is used in Cuba both as a purgative and emetic; for the first purpose in about thirty grain doses, and double as much for an emetic.

Mr. Neppach presented a specimen of genuine Oregon balsam of fir, which is probably the product of *Abies menziesii*, Lindley, a tree growing from Sitka to California and Colorado, and generally known under the name of *balsam*. The factitious so-called Oregon balsam of fir was exhibited alongside of the genuine article, and observed to be of a darker colour and a terebinthinous taste, while the new article resembled Canada balsam in colour and transparency, and had an agreeable, somewhat different aromatic odour. Mr. Neppach stated that the oleoresin brought by him was not an article of commerce in Oregon, where balsam of fir was procured from the eastern section of the continent; he obtained the sample in Oregon by puncturing the small vesicles which formed on the bark of the balsam tree of the Pacific coast.

Professor Remington read a paper by Mr. Henry Trimble, upon—

The Use of Chlorine Water and Ammonia as a Colour Test for Estimating Quinia.

"First a standard solution is prepared by taking one centigram of quinia or one of its salts, dissolving it in about five c.c. of fresh chlorine water, adding ten c.c. of solution of ammonia, and diluting this dark green liquid in a glass cylinder to one hundred c.c.

"In estimating a one-grain quinia pill, for example, a similar cylinder is taken, into which is placed a fractional part of the solution obtained by treating the disintegrated pill with chlorine water and ammonia, and diluting with water until it exactly corresponds in colour with the standard solution; then by a little calculation the amount of quinia is known. By a little practice the results become surprisingly accurate, and the process requires very little time compared with the more exact gravimetric methods. It is true that quinidia if present interferes with the results, but it is not so liable to be fraudulently employed as the cheaper alkaloids.

"To what extent this process may be employed for the estimation of quinia and quinidia in bark the author was not prepared to say, but he thinks that, with certain precautions, it might admit of application for this purpose. The same principle is extensively used in determining the amount of carbon in iron and steel, with very satisfactory results."

Professor Maisch said that he was glad Mr. Trimble had not overlooked the fact that quinidia produced a very similar reaction, and then commented on the common statement, that the presence of chlorohydric acid prevented the appearance of the green coloration, which he stated to be erroneous, the point necessary to a successful result being the presence of sufficient chlorine before the ammonia is added.

Mr. Boring called attention to samples of caraway, the want of flavour of which first called attention to its inferiority; when sieved about 38 per cent. of very small and immature fruits, almost devoid of taste, were separated, the remainder being better, but still inferior to an unobjectionable article; the same remark applies to most of the anise now offered for sale in the Philadelphia market.

SOMERSETSHIRE ARCHÆOLOGICAL AND NATURAL HISTORY SOCIETY.

English Names of Wild Flowers and Plants.*

BY REV. W. TUCKWELL.

(*Concluded from page* 357).

Many names of plants contain the geography of their origin. The Canterbury bell is obvious, so is the Guelder rose. The alexanders, a rare plant round Taunton, but growing in great quantities at Blue Anchor, comes from Alexandria; the candytuft from Candia; the elecampane, from Campania; the medick from Media; the carraway from Caria; the walnut or welsh nut from north of Italy, called *Wälsh* by the Germans. Peach is *persicus*; shalot, *ascalonicus*; spinach, *hispanicus*; the damson, rightly spelt as damascene, tells its own tale, which is less clear in the case of the dame's or damascene violet, a corruption extended and perpetuated, as often happens, by its Latin equivalent, *matronalis*.

All first attempts at classification, etymological or other, leave a large margin of miscellaneous items refusing to be ticketed or systematized; and there remain a few names falling under none of the categories which I have cited, yet too interesting to be omitted. Such is apple, retaining its form in the Teutonic, Celtic, Sclavonic, and Lettish languages, and springing apparently from the Sanskrit *ap*, water, which reappears inverted in the Latin *pa* of *padus*, *po* of *poto* and *pomum*, meaning therefore the water fruit or juice fruit. Such again is daffodil, the daffadowndilly of Spenser and other poets. It is a combination of *sapharoun*, or saffron lily, with *asphodelus*, the old English affodilly. With the taste for alliteration often shown in popular names the sapharoun lily blending with the affodilly became by a mutual compromise daffadowndilly, whence daffodilly and daffodil. Foxglove is the fox's-glew, or tintinnabulum, a ring of bells hung on an arched support. Bedstraw was a plant much used for couches before mattresses were invented, and a species which when dry yields a pleasant scent is still called lady's bedstraw. Carnation is coronation, its flowers being used as crowns or chaplets, just as campion is champion, gathered to crown the champions in a tournament. Cress is possibly from cross, its petals being cruciate; possibly from *crescere*, to grow, in token of its rapid increase. It was used in Chaucer's time, under the form of *kers*, to express any insignificant quantity.

"Of paramours ne raught he not a kers,"

from which comes, perhaps, the vulgar phrase "I do not care a curse," though a yet ruder parallelism has since been manufactured to confuse its spelling and its etymology. Nettle is from *ne*, to spin, indicating that its coarse fibres were used for thread in early times—an idea borne out by Hans Andersen's beautiful tale of the wild swats, in which you remember that the princess was permitted to redeem her brothers from their transformation by weaving them shirts of nettles. Shamrock is from an Erse word signifying the little trefoil. The story of its theological use by St. Patrick is of modern date, and it has been taken by various writers to represent the watercress, the wood sorrel, the Dutch clover, and the black medick. Irishmen are divided in the present day between the two last, which are sold on St. Patrick's day both in London and Dublin. The snowdrop is so called from its resemblance to the large eardrops worn by ladies in the sixteenth century, and represented often by painters of that period. The tobacco was the Indian name for the pipe in which the weed was smoked, not of the weed itself; and potato belonged at first to a tropical convolvulus, and was transferred by mistake to the well-known esculent. The gooseberry was the cross-berry, from its triple spine, which frequently takes the form of a cross. The hollyhock is the caulihock, hock being an old name for the mallow, to whose order it belongs, and cauli, meaning cabbage, either from its lofty cabbage-like stalk, or, as in cabbage rose, with reference to its rich double bloom. The laburnum closes its petals at nightfall like a tired labourer, and the osier is named from the oozy beds, which suit its growth.

I bring my list to an end, not because it is exhausted, but for fear my hearers should become so. I have picked only the most suggestive and curious of our many floral names, leaving an abundant gathering to many gleaners. One branch of the subject I have barely touched, the superstitious practices attaching to many of our wild plants, though not surviving in their names. I have left alone the interesting question of Bible plants, of the hyssop, the juniper, the mustard-seed, the lilies of the field, the burning bush, the shittah, the almug, the gopher, the curiously mis-translated cab of dove's dung, with the light thrown on their identity by the names given to them in the commentaries in our older translations. Nor can I do more than hint at the rich store of literary allusion to our wild flowers which abounds in all English poets, and the beautiful thoughts suggested to many of them by some particular plant. I should have liked to read you Chaucer's lines upon the daisy, Herrick's on the daffodil, Burns' on the dog rose, Shelley's on the sensitive plant, Southey's on the holly, Wordsworth's on the lesser celandine, Longfellow's on the compass plant. I should like to open volume after volume of Elizabethan and of later days—to enumerate and discuss the flowers with which Ben Jonson bids us "Strew, strew the smiling ground;" the "pretty paunce and chevisaunce" of Spenser; the "quaint enamelled eyes" that decked the laureate hearse of Lycidas; "the silver globes of guilder rose" which won the heart of Cowper; the "hawthorn bush beneath the shade" of Goldsmith's lovers; the "slight hairbell" which raised its head, uncrushed by the airy tread of Ellen Douglas. I should like to remind you of the lessons in natural theology which Paley drew from the "little spiral body" of the dodder seed; of the star-shaped shadow of the daisy which Archer Butler showed to Wordsworth, or how Linnæus, when he first saw the wild broom in flower—

* Lecture by Rev. W. Tuckwell before the Somersetshire Archæological and Natural History Society. *Gardeners' Chronicle* for September 22, from *Nature*.

"Knelt before it on the sod,
For its beauty thanking God."

Above all I should love to turn with you the page of Shakspere, to read of the grey discrowned head of Leaf wreathed with "rank fumiters and furrow weeds;" of Perdita at the shearing feast, disparaging the streaked gilliflowers as Nature's bastards; of poor distraught Ophelia distributing her rosemary and herb-of-grace; of Puck telling how love-in-idleness was purpled with love's wound; of Titania gently entwining the "female ivy and sweet honeysuckle" round the sleek smooth ass's head of Bottom; of Helena and Hermia, "a double cherry seeming parted, two lovely berries moulded on one stem." For I should lay on you a spell mightier than I can forge myself—I should invoke allies before whom we all bow as the source of our intellectual happiness and growth; I should remind you how the most creative minds have drawn nutriment from these tenants of our hedgerows and hill-sides, and how the knowledge of their lore helps us in its turn to interpret the sweet thoughts and apt illustrations of the poets they inspired and delighted: how, if the aspirations of my Cambridge botanist were fulfilled—if the daisy could become the *bellis*, the strawberry the *fragaria*, the honeysuckle the *caprifolium*, the the heather the *calluna*, the parting genius of romance and myth and association and folk-lore would be sent sighing from the domain of botany, and the richest and most attractive of the natural sciences would become the dullest and the most neutral.

In conclusion, let me disclaim all merit of originality in the ideas which have been put before you to-night. I have but attempted to bring together, with the interest attaching to cumulative illustration, conjectures which have been started and discoveries which have been worked out by others. Scattered through the old-fashioned tomes of Cole, Lyte, Parkinson—through the pleasant pages of Loudon, Pratt, Johns; above all, in the most valuable work on popular botany which we owe to our Somersetshire naturalist, Dr. Prior, you will find all or nearly all that I have advanced. The flowers were plucked by other hands; mine has been only the *pia dextera* to sort and wreathe them.

Parliamentary and Law Proceedings.

Prosecution under the Pharmacy Act.

At East Dereham Petty Session on the 9th inst. (the magistrates present being R. D. Crowne, Esq., and H. E. Hyde, Esq.), Mr. John Cock, chemist, Shipdham, was charged on the information of Superintendent Symonds, "for that he, on one day between the 23rd of August and the 2nd of October last, did sell by retail a certain poison, to wit, a preparation of poppies, made up in a compound called 'Syrup of Fox's Lungs,' the bottle in which the said poison was contained and so sold not being distinctly labelled with the name of the article and the word 'poison,' contrary to the form of the statute in such case made and provided." The prosecution was instituted under the Pharmacy Act, 31 and 32 Vic., c. 121, sec. 17, which provides that "it shall be unlawful to sell any poison, either by wholesale or retail, unless the box, bottle, vessel, wrapper, or cover in which such poison is contained be distinctly labelled with the name of the article and with the word 'poison,' and with the name and address of the seller of the poison;" and part 2 of Schedule A of the Act specifies "all preparations of poppies" as amongst the poisons, the sale of which is regulated by the statute under the conditions mentioned. It appeared that at the recent Winter Assizes for Norfolk and Suffolk held at Ipswich, William Cross, carpenter, Shipdham, and Emma Spilman, his housekeeper, had been committed to take their trial on the charge of the manslaughter of the infant son of the male prisoner, a child between five and six weeks old, its death having been brought about by the administration of an overdose of the "Syrup of Fox's Lungs." The prisoners were committed on the charge of manslaughter by the Dereham magistrates, as well as by the verdict of a Coroner's inquest held by Mr. Deputy R. T. Culley. On the case going before the grand jury, the bill was ignored so far as the magisterial commitment was concerned. By direction of the Court, however, the prisoners were formally arraigned on the Coroner's inquisition; but as no evidence was offered on behalf of the prosecution, a verdict of not guilty was recorded, and the accused were set at liberty. The present proceedings were the result of something which transpired during the progress of the Coroner's inquest.

In stating the case to the Bench, Superintendent Symonds said that he now proposed to show that the ingredient which had caused the death of Cross's child was purchased at the defendant's shop, without being so labelled as to indicate its dangerous character. Had the defendant, instead of justifying the sending it out in the manner complained of, expressed his regret for so doing, and said it should not be repeated, he (the Superintendent) would not have pressed for more than a nominal penalty; but as he had not done that, he felt it his duty to leave the case to be dealt with by the magistrates as the evidence to be laid before them might seem to warrant.

The first witness called was Emma Spilman, who deposed that once or twice a week during the time the child had lived, she sent to the defendant's for a quantity of "Fox's Lungs," and that on no occasion had the bottle been marked with the word "poison" or anything whatever on it beyond the words, "Fox's Lungs.—Cock, Chemist, etc., Shipdham." The bottle produced was that out of which the syrup was taken and given to the child before its death.

The witness was cross-examined by the defendant as to whether she had not had several illegitimate children, with the object of invalidating the reliable character of her testimony; and on being re-examined, she said that had the word "poison" been on the bottle she would not have given the medicine in such quantities as she did.

Ellen Hall, nine years of age, a step-daughter of William Cross's, deposed that she went for the syrup by direction of the previous witness, and that the word "poison" was never put on it, nor anything more than as now produced in court; and that the last time she went for the syrup it was supplied by the defendant's daughter.

Superintendent Symonds deposed that in a conversation he had with him on the subject of sending out "Fox's Lungs" without being marked "poison," the defendant said that it would not answer his purpose to do so, as in that case he should not sell anything of it; to which witness made answer, "That (their protection) is just what the public require."

In defence, Mr. Cock called Esther Eke, widow, and Keziah Able, an unmarried woman, two neighbours of the father of the deceased child, and they deposed to having seen a bottle at his house like the one produced, and, besides the white label upon it, with the defendant's address, it had also a red label marked "poison;" but neither of the witnesses would undertake to swear that the bottle they saw was the identical one in court.

At the conclusion of his witnesses' testimony, Mr. Cock addressed the Bench, in the course of which he said that his daughter (who had not been called) was exceedingly careful, even unnecessarily so, in not sending out any quantity of "Fox's Lungs" without labelling it "poison;" and in the present instance that was confirmed by two witnesses. If the red label so marked had been removed from the bottle before the holding of the Coroner's inquest, it was very hard that he should have to suffer for it. The charge, he had no doubt, had its origin in personal spite; and in assuring the Bench that during the twenty-four years he was in business no one could be more strict than he was, he trusted that would save him from the consequences of a conviction on a charge made against him from a paltry motive.

The Chairman, in announcing the decision of the Bench, said that they regarded the defendant's conduct as so reprehensible that they had determined to inflict the full penalty of the law. Not only was his conduct reprehensible, but it was most unmanly, inasmuch as he had attempted to hoodwink the magistrates by the way in which he had referred to the character of one of the witnesses for the prosecution. To mark their sense of what the Bench thought of that, he (the Chairman) begged to tell the defendant that they believed every word which they had spoken, while they did not believe his witnesses. The defendant would be fined £5, and £1 10*s.* costs, or one month's imprisonment. The money was paid.

Before leaving the court, Mr. Cock made sundry efforts to address the magistrates in complaining of the severity of the decision, and made some allusion to his daughter; but the only notice taken of it was by Mr. Hyde, who told him that for her acts in selling medicine the law held him liable.—*Eastern Daily Press.*

[*** We think it right to call attention to the fact that the justice of the above decision is challenged by Mr. Cock, for the reasons given in a letter that will be found on p. 500.—Ed. Pharm. Journ.]

Poisoning by an Embrocation.

On Monday last Dr. Diplock held an inquest at Kensington Dispensary, Church Street, Kensington, on the body of Emma Healey, 45 years of age. The deceased was housekeeper at the dispensary. For some time she had been suffering from rheumatism, and for this complaint used an embrocation composed principally of opium, ammonia, and belladonna. A woman named Chinnick, who had lately attended to deceased's duties, said that on Tuesday she took the embrocation bottle, which was labelled "poison" from deceased's room, as she appeared "strange" and "queer." Witness hid the bottle in the kitchen. The bottle was afterwards discovered in deceased's bedroom, where she was found to be insensible. Deceased died on the following day.

A *post-mortem* examination revealed that death was due to poisoning, combined with extensive lung disease. Deceased had been in a lunatic asylum, and a relative of hers died from insanity.

After a long deliberation, the jury returned a verdict of death from misadventure, considering that deceased had mistaken the bottle of embrocation for another.

Review.

Histoire des Drogues d'Origine Végétale, par F. A. Flückiger et Daniel Hanbury; Traduction de l'Ouvrage Anglais 'Pharmacographia,' Augmentée de très-nombreuses Notes, par le Dr. J. L. de Lanessan. Avec une Préface par H. Baillon; et 320 Figures dessinés pour cette traduction, par L. Hugon. Paris: Octave Doin. 1878. (2 vols. 8vo., pp. 668, 672.)

Three years have passed since the appearance of the great work 'Pharmacographia' gave to English students one of the most perfect scientific treatises ever written, and afforded a new starting point for the study of vegetable drugs. Its originality, careful accuracy, and laborious honesty of method, placed it in an almost unique position in a day of rapid book-making, wholesale copying, and unacknowledged quotation at second hand. Such a book was certain to be widely appreciated wherever science is followed, and it is with pleasure that we now see it translated into French. Its high qualities are fully recognized by Professor Baillon in his preface to the volumes, where he gives eloquent expression to his sense of them and to his regret at the premature death of the learned and conscientious man to whom pharmacology throughout the world owes so much.

Probably the first thing that will strike any one who is familiar with the original, is the much greater size of the French edition; the single volume has expanded into two. But in fact there is in the work much more than a translation of 'Pharmacographia.' Dr. de Lanessan's object has been to render the treatise suitable as a text-book for students at schools of medicine and pharmacy, and with this view he has intercalated a large amount of additional matter. Thus we find botanical descriptions of the genera and species named, full histological descriptions of most of the drugs, and the addition of a good number of fresh substances, and there are numerous illustrative woodcuts. All this no doubt in a sense renders the book more complete, and Professor Baillon claims for the editor that he has made it a new work. Without denying this, we are yet unable altogether to feel reconciled to the altered character of such a book as 'Pharmacographia,' which we are inclined to look upon as a classic not to be lightly interfered with. It is true that the text is left intact and all the additions printed in small type, but the homogeneity of the book is destroyed; for it is no disparagement to the French editor to say that his additions do not bear the stamp of the original. Had the plan of this included botanical descriptions we may be very certain that the authors would have been satisfied with nothing short of completely new ones drawn up with care from the plants themselves in all cases, and that errors in synonymy, such as putting two such different plants as *Narthex* and *Scorodosma* under one species, to which, moreover, it cannot be conclusively shown that either belongs, would have been avoided.

Among the additions are Simaruba, Jaborandi (referred to *Pilocarpus pennatifolius*, Lem.), *Eucalyptus globulus*, *Gelsemium*, *Erythræa*, many *Ranunculaceæ*, etc., but there are still many vegetable drugs not treated of, and it was, we think, scarcely well to substitute for the accurate second title of the English volume—"a History of the Principal Drugs of Vegetable Origin met with in Great Britain and British India,"—the comprehensive one given above; for example, there are many much-used American remedies unnoticed. The figures of the plants are too small to be of much service, and the space they occupy would have been better filled by a full quotation of the existing figures and of references to descriptive or geographical works. But Dr. de Lanessan quotes scarcely any one but Professor Baillon. The latter is strictly followed in all taxonomic matters, and the sequence of the plants and in some cases their names have been altered in accordance with his views. Several unfamiliar couplets resulting from this are here, we think, first published. *Delphinium Napellus*, Baill., *Helleborus Tecta*, Baill., are examples.

The most important of the new portion, however, is found in the excellent descriptions of the minute anatomy of the drugs, which have been prepared with evident care; the illustrative figures are also very satisfactory and help to render this part of Dr. de Lanessan's work a very useful contribution to pharmacological knowledge.

The translation is, so far as we are competent to judge, an able one, and has had the great advantage of the supervision of one of the authors of the original, Professor Flückiger, who has enriched it with occasional notes, so that to a certain extent it may be regarded as a new edition in another language. The book is very well printed and possesses an unusually good index.

Obituary.

Notice has been received of the death of the following:—

"Alexander Gow, of Wolverhampton. Died December 10, 1877. Aged 78 years."

Such is the simple record of the end of one who prosperously conducted the duties of a pharmaceutical chemist on the same business premises for nearly half a century, and was looked upon as the Nestor of the local trade. Mr. Gow was one of the founders of the Pharmaceutical Society, and treasurer to the Wolverhampton Chemists' Association, in the success of which he took a lively interest. He was a man of sterling business qualities, and his superior intellectual and professional attainments won for him the confidence and esteem of the local medical practitioners and his brethren in the business. In private life his genial kindly disposition and his inexhaustible fund of joke and anecdote made him a favourite with all classes. Mr. Gow died from injuries caused by a severe fall. Some of the members of the trade accompanied him to his resting-place at the Wolverhampton Cemetery, and many of the houses of business were closed during the funeral.

On the 30th of November, 1877, Mr. Joseph Goddard, Pharmaceutical Chemist, Stoneygate, Leicester. Aged 64 years. Mr. Goddard had been a Member of the Pharmaceutical Society since 1842. For many years he carried on the business of a chemist and druggist in Gallowtree-gate, Leicester, now in the hands of Mr. Young, and he was well known to the trade as the manufacturer of Goddard's plate powder.

On the 19th of July, 1877, Mr. Charles Fielding Palmer, Pharmaceutical Chemist, Islington, Birmingham. Aged 55 years. Mr. Palmer had been a Member of the Pharmaceutical Society since 1853.

On the 23rd of July, 1877, Mr. George Cobden Sidgwick, Chemist and Druggist, Bishopswearmouth. Aged 37 years.

On the 4th of September, 1877, Mr. Edward Ashwell Burnham, Chemist and Druggist, Osmaston Street, Derby. Aged 37 years.

On the 31st of October, 1877, Mr. Robert Royse' Chemist and Druggist, Stockport. Aged 47 years.

On the 13th of November, 1877, Mr. James Larkworthy, jun., Chemist and Druggist, Isleworth. Aged 48 years.

On the 14th of November, 1877, Mr. John Windross, Chemist and Druggist, Salthouse Lane, Hull. Aged 38 years.

On the 22nd of November, 1877, Mr. Hugh E. Gilbert Symmons, Chemist and Druggist, Milford Haven. Aged 34 years.

On the 24th of November, 1877, Mr. Francis Snelling, Pharmaceutical Chhmist, Stockwell. Aged 70 years. Mr. Snelling had been a Member of the Pharmaceutical Society since 1842.

Dispensing Memoranda.

[44]. I think the translation of "℥j bis 7 mana" means an ounce to be taken twice a week, and T. H will probably find this correct.

J. W. B.

[44]. In answer to query No. 44, my translation is—Two tablespoonfuls to be taken twice a week. ℥j bis Septimana."

[45]. What is the best "modus operandi" in mixing the following?

Ext. Belladonnæ . . . . ʒiss.
Ol Hyoscyami . . . . , ... ℥j
M. Ft. Linimentum.

Would it be justifiable to add a little mucilage, as I found a little difficulty to get them to combine?

J. W. Barnes.

[46]. Ung. Galeni.—I have to dispense the following:—

℞ Ung. Hyd. Nitrici Oxydi . . . . . ʒij.
Ung. Galeni . . . . ʒij.

M. To be applied to the edges of the eyelids. Can a correspondent give me a form for ung. galeni?

Apprentice.

[48]. Please inform me which preparation would be correct to use in the following prescription, Hyd. Sulphat. or Hyd. Lak. Sulph. (Turpeth Mineral), B. P.:—

℞ Potassii Iodidi . . . . . ʒj
Hydr. Disulph. . . . . . ℈j
Ung. Cetacei. ad. . . . . ʒj.
M. ft. Ung.

T. H. M.

[49]. Can you kindly inform me through the medium of the Journal how to make a perfectly clear mixture of the following prescription:—

℞ Liq. Ferri. Mur. . . . . . ʒij
Liq. Ammon. Acet. . . . ℥iv
Sp. Chloroform. . . . . . ʒij
Aq. ad . . . . ℥viij.

H. J. H.

[50]. Extractum Ergotæ Liquidum.—I emptied a bottle the other day in which extractum ergotæ liquidum B.P. had been kept for a month or two. The extract had deposited a good deal, and I was proceeding to clean the bottle before refilling it, when I was a little surprised to find the bottom of the bottle covered over with small crystals.

Not having before heard of any crystalline substance existing in ergot, I thought that by writing to you, you might be able, through the medium of the Journal, to give me some information regarding it.

The crystals occur in transparent prisms about from one to three lines in length, and are evidently sparingly, or not at all soluble in water.

I have not been able to get any of them out of the bottle to examine them more minutely, as I do not wish to destroy them. "A Young Pharmacist."

Notes and Queries.

[564]. COFFIN'S COMPOSITION POWDERS:

Bayberry . . . . 4oz.
Pinus Canadensis . . . . 2oz.
Ginger. . . . . 2oz.
Cayenne . . . . ¼oz.
Cloves . . . . ¼oz.

All finely pulverized and well mixed. Ordinary dose, a teaspoonful in a cup of hot water sweetened. Or,

Bayberry . . . . 4oz.
Pinus Canadensis . . . . 4oz.
Ginger . . . . 4oz.
Golden Seal . . . . 2oz.
Sassafras . . . . 2oz.
Cayenne . . . . ½oz.
Cloves. . . . . ½oz.

The above copied from Dr. Coffin's 'Botanic Guide to Health.'

Rothesay. A. Macintosh.

A similar answer has been received from "*Hyacinth*."

[564]. COMPOSITION POWDER.—The form for Dr. Coffin's Composition Powders is—

Cayenne . . . . ¼ oz.
Cinnamon and Cloves, of each . . 1 oz.
Ginger and Poplar Bark, of each . 4 ozs.
Bayberry . . . . 8 ozs.

One-half a teaspoonful in a cupful of warm water.

W. R.

[565]. WHITE FULLERS' EARTH.—In reply to "Tenens," I would say that I have known several instances in which kaolin or china clay has been sold as White Fullers' Earth. It is in my opinion a better absorbent than fullers' earth for irritable surfaces, especially to prevent chafing in young children. Only the pure washed clay should be used.

JOHN LINFORD.

---

[566]. LIQ. COPAIB. C. CUBEB. ET BUCHU.—Can any one give me the formula Liq. Copaib. c. Cubeb. et Buchu?

CHEMICUS.

---

[567]. YORKSHIRE BLACK OILS.—Will any reader please give me a recipe for Yorkshire Black Oils?

A. P. S.

---

[568]. WOOD STAIN.—Will any reader furnish me with a good recipe for a slate colour stain for wood, and oblige?

J. O. SLIPPER.

---

[569]. OIL OF STAVESACRE.—Can any reader supply useful formulæ for utilizing the oil of stavesacre as an external application? There were none given in Dr. Squire's paper.

W. S.

---

[570]. TINCTURE OR SPIRIT TO BURN IN A PERFUME LAMP.—Can any reader give me a form for the above, or tell me where there is a good one?

INCENSE.

Correspondence.

ADMISSION OF WOMEN, ETC.

Sir,—Clap-trap seems to be a disease of the zymotic class; it survives despite the vigorous treatment of common sense to extirpate it.

This peculiar disease of society has taken the form for some years past of "Women: their rights and grievances in general.". There is no other country on the face of the earth where they are more loved, favoured, and protected than ours. It is a free country, and there is no Act of Parliament by which they are prevented from doing anything in particular or all things in general.

I think that the proper sphere and office of women is the direction of the domestic menage, and if they would only devote their energies to raise the standard of home influence and home comforts, to diffuse more knowledge concerning and better results in this respect, many spinsters would soon be married and the race of bachelors soon become extinct; we should hear no more of grievances and every one would be all the better for it.

Concerning the advisability of admitting women as members of the Pharmaceutical Society, *per se*, I will offer no opinion; it does not much matter either way. I will only say in regard to it, how many chemists think of bringing up their daughters to it? I think very few, or their sons either, and they surely must be the best judges.

I should suggest, as a solution of the difficulty and to promote the "early closing" of the discussion, that our respected Registrar should be instructed to affix some distinctive mark against those chemists who are bachelors, with some indication as to whether they would be induced to take compassion on any lady who desires admission to the Society, and if after marriage they still feel anxious to enter and qualify themselves (or we might I think, in justice, place them on the register without examination) then by all means admit them to the Society.

At present they enjoy all the advantages without any of the trouble or difficulties.

HENRY LONG.

48, *High Street, Notting Hill, London,*
December 1, 1877.

Sir,—If "female persons" are eligible to become chemists and druggists they are equally eligible to be elected members of Council and even to fill the presidential chair.

Imagine the Pharmaceutical Society of Great Britain under the supreme sway of an elderly female person!

Is the business of the thousands who are doomed to a life of unremitting toil so inviting, so lucrative, and so short of hands that it requires reinforcement from the ranks of female persons who cannot hit upon a more feminine occupation?

I know of three instances wherein petticoats were admitted to an equal share in the management of drug businesses. The first was sister-in-law to the proprietor, the second and third were widows of deceased chemists; and I can positively state that their presence behind the counter tended to make the reverse of a "little heaven below." Occasionally coarse fellows of high or low degree would come out in a way that caused female modesty to tremble and youth to blush.

One lady eventually retired from public life and made herself generally useful in putting up fancy articles, seidlitz powders, etc., for which her neatness and industry rendered her particularly useful.

The third lady was married to her assistant in self defence, then made her courtesy and backed out.

ANTIPATER.

P.S.—Would it not be as well to be looking out for our general interests as regards legislation which threatens the destruction of our body?—A. P.

Sir,—How much longer are the pages of our Journal to be the platform for the verbose discussion on the vexed question of the admission of females into the Society? Why such a platitude of argument on a subject requiring none? The whole matter lies in a nutshell. It has been brought before a general meeting of the members, and I remember some gentlemen expatiated on the intellectuality of women. Another wanted to take a case to the Queen's Bench to test the legality of their admission. But, sir, it is neither a legal nor an intellectual question. Women have been made M.D.'s, and therefore we must admit their capacity to become pharmacists.

But I presume we have a right to form our own rules, and this question has been most distinctly put before the members, and they have as emphatically said "No." What more is wanted, and what the use of continuing week by week the discussion of a question already settled?

FREDERICK TIBBS.

81, *Chalk Farm Road, Dec.* 1877.

DOCTORS *v.* CHEMISTS.

Sir,—While the vexed question of prescribing is pending, which seems a difficult problem for judges, lawyers, and everybody else connected with it to solve, I think it a very opportune time for pharmacists to improve their position. We all know that the Pharmaceutical Society endeavours to impress on its members that prescribing is not within their limits, but still we must remember that there are several of our poorer members who, from sheer necessity to make both ends meet, are compelled to prescribe a little, as they are generally placed in neighbourhoods where they do not see even the apparition of a prescription from one week's end to another, consequent on the doctors dispensing their own medicines. Supposing that little prescribing is taken away from them, the question arises, what is to be done to recompense them for the loss? Why did England, through her Parliament, pass the Pharmacy Act? Namely, that a chemist should be a man educated in the knowledge of drugs and chemicals and compelled to pass stringent examinations in order that he might be considered a competent man to be entrusted with the dispensing of doctors' prescriptions, so that the safety of her people might be ensured. Alas, many a poor chemist has to go through the ordeal of those examinations, not for that purpose, but only to sell such things as "a pen'orth of cipity powder," as the poor people term it, as the doctor monopolizes all the dispensing of medicines himself.

The proposition I suggest is, not to go against the doctors but to work with them. Why not have a conference composed of delegates chosen by the medical profession and the Pharmaceutical Society to decide what each may give and take? Let us offer to discountenance the practice of prescribing over the counter in every shape and form, on condition that we alone are invested with the sole right of dispensing medicines. If a doctor prefers to dispense his own medicines compel him to comply with our regulations of examinations, and the same with the chemist who wishes to prescribe, and let every offender of either body forfeit his diploma, and not merely be mulcted. At the same time the subject of quackery by the sale of patent medicines might be discussed. If a chemist wishes to prepare a medicine, allow him to do so, and retain the sole right of preparing it on condition that he submits to a council, appointed by both bodies, the formula of such medicine, not for publicity, but merely to show that no poison forms an ingredient of it. Poison should only be administered by a doctor's prescription.

By such a course the safety of the public will be ensured, as it will prevent them from making fatal mistakes by obtaining a poison under the colour of a patent medicine, which anybody who obtains the patent medicine licence can now sell, be he chemist or not. Over-zealous mothers and nurses will then be prevented from administering narcotics in the shape of soothing syrups, teething powders, etc., to young children, and thereby ruining their constitutions for life. If a chemist has a branch establishment it ought to be compulsory for him to employ an assistant, possessing at least the Minor qualification, as manager of it, and not to leave the dispensing of medicines to incompetent persons in such cases, which I am sorry to say occurs often.

If the medical profession refuse to meet us, and the Apothecaries' Company continues to delight in ruining chemists, and endeavours to stamp them out, then as a last resource let all the chemists of the United Kingdom sign their names to petitions placed in the hands of our zealous local secretaries, and under the banner of "Union is strength" appeal to Parliament next session for the exclusive right of dispensing medicines for which it has compelled us by the Pharmacy Act to make ourselves competent. I know that it will be a difficult task to teach the public that their chemists may not prescribe for their slight ailments, but it will be soon found out if the chemist and druggist tells them that it is as much as his diploma is worth to do it.

I am afraid many of my *confrères* will think that I am suggesting very stringent measures but I am sorry to say that I think it absolutely necessary to prevent us from overstepping our bounds. In conclusion, I hope that having broached the subject other gentlemen will more ably take up the discussion, and that it will ultimately lead to a mutual union of the medical profession and pharmacy, and that a chemist's anomalous business may soon become the long looked for profession.

ARTHUR GEORGE RICKARBY.

Walton-on-the-Naze, December, 1877.

COUNTER PRACTICE.

Sir,—The hairdresser, if my hair is coming off or there is any disease of the scalp, examines my head and prescribes ointments, lotions, or sometimes a little quinine or iron internally.

The dentist examines my teeth and gums and general state of my mouth, performs operations, prescribes lotions, liniments, etc., and frequently medicine to be taken internally.

The chiropodist examines my feet, performs operations on corns, etc., and treats diseases of the feet generally.

The "bone-setter" proceeds to examine and criticize the work of the surgeon, and, if there is any abnormal adhesion, performs an operation to set it right.

The nostrum maker, by a general sweep, prescribes like the apothecaries a secret remedy for any, whole Pandora's box and pills.

And now the chemist, the only person specially exempted from the fierce provisions of the Apothecaries Act, is being prosecuted for giving a gargle to a man with a slight sore throat. I ask you, with these facts before us, in the name of common sense, why is the Pharmaceutical Council proposing to fund surplus money, when a greater number of chemists than the Society itself contains are subscribing to defend not their rights only but the common liberty of the subject? If we quietly submit to that, we shall be improved off the face of the earth, and the building in Bloomsbury Square will be an eligible monument, if before we go we let our splendid "freehold" house as the western branch of the Apothecaries' Hall.

GEORGE MEE.

W. Phillips, *A. J. Lewis*, and *M. P. S.*—The statemente in your letters are no doubt consistent with facts which arr sure to receive consideration in all their bearings wheneves the subject referred to comes before the Court, and as this may take place shortly, as well as for other considerations, we do not consider it advisable at present to prolong the discussion in these columns.

PROSECUTION UNDER THE PHARMACY ACT.

Sir,—Will you kindly place the following facts in your next Journal, and elicit the opinion of the members of the trade whether such oppression is to be allowed to pass by unnoticed, and also kindly give me your opinion as to what you think could be done in the case:—A case of alleged manslaughter from starvation came before the Ipswich Quarter Sessions, where in addition a bottle containing two penny-worth of Syr. Poppies was produced, and it was shown that this drug was used to quiet the infant when it should have been supplied with food. When the bottle was shown in court it was labelled with the name of the article, but not the word "poison."

A summons afterwards was issued to me as supplying the article. I appeared to meet the charge, and took with me two respectable witnesses that could swear that they saw two labels on the bottle a day or two before the inquest, the name of the article, and a red label with the word "Poison" distinctly placed below the other. In the face of all this the magistrates fined me the highest penalty they could, £5 and 30s. costs. No one is safe therefore even if labelled properly, unless he can follow the bottle, and see the label is not removed, and this evidently was.

JOHN COCK.

Shipdham, December 12, 1877.

[**** A report, taken from a local newspaper, of the case referred to in the above letter, will be found on p. 496.]

A. Graham.—Apply to Messrs. A. Bel and Co., Maiden Lane, Strand.

"*Occidens.*"—(1) *Ceratodon purpureus*; (2) *Hypnum Swartzii*; (3) *Neckera crispa*; (4) *Leskea sericea*; (5 and 6) Forms of *Rosa canina*: we cannot undertake to name varieties of roses.

A Plymo-Student.—No.

E. R. G.—We believe the name is applied to a preparation sent out by Messrs. Corbyn, Stacey and Co.

Edinburgh Assistants' Supper.—Mr. W. J. Clarke writes to say that in referring to the founders when proposing the toast of the North British Branch he omitted through forgetfulness to mention the names of the late Mr. John Macfarlan and of Mr. H. C. Baildon who has on two occasions been President of the Branch.

A. Laitram and *D. B. Dott.*—We agree with you in thinking that the adoption of the metric system would be very desirable, but the obstacle is precisely the same which has prevented the old apothecaries' weight being superseded, and as yet no adequate means of overcoming that obstacle have been devised.

Mr. T. J. Barrett is thanked for his communication.

"*Apprentice.*"—Apply to the Secretary, 17, Bloomsbury Square, for a copy of the Regulations of the Board of Examiners.

COMMUNICATIONS, LETTERS, etc., have been received from Professor Flückiger, Professor Landerer, Mr. Severs, C. H. A.

"THE MONTH."

Already the glossy dark green holly, profusely covered with its scarlet berries, and the favourite mistletoe with its lovely pearls, are being poured by waggon loads into the great city, and the poorest home no less than the palatial residences of the rich will soon be brightened with the presence of the conventional sprig of holly and spray of mistletoe.

Flowers are now but few and far between, and there are none of medicinal interest to be seen in blossom, save that which, from its time of blossoming and its shape, has been appropriately called the Christmas Rose (*Helleborus niger*). In the country districts of the South of England the fragrant blossoms of the winter heliotrope (*Petasites fragrans*) are beginning to perfume the frosty air, and in spite of rain, or even snow, make the passer-by sensible of their presence.

In the conservatories of the rich the fashionable *Poinsettia* relieves the monotony of green foliage with its brilliant scarlet (petaloid) bracts and its singular flowers. Although not a medicinal plant it belongs to an order which yields many plants used in medicine (Euphorbiaceæ), and on account of its size and of its occurring at a time of year when no wild plants of that order are in blossom, it is worthy of a brief notice.

Each little cup-like flower consists of about five united bracts, which are combined to a pink fringed involucre, on the outside of which may be seen one or more yellow narrowly cup-shaped glands. If the involucre be carefully removed, there will be found inside it five rows of what at first sight appear to be stamens, but which are in reality male flowers, each consisting of a divergent two-celled anther crowning a short scarlet filament, which is placed upon a white pedicel of the same size and shape; at the base of the pedicel of each male flower is a minute hairy palea or bract, and in the centre of the stamens may be found a single female flower, which is not usually developed until most of the stamens are mature.

The top stamen of each row is first raised above the involucre, and as it matures it falls off the white pedicel at the point where the scarlet filament is jointed to it, and each stamen is then succeeded in turn by those below, so that the apparent flower is really an umbellate cyme, consisting of a large number of deciduous male flowers, and one female flower, neither having any trace of calyx or corolla. The stalk of the female flower afterwards elongates very considerably, and raises the characteristic tricoccous fruit above the involucre.

But our old friends the holly and mistletoe deserve somewhat more than a passing notice. The leaves of the holly have been stated to be almost as good as cinchona bark in the treatment of intermittent fevers, and their juice has been recommended in jaundice. The root and bark are also believed to possess deobstruent, expectorant, and diuretic properties, while the berries are supposed to be purgative and emetic in doses of six or eight. Certainly they would form elegant pills, and might prove useful after Christmas festivities. The white wood is much used for inlaying. The young stems dried, according to M. J. Pierre, are given to cattle, from the end of November to April, in Morbihan, and are found to be wholesome and productive of good milk. This statement, however, scarcely accords with the common belief that the lower leaves of the holly only are spinous, so that the cattle should not browse upon the foliage and injure themselves. Although the medicinal properties of the holly do not appear to be clearly understood, it is certain that a relative of the plant, the *Ilex paraguayensis*, furnishes a tea which is highly appreciated in South America, and contains theine. The term spinous is applied to the holly leaves with doubtful correctness, (the term spine being synonymous with thorn according to many botanists,) for in this case the points are formed chiefly from the hardened epidermis which is inrolled at the margin of the leaves, and have therefore more resemblance to a prickle.

The holly has also its economical uses. The middle bark, under proper manipulation, yields birdlime, which, however, may also be obtained from the mistletoe. The Japanese find some curious uses for this substance. Traps for rats are made in the simplest possible manner, by placing pieces of board or card smeared with it near their holes. Spread upon bamboo leaves it is used for catching flies and other insects. Even fleas are no match for Japanese ingenuity, for they are trapped in bed by birdlime spread on pieces of board, the board being arched over with bent bamboo to prevent the birdlime from adhering to the bedding. Possible uses of this viscid article, such as a snare for cockroaches, mice, etc., will at once suggest themselves to our readers Even animals as large as monkeys are caught by its means in Japan. Ornithologists may take a hint as to bird catching from the Japanese method. Long stems of *Wistaria* are smeared with birdlime and floated out in estuaries, and even on the sea, in parts frequented by birds, and wild fowls are in this way bagged in considerable quantities. Many other uses are given in an interesting report on this subject from Mr. Consul Annesley.

If the holly needs to be protected from animals lest it should injure them, much more does the yew tree, as was lately discovered by the Chesham Burial Board, which had to pay £20 damages for not keeping the branches of a yew tree within the bounds of the cemetery. A horse belonging to a veterinary surgeon in the neighbourhood being turned into a field close to the cemetery to graze, browsed on the leaves of the tree and died. It appears that in the legal report it was specially remarked that it was an unconsecrated cemetery, and the *Gardeners' Chronicle* suggests that possibly the writer supposed the yew derived its noxious properties from that damnatory fact! It might have with equal sarcasm further suggested that the soil of the unconsecrated burial ground should have been analysed before the trial.

The medical journals supply very little matter of pharmaceutical interest this month. Hydrophobia still continues to excite attention, and various remedies continue to be suggested. It is interesting to find what varied treatment is used in different districts and countries, and it is instructive to notice how much hidden knowledge can be brought forward when any difficulty excites the attention of the medical public. Were all medical men and pharmaceutists equally liberal minded in publishing the results of their experience both medicine and pharmacy would make more rapid progress than is at present the case.

In the *Chicago Medical Journal* a correspondent recommends as a remedy for violent griping caused by excessive peristaltic action, occasional teaspoonful doses of a solution made by adding a tincture of colocynth to water in sufficient quantity to render it bitter. The homœopathic dose so given is stated to have an excellent sedative effect. If this be true it affords another instance of the fact that some medicines when given in minute quantities produce exactly opposite effects to those following their administration in large doses. Experiments with regard to this peculiarity, might, if made with some of the more potent drugs, reveal that there is much more foundation in fact for the practice of the modern homœopath than is generally supposed.

Glycyrrhizin appears likely to become an important article in elegant pharmacy. It is attracting considerable attention as a means of disguising the taste of bitter and nauseous remedies. Dr. L. Curtis has found that one grain of glycyrrhizin will disguise the taste of one grain of quinine suspended in a drachm of syrup. Probably its use in the form of a lozenge or wafer previous to taking a dose of medicine would answer the purpose equally well.

From *L'Union Pharmaceutique* we learn that St. Martin has proved by careful analysis that glycyrrhizin exerts no influence on the formation of glucose in those suffering from diabetes, and that it may be recovered from the urine in an unchanged condition. The diabetic patient, therefore, may now have gluten biscuits made sweet and palatable without danger.

Curara still continues to attract attention, and it is announced that gelatine discs are being prepared by Messrs. Savory and Moore. As the solution is apt to spoil by keeping, and the discs will keep indefinitely, and are easily soluble in a small quantity of water, they are likely to take their place with those of calabar bean and atropine.

According to the *Lyon Médicale*, sulphate of atropine, in granules containing half a milligramme, given for eight or ten days at intervals varying according to circumstances, has been found very valuable in subduing the excessive perspiration in phthisis, etc.

Dr. Martin in the *Boston Medical and Surgical Journal* describes a new form of plaster which he has invented to supersede ordinary adhesive plaster. It is formed by incorporating Para caoutchouc and Burgundy pitch with a small proportion of balsam of tolu. This mixture is spread on a strongly woven cloth. A sticking plaster which will not cause irritation, which will adhere well, and which will perform its guarantee "not to wash off," is certainly a desideratum, and if this method succeeds it will doubtless be rewarded with commercial success. The Japanese have already solved the difficulty by the very simple plan of spreading birdlime on paper or cloth, or silk, and applying it to wounds or cuts, which it is stated to heal rapidly. It may not be generally known that birdlime can be dried and powdered, and will regain its properties when moistened. The properties of this substance certainly deserve examination from a surgical point of view, and its portability and easy application might permit of its forming a portion of the kit of every soldier, and its use might to some extent prevent such harrowing scenes as have been described as occurring in the Turkish war, when doctors have not been procurable for several days together.

The *American Journal of Pharmacy* contains a paper on hops, in which the author, Mr. E. G. Bissell, comes to the conclusion that the bracts contain no narcotic property and that the tannin contained in hops is neither gallotannic nor moritannic acid.

While Messrs. Senier and Lowe have been experimenting in this country, on the colour of podophyllin, Mr. G. H. C. Klie in America has tried the effect of alcohol of different degrees of specific gravity and finds that root exhausted with alcohol of sp. gr. ·930 gives the largest amount of precipitate, the liquid used to precipitate it being half an ounce of alum to four pints of water, and the next largest amount is obtained by the use of alcohol of sp. gr. ·938, the precipitant being water containing half a drachm of hydrochloric acid to each pint. The colour of the precipitate appears to have varied in each experiment, and it was found that in no case was the product entirely soluble in spirit of the same strength as that from which it was precipitated. It would thus appear to undergo some alteration by precipitation. It is evident that the subject of podophyllin resin is as yet by no means exhausted.

Messrs. Gehe and Co. of Dresden, in their commercial report, convey much interesting information. Alluding to the complaint made some time ago of the presence of ammonia in some specimens of subnitrate of bismuth, they attribute it to the fact that bismuth as well as zinc decomposes water in the presence of nitric acid, and thereby brings about the conditions necessary to the formation of ammonia. Salicylic acid is being largely used in Germany for preserving ale in good condition, and is becoming quite an important manufacture. Crystallized copaivic acid, a form in which that article has not yet been introduced into this country, seems to have been in demand during the past few months.

Messrs. Gehe report also that some samples of Persian opium recently imported are particularly rich in codeia, containing as much as 1·4 per cent. Hydrochlorate of pilocarpine is in great demand, and cotoin continues in high favour. It is singular that this remedy is so little used in this country. In Germany it appears to be used chiefly in those cases of diarrhœa in which opium cannot be safely or conveniently used.

Inulin is being tried as a remedy for diabetes mellitus. It would be very remarkable if this substance, so nearly allied to starch, should prove to be a remedy in this disease, or even be capable of use in food for diabetic patients. Pancreatin capsules will probably soon have to give way to more elegant and pleasant forms of administration; it is likely to be offered in the market shortly in the form of a greenish powder.

Artificial vanillin, which some time ago attracted considerable notice, appears to be a failure from a commercial point of view. It soon loses its delicate perfume, whereas that obtained from vanilla, being associated with an aromatic resinous substance, appears to be much more lasting. Whether the body which is present in the natural state has a retarding action in preventing further change in the vanillin does not appear, but from the fact that vanillin belongs to a group of bodies (aldehydes) which are very prone to change, it is quite possible that it would alter more rapidly in the pure state.

The Colorado beetle panic seems to have died out, with the approach of cold weather. Unfortunately this beetle is not the only rapacious insect injurious to cultivation. During the latter part of last year the valuable plantations of cinchona trees in Java suffered a great deal from the ravages of an hemipterous insect, *Heliopeltis theivora*, the same insect which infests the tea plant. Both the adult and the young insect feed on the sap of the young leaves and bark, which they pierce in a number of places. As the uninjured part of the plant grows, the leaves and young twigs acquire an irregular and twisted appearance. Curiously enough, the insect only attacks cultivated plants, such as tea, stramonium, fuchsias, etc., and is not known to attack plants indigenous to the island. The only means hitherto found successful in limiting its devastations have consisted in removing and burning the injured parts, and in preventing the destruction of insectivorous birds. The Dutch Government have ordered a million more cinchona trees to be planted in the island. The whole of the valuable Ledger bark produced in that island has hitherto been bought up at Amsterdam by quinine manufacturers, so that at present it cannot be said to have come into the retail market, in which it may be hoped the increased cultivation will soon enable it to take an important place.

In some remarks in the *Bulletin General de Thérapeutique*, on the ergot of wheat as compared with that of rye, Dr. Estachy concludes that the action of the former is identical with that of the latter.

'Medicinal Plants' for this month contains figures of the following plants:—*Aconitum ferox* and *A. heterophyllum*, *Melia Azadirachta*, *Liquidambar orientalis*, *Cicuta virosa*, *Œnanthe crocata*, and *Piper Cubeba*, that of *Œnanthe crocata* occupying a double plate. *Aconitum ferox* has been figured only once before, in an Edinburgh journal, and its appearance is therefore most welcome. The remarks under this plant comprise an account of the most recent investigations concerning the aconite alkaloids, of which an admirable *précis* is given. A monograph of the aconites is much wanted, for the species get inextricably mixed in many botanical gardens, owing to the accidental alteration of the labels, and there exists at present no recent work in which all the species of this intricate genus are figured. Under *Melia Azadirachta*, the distinctions between it and *Melia Azedarach*, a tree often confounded with it, are carefully pointed out. The fruit of *Liquidambar orientalis* was drawn from a specimen in the Hanbury herbarium, which has on several former occasions furnished useful material for this great work. The authors have done well in placing *Cicuta virosa* and *Œnanthe crocata* in the same number. These two plants have frequently been confounded together in cases of poisoning, and the symptoms caused by the one have probably been often confounded with those of the other. In the interest of science the distinctions between the two plants cannot be too widely known. With regard to the *Piper Cubeba*, it is singular that no writer on the Piper genus seems to have noticed or described the colour of the mature fruit. The authors have, therefore, wisely left in uncoloured.

It has often been considered remarkable that of all the superior planets, Mars alone should have no satellite. M. Boutigny and others, reasoning from analogy, predicted in a speculative way that at some time in the future, it would be discovered that Mars in reality possesses its moon or moons also, and this prediction has received the attestation of truth quite recently. During last autumn Mars approached within 35,000,000 miles of the earth, and in August Professor Asaph Hall, of Washington, discovered two orbs attendant upon Mars. Since then many astronomers have confirmed this important observation. These moons are evidently smaller than the little asteroids or minor planets, and are indeed probably less than ten miles in diameter.

In the domain of vegetable physiology, Mr. Francis Darwin has made some most interesting observations. He has found that on the leaves of the common teasel there are attached to certain glandular hairs, translucent, highly refracting threads of varying length and form, and exhibiting remarkable spontaneous movements. These filaments consist of protoplasm containing much resinous matter, and they actually protrude from the interior of the glandular hair. They undergo violent contraction under the influence of many reagents, also by a temperature of 40—57°C., by electrical stimulation and by mechanical irritation In certain nutrient fluids, such as infusion of meat, their shape is modified and sometimes they becom detached. Their movements resemble the aggregation movements shown in the tentacles of *Drosera*. Mr. F. Darwin concludes that these filaments are concerned in the secretion of resin and absorption of nitrogenous matter. The power of secretion is attended by the death of the protoplasm, and in the teasel it appears that the protoplasm which by its death and change furnishes resin, has also life of such a nature that under certain conditions it can be utilised by the plant as a mode of nutrition.

The monthly *Microscopical Journal* for November and December contains a paper by Mr. Wentworth L. Scott on the microscopical examination of water. He says that often when the results of a chemical examination of a water make it passable, a microscopical examination furnishes evidence upon which the water should be condemned. This opinion, as will be seen directly, rests upon the possible detection of organisms in the water, as these are generally present in more or less quantity, and as when present in dangerous amount they are accompanied by other organic matters upon which only they can live, and which are detectable and estimable by chemical work, it is not necessary to endorse Mr. Scott's opinion. However, it is by no means an established proposition that such low forms of life are injurious to health; but it is unnecessary to discuss this question here. To assist in the microscopical examination of waters, Mr. Scott filters them through papers, the centre of which is rendered impervious by being coated with a mixture of 35 parts of vaseline and 65 parts of ozokerite. The living and dead suspended matter is thus concentrated within a small volume, and microscopical examination then reveals the number and varieties of organisms in a definite quantity of the water under examination. Mr. Scott says he has employed this method of procedure to learn the nature of the water often added to milk, and that in half-a-pint of one sample of milk he detected decomposing vegetable and animal matters, and also 87 living animalcules.

In the *Contemporary Review* for December, Professor Max von Pettenkofer writes on the hygienic value of plants in rooms and in the open air. In this paper he runs counter to some widely prevalent opinions. It is generally asserted that vegetation exercises three important functions of purification: firstly, by the absorption of carbonic anhydride; secondly, by giving out an equivalent of oxygen; and lastly, by the production of ozone. Now, Professor Pettenkofer admits all this, but at the same time he contends that these functions have not the importance in a hygienic sense which is generally assigned to them.

In Paris, where 2,944,000,000 litres of carbonic acid are (daily?) exhaled by men, animals and fuel, Boussingault found in the atmosphere only 4·13 parts per 10,000, while at St. Cloud it amounted to 4·14 parts. It has been similarly ascertained that in Manchester—a large manufacturing town where enormous quantities of coal are consumed—the proportion of carbonic anhydride in the air exceeds scarcely at all that observed at country stations. Without going into further detail, it may be at once explained that the reason why the atmosphere of large cities does not show the presence of more carbonic acid than the air of country places, is to be found in the currents arising from unequal rarefaction of the atmosphere. The same thing is true of oxygen as an atmospheric constituent; the air from the barren desert and the greenest oasis contain practically the same amount of carbonic acid and the same amount of oxygen. Professor Pettenkofer writes, "It would scarcely be intelligible if I were to calculate how much carbonic acid and oxygen a rose, a geranium, or a bignonia would absorb and give out in a room in a day, and to what extent the air might be changed by it, taking into account the inevitable change of air always going on." No doubt, but then it must never be forgotten that in spite of calculations it is through the growth of vegetation that the amount of carbonic anhydride in the atmosphere is kept balanced. It would be interesting, if we could afford the space, to calculate the volume of carbonic anhydride involved in the production of a eucalyptus tree 200 feet high and 60 feet in circumference at the base. These proportions may under favourable conditions be attained in about ten years, and if the product of our calculation were multiplied by the number of trees in a forest, the ultimate figure would be strikingly large. So, in a room also, plants do absorb carbonic acid and give out oxygen, but of course a man evolves much more carbonic acid than is absorbed by many plants.

Professor Pettenkofer has made no experiments upon ozone but he accepts the old statement of its production by vegetation, and is of opinion that it is a constant purifier of the atmosphere, although the amount of organic matter in the atmosphere is so great that the ozone never penetrates into our houses.

Having exploded all the comfortable opinions in which people have wrapped themselves for years, Pettenkofer seeks to bestow a few grains of comfort. He considers flowers in a room to have a hygienic influence by giving pleasure, just as a dog secretes gastric juice when shown a piece of meat. He also makes some observations upon the absorption of water from soils by vegetation and has a high opinion of the hygienic influences of trees, consisting in their effects of shelter from the sun, among which is the production of cooling breezes.

The paper we have alluded to contains, however, one error, and hence many erroneous deductions. So far as is known, plants do not produce ozone. Atmospheric ozone is probably the result of the action of electricity upon the air. The active agent produced by plants is peroxide of hydrogen, and it is surprising that Pettenkofer should not have been acquainted with this fact. His projected calculation therefore about the amount of oxygen a rose or geranium is capable of generating in a room assumes a new interest, if to the product we add the amount of peroxide of hydrogen also produced as well as the amount of organic matter it is capable of oxidizing, and since the production of that substance is intimately connected with the oxidation of essential oils it would be still more interesting to determine the average rate of volatilization of essential oils generally from plants and trees, and to calculate from this, by ascertained chemical equations, the extent of hygienic influence exerted. A wood containing 10,000 trees, evolving into the atmosphere essential oil at the rate of 10 grams daily from each tree, would furnish in the atmosphere about 25,000 grams of peroxide of hydrogen. Still more prodigious are the results produced by those camphoraceous substances which are found together with peroxide of hydrogen. The hygiene of plant life has many sides; Pettenkofer has studied only a part of these.

On the evening of the 16th inst. Dr. Lauder Brunton, F.R.S., gave an address at the Medical Society of London upon the assimilation of fat. He alluded to its general diffusion in the bodies of animals inhabiting cold regions, and pointed out that in animals living in warmer climates fat collected in localized spots, as for instance in the hump of the camel. He also stated that the softer fats—those containing a predominating quantity of olein—are the most readily absorbed. The digestibility of fats, however, is an individual quantity with different persons, and this has reference also to the nature of the fat. It is by no means certain that, as stated by Dr. Brunton, the digestibility of cod-liver oil is in part due to the presence in it of bile salts. It is true that cod liver oil gives with sulphuric acid and sugar the reaction which Pettenkofer discovered as characteristic of bile, but from recent researches it appears certain that many substances having no direct or known relation to biliary compounds also give this purple reaction.

Very little is known regarding the actual changes to which fats are subject in the body, nor is its economy or the pathology of fatty degeneration at all well understood.

In the stomach, fats are freed from any tissue with which they may be associated, and occur as oils in the intestines, where they are subjected to the combined influence of pancreatic juice and bile. Under the influence of the first of these natural juices, fat is partly decomposed into glycerine and free fatty acid, while another part is emulsified and made fit by subdivision to be more readily absorbed through the small pores of the cells which line the villi of the intestine. It is supposed that the emulsified fat which passes into the lymph ducts, and thus into the blood system, is burned up into carbonic anhydride and water, and in this way acts as a heat producer. Of the deposition of fat in certain parts of the body we are almost without any proper understanding.

In the last "Month" reference was made to the recent dispute about salt in beer. It appears that Mr. Plimsoll has since then avowed his knowledge of a case in which some 70 or 80 tons of salt were taken to a large brewery in a town in the midland counties. A correspondent, writing to the *Brewers' Guardian* of December 11, distinctly denies the accuracy of Mr. Plimsoll's information, and points out that the above quantity of salt if used would suffice to render nauseous no less than 13,667,500 gallons of beer, or 379,652 barrels of 36 gallons each, assuming the salt was added at the rate of 10 grains to half a pint of beer. It appears to us that if salt be added to beer at all it is a practice to which publicans are far more likely to resort than brewers, but no doubt we shall learn more about this subject before long; in the meantime it is perhaps best to suspend judgment.

As regards gin, the publicans are adopting the mode of labelling their bottles either as a mixture of dilute spirit, or as being so many degrees over proof. This is done, of course, to avoid prosecutions and fines, and we may hence expect that milk dealers will be found advertising and selling their commodity at the rate of so much per cent. solid constituents.

The milk "fake" case has attracted a good deal of attention. An *employé* of a milk dealer was charged with putting eight quarts of dirty water into some milk belonging to his employer. The prisoner, in cross-examination of his master, elicited the fact that when the milk run short the deficiency was usually made up by adding a watery solution of condensed milk to the supply.

The Royal Society has awarded the Copley medal to Professor J. D. Dana, of Newhaven, Connecticut, for his biblical, geological, and mineralogical investigations of the last half century. A Royal medal has also been awarded to Mr. F. A. Abel, F.R.S., C.B., for his physico-chemical researches on gun-cotton and explosives. Professor Oswald Heer, of Zurich, is the recipient of another Royal medal, presented in recognition of his numerous researches and writings on botanical subjects, and for his generalizations regarding tertiary plants and their geological and climatic relations. The first award of the Day medal has been made to Professor Bruish, of Heidelberg, and Professor Kirchhoff, of Berlin, for their researches in spectrum analysis.

In a series of papers recently published* by Friedel and Crafts there is described a new general method for the synthesis of hydrocarbons and acetones, through the active agency of aluminum chloride. For instance, when a solution of amylic chloride in benzene is treated with the metallic chloride, hydrochloric acid is set free and amyl-benzene is formed, thus—

$$C_5H_{11}Cl + C_6H_6 = HCl + C_6H_5(C_5H_{11})$$

Bromides and iodides are similarly acted upon, setting free hydrobromic and hydriodic acid respectively; thus ethylic iodide and benzene react upon each other in presence of the metallic chloride, giving hydriodic acid and ethyl-benzene—

$$C_2H_5I + C_6H_6 = HI + C_6H_5(C_2H_5),$$

Methylic chloride and benzene give rise to toluene. When the proportion of methylic chloride is increased, xylene, and mesitylene, also durene, are produced, a corresponding amount of hydrochloric acid being set free.

By the mutual action of benzylic chloride and benzene under similar conditions, diphenylmethane is produced. Bodies containing more than one atom of chlorine are similarly decomposable; thus chloroform gives triphenylmethane and carbon tetrachloride yields tetraphenylmethane.

Benzoic and acetic chlorides give benzophenon and acetaphenon.

Aluminum chloride is not the only metallic chloride which is capable of acting in this way; ferric chloride possesses a similar power, and ferrous chloride likewise, although in the latter case the application of heat is required.

* *Journ. prakt. Chem.*, 1877, xvi., 233.

Friedel and Crafts are of opinion that where aluminum chloride is employed, organic compounds containing the metal are first formed, and that these subsequently decompose giving once more the metallic chloride. The following equations represent this:—

Hypothetical compounds

$$C_2H_6 + Al_2Cl_6 = HCl + Al_2Cl_5(C_6H_5)$$
$$Al_2Cl_5(C_6H_5) + (CH_2C_6H_5)Cl = Al_2Cl_6 + CH_2(C_6H_5)C_6H_5.$$

Here the hypothetical metallic compound reacts on benzylic chloride, giving the metallic chloride and diphenylmethane.

Signor Orazio Silvestri,* in the course of an examination of a prehistoric doleritic lava occurring near the village of Paterno, found that it contains about 1 per cent. of oil. This solidifies at about 17° C., and is of a yellowish-green tint. Its chemical analysis revealed the following composition:—

	Per cent.
Liquid hydrocarbons (b. p. = 79°·28)	17·97
Hydrocarbons solidifying under 0° C. (b. p. = 280°—400°)	31·95
Paraffin, melting point 52°—57°	42·79
Asphalt (leaving 12 per cent. ashes)	2·90
Sulphur	4·32
	99·93

This oil is contained in irregular cavities coated with arragonite.

Fittica† has discovered a fourth isomeric nitrobenzoic acid, and it is pointed out that this discovery will not harmonize with the ordinarily accepted views regarding the structure of the benzene derivatives. He has also prepared a fourth nitro-benzaldehyde by acting upon benzaldehyde with sulphuric acid and ethylic nitrate. This product gives by oxidation the new nitrobenzoic acid $C_6H_4NO_2{\cdot}COOH$.

A. Michael has accomplished the production of halogen derivatives of amines. He replaces the basic hydrogen of the amines by acid residues and then exposes the products to the action of a halogen ethyl-phthalimide. $C_6H_4(CO)_2N.C_2H_5$ thus treated yields with bromine a tribromo-ethyl-phthalimide.

Genth has described‡ several new species of minerals, including coloradoite, which is found in the Keystone and Mountain Lion Mines of Colorado. It is not crystallized, but has an iron-black colour and metallic lustre, with a composition expressed by the formula HgTe.

Mercury	60·98
Tellurium	39·02

A second new mineral is magnolite (Hg_2TeO_4), and another is named ferrotellurite ($FeTeO_4$).

M. Cailletet§ has liquefied binoxide of nitrogen gas by exposing it to a pressure of 104 atmospheres at —11°, and in relation to this, M. Berthelot reminds chemists of the researches of Andrews, who has shown that every vapour exhibits a critical point of temperature, above which liquefaction cannot be obtained no matter what be the observed pressure. For binoxide of nitrogen the critical point lies between + 8° and — 11°.

The value of the ʒ symbol so warmly contested during the last two months in this Journal has finally and authoritatively been set at rest. That burning question, Civil Service Stores, never called forth so

* *Nature*, December 20, 1877.

§ *Comptes Rendus*, No. 22, November 26, 1877.

much controversy. Woman's rights in pharmacy pale before it, and even counter-practice has to hide its diminished head in presence of this great question of the day, How many grains does the symbol ℥ represent?

The correspondence columns have been filled with the most able arguments, equally convincing to the advocates of one side, equally erroneous to those of the other, and it has required the able editor of the British Pharmacopœia, who, scarcely confident in standing alone on such a vital question, seeks the sanction and assistance of one of the committee, to explain what is the hidden meaning of a paragraph which has given rise to so much controversy. Be it observed then that for the future "by authority" A when written thus does not mean B.

And now to refer to the Dispensing Memoranda *seriatim*, as usual. No. 41 is a lotion of salicylic acid in water. The dispenser is not justified in straining out the undissolved acid. Salicylic acid is very sparingly soluble in water, and if the quantity ordered in the prescription be dissolved by heat it will for the most part crystallize out of the solution at a lower temperature. The acid should be rubbed up without the application of heat, and a label "shake the bottle" would indicate that the dispenser was aware of the undissolved acid. If a substance capable of crystallization be ordered in greater quantity than the fluid will hold in solution, it is better not to use heat, but merely powder, and diffuse it through the fluid; if heat be applied there will be such a crystallization within the bottle on cooling as to render it impracticable to divide the quantities correctly, but this can easily be done when the salicylic acid is merely rubbed to a fine powder and mixed with the fluid.

It is just possible that the writer of the prescription was aware of the difficulty, as he ordered the quantity required by the patient at each time "with an equal quantity of warm water." If, however, solution was his intention, warm water is not sufficient, for if a portion of such a mixture of salicylic acid be mixed with an equal quantity of water, it requires to be heated to 70° or 80° cent. to dissolve the acid, and when the temperature of the solution drops to 50° or 60° cent., the acid begins to crystallize out.

The introduction of salicylic acid is of recent date, and the comparative insolubility of the salt may not be known to every member of the medical profession. The prescription well illustrates the class of cases where a pharmacist may show his intelligence, and at the same time do an act of courtesy to the prescriber by bringing this fact under his notice and its bearing on what he has written.

No. 42 is a mixture of tinct. opii with pot. iodid. and liq. hyd. bichlor., and the question is, can this be prepared so as to form a bright solution? This combination cannot result in any other than an opaque mixture, followed by a flocculent deposit, and it should have a label indicating the necessity of shaking the mixture before taking each dose. A solution of iodide of potassium with hyd. bichlor. forms Mayer's test solution for the presence of alkaloids, which it throws down in an amorphous condition from very dilute solutions. In this mixture the alkaloids of opium would be thrown out of solution immediately the tinct. opium is added, as a brownish flocculent deposit, consisting of morphia together with other proximate principles of the opium. From this it will be seen that the precipitate cannot be left out without loss of one of the active constituents of the mixture. It is an instance of chemical incompatibility without its being necessarily medicinally so.

In No. 43 there is most probably an error in the quantity of rectified spirit. To the quantity of ointment stated one drachm of spirit is usual, and there is no difficulty in making a satisfactory ointment by rubbing them together in these proportions in a mortar; but one ounce of spirit is quite exceptional, and suggests some inquiry with reference to its correctness before being dispensed. If it really be required, probably the best mode would be to render the ointment creamy by a water-bath, gradually adding the spirit and stirring till cool; a separation, however, will eventually take place.

44. ℥j bis in 7 mane.—This may be written bis in septimanâ, and is translated twice a week. A direction somewhat similar is occasionally met with —"hora 7 ma matutina," which may be more fully written, "hora septima matutina," and rendered 7 o'clock in the morning. Directions in this form are by no means frequent, but their occasional presence may embarass one who has not had the advantage of great variety in dispensing prescriptions.

45. The extract of belladonna should be rubbed down with sufficient water so that it may be diffused in the ol. hyoscyami. Mucilage would not in this instance be admissible. An emulsion must not be expected. All that can be attained is a minute division of the liquefied extract through the oil, and the mixture should be shaken each time before use.

No. 46. Ung. Galeni.—There is no British pharmacopœia authority for this ointment, although the French Codex contains a Cérat de Galien, made by melting 1 part by weight of white wax in a water-bath, together with 4 parts of oil of sweet almonds and 1½ parts of rose water, pouring the mixture into a warmed mortar and incorporating with it, in small portions at a time, 1½ parts more of rose water whilst cooling. Such a preparation probably derives its name from Galen, who wrote two treatises on the composition of medicines, containing a considerable number of formulæ. It is now understood to mean an ointment free from any chemical ingredient, and would be fairly represented by simple ointment or cold cream.

48. Hyd. disulph. evidently means hydrarg. disulphid. or vermilion. It cannot be either hyd. sulphat., or turpeth mineral, which is an oxysulphate of mercury.

49. If the liquor ammon. acet. be neutral or even acid the mixture can be made clear without difficulty, but should it have much free alkali hydrate of iron will be thrown down as a flocculent precipitate. In the presence of a difficulty of this description, it should be ascertained that the several preparations of which the mixture is composed correspond to the Pharmacopœia standard. If this procedure were more generally adopted there would be less diversity in the same prescription made up at different establishments.

It would certainly add to the interest and probably the value of the Dispensing Memoranda if correspondents would just state what they had themselves done to secure a good result before sending their difficulties to this Journal. In addition, then, to suggesting a better method of procedure a few remarks could be added on the cause of failure. Where no effort has been made little good will result from the memoranda; the same mixture can be dispensed again, and the same ointment repeated, but unless the principle be understood a slight departure from the letter of the last difficulty will find the inquirer once more on the horns of a dilemma.

In last month's Journal a reply was given to an inquiry after a formula for tr. chinæ nit. suggesting the probability of its being a tinct. of *Cinchona nitida*, at the same time recommending a reference to the writer of the prescription. From answers very kindly sent by two correspondents it appears that this preparation is one belonging to homœopathy, and is made by dissolving quinæ disulph. in water acidulated with nitric acid to which sp. vini rect. is added. The Homœopathic, together with with almost every other European Pharmacopœia, was referred to, but there was no indication of any tr. chinæ nit., and it is even now difficult to understand why the name china should be given to a solution of quinine. In the Homœopathic Pharmacopœia china is rendered *Cinchona officinalis*, Engl. Peruvian bark. Quinine is chininum, and sulphate of quinine, chininum sulphuricum. In no language, and in no pharmacopœia, is quinine represented by the word china.

In Hager's 'Medicamenta Homœopathica,' under "Modus Parandi Tincturas," is the following:—"Tincturæ sunt extractiones spirituosæ e substantiis plerumque siccis præcipue ex herbis, foliis, radicibus, corticibus seminibus siccatis." In presence of this view of the preparation of a tincture how can a solution of quinine in nitric acid be properly called in homœopathic phraseology a tincture?

It is no easy matter for a dispenser to grapple satisfactorily with the many varieties of prescriptions coming daily under his notice—some of these containing recently introduced medicinal agents, the composition of which may not be thoroughly known, and their behaviour with other remedies quite untried; but when to this is added ordinary solutions of well-known remedies under "misnomers," constituting an addition to the class of "obscure prescriptions," he may well be pardoned for uttering an indignant protest against conduct embarrassing the many whilst favouring the few.

Amongst novelties connected with pharmacy may be mentioned a very elegant form of capsule for nitrite of amyl, introduced by Mr. Martindale. It is in the form of a tube drawn out to a point at both ends and enveloped in a small wrapper of silk to prevent accidental breakage.

Mr. W. Hay, of Hull, has, after much labour, succeeded in preparing an essence of ginger containing most, if not the whole, of the essential oil or aromatic constituent of the root,* but quite free from the acrid resin which forms so large a portion of the ordinary essence or tincture of ginger. Mr. Hay's essence has the aroma of ginger without the unpleasant taste of the resin, and it is perfectly miscible with water without causing any of the turbidity which results on mixing the tincture with water in consequence of the precipitation of the resin. On this account Mr. Hay's essence is specially adapted for flavouring ginger beer, and it will remove the excuse for using cayenne in that beverage as a substitute for ginger when it is desired to avoid the turbidity caused by the tincture containing resin.

Messrs. James Allen and Son have lately constructed a very convenient form of invalids food warmer, consisting of a tin stand into which fit a small saucepan, a kettle, or a covered earthen pan, the contents of each of which can be heated as required by means of a spirit lamp or a night light, according to the purpose intended. In this way beef-tea, cocoa, or other preparations to be taken at intervals by invalids can be kept moderately warm during the night, and heated up within a few minutes. The compact form of the apparatus will render it a useful adjunct to the appliances of the invalid's bed-side.

* See *Pharm. Journ.*, No. 370, p. 71.

In this "Month" of December it is natural to look back to the time—now twelve months since—when this series of articles was initiated. During the interval there has been an opportunity of referring cursorily to many matters of more or less general interest to the readers of this Journal, which otherwise would not have received notice in these columns. Believing still in the want of such an article as the "Month," which serves not only a journalistic but a public purpose, and in view of its attained success, it is proposed to perpetuate it in the future It will still be attempted to notice all subjects of current interest and importance, and to lend weight to all true advance in pharmacy and the sciences upon which it depends.

COLCHICUM SEED.*

BY NATHAN ROSENWASSER, PH.G.

The author prepared the active principle of the seed, and found it to have a neutral reaction to test paper, and to be not precipitated from aqueous solutions or solutions acidulated with organic acids, by potassio-mercuric iodide, sodium phospho-tungstate, auric chloride, phosphomolybdic acid and solution of iodine, all of which reagents afforded precipitates after the solution had been acidulated with a mineral or oxalic acid, or had been boiled for a few minutes with acetic acid; he argues from this that the principle is naturally neutral, and is converted into an alkaloid by the influences mentioned.† The neutral substance, colchicin, was with some difficulty obtained in crystals by the slow evaporation, in deep vessels, of its solutions in fusel oil and benzol, and found to be insoluble in pure ether, carbon bisulphide and petroleum benzin.

It having been asserted that the active principle resided chiefly in the outer integuments of the seed, and that for this reason they could be almost completely exhausted without being ground, the author experimented with 5000 grains of unbroken seeds, macerated them in diluted alcohol in a warm place for ten days, and washed them well with diluted alcohol; the tincture and washings were used for preparing colchicin by Carter's process (*American Journal of Pharmacy*, 1858, p. 205), of which five grains was obtained. The same seeds afterwards crushed to a uniform powder yielded eleven grains colchicin. 5000 grains of seeds of the same lot were ground, and yielded sixteen grains; and 14,000 grains of the same seeds, rolled and crushed, yielded forty-five grains of colchicin. It follows, therefore, that only less than one-third of the colchicin present can be exhausted from the unbroken seeds. In preparing colchicin, particularly in warm weather, it is found unnecessary to remove the fixed oil by filtration previous to precipitating the colchicin by tannin; it is better to collect the precipitate, dry it carefully by means of a water-bath, and then exhaust the oil by gasolin. For the decomposition of the tannate aluminum hydrate seems to possess decided advantages over ferric or plumbic hydrate, it serving at the same time as a decolorizing agent.

When distilling the alcohol from the tincture the odour of the ground seed was distinctly recognized in the distillate, which turned milky upon the addition of water.

* From the *American Journal of Pharmacy*, Sept., 1877.

† *Colchicien* is formed under these circumstances, which ombines with bases, but not with acids.—EDITOR A. M. P.

On distilling a pound of the ground seeds with water, an aromatic distillate was obtained, but a volatile oil, which probably exists in minute quantity, could not be separated. The distillate was tested for alkaloids with a negative result.

Flückiger and Hanbury give 6·6 per cent. as the amount of fixed oil present in the seeds; the author obtained 14 drachms (8·4 per cent.) from 10,000 grains of the seeds. After purifying it by treatment with benzin and animal charcoal, it had a light-brown colour and a bland taste. It was found to be readily saponifiable.

SOME CONSTITUENTS OF HOPS.*

BY EMERY GILBERT BISSELL, PH.G.

It is pretty generally supposed that lupulin contains all the active principles of the hop. Some doubt in regard to this having been recently expressed, the writer has endeavoured to settle the question, with what success may be judged from the following experiments. The best of hops were selected, those as nearly ripe as could be found during picking; from these the bracts were carefully removed; the ends next to the achenes, to which part of the bracts most of the lupulin adheres, were trimmed off with scissors; the remainder of each bract was then passed between the thumb and finger to remove the remaining particles of lupulin, a magnifying glass being used from time to time to see that the work was thoroughly accomplished. This process is a difficult and tedious one, the lupulin adhering to the bracts with considerable tenacity. The bracts were then allowed to dry, without the aid of artificial heat, and were found to shrink about three-fourths in weight; after much perseverance one troy ounce of the dried bracts was obtained. Some difficulty was next experienced in powdering them; rubbing them with sand in a mortar was first tried, and found to be exceedingly slow work; grinding in a drug mill was next attempted, but found to be simply impossible; the method finally resorted to, and found to work nicely, was to cut the bracts in pieces with shears. This may readily be done by grasping the hand full of them and passing the shears repeatedly through many of them at once, sifting out the fine particles from time to time. The powder thus obtained was exhausted with stronger alcohol, and a tincture obtained possessing a bitter taste and some odour, neither of which would, however, hardly remind one of hops. The alcohol was distilled off from the tincture, and an extract obtained weighing seventy grains. To the distillate was added some water, the alcohol distilled off at a gentle heat, and the heat then raised. The distilled water was observed to have a slight foreign odour, but could not be recognized as the odour of hops; it had no effect on litmus paper, and produced no change in colour with a solution of permanganate of potassa, evidently containing not more than the merest trace of volatile organic matter.

Of the extract obtained twenty grains was reserved for further experiment, the remaining fifty grains being tried in the following manner:—One half of it was given to a healthy person; no effect being experienced, in one hour the remainder was given; no effect whatever was noticed upon either pulse, temperature or respiration. The portion reserved was dried by means of the water-bath until it ceased to lose weight, after which the weight was found to be 1·013 gram; of this, ·225 gram, or about 22 per cent., was insoluble in water; the portion soluble in water was found to give the reactions characteristic of tannin, and also to contain a small amount of bitter extractive. The amount of the extract reserved was, however, too small to admit of many experiments.

I then endeavoured to determine the nature of the tannin contained in hops, 700 grains of which were exhausted with boiling water, the decoction evaporated nearly to extractive consistence, and treated with alcohol to remove the gummy matter. The alcohol was evaporated and the residue dissolved in water; the percentage of tannin was then estimated by means of a standardized solution of gelatin containing alum; only about 6 per cent. of tannin could be found. The remainder of the solution was then precipitated with neutral acetate and with subacetate of lead; the two precipitates had much the same appearance, and both were soluble in acetic acid. They were each thoroughly washed, then suspended in water, and decomposed with sulphuretted hydrogen. The filtrate from each was found to contain the tannin, which gave a blackish-green colour with ferric chloride, and precipitated a solution of gelatin containing alum. The two solutions were mixed and the tannin precipitated with an excess of common salt, from which an unsuccessful attempt was made to entirely free it.

For the final experiment six ounces of hops were taken and exhausted with boiling water; the decoction was concentrated, treated with alcohol, filtered, the alcohol evaporated off, the residue dissolved in water, and the percentage of tannin estimated as before; only a little more than five-tenths per cent. being found. The solution, being acid to test paper, was carefully neutralized with ammonia and precipitated with neutral acetate of lead, a bright yellow precipitate being obtained; the filtrate gave no reaction with subacetate of lead and contained no tannin. The precipitate was thoroughly washed, suspended in water, decomposed with sulphuretted hydrogen, the precipitate washed until the washings gave no colour with ferric chloride, and the filtrate evaporated to a small bulk, and shaken with ether in hopes that the tannin might be dissolved; the ether, however, failed to take up any of the tannin, and portions of the solution were therefore treated with the following reagents:—tartar emetic, which produced a nearly white precipitate on standing; ferrous sulphate, no effect; sulphuric and hydrochloric acid at once produced precipitates; protochloride of tin, no effect; sulphate of copper, no effect; solution of potassa gave a dark reddish-brown colour, but no precipitate; gelatin gave a precipitate on standing. The green-black precipitate with ferric chloride certainly indicates that this is not gallotannic acid, which in other respects it resembles, and the reaction with the mineral acids would seem to show with equal certainty that the tannin is not moritannic acid, which it is stated by Wagner to resemble.

* From the *American Journal of Pharmacy*, Dec., 1877.

THE ADULTERATION OF EXPRESSED OIL OF ALMONDS.*

Mr. J. D. Bieber, of Hamburg, has ascertained that the larger portion of the commercial expressed oil of almonds (oil of sweet almonds) is either adulterated or entirely fictitious. In the most favourable cases peach-kernel oil is substituted in its place. The admissibility of the oil obtained from peach- and apricot-kernels might possibly be defended on the ground that the latter are nearly alike in chemical composition (?) and in price to the small Barbary almonds. The author has succeeded in finding a reliable reagent to distinguish the pure almond oil from sophistications. His results are based on experiments made with the oil of sweet as well as bitter almonds of all commercial varieties, and on those made with other oils. It was first ascertained that the age of the almond oil, or its manner of preparation (by cold or hot pressing), had no influence upon its chemical behaviour towards the reagent. This latter is prepared by mixing equal weights of pure concentrated sulphuric acid, red fuming nitric acid, and water, and allowing the mixture to cool. Mixtures made with five parts of oil and one part of the acid show the following characteristics:—

Pure almond oil: a faintly yellowish-white liniment.

Peach-kernel oil: assumes at once the colour of peach-blossoms, turning afterwards dark orange.

Sesame oil: first pale yellowish-red; afterwards dirty orange-red.

* From the *Pharmaceutische Zeitung*, quoted in *New Remedies*, November, 1877.

Poppy oil and walnut oil: a somewhat whiter liniment than pure almond oil.

Mixed with pure nitric acid of 1·40 specific gravity the behaviour is as follows:—

Almond oil: pale yellowish liniment.

Peach-kernel oil: at once a red liniment.

Sesame oil: dirty greenish-yellow; afterwards reddish.

Poppy oil and walnut oil: an entirely white liniment. With the first-mentioned reagent (mixture of acids and water), an addition of five per cent. of peach or sesame oil may be readily recognized. By making a series of mixtures of almond and peach oil, differing by ten per cent. among themselves, it is easy to discover, with tolerable accuracy, the proportion of the two oils in an adulterated sample. In order to distinguish whether the foreign oil was sesame or peach oil, the reaction with nitric acid of 1·40 specific gravity is had recourse to. Besides the above-mentioned substitutes, there exist some other oils, chiefly prepared in France and Italy, which greatly resemble almond oil, and might be used as adulterants. One of these is the fatty oil expressed from the seeds of the stone pine (zirbel nuts, pine nuts), which has, however, not been examined by the author.

To the above the editor of *New Remedies* adds:—A very common sophistication, namely, oil of mustard, has not been mentioned by the author; but it is well known that it is often sold for sweet almond oil.

THUJA OCCIDENTALIS.

The following memoranda relative to the use of preparation of *Thuja occidentalis*, which appears just now to be attracting some interest in New York, have been contributed to *New Remedies*, by Dr. J. R. Leaming.

"The fluid extract or saturated tincture may be given in drachm doses from three to six times daily.

"It may be given for malignant disease or for pulmonary hemorrhage in a glass of milk or in cod-liver oil.

"It may also be applied to cancerous ulcerations or tumours. It may be applied in the cavity—in the os—or to the cervix of the uterus in malignant disease, or in non-malignant, when there is a flabby condition of the parts with a tendency to bleed; and also, under the same conditions, to the throat. It may be applied to warts, and especially to venereal warts.

"It may be given in amenorrhœa from simple causes, but does not affect a healthy gravid uterus.

"The elixir of thuja and glycerine is a more elegant mode of administering the medicine, and is a valuable substitute for cod-liver oil.

"The glycerole may be made into suppositories, or it may be mixed with the fluid extract, for application to the os uteri upon a pessary of cotton.

"This medicine may become very useful to the practitioner in the treatment of malignant disease, especially in diminishing tendencies to bleeding and rapid progress of the local disease. It also relieves the violence of pain. In some cases the disease has disappeared under its use—not always."

The literature referring to this drug is quite limited. A. Kawalier, of Vienna, discovered a bitter principle, which he called *pinipicrin* (found also in *Pinus sylvestris*), a volatile oil, sugar, gelatinous matter, a variety of wax, resin, and tannic acid (*Chem. Gaz.*, Feb. 1, 1855, p. 45); and more recently a peculiar crystallizable colouring principle, which he termed *thujin*, another yellow substance, which he called *thujetin*, and still a third *thujigenin*; also a variety of acid, which he named *pinitannic*. Kawalier's second paper in the *Chem. Gaz.*, Nos. 392–3, pp. 61 and 68, 1859, is said to contain a full description of the processes he employed.

Regarding the properties of thuja, the wood when burnt gives off an agreeable smell, which led to its former use for sacrificial purposes. A salve made with the leaves used to be a remedy employed by the Indians for the relief of rheumatism, and a poultice of the leaves made with milk has been highly spoken of for the same purpose. By distillation the leaves yield a yellowish-green volatile oil, which has been used as a vermicide. Boerhaave praised the action of the distilled water as a remedy for dropsy.

Some years ago Dr. Leaming contributed to the *N. Y. Journal of Medicine* (N. S., xiv., 406), a paper on the use of thuja in affections believed to be cancerous, and in venereal excrescences, and in 1856, in the same journal, Dr. Benedict recommended the strong tincture as an emmenagogue.

Thus far thuja appears to have been employed empirically only, but it would seem, on reviewing the affections in which it had been of service, that its action may be explained by a property somewhat similar to that possessed by ergot, namely, of causing contraction of unstriped muscular fibres. This would explain, in some degree, its alleged power of controlling capillary hemorrhage, and the growth of vascular tissues like cancer and condylomata.

NUMBER OF KNOWN PLANTS.*

At a Botanical Congress held at Brussels in May, last year, Professor E. Morren, of Liege, in opening the discussion as to the best means of forming a 'Hortus Europæus,' or General Methodical Catalogue of all Cultivated Plants, gave some interesting statistics which are well worth reproducing from 'La Belgique Horticole':—

"It is to be regretted that Adam and his family did not in the leisure time of their youth think of writing an inventory of the garden which was the cradle of humanity. Our first father gave, it appears, each animal its true name, while he busied himself in a very different way with the trees, and this is precisely the reason why botanists are still burdened with naming and classifying, by the sweat of their brow, all the plants on the earth. Mention is made in the Bible of about 500 plants, clearly determined, while some 50 others are designated in more general terms. In the works of Hippocrates we find 234 plants mentioned, and in those of Theophrastes about 500. Dioscorides knew nearly 600, and we find 800 names of plants in Pliny's 'Natural History;' but, like all the sciences of observation and the technical arts, it is only since the renaissance that botany has made much progress. In the sixteenth century we find 800 plants in the works of Conrad Gesner, 1400 in those of Charles de L'Escluse, 2731 in the 'Historia Generalis Plantarum' of J. Dalechamps in 1587, 6000 in the 'Pinax Theatri Botanici' of Gaspard Bauhin. The seventeenth century is marked by the works of Tournefort (1694). He knew 10,146 kinds, and was the first to divide them into genera, to the number of 694. The 'Historia Plantarum' of Jean Ray treats of 18,655 species of plants, among which, however, a rather large number are mentioned twice. In the eighteenth century the immortal Charles Linnæus appeared, the founder of the scientific nomenclature, and the most judicious of botanists. The first edition of his 'Systema Plantarum,' in 1753, comprises 6200 species clearly distinguished. At the latter part of his life he had defined 5790 dicotyledons, 881 monocotyledons, and 623 cryptogams, in all 7294 plants, distributed over 1239 genera. We now arrive at the nineteenth century. According to the 'Synopsis Plantarum' of Persoon (1805—7), 25,000 to 26,000 species were known, divided into 5000 or 6000 cryptogams, 4000 to 5000 monocotyledons, 15,000 dicotyledons. The work comprised only 2303 genera of phanerogams. As to the plants raised in gardens, to give an approximate idea of those which then existed, we find in the most important works of that period 6351 names of plants in the 'Enumeratio Plantarum H. R. Bot. Berolinensis' of Willdenow, 1809; 9123 species, exclusive of varieties, in the second edition of the 'Hortus Kewensis' of W. T. Aiton, 1810—1813; 10,299 species in the 'Enumeratio Plantarum H. R. B. Berolinensis' of H. F. Link, 1821. About the same time (1819) P. De Candolle, in the second edition of his 'Théorie Elementaire de Botanique,' estimates the

* From the *Journal of Applied Science*, October 1, 1877.

number of species then scientifically known at 30,000. If the numbers of Persoon and of De Candolle are compared with those of Willdenow, Aiton, and Link, it will be seen that the number of plants cultivated was about one-third of those known. In 1824 Steudel published the first edition of his 'Nomenclator Botanicus,' a vast compilation, in which he enumerates in alphabetical order, and without criticism, all the names of plants which he had been able to find in the books published after those of Linnæus. He gives 59,684 names of phanerogams, 10,965 cryptogams, in all 70,649 plants, ranged in 3,933 genera. The second and last edition of this catalogue, always useful, in spite of its age, contains 78,000 names of phanerogams, and 6,722 genera. It must, however, be remarked that these figures apply to names existing in science rather than to things existing in nature. At this period some works appeared in England which are particularly worthy of our attention. We mean the 'Hortus Britannicus' of Robert Sweet and John Claude Loudon. That of Sweet appeared in 1827, and was successively improved in its editions of 1830 and 1839. The second (of Loudon), appeared in 1830, 1832, and 1839. If it has not the merit of priority, it offers, at least, the advantage of being classified in the natural orders. These two works treat of all the plants already cultivated in England. Loudon enumerates in 1839, 31,731 species and 3732 genera. In 1845 we find Laseque estimating all known plants at 15,000 cyptogams and 80,000 phanerogams. John Lindley, in 1846, divides these latter into 66,435 dicotyledons, and 13,952 monocotyledons. Etienne Endlicher (1836–40) describes, in his memorable 'Genera Plantarum, 6,895 genera known in the vegetable kingdom, including the fossil plants, or only 6136 genera actually living, and 240 families. The gardens contained, therefore, at this period, about a third of the phanerogams described, and more than half of the existing genera. In 1853 J. Lindley ('Vegetable Kingdom') estimated the number of genera and species in the entire vegetable kingdom as follows:—

	Genera.	Species.
Thallogens	936	8394
Acrogens	310	4086
Monocotyledons . . .	1457	14,005
Dicotyledons	6248	66,435
Or:—Cryptogams	1246	12,480
Phanerogams	7685	80,446
Total	8931	92,920

The augmentation of the contingent is rapid and incessant. In the first half of the century, the number of species cultivated rose in round numbers from 10,000 to 30,003, and that of the plants in herbariums from 30,000 to 90,000; that is to say, they were tripled. Lastly, in 1863, Bentley gives the number of known species at 100,000 phanerogams and 25,000 cryptogams. It is most probable that these figures will be doubled when the whole surface of the earth has been explored. In the meantime, the total of all known plants may be estimated at 90,000 dicotyledons, 20,000 monocotyledons, and 40,000 cryptogams—about 150,000 species, divided in 8000 genera. The 'Synonymia Botanica' of Dr. L. Pfeiffer (1870) gives, it is true, 12,908 names of genera, but these figures include all the fossils, and a great number of doubtful genera. It may therefore be assumed that the number of plants actually cultivated amounts to something like 40,000 botanical species, without counting the races and varieties. At this rate there would be about ten thousand species to add to the 'Hortus' of 1839—say, in round numbers, 250 to 300 species a year. The inventory made by M. André De Vos gives 175 new names of ornamental plants, first described and figured in 1876. The flora of the greenhouses and gardens then comprised about 40,000 cultivated species, and the rural flora of Belgium counts at the most 12,000.

SOUTH LONDON SCHOOL OF PHARMACY.

The fifth annual dinner to the students of this institution was held on Friday, December 21, at the Horns Assembly Rooms, Kennington Park, Dr. Muter occupying the chair.

The toast of "The Queen" having been given,

The Chairman proposed the toast of the evening, "Success to the South London School of Pharmacy." He said the duty he had to perform was a light and easy one, because every one would gladly re-echo the universal cry, "Success to the Old School," a school which had led many to honours that could never be taken from them, and others to the knowledge necessary for gathering together the requisite "little pill" which every one sought to attain in an honourable manner. He had not now met them to explain the mysteries of the terrible theories of chemistry, but merely to again hold out the right hand of friendship. On occasions like the present it was usual for him to say something about the spread of pharmaceutical education, which the South London School of Pharmacy had partly been the means of bringing to its present state of efficiency. He really had little to say upon this matter, except to express his conviction that nothing could possibly be better than the working of things at the parent house in Bloomsbury Square. The examinations were conducted by most competent examiners, and he might say that no body of men were so thoroughly sifted before being let loose upon the public as pharmaceutical chemists. It should be a matter of great thankfulness to the public to know that their lives were in the hands of a body of men whom they might thoroughly trust. The great event of the year had been the unwise proceeding on the part of certain medical men in trying to take out the mote from the eye of the prescribing druggist before they removed the beam from the same organ of the dispensing doctors. He did not propose to enter further into the subject because there were present many of the leading physicians of London. No doubt they would hear from the gentleman who was going to distribute the prizes that the true heads of the medical profession did not approve of the petty persecutions which had lately been indulged in.

Dr. Julius Pollock, in a few appropriate words, then presented the prizes to the successful students.

The Chairman having proposed the health of Dr. Pollock, in response,

Dr. Julius Pollock said reference had been made by Dr. Muter to certain relations between the medical professions and pharmacy, and he trusted he thoroughly appreciated what those relations should be. They all had certain functions to perform, but the functions of the physician and the chemist were of a different character. They need not come into collision with one another any more than did the functions of the House of Commons and the House of Lords. No one knew more than the practical physician how much he owed to the practical chemist. Physicians saw their patients, went into their symptoms, and adopted a certain line of treatment assisted mainly by the administration of certain drugs, but if those drugs were not carefully dispensed he should like to know what success the physician would be likely to attain. The physician was entirely in the hands of the chemist, for his success was dependent upon the care, discrimination, caution, and knowledge possessed by those who subsequently had to administer to the patient in the shape of prescriptions.

Mr. Baxter (Vice-Chairman), in proposing the health of the "Successful Students," said he hoped the time would come when the examinations would be written, believing that by this means the true genius of a man would be seen. He was glad to say that the student who gained the highest number of marks at Bloomsbury Square had been educated at the South London School of Pharmacy.

Messrs. David Jones and Mortlock responded to the toast.

Various other toasts were given during the evening and the proceedings were considerably enlivened by the singing of duets and songs by the students.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 29, 1877.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PARIS SOCIETY OF PHARMACY.

ABOUT twelve months since it was mentioned in this Journal that the wish of the widow of the late Professor GOBLEY to present a sum of money to the Société de Pharmacie had suggested the proposition of securing the recognition of that Society as an "*établissement d'utilité publique*," so that it might be enabled legally to receive gifts of money from its members or others. This proposition was unanimously agreed to, and at a meeting held on the 4th of April, 1877, a Committee was appointed to report on the subject. This it did in the following month, and then took the requisite steps to communicate with the Government officials for the purpose of obtaining the desired object. A decree has now been issued by the President of the Republic granting the privilege sought, and confirming the modified statutes which had been drawn up to suit the altered circumstances of the Society. From among these statutes the following is selected as indicating in a general way the nature of the Society.

The object of the Society is defined to be the establishment of intimate relations among the pharmacists of France and of foreign countries as well as to improve the art of pharmacy and to advance the sciences which relate to it. The number of Members is limited to sixty, resident in Paris, besides which there are twenty Associates and one hundred and twenty Provincial Correspondents; the number of Foreign Correspondents as well as that of Honorary Members is not limited.

One of the necessary steps to obtain the recognition of the Government was the presentation of an historical account of the Society, setting forth its origin, organization, object, and the services it had rendered. From this it appears that the Society took its origin as a consequence of the suppression of the old College of Pharmacy, together with other trade guilds and fraternities, in 1791. The business of the pharmacist being thus thrown open to all without the necessity of special education, accidents became frequent, and gave rise to so many complaints that the Committee of Public Health, then presided over by the celebrated Dr. GUILLOTIN, applied for and obtained a decree reviving the law and regulations relating to pharmaceutical education as well as to the preparation and dispensing of medicines. To quote the report, "The two years of anarchy which preceded this step served at least to teach a lesson that should not be forgotten, for they furnished in a high degree evidence of the necessity of regulating the practice of pharmacy by special laws. It was in vain that the freedom of trade was invoked, since it was out of place, and the interests of the public health ruled the whole discussion of the subject."

Subsequent to this decree the pharmacists of Paris, including, amongst other names eminent in science, VAUQUELIN, PELLETIER, BOUILLON LE GRANGE, LE CANU, and PARMENTIER, formed themselves into a voluntary society, having the object of promoting the progress of science, and especially of pharmacy, chemistry, botany, and natural history. In 1797 the Directory recognized this Society under the title of the Free School of Pharmacy. Subsequently the title was changed to that of the Society of Pharmacy of Paris, its constitution and statutes being almost the same as those of the present day.

In 1809 an important step was taken in the establishment of an official organ of the Society under the title of the *Bulletin de Pharmacie*, which in 1815 became the *Journal de Pharmacie et des Sciences Accessoires*, and this in its turn was succeeded in 1842 by the *Journal de Pharmacie et de Chimie*.

As regards the connection that exists between the teaching organization and the scientific society it is mentioned that the former rarely exists without being accompanied by the latter. In this manner, in France, the Academy of Medicine is the necessary corollary of the faculty of medicine, whilst the Society of Pharmacy bears the same relation to the Superior School of Pharmacy, and the provincial societies are in like manner associated with the local schools.

Since 1830 the Society has had the good fortune to have the position of General Secretary filled by ROBIQUET, SOUBEIRAN and BUIGNET, whose contributions to science have entitled them to hold a high place amongst its cultivators. Other members of the Society have also contributed largely to the advancement of chemistry and its application, amongst whom may be named SERULLAS, BOULLAY, PÉLOUZE, ROBINET, SERTURNER, PELLETIER, CAVENTOU, and BERTHELOT, who also belonged to the ranks of pharmacy, and only a few weeks since exchanged his position of Resident Member for that of Associate.

Among other services rendered by the Society of Pharmacy was the part taken at the Medical Congress in 1845, which, upon that occasion, placed the section of pharmacy upon a level with the section of medicine. The excitement caused among French pharmacists in the following year by the promulgation of the *ordonnance* relating to the sale of poisons induced the Society of Pharmacy to appoint a Commission for the purpose of demanding its revision, and it was successful in effecting this object.

In 1863, when a new edition of the Codex was in preparation, six members of the Society were appointed members of the Commission charged with this duty. At the same time the Society divided its sixty resident members into twenty sub-committees for the purpose of revising the mode of preparation and conservation of one or other class of medicaments, thus lending by virtue of their special competence an effectual support to the Commission, to the Academy of Medicine, and to the School of Pharmacy.

More recently, in response to applications from the provinces, a commission of five members was appointed to define the composition and preparation of new remedies, in regard to which there was want of uniformity and consequent inconvenience to medical men, pharmacists and patients. The report of this Commission has recently appeared in this Journal.

In addition to these claims to be regarded as a "society of public utility" numerous prizes have been conferred for essays on subjects connected with abstract and applied science, among which may be mentioned those of Bussy on animal charcoal, Fremy on the pectous and gelatinous substances of fruit, and Pasteur on tartaric and racemic acids.

COVENTRY AND WARWICKSHIRE PHARMACEUTICAL ASSOCIATION.

The opening meeting of the above Society is announced for the 10th January, 1878. The President (Mr. Councillor Wyley), will deliver the introductory address, and there will be an exhibition of new remedies, chemicals, microscopes, and objects of general scientific interest. The telephone will also be shown, and there will be demonstrations of cigar manufacture, and of the manufacture of the iodides of potassium, mercury, and lead. The Honorary Secretary, Mr. F. J. Barrett, will be glad to receive any donations of books, specimens, and articles for exhibition. We are glad to find also that "Preliminary" and "Minor" classes are to be formed in connection with this new Association, and students wishing to join them are requested to at once send in their names to the Honorary Secretary, 75, Hereford Street, Coventry.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association will be held at 17, Bloomsbury Square, on Friday evening, January 4, when a paper by Mr. Shapley will be read by the Secretary, on "Blood, Chemical and Microscopical." The chair will be taken at 8 o'clock.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

December 19, 1877.

Present—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson and Young.

Professor Maclagan was also present on behalf of the Privy Council.

MINOR EXAMINATION.

Twelve candidates were examined. *Three* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Adamson, William Francis......Blackburn.
Brasnett, Robert John............King's Lynn.
Cairnie, David Dandie............Perth.
Cluckie, Andrew ....Greenock.
Cockburn, James ....Glasgow.
Donaldson, James..................Edinburgh.
Glass, William Stephen ....Friockheim.
Hatton, Frederick William......London.
Horsfield, Edmund ... .Holbeck.

December 20, 1877.

Present—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson, and Young.

MINOR EXAMINATION.

Nine candidates were examined. *Two* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Johnson, Samuel ....Barnard Castle.
Jones, Charles Alfred ....Birkenhead.
Keith, Sydney ....Perth.
Lee, Alexander Milne ....Strichen.
Richmond, William Wilkinson...Carlisle.
Schofield, Frederick Elston......Morpeth.
Wilson, James . ...Buckie.

MODIFIED EXAMINATION.

One candidate was examined, and was declared qualified to be registered as a Chemist and Druggist:—

Farquhar, Robert ....Kilmarnock.

Proceedings of Scientific Societies.

ROYAL SOCIETY.

Researches on the Effect of Light upon Bacteria and other Organisms.

BY ARTHUR DOWNES, M.D., AND THOMAS P. BLUNT, M.A. (OXON.), F.C.S.

At the meeting of the Royal Society on the 6th inst., an interesting paper on the above subject was read on behalf of the authors. The investigation to which it related was undertaken with the view of ascertaining whether light could be shown to exert any appreciable influence, favourable or the reverse, upon the development of bacteria and other organisms in solutions which afford a suitable medium for their appearance and increase. In the experiments the contents of the tubes were in most cases examined under a high power, and the turbidity, when such occurred, was invariably found to be occasioned by swarms of bacteria. The best index of the development of the bacteria was found to be the degree of turbidity and the time of its commencement.

The first observation recorded is that on April 24, eight ordinary thin test tubes, cleansed with strong sulphuric acid, and thoroughly rinsed with tap water, were partially filled with freshly made unboiled Pasteur's solution,* and

* The following is the formula:—Water, 1500; brown sugar candy, 70; tartaric acid, 4; ammonium nitrate, 4; potassic carbonate, 0·6; ammonium phosphate, 1 solution neutralized with ammonia and filtered.

four were encased in thin sheet lead so as entirely to exclude light, and four were left quite bare. The tops of all were loosely covered with sheet lead capsules, and the whole were placed in a test tube stand outside a window facing south-east, about thirty feet above the ground. None of the tubes were plugged.

On May 4 the tubes were examined as to turbidity. The solution was perfectly clear in the four bare tubes, while in each of the encased it had become distinctly and uniformly milky. This turbidity was proved microscopically to be caused by innumerable bacteria. The bare tubes remained quite clear till May 28. This observation was again and again repeated with similar results.

In the large majority of cases the exposed tubes remained clear for an indefinite time, and in every instance were conserved for a distinct period after their encased companions had become turbid. The most marked differences in the conduct of the two sets of tubes were obtained when the sun shone brightly; when for a period of a day or two at the commencement of the experiment the weather was close and sultry, and the sky dull, the conservative effect of light appeared to be less pronounced. Thus, in an observation started on June 12, it was found on the 14th, that while there was a thick zooglœa and advanced turbidity at the upper part of the solution in the encased tubes, there had already commenced a much slighter but recognizable cloudiness in two tubes filled with the same Pasteur's solution, but freely exposed to the light. This result was attributed to the fact that throughout the whole of the 12th and 13th there was not one ray of direct sunlight, the sky being completely overcast and the atmosphere remarkably thick and hazy.

Observation 2.—On May 5 two of the bare tubes used in the previous observation were taken and the contents were found to be equally and perfectly clear. One was then encased, the other left as before, and both again replaced on the window-ledge for exposure. On the 16th the contents of the encased tube were distinctly turbid, those of the bare tube being perfectly clear.

From this observation the authors infer that the fitness of the cultivation-fluid as a nidus for the development of bacteria is not impaired by the action of light, since the solution which remained perfectly clear so long as it was freely exposed to the sun's rays, swarmed with bacteria after being deprived of the access of light. This being so, it seemed important to determine whether light may exert either directly or indirectly a destructive influence on bacteria. The obvious mode of settling this question would be to protect the tube to be insolated from subsequent impregnation, and finally to encase it. If then it remained clear for an indefinite period it might be fairly inferred that the bacteria had been destroyed, either in their rudimentary condition or successively as they came to maturity.

On May 30, therefore, two tubes were partially filled with Pasteur's solution. Both were plugged with cotton wool and one was encased in paper, the other left bare. On June 5 the encased tube was quite turbid. On June 12, the bare tube, which had remained perfectly clear, was encased, and it continued quite free from turbidity up to June 21. On June 28 the solution was quite clear, but a small tuft of mycelium was growing at bottom. On July 7, when examined with a high power, a mass of matted mycelium, but no bacteria or other living organisms were seen. On July 11 the solution teemed with bacteria, having doubtless been impregnated by the dipping rod used on July 7.

In the next experiment, on May 30, two tubes containing unboiled Pasteur's solution were plugged with cotton wool, capsuled, and insolated until June 21, when both were encased in the way previously described, the plug being withdrawn from one, and the lead capsule replaced. Both tubes remaining clear up to July 2, the unplugged one was impregnated by means of a glass rod dipped in a solution containing abundant bacteria. On July 4 the impregnated solution was distinctly turbid. The plugged tube remained perfectly clear up to the date of writing (October 11).

From these observations the authors conclude that so far as bacteria are concerned the solution may be absolutely and perfectly sterilized by sunlight. It is important to note, however, that in observation 3 the germs of a fungus had apparently survived an amount of insolation which was fatal to the development of bacteria.

Observation 5.—On May 5 two of the tubes used in observation 1 were taken; the contents of the one (encased) were turbid and the other (bare) perfectly clear. The contents were well mixed and divided between the two. They were then exposed as before. On the 8th the contents of the encased tube were much the more turbid; those of the bare tube were but slightly, if at all, more turbid than on the 5th. This experiment was considered to indicate that not only is light inimical to the original development of the individual, but also materially retards the rate of increase, even when the organisms are present in a matured condition. The next observation was designed as a crucial test of this.

Observation 6.—On July 10, seven tubes containing Pasteur's solution were inoculated with a glass rod dipped in a solution teeming with bacteria; care being taken not to impair the translucency of that in the tubes in question. Six of these tubes were then insolated, the seventh being encased. The encased tube became turbid on July 14, the rest remained perfectly clear.

The next object was to determine what period of exposure to light might be sufficient to sterilize a given solution.

Observation 7.—On July 10, seven full-sized test tubes were partially filled with solution and plugged with cotton wool. Six were exposed to the light for periods varying from nine hours to seven days, and were then encased. There was but little direct sunlight upon them during this period, the tube exposed for nine hours having three and a-half hours' sun, and the one encased at the end of seven days receiving in the aggregate about twelve hours of direct sunlight. All, however, were sterilized, while the seventh tube, which was encased from the first, and served as a control, became cloudy with bacteria on the fourth day.

Observation 8.—On July 29, a very hot day, with much sunshine, six tubes (series *a*) containing solution were each inoculated with two drops of a similar solution, which was swarming with bacteria. They were all then plugged with cotton wool, exposed to the light for periods varying from thirty minutes to eleven hours, and encased, the duration of sunlight received in each case being carefully noted. On July 31, four which had received half, one, two, and three hours' exposure respectively, were turbid with bacteria. The other two, which had been exposed, the one for five and the other for eleven hours, were clear at this date, but some days later the former contained some bacteria and a tuft of mycelium with sporidia, while the latter showed a similar growth of mycelium but no bacteria. These tubes had received four and a-half and nine hours' direct and powerful sunlight respectively.

On the same day six tubes (series *b*) containing the same solution, but not inoculated, were similarly plugged, insolated, and encased. These tubes all contained countless bacteria on August 2. This apparently contradictory result is attributed to the fact that for series *a* very narrow tubes, not exceeding a third of an inch in diameter, were chosen, while those of series *b* were about two-thirds of an inch. The fact, however, that in observation 7 a solution was sterilized by an exposure of nine hours, only three and a half hours of which were direct sunlight, whilst in observation 8 (series *b*) the same solution broke down after eleven hours, nine of which were true insolation, is explained by supposing that external conditions—notably temperature—may retard or counteract the preservative quality of the solar rays. The putrefactive tendency of warmth, however, did not, in the authors experience, with this solution at least, over-ride the preservative quality of light; for, provided that there was a full amount of sunlight, tubes exposed *continuously* from day to day were preserved as readily in hot weather as in cool.

In the course of the investigation it was found that, when bacteria appeared early and in large numbers in the solutions used, the mycelium of penicillium or other microscopic fungus was rarely seen, the bacteria apparently preoccupying the ground; when, however, the development of the bacteria was from some cause retarded or prevented, tufts of delicate mycelium were frequently found in the solutions after they had been encased or removed into diffused light. No mycelium, however, appeared during the period of exposure of a solution, except under the conditions hereafter stated, nor, indeed, afterwards, if this were sufficiently prolonged. The authors infer accordingly that light may retard or altogether prevent the appearance of mycelial fungi, but that its influence in this respect is slower and less powerful than upon the schizomycetes. They suggest also that this may explain, in part at least, the sparing distribution of bacteria in ordinary air as compared with the prevalence of the spores of penicillium, etc., a fact, observed by Burdon Sanderson and others.

In the course of the investigation it was found that, within certain limits, the rapidity with which bacteria appeared in the solution was proportionate to its dilution. This is illustrated in the following observation, in which the greater resistance to decomposition of the stronger solutions was utilized for the purpose of ascertaining whether diffused light exerts any appreciable influence on the processes under consideration:—

Observation 9, July 24.—Four solutions were prepared, so that—

I was of the ordinary strength.
II ,, twice as strong.
III ,, $3\frac{1}{2}$ times as strong.
IV ,, 5 ,, ,, ,,

One tube of each solution respectively was placed—

(1) In the dark.
(2) In the diffused light of a somewhat badly lighted room.
(3) In broad diffused daylight.

The result is seen in the following table:—

(1) In the dark,

I became turbid with bacteria.	July 27.
II ,, ,, ,, ,,	,, 28.
III ,, ,, ,, ,,	,, 29.
IV ,, ,, ,, ,,	Aug. 2.

(2) In a dull light,

I became turbid with bacteria.	July 26.
II ,, ,, ,, ,,	,, 28.
III ,, ,, ,, ,,	,, 29.
IV contained a tuft of mycelium.	Aug. 2, and became turbid with bacteria and mycelium, etc., Aug. 5.

(3) In diffused day-light,

I contained bacteria. July 29.
II, III, IV } Remained clear.

The tubes of series 3 were inadvertently exposed to about twenty minutes of sunlight on July 24, but the authors do not think that this materially interfered with the result, which demonstrates the preservative influence of diffused daylight alone, although in less degree than that of the direct solar rays.

Repeated attempts to sterilize a solution one-tenth of the ordinary strength were without success. Whether this failure was due to the unfavourable state of the weather and clouded skies which variably supervened, or whether in a solution of this strength the development of the bacteria proceeds with such rapidity that a warm night in its favouring tendencies outbalanced the retarding influence of the day, is uncertain.

Observation 10, July 26.—Three test tubes were partially filled with fresh urine of a golden sherry tint, and the mouth of each was guarded by a pledget of cotton wool. Two were insolated, one encased. On August 1 the contents of the encased tube were turbid and putrid, but the urine in the tubes which were exposed to the light remained perfectly pellucid. One of these (*a*) was now encased, the other (*b*) was left as before. In about a week two small tufts of mycelium had appeared at the bottom of the tube marked *a*, the solution in which, however, was otherwise perfectly clear. On October 13 the urine in tube *b* was as clear as when the experiment was first started, nor could anything except mycelium with sporilia be discovered in tube *a* on close examination. The urine in this tube had a strongly acid reaction. On the other hand, the urine in the tube which was encased from the first was so offensive as to render the examination of even a drop a disagreeable task. It contained rods and dumb-bells in great numbers and an abundance of the micrococci associated with the ammoniacal fermentation of urea. The reaction was alkaline. Prolonged insolation, it may be noted, had a bleaching effect on the urinary colouring matter.

Observation 11, September 22.—Three capillary tubes were filled with infusion made from some very old hay. One end of each was sealed off, the other end having a small plug of cotton wool. The infusion was of a deep yellow brown colour. Two of the tubes (*a*) were insolated, and one (*b*) encased. A portion also of the infusion was boiled for five minutes in a test tube, the mouth of which was closed during ebullition with cotton wool, the tube (which was labelled *c*) being then placed in the dark. On October 7 each sample was closely examined under the microscope, In the encased tube *b* large numbers of moving rod-like bacteria were seen, but in the insolated tubes *a* a very few moving particles alone were visible. The solution *c*, which had been boiled, contained a large number of rods, of greenish tint, with slightly clubbed refractive ends, for the most part motionless, and usually single. None of these were observed in the capillary tubes.

In some observations with turnip infusion it was found that while it became extremely rotten and offensive in those tubes which were encased, in corresponding tubes exposed to the light it was comparatively odourless, although the development of the bacteria had not been wholly prevented.

In an experiment with zymase, light did not appear to exercise any retarding influence on the "indirect ferments."

The question presents itself, with what rays of the spectrum is this property of light coincident? Is it localized in any one part, or is the unbroken pencil of rays necessary? The most definite result was obtained in an experiment, in which small test-tubes partially filled with solution, made of double the strength, were plugged with cotton wool, then placed in boxes, the sides of which were made of blood-red, yellow, deep blue, and ordinary glass respectively, and exposed to the light on an outside window-ledge facing south-east.

This result pointed forcibly to the active rays of the spectrum as the active agents.

In the course of the investigation mycelial fungi proved to be very prone to appear (to the exclusion of bacteria) in solutions which were themselves of a yellow colour, or were subjected to yellow light. Thus tubes containing urine exposed to light have several times developed a tuft of mycelium either during insolation or afterwards when encased.

This result is attributed to the apparent fact that the less deep shades of yellow allow rays to pass which may at least check the development of bacteria, but are less potent in their influence on the germs of the higher fungi, which accordingly develop the more readily, since they have not to struggle with the former for the mastery. This explanation is in accordance with the inference that, although the mycelial fungi are injuriously affected by light, they are more resistant to its influence than bacteria.

On exhausting tubes containing the solution by means of a sprengal pump and sealing them, it was found that not only did no development of organisms occur under these conditions, but that if the vacuum was maintained for a sufficient length of time, the solution become absolutely barren. Knowing the necessity of oxygen to bacteria (of the ordinary kind at least) and taking into consideration the products of their "respiration," it was inferred that this result was attributable to the absence of oxygen, and consequent asphyxia, not only of the mature forms of those organisms visible to the higher powers of the microscope, but also, it necessarily followed, to that rudimentary "germinal" material which, eluding even the piercing test of the electric beam, is distributed with extraordinary uniformity in almost every water. This fact which had been recently demonstrated by Professor Tyndall, with a similar interpretation, rendered it impracticable to ascertain the action of solar light on Pasteur's solution in a vacuum. By employing urine as the experimental material, however, it was ascertained that urine resisted the sterilizing effects of a vacuum for a period sufficiently long to enable the effects of insolation on this fluid in vacuo to be tested.

In carrying the inquiry further the result was on the one hand, the prevention of bacterial development and consequent growth of mycelial forms (the quantity of light being insufficient for the destruction of these), in those tubes which were insolated in the presence of ordinary atmospheric air. On the other hand, the same urines insolated to precisely the same degree as the former, but in the absence of an atmosphere, became turbid, even in vacuo, with bacteria as early as their encased congeners.

The deductions drawn from these experiments are summed up as follows :—

1. Light is inimical to the development of bacteria and the microscopic fungi associated with putrefaction and decay, its action on the latter organisms being apparently less rapid than upon the former.

2. Under favourable conditions it wholly prevents that development, but under less favourable it may only retard.

3. The preservative quality of light, as might be expected, is most powerful in the direct solar ray, but can be demonstrated to exist in ordinary diffused day-light.

4. So far as the investigation has gone it would appear that it is chiefly, but perhaps not entirely, associated with the actinic rays of the spectrum.

5. The fitness of a cultivation-liquid to act as a nidus is not impaired by insolation.

6. The germs originally present in such a liquid may be wholly destroyed, and a putrescible fluid perfectly preserved by the unaided action of light

---

CHEMISTS' ASSISTANTS' ASSOCIATION.

A general meeting of the members of this Association was held in the new room, 29, Brewer Street, Air Street, Regent Street, on Wednesday evening, November 28. There was a full attendance of members and visitors. The chair was taken by the President at 8·30 p.m.

The Hon. Secretary reported the progress of the Association showing that it numbered 60 members and that the funds were in a satisfactory condition.

After a rule had been altered and other business settled, a vote of thanks was proposed and carried to Dr. Dobell for a handsome donation of his complete works towards the formation of a library.

Mr. Marshall then read the following paper :—

Pill Making and Excipients.

On the importance of this branch of the dispensing art, as a convenient means of keeping accurately divided doses of drugs in a portable and permanent form, I need not dwell; nor upon its usefulness for administering those nauseous medicines which are given in small doses, or those heavy mineral powders which are not easily suspended by any fluid. Again, medicines, such as alteratives, required to act slowly, or those the action of which is desired to be retarded until they reach the lower intestines, such as aloes, are best administered in the pilular form.

I will commence by making a few observations on the properties pills (and masses) exhibit, and those they should possess. Pills are liable to absorb moisture and become soft and sticky, sometimes mouldy, at other times they lose their globular form and become flattened or angular, or, again, they become hard and insoluble. In any of these conditions they have failed to be what they ought; substances may have been chosen which ill accord with each other, or are unsuitable for this form of administration, and may not admit of the addition of any simple substance to remedy physical defects. It does not, therefore, necessarily follow that the dispenser is in fault; but with a knowledge of the physical and chemical characters of his materials he may in many cases obviate these objections.

A good pill mass should be sufficiently *plastic* to admit of being rolled or moulded without sticking to the fingers or machine, this condition is dependent on the even balance of two properties : *tenacity* or *adhesiveness* and *firmness*.

Tenacity or adhesiveness is dependent on two conditions—

1st. An inherent property in the particles by which they attach themselves to particles of the same or any other kind.

2nd. A state of partial fluidity, which appears to be essential to the kind of tenacity under consideration. If we deprive otherwise adhesive substances (such as gums, resins, extracts, etc.) of their tendency to fluidity we deprive them of adhesiveness; they become brittle and are readily powdered.

Firmness is that property which enables a mass to retain its shape (therefore of great importance); it may be considered synonymous with hardness and insolubility.

Masses may possess sufficient adhesiveness to form pills, but if all the ingredients are held in a state of solution (*i.e.*, water and gum, or alcohol and resin), that is to say, if there be not a proper proportion of insoluble material present the pills will not retain their globular form, but probably run into a mass.

Again, masses may be so firm as not to take form, in which case they contain too much insoluble material. A pill mass may be said to consist of two parts—*the active ingredients* or basis of the mass and *the excipient* to give the necessary plasticity. The excipient may be active or inert at the will of the prescriber; when inert it is much better left to the judgment of the dispenser by reason of his greater practical experience.

The art of pill making consists in selecting excipients suited to the peculiarities of the other ingredients, and the skill of the dispenser will be shown by the uniformity of his success. Those substances should be chosen which, fulfilling the necessary requirements without inconveniently increasing the size, will not be incompatible with or alter in any way the action of the other ingredients.

Active ingredients (solids) may be divided into *adhesive* and *non-adhesive*; this division is, however, more arbitrary than real, and is only adopted for convevience sake.

Adhesive substances are of very different kinds, varying from powders (such as rhubarb) requiring some simple fluid, acting as a solvent on some of their particles, to develope their tenacity; to extracts (aqueous and resinous) which, when they will not admit of evaporation, need a solid excipient to give the necessary plasticity.

Substances requiring liquid excipients :—

Water and spirit, from their tendency to leave the pills hard and insoluble by evaporation, should when possible be avoided.

Syrup answers better, is more soluble, and the sugar is beneficial in preserving vegetable and other substances liable to oxidation, such as sulphate of iron; it, however, dries and leaves a crumbly mass. The uncrystallizable syrup (treacle) is the best, as it retains its moisture. Both kinds are subject to the objection of sometimes giving too great bulk.

Honey (clarified) is more suited to those substances requiring a small amount of firmness as well as a solvent action, and which will bear a diluent.

Glycerine, the solvent action of which is very extensive, is one of, if not the most important, of fluid excipients; its value is seldom appreciated. Many mineral substances, such as oxide of zinc, subnitrate of bismuth (it being possible to give as much as twenty grains in a pill), oxide of bismuth, antimonial powder, dried sulphate of iron, which show no sign of adhesiveness, form good plastic masses with this excipient and with a very small quantity. Other substances, such as croton chloral, quinine, pepsine, rhubarb, etc., form with it better masses than with any other excipient known to myself.

With regard to rhubarb, I would remark on an error in a well-known work on pharmacy, where one drachm is said to require half a fluid-drachm of water, syrup, or glycerine. It should be half a fluid drachm of syrup or water, and fifteen minims of glycerine.

Glycerine is by many objected to on account of its hygroscopic nature; this, however, may be obviated by the addition of about 15 to 20 per cent. of water, or by spirit, if with spirit it becomes an invaluable excipient for resinous powders, such as jalap (which can be made up with about one-fourth its weight of a mixture of equal parts of glycerine and spirit), and it does not leave the pills hard and insoluble, as when made with spirit alone.

We have in the next place to consider those solid or semi-solid materials, such as extracts, aqueous and resinous, gum resins and resins. As many of these are of good consistence they will not require much attention.

Aqueous extracts when soft (and it being advisable not to evaporate) require absorbent substances. Sugar is sometimes used with advantage, as it absorbs moisture, and helps to preserve vegetable principles. Bread crumb acts as a good absorbent, and the gluten it contains gives the pills firmness. Acacia and tragacanth are too frequently used, but should be avoided on account of rendering the pills hard and insoluble. I do not think tragacanth is so bad as acacia, as it readily absorbs moisture, swells out, and allows the fluids of the stomach to penetrate to the active material; it should, however, be used sparingly as too much makes the pills retentive of shape; they may be readily stretched or squeezed in any given direction, but on removal of the influencing force resume their former shape.

Resinous extracts and gum resins when soft require drying materials, of which several kinds are in use. Sometimes acacia and tragacanth are used, but not with a happy result, or magnesia, of which a small quantity suffices (but should never be used, as it renders resinous matters hard and insoluble), powdered liquorice, phosphate of lime, and fine sifted sawdust are also used, and answer well.

When dry or hard, spirit, or if this gives them a tendency to fall, something of an emulsifying nature answers better, such as liquor potassæ or soap; for gum resins carbonate of potash has been recommended. Resins are substances capable of having their tenacity developed by some simple fluid, such as spirit or volatile oil, but as they are wholly soluble in these liquids masses so made would not be sufficiently firm. An emulsifying substance, such as soap, soft or hard, is more suitable, and renders them more soluble.

Non-adhesive substances, or those to which adhesiveness must be imparted, such as digitalis, conium, ipecacuanha, crystalloids, and mineral powders like calomel and tartar emetic.

The adhesive substances in use (and recommended) are various—honey, confection of hips and roses, glycerine of tragacanth, extract of liquorice, manna, bread crumb, and borotartrate of soda.

Confection of hips and roses, both containing sugar, exert a preservative influence on vegetable substances. The former is used in one official formula (pil. quinæ), probably chosen on account of its slight non-astringent acidity, which enables it to bind the quinine, but, even in the proportion the Pharmacopœia says is sufficient, would in many cases be far too bulky; glycerine answers better, and makes an exceptionally good mass. Confection of roses containing astringent matter is best fitted for astringent extracts, powders, etc.; it is used in several official pill masses, especially in those containing aloes, where firmness is desired as well as tenacity, and in those containing iron preparations. Its utility in these cases has been called in question, as it dries and soon leaves hard or crumbly masses; it certainly seems unfortunate that it should have been chosen in those masses containing iron, for the blackening of the masses shows that some action takes place. As a substitute for confection of roses in these masses, glycerine of tragacanth has been proposed. Without detailing these cases I would suggest that with the iron masses honey be used, as the sugar prevents the iron from oxidizing, it forms a fair mass which retains a brown colour.

Manna and crumb of bread are used with mineral powders, which are given in small doses, such as calomel and tartar emetic, and which require a diluent. Manna answers well and has no chemical activity, bread crumb becomes dry and hard.

Glycerine of tragacanth, by reason of its great tenacity and retention of shape, is in great favour as a dispensing excipient for vegetable and mineral powders, whose bulk will not admit of much excipient. Different forms are in use, varying from one part of tragacanth to five, seven, and nine of fluid, this latter being either glycerine alone, or diluted with water in about the proportion of two parts glycerine and one of water; that with water having a superior tenacity and being less hygroscopic is generally preferable; but with crystalloids (as sulphate of iron or zinc) that made with glycerine alone answers better.

I prefer, myself, to add to these substances glycerine sufficient to damp them, so as to let it have the full play of its solvent action, and then add tragacanth; in this way the materials may be more easily manipulated, and as a rule, a smaller quantity of tragacanth suffices. Borotartarate of soda is a substance that has been recommended for crystalloids and mineral powders, but my experience with it has not been very satisfactory. Resinous excipient has been recommended by Mr. Proctor for crystalloids, and in those cases in which I have tried it it answers well.

Oleo-Resins and Volatile Oils.—Balsam of copaiba being the type of the former, magnesia and hydrate of lime are the excipients recommended, as they form soaps with the resin which absorb the oil, but make such hard masses that they pass through the stomach into the fæces unacted upon. This seems to be the general action of magnesia with resins, therefore it is better avoided in all cases. Beeswax solidifies it, as also does spermaceti and cocoa butter. It is fortunately now never given in the pilular form, but as it is frequently given in the form of an electuary a little spermaceti will be found useful in absorbing the oil, instead of the large quantity of gum and sugar generally used.

Volatile oils also require absorbent and drying materials (with the exception of camphor). Bread crumb is useful for small quantities, magnesia and soap, or beeswax (which is objected to on account of its insolubility) combined with soap, phosphate of calcium or magnesia is used where larger quantities of oil are prescribed. I would here draw attention to the solidifying power of cocoa-butter and spermaceti, as I have found them useful in solidifying considerable quantities of oil when soap is combined with them, and having a low fusing point they are easily reduced by the stomach.

There are certain substances which could not be well tabulated with any of the foregoing.

Camphor, for which the orthodox excipients are castor oil, suet, and soap. Whilst speaking of camphor I would remark (without in any way advocating its use) on its aptitude for forming chloral into pills; one gr. of camphor making up forty grains of chloral.

Phosphorus, for which several solvents are recommended, such as suet, cocoa-butter, resin, and the mixture of balsam of tolu and wax of the Pharmacopœia. To their number I would add spermaceti. Phosphorus can be readily dissolved in this by simply melting and agitating them together in a test-tube, plugged with wool or tow; it should be allowed to thoroughly solidify before exposure to the air. The product can be readily powdered with a little spirit and it will be found very convenient for dispensing purposes.

With regard to manipulation time will not allow me to give more than a few (commonly known) general observations; such as the reduction of friable material (crystalloids, dry extracts, &c.) to powder, the thorough mixing of powders and the advisability of first moistening them when they have to be incorporated with tough hard extracts, and again the need of adding all the excipients at once with other substances. Any further information will be best acquired by practical experience with the various substances met with at the dispensing counter.

A lively discussion then followed in which Messrs. Naylor, Stuart, Hoskin, Wallis, Glover, Coles, etc., took part.

The thanks of the meeting was accorded to Mr. Marshall for his interesting paper. In consequence of the lateness of the hour, the reading of a paper by Mr. Stuart was postponed for a fortnight.

Several microscopes, elastic batteries etc., were exhibited and examined by the members and their friends.

PHILADELPHIA COLLEGE OF PHARMACY.

A meeting of the College was held on the 19th of November, the Vice-President, Mr. C. Bullock, in the chair.

Mr. Mattison called attention to some specimens of malt extract, showing the effects produced by long continued heat with atmospheric contact, in contrast with those obtained by evaporation by means of a vacuum pan. In the former case the heat attained was about 220 to 225° F., and the extract was of a dark-brown colour, transparent, very sweet, and evidently contained much sugar; in the other case, the temperature never rose above 130° F., and the extract obtained was light-brown, somewhat opalescent, less sweet, and contained nearly all the dextrin unaltered.

Professor Maisch said that dextrin was easily altered by heat, which accounted for the different appearance of the two extracts; but from this it did not follow that the officinal extracts, made by the pharmacist by the aid of judiciously applied heat, must necessarily be impaired by this treatment and inferior to those made in vacuo; while the colour did change from the alteration of the extractive, the virtues of the extracts were still retained.

Mr. Shinn stated that with proper and efficient refrigeration the evaporation of tinctures in the pharmaceutic still, introduced to the notice of pharmacists some twenty-five years since, proceeded much faster than in the open air with constant stirring of the liquid.

Professor Maisch showed the white incrustation of the branches of a shrub from Hot Springs, Arkansas; the incrustation, obtained by immersion, in the spring waters, consisted principally of carbonate of calcium, with traces of iron, some magnesium and notable quantities of lithium.

Mr. Shinn presented a specimen of "rock soap" from California, which, mixed with an equal quantity of soap, is employed there as a detergent; it was thought that in composition it was a silicious talc.

Mr. Neppach stated that a similar article was obtained on the coast of Oregon.

Mr. Bullock gave some account of the seeds of *Sophora speciosa*, in which an apparently new alkaloid has been recently observed by Professor H. C. Wood, jun., Philadelphia. One-half of a seed is said to be sufficient to produce delicious exhilaration, followed by a sleep lasting one or two days, and a whole seed is sufficient to kill a man. Through the kindness of a correspondent, in San Antonio, Texas, Mr. Bullock had obtained a sample of the seeds which he exhibited. They are somewhat irregular in shape, with a general disposition to an oval form, the large ones having a longitudinal diameter of $\frac{60}{100}$ of an inch, and a transverse diameter of $\frac{45}{100}$; their colour varies from pale to dark red; the testa is horny, from $\frac{3}{100}$ to $\frac{5}{100}$ of an inch in thickness; the interior is a white oily kernel, having a slightly bitter taste. The seed yields its colouring-matter to dilute but not to strong alcohol; nor has it yet been determined in what part the medicinal activity of the bean resides, but the probability is that it is in the testa. The seeds are contained in a pod of yellowish-brown colour varying from 1 to $2\frac{3}{4}$ inches in length, and enclosing from one to five seeds.

A sample of berries was exhibited by a member present to whom they had been sold as nutgalls; they were recognized by Professor Maisch as orange berries or small immature oranges.

Mr. Boring exhibited a specimen of fluid extract of glycyrrhiza, made by a process of insuccation, published by Mr. H. Biroth in the Chicago *Pharmacist*, his method being essentially the exhaustion of 16 troy ounces of the concised root with 4 pints of water containing 8 fluid ounces of glycerine, followed by another 4 pints of water, and the whole evaporated to the measure of a pint. The objection to this process was the unnecessary amount of evaporation required to bring it to the proper bulk.

This preparation induced considerable discussion relative to the best means of disguising the taste of bitter medicines, particularly that of quinia. Professor Maisch asked whether the members had noticed the occurrence of a precipitate on mixing aqueous solutions of quinia and ammoniacal glycyrrhizin. Mr. McIntyre stated that it had been noticed by him, and Professor Maisch suggested that this might in part account for the tastelessness of the mixture. Mr. Boring stated that it was very important to exclude all alcohol from the quinia mixtures where the taste had to be masked.

Parliamentary and Law Proceedings.

Salt in Beer

On Wednesday, December 19, at the Thames Police Court, James Scott, landlord of the Wellington beerhouse, St. Leonard's Road, Bromley, was summoned at the instance of the Metropolitan Board of Works for the Poplar district, for selling beer adulterated to the extent of 63 grains of salt to the gallon. Mr. Charles Young, solicitor, appeared for the prosecution on behalf of the Board; Mr. Besley, barrister, for the defendant.

William Harrison, one of the inspectors of nuisances to the Board, said that on Thursday, the 29th ult., he went to the Wellington beerhouse, St. Leonard's Road, Bromley, kept by the defendant, and asked his wife, who was serving behind the bar, for a pint and a half of porter. He was served, and then told the wife that he had purchased it to have it analysed. He also applied for a pint of fourpenny ale, but was told it was thick. A few minutes afterwards the defendant entered the house and went into the cellar, and shortly afterwards his wife served the witness with the liquor applied for. He divided it into three parts, and did the same with it as he had done with the porter.

Mr. William Young, analyst to the Board, said that on the 29th ult., he received a sample of porter and ale from the last witness to be analysed. The certificate produced was his, and he there stated it was adulterated to the extent of 63 grains of salt per gallon. In cross-examination by Mr. Besley, the witness said he had never made any beer, but had seen it made. He did not know how much salt there might be in hops. He was not aware of the natural quantity of salt in Burton water. He found that a pot of Truman and Hanbury's strong ale contained 16 grains of salt.

Mr. Charles Heisch, consulting chemist to the Corporation of London, said he found 66 grains of salt to the gallon in the porter, and 70 in the ale. He did not say its presence would be injurious to health. He could not tell the quantity of common salt or the amount of hops used in a gallon of beer.

Laurence Burleigh, head brewer at Truman and Hanbury's, Spital Fields, said he had been in their service over 30 years, and had sole charge of the brewery department. All articles used in the brewery department would come under his personal cognizance. Salt was not bought or used in any shape or form. Saccharine matter was imported, and the duty paid to the Excise. Breweries were always open to inspection. Ale contained hops, saccharine matter, and water. He found some ale of the same brewing as that which had been sold to the defendant. That brewing he superintended. There was no salt put into it, and he did not dare to use bad water. Saccharine matter was not used in ale to the extent it was in porter. No salt whatever came on the premises for brewing purposes. In reply to Mr. Young, the witness said the firm used Hartley's deep-well water and the East London water. He had heard that on some water they had used being analysed three and a half grains of salt to the gallon had been detected. In answer to the magistrate the witness said he had heard country brewers used salt to some extent, but London brewers did not. If it were used to a large extent, it would spoil the beer. The quantity of malt they used was rather more than one half, the other half was saccharine matter.

Mr. Dugald Campbell, an analyst, said he was well acquainted with the ingredients used in brewing beers, and he was surprised at not more than 63 grains of salt being found in the samples referred to. The salt was attributable to the hops, malt, and saccharine matter.

Dr. Henry Bartlett gave similar evidence.

John Scott, the defendant, was then sworn, and said he did not put a particle of salt in the beer.

Mr. de Rutzen said that before he decided the case he wished to see the invoice delivered with the beer to the defendant. He adjourned the case for two weeks.—*Times*

Review.

Year Book of Pharmacy, comprising Abstracts of Papers relating to Pharmacy, Materia Medica, and Chemistry, contributed to British and Foreign Journals, from July 1, 1876, to June 30, 1877. With the Transactions of the British Pharmaceutical Conference at the Fourteenth Annual Meeting held in Plymouth, August, 1877. London: J. and A. Churchill. 1877.

Many readers of this Journal will be pleased to learn that within the next few days they may expect to be in receipt of the green-covered 'Year-Book,' if indeed it has not already reached them. The new volume corresponds in so many respects to those of former years, and Mr. Siebold's work is now so familiar to the members of the Conference, that the time has passed when special criticism would be necessary in the absence of any novel feature; unless indeed it were to repeat in spirit the criticisms of former years.

The "Introduction," to which probably the attention of most will be first turned, is an ably written *résumé* of the pharmaceutical literature of the year specified, as far as it is represented in the 'Year-Book; in fact, it is good enough to raise the desire for more, and also the inquiry whether there is any inflexible rule that limits the Introduction to sixteen pages, neither more nor less. We say the literature as far as represented in the 'Year-Book,' because this is scarcely done so exhaustively as in former years, unless, contrary to our impression, pharmaceutical literature is falling off in quantity or quality, or both. We notice no diminution in the usual fulness of the abstracts, which, by the way, are as good as ever, whilst some articles are noticed that did not appear until September last, or three months beyond the date on the title-page; nevertheless, this section of the 'Year-Book' has fallen off from 404 pages in 1874–75 to 341 in 1876–77. Of course there may be ample reason for this in the editor's judgment as to how much of the ephemeral literature of pharmacy should be placed on record in the more condensed annual volume. If, however, it be due to a desire to confine the volume within certain bounds, we think there are many pages of lists of names, etc., that might be better excluded. For instance, 67 pages, or more than one-tenth of the whole volume, are devoted to recording the names of the members twice over, and a whole page is sacrificed to the names of twelve exchange journals, one of which happens to have ceased to exist twelve months since.

The 'Transactions' have been seen through the press by Professor Attfield with his usual care, and, on the whole, the new 'Year-Book' worthily keeps up the reputation of the series.

Dispensing Memoranda.

We are constantly in receipt of requests for aid in overcoming difficulties met with at the dispensing counter, and so far as lies in our power such assistance is always rendered. But it has been suggested that instead of a reply being given among the Answers to Correspondents, where frequently it stands as an individual opinion, intelligible to only one person, it would be more widely advantageous were such questions published, with an invitation for suggestions as to their solution. We therefore propose as an experiment, to devote a certain amount of space every week specially to these and other "Dispensing Memoranda." In order to assist our younger brethren as much as possible, considerable latitude will be given to the definition of what may be considered to be a difficulty, but it is evident some discretion will have to be exercised in excluding trivial matter. Each note will bear a number, which it is requested may be quoted in all correspondence respecting it. Opportunity will be taken every month of calling attention to the more important points brought out in the various discussions.

[46]. Ung. Galeni.—The formula of the French Codex for Ceratum Galeni, or Galen's Cerate, is as follows:—

℞	Aquæ Rosæ	3 oz.
	Ol. Amygd. Dulc.	4 oz.
	Ceræ Alb.	1 oz.

Heat in a water-bath the wax, oil, and half the rose-water, until the wax is melted; pour into a warm marble mortar and stir the mixture continually. When nearly cold beat in briskly, little by little, the remainder of the water.

Walter A. Powell.

[46]. UNG. GALENI.—In answer to query No. 46, in *Pharmaceutical Journal* of this date, "Ung. Galeni" is cold cream.

J. B.

Cheltenham, December 22, 1877.

---

[46]. UNG. GALENI.—An Apprentice will find "Ung Galeni" to be an old-fashioned term for "cold cream," (*vide* Beasley, "Ceratum Galeni").

Maidstone, Dec. 24, 1877. G. P. L.

---

[46]. UNG. GALENI.—The following is a formula for Unguentum Galeni, taken from Dr. Liveing's book on 'The Treatment of Skin Diseases.'

℞. Ol. Amygdalæ . . . . lb. j.
Ceræ Albæ . . . . oz. 4.

Melt, pour into a warm mortar, and add gradually

Aquæ Rosæ . . . . oz. j.

It should be very light and white.

E. T. G.

---

[49]. If H. J. H. will put his Liq. Ferri Mur. into the bottle, add the water and the Sp. Chlorof., shake, and then add the Liq. Ammon. Acet., and again shake, he will have a clear mixture. Probably his Liq. Ammon. Acet. contains excess of ammonia which would precipitate the iron as hydrate, and of course give a cloudy appearance to the mixture.

PHAINO.

---

[49]. There is nothing to prevent the mixture being clear if the preparation answer the B. P. tests. If the Liq. Ammon. Acet. is alkaline the result will be a turbid mixture. I have dispensed the prescription and never failed to obtain a perfectly clear mixture.

M. P. S.

---

[50]. EXT. ERGOTÆ LIQ.—In answer to query No. 50, I have no doubt that "Young Pharmacist," if he examines the crystals obtained from the ergot extract, will find them to be acid phosphate of potassium, and if he refers to the *Pharmaceutical Journal* of April 10, 1875, he will observe that in a paper on liquid extract of ergot I have made reference to the formation of these crystals.

I may here mention that I consider the presence of these crystals indicate the good quality of the preparation and I have never failed to obtain them in my home-made extract.

A. W. GERRARD.

University College Hospital.

---

[50]. EXTRACTUM ERGOTÆ LIQUIDUM.—The crystals found at the bottom of the bottle containing the extract consist of Potassæ Sulphas. The cause of their presence is the digestion of the ergot with water at 160°; they are not to be found, or only traces of them, in the liquid extract used in France, where it is prepared with cold water.

HUGO W. LANGBECK.

---

[51]. A prescription, of which the enclosed is a *verbatim* copy, was brought to me to be dispensed.

On examination I concluded that the *ounce* of liquid extract of ergot ordered was merely a slip of the pen, therefore I only put a *fluid drachm* into the mixture.

On communicating with the physician next day, he informed me that he very frequently gave ergot in one ounce doses, as *per* prescription, and that there was no error on his part.

I shall be glad if any reader of the Journal will inform me through its columns, if he would have dispensed the prescription as the medical man had intended.

℞ Ext. Ergotæ Liq. . . . . ℥j.
Tr. Opii . . . . ʒj.
Aquæ . . . . ad ℥ij.
M. ½ statim sumend.

SYR. FERRI IODIDI.—Having found a difficulty in having syr. ferri iodidi constantly in good condition, owing to the uncertain demand for it in a country business, I, about this time last year, tried an experiment, and having succeeded in my object, send you the result in the hope that, if sufficiently important to obtain publicity, it may be useful to others.

Having prepared a supply of the syrup, according to the formula in B. P., I filled three 2oz. bottles with the product while hot, and numbered them 1, 2 and 3. No. 1 I placed in a situation where it was at intervals exposed to direct sunlight. Nos. 2 and 3 were put in the dark, the former cork upward, the latter inverted. After the interval of twelve months I find, No. 1 colourless and with a dark deposit; No. 2 (cork upward), has a deep iodine colour; No. 3, of a pale green colour except a slight red tint, where the syrup was in contact with the small quantity of air in the inverted bottle, and which, on being shaken was not sufficient to perceptibly tint the quantity of syrup.

The result of my trial is that I shall in future store syr. fer. iodid. in small vials of the long series (bottling it while hot), and keep the bottles inverted in the dark, and I expect always to have the preparation in good condition.

When I wrote colourless of No. 3, I referred to the absence of red colour; No. 1 was as nearly as possible white.

T. STOKOE.

Clare, Suffolk.

LIN. HYDRARG, B.P.—The unsatisfactory appearance of the Lin. Hydrarg., B.P., led me some time ago to try to invent a preparation which would combine the character of a stimulating liniment with the presence of mercury in solution in oil. I then found that by precipitating a solution of perchloride of mercury of suitable strength with an excess of sapo durus an oleate was obtained which readily dissolved in oil. A solution of this salt in Lin. Camph. would probably answer as well as the Lin. Hydrarg, B.P., while at the same time it would be easier in preparation, more uniform in strength, and unobjectionable in its appearance.—"EXPERIENTIA DOCET."

THE RECENT PROSECUTIONS UNDER THE PHARMACY ACT.

Sir,—In inviting opinions upon the case reported in the Journal, p. 496, Mr. Cock sets a somewhat difficult task. The press is presumably impartial; the defendant's letter may be considered, without offence, *ex parte*, and the facts are variously stated by the two authorities. The charge reads that the defendant "did sell a preparation of poppies made up in a compound called 'Syrup of Fox's Lungs;'" the letter states that a bottle containing syrup of poppies was produced, and Mr. Cock does not dispute the identity of the material. The report states that two witnesses swore to having seen a bottle labelled "poison," but failed to identify it; the letter states that they saw a "poison" label on the bottle, the difference in the grammatical "article" being very material to the case. Syrupus papaveris and syrupus rhœados may be equally "syrup of poppies" in the eye of the law, and may alike require to be labelled "poison." There is an ambiguity in the report and the letter which leaves us in doubt which article was sold, but as nothing appears to have been said about the comparative inertness of the syrup it may be inferred that syrupus papaveris was supplied, although that is not the preparation usually sold for "Syrup of Foxes' Lungs," at least in these neighbourhoods where it is asked for about once in a blue moon. The fact may make no difference in law but it might influence "opinions."

The case shows the insufficiency of separate "poison" labels, particularly for syrup of poppies, which customers will often request may not be labelled so ominously, and when the word "poison" is placed in the centre of a "slip" it is often scratched off, and when separate is sure to be removed. Baby-farmers and mothers who administer narcotics do not like the fact to be placed so nakedly before their own and their friends' eyes.

Indirectly, this incident reads a lesson upon the not unusual but slovenly habit of affixing label upon label, often very slightly adhesive and easily removed. The mother has a mixture, the father a dose of spirit of nitre, the baby again some syrup of rhubarb, and finally syrup of poppies, and four labels, three of which may be easily removed by busy little fingers, testify to the successive uses of the bottle. I have peeled off five labels one after another before now, either of which being removed would bear false witness to the contents of the bottle, and might possibly get somebody into unnecessary trouble.

Taking the facts as Mr. Cock states them, they illustrate the manifold dangers to which a chemist is daily exposed, for we have no guarantee that medicines most carefully dispensed may not be transferred for convenience (the bottle proving perhaps very useful for some other purpose) into another with a very inappropriate label. A short time ago I took up a bottle in a house evidently containing a very poisonous composition, but to which a clean label was still attached, directing a sixth part to be taken three times a day. Our reputation hangs upon a slender thread sometimes. A few months since I was called hurriedly to a person who had taken poison. A physician had been applied to and the label shown to him, and he had referred the parties to the chemist. A woman had taken from the corner of a cupboard a parcel, which she supposed to contain Epsom salt. She did not read the label, the appearance was sufficient for her, and she took a dose and gave a dose to her daughter, and threw the paper into the hearth. Beginning to feel unwell she searched for the paper and found it labelled "Sulphate of zinc—poison." The packet of Epsom salt was still in the cupboard; but despite its presence there, if the label of the salt taken had been thrown into the fire instead of the hearth and had got burned, to say the least, I should have fallen under the suspicion of having supplied a wrong article and, in the event of serious consequences might have had a censure with its baneful effects. *Per tot discrimina rerum*—with increasing dangers and diminishing rewards—the chemist of to-day follows his difficult calling. We need extraordinary care and mutual help.

HENRY H. POLLARD.

Ryde, December 24, 1877.

Sir,—Mr. Cock's case does seem a hard one, and tends to show the necessity of sending out all poisons in properly labelled bottles.

Could not some of our enterprising glass houses introduce bottles of various sizes—either blue or black—with the word "Poison" in raised letters upon them? If this could be done in white upon a blue or black ground so much the better, but the other would suffice to meet the requirements of the Pharmacy Act.

WM. ROBERTSON.

Elgin, Dec. 22, 1877.

A SUGGESTION.

Sir,—I was highly gratified in reading over the account of the proceedings at the Edinburgh Assistant Chemist's Supper to find that the desirability of organizing a permanent association had been mentioned by one of the speakers. This would certainly be a step in the right direction, as such an association by bringing the assistants into closer contact with each other could not fail of being attended with highly beneficial results. The many grievances connected with our profession of which we frequently complain, including those all important too long hours and no time for study, cannot be remedied until as the result of having an association there will exist a better understanding between the assistants, and efforts put forth for their redress be more united. The status of the Edinburgh assistants might also be adduced as another strong reason for promoting such an association. It is a matter of surprise to many connected with and interested in our trade, that in such an important city as our own, at once the capital and centre of pharmaceutical knowledge of Scotland, there should not have been organized long ago an association worthy the name and prestige of Edinburgh assistants. For these and many other reasons therefore it is very much to be desired that, the subject having at length been mooted, some of our older and more competent members will take the matter in hand, and thus place the Edinburgh assistants on at least an equal footing with their brethren in Glasgow, Manchester, Leeds, etc., where associations of the same nature have not only flourished, but exceeded the most sanguine expectations of their promoters.

J. F.

Edinburgh, December 24, 1877.

SANGUINAIRE OR THÉ ARABE.

BY JOHN R. JACKSON,

Curator of Museums, Kew.

From time to time new products of the vegetable kingdom come to light, and new applications of different parts of plants are brought to our notice. New pharmaceutical products have of late been by no means rare; whether, however, these products have or have not any real value is a question upon which authorities are for the most part entirely disagreed. It is well known that the leaves of many plants are applied in different countries for making infusions for use as tea, and indeed are generally known as tea. Some of these have been before referred to in previous volumes of the *Pharmaceutical Journal*, but a sample of a substance new to me has recently been received at the Kew Museum under the name of "Sanguinaire or Thé Arabe." This tea is recommended for use more as a medicine than as a refreshing beverage. It is prepared at L'Arba in Algeria, but is also sold in Paris, by M. Hugot, 19, Rue Vieille-du-Temple, as well as by all druggists. It is neatly done up in packets, on the front of which is a description of its virtues in French, and similar description occurs on the sides in English, German, Italian and Arabic. The English description is as follows:—

'ALGERIAN TEA.—The plant which is used to make this preparation grows on the arid slopes of the Atlas mountains. The flowers and some of the small leaves are dried, and the infusion made from them has a pleasant taste and is decidedly beneficial in its action in all cases of colds, catarrhs, and chest affections. Algerian tea is exceedingly useful in alleviating fevers and in contributing to the enriching of the blood. It is much recommended to persons suffering from a feeling of oppression at the chest, or from any difficulty of digestion. Its daily use after meals gives tone to the organs, and regulates all the functions of the body. A tea spoonful is sufficient to make a breakfast cup of the infusion."

With regard to the medicinal properties, if any, of this tea, I am quite unable to give an opinion, but so far as its "pleasant taste" is concerned my experience of a teaspoonful in a breakfast cup of boiling water, as directed, resulted in an infusion with scarcely any colour and but very little smell, reminding me rather of boiled hay. The flavour, which was not very marked, was herby rather than aromatic. As found in the packets, this tea is composed simply of what at first sight seems to be the flower-heads of a species of *Helichrysum* or some allied composite, but upon closer examination the large silvery bracts are found to belong to the flowers of a species of *Paronychia*; and upon still closer examination and comparison the species appears without doubt to be *Paronychia argentea*, Lam., a plant widely distributed through the Canary Islands, Spain and the Mediterranean region. Though the name of the plant furnishing this tea is not referred to on the packet, a private letter that accompanied the sample forwarded to Kew, states that two species of *Paronychia* are used, namely *P. argentea* and *P. nivea*, and that the term "Thé Arabe" by no means distinguishes this particular kind, inasmuch as it is given also to infusions of *Globularia Alypum*, *Cistus albidus*, and *Verbena triphylla* or *Aloysia citriodora*.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 485.)

ASCLEPIAS CURASSAVICA.—*Local name*, KURKI.

Common in gardens, and in some places has run wild. It has a woody branching root, with light brown bark and numerous fibres, wood white, bark thin. When fresh it exudes a milky juice. The taste is bitter and somewhat acrid. A section of the root bark placed under the microscope shows from without inwards, 1st, a suberous layer; 2nd, several rows of large cells containing conglomerate raphides, with starch and granular matter; 3rd, a vascular zone, two or three large dotted vessels being situated at the cambium end of each medullary ray where it projects into the bark.

LEEA sp.—*Local name*, GEENO.

This is the root of a stout undershrub with large pinnate leaves, very common in Goa. The roots are long and straight, branched; the bark is slightly scabrous, dark brown externally, striated; internally it is red and striated; the wood is porous, and shows very distinct medullary rays. Microscopic appearances not in any way remarkable. The bark has an agreeable astringent taste; the wood appears to be inert. Geeno is the Ratanhia of the Portuguese at Goa, and has a considerable resemblance to that drug. It is administered in diarrhœa and chronic dysentery.

LAURACEÆ, Gen. ? Sp. ?—*Local name*, MIRIO.

A tree. The leaves have a pleasant odour of cinnamon. The bark is very scabrous and of a rusty brown colour; when freshly removed it is dirty white and very mucilaginous internally, but soon becomes of a dull brown colour from exposure. Microscopic examination shows no remarkable peculiarity. The liber cells are very large. The parenchyma is composed of mucilage cells. The taste is feebly bitter and very mucilaginous; when the dry bark is soaked in water the inner surface becomes covered with a thick mucilage like white of egg. Mirio is used in Goa as a demulcent and is given in bowel complaints; its properties very closely resemble those of "Maida Lakri," the bark of *Tetranthera Roxburghii*.

ACONITUM sp. ?—*Local name*, JUDWAR.

The history of this drug is beset with many difficulties on account of the vague meaning of the term Judwar, the name by which it is generally known, and appearing properly to mean zedoary. Under judwar the author of the 'Makhzan ul Adwiya' gives Antila as the Arabic name, and Saturyoos as the Greek. The Indian name, Nirbishi, he explains as Nir the antidote to, Bish the poison.

He describes five kinds—

1st. Khatai; black externally, violet brown internally; scorpioid, knotted, tasting sweetish at first, afterwards very bitter.

2nd. Outside and inside brown or yellowish-brown, bitter, scorpioid.

3rd. Outside and inside black; when rubbed down it has a bluish tinge; bitter. This, and the second kind come from Thibet, Nepal, Morung, and Rungpore.

4th. Blackish; bitter; size of an olive; comes from the Deccan Hills.

5th. Spanish, called Antila; black, soft, very bitter.

Of these the first kind is said to be the best.

It would appear, then, that the term judwar has at different times been applied to various tuberous roots supposed to have alexipharmic properties, and that in India it is applied to the root of an aconite known from an early date to the Hindus as nirbishi. Native medical works abound in absurd stories concerning this article and its wonderful power as a tonic and alexipharmic; it fetches a high price, and is generally kept in metallic mercury to preserve it from insects. What is considered to be genuine judwar in Bombay consists of small black-brown tubers, some irregularly ovoid, some conical, seldom more than one inch long and half an inch in diameter; they are somewhat wrinkled, and bear a few horn-like projections, which are the remains of rootlets; at the crown there is a scaly leafbud. When in good condition the tubers are softish, and cut like a piece of dry liquorice extract, the colour being a uniform brown-black throughout. To the naked eye the cut surface appears structureless; it has a somewhat fruity smell, and is very bitter. A transverse section examined under the microscope shows a dark brown epidermis, composed of compressed cells, an outer ring of parenchyma, the cells of which contain starch granules, and much brown granular matter; within this from 5—10 vascular bundles, connected together by a cambial zone, made up of several rows of small dark brown cells; the position of the bundles is very irregular, consequently the zone has a peculiar waving course. In the central portion of the tuber starchy parenchyma is again met with; the starch has not been affected by heat. Judwar comes to Bombay from Delhi; it is worth about rs. 10 per pound, but is retailed here for double that price.

COPTIS TECTA.—*Local name*, MAMEERAN.

Two distinct varieties of this drug are met with in the Bombay market. The kind most esteemed is a yellowish rhizome as thick as a crow-quill or larger, having a few spinous projections where rootlets have been broken off. The whole rhizome is jointed; but at the upper end the joints become much more marked and a stem-clasping petiole often remains attached to each of them. The second kind is as thick as a goose-quill and covered with thin wiry rootlets. It often branches at the crown into two or three heads, which terminate in a tuft of leaf stalks that are crowded together and never separate as in the first kind. The rhizomes of both kinds are contorted and break with a short fracture. The centre is spongy and the surrounding portion bright yellow and woody. Taste purely bitter. The first kind corresponds with the description of Coptis root in the 'Bengal Dispensatory,' the second with the description of that drug in the 'Pharmacographia' and with all the descriptions of *Thalictrum foliolosum.* The bark of the second kind is much the thickest, and is softer and more corky than that of the first; in both bundles of orange-coloured sclerenchymatous cells are present, and the medullary rays contain starch. The wood is arranged in distinct wedge-shaped bundles, round a central parenchymatous portion having a structure similar to that of the inner cortex. Both kinds of the drug come to Bombay, from China *viâ* Singapore in bulk. The first is worth $3\frac{1}{4}$ rupees per pound. The second 2 rupees.

(*To be continued*).

ÆGLE MARMELOS OR BAEL.*

BY SIR J. FAYRER, M.D.

A short notice of Goa powder had the effect not long ago of attracting attention to, and I hope of extending the utility, in this country, of a remedy much used and valued in India in the treatment of certain forms of skin diseases. I should be glad if a similar result were to follow notice of another Indian remedy that would, I think, also be appreciated and valued were it properly tried—I allude to the ægle marmelos or Indian bael fruit. Of course, I know it is now to be found in most English dispensaries, and that it is perfectly well known (by name) to physicians in this country; but this is in the dry form, when it is old and desiccated, the essential oil and aroma dissipated, and all the merits of freshness gone, in which condition it is probably inert,—or in the form of the fluid extract of the Pharmacopœia, of doubtful efficacy.

Steamers come from Bombay in twenty-six days, and there is no reason that I know of, why they should not bring the bael fruit quite as fresh and fit for use here as in India; and it is only when fresh and nearly ripe that it is of any real value. In this state it would keep for months, and would be useful in a variety of forms of bowel complaint as in India, especially in chronic diarrhœa and dysentery, or in irregular action of the bowels, when it not unfrequently is said to be as beneficial in constipation as in the opposite condition. Given in the form of sherbet it is pleasant and refreshing, soothing and demulcent, from its aromatic and astringent properties, and from the viscous character of the mucilage that surrounds its numerous seeds.

It is hardly necessary to say that the bael is an orange with a ligneous rind in which there is much essential oil; that its pulp is astringent, and contains numerous seeds embedded in the tenacious mucilage. It is common in India, ripens in the autumn, and could be easily brought to England in the imperfectly mature condition. The bael has frequently been described, and is well known to medical men in India as a valuable remedy—not, as sometimes supposed, in the treatment of acute dysentery, but in certain chronic forms of that and other bowel complaints. Martin, Cleghorn, Grant, Waring, Jackson and others, have spoken of its good effects. Sir R. Martin in the *Lancet* of 1853, and Mr. A. Grant in the *Indian Annals* of 1854, call attention to it. The latter says, "It is useful in habitual constipation, taken early in the morning, and also in the irregularity of the bowels attended by periods of looseness alternating with constipation as is so often seen in certain seasons in India. It has been given with good results in mucous diarrhœa, chronic diarrhœa, and dysentery." In fact, many Indian physicians have spoken highly of bael for such purposes, and to a great extent I can confirm their opinion—at all events, quite sufficiently to say that it is a useful and pleasant remedy for some forms of bowel complaint in their chronic conditions; and to express my belief that it would be a valuable addition to our resources in the treatment of similar diseases here.

The preparations of bael are sherbet, and conserve or marmalade—both pleasant to take.

The officinal preparations are the "liq. belæ" liquid of the Pharmacopœia, and the dry fruit. The non-officinal forms are the best.

For further information on the subject I would refer to the *Indian Annals of Medical Science of* 1853, pages 223 to 234; in articles by Dr. Cleghorn and Mr. Grant, giving a full description of the fruit, its preparations, and its properties, and to a paper by the late Sir R. Martin in the *Lancet* of 1853. I think that the facility with which it could, in these days of rapid communication, be imported, may induce some one to try the experiment.

---

The Pharmaceutical Journal.

SATURDAY, JANUARY 5, 1878.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

1877.

"*Le Roi est mort! Vive le Roi!*" The old year, one thousand eight hundred and seventy-seven, has become as a tale that is told, and the thoughts of most men will naturally have "gone to salute the rising morn." Nevertheless, it is our lot to look backward for a few moments and once more to attempt to transcribe the story of a past year of pharmacy in Great Britain. Such a task may not appear to be very ambitious, but we hope the work will prove as useful as some that aspires higher and takes a wider range.

"Little avails it now to know
Of ages passed so long ago,
Nor how they rolled;
Our theme shall be of yesterday,
Which to oblivion sweeps away
Like days of old."

Not much can be said of what may be called the political history of pharmacy in this country dissociated from the history of the Pharmaceutical Society as represented by its Council. It is no exaggeration to say that every subject of interest to British pharmacists comes under the consideration of that body, and that, although sometimes it cannot do all that is possible in the minds of its irresponsible advisers and critics, it exercises continually an extensive and beneficial influence upon the events that make pharmaceutical history. The Council has during the past year received two new members, Mr. WALTER JOHN CHURCHILL, of Birmingham, and Mr. THOMAS PRESTON GOSTLING, of Diss, elected by the Society in the place of Mr. DANIEL FRAZER, of Glasgow, and Mr. SAMUEL LLOYD STACEY, of London. This has been the only change in the executive of the Society, the President, Mr. JOHN WILLIAMS, the Vice-President, Mr. WILLIAM DAWSON SAVAGE, and the Treasurer, Mr. CORNELIUS HANBURY, having been elected to fill their respective offices for another year.

Nearly the first subject of discussion by the Council, at its January meeting, was one of the Pharmacy Acts to which it owes its existence. Being of opinion that the Act of 1868, as applied to public companies, had to some extent become a dead letter, Mr. HAMPSON proposed that a Committee should be appointed to consider and suggest amendments that appeared desirable so that the Council should be prepared to profit by any opportunity that might arise during the forthcoming session of Parliament to secure its amendment. After considerable discussion, the proposition was accepted so far that the Parliamentary and Law Committee was requested to appoint a small sub-committee to consider the provisions of the Act with a view of preparing or suggesting any alterations which it might deem expedient. The sub-committee appointed consisted of Messrs. BETTY, GREENISH, HAMPSON, HANBURY, HILLS and SANDFORD, but no legislation being proposed in Parliament that furnished the required opportunity, the report of the sub-committee did not come before the Council until November, and it is still under consideration.

Early in the year, too, the presumed laxity of the Council in carrying out the provisions of the Pharmacy Act led to a lively little interlude. The Chemists and Druggists' Trade Association, having been at the trouble and expense of collecting evidence which its executive considered to be conclusive as to breaches of the Act, an intimation of this fact was forwarded to the Secretary of the Pharmaceutical Society, together with an inquiry as to the employment of the Society's Solicitor that was as suggestive in its way, and as open to misconstruction, as the celebrated experiment of Prince HENRY with his father's crown. The Council of the Pharmaceutical Society, however, showed no disposition to abandon or to delegate the powers confided to it by Parliament, and passed a resolution that it would not instruct any solicitor to sue for penalties for alleged infringements of the Pharmacy Act until the evidence in support of each charge had been considered and found sufficient by the Council itself. On the other hand the executive of the Trade Association subsequently passed a resolution to the effect that its letters had been misunderstood, and that there had been no intention of forcing on the Pharmaceutical Council any cases, but simply of supplying such evidence as might be deemed necessary, if the Council were willing to make use of it.

Probably the misunderstanding is best explained in the light of what took place subsequently at the Annual Meeting of the Pharmaceutical Society, when Mr. CHURCHILL, of Birmingham, expressed his opinion that there existed a strong feeling that the practice of first warning unregistered persons against whom evidence of a breach of the Pharmacy Act had been procured, instead of proceeding against them at once, had acted prejudicially. The PRESIDENT explained that the Council had not thought it advisable to carry out the Act with any appearance of vindictiveness, and had therefore instructed the Secretary, when he received information of offences against the registration section of the Pharmacy Act, to write to the inculpated person, if his name was not on the Register, to know why he was carrying on the business of a chemist and druggist, and to warn him against doing so illegally. Occasionally the alleged offender so written to proved to be acting within his right, but if not, and the warning was disregarded, a prosecution was commenced. The meeting appeared satisfied with the explanation, and the subject then dropped. At the July meeting of the Council, however, it was revived on the presentation of a report from the Law and Parliamentary Committee, referring to a letter the Secretary had received from Mr. CHURCHILL, who had meanwhile become a member of the Council, in which, in respect to some alleged infringements of the Act, particulars of which had been sent up by the Trade Association, he expressed a hope that proceedings would be taken without sending the usual premonitory letter. The report referred also to a motion to the same effect which had been made in committee by Mr. CHURCHILL, and lost. The rejection of this part of the report was moved by Mr. HAMPSON and afterwards by Mr. BROWN, whilst Mr. SANDFORD moved that all reports of infringements should be brought first to the notice of the Law and Parliamentary Committee, and that it should rest with that Committee to send premonitory letters to alleged offenders or not, at its discretion. Mr. MACKAY pointed out that the Secretary only sent letters to persons who were complained of for the first time, whilst the majority of the members considered there was nothing in the special circumstances then under consideration necessitating a departure from the rule that had worked well for two years. The amendments were consequently lost, a result that evoked an expression of regret from the executive of the Trade Association.

It should be clearly understood that there are two classes of offences under the Pharmacy Act, 1868, and that the above discussion related to the class of offences against the fifteenth section of that Act, which confines the use of the titles pharmaceutical chemist, chemist and druggist, etc., and the retailing and dispensing of poisons to registered persons. In these cases the liability to pay a penalty of five pounds accrues absolutely upon the commission of the offence, and that sum is recoverable in the ordinary way as a small debt, without reduction, by the Registrar under the Act for the time being, and by him alone. It is found in a large proportion of the cases that a warning is sufficient to secure a cessation of the offence, and as this result and not the recovery of penalties is the object sought by the Council, no further proceedings are then taken. When the offence is persisted in, however, the penalty is applied for, and sometimes this is paid without further proceedings, whilst at other times the penalty has to be recovered through the intervention of a court. The other class of offences under the Act is against the seventeenth section, relating to the registration of sales and the labelling of poisons. In these cases any person is at liberty to institute the prosecution, and the amount of the penalty—a sum not exceeding five pounds for a first offence or ten pounds for a subsequent one—has to be decided by a magistrate and is dependent upon a conviction. During the past year five such convictions, in which the police have been prosecutors, have been recorded in this Journal: two for the sale of an article included in the first part of the poison schedule without entering the sale in the poison book, and three for the sale of a preparation of laudanum without a poison label. Besides these the Trade Association has been successful in obtaining three convictions for the sale of poison not labelled with the name of the actual seller, in one case the magistrates remarking that though with regard to a mercantile house trade could be carried on under an assumed name, they thought the Act of Parliament made it very clear that a person who sells a poison should put his own name on the label. In consequence of unacquaintance with the distinction above pointed out, in respect to the two classes of offences, magistrates have during the year twice imposed modified penalties that they had no right to diminish, or even to inflict, at the suit of the police who are not entitled to prosecute under the fifteenth section.

The inconsistency of fining a chemist and druggist for selling a pennyworth of narcotic cordial without a poison label, whilst the most ignorant huckster is allowed to sell an unlimited quantity providing it bears the patent medicine stamp, has been frequently commented on, and in April a communication was received by the Council from the Hull Chemists' Association urging that the sale of all articles containing a scheduled poison, although covered by a patent medicine stamp, should be strictly confined to registered chemists and druggists.

Whilst referring to the poison schedule it may here be recalled that at its November meeting the Council by virtue and in exercise of the powers conferred on it by the Pharmacy Act, resolved that chloral hydrate and its preparations should be deemed a poison within the meaning of the Pharmacy Act, 1868, and included in the second part of the schedule. The prescribed approval of the Lords of the Privy Council appeared in the *London Gazette* for December 15.

Closely associated with this subject was another that occupied the attention of the Council early in the year. The Pharmacy Acts provide that all sums of money arising from the recovery of penalties under them shall be paid as the Commissioners of Her Majesty's Treasury shall direct. As the carrying out of the Acts by the Pharmaceutical Society on behalf of the public involves an expenditure far in excess of the penalties recovered it had been assumed that they would be left in possession of the Society. Rather unexpectedly, however, an order was received from the Treasury to pay over all the penalties recovered under the Acts since they were passed. A deputation was thereupon appointed to lay before the Commissioners of the Treasury the views of the

Council upon the subject, and in February a communication was received stating that the Council was at liberty to retain these penalties.

But perhaps the subject that has occupied the largest share of the attention of the Council and of chemists and druggists generally during the year has been the prolongation of the attempt made by a certain section of the medical profession to interfere with the right to prescribe. The subject was not a new one, having been considered in the year 1876, when the Council announced that it was prepared to consider the case of any chemist and druggist threatened with vexatious proceedings, and, if the circumstances warranted, to provide for his defence. In March a suit which promises to become a notable one in the history of this dispute was instituted at Nottingham, against a chemist and druggist named SHEPPERLEY, to recover a penalty of twenty pounds, for the offence of having acted as an apothecary, he being unqualified. The case was defended by counsel instructed by the Trade Association, but notwithstanding that evidence was given as to the custom prevailing before the passing of the Apothecaries Act which might have been supposed to bring the practice in dispute within the operation of the section reserving to chemists and druggists all previously existing rights, the County Court judge gave judgment against the defendant. Upon this decision notice of appeal was immediately given. Other similar prosecutions have since been commenced in various parts of the country, but the decisions have been postponed until this appeal has been decided.

The fact that the Annual Report of the Council, issued shortly afterwards, contained no allusion to the Nottingham case, or even to the subject, evoked criticism at the Annual Meeting of the Society from some members who appeared to fear that this silence was a sign of apathy. Additional pungency was imparted to the discussion through the appearance the day before of a Bill that had been introduced into Parliament by the East London Medical Defence Association, containing a clause which would have made any person not registered under the Medical Act who practised medicine or surgery for gain liable to a penalty of twenty pounds. The PRESIDENT was able to show that the Council was alive to the gravity of the situation, it having already had the Bill under its consideration, whilst the Solicitor probably defined with tolerable exactness the course the Council had decided to take on the general question, in advising that a stand should be taken on "counter practice as a necessity of the case for chemists and druggists and the public convenience," and expressed his conviction that if there were a well conducted fight on this point, no chemist and druggist who kept within his own doors had anything to fear. This opinion as to the Council's position is confirmed by the fact that in August, when Messrs. HAMPSON and ATKINS brought forward a motion that the Council should defend, if necessary, a member of the Society who had been threatened with prosecution under the Apothecaries Act, the Council authorized its Solicitor to undertake the defence at his discretion and at the expense of the Society. This is not the place to enlarge upon the subject, but it must be evident that where such important interests are involved the fight to be "well conducted" need not necessarily be fought in defence of the first case that presents itself, nor need it even involve an appearance in the law courts at all. The marked indifference, if not disfavour, shown by the heads of the medical profession to the Bill of the East London Medical Defence Association—the Medical Council having virtually recommended its postponement to the Greek Kalends—was significant that there is no disposition on their part to push matters to extremes any more than the majority of chemists and druggists would wish to spend their money in defence of all the practices objected to. This cannot be without its influence on the counsels of the Apothecaries' Company before it risks an Act that by no means warrants the strained interpretation put upon it, and which in its verbiage does not evidently confer upon the apothecary any privilege in respect to the supplying of medicines that it does not reserve also to the chemist and druggist, except the privilege of being fined if his duties are not performed faithfully. In October, Mr. SCHACHT moved that an effort should be made by the Pharmaceutical Society to arrive at an understanding with the Apothecaries' Company as to the class of cases of alleged infringement of the Apothecaries Act that should be open to prosecution, and that a committee should be appointed to confer with the Company. Although this proposition did not meet with much support, it appears that when the subject was again under discussion at the December meeting the Solicitor was instructed to communicate with the Solicitor to the Apothecaries' Company, and since a decision obtained in a law court, whilst it involved defeat to one side, might prove to be a Pyrrhic victory to the other, it may be hoped that some action taken in the spirit of Mr. SCHACHT'S proposition may lead to a practical settlement.

Since writing the foregoing paragraph some progress appears to have been made in that direction, as will be seen on reference to the report of this week's Council meeting, and the report furnished by the Solicitor of his conference with the Solicitor of the Society of Apothecaries was understood to contain a distinct disavowal of any desire to institute vexatious proceedings against chemists in regard to giving that amount of advice to their customers which is necessarily involved in the ordinary course of their business. From this, as well as from the facts stated in connection with Dr. LUSH'S Bill, it will appear that those persons are very much in error who believe that this subject has not received the careful attention of the Council. It affords another illustration of the fact that, thanks to the influence that can be brought to bear by the Council on behalf of the pharmaceutical body, very important ends can be attained without the inconvenience and expense involved in legal contests.

The remainder of the history of this subject may be quickly told. The Bill introduced into Parliament by the Defence Association had a brief existence of less than three weeks. A deputation from the Council, consisting of the President, Messrs. SANDFORD, ATKINS, and HILLS, having been appointed to wait upon Dr. LUSH, who had charge of the Bill, that gentleman, in deference to the representations made on behalf of the Pharmaceutical Society, withdrew the Bill a few days afterwards. It is true that he introduced another which differed only in a few words, but in this form it was met with the contempt of the original promoters and the indifference of those against whom it was originally directed, and it perished with other "innocents" at the end of the session almost without a sign. The appeal against the decision in the Nottingham case, which was carried on at the expense and under the direction of the Chemists and Druggists' Trade Association, came on for hearing in the Exchequer Division of the High Court of Justice on the 20th and 22nd of November, before the Lord Chief Baron and Mr. Baron CLEASBY. Before the leading counsel, Sir HENRY JAMES, had finished his opening argument, their Lordships intimated that the materials before them,—the evidence given in the County Court,—seemed insufficient to enable them to give judgment in so important a suit, and expressed a wish that there should be a new trial of the case in that Court, Mr. Baron CLEASBY saying that if it could be shown, going back as far as living memory does, that chemists and druggists have been in the habit of dispensing across the counter, and that now and for a considerable time it has been part of the business of a chemist and druggist to do that, it would be very important. This course, after some objection on the part of the counsel for the Apothecaries' Company, was eventually agreed to, but up to the present time no further steps in the case have been made public.

Another subject that gave rise to a lively discussion at the Annual Meeting was the sale of scheduled poisons at Co-operative Stores, a motion having been made, though afterwards withdrawn, instructing the Council to take legal steps against the proprietors of one of the stores. Mr. SANDFORD stated that co-operative stores had occupied the attention of the Council a great deal, and probably the same may be assumed concerning the executive of the Trade Association, but no more definite result seems to have been attained than a more widely extended recognition of the difficulties that beset the question.

Not the least important among the public functions of the Council of the Pharmaceutical Society is that relating to examination. During the past year the usual four Preliminary examinations have been held. The number of candidates presenting themselves at the respective centres were 1083, being 29 in excess of the number in the preceding year; of these 577 passed, whilst 506, or 45·8 per cent. failed, against 42·4 per cent. of failures in 1876. Besides these, 30 certificates of other examining boards have been received in lieu of the Preliminary examination, making a total of 536 persons registered as apprentices or students during the year. At the Minor examinations 536 candidates presented themselves; of these 299 passed and 237 failed, being 44·2 per cent. of failures, against 46·3 per cent. in 1876, and 50 per cent. in 1875. Of Major candidates there were 98, with 45 failures, or 45·9 per cent., against 38·6 per cent. in 1876. The gross number of candidates presenting themselves for examination during 1877 was 1742, being 103 in excess of the number in the previous year.

It will be seen by the above figures that the percentages of failures in the three examinations are remarkably close, being 45·8, 44·2 and 45·9. From this it may be inferred that whatever may be said of the absolute standard of the whole of these examinations, the relation in which they stand to each other in respect to stringency is as near perfection as is likely to be attained. Nor is the proportion of failures, compared as a whole with the known results of other examining bodies, at all suggestive of the standard being fixed unduly high. But in the opinion of the Glasgow Chemists and Druggists' Association the questions in the Preliminary examination papers are now more difficult than formerly, and are likely to deter lads from entering the business, and so to cause a greater dearth of apprentices. This opinion was communicated to the Council at its December meeting, with a request that it would instruct the examiners, in this case the College of Preceptors, on the point, but a comparison with the statistics of former years led the Council to the conclusion that the proportion of failures has by no means increased, and the Secretary was instructed to inform the Association of this result. In view of the present apparent equality of the examinations, just pointed out, it is not quite clear what advantage there would be in dealing with the first examination in a way that would relatively intensify the difficulty of that which is to come after, or why there should be such anxiety to facilitate unduly the entrance of youths into a business that is continually described as being already overcrowded. There is also another element to be taken into consideration. It must not be forgotten that these examinations are conducted on behalf of the public, and are in its interest placed under the supervision of the Lords of the Privy Council. Although the Visitors appointed by the Privy

Council have again reported most favourably of the examinations as at present conducted, one of them stating that the examiners discharge their duties with a judicious combination of strictness, impartiality and consideration for the candidates, there is no evidence in their reports that they would look with favour upon the lowering of the standard of any of the examinations; in fact the indications are in the opposite direction.

With respect to measures for securing the education of which these examinations are designed to be the test, it would appear from the reports of the Professors that a fair average number of pupils is in attendance at the School of Pharmacy in Bloomsbury Square. Considering the many competing establishments that now exist in the metropolis and its neighbourhood, having for their professed object the supplying of the demand for pharmaceutical education that has been created by the past policy of the Society, this is perhaps as much as can be expected. There is little fear that under its present leaders the old school will hold its own, and justify its position as the model school of pharmacy. Last year again the pharmaceutical blue ribbon and the next open prize were carried off by two of its pupils; but a pupil from the north was close upon their heels, and the possibility that positions may be reversed in another year must be admitted. Naturally the sympathies of many will be with *alma mater* in the struggle, but the keener the contest the healthier will be the result, and the more completely will the educational policy of the Council be vindicated.

It cannot be said, however, that pharmaceutical education in the provinces is on the whole in a very robust condition. It has recently been alleged by Mr. Fairlie, of Glasgow, that this is to be attributed to the neglect of the Council, and he suggests the formation of a central educational board, the apportionment of the country into twelve districts, the establishment of a school of pharmacy modelled on that at Bloomsbury Square in a centre in each district, and the subsidizing of each school from the funds of the Society. There is nothing, however, in the reports from provincial societies that have been forwarded to the Journal during the past year to indicate that the predominant want is that of schools, but there is a continual complaint that where educational facilities are provided, having the advantage of local supervision, students do not make their appearance to utilize them. In some of the larger centres, where there is some demand for pharmaceutical education, such as Manchester, Birmingham and Edinburgh, the demand is fully met, and the schools become practically self-supporting, or if there be a little timely help wanted there is no real difficulty in obtaining it from the Pharmaceutical Society. Thus in 1876 a grant was readily accorded to the Manchester school, but in 1877 it was in so prosperous a condition as not to need its repetition. Two grants in aid have been made during the past year, one of fifty pounds to the Bristol Pharmaceutical Association, and one of five pounds to the Oldham Chemists' Association, and these are all that have been applied for. From a return made in June, by direction of the Council it appeared that the amount expended during the previous year on purposes connected with pharmaceutical education, including the endowment of the professorial chairs, was £718.

The result of the alteration in the regulations relating to the prizes offered by the Council for competition between the best men of the year, irrespective of the school where they may study, has been very marked. It will be remembered that these prizes consist of the "Pereira Medal" and two "Pharmaceutical Society's Medals," one in silver and one in bronze, to which presents of books have been added by Mr. Thomas Hyde Hills, and these are offered for competition amongst the successful Major candidates of the year. At the last examination there were thirteen competitors, against nine in 1876 (the first year of the new regulations), whilst in 1875 the Pereira medal was not awarded for want of a competent applicant. The prizemen of the past year were Mr. George William Bullen (Pereira Medal), Mr. Henry George Greenish (Society's Medal, silver), and Mr. William Inglis Clark (Society's Medal, bronze). Of the prizes awarded to the students in the Society's school, Mr. Bullen gained the Silver Medal in the Chemistry and Pharmacy Class, and Mr. Robert Henry Parker gained the Silver Medals in both the Botany and Materia Medica and the Practical Chemistry Class. The Herbarium Silver Medal was awarded to Mr. J. T. Creswick Williams.

The opening of the present session of the school, at which as usual the prizes awarded to the students of the previous session were distributed, was signalized by an admirable address delivered by Mr. William Southall, of Birmingham. It may be remarked, as probably it escaped the notice of most readers, that this address was in some respects a curious instance of the fact that a successful oration is frequently but the happy expression by one man of thoughts that are floating more or less indefinitely in the minds of many. In Mr. Southall's address there were some ideas almost identical with those to which Professor Tyndall gave utterance in a speech that created some stir about the same time, although the fact that Mr. Southall's address had been in type several days before that of Professor Tyndall was delivered at Birmingham precludes any possibility of closer relationship. It will not be inappropriate to note here, too, that although the attendance of ladies at such meetings is specially invited, whilst the Conversazione is entirely dependent for its success upon their presence, the Council has been again very much exercised as to whether it shall receive them in any other character than as guests, and the renewed proposition to admit them, if otherwise qualified, as Members or Associates of the Society, is to be once more referred to the Annual General Meeting for decision.

The other Evening Meetings of the Society were moderately successful both in respect to papers and auditors to listen to them; the December meeting, however, showed a promise of some improvement in the coming year, under the auspices of the new Committee to whom the management of these meetings has been entrusted. The papers read were:—"The Admixture of White Hellebore with Valerian Root," by Professor Bentley; "The Colouring Matter of the Petals of Rosa Gallica," and a "Note on *Rheum officinale* grown in England," by Mr. Harold Senier; "Note on the Action of Dilute Nitric Acid on Brucia," and "False Angostura Bark and Brucia," by Mr. W. A. Shenstone; "The Pharmacopœia Test for Sulphate of Quinine," by Dr. B. H. Paul; "Notes on the Action of Chlorine upon a Beam of Light and on the Preparation of Chlorine," and "The Colour of Podophyllum Resin," by Dr. A. Senier and Mr. A. J. G. Lowe; "Medicine Measures," by Mr. B. S. Proctor; "The Poisonous Properties of Yew Leaves," by Professor Redwood; "Remarks on Sweet Spirit of Nitre," by Mr. F. M. Rimmington; "Notes on Casual Drugs," by Mr. E. M. Holmes; "Nitrite of Ethyl," by Mr. John Williams; "Observations on Russian Turpentine Oil and on Oleum Foliorum Pini sylvestris," by Dr. Tilden; and "The Use of Russian Turpentine Oil in Pharmacy and Medicine," by Mr. A. W. Postans. In addition these, in May, Professor Redwood delivered an admirable lecture on "Spectrum Analysis," which was illustrated by means of new apparatus, purchased by the Society for the use of the Chemistry and Pharmacy class.

The Library and the Museum of the Society have both been well maintained in their efficiency under the careful supervision of the Committee and officers to whom they are entrusted. The Library has been increased by about three hundred books and pamphlets, many of them of considerable value, as will be seen by the catalogue that accompanies this number of the Journal. Particularly may be noticed the completion of the set of the *Philosophical Magazine* from the year 1751, so that the volumes of this celebrated scientific journal for a century and a quarter are now available. The circulation has amounted to about two thousand entries, about one-fifth of which have been to country members, and in respect to these the Society has paid nearly £7 for carriage, by virtue of the regulations under which the carriage, one way, of books borrowed by country members is paid. The attendance, as shown by the signatures, has been smaller during the day time, compared with the preceding year, but rather larger during the evening.

The Museum has been enriched by many specimens of Indian drugs, presented by Professor Dymock, of Bombay, in illustration of the series of notes that have appeared from time to time in this Journal. From Mr. John Eliot Howard have been received an excellent series of specimens of cinchona bark, completing the set previously in the Museum. Specimens have also been received from Professors Bonmer, Dragendorff, Fluckiger, Maisch, and others. Much time and care has been devoted during the past year to the preparation of a catalogue of the specimens, which is now all but finished, and will be probably ready for issue by the end of the present month. The numbers of students connected with the Society using the Museum has been about the average of former years, but it has been consulted by many scientific men, including some from the Continent and the United States. Many duplicates that were available for the purpose have been sent to increase the collection of the North British Branch in Edinburgh, and donations of specimens have also been made to local societies. In order to facilitate this portion of the Museum work a list of duplicates is to be published shortly.

Having thus recapitulated the principal trade and educational interests that have come more or less specially under the cognizance of the members of the Council during the year, it would be wrong to leave unmentioned their work as the almoners of the trade. The past year has been notable in the history of the Benevolent Fund. Ten years having passed since the last Festival in aid of the Fund, and the right of many firms to vote by virtue of donations then given having lapsed in consequence, it was wisely suggested by the President that another Dinner would be the most pleasant way of giving them an opportunity of renewing their interest in the Fund. The suggestion was at once adopted, an appeal was issued, and on the evening before the Annual Meeting a large company, including eminent representatives of the medical profession and of nearly every interest associated with pharmacy, dined together at the Freemasons' Tavern. After an eloquent appeal from the President, a list of subscriptions and donations was read that eventually represented the sum of £1600. In addition to this special effort, there have been received during the year subscriptions and donations to the amount of about £1200, being about £160 less than that received in the previous year. On the other hand, a larger sum was dispensed in relief. In June the Council decided that six more annuitants on the Fund should be elected in October, and the amount paid in annuities during the year reached £675. A large number of cases were also temporarily relieved at an expenditure of nearly £600.

The regulations under which the Fund is administered have undergone general revision and some important modifications have been made. In August, at the meeting of the Council, Mr. Robbins moved that some of the surplus income derived from subscriptions should be devoted to securing the admission of children of deceased members and associates to orphan institutions, a certain number to be elected by the subscribers from suitable cases nominated by the Council. The discussion was adjourned until October, when the motion was withdrawn, the general opinion being that sufficient provision was already made in the power which the Council possessed and had exercised during the year, to spend money in providing or assisting in providing for an orphan a home by purchase in one of the public orphan asylums; a slight alteration has since been made, however, in the regulations to render this more apparent. Of the other alterations the principal are the shifting of the time for the election of annuitants from October to December, so as to be coincident with the close of the financial year,—the increase of the payment of annuitants of sixty-five years of age and upwards to £35 per annum,—the crediting of a candidate for an annuity with the number of votes represented by his previous subscriptions to the Fund, or in the case of a widow those of her husband,—and the admission at the elections for annuitants of proxies from subscribers residing abroad.

The annual meeting of the North British Branch of the Society was held in April, when the Council was able to present a very favourable report showing that the present arrangements work satisfactorily. The students still prove their appreciation of the new rooms, the library has been more extensively used than ever, and the interest of the scientific meetings has been well sustained. After serving the Branch effectively as President and Vice-President for three years, Mr. William Gilmour and Mr. Alexander Kinninmont expressed a wish to retire from office, and Mr. J. B. Stephenson and Mr. Alexander Napier were elected in their stead, but the Branch is still privileged with the indefatigable services of Mr. John Mackay as Honorary Secretary. Amongst the gentlemen to whom the Branch has been indebted for papers during the past year may be mentioned the names of Dr. Stevenson Macadam, Mr. W. I. Macadam, Dr. F. W. Moinet, Dr. Andrew Wilson, Mr. H. B. Baildon, Mr. F. King, Dr. A. P. Aitken, and Dr. William Craig.

Before leaving this part of the record it is satisfactory to mention that three new local associations have been formed in the provinces,—at Crewe, Blackburn, and Coventry. In June, a meeting of assistants was held, by permission of the Council, in the Theatre, Bloomsbury Square, which resulted in the formation of what promises to be a useful Chemists' Assistants' Association for London. The School of Pharmacy Students' Association has also been pursuing a fairly successful career.

With respect to the movement to secure earlier closing, upon which the success of these and similar societies so much depends, it is to be regretted that more progress has not been made. A meeting was held in April, under the presidency of Mr. Sandford, in the Theatre, Bloomsbury Square, when it was agreed that it was desirable that the window shutters should be put up at 8 o'clock and the door closed at 8.30 on week-days, except Saturday. It was understood that local meetings would be held to secure this object, but up to the present time none have been reported.

With the exception of the short-lived Medical Acts Amendment Bill before referred to, the Parliamentary Session was singularly barren of special interest to pharmacists. It is true that another Bill to amend the Sale of Food and Drugs Act was introduced, but its *raison d'être* was not very apparent, and it disappeared. In carrying out the existing law, however, several cases occurred that are worth notice.

First must be placed the settlement of the long-vexed "milk of sulphur" question by the result of an appeal to the Knutsford Quarter Sessions, the magistrates having decided that there are two distinct substances known in the trade and the medical profession as lac sulphuris and sulphur præcipitatum, and that they are supplied to the trade and the public by these names as two distinct things. This decision was given at the beginning of April, and since that time the chemist and druggist has been free to sell, if he chose, the well known lime preparation under the name by which it has been familiar to the public for more than a century without fear of being prosecuted as a cheat, and yet no very great disaster has followed. Prosecutions for the sale of aloetic or mercurial pills under the name of "castor oil pills" have on the other hand been followed by convictions. Attention was also called in a medical contemporary early in the year to the sale of lozenges containing a considerable quantity of calomel under the name of "castor oil lozenges," and the correctness of this statement was confirmed by an examination made by Mr. A. R. Wilson. Probably prosecutions for the sale of these would have had a like result, and it must be admitted that although there are many other substances sold under names quite as little representative of their composition, no good purpose is to be served by the multiplication of such misnomers. There have also been several prosecutions for the sale of soda and potash waters that did not contain the Pharmacopœia quantity of alkali, but the absurdity of this course was too transparent, and the cases were dismissed; there has been a disposition, however, on the part of magistrates to convict in cases where the alkali was quite absent. The presence of 1 part of lead in 20,000 parts of citrate of magnesia was deemed sufficient warrant by the Procurator-Fiscal of Glasgow for charging certain of his townsmen with offences against the Sale of Food and Drugs Act, but this amount of impurity was decided to come within the exemption as to extraneous matter unavoidably mixed in the process of preparation, and the cases were dismissed. Incidentally they illustrated not only the mischief that may result from zeal without knowledge, but also an unacquaintance of a public official with decimals—he considering that the difference between 0·37 grain and 0·40 grain of lead per pound constituted the latter a much grosser offence—that speaks volumes as to obstacles that stand in the way of the more general adoption of the metric system in this country.

The sale of preserved peas containing equal to from one quarter to one half grain of copper in the pound tin, gave rise to several prosecutions under this Act in different parts of the country. As to the presence of the copper the evidence left no doubt; but with respect to the medical question as to the influence the consumption of such peas would have upon the health the evidence was very conflicting. Upon this evidence, however, the magistrates decided to convict. Considerable discussion occurred about the same time upon this subject in France also. With the object of throwing some light upon the disputed physiological point, quite apart from the morality of the object for which a copper salt might be presumed to be added to preserved peas, Messrs. Paul and Kingzett made some experiments, the results of which they reported at the meeting of the British Pharmaceutical Conference. From these they inferred that when such preserved peas are eaten, even if a part of the copper be absorbed into the system, probably the greater part passes into the fæces, and that it is likely that quite as much copper finds its way into the system through the handling of copper coins, the use of copper vessels in cooking operations, or the consumption of pickles and similar substances which are frequently prepared in copper vessels. The paper gave rise to a lively discussion at the Conference meeting, and this has been continued until a recent date, when it occasioned a development of unscientific heat that rendered its prolongation by gentlemen impossible. Other prosecutions under this Act presenting special points of interest were three for adulteration of balsam of copaiba, two of which broke down in a disgraceful manner; one for the sale of jalap with which nux vomica had become in some way mixed; one for the supply of quinine pills deficient in quinine; several for the sale of "sweet spirit of nitre" containing little or no nitrous ether, not by chemists and druggists, as alleged by a medical contemporary, but by co-operative stores and grocers; and one for exposing for sale hams coated with chromate of lead, which was held not to be an offence since the covering was not an article of food. Cream of tartar has also been met with containing barium sulphate, the source of which has hardly yet been explained. Also Professor Bentley has noticed an admixture of white hellebore with valerian root. The prosecutions with respect to beer have been rather unsuccessful. In one case the assertion that quassia was present in a sample was not satisfactorily sustained, and if it had been it was admitted that the use of quassia as a substitute for hops is now allowed by the Excise. The presence of salt in beer, which has hitherto been looked upon as an infallible sign of trickery, has been shown to be due within certain limits to natural causes, and a recent case, where it was charged that beer contained 63 grains of common salt per gallon, was dismissed on the ground that the materials legitimately used in its manufacture would yield a larger quantity, though the defendant was mulcted in £10 for expenses because he had not given notice of his intention to set up this defence!

The last annual report of the Local Government Board contained some data which, although not fully representative, as the Act is still practically ignored in some districts, are sufficiently so to throw considerable light on the question as to the amount of adulteration practised. Of 4177 samples of food submitted, presumably obtained from what were deemed suspicious sources, 515 were reported to be adulterated, and of 115 samples of drugs only 7 were reported against. It is admitted that in a considerable proportion of the cases of alleged adulteration the amount was so slight as not to warrant their being carried into court, and judging from experience if they had been many of them would have failed.

It is thus apparent that if, on the one hand, the Sale of Food and Drugs Act has diminished the practice of adulteration, it has, on the other, demonstrated that certain forms of adulteration formerly believed to be all-prevalent are practically non-existent. Twenty years ago the words placed by the Poet-Laureate in the mouth of one of his characters fairly reflected the public creed—

> "And the vitriol madness flushes up in the ruffian's head,
> Till the filthy bye-lane rings to the yell of the trampled wife,
> And chalk and alum and plaster are sold to the poor for bread,
> And the spirit of murder works in the very means of life. . . .
> While another is cheating the sick of a few last gasps, as he sits
> To pestle a poison'd poison behind his crimson lights."

It is true that this view of the case is affected by certain persons still, but to sincerely endorse such language now, in the light afforded by the operation of the Sale of Food and Drugs Act, one would need to be as madly misanthropic as Maud's lover.

Early in the year it became currently reported that certain manufacturers were using methylated spirit in the preparation of medicines capable of internal use, and Mr. Greenish stated that the Law and Parliamentary Committee had had under its notice several samples of laudanum prepared from methylated spirit. In one case the Excise authorities recovered a penalty of £25 for its use in a "patent medicine." Shortly afterwards Excise officers were directed to caution chemists and druggists against the use of cleaned spirit. There have also been convictions for selling rectified spirit and methylated spirit without a licence.

In defending several of the legal cases above referred to an active part was taken by the Chemists and Druggists' Trade Association, especially in the "milk of sulphur" appeal and the "soda water" prosecutions. The defence of the prescribing case at Nottingham has also been conducted up to the present stage by it. The annual meeting of this Association was held in London in May, and a Scotch branch has also been organized.

During the year, 41 cases of fatal poisoning have been reported in this Journal, which though not presumed to be nearly all that have occurred in Great Britain, give some clue as to the relative frequency of the fatalities from each substance and include the most interesting cases. The cases have been from arsenic, 1; atropia sulphate, 2; carbolic acid, 8; chloral hydrate, 4; corrosive sublimate, 1; cyanide of potassium, 1; an embrocation, 1; hemlock, 1; laudanum, 2; mercurial powder, 1; "nurses' drops," 1; opiate draught, 1; opium, 3; paregoric, 1; phosphorus paste, 1; prussic acid, 5; strychnia, 5; and teething powders, 2. Concerning these it may be remarked that carbolic acid was administered for medicine three times in public institutions, and mistaken once for cough mixture and once for water. The sulphate of atropia was in the form of eye water and not labelled "poison." The strychnia was in three cases taken in the form of vermin killer, but in one had become mixed with santonin, and a similar accident has led to two cases of poisoning in Canada during the year.

Although there have been several additions to the materia medica during the year just closed it cannot be said that any one of them has created an equal amount of interest to that excited more or less temporarily in previous years by trimethylamine, jaborandi, salicin and salicylic acid. In fact the latter substance, together with salicylate of soda, may be said to obtain the lion's share of attention even at the present time, and there is little doubt that they will take a permanent place in medicine, whilst the conservative properties of salicylic acid are now extensively utilized in beer brewing, the preservation of fruits, and in other directions. Some medical observers have, however, reported unfavourable results following the internal use of such substances, and more than hinted that they have a detrimental action upon the bones and teeth, the urine becoming loaded with lime salts during their use. Other unexpected results have pointed to the presence of impurities in the acid, which would in some cases have a very detrimental action; but whatever might have been the case in the early use of these substances as a medicine, there is no doubt that they can both now be easily obtained pure. Tests for their purity have been published, but there is some difficulty in detecting carbolic acid in the presence of salicylic acid. ALMEN recommends the treatment of a dilute solution with sodium hypochlorite, and sufficient ammonia to maintain the solution alkaline, which gives an intensely blue colour with carbolic acid, but not with salicylic acid. KOLBE recommends the evaporation, in a watch-glass, of a solution of one part of salicylic acid in ten parts of strong alcohol, when a crystalline ring is formed, which is white if the acid be pure, but yellowish or yellow if impure. No further suggestions have been made to overcome the inconvenience in dispensing caused by the sparing solubility of salicylic acid in water.

Another comparatively new remedy, monobromated camphor, which is practically insoluble in water, has been the subject of much pharmaceutical ingenuity. M. DAMBIER has proposed an alcoholic syrup made by dissolving 5 parts of monobromated camphor in a solution of 400 parts of sugar in 600 parts of 56 per cent. alcohol. Mr. MUNDAY proposed an elixir double this strength, substituting glycerine for sugar, using 90 per cent. alcohol, and flavouring with orange flower water. This he afterwards modified by dissolving the monobromated camphor in a mixture of spirit of cinnamon, alcoholic solution of cochineal (red elixir), and syrup. Lastly LEPAGE recommends to rub up the monobromated camphor with almond oil, which dissolves one sixth of its weight, when the product can be readily made into an emulsion. A formula for the preparation of monobromated camphor is among those recently adopted by the Paris Society. A statement by Dr. FOTHERGILL that hydrobromic acid has the property of modifying in a remarkable degree the cerebral effects that sometimes follow the administration of quinine has turned considerable attention to this compound. The observation was originally due to Dr. WADE, of Michigan, who gave a formula for what he considered to be a sufficiently pure solution of hydrobromic acid, representing ten grains of bromine to the fluid drachm. It consisted in dissolving 120 grains of potassium bromide and 153 grains of tartaric acid in a fluid ounce of water, keeping it cool until precipitation ceases, and decanting the clear liquor from the acid tartrate of potassium formed. Dr. WADE has also supplied formulæ for dispensing this hydrobromic acid solution in combination with iron, mercury, bismuth, pepsin, stramonium and ergot, all of which compounds he reports that he has used beneficially.

The great increase in the number of deaths from hydrophobia, which has so markedly affected the public mind, has naturally given rise to a host of specifics. *Xanthium spinosum*, which had been much vaunted as one, has failed to stand a crucial test upon inoculated dogs. Of those still under trial perhaps curare may be considered the most important, and Mr. Moss, who has recently collected the existing information respecting this drug, has recommended an aqueous solution of one grain in twelve minims as suitable for hypodermic injection. It is evident, however, considering the crude and probably variable nature of this substance, and its great virulence, that its pharmacy cannot be yet considered to be in a satisfactory state. Under these circumstances it might be worth notice that cyclamin, the crystalline glucoside obtained from the *Cyclamen Europæum*, L., a classic remedy against serpents' bites, has been found to have antitetanic properties, and has been recommended by Professor De Luca, of Naples, as a substitute for curare in the treatment of tetanus. It is rather curious in the face of curare being reputed as an antidote to strychnia, that hoang-nan bark, obtained from a species of *Strychnos*, and supposed to depend for any activity it may possess upon the presence of strychnia, which it contains together with brucia, is also recommended from China as a remedy against hydrophobia. False angostura bark (*Strychnos Nux-vomica*), a very similar bark, has been examined by Mr. Shenstone, who found that it also contains strychnia as well as brucia. The same gentleman has, in addition, confirmed Mr. Cownley's disproval of the conversion of brucia into strychnia announced by Sonnenschein.

A great deal of good work has been done during the year in respect to the vegetable alkaloids, but one of the principal results has been to demonstrate how much remains to be done. Of none can this be said more truly than of the aconite alkaloids. At the meeting of the Pharmaceutical Conference the third report of a committee appointed to investigate this subject was presented by Dr. Wright. It stated that *Aconitum Napellus* roots as met with in commerce contain a highly active crystallizable alkaloid, "aconitine," represented by the formula $C_{33}H_{43}NO_{12}$, and yielding crystallizable salts; a second active crystallizable alkaloid, "pseudaconitine," having the formula $C_{36}H_{49}NO_{11}$, and not readily yielding crystallizable salts; and a third apparently non-crystalline alkaloid, yielding non-crystalline salts, containing a higher percentage of carbon and apparently of little physiological activity. In the extract, and possibly existing in the root, were found decomposition products of the first two alkaloids, to which the names of aconine and pseudaconine have been given, the decomposition being represented as follows:—

$$\underset{\text{Aconitine.}}{C_{32}H_{43}NO_{12}} + H_2O = \underset{\text{Benzoic Acid.}}{C_7H_6O_2} + \underset{\text{Aconine.}}{C_{26}H_{39}NO_{11}}.$$

$$\underset{\text{Pseudaconitine}}{C_{36}H_{49}NO_{11}} + H_2O = \underset{\text{Dimethyl-protocatechuic acid.}}{C_9H_{10}O_4} + \underset{\text{Pseudaconine.}}{C_{27}H_{41}NO_8}.$$

From the ease with which this decomposition takes place by saponification, the reporters considered it probable that liquid preparations of aconite, such as the tincture, gradually lose activity if kept, and inevitably so if in a neutral or alkaline condition. The report further stated that *A. ferox* roots contain relatively much pseudaconitine, little aconitine, and another base containing a high percentage of carbon; that *A. Lycoctonum* roots contain aconitine and pseudaconitine, and that the "aconitine" of commerce is a mixture of true aconitine and pseudaconitine with variable quantities of their decomposition products and of the unnamed amorphous bases. In respect to this statement the doubtful origin of most of the aconite root coming into the market must be borne in mind. In fact Mr. Holmes has recently reported meeting with it mixed with masterwort root. At the same meeting Messrs. Paul and Kingzett gave the results they had arrived at by working upon Japanese aconite root, a clean and characteristic variety that had recently come into the market. After criticizing some statements of previous workers they stated that they had obtained from the Japanese aconite root a crystallizable alkaloid, represented by the formula $C_{29}H_{43}NO_9$, which did not give crystallizable salts, and a substance that behaved as a salt of the crystallizable alkaloid; from these facts the inference was drawn that part of the alkaloid was present in the root in combination with an acid, possibly aconitic acid. It may be mentioned here that Professor Dymock has recently described another aconite root, from an unknown species, which is used in India, under the name of "wakma," to stop vomiting and purging, to allay pain in the bowels, and as a powerful bitter and antiperiodic.

The cinchona alkaloids have again contributed their quota to pharmaceutical literature. The distribution of these alkaloids in cinchona trees has been investigated by Mr. D. Howard, who finds that there is a marked increase in the development of alkaloid in the root bark over that of the stem or branches, the tendency being to produce the dextrogyrate alkaloids, cinchonine and quinidine, in greatly increased proportions. On the other hand, the total quantity of alkaloids in the quill bark from the branches is much less than in that from the stem, but the proportion of quinine and cinchonidine is larger and that of quinidine and cinchonine is smaller. In the Ledger bark the increase of total alkaloid is slight, but the proportion of quinidine is doubled and that of cinchonine trebled, the amorphous alkaloid being also increased. In the renewed stem bark there is also an increase of alkaloid, but in this case it is of the more highly oxidized alkaloids, quinine and its isomers, whilst there is a distinct diminution of cinchonine and cinchonidine. Dr. Paul has called attention to the fact that in consequence of the increased solubility of cinchonidine in ether in the presence of quinine the quantity of ether prescribed in the official test for quinine sulphate would allow 30 per cent. of cinchonidine to pass unnoticed, and he has described a process of fractional crystallization for its detection. Dr. PAUL has also reported on an examination of some commercial specimens of citrate of quinine which showed a great deficiency of alkaloid, a result that was confirmed by the experience of Professor ATTFIELD with some other samples. Professor PRESCOTT has supplied some useful laboratory notes on the estimation of quinine. The extremely high price attained by quinine at one period of the year turned increased attention to the other alkaloids accompanying it in cinchona bark, and Mr. J. E. HOWARD brought the subject under the consideration of the Conference at Plymouth. Some conflicting experiences were mentioned, but the general opinion appeared to be that these alkaloids are not so much used as they deserve, though the matter must be left with the medical profession. In connection with this subject it may be of interest to state that Mr. HOWARD has lately received a letter from Sir LOUIS MALLET, in which the results of two years' trial of cinchonidine sulphate by the Government of Bombay are described as successful, the general medical opinion in the Presidency being that cinchonidine sulphate is a very valuable addition to the Pharmacopœia, and that it should be more generally used in civil hospitals and regiments. Finally, a compound of quinine with thymol and citric acid has been described by Signor PAVESI; formulæ for quinine hydroferrocyanide, neutral and basic quinine hydrobromides, and quinine tannate, are among the preparations recently recognized by the Paris Society; and quinine hydrochlorate has been suggested by Mr. WHITFIELD as superior to the sulphate in the preparation of tincture of quinine.

The alkaloids of *Atropa Belladonna* have been investigated by BUCHHEIM, who finds that when atropine is treated with baryta water it is decomposed into "tropine" and "tropic acid." In like manner belladonnine, an alkaloid found by HUBSCHMANN in crude atropine, is decomposed into "tropine" and "belladonnic acid." Until recently it was supposed that the calabar bean only contained one alkaloid, known as physostigmine or eserine. HARNACK has however succeeded in isolating a second alkaloid, differing from physostigmine in its insolubility in ether and easier solubility in water, and having a different and in some respects opposite physiological action. According to the same authority commercial physostigmine has frequently been a mixture of these two alkaloids, but they are now being prepared separately in Germany. Hashish, the celebrated preparation of Indian hemp, has been examined by Dr. PREOBRASCHENSKY, who states that the active principle is not a resinous matter, as was supposed, but nicotine, and that he has found this alkaloid not only in commercial hashish, but also in the flowering tops of the *Cannabis sativa* itself. Some experiments as to the alkaloidal value of colchicum root by Mr. BOWMAN seem to show that whether the root is white, black, or grey, is not of much importance, the proportion of colchicine varying but little; but that there is a considerable diminution after the root has been kept some time. An analysis by Mr. KINGZETT, of some nitrate of pilocarpine, prepared by Mr. GERRARD, has shown that the alkaloidal substance obtained by these two observers is identical, and that probably it is the only one present in jaborandi. The jaborandi leaves themselves are now little used, but the alkaloid is still in demand, and a formula for its preparation has been published by the Paris Society. An exhaustive paper on the microscopic structure of the stem of this (*Pilocarpus*) jaborandi has been made by Mr. STILES. Another "jaborandi," from *Piper reticulatum* has been examined by M. HARDY, who has obtained from it an alkaloid that differs widely from pilocarpine, and is supposed to be closely allied to curare. Dr. GREENE has described a process for obtaining the caffeine from guarana, which consists in boiling it with litharge, filtering, removing dissolved lead with sulphuretted hydrogen, and evaporating to crystallization. Timbo root, from the *Paulinia pinnata*, used as a poultice in Brazil in affections of the liver, has been examined by M. MARTIN, who has separated from it an alkaloid that he has named "timbonine." An Australian stimulant, said to have properties similar to coca, has been referred to *Duboisia Hopwoodii*, Muell., but does not appear to have been chemically examined. The hypophosphite of berberine has been prepared in yellow crystals, very soluble in water, by Mr. LLOYD, by digesting the sulphate with lead oxide at 180° F., removing excess of lead, and adding hypophosphorous acid in slight excess, a magma of crystals separating on cooling. Other vegetable alkaloids that have been described, are "sophoria," an exceedingly active paralysing poison, obtained by Professor WOOD from the seeds of *Sophora speciosa*, Benth., and "strophantine" and "ineine," obtained from the seeds of *Strophantus hispidus*, DC., used in Africa as an arrow poison. A useful table for the identification of the principal alkaloids, acids, etc., has been published by Dr. SENIER, whilst Dr. GODEFFROY has recommended silicotungstic acid as probably the most delicate test known for alkaloids.

Dr. TILDEN, to whom the old saying, "*plus aloes quam mellis habet*," might without any disrespect be suggested as a motto, has again been at work on the aloins, and described a yellow colouring matter, "aloxanthin," bearing an interesting relation to chrysophanic acid and emodin, the yellow compounds found in rhubarb root. The relation is shown in the following equations:—

Chrysophanic Acid . $C_{15}H_{10}O_4 = C_{14}H_5 \cdot CH_3(OH)_2O_2$.
Emodin . . . . . $C_{15}H_{10}O_5 = C_{14}H_4 \cdot CH_3(OH)_3O_2$.
Aloxanthin . . . . $C_{15}H_{10}O_6 = C_{14}H_3 \cdot CH_3(OH)_4O_2$.

The use of chrysophanic acid in medicine has much increased, and the common yellow wall lichen, *Physcia parietina*, has been indicated by Dr. Lindsay as capable of yielding a plentiful supply of it. Emodin has been found also in old black alder bark, and appears to be at least coincident with the condition in which this bark is most suitable for medicinal purposes, which it acquires after being kept some time. The obscurity as to the origin of the official rhubarb, which it was hoped had been dispersed by the introduction of *Rheum officinale*, still remains, the examination of a piece grown at Banbury, where the plant is cultivated by Mr. Usher, leading Mr. Holmes to the conclusion that the Russian rhubarb is produced by a plant of less rapid growth than *Rheum officinale*. In some experiments made with a sample of Banbury root by Mr. Harold Senier, he obtained, as compared with East Indian rhubarb, a brighter powder, a slightly darker infusion, and less extract.

Scammony root has been examined by Messrs. Kingzett and Farries for the doubtful alkaloid, convolvuline, but none was found; the authors report that scammony resin is a glucoside, resembling jalapin. A valuable series of papers on galbanum, ammoniacum, asafœtida, and others of the more important resins, gum resins, and balsams, has been furnished by Mr. Hirschsohn. Dikamali resin has been examined by Professor Flückiger and Dr. Stenhouse, who do not quite agree as to the composition of gardenin, its crystalline principle. Interesting information respecting hingra, kandaharee hing, and other similar bodies has been supplied by Professor Dymock. An assertion that a plant growing in the Cyrenaica district, and introduced into commerce under the name of *Silphium Cyrenaicum*, is the plant that yielded the Greek "silphion," has given rise to considerable discussion, and the plant has been identified botanically with the *Thapsia garganica*. But some experiments made by M. Yvon show that the resin from the African plant has much greater activity than that from the plant grown in Europe. Podophyllum resin has been investigated by Dr. Senier, who finds that the differences in shade of this resin depend upon physical conditions, and that they do not indicate differences of physiological activity.

Willow bark, which has acquired considerable interest in consequence of the demand for salicin, has been examined by Mr. Dott, who reports the presence of lactic acid in it. The red colouring matter of rose petals has yielded to Mr. H. Senier a body having acid properties and forming crystalline salts. Coto bark has been further investigated by Messrs. Jobst and Hesse, who have succeeded in isolating from it three more crystalline bodies, paracotoin, oxyleucotin, and leucotin. Sclerotic acid, which Professor Dragendorff considers to be the active principle of ergot, is now being used in medicine, and the detailed process for preparing it has been described; the same author has obtained from ergot three other bodies besides those referred to in his first paper published on the subject in this Journal.

The Paris Society of Pharmacy, recognizing the inconvenience arising from want of uniformity in the preparation of remedies that have lately come into use, has adopted a report containing a number of formulæ drawn up by a Commission headed by M. Petit. Some of these have already been referred to; amongst others may be mentioned those for crystallized aconitine and digitalin, narceine, apomorphine, caffeine, eserine, picrotoxin, iodoform diastase, extract of malt, pancreatin, syrups of lactophosphates and chlorhydrophosphates, thymol, preparations of jaborandi, coca, and eucalyptus, etc. Joyote (*Thevetia yccali*, DC.) is the name of a Mexican plant having powerful emetic properties, which Professor Herrera thinks should be tried in medicine; and the bark of pao-pereira (*Geissospermum læve*) is said to be used as a febrifuge and antiperiodic in Brazil.

Spirit of nitrous ether has attracted considerable attention during the year, and was the subject of two papers by Mr. Rimmington, in which he discussed the causes that have led to what he considers to be unsatisfactory results. These were followed by a very important communication from Mr. John Williams, in which he described the preparation of a solution of pure nitrite of ethyl in alcohol that should certainly receive a trial in medicine. Another compound of ethyl, the bromide, has had its anæsthetic properties described by M. Rabuteau.

Dialysed iron is the name given to a basic oxychloride of iron, which promises to become one of the most valuable ferruginous medicinal agents; its preparation by dialysis has been described in several papers. Mr. Rother has also suggested an application of dialysis in the preparation of alkaloids. A formula for dialysed iron is included in the Paris report, which also contains others for ferrous chloride and ferrous bromide. The addition of hyposulphite of soda to syrup of iodide of iron to preserve it has been recommended; but Mr. Meier raises his voice against this practice, and recommends the addition of a little free hydriodic acid. The syrup of the phosphates and Easton's syrup have furnished the topics of two more papers recently, by Mr. Laurie and Mr. Masson.

A suspicion as to the true nature of the cerium oxalate of commerce caused Mr. H. Greenish to undertake its investigation, and some specimens examined showed so large a proportion of the oxalates of lanthanum and didymium present as to render it doubtful whether the therapeutic action is to be attributed to cerium alone. The preparation of lithium carbonate and other lithium compounds from lepidolite has been described by Mr.

FILSINGER. The presence of small quantities of ammonia in subnitrate of bismuth has been noted by Mr. PIPER, who considered it to be a sign of defective manufacture, but it has since been attributed to the fact that bismuth decomposes water in the presence of nitric acid, giving rise to conditions favourable to the formation of ammonia. Several investigators have recently demonstrated conditions under which calomel is converted into mercuric chloride; the results are such as make it very desirable, considering the nature of some accidents that have been attributed to the use of calomel, that the subject should be thoroughly investigated. Paraffin oil is generally considered to be without action upon metals, but Dr. MACADAM has found that this is erroneous, and that the oil is sensibly injured for burning purposes by storing it in lead, zinc, or galvanized iron vessels.

The subject of the application of the spectroscope in pharmacy has been taken up by Mr. GILMOUR, who has contributed some interesting papers in reference to it; he has also discussed the tinctorial power of some preparations as a means of ascertaining their strength and quality. A new method of preparing extracts without heat—in fact, by separating the water by congelation—is the subject of a very suggestive paper by Professor HERRERA. Several papers have shown that glycerine of tragacanth, as a pill excipient, is growing in favour; while the whole subject of pills and pill coating has been recently dealt with in two papers by Dr. SYMES and Mr. MARSHALL. Dr. SYMES also contributed a valuable paper on the use of sugar in pharmacy to the Conference. Among the more prominent remaining points having pharmaceutical interest may be mentioned Mr. URWICK's interesting solution of phosphorus in alcohol and glycerine, with the addition of albumen; the utilization of the fixed oil of stavesacre by Mr. B. SQUIRE; the use of Russian oil of turpentine, by Mr. POSTANS; phenicated camphor; carbolate of iodine; croton oil pencils; the preparation of "pearls;" a series of recipes for perfumes by Mr. SAUNDERS, and the introduction of salicylic acid into colognes for sick rooms by Mr. LEIS. Last, but not least, comes the illustrated description of a working laboratory by Mr. SCHACHT.

It will not do to take a very wide excursion into the history of pharmacy abroad. Suffice it to say that in the United States the preparation of the next pharmacopœia is an absorbing topic; in Victoria a Pharmacy Act has been passed; and in Ceylon poison regulations based on the English Pharmacy Act have been established. Much valuable work has also been done abroad in the acclimatization of medicinal plants; for instance, in the cultivation of the jalap plant in Jamaica and the balsam of copaiba and the balsam of tolu plants in India. On the other hand, the ipecacuanha experiment in India is not very successful, and the cinchona plantations in St. Helena have been abandoned.

There have been numerous meetings having special interest to pharmacists. The British Pharmaceutical Conference met at Plymouth on the 14th and 15th of August, under the presidency of Professor REDWOOD. The British Association met in the same town on the 15th of August and following days. The meeting of the British Medical Association was held in Manchester during the preceding week. Across the Atlantic the American Pharmaceutical Association held its twenty-fifth meeting in Toronto in the first week in September. There was also a discussion on the International Pharmacopœia at the International Medical Congress held in Geneva in August. Here also reference may be made to the movement among professional chemists that has resulted in the foundation of an "Institute of Chemistry."

There are many topics that, although not pharmaceutical, are of such a nature as to justify their admittance into the columns of this Journal. Of this class there have been during the past year the lectures of Professor TYNDALL and Professor LISTER on "Germs," of Sir JOHN LUBBOCK on "Flowers in Relation to Insects;" Professor BARKER on "The Molecule and Atom;" Dr. REYNOLDS on "The Influence of Chemical Constitution on Physiological Activity;" Dr. PAVY on "The Means of Detecting Sugar in the Blood;" and Messrs. DOWNES and BLUNT's Researches on the Influence of Sunlight on Bacteria. Professor FLÜCKIGER's "Holiday in Liguria" furnished a very interesting paper, and Dr. MOREL is still contributing what it is hoped will be found to be a useful account of "The Products of the Coniferæ." In the scientific world perhaps the greatest noise has been made by the telephone; the liquefaction of oxygen which has just been announced is also a most interesting fact.

New books, and new editions of old ones, have not been wanting. Our old friend 'FOWNES' has become two handy volumes instead of one unwieldy one. The 'Medicinal Plants' of BENTLEY and TRIMEN has been continued regularly. Dr. KING, of Calcutta, has given us a valuable 'Manual of Cinchona Cultivation.' KINGZETT's 'History of the Alkali Trade' is a work *sui generis*, and likely to remain a standard one. Botanists have been favoured by Mr. BENNETT with a translation of THOMÉ's 'Text-Book.' UDOY CHUNDER DUTT has described the Materia Medica of the Hindoos. PASTEUR has applied Science to Beer Brewing. Finally there have been the Year-Books of the British Pharmaceutical Conference and the American Pharmaceutical Association, and the Jahresbericht der Pharmacie of DRAGENDORFF.

The story cannot be completed without one mournful paragraph. Pharmacy has again lost a few names that have done her honour. Abroad, CAVENTOU, the discoverer of quinine, and WEDDELL, the historian of the cinchonas, have been lost by France. Germany has lost POGGENDORFF, and Switzerland has lost AUGUST HUSEMANN, but they enjoy as legacies the 'Annalen' of the one and the 'Pflanzenstoffe' of the other. In the United States a former editor of its oldest pharmaceutical journal has passed away in Professer CARSON. In England WILLIAM GOSSAGE'S name will long be associated with the alkali manufacture. JOHN HUSKISSON before he died had acquired the name of the "father of the chemical trade." ALFRED SMEE, MARTIN MURPHY, JOHN SANGER, and FRANCIS GEORGE WARRICK were names familiar to English pharmacists. Both Mr. SHENSTONE and Mr. LAIRD had acted as Presidents of local associations, whilst the former had also rendered good service to the Pharmaceutical Society as a Local Secretary.

Enough of the story has now been told to show that last year was by no means deficient in pharmaceutical life, and also to task our readers' patience. Many topics have been left unnoticed, the periodical recapitulation in the "Month" having lightened the present task somewhat. Looking back upon the multitude of subjects of interest that have appeared during a single year in this Journal, from which the materials for the foregoing sketch are entirely drawn, we feel warranted in saying that the interests and progress of pharmacy have been fairly represented. To do this again in the coming year, which we hope will be a prosperous one to all our readers, will be our earnest endeavour.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, January 2nd, 1878.

MR. JOHN WILLIAMS, PRESIDENT.

MR. WILLIAM DAWSON SAVAGE, VICE-PRESIDENT.

Present—Messrs. Betty, Churchill, Cracknell, Gostling, Greenish, Hampson, Hanbury, Hills, Robbins, and Sandford.

The minutes of the previous meeting were read and confirmed.

The SECRETARY read a communication from the Privy Council approving the resolution recently passed for placing chloral hydrate in part 2 of the Schedule of Poisons, and also of the examiners appointed for the ensuing year.

DIPLOMAS TO PHARMACEUTICAL CHEMISTS.

The following being duly registered as Pharmaceutical Chemists were respectively granted a diploma stamped with the seal of the Society:—

Duncalf, James Mills Woolfenden.
Mortlock, William John.
Phillips, Evan.
Tamplin, Charles Edward.
Turner, George Thomas.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

Blunt, Thomas Porter ....Shewsbury.
Dear, Theophilus ....London.
Duncalf, James M. W............Manchester.
Fell, John James ....Lancaster.
Giles, William Egbert.............Birmingham.
Gorrie, Daniel ....Edinburgh.
Mortlock, William John ....Huntingdon.
Peirson, Henry ....Hertford.
Robinson, William Prior..........London.
Savory, Arthur Ledsam ....London.
Tamplin, Charles Edward.........Kingston on Thames.

Chemists and Druggists.

Crawshaw, Edward ....London.
George, Charles Albert............Sheffield.
Gibson, John Pattison ....Hexham.
Lewis, Richard ....London.
Read, Thomas ....New Clee.

ASSOCIATES IN BUSINESS.

The following having passed their respective examinations, being in business on their own account and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Izod, James Hickman ....Upper Norwood.
Prebble, John George ....Norwood.
Simpson, Allwood..................Stalybridge.
Taplin, Joseph Whelan ....Paddington.
Tice, Richard.........................Norwich.
Troughton, Henry..................Lancaster.
Weatherley, Richard John......Devonport.

Modified.

Key, Hobson........................Monmouth.
Stickler, Francis Miles............South Norwood.
Strachan, James ....Orange, N.S. Wales.
Thornley, Charles ....Carshalton.

ASSOCIATES.

The following having passed their respective examinations and tendered their subscriptions for the current year were elected "Associates" of the Society:—

Minor.

Bascombe, William ....Nottingham.
Billington, Arthur ....London.
Carlton, Arthur.....................Horncastle.
Collinson Frederick William ...Alnwick.
Cowap, John William ....Stockport.
Delamar, Edward Thomas ......Edinburgh.
Fisher, John Hutchison ....Edinburgh.
Fraser, Jonathan Innes ....Elgin.
Hutton, Harry ....Warwick.
Jenkins, Henry ....Salisbury.
Longbotham, Alonzo ....Ripon.
Mansergh, William ....Burton in Lonsdale.
Payne, Henry ....Bristol.
Peet, Henry ....Gosberton Hall.
Saunders, William Josiah ......Cardiff.
Smith, Joseph ....Sneinton.
Sugden, Samuel ....Newchurch.
Will, William Watson ....Montrose.
Wilson, James ....Buckie.

Modified.

McLean, Andrew Leith Hay A..Aberdeen.
Mills, William Drew ....London.
Milne, George ....Arbroath.

APPRENTICES OR STUDENTS.

The following having passed the Prelimenary examination were elected "Apprentices or Students" of the Society:—

Baker, Henry William Burgess.Haddenham.
Beeby, Robert Berry ....Coventry.
Bennett, Frank William.........London.
Brown, Alexander ....Dumbarton.
Burnett, Joseph Fearon.........Hyde.
Coley, William Henry............Wednesbury.
Cooper, Henry Scarborough ...Grantham.
Fox, Alfred ....Hull.
Gaylard, James Ratcliff ....Uxbridge.
Godfrey, Henry ....Godalming.
Haythornthwaite, William......Giggleswick.
Hill, Albert Clarence ....London.

Holden, John..........................Burnley.
Humphrey, John Thurlbeck ...Sunderland.
Ison, Harry John..................Wellington.
John, Dan ....St. Clears.
Lamplough, Frederick William Gt. Driffield.
Last, Alfred ....Rochford.
Lockyer, Joseph Ernest ....Deptford.
Mason, Frederic Silvester ......Leicester.
Moon, George William ....Malton.
Moore, Frank ....Mirfield.
Nobbs, Arthur Perkins ....Newport. I. W.
Palmer, Frederick Henry ......Lynn.
Pinder, Robert ....Bourne.
Preston, Henry.......................Mansfield.
Provis, Charles ....Emsworth.
Salmon, Ernest Frederick ......London.
Scott, Joseph..........................Dumfries.
Smith, Joseph ....York.
Spoor, William Joseph............Milford Haven.
Taylor, James Bennett............Bedford.
Taylor, John Cleasby ....Kendal.
Thompson, John Hartley.........Sheffield.
Waters, William Allen ....Emsworth.
Webb, George Frederick.........London.
Willet, John Algernon............London,
Willis, William......................Enstone.
Williams, Stephen..................Cardigan.
Wood, John ....Leighton Buzzard.
Yeatman, Frederick James......London.
Young, Thomas......................Cheddar.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The names of the following persons were restored to the Register of Chemists and Druggists:—

John Chirm, 23, Guildford Terrace, Guildford Street, Birmingham.

Henry Rutler Baker, 3 Spital Street, Guildford.

Reports of Committees.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts were ordered to be paid.

The Secretary drew attention to the large amount of the legal expenses incurred in prosecuting two cases of personation at the Society's examinations. He thought it was a great hardship that the funds of the Society should be called upon to bear expenses really incurred for the benefit of the public, and that it showed the great need of a public prosecutor.

BENEVOLENT FUND.

The report of this Committee was read and adopted.

Mr. Owen said that he found there was no chance of securing the election to St. Anne's School of the orphan, for which a sum of money had been placed in his hands, and he had therefore returned the money to the Society, but the friends of the child had used every effort, and spent a great deal of money, and were determined to carry the election next time.

The President said the grant having been already made, the money would of course be available at the next election.

The Secretary reported that in another case the amount granted had secured the admission of an orphan, at the late election, to the above school.

An Impostor.

The Secretary drew the attention of the Council to the fact that a woman was going about soliciting charity from members of the Society, professing to be the wife of a chemist and druggist, formerly in business in Plymouth. Inquiry showed, however, that her story was utterly unfounded.

Mr. Robbins said the case had been mentioned to him by a member of the trade, who thought it was one well deserving relief from the Benevolent Fund.

The President said the person referred to had called on him, professing to be recommended by a chemist in Sloane Street, and by other persons, and telling a very painful story. He gave her a little relief, and referred her to the Secretary, in order that she might make a regular application to the Benevolent Fund Committee. He found, however, that she had not done so.

The Secretary read a letter he had received from the Local Secretary at Bridlington Quay, thanking him for a donation of £2 from his Casual Relief Fund, which he had sent for the benefit of an old man eighty years of age, formerly in business, who was now in very reduced circumstances, but who never having been on the Register nor ever connected with the Society could not have a grant from the Benevolent Fund.

The President suggested that it would be very well if the Council voted a small sum to be placed in the hands of the Secretary to meet cases of emergency, or cases which were not within the conditions imposed by the Benevolent Fund regulations.

After some conversation, the Vice-President said he would give notice of a motion to this effect for next month.

LOCAL SECRETARIES.

Mr. William Bains Cordley, Colchester, and Mr. George Elliott, Walsall, were appointed Local Secretaries of the Society.

LIBRARY, MUSEUM AND LABORATORY.

The report of this Committee included the monthly report from the Librarian, showing an average attendance in the library of 21 in the day; 10 in the evening. Books circulated: in town, 161; country, to 20 places, 36. Carriage paid, 9s. The following donations to the library had been received:—

'Elements of Pharmacy,' and
'Manual of Vegetable Materia Medica.' 2nd edition. From Mr. G. S. V. Wills.
'The Microscope in Medicine.' From Dr. L. S. Beale.
'Proceedings of the Medical Society of London.' Vol. 3. From the Society.
'Select Practical Notes and Formulæ.' From Mr. W. Canning.
'Free Phosphorus in Medicine.' By J. A. Thompson. From Mr. A. W. Postans.
'Medico-Chirurgical Transactions.' Vol. 60. From the Royal Medical and Chirurgical Society.
'The Chemists and Druggists' Diary.'
'Calendar of University College, 1877–8.' From the College.
'Smithsonian Report, 1876.' From the Smithsonian Institution.
'Experimental Researches in Pure, Applied, and Physical Chemistry.' From Professor Frankland.

The special loan of a volume of reference marked with an asterisk was reported, and the Committee recommended that an asterisk be placed against the following books:—

'Thesaurus Literaturæ Botanicæ.' (Pritzel.)
'Catalogue of Scientific Papers.' (Royal Society.)

The purchase of the following books was recommended:—

General Fund.

'Library Journal.' Vol. 1, to complete set.
Hager's 'Pharmacopœia Homœopathica.'
Stocken's 'Dental Materia Medica and Pharmacopœia.'
Oliver's 'Flora of Tropical Africa.' Vol. 3.
'Supplement to Ure's Dictionary of Arts.'
Watson's 'Compendium of Cybele Britannica.'
Beasley's 'Pocket Formulary.' 10th edition.

Hanbury Fund.

'Baker's 'Flora of Mauritius.'

The Committee also recommended that the *Pharma-*

ceutical Journal be sent to the Medical Society of King's County, U. S., in exchange for its Proceedings.

The Curator had reported that the average attendance in the Museum during the preceding month had been, in the day, 12; evening, 4. The following donations had been received :—

Specimen of *Boswellia barteru*, one of the species yielding *olibanum*, grown at Aden. From Mr. J. Collins.

Specimen of Wax obtained from Lac. From Mr. E. Fielding.

Recent Specimen of Araroba. Dr. Symes.

The Curator also reported that the Index of the Museum Catalogue had been revised, and was in the hands of the printer. Also that the Secretary of the Leicester Chemists' Association had forwarded a list of labels required, which he would send immediately, with the specimens recently authorized to be sent.

The Professors had reported very favourably of their respective classes.

Mr. Churchill said he believed many country members were not aware that they could have books from the library on paying the carriage one way. He suggested that it should be occasionally brought under their notice on the front page of the Journal.

Mr. Greenish said the matter had been brought under the notice of members many times.

The Vice-President said there could be no objection to another notice being inserted. It was a very important privilege to country members, and the more it was made use of the better.

The report and recommendations of the Committee were received and adopted.

Coventry and Warwickshire Association.

A letter was read from the Secretary of this newly formed Pharmaceutical Association, asking that it might be supplied with a copy of the Journal as it appeared, as also the Calendar and Register of the Society.

A resolution was passed authorizing this to be done.

The President read a letter from Mr. Haselden thanking the Council for the resolution of sympathy passed at the last meeting.

House.

The report of this Committee was received and adopted.

Counter Practice.

The Solicitor attended to confer with the Council on the question of "counter practice," he having been in communication with the Solicitor of the Society of Apothecaries on that subject, agreeably to instructions given him in December.

The Council resolved itself into Committee for the purpose of receiving his report, which was understood to contain an assurance that the Society of Apothecaries had never instituted, and had no desire to institute, vexatious proceedings against chemists in the ordinary exercise of their business which necessarily involves a certain amount of advice to their customers.

Law and Parliamentary.

The report of this Committee included the usual report from the Solicitor as to the conduct of cases which had been placed in his hands.

A letter had been received from the surgeon who had signed the declaration in favour of Henry Povall, 62, High Park Street, Liverpool, desiring to withdraw his signature. In the case of David Brown von Cavania, 4, Upper Fountain Street, Leeds, the magistrate who had signed the declaration enabling him to be placed upon the Register had since stated that he knew nothing of him, and that his signature must have been improperly obtained. The Committee therefore recommended that Mr. Povall's and Mr. Cavania's names be removed from the Register.

A letter had been received referring to the sale, by an unregistered person, of homœopathic preparations of scheduled poisons. The Secretary had written to the informant asking him if he could procure evidence of the sale, by the person referred to, of any substance which could be proved to be a poison within the meaning of the Act.

Chloral Hydrate and its Preparations.

The Committee recommended that a copy of the tabulated list of poisons, with the addition of chloral hydrate and its preparations, be sent to each chemist and druggist on the Register, with a footnote drawing special attention to the recent addition.

The report and recommendations were received and adopted, and the names of—

Henry Povall, 62, High Park Street, Liverpool, and

David Brown von Cavania, 4, Upper Fountain Street, Leeds,

were ordered to be removed from the Register.

Report of Examinations.

December, 1877.

PRELIMINARY EXAMINATION.

Seven certificates were received in lieu of examination :—

1 Law Society.
1 Royal College of Surgeons.
4 University of Cambridge.
1 University of Durham.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, Dec. 20, Dr. Gladstone, F.R.S., President, in the chair. After the visitors had been announced, the minutes confirmed, and a list of presents to the library read, the following certificates were read for the first time :—G. S. Taylor, G H. Spring, J. V. Elsden, and A. H. Hooker.

The first paper was "*On the Bromo-derivatives of Camphor*," by Dr. Armstrong and Mr. Matthews. In preparing monobromcamphor, the authors find that it is merely necessary to add the requisite amount of bromine to the camphor heated in a water-bath, care being taken to add only a small quantity of bromine at first; heat is then applied to effect the decomposition of the resulting dibromide: on further addition of bromine the decomposition proceeds in a perfectly regular manner. The product is purified by washing with an alkali and recrystallization from alcohol. By the action of agents which convert camphor into cymene, bromocamphor is, apparently, completely decomposed. It is readily oxidized by nitric acid sp. gr. 1·3, furnishing much camphoric acid and a magnificently crystalline body at present under investigation. The authors find that if bromine be added to camphor (2 molecules of the former to 1 of the latter), and the mixture heated for a short time in the water-bath, dibromcamphor is obtained, melting at 57°–58° in colourless glistening prisms. This substance is dissolved and decomposed by nitric acid sp. gr. 1·4, furnishing a neutral substance with properties far less characteristic than the product from monobromcamphor, but no camphoric acid.

The next communication was "*On the action of Iodine on Camphor*," by Dr. ARMSTRONG and Mr. EASKELL. The authors have investigated the so-called camphin of Claus, which they obtained in quantity as a bye-product in preparing carvacrol from camphor by Fleischer and Kekulé's method. After extracting the carvacrol with sodic hydrate, a current of steam was passed through the residue: the distillate freed from camphor by extraction with dilute sulphuric acid (5 acid 2 water) was re-distilled in presence of sodium. In fractionating the product the authors found a slightly modified form of Le Bel and Henninger's fractional distillation apparatus of the greatest use (it can be obtained from Messrs. Cetti). Almost the whole passed over between 115° and 215°. The quantity below 160° was small. The quantity between 160° and 168° was very considerable. On examination it was found to consist, in all probability, of the hydrocarbon $C_{10}H_{20}$, but resembles in some respects the paraffin $C_{10}H_{22}$. The next considerable fraction boiled at 174–176°: it consisted chiefly of cymene. The higher portions, which in the aggregate constitute a by no means unimportant proportion of the entire product, contained much laurene (of Fittig, Köbrich, and Jilke), and one, if not two, hydrocarbons. The authors are continuing these investigations, and Dr. Armstrong stated that he had made much progress in the examination of the mixtures of hydrocarbons obtained from camphor by the action of the so-called dehydrating agents, for in no case, apparently, is cymene the only product. He proposes also to repeat Weyl's experiments on the action of hydriodic acid on camphor, and to prepare hydrides from cymene.

The third paper was read by Dr. ARMSTRONG, "*On the constitution of Terpenes and of Camphor.*" In the author's opinion, the generally received hypothesis that the terpenes are dihydrides of cymene is quite irreconcilable with their properties. They do not yield acids related to the hydrocarbons of the benzene series in any quantity on oxidation, neither do they furnish characteristic nitration products; moreover, they combine with bromine with great facility, they unite with the haloid acids at ordinary temperatures and combine with water, forming compounds such as terpin $C_{10}H_{18}(OH)_2$. A dihydride of cymene might be expected on oxidation to lose the "added" hydrogen, or to have its side chains affected; but the formation of compounds whose constitution is probably (Mielak and Williams) diaterebic and terebic acids is quite without analogy. The readiness with which the terpenes undergo isomeric change and are polymerized is also at variance with the above hypothesis. The evidence as to the real constitution of the terpenes is at present extremely unsatisfactory and insufficient, their conversion into cymene and behaviour on oxidation, the two most important elements for discussion, involving apparently opposite conclusions. The facility with which they form additive compounds tends, however, to support the conclusions derived from their behaviour on oxidation, *i.e.*, that they do not contain a closed chain of six carbon atoms, and, if this be the case, cymene is doubtless the end product of a series of changes. Whether the carbon atoms are all united in an open chain, or partially in a closed chain of perhaps fewer than six, seems quite uncertain. The evidence as to the constitution of camphor is equally incomplete. It is by no means established that camphor and the terpenes are so closely related as has been supposed. There is little doubt that it does not belong to the alcohols or aldehydes, but probably contains oxygen in the form in which it exists in ethylene oxide or in the ketones. From the fact that *homologous hydrocarbons* are formed with cymene by the action of the so-called dehydrating agents and other considerations, the author concludes that camphor does not contain a cymene nucleus in which the propyl and methyl groups are relatively in the "para" position. No formula hitherto proposed explains satisfactorily the ready formation of an anhydride from camphoric acid. In conclusion, the author states that the evidence as to the constitution of terpenes and of camphor is very conflicting, but that, from their entire behaviour, these bodies appear to be compounds of an altogether peculiar constitution.

The President remarked that as Dr. Tilden had a paper on a similar subject, he would ask him to read it before any discussion took place on the papers which had just been read.

Dr. Tilden accordingly read his paper "On the Hydrocarbons obtained from *Pinus sylvestris*, with remarks on the constitution of the Terpenes." 1. *Russian Turpentine Oil*; obtained as a by-product during the distillation of wood, chiefly from *P. sylvestris* and *P. Ledebourii*, for the purpose of preparing tar. Sp. gr. ·8682. 100 mm. rotated 17° to the right. It had a yellowish colour and pleasant odour. After removing small quantities of acetic acid and creasote it was distilled, four principal ingredients being ultimately obtained. Ten to 15 per cent. of a terpene boiling at the same temperature as australene 156° and identical with it chemically; 100 mm., however, rotate +23·3°. About 66 per cent. of a terpene boiling at 171° having a characteristic odour, rotation +17°, sp. gr. 0·86529 at 15°. The remaining ingredients consisted of about 7·5 per cent. of cymene and a terpene boiling at 173-175°. No solid hydrochloride could be obtained from this terpene nor any crystalline nitrochloride. In addition to the above ingredients the oil contains small quantities of viscid hydrocarbons having high boiling points. 2. *Oleum Foliorum Pini Sylvestris* obtained by distilling the leaves of the Scotch fir with water: sp. gr. ·8756, rotation = + 5° 30′. Careful fractionation yielded two terpenes corresponding in boiling point with those above described, the first boiling at 156-159°, rotation +18° 48′, and in odour resembling common turpentine; the second, constituting two-thirds of the oil, boiling at 171°, rotation = —4°, sp. gr. ·86529: no solid hydrochloride could be prepared. In addition, a little cymene and some pleasant smelling liquids of higher boiling point were obtained. The author then proceeded to discuss the constitution of the terpenes, and pointed out that there are probably only three isomerides amongst the natural terpenes, the differences in odour, action on polarized light, etc., can be accounted for without assuming any but mechanical differences of constitution. Thus we have terpenes from American and Russian turpentine, and that from the oil of the leaf of *Pinus sylvestris*, all boiling at 156-159°, sp. gr. ·860, and dextrorotatory; the terpenes from French turpentine, oil of sage, and oil of juniper have the same boiling point but are lævorotatory. The above form the first group and all yield the same nitroso-derivatives; terebene probably belongs to the same group. The members of the second group boil at 174°, sp. gr. ·85, and yield the same nitroso-substitution compounds; they are obtained from the oils of bergamot, sweet orange peel, lemon and caraway, and are all dextrorotatory. The third class comprises the two terpenes of higher boiling point (171-173°) described above, as obtained from Russian turpentine (probably Atterberg's sylvestrene) and oil of *P. sylvestris*, sp. gr. ·865, yield no crystalline monohydrochloride or nitroso-chloride. All terpenes yield by the action of bromine α cymene, *i.e.*, methyl-propyl-benzene; by oxidation they furnish carbonic and acetic acids. Cymene will not combine with hydrogen to produce a terpene; terebene has been obtained from diamylene by removing 4 atoms of hydrogen. From a consideration of the above facts the author suggests the formula—

$$\begin{array}{ccccccccccccc} & & C_3H_7 & & H & & H & & CH_3 & & H & & H \\ & & | & & | & & | & & | & & | & & | \\ H & — & C & = & C & — & C & = & C & — & C & = & C & — & H \end{array}$$

for α terpene. Similarly by shifting C_3H_7 and CH_3 one atom of carbon to the right the formula of β terpene, whilst by shifting the propyl and methyl groups two atoms in the carbon chain, that of γ terpene is obtained. These three formulæ furnish a cymene identical in each case. As regards camphor, the author is disposed to consider it as a benzene or cymene derivative, notwithstanding the fact that he has represented the terpenes as consisting of an open chain of carbon, the reasons for which constitution conclude his paper.

The President thought that it would be convenient to discuss the new facts brought forward by Dr. Tilden before proceeding to any arguments as to the theoretical views propounded; he was interested to know if the mechanical differences existing in the structure of the various members of the terpenes involved any difference of odour or whether the odour was due to oxidized substances.

Dr. Wright had some hesitation in accepting only three modifications of the terpenes. Thus the oils of orange peel and lemon were classed together; yet whilst the former yielded 80-90 per cent. of cymene, the latter furnished only 15 to 20 per cent. Moreover their boiling points were 2°-3° apart, and admitting there were at least four terpenes it was difficult to see how the proposed formula could form the same cymene by a simple reaction.

Mr. Kingzett agreed generally with Dr. Tilden, but pointed out that all terpenes by aerial oxidation formed peroxide of hydrogen and that cymene similarly yielded peroxide of hydrogen. On the whole he was inclined to believe that terpenes were dihydrides of cymene. He had found on oxidizing large quantities of oil of turpentine that the American oil oxidized slowly, the Russian oxidized four times as quickly, whilst the Sweedish was still swifter; the French oxidized at about the same rate as the Russian. The purer the oil the less readily did it oxidize. Camphor he regarded as resembling the alcohols in its constitution. The constitution as expressed by structural formulæ represents the way in which a body splits up when subjected to a certain mode of decomposition and as the products differ according to the mode, the derived formulæ cannot represent true constitution.

Dr. Tilden in reply to Dr. Wright thought that the difference in the yield of cymene from the oils of lemon and orange was due rather to a difference in mechanical than in chemical constitution.

Dr. Witt pointed out that one benzophenol was converted into its isomer with great evolution of heat, so that here there was an instance of two isomers having a different physical constitution.

Dr. Armstrong objected to dividing the terpenes into three classes, because there were the camphenes, which must constitute a fourth class. The formula of diamylene, on which Dr. Tilden founded his formula of terpene, was not by any means established. That Dr. Tilden's formula only accounted for three classes of terpenes he regarded as but a slight objection; there was no doubt that our present formulæ were insufficient.

The President said that such discussions were valuable not only for adding to our knowledge, but for revealing our ignorance; it would be necessary, as science advances, to revise our theories. Our present formulæ simply represented our present state of knowledge, and we must not expect them to survive, but to change for something more true and more perfect. Another point raised was, how far we are to distinguish between the chemical and the mechanical structure of a body. After some remarks as to the value and interest of the physical properties of a body, Dr. Gladstone concluded by stating that if cymene was contained in these terpenes, he should have expected their dispersion to have been higher.

The next paper was "*On Citric Acid as a constituent of imperfectly ripe Mulberry Juice*," by Dr. Wright and Mr. Patterson.—A large quantity of unripe mulberries was expressed, furnishing a turbid, light brown liquid, having a very acid taste. This was subjected to analysis, and found to contain 70·16 grams of total solids per litre. The solid matter consisted of citric acid, 26·83 grams, malic acid, 7·82 grams, glucose, 2·74 grams, ash, 9·4 grams. Mucilage portion, etc., 23·37 grams per litre. The presence of citric acid was confirmed by the preparation and analysis of the lime salt. In conclusion, the authors pointed out that the juice of imperfectly ripe mulberries, as it contains such a quantity of citric acid, and 3·26 grams per litre of potash salts (calculated as carbonate), may be valuable as an antiscorbutic and as a substitute for lime juice.

The next communication was made by Mr. Thomas "*On Cuprous Chloride and the absorption of Carbonic Oxide and Hydrochloric Acid Gas.*" The author, after many trials, found the following method for the preparation of the solution of cuprous chloride to give the best results. A long, narrow, 4 oz. stoppered bottle is filled three parts full with copper turnings, 6 grams of ordinary hydrous cupric chloride, and 20 c.c. of strong hydrochloric are introduced, and the bottle shaken until the $CuCl_2$ is dissolved; 10 c.c. of water are run in so as to float on the acid liquid, the bottle is then violently shaken; the solution becomes colourless instantly and after the addition of 30 c.c. of water is ready for use. The author finds that such a solution absorbs carbonic oxide with facility, but that when the free hydrochloric acid is suddenly neutralized with potassic hydrate as much as 63 per cent. of the carbonic oxide is again liberated and will remain unabsorbed. If the neutralization be effected slowly, about 4 per cent. only will be set free. To avoid any error from this reaction the author neutralizes the hydrochloric acid with ammonia before introducing the cuprous chloride solution. He prepares his solution thus: Some of the above cuprous chloride solution is poured into a small porcelain crucible, and to it is added by means of a fine pipette ammonia (1 of ·880 to 1 of water) until the slightest shade of blue remains permanent. This solution is introduced at once into the absorption tube by this method. Neither free ammonia nor free acid is introduced whilst the reagent absorbs carbonic oxide nearly as well as the original acid solution. The absorption is complete in half an hour. It is stated (Sutton's 'Volumetric Analysis,' p. 367) that sodic phosphate and sodic sulphate owe their absorbent powers, for hydrochloric acid gas, to their water of crystallization. The author has found that this is not the case, but that these substances form with HCl acid salts and sodic chloride. Ammonic sulphate in saturated solution is, however, the most convenient reagent, and by adding an equal volume of such a solution to the above cuprous chloride solution, the hydrochloric acid is neutralized without the liberation of any carbonic oxide. Or the solutions can be mixed before introducing them into the obsorption tube, as the mixture absorbs carbonic oxide with facility.

After the thanks of the meeting had been given to the authors for their respective communications, the Society adjourned to Jan. 17th, when the following papers will be read—

On the action of reducing agents on Potassium Permanganate, by F. Jones.

On the Alkaloids of the Aconite family. Part II. *Alkaloids of Aconitum Ferox*, by Dr. Wright and Mr. Luff.

On the Action of Sulphuric Acid on Copper, by Spencer Pickering.

Communications, Letters, etc., have been received from Mr. Hanley, Mr. Harrison, Mr. Holgate, Dr. Morel, Messrs. Kilner, Mr. Davies, Mr. Sainsbury, Mr. Haffenden, Mr. Willmott, Mr. Langbeck, Mr. Prebble, W. G. W., C. E. S., Syrupus, Apprentice.

We are compelled to postpone the answers to several communications.

THE ARTICULATING TELEPHONE.

The articulating telephone of Professor A. Graham Bell has attracted an amount of popular interest such as few, if indeed any, of our most remarkable modern inventions have approached. The handiness of the instrument and the conditions of simplicity and perfectness under which it has been introduced into this country have conduced largely to these favourable opinions and results.

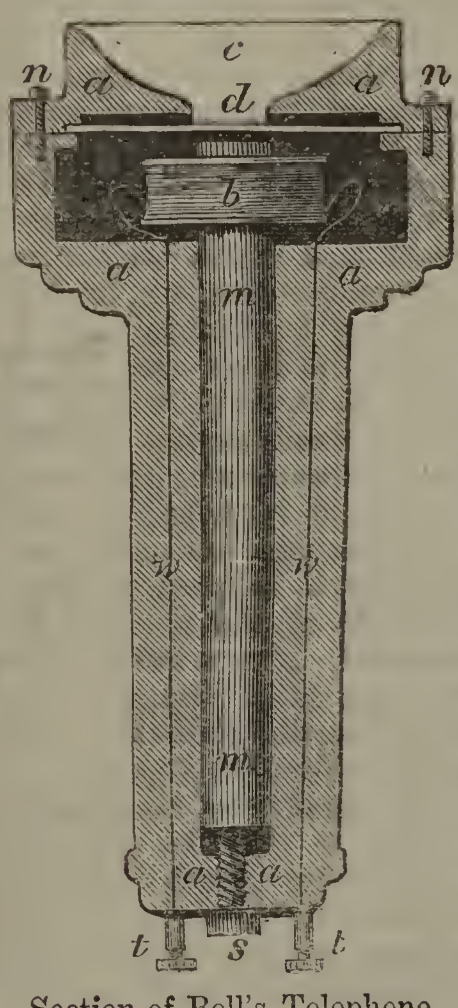
Sound is produced by vibrations of the air, and musical notes depend upon the respective particular numbers of vibrations per second of time. Vibrations of the air are produced if electric currents are passed through an electro-magnet, and the contact of its armature made and broken. If, therefore, this be done more than sixteen times per second, distinct tones are produced by the vibrations. This is the fundamental principle of the electrical telephones. The notes or sounds they emit are not transmitted in the sense that the vibrations of musical notes were actually and mechanically transmitted in the early experiments, in which, by connecting the sounding-boards of two pianos by a wooden rod, the strings of the one were caused to respond to the playing of the other; but the sounds received by hearers are reproductions, by means of electrical currents of peculiar qualities, of the sounds spoken by the converser.

The discovery of this "galvanic music," formed by the rapid magnetization and demagnetization of iron bars, is attributed to an American physicist, Page, in 1837; and the first telephone which produced rudimentary musical sounds at a distance is said to have been made by Reiss, of Friedrichsdorff, in 1861.

The tone of a musical note is dependent on the number of vibrations in time only; the intensity of the sound depends on the amplitude or extent of the vibrations; and the *timbre*, or quality, on the peculiarity of the motions of the moving particles of air in the waves produced in the atmosphere. The vibrations producing musical notes can be communicated to an electric current and reproduced at any distance by the rapid charging and discharging of an electrical condenser by simple intermittent or pulsatory currents, as was done by Cromwell Varley in 1870, and still more perfectly and publicly last year at the Promenade Concerts at the Queen's Theatre in London. It is the speciality of Professor Bell's telephone that the *timbre* or quality of the sound is reproduced; and thus it has been rendered practicable to carry on conversation by actual words between any two points in electrical communication however distant those points may be apart.

The instrument which Professor Bell has produced is very compact, being enclosed in a wooden case not much bigger than an ordinary single opera glass. For the transmission of words the broad end is spoken into: and for the comprehension of speech produced the broad end must similarly be held to the ear. For conversational purposes two instruments are needful, otherwise both parties may be trying to talk, or be listening together, at the same time and some confusion of purpose arise.

It is not essential, in a concise notice like the present, to trace in detail the various stages of the development of the invention; but it is notable that two lives have been concerned in the ultimate results. The inventor's father, Mr. A. Melville Bell, of Edinburgh, was, many years ago, well known for the attention he gave to the mechanism of speech, and the son in this way has, from his earliest years, been an associate in numerous experiments and researches on the musical relations of vocal sounds—indeed, the immediate origin of the articulating telephone appears to have been laid in a continuation of such researches. Every vowel has its particular pitch; and Professor Bell, whilst resident in Canada, carried on a series of experiments with tuning-forks held in front of the mouth, the results of which he communicated to our countryman, Mr. A. J. Ellis, from whom he learnt that he was only following in the footsteps of Helmholtz, who had already advanced to the extent of reproducing vowel sounds artificially by electrical means. From that period Professor Bell devoted his attention to the study of electricity as a means of advancing telephony, under the idea of the great practical utility of transmitting by musical sounds several telegraphic messages simultaneously. By an arrangement of tuning forks with resonators to reinforce the sound Helmholtz had found that, by varying the loudness of the forks by the influence of resonators so as to combine musical tones in different proportions, he was enabled to copy the *timbre* of certain vowel sounds. In this composite character of articulate sounds was a clue of primary importance. A harp was made of steel rods, attached to a powerful permanent magnet, which vibrated in the presence of an electro-magnet; and a similar arrangement was repeated at the other end of the electrical circuit. By the vibrations of a permanent magnet in the neighbourhood of an electro-magnet, a current of electricity is produced, the intensity of which is proportional to the velocity of the motion of the magnet, and its polarity is dependent on the direction of the motion. If then a vowel sound can be produced by vibrating simultaneously a number of these rods, a current of electricity will be transmitted to a line which will produce the same sound upon a similar harp at the distant end of the connecting wire. If vowels are sung into a piano, the pedal being down to allow free vibrations of the strings, not only will the voice be echoed back, but approximations to the quaities of the particular vowel sounds will be heard: and theory shows that if the piano had a very much larger number of strings to the octave, a *fac-simile* would be produced.



Section of Bell's Telephone.

A simple metal disc may be regarded as a harp with an infinity of forks or strings, and if by the vibrations of such a disc, under the influence of a musical note or vocal sound, characters can be given to an electric current similar to the motions of a particle of air concerned in the production of that sound, then the transmission of that current to the metal disc of a distant instrument should set up in it like mechanical or molecular motions, which, there transferred from its surface to another portion of the atmosphere, should repeat, or rather reproduce, in it sounds like those produced at the actuating origin. This particular species of electrical current Professor Bell terms undulatory.

The figure represents a section of one of Professor Bell's telephones, *half* the actual size. The wooden case is indicated by shading, and is lettered *a*. Within the cylindrical handle is the permanent magnet (*m*), above which is the soft iron core of the electro-magnet, with its surrounding coil or bobbin of fine insulated wire (*b*), contained in a cavity or chamber turned out of the expanded head of the case; the ends of the conducting wires from the bobbin pass from within the handle to the terminals (*t t*), to which is afterwards attached the cord by which the instrument is secured to the electric carrying wires. In front of the pole of the compound magnet is a small disc of ordinary tinned or japanned sheet iron (*d*) about the size of a crown piece. The insertion of this disc is managed in this way: The wooden box or cylindrical head is cut horizontally across, and a further slice being taken off the roof in the upper portion, the disc is gripped all round its outer margin by the bevelled edges of the two halves of the box when these are brought tightly together by screws. Over the central portion of the metal disc (*d*) is an orifice about half an inch in diameter which is expanded outward into a bell-mouth form (*e*), for speaking into or listening from. At the bottom of the wooden handle is a copper screw for adjusting the distance of the pole of the magnet (*m*) from the metal disc (*d*). Here is the whole affair: and simple enough. So simple indeed, that one wonders at the extremeness of its simplicity.

Batteries are dispensed with altogether; for it was found that even the residual magnetism left in the electro-magnet was sufficient; hence, the substitution of the permanent magnet. Enclosing the whole of the magnet in a coil of insulated wire was also found unnecessary; it was needful to surround the pole of the magnet alone. The needful extent of area and thickness of the metal disc has been also worked out, and experiments have shown that by varying the size, diameter and thickness of the iron plate, comparatively little change is brought about; the chief difference being a peculiar effect on the quality of the voice. Professor Bell states that he has produced distinct articulations from iron plates all the way from one inch to two feet in diameter, and from one sixty-fourth to three-eighths of an inch in thickness. If the plates be of uniform thickness and the diameters varied, there is with the small plate a perfectly distinct articulation, but a nasal twang. Enlarge the diameter, the nasal sound disappears; and a point is obtained when a good quality of telephonic voice is obtained. Increase the diameter yet more, and a coarse hollow drum-like effect is induced, which advances with the enlargement of the plate, until a reverberating sound is reached. If now the thickness of the plate be increased this effect disappears, and distinctness of articulation is again attained. But if the thickness be increased beyond this point, a return is made to the nasal quality of sound. The inference from these effects is that the vibrations which give rise to the articulate speech of the telephone may be molecular and not due to the vibration of the plate as a whole; but as audible sounds are said to be produced by vibrations of $\frac{1}{25000000}$ of an inch, this point is open to further very delicate investigations.

In laboratory experiments with artificial resistances, there is no impediment whatever to the free use of the Bell instruments through circuits equivalent to 6000 miles; and, indeed, there seems no practical limit to the distances at which conversations can be conducted. The longest actual distance which the inventor has been able to avail himself of has been the telegraph line from New York to Boston, in the United States, 258 miles. At the last meeting of the British Association, Mr. Preece asserted that he had conversed with others up to distances of thirty miles, and that through a quarter of a mile of wire he had heard Professor Bell "breathe, laugh, sneeze, cough, in fact make any sound the human voice can produce." It must be understood, however, that although messages spoken in the ordinary voice, or even whispered, are distinctly audible after miles of transmission, without any effort, this takes place only when the instrument is held like an ear-trumpet close to the ear; persons of the very quickest hearing fail to catch what is said at little more than a foot or two away. The most remarkable feature of Professor Bell's telephone, is its decided tendency, nothwithstanding its own metallic *timbre*, to represent the qualities of the speaker's voice.

Conversations were recently carried on through the submarine telegraph cable between Dover and Calais. This cable has four wires, and whilst one was in use for the telephone, the other three were carrying Morse messages between London and Glasgow to Paris, Calais and Lille. Nevertheless, the voice message was perfectly distinguishable. This cable is twenty-one miles and three quarters in length, and has a copper resistance of 236 British Association units. Telephonic intercourse was kept up along it for over two hours, in French and English speech, as well as by tunes played by a musical box. Conversations have also been also carried on through the postal wires between Manchester and Liverpool, and, still more recently, by Mr. Preece and Mr. Wilson, through the submarine cable between Dublin and Holyhead, a distance of a hundred miles. The inductive influence of other lines of telegraph wires in contiguity with the one in telephonic use is, however, rather embarrassing when those other wires are busy; but this influence, it is said, can be overcome and negatived.

The widest application of the telephone is, without doubt, only a mere question of time; for the one point that actual conversation can be carried on by every person who can speak, and that, too, without any special training in the manipulation of instruments or symbols, will ultimately ensure to telephonic telegraphy the preference over every other system.

THE TURPENTINES AND RESINOUS PRODUCTS OF THE CONIFERÆ.

BY DR. JULIUS MOREL,

Professor of Chemistry in the Industrial School, Ghent.

(*Continued from page* 344.)

In studying the various kinds of commercial turpentines mention has been made, according to the actual state of science, of their composition, and it has been evident how that composition is variable according to the species examined. Whatever may be the method of extraction of the essential oils, which will next be dealt with, whether from the turpentines or from the juniper or savin, they all resemble each other in a certain number of characters, and group themselves around oil of turpentine, which may be taken as a type. Further, all the essential oils of the Coniferæ are hydrocarbons that readily absorb oxygen from the air, and combining with it become resinified under its influence. Iodine reacts with them energetically and produces a detonation.

XV. OIL OF TURPENTINE.

Synonyms.—L.: Oleum Terebinthinæ; Oleum volatile Pini s. Laricis.—G.: Terpenthinöl.—F.: Esprit de Térébenthine; Essence de Térébenthine; Erypèle de Térébenthine.

Botanical Origin.—This is very various. In fact all the turpentines which contain a suitable proportion of volatile oil can yield such products varying but slightly in their properties. According to Planchon the commercial oils of turpentine are divided into the *French*, produced especially from the turpentine of *Pinus maritima* and *P. Pinaster;* the *German*, yielded by *Pinus sylvestris*, L., *Abies pectinata* and *A. excelsa*, DC.; the *Venetian*, extracted from *Larix Europœa;* and the *English*, a product extracted from the American turpentines yielded by *Pinus Tœda*, L., and *P. australis*, Mich. All these volatile oils are grouped under the common name of oil of turpentine, because of the analogies that exist between them; their distinguishing characters, as will be seen, are especially based upon their rotatory powers, some being dextrogyre and others lævogyre.

Preparation.—Oil of turpentine is prepared by submitting to distillation one or other of the turpentines that have been described. Thus obtained it is known as "crude" (*brute*), and generally contains certain acids, such as acetic acid, formic acid, and even some of the resin acids. In order to purify it it is submitted to rectification by redistilling it from water and carbonate of potash, carbonate of soda, or even lime.

In America the oil is prepared in copper stills capable of holding 500 to 2000 kilograms of turpentine. The distillation is effected without the use of water, and the oil passing through the worm is collected in the barrels in which it is to be carried away. When the rectification is effected with alkaline carbonates or lime, these bodies saturate the free acids and remain in the retort; the water that the oil still retains is removed by a fresh distillation over fused calcium chloride.

Dragendorff has made numerous experiments upon the rectification of essential oils, and especially with oil of turpentine. The following are his remarks upon the subject in the *Pharmaceutical Journal* (3rd ser., vol. vi., p. 641):—

"For this purpose they may either be carried over by a current of steam, or the oil may be distilled, with about six volumes of water, so that one part of the oil shall remain behind in the retort. In the former case, it must be laid down as a rule that the current of steam shall reach the oil under a pressure exceeding *one* atmosphere, or at a temperature above 100° C. The fact that the oil, of which the boiling point often lies far beyond 100° C., will pass over with the aqueous vapour has in it nothing surprising. It is otherwise in the distillation of oils which contain water dissolved in them. If in this case water and oil occur together in the distillate, they pass over at a pressure of one atmosphere and at a temperature not over, but under, 100° C., as Dragendorff has proved. The oil, therefore, becomes modified in its boiling point by the water present; and this is in accordance with what has already been observed by Magnus that liquids which are not miscible with each other, when heated together, will distil at a temperature lower than the boiling point of the most volatile."

For oil of turpentine, according to the quantity of water, the boiling point is between 96·5° and 98·5° C.

Dragendorff made his experiments "in a tubulated glass retort containing 200 c.c. of oil of turpentine, and into which a glass tube passed almost to the bottom. The latter was connected by means of tubing, as short as possible, and packed with cotton, with a flask in which water was heated to strong ebullition." The distillate produced was colourless, mobile, and of good odour; also the exact quantity of water required was used, so that the loss through becoming dissolved in the water distilling over was the smallest possible.

Properties.—Oil of turpentine, when pure, is colourless, of oleaginous consistency, and variable in density, boiling point and rotatory power, according to the kind of turpentine from which it has been extracted. It has a strong characteristic odour and a hot and burning taste. It is soluble in absolute alcohol, ether, chloroform, benzol, carbon bisulphide, and the fixed and volatile oils. Dilute alcohol dissolves it less readily; it requires 4 volumes of 90° alcohol, 8 volumes of 88°, and 12 volumes of 81°. Shaken with water, oil of turpentine communicates to the water its smell and taste. Oil of turpentine volatilizes without decomposition between 150° and 160° C. Cooled to —17° C. it deposits a crystalline hydrocarbon that liquefies at —7° C. The presence of oxygen in unrectified oil of turpentine, and even in some rectified oils, can be demonstrated by the addition of a little metallic sodium, which undergoes oxidation immediately, and hydrogen is set free. Chloride of antimony produces a very energetic reaction, accompanied by the evolution of heat and the formation of a yellow resinous mass. Iodine produces an energetic reaction with oil of turpentine, accompanied by a detonation louder in proportion as the oil is more recent. Nitric acid also reacts very energetically upon it. A mixture of nitric and sulphuric acids will give rise to such an elevation of temperature as to inflame the oil.

Gaseous hydrochloric acid forms with most of the oils of turpentine a combination, one portion of which separates under the form of crystals resembling camphor in their appearance. This is an "artificial camphor," having a rotatory power equal to, and in the same direction as, that shown by the oil that has been used in its preparation.

If exposed to the air, oil of turpentine easily becomes resinified by the action of oxygen, and besides the resin a certain amount of formic acid is formed. The resinous matter that is formed under such circumstances does not resemble any of the natural resins at present known. Moreover there is no evidence at present of the formation of resins by the simple oxidation of volatile oils. However, Hlaziwetz and Barth have obtained substances that approach very closely to the resins of the Coniferæ, by heating oil of turpentine, oil of savin, and other oils with an alcoholic solution of caustic potash in sealed tubes.

The presence of resin in oil of turpentine can be recognized not only by evaporating carefully after previous distillation, but by the addition of ammonia, which determines a white crystalline precipitate, and even the more or less complete solidification of the mass, according to the proportion of resin it contains. The presence of a centigram of colophony in 20 c.c. is sufficient to give with caustic ammonia a characteristic turbidity.

In contact with water, and especially in the presence of a small quantity of nitric acid, oil of turpentine will form a hydrate which is inodorous, tasteless, and soluble in hot water, alcohol and ether. This product has been described under the names hydrate of "terpilene" and "terpene."

According to C. T. Kingzett (*Pharm. Journ.* [3], vol. vii. p. 225), oil of turpentine, when oxidized by air in the presence of water, yields peroxide of hydrogen and camphoric acid (both of which may result from the action of water upon camphoric peroxide $C_{10}H_{14}O_4$), acetic acid, camphor, and certain other less definite substances. The oil itself increases in specific gravity, and contains after this treatment certain oxidized bodies, among which is a further quantity of this camphoric peroxide. Kingzett's process is now being carried out commercially in this country, the product being sent out as an antiseptic under the name "Sanitas."

Characteristic Reactions.—The physical and chemical characters of oil of turpentine that have been briefly given are not sufficient to enable an analysis of that substance to be made with certainty. It has only been since the appearance of the valuable memoir of Dragendorff, in the *Pharmaceutical Journal* in 1876, that we have been able to state precisely by the aid of a series of reactions whether the product offered in commerce is really pure. The reagents employed for this purpose are six in number.

1°. Chloroformic Solution of Bromine (1 part of bromine to 20 parts of chloroform).—Added in the proportion of 10 to 15 drops to 1 drop of oil of turpentine, crude or rectified, after a time it is completely decolorized.

2°. Impure Hydrate of Chloral, especially that which gives with oil of peppermint an intense red colour, is a very good reagent. If a few drops of this solution are added to one drop of oil of turpentine (pure or crude) placed in a watch glass, at first no coloration is produced, but after some time the oil is coloured pale red.

3°. Alcoholic Solution of Hydrochloric Acid, which can be employed either in the concentrated or dilute form. 1 drop of oil of turpentine (crude or rectified) treated with 15 to 20 drops of the reagent gives, when this is concentrated, a brownish yellow colour which disappears promptly leaving the mixture colourless. With the reagent diluted the coloration is less intense and disappears more slowly.

4°. Pure Concentrated Sulphuric Acid is employed by bringing into contact in a watch-glass 2 or 3 drops of the acid and 1 drop of the oil. A deep red colour is produced which becomes slightly paler with crude oil, but becomes blood red with the rectified oil.

5°. Frohde's Reagent, which contains 1 centigram of molybdate of sodium* in 1 c.c. of strong sulphuric acid, added in the proportion of 3 drops to 1 drop of oil of turpentine (crude or pure), determines a brownish coloration, which passes to a blood red. This reaction is more definite than that with sulphuric acid.

6°. Fuming Nitric Acid, added in the proportion of 3 to 5 drops to 1 drop of the oil (crude or pure), determines a very energetic reaction and produces a red colour that passes to brown.

7°. Picric Acid—5 to 10 drops of the oil added to 5 centigrams of this acid dissolves it with difficulty in the cold, but easily when heated, and gives with a pure oil a yellow solution that upon cooling yields a crystalline deposit. Ether dissolves this yellow matter and upon shaking the ethereal solution with water this vehicle separates a portion of the picric acid. The crude oil gives the same reaction, but an elevation of temperature brings the yellow solution to a blood red colour.

Quantitative Determination of Oil of Turpentine.—Osse, according to the statement of Dragendorff, was occupied in 1875 with this important question, not only for oil of turpentine but essential oils in general. The process is based upon the extraction of the essential oils by means of a solvent having a low boiling point, evaporation at the ordinary temperature of the solution so obtained, and weighing the residue. The solvent employed is light petroleum spirit, boiling below 40° C., which has been previously freed from its odour by distillation in the presence of fat. As might be expected, the evaporation of the petroleum spirit carries with it a certain quantity of essential oil, but the loss was found to be very small in operating upon small quantities, evaporating at a temperature about 15° C. in a current of dry air, seizing exactly the point of the complete disappearance of the solvent, and then closing hermetically the vessel in which the evaporation has taken place and weighing. The following is the method of procedure adopted by Osse:—

The solution is evaporated in a current of dry air (underneath a bell glass resting upon a ground glass plate) until the residue no longer presents more than a slight odour of petroleum; then it is weighed. The weighings are repeated several times after the watch-glass containing the oil had been exposed to the air for *one* minute. Starting at the point when the weighings show a constant diminution of weight per minute, after several weighings, the loss of the last is noted; from this is obtained what Osse calls the coefficient of evaporation. Osse admits that for oils of which the coefficient of evaporation exceeds one milligram per minute, commencing with the first weighing there is evaporated, besides the petroleum spirit, a quantity of essential oil equal to the coefficient of evaporation, and in his calculation of the quantity of essential oil found he adds as many times the coefficient of evaporation as evaporations and subsequent weighings have been made.

Oil of turpentine is one of those of which the coefficient of evaporation exceeds one milligram per minute; it is necessary therefore in making a quantitative analysis to have recourse to the correction just described. The following are results obtained by Osse:

0·0277 gram of oil of terpentine, dissolved in one c.c. of petroleum spirit, gave—

At the 1st weighing	0·0460	gram of residue.	
„ 2nd	0·0260	„	„
„ 3rd	0·0205	„	„
„ 4th	0·0170	„	„
„ 5th	0·0135	„	„

The difference between the 3rd and 4th and the

* Buckingham recommends the substitution of this salt by molybdate of ammonium.

4th and 5th weighing being 0·0035 gram, this figure was taken as the coefficient of evaporation. Therefore to the result of the 3rd weighing=0·0205 gram was added 0·0035×2=0·007, the total being 0·0275 gram. The same experiment, repeated a second time, gave 0·0267 gram. The difference therefore did not exceed 3·61 per cent. of the weight of the substance examined.

Osse also made some experiments with carbon bisulphide alone and combined with petroleum spirit; the results obtained were less satisfactory than those with spirit.

Composition.—Oil of turpentine, as met with in commerce, is a mixture of various hydrocarbons of analogous composition, corresponding to the formula $C_{10}H_{16}$, or multiples of that formula. These hydrocarbons vary among themselves in their boiling point and rotatory power. Berthelot has shown that if, instead of employing the usual processes of distillation, the precaution is taken of previously incorporating with the crude turpentine a mixture of carbonate of potassium and carbonate of lime, and afterwards distilling, then heating in a water-bath to a temperature between 60° and 80° C., a well defined hydrocarbon is obtained, answering to the formula $C_{10}H_{16}$, which is mobile, very refrangent, has a density of 0·863, boils at 151° C., and has, when prepared from common turpentine (from *Pinus maritima*, etc.), a rotatory power of 42·30° to the left.

(*To be continued.*)

NOTE ON THE SPECIFIC GRAVITY AND STRENGTH OF DIALYSED IRON.*

BY E. B. SHUTTLEWORTH.

There exists, at present, some difference of opinion in regard to the specific gravity of the ordinary medicinal solution of dialysed iron. In a paper read at the last meeting of the American Pharmaceutical Association, Dr. Pile stated the specific gravity of a solution containing 5 per cent. of oxide to be 1·029. In making some remarks on the subject, Dr. Squibb gave the sp. gr. at 1·03—(the third decimal figure I do not exactly recollect—while Professor Diehl said that according to Dr. Wagner, of Buda, by whom the remedy was first introduced to the medical profession, it should be 1·046. The latter statement is borne out by Dr. Hager and Mr. Grossinger, who examined Wagner's preparation, and it is also repeated or accepted in a number of papers which have since appeared.

In order to reconcile these difficulties and to determine the point for my own satisfaction, and also to ascertain whether the test of specific gravity may be relied on as an indication of the strength of this preparation, I have made a number of experiments, of which the results are subjoined.

It was premised that a thoroughly dialysed solution would contain more iron for a given specific gravity than one in which the process had not been completely carried out. This was of course found to be true, but not to the extent which might be at first imagined. The rule holds perfectly good with regard to solutions in which the diffusion has only just commenced, but after two or three days most of the hydrochloric acid, chloride of sodium, or chloride of ammonium will have passed through the septum, while a considerable portion of the chloride of iron will remain. Such a solution will not show much difference in iron strength to that containing nothing but the oxychloride.

* From the *Canadian Pharmaceutical Journal* for December, 1877.

I think that the differences above alluded to may be in great part accounted for by the supposition that the drying of the oxide was not carried in each case to the same extent. If 100 grains of a thoroughly dialysed solution be evaporated on a water-bath and the product be weighed when apparently dry, the quantity of residue will be much greater than if the drying be continued until the weight is constant. This residue, if heated in an evaporating dish over an open flame, will again lose weight, and if the product be placed in a platinum capsule and brought to a red heat a still further diminution will be observed. Wagner's solution, referred to by Professor Diehl as of sp. gr. 1·046, was estimated for the normal oxide—that obtained by calcination; Dr. Pile probably estimated his solution by evaporation over a water-bath, though, as far as my own experiments are concerned, I have not been able to obtain a solution of quite so low a specific gravity and which would yield 5 per cent. residue in a pulverulent condition, *if weighed at once and while warm.*

This brings me to a point which to the uninitiated would certainly, to say the least of it, be very puzzling. If the warm and apparently dry residue be weighed and then allowed to cool, it will be found to be appreciably heavier. In one hour five grains will have increased perhaps six per cent.; and after a night's exposure—according to the hygroscopic condition of the air—the five grains may have become six.

The following table shows the percentage weights obtained from several strengths of a solution which had been dialysed for twenty-four days, and which did not blacken infusion of galls:—

Sp. Gr.	Pulverulent on Water-Bath.	Well Dried on Water-Bath.	Exposed during one night.	Calcined.
1·046	—	5·6	—	5·0
1·040	5·5	5·0	6·0	—
1·038	5·2	4·7	5·6	4·3
1·034	5·0	4·3	—	—

It will thus be seen that three of the above solutions might be described in common language as containing five per cent. of oxide, though only the first is properly of that strength.

Taking into account the liability of strong and well dialysed solutions to become gelatinous, I think a liquor of 1·010 yielding, when evaporated and well dried over a water-bath, five per cent. of residue, best fitted for medical use. Such a solution keeps well; it can be readily estimated by the pharmacist—a simple evaporating dish being all that is required—and, moreover, the strength corresponds as nearly as possible with that of the ordinary tincture of perchloride of iron.

A word in regard to the asserted tastelessness of dialysed iron. I have now on hand a solution which has been dialysing for forty-two days and is quite gelatinous. It cannot, however, be strictly described as tasteless. Though it is not in the least ferruginous it is slightly styptic, and produces, when applied to the tongue, an effect similar to that of astringents. This is, I think, to be attributed to the precipitation of oxide, which occurs the moment the solution comes in contact with the saliva, thus giving rise to the sensation alluded to.

Provided, then, that a solution is deprived of ferruginous taste, that it is not distinctly *blackened* by infusion or tincture of galls, and does not give direct evidence of containing hydrochloric acid, I think the test of specific gravity may be, for common purposes, relied on.

PRESERVATIVE PROPERTIES OF EUCALYPTI.*

BY THOMAS TAYLOR.

In consideration of a request to investigate the preservative properties of the Eucalypti, I have made a series of experiments, as follows: Twelve glass jars, each

* Extract from the Report of the United States Commissioner of Agriculture.

holding one quart, were arranged side by side. In six of them I placed a quantity of the leaves of several species of the *Eucalyptus*, taking care that each jar should contain the leaves of a distinct species. The jars were then filled with pure water. Ground stoppers were used to exclude air and dust from the solution. Each jar was numbered, respectively, from one to six. No. 6 contained leaves of the *Eucalyptus globulus*. Seven other jars, numbering from seven to thirteen, were filled with solutions, and various plant leaves, as follows: No. 7 contained a solution of sulphate of quinine in the proportion of about 3 per cent. of the alkaloid. In this solution I immersed a foreign grape leaf. No. 8 contained a grape-leaf and pure water; No. 9, a grape-leaf and pure acetic acid; No. 10, equal parts water; No. 11, a large cinchona-leaf and a weak solution of the essential oil of the *Eucalyptus globulus*, made by immersing a few leaves of that plant in pure water, by which the water became impregnated with the oil. No. 13 contained water, a grape leaf, and about half an ounce of the flowers of sulphur. At the termination of ten days I found that nearly all the plant-leaves had fermented; the exceptions were those contained in numbers 6, 9, 10, 11, and 13. Although eucalyptol oil is very sparingly soluble in water, its weak solutions prove highly antiseptic and deodorizing; and when the amount of albuminoids held in solution is reasonably limited, they are preserved. Solutions of the alkaloids, and some of their medicinal preparations, may, therefore, be prevented from decaying by fermentation when alcohol cannot be used successfully with them. The foregoing results induced me to extend my experiments to other well-known essential odorous oils, first, to ascertain their relative value as antiseptics and deodorizers; second, whether their oxidizing power is proportional to the strength of their odours; and, third, their immediate chemical action on the soluble alkaline sulphides of potassium and ammonium. For this purpose I arranged a series of test-tubes, about ten inches in length by one in diameter, each of which I filled to within half an inch of the top with water, adding a few drops of an essential odorous oil, combining the mixture as well as could be done by shaking it. All of the essential oils are sparingly soluble in water. In this series of experiments I used the oils of bergamot, spearmint, cloves, caraway, cinnamon, lavender, peppermint, lemon, winter green, rosemary, origanum, and cajeput. The results demonstrate that several of them decompose the sulphide of potassium quickly, while others, although highly odorous, are slow deodorizers, and do not seem to decompose these sulphides under the conditions stated. Rosemary, peppermint, wintergreen, and lavender are of this class.

If concentrated solutions of the oils of pennyroyal, tincture of myrrh, the oil of rose geranium, and oil of horse-mint are combined in separate test-tubes with sulphide of ammonium, it will be found that pennyroyal and myrrh produce a heavier precipitate than either of the other two oils, rose geranium and horse-mint.

The oil of cloves oxidizes quickly the potassium of the sulphide and precipitates sulphur when both solutions are combined in concentrated form, and it also decomposes this sulphide when it is highly diluted; but it exhibits no decomposing properties when combined with the sulphide of ammonium. Concentrated sulphide of potassium and ammonium exhibit but very slight action on cajeput. Origanum decomposes concentrated sulphide of potassium, while it exhibits no reaction on the sulphide of ammonium. Turpentine and eucalyptol oil have a similar action on the concentrated solutions of potassium and ammonium sulphides; but the eucalyptol exhibits a higher precipitating power than turpentine or any other of the essential oils with which I have experimented.

It is generally believed that the atmosphere of pine forests is highly favourable to invalids suffering from pulmonary complaints, and it has been supposed that the oxidation of the oil of turpentine exuded from pine-trees, and of other essential oils, such as the odorous oils of flowers in the air, is attended by the formation of ozone, inasmuch as the oxidized oils and the air in their vicinity exhibit the reaction of ozone with potassium iodide and starch. Kingzett attributes the active properties of the oxidized turpentine oil to the formation of monohydrated terpene oxide $C_{10}H_{16}O.H_2O$, which was shown some time ago by Sobrero ('Ann. Ch. Pharm.', p. xxx. 106) to be formed when turpentine oil containing water is exposed to the sun's rays in a vessel filled with oxygen (see page 887, Watt's 'Chemistry,' second supplement), and it has been shown that the air of the country contains an odoriferous and oxidizing principle which imparts to it a peculiar odour and the power of bluing iodized red litmus paper; also of decolorizing blue litmus paper without previously reddening it, and of destroying bad odours. This principle is called ozone.*

When a varnish containing commercial turpentine is applied to a bronzed surface, the metallic powder is oxidized by the turpentine. If copper-bronze powder is combined with turpentine, the bronze is first oxidized and ultimately dissolved by it. Since, then, turpentine has an acid reaction on copper bronzed, it will necessarily have a reaction on the alkaline metals. When common oil of turpentine is added to the sulphide of potassium, the potassium is oxidized, and sulphur precipitated. In this way we may be able to explain *in part* the deodorizing action of essential oils on soluble sulphides and gaseous sulphur compounds. To test this, I poured an ounce of turpentine into a transparent glass quart jar, in the atmosphere of which I suspended a sheet of bibulous paper which was saturated with a composition of the iodide of potassium and starch. The mouth of the jar was quickly covered with a sheet of glass to exclude the action of the air. Within ten minutes the paper appeared brown. The turpentine had oxidized the potassium and liberated the iodine, which in turn coloured the starch purple; but, to render this fact more apparent, I combined a drop of turpentine with a drop of the composition of iodide of potassium and starch. When the composition became visibly brown to the naked eye, and was placed under a suitable power of the microscope, it was observed that many of the starch granules were stained purple by the iodine. Subsequent experiments with concentrated eucalyptus oil and the starch composition gave similar results. Had these experiments been made in a pine forest or plantation of *Eucalypti*, the liberation of the iodine, and consequent coloration of the starch-paper, would have been attributed to the presence of ozone in the atmosphere. Nearly all the essential oils give similar results when combined directly with the iodide of potassium and starch. Since the preceding experiments were made, I have placed a paper moistened in the starch composition in an inclosed atmosphere of turpentine, placing the jar containing it in a dark closet; but the action of the turpentine vapour seemed to be as powerful in darkness as in the presence of light.

Some suppose that ozone, or active oxygen, is in great abundance in the atmosphere of eucalyptus plantations, and, as a consequence, the poisonous gases of marshy districts in their vicinity are decomposed by it, ozone acting the part of an acid; while others have supposed that such unhealthy regions are purified by the rapid absorption of the marsh-waters, owing to the very great rapidity of the growth of the eucalyptus family. It is not my purpose to discredit the views of those who attribute so much importance to the production of ozone under such conditions, but to remind those who insist that oxidation of the gases of malarial districts, and the consequent improved healthy condition of them, in the presence of the essential oils of the eucalyptus family, or of other odoriferous plants, are not necessarily the result of ozone. Any acid or substance having an acid reaction will oxidize the potassium of iodide of potassium. My

* Ozone is supposed to be oxygen in a positive state, or allotropic form, having acid properties.

experiments demonstrate that eucalyptol, turpentine, benzole, or any of the essential oils will oxidize potassium when it is combined with iodine or sulphur; and we are, therefore, in a position to explain how the favourable changes and purifications of the atmosphere to some extent are affected, independent of the theory of ozone. Turpentine of commerce contains formic and succinic acid (Löwig); but turpentine itself is an oxidizable body, as has been shown, and will oxidize some foreign bodies in the atmosphere. Mix turpentine of commerce with caustic potash, and suspend in its atmosphere a slip of paper moistened with the starch mixture; after the lapse of twelve hours it will be found that the starch is colourless or tinged yellow, instead of a very dark purple; in this case demonstrating that the presence of an alkalic atmosphere may modify the oxidizing conditions. Place half an ounce of turpentine in a quart jar, and put in the jar a test-tube containing the sulphide of ammonium, which is very volatile, taking care that only the gases of each liquid will come in contact. Suspend in this mixed atmosphere a slip of the starch-paper * and exclude common air. After the lapse of twelve hours it will be found that the test-paper is saturated with the sulphide of ammonium, and no tinge of purple or other indication of free iodine is observed; in this case the atmosphere is highly alkaline.

If to an aqueous solution of iodide of potassium and starch a few drops of commercial turpentine be added, by agitation a purple colour will appear, first on the top, but ultimately the entire mass will appear beautifully stained. If a portion of the liquid be examined under a suitable power of the microscope, it will be seen that the starch granules have become swollen and are tinged a blue-purple. The granules have an appearance of partially-boiled starch, and remain suspended for a long period in the liquid. Slips of iodized starch-paper prepared with *very* weak solutions of iodide of potassium, hung in an inclosed atmosphere of turpentine, take a very slight tinge after a lapse of twelve hours. The same changes are observed when other essential oils are used, but when a saturated solution of the iodide of potassium and starch are used instead, a very deep colour is quickly obtained. Sometimes the colour will approach to blackness, but it is in reality a deep purple, as seen under the microscope. When the oil of bergamot is used with the weak solutions, a very slight change is effected; but should a drop of the starch mixture fall into this oil, it will make a very deep stain. Nearly all the essential oils behave in a similar manner under similar conditions. The vapour of benzole, supposed to be chemically pure, does not give any appreciable colour to iodized paper; but when droppings of the starch mixture are immersed in the benzole from ten to twenty hours, they become deeply stained brown or purplish. It will be seen that various substances of a very dissimilar character, chemically considered, give acid reaction; and those who favour the ozone theory in eucalyptus, coniferous, and other essential oils, will do well to consider the facts above recited. It is only by a full and faithful consideration of all the facts which relate to the changes and conditions that affect the (ozone) test-paper that a knowledge of its value or worthlessness may be understood.

The fleshy sides of the skins of animals may be preserved from putrefaction by rubbing on them eucalyptus oil. It may also be combined with plaster, and injected into the veins and arteries of animals for the purpose of preservation.

As a result of actual experiment, I find that beef or any animal matter may be preserved by it. I placed two ounces of solid beef in a glass jar with a few drops of this oil, securing the contents from contact with the atmosphere by means of a glass stopper. At the expiration of three months I examined the beef and found it fresh, and on cutting into it the fresh surfaces appeared of a healthy flesh colour. I examined the surface by removing portions of it and placing them in the usual manner under a power of about 350 diameters, but no organic germs of any kind were visible. I next removed the beef from the jar, and exposed it to an atmosphere of about 75 deg. F. Within twenty-four hours afterward the beef dried up, and became very hard, showing no sign of mouldiness or putrefaction. In consideration of these facts, I deem it probable that eucalyptus oil may be safely employed, and with advantage, in cases of humid gangrene, as it certainly will preserve animal matter from decay, and deodorize that which is putrescent.

The preceding experiments demonstrate that eucalyptus oil, turpentine, and, indeed, nearly all the essential oils, possess an oxidizing property. To speak in figurative language, they have the power to burn up or decompose some products deleterious to health, which are always present in malarial regions, and are well known as products of animal and vegetable decay.

* Paper dipped in a solution of iodide of potassium and starch.

CARDAMOM CULTIVATION IN MYSORE.*

Some time in February or March the felling party, one half of them provided with axes, and the rest with large hack-knives for clearing the underwood, proceed to the forest and commence operations by building, near some stream, a temporary hut to shelter them at night. The next morning the head man of the party, who is necessarily well acquainted with the forest, and who has previously chosen the sites for the projected gardens, points out to the coolies the trees that are to be felled. Half of the party then commence to clear the underwood, while the remainder set to work with their axes and fell the large forest trees. The Coorgs have an idea that it is of great importance that the ground should be well shaken by the fall of some heavy tree, and if from any cause a tree does not crash down with sufficient force, they fell another across it. Each plot generally consists of about the tenth part of an acre, and care is taken to leave about twenty or thirty yards of jungle between each garden, as well as not to make too many gardens in one year, lest there should be a too great and sudden diminution of the moisture, which is so much required by cardamom plants. From fifty to one hundred gardens are made annually, until the whole jungle is under cultivation. If represented on a plan a cardamom jungle fully cultivated would be not unlike a checkered board. In May, during the early rains of the south-west monsoon, the young plants shoot up in all the cleared grounds, but especially near to the root and stem of the fallen tree. By the October following they will have grown three or four inches, and by the ensuing February will have attained a height of about one foot, with from eight to ten leaves on each plant. The seed ripen in October, and in the fourth year, or about three years and a half from the springing of the plant, a small crop, called by the Coorgs "God fruit," will be gathered. At this time each rhizome will have thrown up two feet; the garden must be annually weeded. When trees have reached the height of about four feet, or say in the third year, a little culling will be required, for each plant must have six feet of clear ground left round it. In removing superfluous plants, care must be exercised in preserving the strongest and healthiest specimens. In the fifth year the plants will give a good crop, and will probably continue to do so for the following seven years, when they will begin to present a sickly and exhausted appearance. It will then be necessary to select some large trees from the surrounding jungle, and fell them right across the sickly plots. This is generally done during the months of February and March, when the lands were originally prepared for cardamoms, but may also be done with great advantage

* Reprinted from Elliott's 'Planter in Mysore.'

some month earlier. Young plants will then spring up as before, and many of the old plants will have their stems and racemes killed by the fall, but from their rhizomes fresh stems will shoot, and the plants will bear with increased vigour for the next eight years, when the same process of renovation will have to be gone through again. The year in which the forest trees are thus felled the cardamom plots naturally give but little or nothing, and during the ensuing year but a light crop will be gathered; but this very much depends upon the quality of the soil, and on this also depends the early or late coming into bearing of the original garden. A cardamom jungle if thus carefully worked never becomes exhausted, and the cultivation may be continued on the same land for an indefinite period. One rhizome will often have over twenty stems, and, as these die off (and they seldom last longer than seven or eight years), fresh ones spring up to supply their place. The fruit is occasionally borne on the upper part of the stem, but this is extremely rare, and I may mention that in Munzerabad I have never seen or heard of an instance of this departure from the ordinary habit of the plant. When from the stem four racemes are thrown out it is called by the natives the true or full crop; if three only, three-quarter crop; if two, half crop; and if only one, quarter crop. One raceme will have from eight to fourteen branches, and each branch from three to six pedicles. When the plant is grown under the most favourable conditions these branches are grown close together; when, however, the conditions are unfavourable, the racemes are long and weak, and the branches far apart.

TANNING MATERIALS OF SOUTH AMERICA.*

BY PROFESSOR MAX SIEWERT.

The tanning of heavy leather is one of the principal occupations of the northern provinces of the Argentine Republic. This country struggles under difficulties unknown in Europe, on account of the climate, which frequently causes the putrefaction of the skins during the process of tanning. It is therefore necessary to abridge as much as possible the duration of the operation. No rational method is followed in the manufacture, which is entirely empirical as yet. The tanners of the Old World prefer to employ the bark of the oak, which, although it does not possess a large quantity of tannin, produces an excellent article when the operation has been well conducted.

But the oak is not indigenous here, and has not yet been imported. The carob tree (Spanish algarrobo), which might be called the oak of the country, from its slow growth and general aspect, unfortunately does not possess a bark rich in tannin.

Nevertheless, we have the cebil in two varieties—the red and the white—forming in the provinces of Tucuman, Salta, and Jujui, immense forests, which cover the mountain slopes to a considerable height. The bark of the red cebil contains more tannin than that of the oak, but it has the unsuitable property of giving a characteristic red colour to the hides, which, above all, appears when the tanning is completed and drying commences. This disadvantage having made it desirable to find a tanning material which will give the customary appearance to the skins, all the trees of our flora have been submitted to chemical analysis. I have separately investigated the wood, bark, and leaves, and the subjoined table gives an adequate idea of their tannic importance. The figures speak for themselves, but I will add such descriptive and general information on them as seems necessary.

Red Cebil (*Acacia Cebil*, Gries.).—Experience, as well as chemical analysis, teaches us that the mature tree produces the greatest quantity of tannin, and that when the bark of old trees is used, the exterior layers, which are in general the hardest, should be rejected. I cannot affirm from my investigations that the trees of the plains contain more tannin than those of the mountains. The analyses not giving one constant result, I have been led to believe that the differences which have been frequently met with are all individual, and independent of the composition of the soil.

Experiments, the object of which was to isolate the tannin combined with the lime of the bark by boiling this with carbonate of soda, gave 1 per cent. of increase. The quantity of carbonate of soda was calculated from the weight of lime contained in the ash. It is remarkable that the wood holds no trace of tannin, whilst the leaves generally give one-half the quantity found in the bark.

White Cebil.—This tree is distinguished from the red species by its leaves, which are more finely feathered, and by the facility with which its bark dries and ceases to take part in the circulation of the tree. It therefore results that the tannic acid is very rapidly decomposed in the exterior of the bark, and becomes oxidized or else withdraws to the interior, according as the bark dries. The proportion of tannic acid contained in the exterior and interior parts of the bark is as one to ten.

The young trees of the two species of cebil contain almost the same quantity of tannin; their wood contains a little, and the quantity in the leaves is somewhat superior to the half of that found in the bark of good quality.

White Quebracho (*Aspidosperma Quebracho*).—The trees which bear this name in the province of Cordoba do not belong to the same species as the white quebracho of Salta. I do not believe that the climate could cause a variety of this tree; in my opinion they are different species. The leaves of the quebracho of Cordoba are armed at their extremities with small thorns, which the species of Salta does not possess. The form and size of the leaves are alike, although those of the northern province are thicker. The aspect of the trees is also the same, although the quantity of tannin is very different.

The white quebracho of Salta is very similar to the German oak, and little inferior to the red cebil, whilst its leaves are one of the richest tanning substances in all the Republic, since they contain 27·5 per cent. Moreover, the tannic solution of the bark, as well as that of the leaves, is almost colourless; the red colour imparted to the hide may therefore be prevented, by operating with a mixture of the cebil and the white quebracho.

Espinillo (*Acacia Cavenia*).—This tree is more disseminated in the country than the algarrobo. It attains a greater or less height, according to the nature of the soil, but never exceeds twelve feet. It is recognized by its tender and finely feathered leaves and numerous thorns and fruit. The wood and leaves contain but little tannin (0·56 and 0·93 respectively); the bark (5·84), even if it contained more, it would not serve for tannin, because it is too thin and too difficult to separate from the trunk. The fruit, on the contrary, is rich in tannin, and although the seeds contain a very small quantity (12·03), the husks or shells contain 33·2 of pure tannin.

Algarrobo, black and white (*Prosopis Algarrobo.*—These two magnificent representatives of the Mimosa family thoroughly overspread our country. Unfortunately in the populated districts they will soon disappear, on account of their slow growth, the small care taken of them, and the complete want of new plantations. The wood of the algarrobo is of extraordinary strength, therefore it is employed for all purposes.

It is not known why the designations, black and white, have been given to the two species. The flowers of both are white; the leaves of the black algarrobo are more finely feathered, and its fruit spotted with black and red, is a little longer and narrower than that of the species called white, whose wood is dark brown, whilst that of

* From the *Journal of Applied Science*, January 1, 1878.

the species called black is much lighter in colour and almost white in the young trees.

When the aged white algarrobo, with a trunk of more than a foot in diameter, is cut, a black and viscous liquid, bitter to the taste, escapes from the vessels nearest the bark; it contains much tannic acid.

The leaves, the bark and the wood of the two species of algarrobo are equally poor in tannin; they are therefore of no interest to tanners. Their economic importance is however great, not only on account of their magnificent timber, but also for the fruit, which is an excellent food for domestic animals and even for man. A glance at the following analysis will prove this assertion:—

	Fruit of Black Algarrobo.		Fruit of White Algarrobo.

The sugar in the fruit is identical with that contained in the grape and the apple, consequently it is very fermentable: therefore, the country people make an alcoholic sparkling drink from the fruit after macerating it in water, which they call aloja. That of the black algarrobo is preferred for this purpose, and the fermentation is caused by the protein substances which it contains. Here is the composition of the ashes of these fruits:—

The ashes, entirely destitute of soda, manifest such a large quantity of the salts of potash and of the phosphates, as to prove that this fruit is clearly of great importance as food. In several districts of the country it is collected by the population, and forms their principal nourishment during the winter.

The algarrobillo, the wild walnut, the tipa, the coco or cochuchu (*Xanthoxylum Coco*), the tala (*Celtis Tala*), the lapacho (*Tecoma asper*, Gries.), the chanar (*Gourliaca decorticans*), and the cedar, are only of secondary importance to the tanner. We will make special mention, however, of the lecheron and the molles.

Lecheron.—In its leaves, its height, and its branches, this tree bears an external resemblance to the willow of Europe, and, like it, prefers a humid or marshy soil.

Its name, derived from *leche* (Spanish for milk), is due to its property, when a leaf or branch is cut or broken, of exuding a species of white sap, similar to the milky juice of the euphorbia. The leaves contain but one-third part of the tannic acid of the bark, and the wood is entirely destitute of it. Although the bark only contains ten per cent. of tannin, it merits attention from its freedom from colour. The lecheron, moreover, has the advantage of being widely disseminated, and it grows much more rapidly than the cebil.

Molles.—In this country a number of trees and plants are designated by this name, although they bear no resemblance to each other, either in appearance of leaves, flowers, or fruit, and in reality belong to different families.

To distinguish them a qualifying term is added to the generic name, such as molle for drinking, molle for tanning, molle for dyeing, etc. The "molle a biber," literally good for drinking (*Lithrœa Gilliesii*), is a handsome tree, found in the mountainous regions, which is utilized in different ways. The sweet and aromatic fruit is employed, as also an infusion of its leaves, in the manufacture of a refreshing drink, slightly alcoholic, a species of "aloja." The leaves contain 0·25 of colourless tannin; infused in water they serve as a black dye, and also to prepare a species of ink. Molle for dyeing and tanning is a species of *Duvana*. This variety contains more tannin than the preceding, and is used both for dyeing and for tanning. For this purpose the fruit is gathered before its maturity, when it is no larger than a grain of vetch.

The sprouts of a year old, despoiled of their leaves and fruit, do not contain more than 4·6 per cent. of tannic acid, whilst the leaves and fruit contain from 19·2 to 20. This variety of the tree does not exceed the height of twelve feet, and its leaves are very small. It is, therefore, difficult to procure large quantities; nevertheless, were the inhabitants to take the trouble to pick the leaves and the fruit from the dried branches, something could be made out of this rich tanning substance, especially in view of the fact that it is almost colourless.

Tannic acid contained in 100 parts of the following substances, previously dried in the air:—

THE MEDICINAL CHLORINE-DERIVATIVES OF ALCOHOL.*

Among the chemicals which have been adopted into the list of medical agents, the chlorine-derivatives of alcohol occupy a very prominent place. Starting from the single chloroform, which came into use about 1831, their number has since then steadily increased, until there are now no less than about ten such compounds. Many of these are so closely allied in properties, that a sharp determination of boiling-point and specific gravity is necessary to distinguish them. In determining the

* From a paper by J. Biel, in *Pharm. Zeit. f. Russl.* 1877, No. 11, and a paper in *L'Union Pharm.*, 1877, 181, with additions by Ed. N. R. From *New Remedies*, October 1877.

boiling-point, it may be incidentally remarked, the thermometer must not dip into the liquid, but must be wholly immersed in the vapour of the boiling liquid, and the latter must be carefully distilled to dryness.

Since nearly all these bodies are at present obtained as by-products in the preparation of chloral hydrate, we shall first describe the preparation of the latter, as carried on at a large scale.

Chloral Hydrate. Into a series of 30 to 40 large glass carboys, each of which contains 108 to 144 pounds of 98 per cent. alcohol, a current of chlorine gas, washed and dried by sulphuric acid, is passed without intermission for twelve to fourteen days. In the beginning of the operation the action is sufficiently energetic to necessitate the cooling of the carboys, while towards the end they must be warmed to 60 and 75° C. (140 to 167° F.). As soon as the liquid in the carboys has reached a specific gravity of 1·400, the chlorination is interrupted, the chlorinated alcohol is transferred to copper stills lined with lead, and carefully boiled with an equal weight of sulphuric acid. This causes the elimination of large quantities of *ethyl chloride* gas (hydrochloric ether C_2H_5Cl), hydrochloric acid, and a whole series of by-products, which are condensed. After a while, chloral passes over, which boils at 94° (C. 201·2° F.). A rise of the thermometer to 100° C. (212° F.), indicates that all chloral has passed over, and the distillation is stopped. The distilled chloral, a colourless liquid, is neutralized with chalk, again distilled, the distillate brought into contact with just sufficient water to form the solid hydrate, and rapidly cooled off. The mass thereby congeals, and forms the product known as "chloral hydrate in crusts." More recently this is being displaced by chloral hydrate crystallized from boiling chloroform, which forms brilliant pellucid rhombohedra, and is much more capable of resisting change by exposure to air than the ordinary kind.

Soon after the discovery of chloral, a number of works on the largest scale were erected for its preparation; but competition soon lowered the market price of the product to such a degree that it became a question of life and existence with some manufacturers to find use for the large quantity of apparently useless by-products obtained. In this way Kraemer, of Berlin, who was supplied with material by Schering's factory, discovered in these accompanying products large quantities of *Monochlorinated ethyl chloride*, or *Dichlorethane* ($C_2H_4Cl_2$, æthyliden-chloride), and afterwards, together with Pinner, he discovered a new chloral, which was named *croton-chloral*, and which was examined therapeutically by Liebreich, who proved it to be a valuable agent. Kraemer also believed to have recognized in the mixture small quantities of *ethene chloride* ($C_2H_4Cl_2$, Dutch liquid); but this was disproved by Geuther, Stapf, and Staedel.

To arrive at a clear understanding of the origin of these secondary products, it is necessary to study the chemical reactions occurring during the generation of chloral:

Chlorine acting upon anhydrous alcohol produces in the first place *aldehyde:*

$$C_2H_6O + Cl_2 = C_2H_4O + 2\,HCl$$
$$\text{alcohol} + \text{chlorine} = \textit{aldehyde} + \text{hydrochloric acid.}$$

This, with more alcohol, forms *acetal:*

$$C_2H_4O + 2C_2H_6O = C_2H_4(C_2H_5O)_2 + H_2O$$
$$\text{aldehyde} + \text{alcohol} = \textit{acetal} + \text{water,}$$

which, by substitution of chlorine for hydrogen, forms *trichloracetal:*

$$C_2H_4(C_2H_5O)_2 + Cl_6 = C_2HCl_3(C_2H_5O)_2 + 3HCl$$
$$\text{acetal} \quad \text{chlorine} = \textit{trichloracetal} + \text{hydrochloric acid.}$$

This yields, with the generated hydrochloric acid, *chloral alcoholate* and *ethyl chloride:*

$$C_2HCl_3(C_2H_5O)_2 + HCl = C_2HCl_3(C_2H_6O_2) + C_2H_5Cl$$
$$\text{trichloracetal} + \text{hydrochloric acid} = \textit{chloral alcholate} + \textit{ethyl chloride.}$$

Most of the latter is decomposed with some of the still present alcohol to *ether:*

$$C_2H_5Cl + C_2H_6O_2 = (C_2H_5)_2O + HCl$$
$$\text{ethyl chloride} + \text{alcohol} = \textit{ether} + \text{hydrochloric acid}$$

which is converted by fresh chlorine into mono-, bi-, tri-, and finally, *tetrachlorinated* (*ethylic*) *ether:*

$$(C_2H_5)_2O \text{ or } C_2H_5.O.C_2H_5 + 4Cl_2 = C_4H_6Cl_4O \text{ or } C_2H_5.O.C_2HCl_4 + 4\,HCl$$
$$\text{ether} + \text{chlorine} = \textit{tetrachlorinated ether} + \text{hydrochloric acid.}$$

During the subsequent distillation with concentrated sulphuric acid, the generated chloral alcoholate splits into *chloral* and *ethyl-sulphuric acid:*

$$C_2HCl_3(C_2H_6O_2) + H_2SO_4 = C_2HCl_3O + H_2O + (C_2H_5)HSO_4$$
$$\text{chloral alcholate} + \text{sulphuric acid} = \text{chloral} + \text{water} + \textit{ethyl-sulphuric acid,}$$

and the tetrachlorinated ether undergoes the same change:

$$C_2H_5.O.C_2HCl_4 + H_2SO_4 = C_2HCl_3O + HCl + (C_2H_5)HSO_4$$
$$\text{tetrachlorinated ether} + \text{sulphuric acid} = \textit{chloral} + \text{hydrochloric acid} + \textit{ethyl-sulphuric acid,}$$

and the ethyl-sulphuric reacts with muriatic acid to form *sulphuric acid* and *ethyl chloride:*

$$(C_2H_5)HSO_4 + HCl = H_2SO_4 + C_3H_5Cl$$
$$\text{ethyl-sulphuric acid} + \text{hydrochloric acid} = \text{sulphuric acid} + \textit{ethyl chloride.}$$

On the other hand, if chlorine continues to act upon tetrachlorinated ether, there is produced *pentachlorinated ether*, $C_2H_5.O\text{-}C_2Cl_5$, which has a specific gravity of 1·650, and *does not yield chloral*, when treated with sulphuric acid. This is the reason why, in the manufacture of chloral, the current of chlorine gas is interrupted, when the liquid in the carboys has reached a specific gravity of 1·400.

From the *ethyl chloride* generated during the process, chlorine produces the following substitution-products:—

(C_2H_5Cl ethyl chloride, or chlorethane);
$C_2H_4Cl_2$ di-bhlorethane (æthyliden-chloride);
$C_2H_3Cl_3$ tri-chlorethane);
$C_2H_2Cl_4$ tetra-chlorethane);
C_2HCl_5 penta-chlorethane);
C_2Cl_6 carbon hexachloride, or rather carbon trichloride, a crystalline substance identical with that produced by the action of chlorine gas upon the Dutch liquid.

A very variable mixture of the middle members of this series is at present an article of commerce under the name of *Liquor anæstheticus.* Another similar mixture, containing the lower members, is the *Æther anæstheticus Aranii*, boiling between 64° and 100° C. (140-212° F.); and the *Æther anæstheticus Wiggers*, which contains the higher chlorides, and boils between 100 and 140° C. (212–184° F.)

As regards the other chloral, *croton-chloral*, or, as it is now more correctly termed, *butyl-chloral*, the investigations have not yet led to such detailed results. We are, however, certain that it is produced by the chlorination of two associated molecules of aldehyde. As croton-chloral its formula would be $C_4H_3Cl_3O$; but as butyl-chloral its formula is $C_4H_5Cl_3O$.*

(*To be continued.*)

* The name *croton*-chloral is owing to the relationship of this compound to *crotonic* acid found in *Croton Tiglium.* Crotonic acid, isomeric with methacrylic acid is $C_4H_6O_2$; croton-aldehyde, C_4H_6O; croton-chloral, $C_4H_3Cl_3O$. Starting from *butyric acid*, $C_4H_8O_2$, we have butyl-aldehyde, C_4H_8O, and butyl-chloral, $C_4H_5Cl_3O$.

THE LIQUEFACTION OF THE GASES.

DURING the last fortnight a considerable amount of interest has been excited in the scientific world, and in fact outside of it, by the announcement that what had been foreseen as possible by the father of modern chemistry, but had foiled the utmost efforts of DAVY, FARADAY, and others to realize, had been demonstrated almost simultaneously by a French iron-master and a Swiss ice manufacturer, and that oxygen, nitrogen, and hydrogen, the gases which had longest resisted compression into the liquid state, had been at last conquered. A century ago, LAVOISIER, exercising his scientific imagination, theorized as to what change might take place in the substances that compose the globe if the temperature underwent a violent change, such, for instance as might follow were the earth suddenly transported to a region where the ordinary temperature exceeded that of boiling water, or into a very cold one similar to those occupied by Jupiter and Saturn. In the latter case he conjectured that the water at present forming our rivers and seas, and most of the liquids known to us, would be transformed into solids, whilst the atmosphere, or at least a portion of the aeriform substances of which it is composed, would cease to exist in the state of an invisible fluid, but would become liquid, producing new, and at that time, unknown liquids. How universal this change would be is shown by these latest researches of MM. CAILLETET and PICTET.

The first to accomplish the conditions necessary to the liquefaction of a permanent gas were probably MONGE and CLOUET, who at the end of the last century claimed to have liquefied sulphurous acid gas by cooling; NORTHMORE, who in 1805 liquefied chlorine; MORVEAU who liquefied ammonia; and STROMEYER, who liquefied arseniuretted hydrogen gas. Very little regard was paid to these experiments, however, at the time, the results being partially, but as it appears probably erroneously, attributed to the presence of small quantities of water. But the true advance began in 1823, when FARADAY, whilst examining, at the suggestion of Sir HUMPHREY DAVY, the solid hydrate of chlorine, found that when this substance was heated to 100° in a sealed tube it was decomposed, forming two layers, one consisting of chlorine in the liquid state, which it had assumed through the pressure resulting upon the dissociation, and the other of water, containing a little chlorine in solution. DAVY, who claimed to have foreseen this as an alternative result, immediately made some other experiments in the same direction, and at the same meeting of the Royal Society to which he communicated FARADAY'S memoir, he stated that he had liquefied hydrochloric acid gas by partially heating a sealed tube containing muriate of ammonia and concentrated sulphuric acid, and that he believed by substituting carbonate for muriate of ammonia carbonic acid might be obtained in the liquid state.

FARADAY continued his researches, and a few weeks later he was able to announce that by similar means he had succeeded in condensing to a liquid not only carbonic acid, but also sulphurous acid, sulphuretted hydrogen, euchlorine, nitrous oxide, cyanogen, and ammonia, and to describe some of the properties belonging to them as liquids. Experiments made at the same time, however, with oxygen, hydrogen, fluoboracic acid, fluosilicic acid, and phosphuretted hydrogen gases failed, although all of them were subjected to great pressure. In the same year Sir HUMPHREY DAVY published a memoir on the application of liquids formed by the condensation of gases as mechanical agents.

The research was continued by other investigators at home and abroad, but with little result beyond some modifications in the processes, although in 1835, THILORIER succeeded in carrying the condensation further, and obtained carbonic acid as a solid, it being the first gas brought to that condition. In 1845 FARADAY took up the work again, moved partly by the hope, as he says, of seeing "nitrogen, oxygen and hydrogen, either as liquid or solid bodies, and the latter probably as a metal." Although he was foiled in each of these particulars, he was successful in many others, using the combined influences of pressure and cold, the memoir describing his research and results forming virtually the latest stage in the history of the subject until within the last few weeks. All the known gases, with the exception of oxygen, hydrogen, nitrogen, nitric oxide, carbonic oxide and coal gas, were successively condensed to liquids, and many of them to solids. With respect to the ultimate fate of the remainder, FARADAY'S opinion may be estimated from his cautious remark that after carrying the pressure of oxygen to 58·5 atmospheres, the cement of a joint gave way, and he "could carry the observation no further with that apparatus."

It was left for CAILLETET to resume the progress in this investigation, and a few weeks since it was announced that nitric oxide, one of the few remaining refractory gases, had given way under his manipulation. On the 24th of last month the French Academy of Sciences was gratified by the announcement that oxygen had at last been liquefied in Geneva by PICTET, but greater was the surprise when it appeared that the Secretary of the Academy had had in his possession for nearly three weeks a sealed packet, stating that, CAILLETET, following up his recent work with nitric oxide, had attained a similar result with oxygen and carbonic oxide. Only another week elapsed and then CAILLETET was able to show that the end was full in view, for whilst nitrogen and atmospheric air had been unmistakably liquefied, hydrogen submitted to similar conditions gave indications that admit of little or no doubt that it had passed from the gaseous to the liquid state. The methods adopted by these investigators in obtaining their remarkable results will be found amply described in another part of this Journal.

It will be obvious upon reading the account given that the work is not yet done. Neither M. CAILLETET nor M. PICTET has obtained more than a momentary glance at the precious liquids. Before the research can be said to be complete a way must be found of obtaining and retaining these bodies in the liquid form, so that their nature and properties may be more closely studied. Nevertheless, that such good work has been done by two investigators, who appear to be engaged also in business pursuits, is a notable fact in the scientific history of their respective countries.

THE CHEMISTS' BALL.

No doubt many of our readers will have made themselves acquainted with the subject matter of an advertisement that has already appeared in respect to the Chemists' Annual Ball. To ensure as far as possible, however, that the subject shall not escape notice, it will be as well, perhaps, to repeat here that the Twelfth Annual Ball is to be held on Wednesday next, in Willis's Rooms. A list of the Stewards, from whom tickets may be had, will be found on another page. This annual gathering has now become so firmly established in the good opinion of many of our pharmaceutical brethren that it would be almost an impertinence to do more than call attention to the fact that the next is close at hand.

DEATH OF FRANCOIS VINCENT RASPAIL.

THE death has been announced from France of M. RASPAIL, who has played many parts during his long life, and created no inconsiderable stir both as a would-be medical and political reformer. Originally intending to follow the legal profession, he became successively botanist, zoologist, chemist, and doctor, but, above all, a politician. In camphor he saw, or pretended to see, a panacea, and camphor formed the basis of the specialities that have become associated with his name. M. RASPAIL was born in 1794, but it will be remembered that so recently as 1874 he was condemned to a fine and one year's imprisonment for an offence which was the outcome of his extreme political opinions.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of the above Association will be held at 17, Bloomsbury Square, on Thursday evening, January 17, when a paper will be read by Mr. ALLEN, on "Some Odds and Ends of Science some Two Hundred Years Ago."

Provincial Transactions.

ABERDEEN SOCIETY OF CHEMISTS AND DRUGGISTS.

The opening lecture of the recently formed joint Society was delivered on Tuesday, December 18, 1877, by Mr. D. Ritchie, Market Street.

Mr. James Paterson (of William Paterson and Sons) occupied the chair, and remarked on the good attendance, expressing a desire that the meetings would be alike patronized by masters and assistants.

Mr. Ritchie then delivered a very interesting lecture upon the "Chemical Composition and Formation of the Various Tissues of the Human Body," amply illustrating his lecture with specimens of blood and bone, separated into their various proximate constituents; also with a display of life-sized diagrams of the osseous, muscular, nervous, and arterial systems. The demonstrations from these objects were listened to with great attention and were much appreciated by the large audience.

Hearty votes of thanks to the Lecturer and Chairman terminated the proceedings.

The next lecture is to be delivered during the present month by Mr. Miller, of the Sandilands Chemical Works, upon the "Coal Tar Products."

The Society's social meeting is expected to take place during February.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

ASSISTANTS' SECTION.

The second meeting of the present session was held in Anderson's College, on Wednesday, 19th Dec. In the absence of the Vice-President, Mr. R. A. Taylor took the chair. The minutes of last meeting having been read and confirmed, Mr. W. Simpson was unanimously elected President in room of Mr. Boa, resigned.

Mr. W. Paris then read a paper on "Phosphorus," in which he described the various processes which have been employed in manufacturing it from its accidental discovery by Brandt in 1677 up to the present time, and explained, by equations, the present method of manufacturing it from bone ash. He also gave the method of purification, and said he believed phosphorus was best administered medicinally in solution in cod liver oil.

At the close of the paper the reader was awarded the usual vote of thanks.

The desirability of having a festival in direct connection with the Assistants' Section, came up for consideration. After a number of the members had spoken in favour of the movement, Mr. G. Arnott proposed and Mr. W. T. Law seconded that a supper be held.

Mr. Ballock moved, as an amendement, that a conversazione and ball be held, which was seconded by Mr. De Nauce.

On a vote being taken the motion was declared carried by a large majority. A committee was afterwards appointed to carry out arrangements.

Mr. W. Philp was elected Assistant-Librarian, and Messrs. Arnot, Blain, and McLeish members of Committee. After a few new members were proposed and elected, the meeting was brought to a close.

Proceedings of Scientific Societies.

PARIS ACADEMIE DES SCIENCES.

THE LIQUEFACTION OF OXYGEN, NITROGEN, HYDROGEN, AND ATMOSPHERIC AIR.

Towards the end of last month considerable interest was excited by the announcement that the liquefaction of oxygen had been effected at Geneva by M. Raoul Pictet, on the 22nd of December. When, however, the subject came before the Academy of Sciences at its *séance* on the 24th, the interest was heightened by the announcement that M. Pictet had been to some extent anticipated, in that M. Cailletet, who a short time since succeeded in liquefying binoxide of nitrogen, had also effected the liquefaction of oxygen and of carbonic oxide on the 2nd of December, although in consequence of some consideration as to his pending election to the body instead of the fact being published at once a record of it had been entrusted in a sealed packet to the custody of the Secretary to the Academy on the 3rd. At the sitting of the Academy on the 31st December it was announced that M. Cailletet had succeeded in liquefying nitrogen, hydrogen, and atmospheric air. The following account of the operations by which these results were effected is taken from *Comptes Rendus* of December 24 and 31.

To give M. Cailletet precedence. The following are the terms in which M. Cailletet communicated his success with oxygen and carbonic oxide to his old master, M. Sainte-Claire Deville, and which formed the basis of the sealed packet:—

"I am anxious to tell you first and without the loss of a moment that I have to-day liquefied carbonic oxide and oxygen. I am, perhaps, wrong to say liquefy, for at the temperature obtained by the evaporation of sulphurous acid, *i.e.*, —29° and 300 atmospheres, I do not see the liquid, but a fog so thick that I may conclude it to be a vapour very near its point of liquefaction. I am writing to-day to M. Deleuil for protoxide of nitrogen, by the help of which I shall, no doubt, be able to watch the flow of a stream of carbonic oxide and oxygen.

"P.S. I have just made an experiment that puts my mind at rest. I compressed hydrogen at 300 atmospheres, and after cooling at —28°, I allowed it to expand suddenly. There was no trace of fog in the tube. My gases (CO and O) are therefore near upon liquefaction, this fog being produced only with vapours near liquefying. M. Berthelot's anticipations are, consequently, being completely realized."

The following is the more detailed account read before the Academy on the 24th of December:—

"If oxygen or pure carbonic oxide be enclosed in a tube of the form I have previously described, and placed in the compression apparatus already exhibited before the Academy,* and then the gas be brought down to a temperature of —29° by means of sulphurous acid at the pressure of about 300 atmospheres, these two gases retain their gaseous condition. But if they are suddenly allowed to expand, so as to produce, according to Poisson's law, a temperature of at least 200° below the initial temperature, immediately an intense fog produced by the liquefaction and perhaps solidification of the oxygen or carbonic oxide become perceptible.

"This phenomenon is observed also on the expansion of carbonic acid and the protoxide and binoxide of nitrogen when under strong pressure.

"This fog is produced with oxygen even when the gas is at the common temperature, provided time is given for the escape of the heat it acquires by the mere act of compression. This I demonstrated by experiments conducted on Sunday, December 16, at the chemical laboratory of the Ecole Normale Supérieure, before a number of scientific men, among whom were some members of the Academy of Sciences. I had hoped to find at Paris, together with the materials necessary for the production of a high degree of cold (protoxide of nitrogen or liquid carbonic acid), a pump capable of taking the place of my compression apparatus at Châtillon-sur-Seine. Unfortunately, a pump well-fixed and suited to this kind of experiment could not be found at Paris, and I was obliged to send to Châtillon-sur-Seine for the refrigerating material for collecting the condensed matters on the walls of the tube.

"To know whether oxygen and carbonic oxide are in a liquid or solid form in the fog, would require an optical experiment, more easy to imagine than to carry out, on account of the form and thickness of the tubes containing them. Chemical reactions will also allow of the demonstration that the oxygen is not transformed into ozone in the act of compression. These questions I shall endeavour to solve with the help of apparatus which I am now having made.

"Under the same conditions of temperature and pressure even the most rapid expansion of pure hydrogen gives no trace of nebulous matter. There remains therefore only nitrogen to study, and the small solubility of this gas in water leads me to suppose that it will be very refractory to any change of condition."

At the meeting of the following week, however, M. Cailletet was able to report a great advance towards the solution of this problem in the following "Note on the Condensation of Reputedly Incoercible Gases":—

"I have continued my experiments upon the liquefaction of gas, and I am happy to announce that I have succeeded in liquefying nitrogen and atmospheric air. Hydrogen itself has given indications of liquefaction as will presently appear. The following are some details of my experiments:—

"*Nitrogen.*—Pure and dry nitrogen, submitted to a pressure of about 200 atmospheres, at a temperature of +13°, and the pressure then suddenly relaxed, is condensed in the clearest manner. There is produced at first a matter similar to a powdery liquid (*liquide pulvérisé*), in particles of an appreciable volume; then the liquid gradually disappears from the sides towards the centre of the tube, forming at last a sort of vertical column directed along the axis of the tube itself. The total duration of the phenomenon is about three seconds.

"These appearances leave no doubt of the true character of the phenomenon. I first made the experiment at home, at the temperature of —29°, and I repeated it yesterday, a great number of times in the laboratory of the Normal School, in the presence of several scientific men and members of the Academy, among whom I may mention, with his consent, the venerated M. Boussingault.

"*Hydrogen.*—Hydrogen has always been regarded as the most incoercible gas, because of its slight density and the nearly complete conformity of its mechanical properties with those of a perfect gas. It was therefore only with extreme distrust as to the result that I decided to submit it to the same tests as have determined the liquefaction of the other gases.

"In my first attempts I could not recognize anything unusual, but as it often happens in experimental science the habit of observing the phenomena leads to being able to recognize signs under conditions where at first they passed unperceived. This is what occurred with hydrogen. In repeating only to-day, in the presence of MM. Berthelot, H. Sainte-Claire Deville, and Maseart, who have kindly authorized me to invoke their testimony, I have succeeded in observing indications of the liquefaction of hydrogen, in conditions of evidence which did not appear doubtful to any of the learned men who witnessed the experiment. This has been repeated a great number of times. In operating with pure hydrogen, submitted to a pressure of about 280 atmospheres and then suddenly released, we have observed the formation of an excessively fine and subtil fog suspended throughout the length of the tube and which disappeared suddenly. The appearance of this fog, notwithstanding its extreme subtility, has appeared incontestable to all the scientific men who have witnessed the experiment to-day, and they have taken care to repeat the experiment several times so as not to allow of any doubt as to its reality.

"*Air.*—Having liquefied oxygen and nitrogen, the liquefaction of air had been thus demonstrated; however

* This apparatus, which is described in the *Comptes Rendus* for November 5 last, is a hollow steel cylinder in which the gas is compressed by means of a hydraulic pump with the intervention of a layer of mercury.

it appeared to me to be interesting to make the direct experiment, and as might be expected, it has succeeded perfectly. It is unnecessary to say that the air had been previously dried and deprived of carbonic acid. Thus has been confirmed the exactitude of the views put forward by the founder of modern chemistry, M. Lavoisier, upon the possibility of making air assume the liquid state, producing matters endowed with new and unknown properties."

M. Pictet, although obtaining virtually the same results, worked in a somewhat different manner. The apparatus used is thus described by him (*Comptes Rendus*, Dec. 24, p. 1215):—"A and B (fig. 1) are two double-action suction and force pumps, coupled together on the 'compound' system, one creating a vacuum in the other in such a way as to obtain the widest possible difference between the pressures of suction and forcing. These pumps acts on anhydrous sulphurous acid contained in the cylindrical receiver, C. The pressure within this receiver is such that the sulphurous acid is evaporated at 65° below zero. The sulphurous acid is forced into a condenser, D, cooled by a current of cold water, where it liquefies at a temperature of 25° above zero, and at a pressure of about $2\frac{3}{4}$ atmospheres. As it liquefies the sulphurous acid returns to C, through a small tube, *d.* E and F are two pumps similar to A and B, and similarly coupled. They act on carbonic acid combined in a

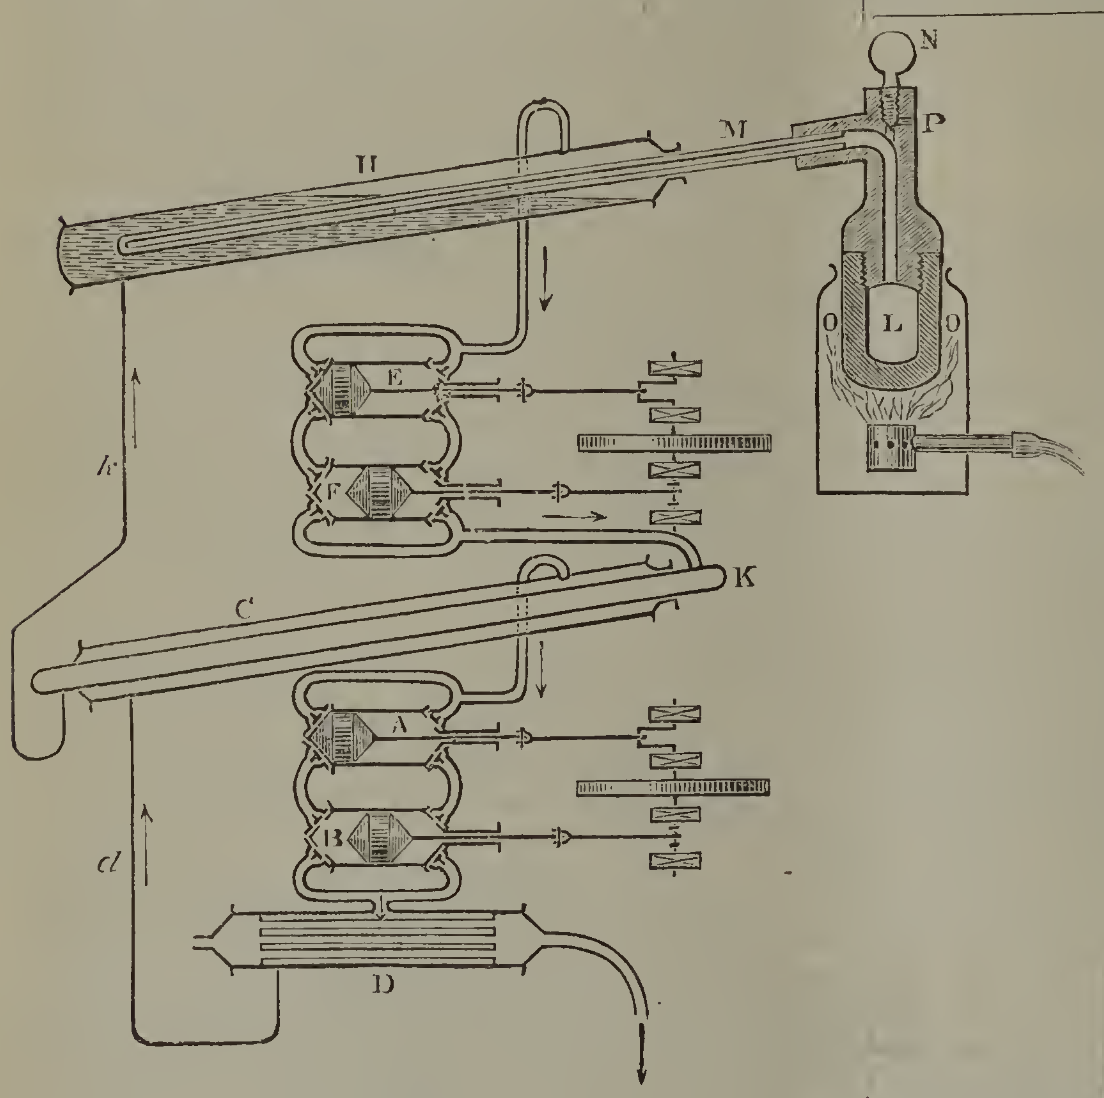

Fig. 1.

cylindrical receiver, H. The pressure in this receiver is such that the carbonic acid is evaporated in it at 140° below zero. The carbonic acid, driven back by the pumps, is forced into the condenser, K, inclosed in the sulphurous acid receiver, C, which is at 65° below zero: the carbonic acid is here liquefied at the pressure of 5 atmospheres. It returns gradually, as liquefied, through the small tube, K, to the receiver, H.

"L is a wrought-iron retort, sufficiently thick to resist a pressure of 500 atmospheres. It contains chlorate of potassium, and is heated so as to give off pure oxygen; it communicates by means of a tubulure with a slanting tube, M, made of very thick glass, one metre long, which is surrounded by the carbonic acid receiver, H, the temperature of which is 140° below zero. A tap, N, in the neck of the retort, allows of the opening of an orifice, P, which communicates with the air. After the pumps, worked by an engine of 15 horse power, have been kept in action for several hours, and when all the oxygen has been given off by the chlorate of potassium, the pressure in the glass tube is 320 atmospheres, and the temperature is 140° below zero. If the orifice, P, be now suddenly opened, the oxygen escapes with violence, producing an expansion and absorption of heat sufficient to cause a liquefied portion to appear in the glass tube and spirt from its orifice upon sloping the apparatus. It may be added that the quantity of liquefied oxygen contained in the tube, one metre in length, and 0·10 m. in internal diameter, occupied about two-thirds of its length and issued at the orifice, P, in the form of a liquid jet."

After the close of the same sitting, M. Dumas received a communication from M. Pictet, stating that the experiments had been successfully repeated and giving further details, from which the following is an abstract:—

"The object at which I have been aiming for three years past is to demonstrate experimentally that molecular cohesion is a general property of bodies without any exception. If the permanent gases cannot be liquefied it would be necessary to conclude that their constituent particles do not attract each other, and are thus exempt from this law. To succeed by experimental means in bringing the particles of a gas into the closest possible proximity, and thus accomplish its liquefaction, certain indispensable conditions have to be complied with, which I summarize as follows:—(1) To have an absolutely pure gas, free from any trace of a foreign gas; (2) to have at command very powerful means of compression; (3) to obtain an intense degree of cold, and the abstraction of heat at these low temperatures; (4) to have a large surface of condensation maintained at these low temperatures; (5) to be able to utilize the expansion of the gas under considerable pressure to the atmospheric pressure, which expansion, added to the preceding means, compels liquefaction. These five conditions being fulfilled, we may formulate the following problem:—When a gas is compressed at 500 or 600 atmospheres, and kept at a temperature of —100° or —140° and then allowed to expand to the pressure of the atmosphere, one of two things must happen. Either the gas, obeying the action of cohesion, becomes liquid, giving up its heat of condensation to the portion of the gas, which expands and is lost in the gaseous form; or, under the assumption that cohesion is not a general law, the gas passes beyond absolute zero, that is, becomes inert, a dust without consistence. The work of expansion would be impossible, and the loss of heat absolute.

"Impressed with the certainty that thermodynamic equations rest upon fixed numerical forms, I sought to contrive some mechanical means for realizing the conditions summarized above, and selected a complex apparatus that I may describe as follows:—

"I took two suction force pumps such as I use industrially in my ice-making apparatus. These I coupled so that the suction of the one corresponds to the compression of the other. The suction in the first communicates with a tube 1·10 m. long, filled with liquid sulphurous acid. Under the influence of a perfect vacuum the temperature of this liquid is rapidly lowered to —65° or even —73°, the extreme limit which has been obtained. Into this tube of sulphurous acid there passes a second smaller tube, measuring six centimetres in exterior diameter, and of the same length as the tube in which it is enclosed. These two tubes have a common bottom. In the central tube I compressed carbonic acid produced by the decomposition of Carrara marble with hydrochloric acid. This gas was dried, then collected under an oil-gas holder of one cubic metre capacity. With a pressure varying between four and six atmospheres carbonic acid is easily liquefied under these conditions. The fluid flows down by its own weight into a copper tube four metres in length and four centimetres in diameter.

"Two pumps, coupled in the same way as the first pair, volatilize the carbonic acid in the gasometer, and the long tube filled with the liquid acid. Admission to the pumps is regulated by a three-way tap; a screw-regulating tap intercepts, if desired, the entry of liquid carbonic acid into the long tube; it is placed between the carbonic acid condenser and this long tube. When the regulating tap is closed, and the two pumps suck up the vapour from the liquid carbonic acid contained in the four-metre tube, the lowest temperature is produced that can be got: the carbonic acid solidifies, its temperature falling to about —140°. The work of abstracting heat is kept up by the pumps, which have a joint cylinder capacity of three litres per stroke and make 100 strokes per minute. Both the sulphurous acid tube and the carbonic acid tube are enclosed in sawdust and baize to prevent radiation.

"Into the interior of the carbonic acid tube there passes a fourth tube, five metres in length, fourteen millimetres in external diameter and four millimetres in internal diameter, which serves as the oxygen compressor. This long tube is surrounded by solid carbonic acid, and the whole of its surface is brought to the lowest temperature that it is possible to obtain. These two long tubes are connected at the lower ends with the carbonic acid tube; consequently the small tube goes beyond the other by about one metre. This portion I bend towards the ground, giving both tubes a slightly inclined position, but still near enough to the horizontal as shown in the subjoined sketch. The small central tube is bent down

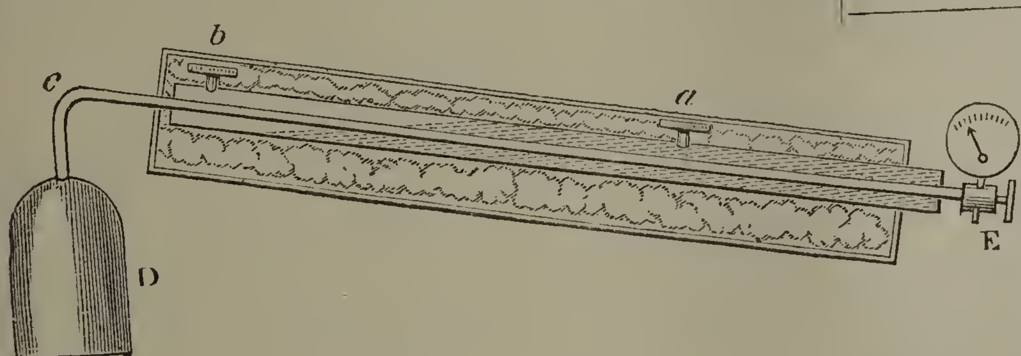

Fig. 2.

a. Opening for liquid carbonic acid.

b. Exit of vapours, corresponding with action of pumps.

at *c*, and screwed into the neck of a strong cylindro-conical retort, made of wrought iron, the walls of which are 35 millimetres thick. Its height is 28 centimetres, and diameter 17 centimetres. This retort contains 700 grammes of potassium chlorate and 256 grammes of potassium chloride mixed together, fused, pulverized and placed in the retort perfectly dry. I heat the retort when the double circulations of sulphurous acid and carbonic acid have lowered the temperature to the point desired. The chlorate of potassium is decomposed slowly at first, but tolerably rapidly at the end of the operation. A pressure-gauge at the end of the long tube enables me to watch the pressure and the progress of the reaction. It was made on purpose for me by Bourdon, of Paris, this last summer, and is graduated up to 800 atmospheres.

"When the reaction is finished the pressure exceeds 500 atmospheres; but it almost immediately falls, stopping at 320 atmospheres. If the screw-tap, E, at the end of the tube be opened at this moment, a jet of liquid may be distinctly seen escaping with extreme violence. If the tap be then closed a few seconds later, a second jet may be obtained, this time less abundant. Pieces of charcoal, slightly kindled, placed in this jet, ignite spontaneously with incredible violence. I have not yet been able to collect the liquid on account of the force with which it is projected; but I am now endeavouring to combine a cooled gauge, which may, by means of cloths, retain a little of the liquid.

"Yesterday (Monday, December 24th, 1877), I performed this experiment a second time before a good part of the members of our Physical Society, and we had three well-defined jets, one after the other. I cannot yet give the minimum pressure necessary, for it is evident that I must have had an exaggeration of the pressure produced by an accumulation of the gas in the retort, which resisted condensation in the narrow space represented by the inner tube.

"I intend using a similar apparatus to attempt the condensation of hydrogen and nitrogen, and I rely especially on my ability to maintain low temperatures with ease, by means of my four large pumps, worked by steam-power.

"I believe that it is in this direction particularly that it is necessary to work to effect the rebellious condensations, since the tension of saturated vapours is a direct function of the temperature. I am having a plan of my apparatus drawn up, and it will be my pleasure and duty to send it to you in the course of the week. I have learned with great interest that M. Cailletet has arrived at the same result with myself, and almost at the same moment. I have no idea as to what his process may be, but we shall doubtless enter into correspondence before long, and exchange our ideas on this interesting subject."

PATHOLOGICAL SOCIETY OF LONDON.*

Lactic Fermentation and its Bearings on Pathology.

BY JOSEPH LISTER, F.R.S.

A few years ago, it would have seemed very improbable that the souring of milk should have any bearings upon human pathology; but the large, influential, and highly interested audience that listened to Dr. Burdon Sanderson's lecture at the University of London yesterday was of itself sufficient evidence that the question of the essential nature of fermentative changes occupies a foremost place in the minds of pathologists at the present day.

In reading reports of discussions with regard to diseases presumably of such a nature, for example, the discussion that took place with regard to pyæmia in this Society some time ago, it has struck me that medical men were disposed to begin at the wrong end, so to speak, in this matter, to look at it from the clinical rather than from the physiological point of view.

It seemed to me that, in order that any sure steps should be taken with regard to the elucidation of the nature of presumably fermentative diseases in the human subject, the first thing should be that we should have clear ideas, distinct opinions, positive knowledge with regard to the more simple forms of fermentation, if I may so speak—more simple because they can be conducted and observed, investigated in our laboratories. It may be said, indeed, that such information has been already afforded to us by the researches of Pasteur and others who followed in his wake; and I must confess, Mr. President, that, for my own part, I should be much disposed to take such a view. But this opinion is by no means universal in our profession. We find men of very high position, both as physiologists and pathologists, expressing the view that, though in various fermentative changes, such, for example, as putrefaction, we do find organisms present, yet these organisms, these bacteria

* Address delivered Tuesday, December 18, 1877.

may, for aught we know, be mere accidental concomitants, not causes, of the fermentative changes. Some time ago I made an attempt in the special case of the lactic fermentation to decide this point one way or the other to the complete satisfaction of my own mind. So far as I am able to judge, I did succeed in this endeavour; and it occurred to me that it might not be without interest to the members of the Pathological Society to see with their own eyes the preparations, or samples of the preparations, which resulted from this inquiry, and on which my conclusions are based, before, from the lapse of time, they had lost their value. At the same time, I should not have presumed to bring this matter before the Pathological Society, if I were merely to bring forward what has been already sufficiently explained on a former occasion; but, while very briefly bringing forward those matters, I wish at the same time to place before the Society certain points that have not yet been published with regard to this particular fermentation.

First, I wish to make remarks regarding my method of experimentation, which, in its present simplified form, has never been published. The method of experimenting depends, in the first instance, upon the fact which experience has now amply demonstrated, that, if we have a pure glass—pure, that is to say, of anything living—such as this liqueur glass, have it covered over with a glass cap, and again this covered with a glass shade, such as I have here, and, for convenience, the apparatus reposing on a plate of glass; having this arrangement of pure glasses, if we have in such a glass any organic liquid, whatever it may be, so far at least as my experience has gone (and it has been considerable), if the liquid be pure from organisms in the glass, so long as this arrangement is maintained intact, no organisms will occur in the substance; or, in other words, although the atmosphere gains access to the interior of the glass—for the glass cap does not fit at all, the glass shade is not designed to fit, but may happen to project beyond the glass plate so as to leave a distinct palpable gap—it does not affect the result, but the double protection of the glass cap and the glass shade, while not excluding the gases of the atmosphere, excludes effectually the atmospheric dust, and, if the dust be excluded, organisms are prevented from occurring.

The glasses are obtained pure by means of heat. I find that exposure to a temperature of about 300° Fahr. for two hours is sufficient, so far as my experience is concerned, to destroy the life of all living material. But it is not enough that the glasses should be heated; it is necessary that the air that enters them during cooling should be filtered of dust. This I provide for by heating a cast iron box, the door of which I have brought; the box itself is too cumbersome to bring. This door has its circumference in the form of a considerable groove capable of being packed with a mass of cotton-wool. This door can be screwed up by nuts against the edge of the box, so that the edge of the box becomes firmly pressed against the cotton-wool. The cotton-wool then will serve as an effectual filter of the air that passes in during cooling; but then it is essential that the box should be so arranged that it may be equably heated. This cotton-wool has been used for several experiments, and you see it is only slightly browned; it is not singed. This is provided for by having the box heated by a large Bunsen's burner; between the Bunsen's burner and the bottom of the box are three shelves to prevent the heat from acting directly on the bottom of the box; at the same time, the box is covered over with a cover which confines the heat and compels the heated air to pass round the box and escape at the top of the cover. By these two means combined, the shelves below and the cover round about, we get the result which you see indicated here. The cotton at the top of the box is just in the same degree browned as the cotton at the bottom. Into such a box we may put a dozen glasses like these. We have a thermometer packed with cotton-wool in an aperture in the top of the box, to let us know when the temperature of 300° has been attained. When this temperature has been continued for two hours, the Bunsen's burner is extinguished, cooling is allowed to take place; and, when the apparatus is perfectly cooled, then the glasses are removed, and we are sure that they are taken out perfectly free from living organisms.

In the next place, how shall the organic liquid be introduced pure into such a glass? In my last publication on this subject, an exceedingly complicated method of decantation was described, enough, I confess, to deter anyone from repeating similar experiments. I am happy to say that we now manage the thing in a comparatively simple manner. The means of decanting is a flask of this form, having a bent spout large at the commencement and comparatively narrow in its shorter terminal part. The result of this arrangement is that, when a liquid is poured from such a flask, and then after the pouring the flask is returned to the erect position, the end of the nozzle is always valved by a drop of liquid. The large size of the first part of the spout prevents it from acting like a syphon. There is always a guarding drop at the orifice; regurgitation of air never can take place through the nozzle. The mouth of the flask has been previously covered with cotton-wool; and any air that enters the flask during the pouring out of the liquid passes through the cotton, and is filtered of its dust by so doing. As I have already explained, the guarding drop at the end prevents the regurgitation of any air through the orifice of the nozzle. When the decantation is complete, a piece of rag dipped in carbolic acid lotion is applied to the orifice, and by that means, by capillary attraction, the drop is sucked out, and a piece of pure carbolized cotton-wool is then applied. A convenient mode of carbolizing is to treat the cotton-wool with a solution of one part of carbolic acid and one hundred parts of anhydrous ether. The ether flies off and leaves the carbolic acid behind in a highly pungent and antiseptic condition. The nozzle having been deprived of its drop, the carbolized cotton cap is tied—and here is a little projection on the spout to secure the tying—and then the liquid, provided it is pure to begin with and the flask is pure, will remain ready to hand a week, or even a month or a year hence, according to your convenience.

Now, as to the protection of the liqueur-glass that is to be charged. Suppose I were going to charge this glass, say from this vessel—a flask of the same kind charged with Pasteur's solution on the 7th of August of the present year, which, you observe, remains as pure and as clear as when it was first prepared, although from it have been charged various liqueur glasses—I should remove the cotton-cap from the nozzle, and the instant that was done should slip the end of the nozzle into the opening which exists in this half of an India-rubber ball which had been previously steeped in a solution of carbolic acid and water. The India-rubber absorbs into its consistence carbolic acid, so that, even though dry after such steeping, it is powerfully antiseptic. The moment the cotton-cap is removed, this cap of caoutchouc is applied with its concavity downwards, and then I proceed to decant. I take off the glass cap, and instantly substitute the cap of India-rubber; the flexible India-rubber acting as a hinge. Fluid is poured in, while the antiseptic cap securely excludes any living organisms; and then, the instant the process is complete, the glass cap is replaced and the shade put on. The hemispherical form of the cap prevents lateral currents of air from depositing dust on the end of the nozzle of the flask, and a second glass, a third glasss, or a dozen glasses may be so charged; and experience shows that by this mode of procedure such a dozen glasses, provided the flask has been pure and the liquid pure in it, will remain with their contents unaltered till they dry up through atmospheric influence.

The last point is, how do we get the flask in a pure state with a pure liquid in it? The flask is purified with its caps of cotton over the mouth and nozzle by being put into the hot box. That is so far simple; we have, therefore, a pure flask to begin with.

Next, we wish to introduce into it a pure liquid. There is one liquid which we may very easily get in the pure state with very little trouble indeed, and that is unboiled urine, provided we have a healthy urethra to deal with and a healthy bladder. All we have to do is to apply the 1 to 40 carbolic acid solution to the glans penis and the meatus urinarius of the patient; then, taking off the cotton-cap, apply to the orifice the glans penis. The glans penis takes the place of the caoutchouc cap, and urine passes in, no regurgitation of air being possible. As soon as the act of micturition is over, a carbolized cotton-cap is tied over, and as surely as you do that will you have the unboiled urine, with its vesical mucus (which used to be regarded as the special ferment of urine) remaining for any length of time perfectly unaltered, without any bacteric development whatever.

But, suppose we have to deal with a liquid like milk, where we cannot have it pure to start with, we must purify it by heat. I do not know what I may find in this densely populated metropolis; but in the comparatively pure metropolis which I have lately inhabited, Edinburgh, I have never yet found any organism which resisted the temperature of 210° continued for half an hour; I mean to say in the moist state. I have found no organisms in a liquid continue fertile after exposure to 210° Fahr. for half an hour. I say 210°, and not 212°, which is boiling point, because the way in which we have proceeded is, after introducing the liquid into the flask, to immerse the flask in boiling water, and, in consequence of a certain degree of evaporation which takes place through the cotton, the temperature in the flask is prevented from ever rising fully to the boiling point. You do not have ebullition take place, and that is a great convenience, as we have no frothing; but you have a temperature somewhat short of 212°; we may say 210°. All we have to do then, having got the flask pure, is to introduce the liquid into the lower part of the flask, with a view to immersion in a saucepan of boiling water; but there must be the most scrupulous care taken that the liquid so introduced shall not come into contact with the upper parts of the interior of the flask; for, if they do, they will fail to be acted on by the full heat of the water in the saucepan. Now, the mode in which I filled my flasks in my first experiment of this kind was, having provided myself with a rag dipped in carbolic acid lotion, I took a long funnel and purified the exterior of the funnel with carbolic acid lotion, which answers just as well (1 to 20 lotion) as exposing it to the gas-flame or the spirit-lamp. I then passed the funnel down through the rag, which I had previously wrapped round it; then poured in the liquid, then withdrew the funnel, taking scrupulous care that the drop at the end of the funnel does not touch the sides of the flask; then substituted a carbolized cotton-cap, and immersed the flask in the saucepan. If I proceeded in this way with Pasteur's solution, with turnip-infusion, with simple water, with other materials I need not describe, I always had success; but, when I did the same thing with milk, time after time, to my great disappointment, I failed altogether. What was the explanation of the failure? Some persons might have said: "Oh! the explanation is very easy to find. There are in the milk complex molecules ready to develop, though as yet chemical substances, into living beings, and, because of the complex constitution of the milk, therefore it is that you fail; whereas your Pasteur's solution is a comparatively simple material, and your turnip-infusion, compared with milk, is simple." I felt sure that that was not the explanation, but that there must be some defect in my method of procedure. It may perhaps have occurred to some of you what that defect was; it was simply that, if we pour in any liquid through a funnel, we invariably have air passing with it. Air-bubbles appear upon the surface of the liquid, and those bubbles bursting carry with them their dust, and it may be that that dust may be deposited upon the upper part of the interior of the flask. But why should you be more likely to succeed with Pasteur's solution than with milk? Simply for this reason: that milk is a material which serves as a pabulum for almost all organisms. I once met with a bacterium, and only once, that would not live in milk; for it appears that almost all varieties of bacteria (which appear to be excessively numerous) will live in milk, whereas it is only a comparatively small proportion of bacteria that, if put alive into Pasteur's solution, will live in it at all. How, then, was the difficulty to be overcome? Of course, when we saw what the difficulty was, there was no great difficulty in overcoming it. It was done by substituting a syphon for the funnel. Here is the syphon that I used, consisting partly of two glass tubes, partly of India-rubber, with a stopcock in the course of the India rubber. This syphon is charged with water, the temperature of which should be higher than that of the air, so that there will be no dissolved air given off to form air-bubbles. Then suppose this is the fluid you wish to introduce into the flask. We pass one leg of the syphon into it, then turn the tap and permit a sufficient amount of fluid to flow out for all the existing water to escape from the syphon, and then we proceed just as with the funnel. Carbolized rag is wrapped round the end of the syphon; and, just as the cotton-cap is removed from the pure flask, a carbolized rag is put on; the syphon is slipped down, the tap is turned, and the liquid is introduced without the introduction of the smallest bubble of air. When a sufficient quantity of the liquid has been so passed in, the tap is turned, and then the syphon is withdrawn, scrupulous care being taken that it does not touch the inside of the flask; then a carbolized cap is instantaneously substituted for the carbolized rag, and the charging is completed.

Now, I have said that, before I saw my mistake as regards the use of the funnel, I never succeeded with milk. Since I have adopted this method, I have charged many flasks, and never failed. Here is a flask of boiled milk, that is to say, exposed to a temperature of 210°, on the 7th of August, and here it remains, I venture to say, as pure as it was immediately after the exposure to the heat. Now, I venture to say that this failure and correction of the failure are instructive, as showing how the development of organisms, under circumstances in which we wish that they shall not develop, is liable to be explained by fault on our part, defect in our own manipulation.

Having said so much with regard to our method, I will proceed as quickly as I can with the facts that I wish to bring before the Society. I selected the lactic fermentation as one peculiarly favourable for the purpose of investigation: first, because the lactic fermentation is a very remarkable change in milk, a very conspicuous fermentation in its results, conspicuous in the solidification that ensues, conspicuous in the marked souring that takes place; and, in the second place, because the ferment which causes the lactic fermentation is a rare ferment, speaking of the world generally, and, if it be a rare ferment, it is not likely that any accidental defect in the manipulation will lead to its introduction. I say it is a rare ferment; in dairies it seems to be universal, but in the world in general it is rare. If you charge a series of glasses like this with boiled milk, and take off their caps, exposing them to the air for half-an-hour at different times in the day, or exposing them in different rooms, say for half-an-hour, so far as my experience goes, you will be certain to have fermentative changes result, you will be certain to have organisms produced; but, so far as my experience goes, you will be certain not to have the lactic fermentation take place, you will be certain not to have the coagulation and the souring, and you will not find the peculiar organism to which I have given the name Bacterium Lactis, which I have represented here as it occurs in curdled milk, and which, as I left one of those microscopes, was to be seen in souring milk of yesterday.

This bacterium is a motionless bacterium, occurring most commonly in pairs, frequently in threes, fours, or even more. You always find these, as far as I know, in souring milk; but you will not find them under the circumstances to which I have alluded as the result of mere exposure to the air. The glasses I have brought before you here illustrate the same point as regards unboiled milk; these little glasses have been repurified in the hot-box in the way described, each one bring fitted with a little test-tube cap. The milk was received from the cow into a pure glass, purified by heat, within about two yards of a dairy—in a little orchard beside a dairy—and from the pure vessel it was transferred with a syringe and a purified pipette into the several glasses. Here we had unboiled milk to deal with. Every one of these twenty-four glasses has undergone fermentative changes, and, though I have not yet had the opportunity of examining them microscopically, I have not the least doubt that they all contain organisms, because, in a former experiment, performed in the same sort of way with half the number of glasses, I saw similar appearances to a considerable extent to those which are the only doubtful ones, and I found on examination that those appearances did depend on organisms. I say the only doubtful ones, because there are some here with regard to which inspection with a pocket-lens is quite sufficient to show that organisms are present. No fewer than seven of these twenty-four glasses have filamentous fungi in them; apparently — I have not yet examined them microscopically—of five different species. In spite of the care which I then took, organisms entered into all those glasses, but in not one of them did the lactic fermentation take place; all had fermentations of other kinds. Some of these milks, if members of the Society will examine them, will be seen to be exceedingly peculiar, indeed beautiful; there are scarlet or almost vermilion coloured spots, for example, here; some have a golden-yellow aspect, less seen by this light than by daylight. Numbers of different organisms have developed here, but not a bacterium lactis, or at all events nothing that caused the lactic fermentation.

Here, again, I have a set of glasses with which the same experiment was performed, only still more carefully. In this case, the experiment was more rigorously conducted, and here, in the majority of the glasses, at first sight you will suppose that no change at all had occurred; and in two of them I found, at the end of six weeks, that there was no indication whatever of any organisms. I tapped one of them and found the milk still perfectly fluid, of normal taste and reaction and without any organisms in it; showing that unboiled milk, as coming from the healthy cow, really has no ferment in it capable of leading to lactic fermentation, or any other fermentation, or to any organic development whatever.

The same scarcity of the lactic ferment is found in water as in air. If I prepare a series of glasses of boiled milk, and add water to them, say from an ordinary tap, a corresponding result is obtained. A very instructive mode of performing the experiment is to add very small drops of water by means of a syringe having a graduated nut, revolving on a fine screw on the piston-rod so that you are able to have exactly one hundredth of a minim—each degree on the nut corresponds to one hundredth—expelled at your pleasure. If I take water from the tap, and introduce one hundredth of a minim into, say ten glasses of boiled milk, which I do by simply taking off the cap and applying the hundredth to the surface, and applying the cap without loss of time, the result is that you get in some of the glasses certainly fermentative changes and organisms, but you do not get the lactic fermentation. And what is extremely interesting is, that you get different fermentations in different glasses, and some glasses escape altogether. That proves at once this important truth, that the fermentative agency in water, the existence of which was pointed out by one of the members of this Society, Dr. Burdon Sanderson, long ago, is not in the form of any matter dissolved in the water, but in the form of suspended particles of some kind or other; for, if it were dissolved in the water, every equal-sized drop would produce an equal effect. But some glasses escape altogether, and those which are affected are affected with different kinds of fermentation.

If the cream happen to be thick, you will see just at the spot of inoculation in course of time the first appearance of alteration when the bacterium happens to be a motionless bacterium, indicated, perhaps, by some curious colour—a vermilion tint, in one instance—spreading gradually over the cream, the vermilion part shown by the microscope to teem with bacteria, the uncoloured part free from bacteria, and so forth. But various as the fermentations were, there was no instance of the lactic fermentation, *i.e.*, curdling and souring of the milk. Therefore, you see, Mr. President, from these facts, that the souring of milk instead of being what one might suppose *à priori*, perhaps, from seeing it constantly occur in course of time in all milk brought from a dairy—instead of supposing it to be something inherent in the nature of the milk—is something which, whether in boiled milk or in unboiled, requires the introduction of something from without, and that something a scarce article, both in air and in water, except in dairies. I may say that, even in a dairy, I once exposed a glass of boiled milk by taking off the glass shade and glass cap for a quarter-of-an-hour, thinking very likely I should find the lactic fermentation as the result, as I should have had if I had introduced the smallest quantity of milk from any one of the pans. It so happened that I did not get the lactic fermentation even there; I got a filamentous fungus, and I got a bacterium also, but a bacterium associated with a most extraordinary alteration—a degree of viscidity that I dare say was never seen before—a viscidity that reminded one of the drops that bead the spider's web. By introducing a mere needle into the top of the liquid, I could draw it up a yard and two inches before the barely visible thread broke. That was the special fermentation that resulted from exposure on that occasion, even in the dairy; it so happened that no particles of the lactic ferment had been floating in the air so as to fall into that glass.

Well, then, this particular fermentation, from the conspicuousness of its effects and the rarity of the ferment, seemed a particularly favourable one for investigation.

(To be continued.)

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held on Friday evening, January 4th, when a paper by Mr. Shapley, on "Blood Chemically and Microscopically considered," was read by the Secretary.

After a short review of the work done by the principal investigators of this substance, the author proceeded, with the assistance of a table, to enumerate the compounds contained in blood, and state the percentage of each, the more important, including fibrin, albumin and colouring matter, receiving special attention. Coagulation was explained and the theories which have been advanced as reasons for coagulation were entered into, the one most probably correct being that of Schmidt, which depends upon the formation of fibrin from fibrinogenous and fibrinoplastic elements after the removal of the blood from the body. Corpuscles, their shape, size, and microscopical appearance, were next described, and the paper was concluded by illustrations of the absorption spectra of freshly drawn arterial and venous blood, and of hæmatin.

The paper was followed by a considerable discussion, and after passing a unanimous vote of thanks to Mr. Shapley, the meeting adjourned.

Parliamentary and Law Proceedings.

Death from Chloral.

On December 21st, Dr. Diplock held an adjourned inquiry at South Kensington, touching the death of Mrs. Amelia Cleverly, a widow, 70 years of age. From the evidence given on the former occasion, it appeared that the deceased was found dead in bed on the morning of the 23rd ult. A bottle that had contained syrup of chloral was found in her room. A *post-mortem* was made, and the medical evidence showed that deceased had swallowed sufficient chloral to kill four persons. Mr. John Mark Brock, assistant to Mr. G. Hardy, chemist, 10, Fulham Road, Brompton, was sworn, and stated that deceased, accompanied by a woman, came to the shop on the evening of the 22nd ult., and was served with sixpennyworth (an ounce) of chloral syrup, which contained 80 grains of chloral. The deceased said she had been in the habit of taking chloral, and after being served she was instructed as to the quantity to take. In reply to a juryman, the witness said the label on the bottle was not marked "Poison," as it was not necessary. The jury returned a verdict "That deceased died from accidentally swallowing an overdose of syrup of chloral."

Thr Charge of Adulterating Beer with Salt.

On Dec. 31st, James Scott, landlord of the Wellington beerhouse, Bromley, appeared before Mr. De Rutzen at the Thames Police Court, to answer an adjourned summons taken out at the instance of the Metropolitan Board of Works for the Poplar district for selling beer adulterated to the extent of 63 grains of salt to the gallon. The case was reported before and adjourned for judgment.

Mr. De Rutzen now said one thing was clear, namely, that the defendant did not adulterate this beer by putting salt into it, because the evidence of the foreman of Messrs. Truman, Hanbury and Buxton, the brewers who supplied the beer, and scientific witnesses, was to the effect that if the public analyst had been a little more careful he would have found a greater portion of salt in the beer than he did. They further said that the salt found was only the natural product of the malt, hops, and saccharine matter which they use in brewing, and that they put no salt in the beer. The delivery note given by the brewers to the defendant amounted to a warranty that the article supplied was of the same substance, quality, and nature as that ordered, and it appeared that the defendant sold it in the same state. The defendant, therefore, came within the 25th section of the Food and Drugs Act, and the summons would be dismissed, but as he did not give notice of the defence he was going to set up he would have to pay £10 costs.

Attempted Poisoning by Sugar of Lead.

On January 2nd, Alfred Bellchambers was charged at Woolwich with attempting to poison his wife. Mr. Robertson, surgeon, said that he was called by the prisoner to attend his wife, and told her that she had been taking lead poison, when she replied in the prisoner's presence that she had taken sugar of lead accidentally by putting it into her tea in mistake for carbonate of soda. The prisoner confirmed this statement, and when witness saw the woman again next day, and remarked that the poisoning must have been going on for some time from the quantity of lead in her gums, they both said that it had been going on for a long while. On Monday, having received a hint, witness spoke plainly to Mrs. Bellchambers, when she made a statement which induced him to inform the police. Some sugar of lead and a mixture of tea were produced by the witness. In cross-examination by Mr. Whale, on behalf of the prisoner, Mr. Robertson said that sugar of lead could not well be mistaken for carbonate of soda, being heavier and of a bluish colour. He had not heard that the prisoner's wife had used it for a lotion. Mr. Balguy remanded the prisoner, and refused to accept bail.

Poisoning by Potassium Cyanide.

On January 2nd, Mr. John Humphreys held an inquest at the Hope Tavern, St. Luke's, on the body of Frederick Bailey, aged 45, a hairdresser. On Monday the deceased suddenly left the room, at the rear of his shop, and went to a show-case in the shop, and drank a quantity of cyanide of potassium used in his business for the purpose of hair dyeing, returning to the parlour with the empty glass. For some past he had given way to intemperate habits. Death ensued shortly afterwards. The jury returned a verdict of Suicide whilst in an unsound state of mind.

Poisoning by Sulphuric Acid.

On January 2nd, Mr. Humphreys held an inquest at Bethnal Green, touching the death of Emma Cox, a single woman aged 24. It appeared that on Sunday last, the deceased and a younger sister had an altercation, and the father reprimanded both the girls. The deceased left the table, and in a few minutes afterwards she was found vomiting in her bedroom. A surgeon who was fetched found that the deceased had taken nearly three ounces of sulphuric acid. She died a few hours afterwards from the effects of the poison. Verdict, Suicide whilst in an unsound state of mind.

Dispensing Memoranda.

[50]. Extract. Ergotæ Liq.—Will you kindly allow me to make some observations concerning dispensing memorandum No. 50? The answer of Mr. A. W. Gerard to No. 50, extr. ergotæ liquidum, induced me to repeat the test, and having no more sediment at my disposition I evaporated some of the liquid extract and reduced the organic matter to coal. I washed the remnant repeatedly with hot distilled water, acidulated the collected liquids with hydrochloric acid, and ascertained the presence of potash with bichloride of platinum. Chloride of barium produced a white precipitate in the liquid, which is partly soluble in nitric acid, and gives with molybdate of ammonia a yellow precipitate, consisting of molybdic acid, ammonia, and phosphoric acid. The undissolved part of the white precipitate melted with carbonate of potash, dissolved in hot distilled water, and filtered, gives with chloride of barium a white precipitate = sulphuric acid; so much for the presence of phosphate and sulphate of potash. The sulphate not being so easily soluble in water as the phosphate, I must conclude that the crystals found by "Young Pharmacist" consist of sulphate of potash.

H. W. Langbeck.

[52]. A short time since I had the following prescription to dispense:—

℞ Ext. Hyoscyami . . . . gr. iij.
Pil. Rhei Co. . . . . gr. iv.
Ft. pil. cap. j. h. s. s. Mitte xij.

Will some of the readers of the Journal kindly inform me whether they would have sent out 7 grain pills or divided the mass into 24, and directed two for a dose?

Henry Cumber.

[53]. Can you inform me if the following can be dispensed so as to form an "inseparable mixture," as I have been told it has been by a first-class London house?—

℞ Ol. Amygd. Dulc.
Liq. Ammoniæ, P.L. . . . . . āā ℥j.
Spt. Rosmarini, P.L. . . . . . ℥vj.
Ol. Ess. Limon. . . . . ℥j.
M. Ft. lotio.

H. B. Sainsbury.

[54]. Could anyone suggest a method of making a suitable pill of the following—not a bolus:—

℞ Kreosot. . . . . ♏ ii.
Pil. Rhei Comp. . . . . grs. ii.
M. Ft. pil.

Aderyn.

[55]. Kindly inform me how to make a clear solution of the following:—

℞. Pot. Chlor. . . . . ʒi.
Acid. Salicylic. . . . . ʒss.
Sp. Juniper. . . . . ℥vi.
Aq. Camph. . . . . ad ℥viii.
M. Ft. mist.

AN APPRENTICE.

---

[56]. I shall be glad if any of your readers will inform me how they would dispense the enclosed prescription:—

℞. Phosphori . . . . gr. i.
Micæ Panis. . . . . ʒi.
Aq. . . . . q. s.
Ft. pil. xx. j. bis die. s. d.

C. E. S.

Notes and Queries.

[569]. OIL OF STAVESACRE may be utilized for external application by working it up after the manner of unguentum simplex, substituting oil of stavesacre for almond oil.—G. HERBERT.

---

[571]. BLUE COLOUR.—Solution of sulphate of copper mixed with an excess of solution of ammonia until the first formed precipitate is dissolved and diluted with distilled water gives a fine blue colour that will not form a deposit.—H. W. LANGBECK.

---

[573]. SILVERING LIQUID.—C. H. A. will find the following very useful:—

Take—
Chloride of Silver . . . . 3 parts.
Cream of Tartar, in fine powder . . 20 ,,
Common Salt, in fine powder . . . 15 ,,

Mix and rub with a little water into a thin paste, then spread with a soft paint brush over the cleansed metal, and when dried, polish with precipitated carbonate of lime. I have silvered in this way spoons, forks, scales, and even copper vessels used in the preparation of syrups containing acids.—H. W. LANGBECK.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE DEATH POINT OF BACTERIA.

Sir,—In my paper on "Putrescible Liquids," communicated to the Pharmaceutical Conference in the autumn of 1877, I stated that bacteria and their germs were utterly destroyed when placed in a temperature of 150° Fah. and upwards, providing the heat were continuously applied for a period of from three to six days. This was quite a new point in the inquiry, inasmuch as all previous experimenters had sterilized their infusions by actual boiling, the periods varying from five minutes to as many hours. It affords me much gratification to find my statement now corroborated by no less an authority than Professor Tyndall himself. In a long and able article on "Spontaneous Generation," published in the *Nineteenth Century* for the present month, the Professor says:—"An infusion which will resist five hours' continuous exposure to the boiling temperature will succumb to five days' exposure to a temperature 50° below that of boiling." This is precisely my own experiment re-stated. Be it observed that not until now (three months after the date of my paper) has the Professor advanced so far, his previous method consisting of "discontinuous heating," or boiling at intervals. In my own plan no tedious boilings or elaborate protecting media are required. Liability to error ceases and certainty of result ensues. Working in an atmosphere of 120° and above, with my sterilized infusions in open vessels and freely exposed to the air, I could get no results whatever, simply because heat being a true germicide no living matter could exist within its range. Am I too sanguine in anticipating that ere long simple heat will vie with, if not supersede, those elaborate antiseptic dressings which are fast becoming the *sine quâ non* of successful surgical practice?

I need scarcely say, however, that there is still much to learn on this subject. The theory of "softening," as applied to these supposed desiccated germs, I believe to be erroneous, except so far as the softening may be co-existent with their partial or actual development. Again, the fact that a properly prepared saline solution will nourish and sustain bacteria and yet be without vivifying action on bacteria germs is suggestive of much that has yet to be worked out and explained. Nevertheless, the results obtained in the practical application of the germ theory by means of antiseptics are (so far as they can be fairly observed) sufficiently clear and conclusive.

I have only to add that the infusions of hay, cucumber, beef, etc., prepared some months since without boiling, as above intimated, are still quite clear and pellucid and free from all signs of infusorial life.

King's College Hospital. W. WILLMOTT.

G. S.—(1) *Trifolium arvense*; (2) *Calamintha officinalis*; (3) *Bryonia dioica*; (4) *Carpinus Betula*; (5) *Gnaphalium uliginosum*.

J. B. C.—Respecting the subject of your question we have received a letter from the Board of Inland Revenue stating that the Acts relating to the Stamp Duty on Medicines do not extend to Ireland, but that medicines exported from Great Britain for sale in Ireland or elsewhere require to be stamped before exportation.

J. G. Prebble.—See *Pharm. Journ.* for July 15, 1876, p. 42.

W. P. Harrison is recommended to submit the powder to an analytical chemist for examination.

A. Davis.—The regulations respecting dispensing in the Naval Hospitals will be found in the Pharmaceutical Society's Calendar and in the present series of this Journal, vol. iii., p. 364. There is no similar appointment in the army to be obtained without enlisting.

S. V. Holgate.—We should think the whole of the preparations would be liable for the reason named and because they are recommended for the relief of human ailments.

W. J. W.—Apply at Apothecaries' Hall.

M. Hanley.—The form for making the preparation has not been published.

Vaseline.—There are now several preparations of the nature indicated in the market.

B. N. S.—The only really valuable book on the subject in the English language is Wilson's 'Bryologia Britannica,' which is now out of print and very scarce. A new edition of it will probably be issued this year. Stark's 'History of British Mosses' is a small work, very useful for details of structure but useless as regards classification.

Poison Bottles.—With respect to the communication from Mr. Robertson, of Elgin, in last week's Journal upon this subject, we are informed that Messrs. Kilner Bros., of Thornhill Lees, near Dewsbury, have for some past supplied bottles in blue glass, with two sides ribbed, and the words "Not to be taken" on a plain side. It has not been found practicable to make the letters different in colour to the bottle.

The "London Glass Bottle Company" remark that blue fluted poison bottles are made, but not greatly used, owing to their extra cost, and express an opinion that if their use for poisons were made compulsory there would be fewer accidental poisonings.

The "Barnsbury Glass Company" are of opinion that ruby and myrtle green glass, indicating danger and caution, might be substituted for blue glass in poison bottles, and state that this would not add to the cost of production.

COMMUNICATIONS, LETTERS, etc., have been received from Professor Dragendorff, Mr. Langbeck, Dr. Schacht, Mr. Fairlie, Mr. Urwick, Mr. Morris, Mr. Slatter, Mr. Bate, Mr. Baldock, B. H., W. G. F., Aderyn.

LOBELIA INFLATA: ITS PROXIMATE PRINCIPLES.

BY WILLIAM H. D. LEWIS, PH.C.

Lobelina, the active principle of *Lobelia inflata*, was first isolated by Proctor* in 1836, and subsequently by Bastick in 1851. The former, who in 1841 studied the drug more particularly, dissolved out an impure acetate in alcohol, triturated it with magnesia, and removed the alkaloid by agitating with ether, which was allowed to evaporate spontaneously. By dissolving the *lobelina* thus obtained in water and dilute sulphuric acid, boiling with purified animal charcoal, and removing as before by the use of magnesia and ether, it was deprived, to a certain extent, of colouring matter.

Bastick† adopted for the separation of the active principle a process similar to that recommended by Liebig for obtaining hyoscyamia. It differed from Proctor's method only in the use of sulphuric acid instead of acetic, and of lime and carbonate of potash in the place of magnesia as a means of removal from the acid. The alkaloid was freed from colouring matter by dissolving in alcohol, agitating the solution with purified animal charcoal until decolorized, filtering, and evaporating until the residue no longer lost weight.

Richardson's‡ process consists in dissolving the precipitate obtained by the addition of potassio-mercuric-iodide to an infusion of the drug, in ammonia, and, after removing the mercury with hydric sulphide, the iodine with nitrate of silver, and the excess of silver with hydric sulphide, concentrating the solution, and allowing the nitrate of lobelina to crystallize out. No directions are given for separating the alkaloid from this salt, but in the present experiments it was accomplished by dissolving in a small quantity of water, and triturating for several hours with an excess of calcined magnesia. The lobelina was then extracted from the solution by agitating with successive portions of amylic alcohol and allowing the latter to evaporate spontaneously. Lobelina may also be prepared from the cold infusion of the drug by precipitating with phosphomolybdic acid, collecting the precipitate on a filter and washing thoroughly with cold water; then, suspending in water and, after triturating for some time with carbonate of barium, extracting with alcohol, ether or amylic alcohol. In all of these methods there is difficulty in separating the alkaloid from colouring matter. By the following process the lobelina was obtained in a much purer state than by any of the methods above described.

The powdered drug is mixed with purified animal charcoal, and, after moistening with water to which a small quantity of acetic acid has previously been added, it is packed firmly in a percolator and allowed to macerate for several days. More of the menstruum is then poured on and the percolation continued as long as the percolate possesses any bitterness. The solution is then gently evaporated to the consistency of an extract, triturated with an excess of calcined magnesia, and the filtered liquid agitated with amylic alcohol, which is decanted and allowed to evaporate spontaneously. The lobelina may be further purified by dissolving in water, and filtering through animal charcoal. In this case the alkaloid is retained in the charcoal, from which it may be removed by ether or by amylic alcohol. Sulphuric acid may be used in the place of acetic, but, as the latter forms a salt more soluble in water than any other, it is to be preferred.

Lobelina, as obtained by either of these methods, is of a light yellow colour and the consistency of honey. It has a strong alkaline reaction and forms crystallizable salts with acids (not acetic), but is itself uncrystallizable, in this respect differing from hyoscyamia.

Caustic alkalies decompose it readily, hence it cannot be prepared from the plant by the ordinary methods of obtaining the non-volatile alkaloids; neither can it be separated by distillation, as conia or nicotina. It has a somewhat aromatic odour, and a sharp acrid taste. It is lighter than water but dissolves in it to a yellow colour. It is also soluble in alcohol, chloroform, ether, benzol, petroleum, naphtha, amylic alcohol, bisulphide of carbon, and many fixed and volatile oils. Petroleum naphtha dissolves it sparingly, and amylic alcohol freely from acid solution. The fixed and volatile alkalies with water dissolve it with more or less decomposition.

Nitric and hydrochloric acids dissolve it to a yellow colour. Sulphuric acid decomposes it with the formation of a red brown colour, which is intensified on the addition of a fragment of bichromate of potassium. Fröhde's reagent reacts the same as sulphuric acid. On exposure to the air lobelina slowly resinifies. In aqueous solution it is precipitated red brown by iodine in solution of potassic iodide, and white by tannic acid, the latter precipitate being soluble in ammonia and in excess of the precipitant. Potassio-mercuric-iodide gives a pale yellow precipitate, slightly soluble in excess, and nitrate of silver a white precipitate, soluble in ammonia and nitric acid. Chloride of gold produces a pale yellow precipitate, insoluble in hydrochloric acid. Acetate of lead throws down a white acicular precipitate. Chloride of platinum gives a yellow precipitate, which swims on the surface of water, and is slightly soluble in it. Sulphate of iron precipitates it brown. Mercuric chloride does not affect the solution. Gallic acid produces no change. Albumen is not coagulated. Ammonia gives a white precipitate; metatungstic and picric acids also produce precipitates. On the addition of phosphomolybdic acid a yellowish white precipitate results, which on the addition of ammonia, changes to a blue sediment, dissolving, on continued addition, to a faint blue colour, and gradually becoming colourless. This solution is unchanged by boiling.

Richardson (*loc. cit.*) asserts that when lobelina is boiled with dilute sulphuric acid no glucose is formed. In the present experiments this was not found to be the case. Continued boiling is necessary and a dilute solution of acid, but a certain amount of glucose is invariably produced. Dilute potassic hydrate may be used in the place of the acid with the same result. Lobelina is also decomposed when heated at 212° F., unless in combination with an acid.

The peculiar acid in the drug, called *lobelic acid*

---

† "Lobelina, a volatile organic base from *Lobelia inflata*." By Mr. William Bastick.—*Pharmaceutical Journal*, 1st series, vol. x., p. 270.

‡ *American Journal of Pharmacy*, iv., series ii., p. 293.

by Pereira,* was examined more in detail by Proctor (*loc. cit.*) who, in 1836, had mistaken it for gallic acid.

It may be best prepared by adding a solution of sulphate of copper to the decoction of the drug as long as a precipitate falls, washing the precipitate on a filter, suspending in water, and passing in sulphuretted hydrogen until the mixture becomes of a uniform deep brown hue. The solution is then gently heated, and the cupric sulphide formed is removed by filtration. The filtrate is now carefully evaporated, and from the residue thus obtained the lobelic acid is extracted with boiling ether. On the evaporation of the ether a yellow crystalline mass was obtained, having a decided acid reaction. By dissolving in cold ether and evaporating, the acid is obtained in small acicular crystals.

Lobelic acid is soluble in water, alcohol, and ether, and is non-volatile. In water solution it is precipitated green by sulphate of copper, the precipitate being soluble in acetic acid and the alkalies. Ferric chloride produces a brown precipitate, but slightly soluble in acids or alkalies. Acetate of lead gives a copious yellow precipitate; nitrate of silver a white precipitate, becoming of a red brown colour on standing. Mercuric nitrate gives a dirty white precipitate, while chloride of barium produces no change in the solution.

The decoction, obtained by boiling two ounces of the drug in a pint of water for half an hour, and filtering, is of a red brown colour. It is rendered slightly turbid on the addition of alcohol; becomes brown, then yellow, when treated with ammonia; yellow, then red, when sulphuric acid is added, and is not turned blue by iodine. On the addition of the metals mentioned under lobelic acid, precipitates are obtained of a darker colour than those obtained with a solution of the pure acid.

Lobelina exists in the plant as a salt of lobelic acid—the *lobeliate of lobelina.* It was prepared by Proctor, and by the writer, by mixing aqueous solutions of the two principles, concentrating slightly, and allowing the salt to crystallize out, it being but moderately soluble in water. On boiling it is decomposed, and on treating with alkalies or acids the lobelina undergoes the glucose fermentation.

The acrid principle of the drug, called *lobelacrin* by Enders, and described by him in Flückiger and Hanbury's 'Pharmacographia,' pp. 357-9, I am forced to believe is simply this salt—the lobeliate of lobelina—with possibly an excess of lobelic acid. It is directed to be prepared by exhausting the drug with spirit of wine, and distilling in the presence of charcoal; the charcoal is then to be washed with water and treated with boiling alcohol. This, on evaporation, gives a green extract, which is purified with chloroform. Warty tufts are thus obtained of a brown colour, soluble in ether and chloroform, only slightly soluble in water. They possess, of course, the acrid taste of lobelia, and are decomposed by boiling with water; by acids and alkalies they are resolved into sugar and lobelic acid.

In the present operations these tufts were found to have an acid reaction. They are soluble in alcohol, chloroform, ether, and amylic alcohol. Nitric and hydrochloric acids dissolve them colourless. Sulphuric acid blackens them.

* 'A Treatise on Materia Medica,' by Jonathan Pereira, vol ii., p. 584.

On dissolving in alcohol and applying solutions of iodine in iodide of potassium, tannic acid, potassic-mercuric-iodide, nitrate of silver, acetate of lead, chloride of platinum, and the other reagents named under lobelina, precipitates are obtained, identical in solubility and reaction with those produced with a solution of the alkaloid alone. Sulphate of copper, ferric chloride, mercuric nitrate, and the other precipitants of lobelic acid also give precipitates resembling those produced by the use of the decoction or a solution of the pure acid. After the removal of the precipitate formed on the addition of potassic-mercuric-iodide, no sugar could be formed by boiling with potassa or dilute sulphuric acid. A dilute solution, applied to the eye, causes instant and excessive dilation of the pupil. A small quantity, administered to a cat, caused violent retching and vomiting and much prostration.

In 1840, Pereira announced the existence of "a volatile acrid principle (oil?), called *lobelianin*, an acid (peculiar), resin, gum, etc."

Water distilled from lobelia is asserted to possess the "peculiar smell and nauseous acrid taste of the plant." In one experiment he obtained "a film of what appeared to be a solid volatile oil."

Proctor (*loc. cit.*), however, from an extended course of experiments finds the distillate to be entirely without the acrid taste of the herb. The present writer found the light brown liquid which comes over when the herb is distilled with water, to have the odour of lobelia somewhat intensified, but nothing that could be said to approach the characteristic taste of the plant. On the addition of sulphuric acid it is turned darker. Ferric chloride also darkened it without causing a precipitate. Tannic acid produced no change. Phosphomolybdic acid gave a yellow precipitate which dissolved to a green colour in ammonic hydrate, the solutions becoming yellow on boiling.

According to Reinsch,* the odour of the plant is due to an indeterminate amount of volatile oil, having "a bland taste and pungent odour." The aqueous distillate undoubtedly contains most of this oil, together with indeterminate matter resulting from the decomposition of the lobelina.

In the analysis of the writer above quoted, a "peculiar substance" is mentioned, to which he has applied the name *lobeliin.* It was evidently supposed to be the active principle of the plant. It was obtained by treating an alcoholic extract with ether, evaporating and digesting with alcohol of ninety-four per cent., again evaporating the solution, and dissolving the extract in water. This solution has an acid reaction, is of a brown colour, tastes slightly bitter and leaves a pungent after-taste, similar to that of tobacco. On evaporating it, the lobelin remains. It is soluble in water and alcohol, not in ether. The aqueous solution is not rendered turbid by ammonia, but the colour is slightly increased. Acids effect no alterations in it. Tincture of iodine renders even a weak solution turbid, and produces a reddish—brown colour. Nitrate of mercury gives a light yellow, and nitrate of silver a white precipitate, the latter quickly changing colour and assuming a reddish-brown tint. "Acetate of lead, acetate of copper, bichloride of mercury do not react on it."

Reinsch admits that the lobeliin thus obtained

* 'Analysis of Lobelia,' by Reinsch. *Pharmaceutischer Central-Blatt*, No. 31, July 5, 1843.

was not pure. It was evidently not considered as a vegetable base. In the original paper as found in the *Pharmaceutical Journal*, III., p. 125, no mention is made of its having an alkaline reaction, although Husemann reports Reinsch as claiming it to be a "yellow, gum-like, hygroscopic substance, *with an alkaline reaction*."

It is evidently a very indefinite compound. Some traces of lobelina possibly escape decomposition and afford the tests with iodine, tincture of galls, nitrate of mercury and nitrate of silver. Owing to the small amount present no precipitate was obtained with acetate of lead which reacts with lobelina only in concentrated solution. These precipitates may also be due in part to the presence of lobelic acid with which the lobelina exists in combination in the plant. Much indeterminate matter must also accompany these two principles.

The substance isolated by Colhoun* as the active principle of the drug, and called by him *Lobelia*, has since been shown by Proctor (*loc. cit.*), to be the hydrochlorate of lobelina.

The so-called "mucous gum" and "vegetable gluten" of Reinsch, obtained respectively from the decoction and tincture of the plant, as well as the "resin" mentioned by Pereira, were prepared, but were not deemed of sufficient importance to justify extended investigation.

NOTES ON THE MEDICINAL PLANTS OF LIBERIA.

BY E. M. HOLMES, F.L.S.

Curator of the Museum of the Pharmaceutical Society.

Although many of the productions of the Western Coast of Africa are known by name, yet comparatively little has been recorded concerning the plants used in medicine by the natives, especially in Liberia, where the people are very jealous of Europeans. The nephew of the late president of that country, Dr. Roberts, believing that there are in Liberia some plants sufficiently valuable to be used in medicine in other countries, has promised to send over various kinds for trial in this country, through his business agent Mr. T. Christy of Fenchurch Street, and it is proposed from time to time to notice in this Journal such of them as can be identified.

"FEVER PLANT" (*Ocymum viride*, Willd.).—This is an erect somewhat shrubby plant, about three feet high, with ovate lanceolate acuminate leaves from one to two inches long, the leaves being crenate at the margin and abundantly dotted underneath with oil glands. From *O. gratissimum*, L., a closely allied species, it differs chiefly in its lesser size and in the teeth of the calyx being less united. The plant when rubbed or chewed gives off a strong odour like that of lemon thyme (*Thymus citriodorus*, Schreb).

Lindley states that *Ocymum viride*, is used in Sierra Leone as a remedy for the fevers prevalent in that country.

Dr. Roberts assures me that in Liberia it is the common remedy for fever of any kind, and that he has entirely substituted it for quinine in his practice, since he finds it much cheaper and equally effectual. It is given in the form of infusion, a wineglassful being administered at intervals until perspiration is freely induced, the patient being kept warm in bed.

The thyme-like odour of the plant suggests that its properties may possibly be due to the presence of thymol, a substance which has recently attracted some attention, and deservedly so, since it belongs to the highly antiseptic group of phenols, and can be taken internally with much less danger than carbolic acid. The knowledge we possess of the properties of *O. viride*, and a few other species nearly allied to it, still further strengthens this supposition. *O. canum*, Sims, *O. gratissimum*, L., in India, and *O. crispum*, Thunb., in Japan, are used to restrain mucous discharge in catarrh; *O. sanctum*, L., is used in India, according to Ainslie, as a febrifuge, and a decoction of the seeds of *O. gratissimum* is used in Brazil for gonorrhœa. Dr. Waitz found the same plant cure aphthæ in children when ordinary European remedies failed. *O. tenuiflorum*, L., is used as an aromatic stimulant in Java.

Dr. Lewin, in Virchow's 'Archives,' has lately pointed out that thymol, in the proportion of 1 part to 1000, is capable of arresting various processes of fermentation, and recommends it as a remedy for stomachic fermentation and dilatation, and in diseases depending upon the action of living organic germs, such as diphtheria. He states also that it arrests excessive secretion from mucous membranes. From the above remarks it will be seen that the properties of the fever plant very closely resemble those of thymol. It remains to be determined, however, whether its efficacy is due to thymol alone or to some other constituent as well.

"HÆMORRHAGE PLANT" (*Aspilia latifolia*, O. and H.).—This is a herbaceous plant belonging to the natural order Compositæ, from one and a-half to four feet high, with spreading branches and opposite very rough foliage. The leaves are ovate, acuminate, minutely serrate, and very hard to the touch, owing to the leaf being covered with very short rigid hairs. The flowers are yellow and about the size of those of the fleabane (*Pulicaria dysenterica*, Gaertn). The florets of the ray are neuter, a feature which readily distinguishes this genus from those African genera to which it is most nearly allied. From the other African species of the same genus, it is known by the pappus being almost obsolete, by the shape of the leaves, and by the scales of the involucre being equal in height to the florets of the disc. The account given by Dr. Roberts of the hæmostatic properties of this plant partake of the marvellous. He states (*in litt.*) that the natives always prefer to use it to any treatment adopted by the Europeans. He further says that he has witnessed its use in several cuts where the arteries have been severed, the leaves and flowers being pounded together and applied to the wound, the hæmorrhage stopping in a few minutes and the wound healing rapidly without any other application. The decoction, in doses of ℥ss three times a day, is used in hæmorrhage from the lungs. Dr. Roberts is not sure, however, whether the dried plant would answer as well, as he had only seen the fresh plant used. The properties of this plant certainly are worth investigation, so that it may be determined whether its action is merely mechanical, like that of matico, or whether its juice, like that of *Jatropha*

Curcas, L., possesses an inherent property of coagulating the fibrine of the blood.

Small Senna (*Cassia occidentalis*, L.).—The leaves of this plant are used in Liberia as a purgative, and are known under the above name, while those of a plant with larger leaves, apparently a *Croton*, are known as "large senna." The materials as yet received are not sufficient to identify the latter plant. According to the 'Plants Médicinales de Maurice,' Dr. Livingstone brought to the Botanical Gardens at the Mauritius the seeds of this plant, which he stated that the natives in the interior of Africa roasted and used like coffee. It is now naturalized in the Mauritius, and is said to be used occasionally with good effect in certain cases of asthma and also as a fomentation in some diseases of the skin. According to Macfayden a decoction of the root possesses diuretic properties and the leaves are used by the negroes, when smeared with a little candle grease, as a substitute for adhesive plaister. Martius states that in Brazil, where the plant is called *Gaja marioba*, the root is used in incipient dropsy and in obstructions and weakness of the stomach, it being considered a powerful stimulant to the lymphatic system. It does not appear that the seeds, leaves, or roots are so used in Liberia. *C. occidentalis* is also common in both the East and West Indies.

Pipybras (*Scoparia dulcis*, L.).—This scrophulariaceous plant, which is common in tropical countries in all parts of the world, is used in Liberia for gravel and kidney complaints. A wineglassful of the decoction is taken when cold, three times a day, tea and coffee being forbidden during its use. The leaves are broadly lanceolate, serrate, thin and smooth. The two-valved fruit when mature dehisces septicidally, showing the placenta and seeds free in the centre. The plant is herbaceous, one to three feet high, and much branched, the leaves and branches being usually in whorls of three. The small white flowers have remarkably slender short pedicels and are arranged in a racemose manner.

Sassy Bark (*Erythrophlœum Guineense*, Don).—This tree which is abundant in Liberia, is only used as a poison. Its medicinal properties have only recently been investigated by Dr. T. Lauder Brunton.* The plant has already been figured in this Journal and a full description of it given.†

NOTE ON GERANIUM OIL.

BY PROFESSOR DRAGENDORFF.

In the year 1876 I described in the *Pharmaceutical Journal* a number of reactions by which the more important essential oils could be recognized and distinguished from each other. Part of the oils used in the experiments referred to, upon which I based my statements, were prepared in my laboratory, but some of them were obtained from commercial sources. Among the latter, for the purity of which I could not guarantee, there were a French and a Turkish geranium oil. Through the kindness of Mr. H. W. Langbeck, Leman Street, Whitechapel, London, my attention has been called to the fact, that a good freshly rectified reputed geranium oil, derived from a species of *Andropogon*, does not correspond in its reactions either with the Turkish or the French oil. Mr. Langbeck, who is engaged in the rectification of geranium oil for commercial purposes, was so kind as to send me a sample of his manufacture, and upon the ground of experiments that I have made with this oil I can entirely confirm his opinion.

The oil which Mr. Langbeck has sent to me is perfectly colourless, and has an agreeable geranium odour; it decolorizes bromochloroform, and does not acquire with it any colour even after standing some time. With chloral it forms an almost colourless mixture. In alcoholic hydrochloric acid it dissolves equally colourless, but becomes very slowly reddish, and subsequently of a turbid red-brown colour. The oil is dissolved by concentrated sulphuric acid with a dark gamboge colour, but with it as well as with Fröhde's reagent it soon assumes a brown colour. A mixture of alcoholic hydrochloric acid and chloral forms with it, as pointed out to me by Mr. Langbeck, a rose-coloured solution.

The difference between the results obtained in my former experiments and the present is probably hardly to be referred to difference in age of the oils used. I conjecture that they were obtained from different plants, and that either both of the oils formerly examined by me were actually prepared from the rose geranium, or from a species of *Andropogon* different from that from which the oil of Mr. Langbeck was obtained.

Dorpat.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 522.)

Urticaceæ, Gen. ? Sp. ?—*Local name*, Pokli.

Herbaceous plant, with serrate leaves and minute green flowers; found in Goa. The fresh roots are tuberous and spindle-shaped, eight to twelve inches long, one to two inches in diameter; they diverge from a central woody stock, and are covered by a thin brown scaly epidermis; they consist of a thick cortical portion and a soft central woody part easily cut when fresh. Sections examined under the microscope show a layer of cells beneath the epidermis loaded with red colouring matter, and within this a vascular system of jointed vessels, which also contain red pigment. The remainder of the root is composed of soft woody tissue loaded with starch. The medullary rays are well marked, and their extension into the cortex is very distinctly seen. Pokli is sweetish and feebly astringent to the taste; its action is purgative.

Berberis (Several Species).—*Local name of the wood*, Darhalad; *the extract*, Rusot; *the fruit*, Zirishk.

Darhalad occurs in pieces one to two inches in diameter, covered by a soft, corky, light brown bark, beneath this is a hard layer of stony cells, forming a complete coating to the stem; this layer is marked by longitudinal furrows, corresponding to the medullary rays, which are very prominent and close grained, and contain many stony cells. Between the rays are wedge-shaped portions of wood supplied with very large fenestrated vessels, and external to each wedge-shaped portion is situated a peculiar band of a pale yellow colour, which lies in contact with the stony envelope. There is a small close-grained central column consisting of cells containing starch. All parts of the wood are impregnated with yellow colouring matter, freely soluble in water.

Rusot is a dark brown extract of the consistence of opium, having a bitter and astringent taste, readily

* *Lancet*, March 17, 1877, p. 377.

† *Pharmaceutical Journal* [1], vol. xvi., p. 235.

soluble in water, partly so in rectified spirit, forming rich yellowish-brown solutions which become bright yellow when diluted.

Zirishk is a moist sticky mass of small black fruit rather larger than English barberries; most of them are abortive, but a few contain one or two oblong seeds about $\frac{3}{20}$ths of an inch in length, with a thin roughish brown testa, beneath which is a membranaceous covering. The perisperm is yellow; embryo nearly as long as the perisperm, yellow, erect; cotyledons oblong; radicle sub-cylindric, inferior.

Darhalad comes to Bombay from Northern India, and from the Madras Presidency. Rusot and Zirishk from Northern India.

NELUMBIUM SPECIOSUM.—*Local name*, KAMAL.

The calyx consists of four or five deciduous sepals, the corolla of numerous deciduous petals, arranged in several rows; the stamens are numerous, in several rows, attached with the petals to the base of the receptacle; the stigma is sessile; the dry flowers have a brown colour. The seeds (Kamal Kahri) are black, and like small acorns. Both Hindus and Mahometans consider the flowers to be cooling and astringent. As an external cooling application lotus flowers are made into a paste with sandal wood or emblic myrobalans. The seeds are used as a food, and in times of scarcity the roots are eaten, but they are bitter and unpalatable. The seeds are imported from Persia in large quantities. The dried flowers are sold in the shops, but those of Nymphæa are generally substituted for them, and are accepted by the natives as having the same properties.

ANASTATICA HIEROCHUNTINA.—*Local name*, KAF-I-MARYAM.

There can be little doubt that the dried plant was first introduced into India by the Mahometans. It is kept in all the druggists' shops and is prescribed in difficult labour, being placed in water until it expands; the water is administered to the patient. The whole plant is used. It has a short woody stem, branched in a corymbose manner at the top; leaves obovate, the lower ones entire, the upper remotely toothed (seldom present in the dry specimens). The fruit forms spikes along the branches; it consists of a short pouch with a strong curved beak, and two earlike projections on each side, which is divided into four cells, each cell containing a yellow concavo-convex seed. The whole plant is tomatose and has hardly any taste. As seen in the shops it presents the appearance of a little ball of wickerwork. It is imported from Syria by way of the Persian Gulf.

CAPPARIS SPINOSA.—*Local name of Rootbark*, KABAR.

This plant is widely distributed, being found in Asia, Europe, Africa and Australia. The common Indian and Oriental form (Var. 3 of Hooker's 'Indian Flora') grows in the Bombay Presidency. Caper bark does not appear to have been known as a medicine to the Hindus until introduced by the Mahometans, but another species of capparis (*C. aphylla*), very common in Indian and having somewhat similar properties, has a Sanskrit name (*Karira*), and its berries are used by the natives. Capparis is mentioned by both Greek and Latin writers, and its medical properties were probably made known to the Arabs through them. The author of the Makhzan-ul-Adwiya gives a good description of the plant and says that the root bark is the most active part. He considers its action to be detergent and astringent, and recommends it in palsy, dropsy, and gouty and rheumatic affections. The juice of the fresh plant is directed to be dropped into the ear to kill worms, just as cleome juice is used in India. All parts of the plant are said to have a stimulating and astringent effect when applied externally. Ainslie mentions the bark as an imported article, and notices its use as an external application to malignant ulcers. Caper root bark occurs in half quills, several inches in length, it is very thick and transversely fissured; the external surface grey, the internal white; taste bitter and pungent. It is imported *viâ* the Persian Gulf.

PORTULACA QUADRIFIDA.—*Local name*, KURFA.

The creeping annual purslane has probably been long used as a domestic remedy by the Hindus. The Sanskrit name is Loni. The fresh leaves are acid, and are prescribed when bruised as a cooling external application in erysipelas, and an infusion of them is given as a diuretic. In Arabic and Persian books the herb is called baklat-ul-humaka or baklat-ul-mubarika and kurfa. Two kinds are described, the large and the small, the former is probably *P. oleracea*, as its use as a vegetable is noticed. Both are said to be cold or moist, and to have detergent and astringent properties. These herbs can be obtained in most vegetable markets, and the seeds are kept in the druggists' shops. The two portulacas, called burra and chota lonia in Hindustani, may be readily distinguished by their low growth, succulent flat or nearly cylindrical leaves, and small yellow flowers. In *P. quadrifida* there are tufts of bristles in the axils; the seeds are black, minutely tubercled, and kidney shaped.

GARCINIA INDICA.—*Local name*, KOKUM.

The tree is common on the western coast between Damann and Goa; it grows wild upon the hills of the Concan, but is often to be seen in gardens close to the sea. It flowers about Christmas, and ripens its fruit in April and May. The fruit is largely used all along the western coast as an acid ingredient in curries, and is an article of commerce in the dry state. It is generally prepared by removing the seeds and drying the pulp in the sun; the latter is then slightly salted, and is ready for the market. In Goa the pulp is sometimes separated from the skin, and made into large globular or elongated masses. The seeds are pounded and boiled to extract the oil, which on cooling becomes gradually solid, and is roughly moulded by hand into egg-shaped balls, or concavo-convex cakes. This is the substance known as kokum butter; the natives occasionally use it for cooking, but the statement that it is largely used in Goa to adulterate ghee (liquid butter) is incorrect. The apothecaries of Goa prepare a very fine purple syrup from the fruit which is worthy of attention. The fruit is spherical, about the size of a small orange, purple, containing an acid pulp of a still deeper colour, in which from five to eight reniform seeds are imbedded. The seeds are compressed laterally, wrinkled, about three-fourths of an inch long, by four-tenths broad. The cotyledons are very thick, closely adherent, and have a sweet oily taste. Kokum butter is of a dirty white colour, firm, dry, and friable in the hottest weather, and greasy to the touch like spermaceti; its structure is crystalline. It generally contains impurities, and requires to be remelted and strained before it can be used for pharmaceutical purposes. Its chief fault is that it has a yellowish tinge, which makes ointment prepared with it inferior in appearance to that made with spermaceti.

(*To be continued.*)

THE MEDICINAL CHLORINE-DERIVATIVES OF ALCOHOL.*

(*Concluded from page* 550.)

Croton-chloral is distinguished from the ordinary chloral, first, by its melting-point, which is at 78° C. (173° F.), while common chloral melts at 56° C. (133° F.); and second, by the products of its decomposition. *Ethyl-chloral*, when brought into contact with alkalies, splits into *chloroform* and *formic acid:*

$C_2HCl_3O + KHO = CHCl_3 + KCHO_2$
ethyl-chloral + potassa = *chloroform* + potassium *formate*,

while *croton-chloral*, under the same conditions, splits into *dichlorallylene* and *formic acid:*

$C_4H_3Cl_3O + 2KHO = C_3H_2Cl_2 + KCl + KCHO + H_2O$
croton-chloral + potassa = *dichlorallylene* + potassium chloride + potassium formate + water.

Dichlorallylene is an aromatic liquid, boiling at 78° C. (172° F.), but is very unstable, being gradually decomposed, even at ordinary temperatures, acquiring a disagreeable odour, and setting free hydrochloric acid gas. The same phenomena are observed in impure samples of chloroform, and the readiness with which the latter decomposes and becomes acid makes it highly probable that this is owing to a contamination with dichlorallylene. Its presence is easily accounted for by the fact that many manufacturers prepare chloroform from crude alcohol, which contains considerable quantities of *aldehyde*. The latter is converted into croton-chloral, and this, by contact with the chalk during the rectification, into dichlorallylene.

If we, however, accept the new views of the constitution of croton-chloral, according to which it is in reality *butyl-chloral*, we should have the following products of decomposition:

$C_4H_5Cl_3O + 2KHO = C_3H_4Cl_2 + KCl + KCHO_2 + H_2O$
butyl-chloral + potassa = *dichloride of allylene* + potassium chloride + potassium *formate* + water;

and in this case dichloride of allylene is just as unstable as the dichlorallylene mentioned previously, so that the deterioration of chloroform may be owing to the presence of either compound.

Now, since, in the preparation of chloroform from alcohol and chlorinated lime, the intermediate formation of chloral is generally accepted as a fact, it was supposed that an absolutely pure chloroform could be produced by decomposing pure chloral hydrate with alkalies; and this idea was actually carried out in practice, very large quantities of such chloroform being manufactured in Germany, chiefly by Saame and Co., in Ludwigshafen.

Unfortunately, however, the expectation of its superior purity and stability has not been realized. It costs a good deal more than ordinary chloroform, but it is not by any means more stable than the latter. Of three samples of chloroform, one of which was prepared from chloral, which were exposed to the sunlight in half-filled bottles, one sample, consisting of ordinary, and the sample of chloral-chloroform were decomposed with equal rapidity, while the third sample, being purified ordinary chloroform, remained unaltered even after standing six months.

In connection with the above mentioned compounds, which are mostly derived from the ethyl series, may be mentioned another substance also used as an anæsthetic, and frequently used as a substitute for chloroform. We mean the compound CH_2Cl_2, methene chloride, or dichloromethane, usually called *bichloride of methylene*. The chemistry of the latter may be briefly explained as follows: The starting-point of the methyl series is the saturated hydrocarbon CH_4, methane, or marsh-gas, an incondensable gas of sp. gr. 0·559. Chlorine does not act upon it in the dark; in diffused daylight it displaces one atom of hydrogen, forming methyl chloride, or chloromethane:

$$CH_4 + Cl_2 = CH_3Cl + HCl.$$

This latter body, however, may be more easily prepared by heating a mixture of 2 parts of sodium chloride, 1 part of methylic alcohol, and 3 parts of sulphuric acid. It is a colourless gas of sweetish taste and peculiar ethereal odour. The presence of an excess of chlorine successively causes the replacement of more atoms of hydrogen by chlorine, so that we have the following series:

CH_4 methane;
CH_3Cl methyl cloride, chloromethane;
CH_2Cl_2 methene chloride, dichloromethane (*bichloride of methylene*);
$CHCl_3$ methenyl chloride, trichloromethane (*chloroform*);
CCl_4 carbon tetrachloride.

The third compound of this series, the commercial *bichloride of methylene*, is generally prepared by exposing to daylight in a glass globe chlorine gas and gaseous methyl chloride. The globe is provided with two lateral tubes for the admission of the gases, and below with an open neck, which communicates with one of the tubulures of a Woulff's bottle, of which the other tubulure communicates by means of a bent tube with another Woulff's bottle, and this by another bent tube with a flask. The second bottle is surrounded with ice, and the flask immersed in a freezing mixture to condense the volatile products. The bichloride condenses in the flask in a pure state, while the contents of the two Woulff's bottles consist chiefly of chloroform.

Methene chloride, or, to retain the less correct term, *bichloride of methylene*, is therefore rather troublesome to prepare, and higher in price than chloroform, which latter may be prepared in many ways, starting from methyl, ethyl, or even amyl alcohols. Hence it is not uncommon to find chloroform substituted and sold for the other more expensive anæsthetic. They may, however, be distinguished by their boiling-points and specific gravities: chloroform has a sp. gr. of 1492 at 17° C. (62·6° F)., and boils at 63·5° C. (146° F. according to Pierre, but 142° F. according to U. S. Ph.); bichloride of methylene has a sp. gr. of 1360, and boils at 41° C. (106° F.).* A further distinction is their behaviour to a flame; chloroform burns with difficulty with a green-bordered flame, while the other liquid burns with a smoky flame. A solution of iodine in chloroform has a reddish-violet colour, while a solution in bichloride of methylene looks more like an alcoholic tincture. It has also happened that chloroform mixed with alcohol, to reduce the specific gravity, has been substituted and sold for the bichloride. This fraud may, however, easily be detected by shaking it with water, which removes the alcohol.

* From a paper by J. Biel, in *Pharm. Zeit. f. Russl.* 1877, No. 11, and a paper in *L'Union Pharm.*, 1877, 181, with additions by Ed. N. R. From *New Remedies*, October 1877.

*Not at 30·5° C. (87° F.) as Fownes has it. This is the boiling point of the isomer of bichloride of methylene, namely chlorinated methyl chloride CH_2Cl_2, which has a sp. gr. of 1344.

HYPOPHOSPHORIC ACID.*

BY T. SALZER.

The acid syrup formed when phosphorus, partially covered with water, is exposed to the air (Pelletier's *acide phosphatique*), contains phosphorous, phosphoric, and hypophosphoric acids. The last-named acid is produced by the action of the air on phosphorous acid. It may be separated in the form of a sparingly soluble sodium salt by treating the mixed acids with sodium carbonate or acetate.

Pure hypophosphoric acid is best obtained by treating the lead salt suspended in water with hydrogen sulphide. Its aqueous solution is strongly acid, colourless, and inodorous, and may be boiled without decomposition, but when evaporated to a syrupy consistence it is resolved by heat into phosphorous and phosphoric acids. In its behaviour with reagents it is intermediate between phosphorous and phosphoric acids, which circumstance accounts for its having been so long overlooked in a mixture of these acids.

The acid is perfectly stable in aqueous solution, and is not affected by strong acids in the cold, but when boiled with dilute sulphuric or nitric acid, it is resolved, at a certain state of concentration, into phosphorous and phosphoric acids. The solution of the acid is not oxidized when warmed with dilute hydrogen peroxide, and is not affected by potassium chromate, chlorine, or iodine, even at the boiling heat; neither does it reduce mercuric, auric, or platinic chloride. It produces in solutions of silver a white precipitate, which does not blacken on boiling. The solution is oxidized by potassium permanganate, slowly in the cold, and very rapidly when heated, being converted into phosphoric acid. It is not affected by hydrogen sulphide, sulphur trioxide, or nascent hydrogen.

Hypophosphoric acid is bibasic, and is represented by the formula, H_2PO_3, corresponding with the anhydride, P_2O_4.

The salts of hypophosphoric acid resemble in general those of hypophosphorous and phosphorous acids, being, however, much more stable. At high temperatures they give off hydrogen or hydrogen phosphide, leaving metallic phosphide or phosphate.

The *acid sodium salt*, $NaHPO_3+3H_2O$, is formed on adding sodium acetate in excess to the syrupy liquid produced by the oxidation of moist phosphorus in the air. It crystallizes in oblique rhombic prisms, which dissolve in 45 parts of cold, and 5 parts of boiling water. When gently warmed it loses its water of crystallization, and afterwards gives off inflammable hydrogen, leaving metaphosphate. At ordinary temperatures, both the salt and its aqueous solution are perfectly stable.

The *neutral sodium salt*, $Na_2PO_3+5H_2O$, obtained by neutralizing the acid salt with sodium carbonate, crystallizes in needles, which dissolve in about thirty parts of cold water, forming a feebly alkaline solution.

The *lead salt*, $PbPO_3$, is precipitated by the acid sodium salt from a solution of neutral or basic acetate in the form of a white powder, insoluble in water, dilute acetic acid, and hypophosphoric acid, but soluble in dilute nitric acid. It is easily decomposed by dilute sulphuric acid.

BERBERINA PHOSPHATE.†

BY H. B. PARSONS.

There has been a considerable call during the past year for a freely soluble salt of berberina, to be used as a topical application to inflamed mucous membranes. The muriate and acid sulphate are so nearly insoluble as to be of little service. The phosphate and hypophosphite are freely soluble, but their preparation is expensive owing to the high price of phosphoric and hypophosphorous acids. Accordingly, many spurious phosphates are now upon the market, most of which consist, wholly or in part, of the acid sulphate.

Quantitative analyses of commercial samples of the acid sulphate, and of a so-called "phosphate of hydrastia," gave the the following results, one gram being taken in each case:—

	Acid Sulphate.	"Phosphate."
Berberina ($C_{20}H_{17}NO_4$) . . .	·7650*	·7969†
Sulphuric Acid (H_2SO_4) . . .	·2250‡	·1343§
Phosphate of Calcium $Ca_3(PO_4)_2$		·0600‖
Total . . .	·9900	·9912

The first salt was a true acid sulphate, and was sold as such; the analysis confirms the formula already given by Perrin¶—$C_{20}H_{17}NO_4H_2SO_4$.

The "hydrastia phosphate" contained no hydrastia, which is a *white* alkaloid, found together with berberina in the root of *Hydrastis Canadensis.* Only a trace of phosphoric acid was present, and that as an impurity of calcium phosphate. This preparation has had quite a sale in Cincinnati, under the trade name of "Greve's Phosphate of Hydrastia." The method of preparation is described by Dr. T. L. A. Greve, in the *Eclectic Medical Journal*, July, 1877:—"By saturating diluted phosphoric acid with this alkaloid" (berberina), "a solution of phosphate of berberina is obtained, which is, however, more readily made from the sulphate by boiling with water and precipitated phosphate of lime, when sulphate of lime and phosphate of berberina are formed." That the doctor is mistaken as to the composition of the berberina salt is evident. Some change must certainly have taken place, as "Greve's Phosphate" is more freely soluble than the acid sulphate. The phosphate of calcium in reality abstracted *one half* the sulphuric acid of the acid sulphate, leaving in solution a more soluble normal sulphate, of the composition $(C_{20}H_{17}NO_4)_2H_2SO_4$. The following equation explains the reaction, and is, I believe, substantially correct:—

$$2C_{20}H_{17}NO_4H_2SO_4+Ca_3(PO_4)_2=(C_{20}H_{17}NO_4)_2H_2SO_4+CaSO_4+2CaHPO_4.$$

That this salt is quite soluble, and may answer in medicine is very probable; but to sell it as *phosphate* seems hardly right, as the real phosphate sells at a figure very much above the sulphate or muriate.

Several other phosphates were examined. A sample of the true phosphate, made by precipitation, was found quite acid, because imperfectly washed. A Cincinnati "phosphate of hydrastia" consisted of a sticky, greenish mass, containing much extractive organic matter, the remainder being sulphate of berberina. It was only partially soluble in much hot water, was very acid, and entirely unfit for medicinal uses.

By studying the reactions of berberina sulphate with the various phosphates of calcium, I was led to believe that a *soluble* phosphate of calcium, if boiled with berberina sulphate, would form berberina phosphate and calcium sulphate, and such is the case.

By repeated experiments I find the following process will give satisfactory results:—

℞	Bone Ash—well burned . .	1 troy oz.
	Sulphuric Acid, concent. . .	gr. clxxxv.
	Berberina Sulphate	1 troy oz.
	Alcohol,	
	Water āā	q. s.

---

* ·200 grm. required 3·6 c.c. Mayer's solution potassic mercuric iodide. "One c.c. Mayer's solution precipitates 0·425 grm. berberina, weighed as base." Contributions:—School of Pharmacy, Univ. of Mich.; L. F. Beach, *Amer. Journ. Phar.*, September, 1876.

† ·200 grm. required 3·7 to 3·8 c.c. Mayer's solution.

‡ Barium sulphate from one grm. weighed ·535 grm.

§ ,, ,, ,, ·3195 ,,

‖ Magnesium pyrophosphate from ·5 grm. weighed ·0215 grm.

¶ *Journ. Chem. Soc.*, vol. xv., p. 339.

Mix the bone ash with one fluid ounce of water, add the sulphuric acid, stir well, add eight or ten fluid ounces more of water, boil for twenty minutes, strain through fine muslin. To the filtrate add the berberina sulphate, and evaporate to dryness on the steam-bath. Pulverize the residue and treat several times with boiling diluted alcohol. Filter, and allow the filtrate to drop into cold alcohol. The yellow precipitate thus formed is to be dried on filter paper with a gentle heat. More of the phosphate may be obtained by concentrating the alcoholic mother liquor.

As thus prepared, phosphate of berberina is a canary-yellow powder, very freely soluble in water, moderately soluble in cold diluted alcohol and in hot alcohol, slightly soluble in cold alcohol. As will be seen, this process has one advantage, cheapness, and repeated experiments justify me in saying that, with care, a very pure phosphate may be produced.

I hope at some later day to make a fuller report upon this subject.

THE CAVE MUSHROOM.

The following extract is taken from an interesting account of the cave mushroom, by M. Lachaume, a translation of which, with illustrations, is in the course of publication in *The Garden*:—

The mushroom which is reared in the Paris quarries is always much smaller than that which grows naturally in old melon beds, in meadows, or similar places. The earth for "soiling" is very poor, and contains but little humus; but this comparatively slow growth is advantageous from a commercial point of view, medium-sized mushrooms selling better than very large ones in the Paris market. At Vitry, however, a specimen was grown which weighed no less than 6lb. 2oz.; the cap was 13in. in diameter in its widest part, and 6in. where it joined the stem. It was presented, in 1846, by MM. David and Auguste Amiable to Louis Phillippe, who presented them with a reward of 100 francs. It is somewhat singular that the bed which produced this wonder was otherwise most unproductive, the subsequent growings yielded nothing, its whole power having been apparently concentrated upon this single mushroom. M. Carrière also mentions an enormous mushroom which appeared suddenly, in October, 1872, in one of the nursery beds at the Jardin des Plantes after a violent rain storm; the cap measured 8in. in diameter at the widest part and 6in. at the stem, which at $1\frac{1}{2}$in. from the soil measured $2\frac{3}{8}$in. in diameter. The weight was nearly $3\frac{3}{4}$lbs. It was of a dark grey colour, and when cooked was of excellent flavour.

The mushroom, as grown in the Paris quarries, is, so to speak, an artificial production. It is whiter and smaller than those grown in the open air, which is the result of the poorness of the soil and of the deficiency of light. Be this as it may, it has won its position in the market; it is liked and, so to speak, trusted, and the mushroom grower would gain nothing if he tried to increase its size.

In the Department of the Seine there are 3000 quarries; those which have been abandoned and which are situated close to Paris at Montrouge, Bagneux, Vaugirard, Méry, Châtillon, Vitry, Honilles, and St. Denis are used by the 250 mushroom growers of the Department. There are several of these quarries with horizontal galleries driven into the calcareous rock from the level of the road which are mostly large enough to accommodate a good sized cart, but the majority can only be entered, like a coal mine, by vertical shafts 100 to 125ft. deep, down which everything has to pass. The labourers climb up and down a ladder, and the fresh manure is shovelled down the shaft from above, the waste stuff and the mushrooms being hauled up in baskets from below by means of a windlass. The inside of these quarries consists of a number of irregular corridors, varying in height from 2ft. 6in. to 7ft. The manure for making the beds has often to be wheeled to a distance of nearly 350 yards from the mouth of the shaft. When there is plenty of headway, the work is comparatively easy, and the labourer rolls his load merrily along, lighted by the lamp which hangs at the head of his wheelbarrow; but, when the roof is less than a yard from the floor of the gallery, he must walk in a stooping or even in a sitting posture, pushing his heavy wheelbarrow painfully along. This part of the work is somewhat lightened by establishing relays at more or less frequent intervals. These galleries are all thoroughly ventilated, not only for the sake of the labourers, but for that of the mushrooms, which would not thrive in confined air. If the air were not frequently changed, the breath of the labourers, the products of combustion of the lamps, and the gases given off by the slow fermentation of the manure would soon render these quarries uninhabitable. The ventilation is accomplished by means of small shafts sunk in different parts, and surmounted by a tall wooden chimney, the upper end of which is cut at an angle. The top of the chimneys should be above the level of the mouth of the principal shaft, and the bevelled edge should be turned towards the north. The number of ventilating shafts and their distance apart must be regulated by the special wants of each mine. Frequently the mushroom growers content themselves with using the ventilating shafts constructed by the former owners of the quarry, since the construction of each shaft costs from £8 to £40, according to its depth. It sometimes happens that two quarries communicate with each other, in which case the ventilation is an easy matter; it is, however, necessary to guard against strong draughts and sudden changes of temperature, which would interfere with the well-being both of the men and the mushrooms. For this purpose, the usual means employed for the ventilation of coal mines, such as fires and trap doors, are adopted. When the entrance to the quarry is by a horizontal gallery, level with the road, the ventilation is comparatively simple and the work of cultivation much easier. The quarries are let at from £6 to £16 per month, according to the extent and height of their galleries, and the facilities for ventilating them. Not only should the ventilating currents be regular in their strength and motion, but it is advisable that they should always circulate in one direction. In fact, whenever the direction of a current changes, it is a sure sign that there has been a sudden change of temperature, either in some parts of the quarry, or on the surface outside, which is always dangerous to the mushroom crop growing at the time. Atmospheric variations, both inside and out, must, therefore, be narrowly watched, so that the temperature of the quarry may not rise or fall too far above or below the average, and that the ventilating currents should always be kept in the same direction and of the same strength. If the beds are in a cavern, the draughts should be in the direction of from north to south, and the ventilating shafts, and their dampers, should be so constructed that the quantity of air necessary for the proper growth of the mushrooms may be obtained at will. Proper watering plays a great part in mushroom culture; means must, therefore, be taken for obtaining a sufficient supply of water in the quarry itself. It often happens, however, that the opening of the quarry and the locality of the beds are far away from any dwelling, or well, in which case the water is conveyed to the mouth of the shaft in large barrels, holding about 130 gallons, and mounted on wheels. By means of a sail-cloth hose, which is attached to the tap of the barrel, the water is led to the bottom of the shaft, where it is stored in large tubs or tanks. In some quarries sufficient water filters through the rock for the supply of the beds. This, of course, is a piece of good luck for the mushroom grower. In either case, the water is distributed by hand watering cans—a long and laborious process; but M. Renaudot hit on the happy notion of using a machine, consisting of a large tin or zinc barrel capable of holding 5 or 6 gallons of water, and carried on a man's shoulders like a knapsack. To the lower part is attached a tube, ending with a rose, and provided with a tap for turning the supply on and off at will, so that the labourer can water the beds as he walks along, copiously or slightly, according to the amount of watering they require in different spots. It is true that this method is not applicable in caves where the height of the roof of the galleries is less than that of a man; but in other caves, such as those of M. Renaudot, at Méry, it is of great service, both to master and man. It may be mentioned incidentally that the galleries of M. Renaudot's magnificent quarries are no less than 1⅛ mile long, and 13ft. high from floor to roof. The principal entrance of the quarries is in Méry itself, close to the station of the railway which conveys the manure from Paris. When visiting M. Renaudot's quarries, in May, 1873, we had the opportunity of witnessing the influence of keeping the air at a proper temperature. The outside temperature was 53½° F., the inside nearly 5° lower. The beds which were protected from the draught by the windings of the galleries were covered with mushrooms ready for gathering; whilst on those which were in the full current, the mushrooms had hardly begun to make their appearance, even on those beds which had been made a day earlier.

PRODUCTION OF SOLUBLE GLASS AND SILICATE OF POTASH.*

Twenty years since, Liebig suggested that the most rational material for the production of soluble glass was the *farine fossile*. M. F. Capitaine has recently taken up the subject, and has treated it in the pages of *Dingler's Polytechnische Journal*.

It appears that, with the exception of a small production of silicate of potash, the makers of soluble glass have not made any use, or very little, of this peculiar form of soluble silicic acid. The old methods are still in favour, the principal of these being two, one that which is employed in England, and the other that adopted on the Continent. In the English method the glass is produced by boiling silica in a caustic solution, while on the Continent the mode is, first, to make glass with sand, sulphate of soda and charcoal; afterwards, to render it soluble by means of the action of steam under high pressure. M. Capitaine does not think that the *farine* can compete in cheapness with flint when the latter is abundant, but then it has the advantage of being much more soluble.

Flint, broken up into pieces of about a cubic centimetre and submitted, under a pressure of steam of 4½ to 6 atmospheres, to the action of an alkaline lye of the density of 1·25 to 1·30 for six or eight hours, yields glass which is very alkaline and caustic, containing about one part of alkali to two parts of silica. With *farine fossile* a lye of 1·2 density and a pressure of three atmospheres are employed, and in three or four hours' process there is a yield of a much more neutral glass than the preceding, containing about three parts of silica to one part of alkali.

The production of silicate is said to be very easy with *farine fossile*, and M. Capitaine thinks that the causes which have prevented the *farine* being used instead of flint are purely accidental.

The *farine* is first calcined, an operation which takes a long time, because not a trace of the organic matters found in natural earths must be allowed to remain in the product; if this condition be not observed the solution obtained by means of the lye will have a yellowish or brownish tint, which will make it difficult of sale. The mineral is a bad conductor of heat, so that it does not calcine with facility. This inconvenience alone has perhaps caused the *farine* to be neglected by the makers of soluble glass on the score of economy. It is only within a short time that MM. Grüne and Hagermann have produced the calcined product at a relatively low price, and have thus afforded the opportunity of again raising the question whether the wet process with *farine fossile* is not really preferable to the employment of flint.

M. Capitaine with this idea undertook a series of experiments on a large scale. The lyes being prepared partly with caustic soda and partly with carbonate of soda, had densities ranging from 1·22 to 1·24, which were found to be the most advantageous. A reservoir, furnished with mechanical agitators, was about two-thirds filled with lye and the necessary quantity of calcined *farine* added, the stirring being kept up continually. The proportion of *farine* is easily calculated on the *datum* that one part of hydrate of soda dissolves about 2·8 parts of chemically pure *farine*, the quality of which varies but little. Lye of the density indicated produces a rather light solution which presents little resistance to the agitators. If steam is afterwards introduced, the solution becomes very rapid when the pressure reaches about three atmospheres, and at the end of about three hours the silica is completely dissolved. Practice soon shows when the operation is complete by the colour of the liquid, and by the fact that a sample taken out of the reservoir clarifies very rapidly. The colour of the foreign matters then in suspension is of a dark red brick. If an excess of *farine* has been employed, or the boiling has not been continued sufficiently long, the colour will be of a reddish white, and the solution will not clear itself when allowed to stand at rest. A small excess of silica left undissolved will cause the solution to remain turbid for a very long time, and it is extremely difficult to get rid of the excess by filtration. But this inconvenience is easily avoided by care in practice, and a uniform solution is obtained, which clears itself readily. One condition must, however, be always observed. If the lye be too concentrated, of a density of 1·3, for instance, the solution precipitates but very slowly the fine sand and oxide of iron which it holds in solution; a week is hardly sufficient for this to be completed. Too strong a lye should, therefore, not be employed; the density of the solution should not exceed 1·18.

If the silicate has a density exceeding 1·18, the best way is to reduce it by the addition of water; the clarification will proceed very quickly, and at the end of four-and-twenty hours the liquid will be perfectly white and clear. The deposit which is thrown down, composed of sand and oxide of iron, is rather more abundant than in the case of a solution of flint, but it is easily washed, and if mixed with diluted soluble glass, forms good glaze or dressing.

For the preparation of silicate of potash, which is to contain as strong a proportion as possible of silica, for surgical purposes, the *farine fossile* is said to be peculiarly adapted. In this case the boiling must be continued for one or two hours longer than in the case of soluble glass, with an addition of 10 to 15 per cent. of *farine*; by these means a liquid is obtained rich in silica, which begins to congeal when its density is 1·32.

Farine fossile may also be employed in combination with flint. A glass is first produced from flint, which is afterwards converted into a neutral silicate by being well agitated with *farine* in a second vessel; or, a single apparatus may be made to suffice, by adding to the flint the necessary quantity of *farine*.

SOLUTION OF DIALYSED IRON AS AN ANTIDOTE FOR ARSENICAL POISONING.*

BY RICH. V. MATTISON, PH.G

The statement having been currently made by a number of manufacturers of solution of dialysed iron that this article was of great value as an antidote in cases of arsenical poisoning, and this statement having subsequently been either doubted or "damned with faint praise" by recent writers, led the author to undertake,

* From the *American Journal of Pharmacy*, January.

for personal satisfaction no less than the general good, to perform the following experiments, with the idea of directly confirming one or the other of the above views. In furtherance of this object, a careful test was made of the glassware and reagents employed for the presence of arsenic, with negative results.

A. Ten centigrams of arsenious acid was dissolved in 25 cubic centimetres of distilled water, and tested for arsenic, abundant evidence of which was readily shown. To this solution 5 cubic centimetres of a 5 per cent. solution of dialysed iron was added, and the whole diluted with distilled water to the measure of 100 cubic centimetres, and filtered. No apparent change was effected, the filtrate giving abundant evidence of the presence of arsenic. The experiment was again performed, substituting ordinary water, with like result.

B. A like quantity of arsenious acid was dissolved in the same amount of distilled water as before, with the addition of a few drops of hydrochloric acid, and to this solution 5 cubic centimetres of solution of dialysed iron was added, and the filtrate tested as before, with like result. The experiment was then varied by the substitution of ordinary water and the addition of, first, 1 cubic centimetre of the iron solution, and afterward the addition of 25 cubic centimetres, and dilution of the whole with water to the measure of 100 cubic centimetres; the various testings were without change, the abundance of arsenic being readily shown.

C. A third experiment was now instituted. Ten centigrams of arsenious acid being taken as before, and dissolved in the same quantity of water, this was added to 1000 cubic centimetres of a solution made to represent the gastric secretion of the human stomach, and composed as follows:

Water	994·40
Pepsin	3·19
Chloride Sodium	1·46
Chloride Potassium	0·55
Chloride Calcium.	0·06
Hydrochloric Acid	0·20
Phosphate Magnesium	0·12

The quantity of this fluid taken (1000 cubic centimetres) was believed to represent about the normal quantity of gastric juice present in the human stomach during digestion, or that would be induced upon the ingestion of a quantity of arsenic. Immediately after the addition of the iron solution, the whole was transferred to a filter, and the colourless filtrate tested by Fleitmann's and Marsh's test. No evidence of the presence of arsenic could be discovered, and the experiment was repeated with like result.

The experiment was then varied by dissolving 50 centigrams of arsenious acid in the above quantity of artificial gastric fluid, and allowing the whole to remain at a temperature of 38°C. (100°F) for two hours, with occasional agitation. The mixture was then transferred to a filter, and 100 cubic centimetres of the filtrate evaporated to 5 cubic centimetres and this added to a Marsh's apparatus of 100 cubic centimetres capacity, without the slightest trace of arsenic being shown on the application of the test.

This experiment was repeated with like result, with both Fleitmann's and Marsh's tests, without a trace of arsenic being obtained.

After the repeated unsuccessful attempts to detect the presence of arsenic in this way, one drop of liquor arsenii chloridi was added to each flask (still containing the filtrates as above described), and the result was immediate, the presence of arsenic in considerable quantity being instantly shown by the characteristic reactions.

Through these experiments, then, the facts seem clearly set forth, (1) that dialysed iron, to be of value as an arsenical antidote, must be first precipitated by the action of some neutral salt; (2) that this precipitation, and the consequent production of ferric hydrate, is accomplished when this preparation is taken into the stomach, and that, (3) therefore, the solution of dialysed iron is a valuable antidote for arsenical poisoning, and should be administered promptly in cases of emergency, followed, of course, by an emetic until more efficient remedies can be used.

It, however, may readily be conceived that an antidote may be necessary in cases where the enfeebled stomach of the invalid may not be able to secrete sufficient gastric juice, even under the direct stimulus of the poison, or that the arsenic may be ingested into a stomach that is free from the presence of any gastric secretion. Now, while under these circumstances the mucous secretion might prevent absorption for a certain length of time, yet in these cases, and, indeed, we believe in *all* cases, the administration of solution of dialysed iron as an antidote for arsenical poisoning should be immediately followed by a teaspoonful or more of sodium chloride, thus insuring the formation of ferric hydrate and the consequent neutralization of the poison.

With this addition, solution of dialysed iron is the most convenient antidote, certainly, to be obtained, and should be kept in every well-regulated pharmacy for cases of emergency; and manufacturers should make the addition to their labels directing the additional use of this salt (sodium chloride), as through its use, while no harm can be done, many valuable lives might be saved, which, through the use of dialysed iron alone, would possibly be sacrificed.

Since the above was in the hands of the publishers, we note a case of arsenical poisoning successfully treated by the administration of solution of dialysed iron alone, as reported in the Philadelphia *Medical Times*, Dec. 8th, pp. 104, 105. The patient, a young lady of normal health, inadvertently swallowed a considerable quantity of arsenic, which had became by accident mixed with some confectionery, and when the attending physician saw her she presented the symptoms of poisoning in a well-marked degree. Solution of dialysed iron was administered with prompt relief, yet, strange to say, this was not followed by an emetic, but the use of the dialysed iron continued in doses of 2 fluidrachms, largely diluted with water. The doctor notes the recovery of the patient.
