FINAL ENVIRONMENTAL STATEMENT

FEDERAL COAL MANAGEMENT PROGRAM

Bureau of Land Management
Library
Bldg. 50, Denver Federal Center
Denver, CO 80225

IN REPLY REFER TO:
1972 (142)

United States Department of the Interior

BUREAU OF LAND MANAGEMENT
WASHINGTON, D.C. 20240

Enclosed with this letter of introduction is the final environmental statement (FES) for the new Federal Coal Management Program.

This programmatic statement is based on information development by the Bureau of Land Management and the Department of the Interior. Information and data were supplied by Federal, State and local governmental departments and agencies, and non-governmental entities such as conservation and environmental groups, industrial organizations, mining companies, libraries, and others.

On December 15, 1978, Secretary Cecil D. Andrus released the draft version of this statement (DES) and urged the widest possible public participation in the review of the document. During January and February of 1979, the Department conducted special public informational meetings in 12 separate cities, followed by 10 formal public hearings to receive comments on the DES. During the extended, 60-day review period (a 45-day period is mandatory), the Department received and evaluated over 1600 separate comments on the DES.

The purpose of the statement is to address various alternatives for a Federal Coal Management Program, including a preferred program alternative, and to assess the possible impacts from the various alternatives. The statement is programmatic in scope and discusses the national and interregional impacts associated with the Federal Coal Management Program. Impact assessment includes coverage of 12 coal supply regions, 3 production levels (low, medium, and high), 7 alternative management strategies, 2 projection periods (1985 and 1990), 5 phases of the coal production and use cycle, and 27 impact categories. The statement also includes a set of proposed regulations which could be used to implement all or portions of each alternative management program. Availability of those regulations was announced in the March 19, 1979, edition of the Federal Register.

This statement will assist the Secretary in carrying out President Carter's directive to manage Federal coal lands in an environmentally acceptable manner.

Sincerely yours,

Director

Bureau of Land Management

ACKNOWLEDGEMENTS

Guidance in the preparation of this statement was provided by the following offices of the U.S. Department of the Interior:

- Office of Coal Management; Bureau of Land Management
- Office of Coal Leasing, Planning, and Coordination; Assistant Secretary - Land and Water Resources
- Office of Policy Analysis; Assistant Secretary - Policy, Budget, and Administration

Assistance in the preparation of certain portions of this Final Environmental Statement was provided by the MITRE Corporation, McLean, Virginia.

1. Type of Action: Administrative (X) Legislative ()

2. **Brief Description of Action :** This final programmatic environmental statement considers the environmental impacts of seven alternatives for a Federal coal management program to be adopted by the Department of the Interior. The proposed action is the adoption of the preferred Federal coal management program. In addition to providing for the administration of existing leases (lease readjustments, assignments, relinquishments, etc.), the processing of preference right lease applications, the review of Federal lands to determine unsuitability for all or certain types of mining, and other coal management activities, the program would establish standards and procedures for determining when, where, and in what manner the right to mine coal owned by the United States government should, through competitive sales, be leased to parties who would cause the coal to be mined. As a part of the program, before competitive lease sales would be held, the Secretary of the Interior would determine whether there is a need for such sales in order to make federally-owned coal available for production. Determination of the need for leasing would be based mainly on analyses of expected coal production in relation to projected demand for coal.

Identification of Federal coal that can be considered for leasing would be done through the land use planning process of the Bureau of Land Management, Department of the Interior, under the Federal Land Policy and Management Act of 1976 and the Federal Coal Leasing Amendments Act of 1976, and the Forest Service, Department of Agriculture, under the Multiple-Use Sustained-Yield Act of 1960 and the National Forest Management Act of 1976. Selection of specific tracts of coal to be offered for lease and the administration of the lease sales would be managed by the Bureau of Land Management. Specific standards would be used to identify lands where mining Federal coal would cause unacceptable damage to lands or resources. Areas not found unsuitable for mining would be further evaluated and the value of potential coal development considered in comparison to other values, such as wildlife management, recreation, watershed protection, or stock grazing, which might be foreclosed or diminished if the coal were to be developed. From areas found to be acceptable for further consideration for coal leasing in the land use plans of the Federal land management agencies, tracts would be delineated. All tracts delineated in the planning units in each of eight Federal coal regions would be selected for possible leasing by ranking them region-wide on the basis of coal quantity and quality, cost of extraction, and social, economic, and environmental impacts of mining. Priority in selecting tracts to be offered for lease sales in each region would be assigned to those tracts which could be most productively developed with the least social, economic, and environmental damage.

A central feature of the preferred Federal coal management program would be emphasis on participation by the public and by state and local governments in all aspects of the program. Information, advice, and opinion would be sought from all parties interested in decisions about Federal coal management. Assessment of the need for leasing, establishment of coal production goals and leasing targets, application of standards for determining lands unsuitable for leasing, planning to decide which of those areas that could be leased should be leased rather than be put to other uses, and ranking and selection of tracts to be offered for lease sale would be conducted in an open, accountable way, in a process designed to make decisions as responsive as possible to suggestions from those interests most affected by the decisions. Consideration of social and economic consequences as evaluated by state governments would be given special weight when decisions about Federal coal management are made through participation of regional coal management teams.

3. **Summary of Environmental Impacts:** This is a programmatic environmental statement. The Federal coal management program would be established in June 1979. As a result of the operation of the program, decisions could be made that would result in competitive coal lease sales in some areas; deferral of decisions about whether leasing should take place in other areas, and the elimination of still other areas from further consideration as potential sites for leasing and mining of Federal coal.

The environmental impacts which are expected to result from implementation of the Federal coal management program will vary among regions and over time. In the short term, many regions will experience substantial increases in coal production for several years, with or without additional leasing. Demand for coal in those regions will lead producers to develop available reserves. Leasing under such circumstances would not add significantly to cumulative social, economic, and environmental impacts within the region, but could cause intra-regional shifts in specific production sites if producers responded to more attractive development opportunities created by the availability of new Federal leases. A decision not to lease in the next several years could also diminish or foreclose production opportunities in an area, causing producers to turn their attention to other reserves, within or outside of a given area, which could be developed without Federal leasing. Whether the environmental consequences of production shifts caused by a Federal coal management program, and the decision which would be made under the program to lease or not to lease in the next several years, would be generally more or less damaging to the environment could only be determined through analysis of specific management decisions. As described in this statement, such specific management decisions would be made only after land use planning and environmental analyses designed to minimize environmental damage have been conducted.

Over time, production from additional Federal leasing could account for a larger share of total national production, and so would be responsible for a larger percentage of the environmental consequences of production.

Decisions not to lease could severely limit the production of coal in the western United States. The social, economic, and environmental consequences of program decisions under such circumstances would depend on the type and location of energy sources that would be used as alternatives to coal from the western United States.

In this statement, the environmental consequences of implementation of a Federal coal management program are described on a national and inter-regional basis. While many impacts, both beneficial and damaging, can be directly attributed to coal production that would result from decisions made under such a program, a wide range of impacts would result from decisions about the transportation, conversion and use of coal. Furthermore, certain intra-regional impacts are too site-specific, or require management decisions not yet made which are too detailed or incapable of discernment, to be considered in a programmatic environmental impact statement. Thus, a tiered

structure of increasingly site-specific environmental analysis is proposed. The unavoidable national and inter-regional impacts of coal production that could be affected by decisions made under the program include:

- Subsidence of land could result from underground mining activities.
 - Existing vegetation would be destroyed on sites cleared for development and surface mining, and wildlife habitat would be lost or temporarily displaced.
 - Present agricultural use in some areas would be converted to residential, commercial or industrial uses.
 - Industrial and municipal demand for water would increase; generally, water would be available for these uses but in some western states the new demands may compete with present water uses, and the competition will cause price increases that may cause economic problems for agricultural water users.
 - Water quality may be lowered and totally dissolved and suspended solids would increase due to industrial return flows and construction activities.
 - Aquifers may be disrupted and their long-term productivity could be reduced.
 - Increases in emissions of sulfur oxides, nitrogen oxides, carbon monoxide, carbon dioxide, hydrocarbons, trace elements, and particulates would occur with some degradation of local and regional air quality and possible long-term climatic effects.
 - Topographical features would be altered during construction and mining activities.
 - There could be some loss of archaeological and historical sites.
 - The present visual quality of the landscape would be changed as a result of new coal mining and cleaning facilities, transportation networks, coal conversion plants, transmission lines, and urban expansion.
 - Population would increase in some areas and decrease in others.
 - Educational, police and fire protection, sewage and water, recreational, and other public facilities and services would not keep pace with population increases in some regions, straining personnel and budget levels of local and state governments and lowering the local quality of life for some.
 - Communities could lose their small town atmosphere and residents of rural areas would experience a change in their traditional life-styles.
 - Transportation arteries, including rail lines, would experience heavier average daily traffic with significant impact at rail grade crossings.
 - Employment increases would occur from coal development, and increased construction wages and investment in the impacted regions would lead to higher personal income, retail sales, and property values. This could also result in tight housing markets and inflation adversely affecting those persons on fixed incomes.
 - Fatal accidents and disabling injuries would undoubtedly occur as a result of coal development activities.
4. **Alternatives Considered:** Considered in this environmental impact statement are seven alternatives: the preferred program, no new Federal leasing, issue preference right lease applications (PRLA'S) only, emergency leasing only, lease to meet industry indications of needs, lease to meet the United States Department of Energy production goals, and state determination of leasing levels. Numerous policy alternatives are capable of incorporation in various of the alternatives. Twelve coal regions are specified: Northern Appalachian Coal Region (Pennsylvania, Ohio, Maryland, West Virginia); Central Appalachian Coal Region (Virginia, Kentucky); Southern Appalachian Coal Region (Tennessee, Alabama); Eastern Interior Coal Region (Illinois, Indiana, Kentucky), Western Interior Coal Region (Iowa, Kansas, Missouri, Nebraska, Arkansas, Oklahoma); Texas Coal Region (Texas, Louisiana); Denver-Raton Mesa Coal Region (Colorado, New Mexico); San Juan River Coal Region (Colorado, New Mexico); Uinta-Southwestern Utah Coal Region (Colorado, Utah); Green River - Hams Fork Coal Region (Colorado, Utah, Wyoming); Powder River Coal Region (Montana, Wyoming); and Fort Union Coal Region (Montana, North Dakota).
5. **Comments on the draft environmental statement:** Comments have been received from various individuals, organizations and governmental agencies indicated in Chapter 8.

CHAPTER 1

INTRODUCTION AND BACKGROUND OF FEDERAL COAL MANAGEMENT PROGRAM AND ENVIRONMENTAL IMPACT STATEMENT

1.1 INTRODUCTION

This environmental impact statement comes at a critical juncture in a long history of starts and stops for a Federal coal management program administered by the Department of the Interior. The purpose of this impact statement is to meet the Department's responsibilities under the National Environmental Policy Act of 1969 (NEPA), 83 Stat. 852, and to help the Department address four major questions: (1) Should a new Federal coal management program be adopted by the Department of the Interior; (2) How should the program be designed; (3) Is Federal coal leasing necessary to meet the Nation's future energy needs; and (4) What environmental impacts might result from the adoption of alternative new Federal coal management programs?

Why these questions need resolution at this time can be placed in a proper perspective through a brief review of the history of Federal coal policies and activities. From the beginning of Federal land ownership, a policy of disposal of public domain lands was followed. In the century and a half during which this policy held sway, 1.1 billion acres, or more than half of the public domain, was sold or granted to states and private owners. Until the early 1900's, the policy of disposal of Federal lands included the practice of transferring coal and other mineral resources to private owners. However, with the passage of various mineral reservation statutes and the Mineral Leasing Act of 1920, 41 Stat. 438, it became Federal policy to retain and lease rather than to sell Federally-owned coal. Under a leasing system, only the leased mineral, and not the land itself or other associated resources, becomes the property of the lessee. Even that property right is conditioned on lessee compliance with stipulations to protect the mined land, and requirements that the mineral be diligently developed. Particularly between 1955 and 1970, large amounts of Federal coal were leased under the Mineral Leasing Act with little

regard to the need for leasing, or when (or if) the leases would be developed. There was no enforcement of the Mineral Leasing Act's requirement that leases be diligently developed.

A Bureau of Land Management (BLM) study [1] issued in 1970 reported that, while the amount of Federal coal under lease was rapidly increasing, production was declining. As a result of that study, the Department of the Interior, in May 1971, imposed an informal leasing moratorium in order to reassess its leasing policy. In February 1973, the Secretary of the Interior instituted a formal leasing moratorium and announced his intention to establish a new coal leasing policy. In the short term, the Department would issue leases only to avoid losing coal where it would be bypassed, to maintain existing coal operations, or to provide reserves for production needed in the near future.

The newly designed long-term leasing program was presented in the Department of the Interior's May 1974 draft environmental impact statement on its proposed coal leasing program [2]. The heart of the program was the Energy Minerals Allocation Recommendation System (EMARS I), under which the Department of the Interior would specify leasing needs on the basis of estimates of national energy requirements. The final environmental impact statement issued in September 1975 modified the system to the Energy Minerals Activity Recommendation System (EMARS II)[3]. Under the revised program, the Department adopted procedures which made greater use of industry nominations of leasing tracts and placed a much stronger emphasis on market determination of the amounts and location of future Federal coal to be leased.

The new Federal coal leasing program was short-lived. It was altered by statute and halted by litigation. From 1975 on, the development of a Federal coal management program has been significantly influenced by actions of each branch of government. Congress enacted four major

statutes with important consequences for Federal coal management. The first, the Federal Coal Leasing Amendments Act of 1976 (FCLAA), 90 Stat. 1088, passed in August 1976 over President Ford's veto, is designed to correct the leasing problems that had been experienced under the Mineral Leasing Act of 1920. The Federal Land Policy and Management Act of 1976 (FLPMA), 90 Stat. 2743, passed in October 1976, provides the Bureau of Land Management with a modern management mandate, including requirements for land use planning. The third major statute was the Surface Mining Control and Reclamation Act of 1977 (SMCRA), 91 Stat. 445, passed in August 1977. SMCRA, a result of Congressional concern over the adverse environmental effects associated with the significant shift in technology from underground to surface coal mining methods, requires control over these effects by the Federal and state governments. Finally, the Department of Energy Organization Act (DOE Act), 91 Stat. 565, also passed in August 1977, transferred from the Department of the Interior to the Department of Energy several important coal-related responsibilities, including issuance of regulations governing diligent development and bidding systems.

The Judiciary has provided guidance for the preparation of a new Federal coal management program, particularly in two recent decisions. The Supreme Court's 1976 decision, *Sierra Club v. Kleppe*, 427 U.S. 390, provided judicial instruction concerning what kind of environmental review must accompany major coal management decisions. Of more direct importance, however, is the decision in *NRDC v. Hughes*, 437 F.Supp. 981 (D.D.C. 1977), amended, 454 F. Supp. 148 (D.D.C. 1978), *appeal pending*. The court's order enjoined most Federal coal leasing activity until the Department of the Interior issues supplemental draft and final environmental impact statements on its coal management program. The Department has prepared this statement to comply with the environmental impact requirements of Section 102 (2)(C) of NEPA and that court order.

This discussion provides a brief overview of the recent history of Federal coal management activities. The background of Federal leasing, beginning with the Mineral Leasing Act of 1920, is presented in more detail in subsequent sections of this chapter.

1.1.1 Purpose of Final Environmental Impact Statement

This statement addresses the overall national and inter-regional environmental impacts of a Federal coal management program administered by the Department of the Interior.

1.1.2 Summary of Program Alternatives

Seven broad Federal coal management program alternatives, including a preferred program, are analyzed in this statement. Unlike most impact statements prepared by the Department and other Federal agencies, a proposed "action" and its alternatives are not treated in separate chapters. Rather, the statement presents a series of alternatives, one of which is tentatively "preferred" by the Department. Major subalternatives are also described and analyzed. This is consistent with the Secretary of the Interior's desire that the Department critically evaluate its entire coal management process. An integral part of this evaluation is and will continue to be comments from interested parties, including other Federal agencies, state and local governments, private and public organizations, and concerned individuals. Furthermore, additional public comments will be invited and considered during the program decision-making process which will follow issuance of this final statement.

A brief overview of the program alternatives follows. A more detailed description is contained in Chapter 3.

- *Preferred Alternative.* Decisions to lease Federal coal would be made as an integral part of the Federal land planning process. Federal lands would be considered for leasing which have not been found unsuitable for coal mining or more valuable for resource protection or other development activities in the land use planning process of the Federal land management agencies. In the activity planning process, tracts would be delineated, ranked on the basis of coal quality, cost, and environmental, social, and economic effects and selected for sale by regional coal teams. Regional leasing targets, derived from production goals submitted biennially by the Department of Energy and comments received from the states, industry, and the public, would be applied during the activity planning process

- to ensure that sufficient tracts would be ranked and selected to meet national energy needs. The preferred alternative is similar to EMARS I as proposed in the Department's 1974 draft programmatic environmental impact statement on the Federal coal leasing program (see Section 1.2.4) [2] in that both rely on national energy projections to establish how much coal is to be leased. The preferred alternative, however, differs markedly from EMARS I by, among other things, placing greater emphasis on land-use planning and consultation with the states than did the earlier proposal.
- *No new Federal Leasing.* No new Federal coal would be leased until at least 1985, including coal needed for by-pass situations or to maintain existing operations (see Section 1.2.6 for description of terms). Preference right lease applications (PRLAs) would be either rejected, not processed, exchanged for other mineral leases, or purchased.
 - *Process Outstanding Noncompetitive Coal Lease Applications (PRLAs).* Leasing until at least 1985 would be limited to PRLAs which meet the commercial quantities test.
 - *Emergency Leasing.* There would be limited competitive leasing and issuing of PRLAs to prevent coal from being bypassed and to maintain existing coal mining operations. The need for new competitive leasing would be reviewed in 1985. This option is a continuation of the status quo and would be similar to the type of leasing permitted under *NRDC v. Hughes*. (See Section 1.2.6 for a further explanation of this policy.)
 - *Satisfy Industry Indications of Need.* This alternative is effectively the Energy Minerals Activity Recommendation System (EMARS II), as proposed in the Department's 1975 final programmatic environmental impact statement on the Federal coal leasing program (see Section 1.2.4) [3], and as adopted in regulations published in the Federal Register (42 Federal Register 4422, corrected 42 Federal Register 12546 (1977)).
 - *State Determination of Leasing Levels.* The states would have the responsibility to

determine the timing and extent of new leasing.

- *Lease to meet Department of Energy (DOE) Production Goals.* Under this alternative, no adjustments (as envisioned in the preferred alternative) would be made to the DOE production goals to reflect the Department's diverse responsibilities or the views received from consulting with the states, industry, and the public. Leasing decisions would be required to meet the DOE goals.

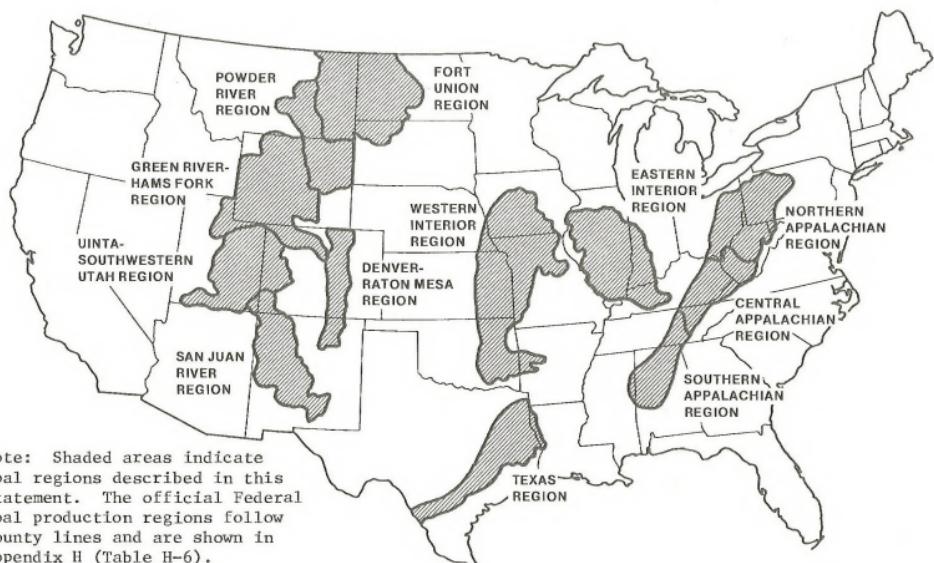

In the implementation of any of these alternatives, the Department would assure compliance with all new statutory requirements including those for land use planning, lease terms, reclamation of mined lands, and payment of fair market value for competitive leases.

1.1.3 Approach to Environmental Impact Statement

This is a programmatic statement which assesses the national impacts of a Federal coal management program and related Federal coal policies. The statement covers all major national aspects of a preferred Federal coal management program and alternatives, and assesses the effects of the alternatives in twelve specific coal regions (see Figure 1-1). Thus, the issues analyzed are quite different from those discussed for a particular lease area. A broad statement of overall impacts of the program will allow the Department to make decisions concerning national and multiregional questions.

The statement uses a general predictive approach based on national and regional data and makes necessary assumptions where firm data are not available. Reasonable forecasting is implicit in NEPA. With 27 coal states and 12 regions which could be directly affected by coal extraction, and other states indirectly affected by the consumptive use of coal, data used in this statement must be generic and cannot be site specific; however, impacts are quantified, wherever possible, to display the differences between the various alternatives. Nonquantifiable aspects (such as aesthetics, lifestyle changes, and cultural values) are also addressed.

The impact analysis uses two principal models. One is the Department of Energy's National Coal Model, which predicts the high, moderate, and low coal demands for coal regions, in 1985 and 1990, under various demand scenarios and constraints.

Note: Shaded areas indicate coal regions described in this statement. The official Federal coal production regions follow county lines and are shown in Appendix H (Table H-6).

FIGURE 1-1
TWELVE COAL SUPPLY REGIONS OF THE UNITED STATES

The second model used is the Department's Coal Impact Estimation Program which relates quantifiable "environmental loading factors" to predicted coal production and use levels by region. This model was developed by the MITRE Corporation for the Department and is more fully explained in Chapter 5.

This statement addresses the total national demand for coal, and impacts associated with Federal and non-Federal coal development. Consideration of non-Federal coal resources is necessary, first, to place impacts of the Federal coal management program in a broader perspective; and second, because Federal actions have the potential to shift production between private and public coal. Presentation of total coal demand establishes a base-line from which environmental analysis may proceed.

The content and format of this statement, as outlined in the table of contents, represents a combination of approaches. It contains a modified standard format as required in the BLM Manual, Section 1792, revised to incorporate some of the principles of the Council on Environmental Quality's (CEQ) recent NEPA regulations [4], with emphasis on the requirements of the *NRDC v. Hughes* court order. This chapter provides the background to this statement. Included is a discussion of prior and current coal policy directives and applicable laws and regulations. The importance of coal as an energy resource is discussed in Chapter 2. Chapter 2 also describes the characteristics of coal development activities as well as how coal development might be affected by the development of other energy sources. Past and projected coal production levels and the need for additional Federal coal leasing are then addressed.

Chapter 3 presents the issues and options identified during the course of the Department's review of its coal management responsibilities, the Secretary of the Interior's preferences among the options, and alternatives to that program. Chapter 4 provides an overview of the existing environmental conditions in each of the twelve regions.

Chapter 5 assesses the environmental impacts related to the preferred and alternative coal management programs, including a comparative analysis of policy subalternatives. Chapters 6 and 7 contain the summary analyses required by Section 102(2)(C)(ii-v) of NEPA. Finally, the coordination activities involved in preparation of this statement

are summarized in Chapter 8, including the Department's responses to comments on the draft environmental impact statement.

1.1.4 Relationship to Ongoing Regional Environmental Statements and Studies

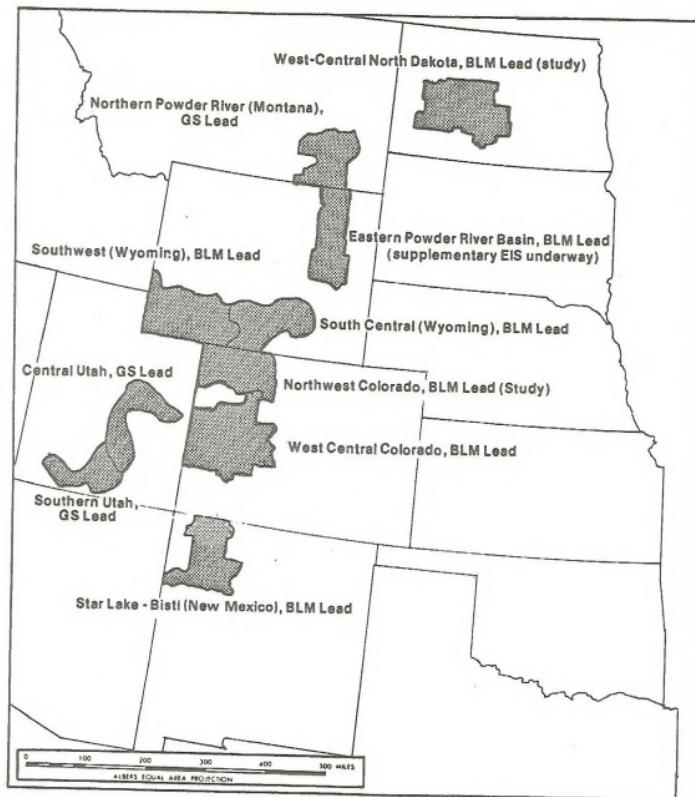

The Department is currently preparing comprehensive coal environmental impact statements on activities occurring in eight geographic areas. Under a policy formally adopted in 1976, this type of comprehensive analysis is called for whenever the Department is faced with multiple coal-related actions in a broad geographic area.

The areas covered by these statements were chosen after consideration of coal basin boundaries, drainage areas, areas of common reclamation characteristics, administrative boundaries, areas of economic interdependence, and other relevant factors. The regional statements include a broad, overview analysis of environmental impacts associated with current and potential coal development activities, as well as site-specific analyses of mine plans, and right-of-way permits for which administrative action is proposed. These statements also address related coal development activities not requiring specific Departmental approval, such as mine-mouth electrical generating or energy conversion facilities, and the expansion of existing or construction of new communities to accommodate coal-induced population increases. The eight areas covered by these statements are depicted in Figure 1-2. These areas are smaller than the twelve regions assessed in this statement. Table 1-1 summarizes pertinent coal development activities analyzed in the ongoing statements.

The Department will complete these ongoing statements; initiation of new statements of this type is contingent on program decisions which may be made after this final programmatic statement is published.

Additionally, for each individual coal lease and mining plan an environmental analysis is prepared to determine whether a detailed environmental impact statement is required. If associated impacts are significant within the meaning of NEPA, a site-specific statement is prepared, either separately or as part of a regional analysis.

Current Departmental policy for preparing environmental assessments and impact statements thus covers generic (programmatic), regional, and site-specific considerations. Proposals to modify

NOTE: "BLM Lead" signifies that the Bureau of Land Management has lead agency responsibility for preparing the document.
 "GS Lead" signifies that the U.S. Geological Survey has lead agency responsibility for preparing the document.

this approach as part of a new coal management program are discussed in Chapter 3.

1.1.5 General Purpose of Coal Management Policy

The need for a new look at the Federal coal management program is related to three broad conditions. The first is the Nation's serious energy problem, characterized by declining domestic oil and gas resources and limited alternatives. A national policy goal has been advanced to reduce reliance on imported oil. The National Energy Plan (NEP) [5] announced by President Carter in April 1977 presents detailed steps to be taken to achieve this goal. Salient features of the NEP include energy conservation, rational fuel pricing policies, and increased use of abundant domestic energy sources. Although coal comprises 90 percent of the country's fossil fuel reserve, only 18 percent of the national energy needs are met by coal. A cornerstone of the NEP is the goal of correcting this imbalance between coal reserves and consumption by doubling 1977 annual production by 1985. Coal from mines under Federal leases has accounted and is expected to continue to account for a significant share in the expanding use of this resource.

The second condition results from the failure of former coal management practices to address current concerns. Major concerns expressed both within and outside of the Department are the government's historically passive role in coal leasing decisions, lack of active control over production from Federal leases, absence of an effective system to ensure fair market return for the right to mine Federal coal, and the potential for serious social, economic, and ecological impacts of expanded coal production and use.

Finally, as briefly discussed in the introduction to this chapter, a reassessment of the coal management program has been precipitated by recent critical reviews of management practices by the Executive, Judicial, and Legislative branches of the Federal government.

1.2 HISTORICAL BACKGROUND

The Federal coal management program is concerned with the development of coal resources on public domain lands and acquired lands. The public domain refers to those lands which are subject to the public land laws of the United States. These lands were obtained primarily by

cession, treaty, and purchase from other countries. Acquired lands are purchased by the United States from private owners after the lands became part of the United States.

Almost as fast as public domain was obtained, it was disposed of by the Federal government to further national goals. These dispositions provided rewards for soldiers and other deserving persons, encouragement for the rapid settlement and development of the western states, incentives for construction of railroads and canals, and many other purposes. Dispositions of public lands included more than 1.1 billion acres between 1781 and 1963.

Early development of Federal coal lands was governed by a law controlling land entry and sale [6]. Under this law a maximum of 160 acres could be granted to an individual; up to 640 acres were allowed to groups of four or more persons who had expended at least \$5,000 in work and improvements, where mines were opened and improved, and when the group was in actual possession. Land payments ranged from \$10 to \$20 per acre, depending upon the distance from a railroad. A claimant who discovered minerals on public domain land received complete transfer of mineral ownership.

Another factor of some importance is that Congress granted nearly 100 million acres of land to railroads in the West. To settle the West, the building of railroads was essential. But to build a railroad was a costly venture, and railroad companies would not begin construction in what was then virtual wilderness without financial inducement. The grants of land by the government to the companies were that inducement.

Typically, Congress granted the railroads the odd-numbered sections on both sides of the proposed railroad right-of-way extending back from the right-of-way some 10 or 20 miles on each side of the railroad. The even-numbered sections, which were not conveyed to the railroad, continued to be in the public domain. By granting to the railroad the odd-numbered sections, and retaining the even-numbered sections, a checkerboard effect resulted. Although Congress probably expected that the granted land would be sold by the railroads to other citizens, and much of it has been conveyed, millions of acres of land or mineral interests have been retained by the original grantees. The resulting checkerboard land patterns

continue to influence western coal development, particularly in areas of Montana, Wyoming, and New Mexico.

1.2.1 Mineral Leasing Act of 1920

Enactment of the Mineral Leasing Act of 1920 provided a radical policy change for disposal of Federal coal lands. The new policy was to lease coal rather than sell it. Under the law, rights to explore, develop, and remove coal (and other specified minerals) were acquired through a lease or prospecting permit issued by the Bureau of Land Management.

In areas with no known coal deposits, the Secretary of the Interior could issue prospecting permits which entitled the permittee to the exclusive right to prospect for coal. Each permit had an initial two-year term, but could be extended for an additional two years if the permittee was unable, with the exercise of reasonable diligence, to determine the existence or workability of coal deposits in the area to which the permit applied. Permittees were entitled to preference right leases if they could demonstrate that the lands contained coal in commercial quantities.

Lands containing known coal deposits were not subject to prospecting permits. Instead, the lands were divided into leasing tracts and leases were awarded competitively. The competitive leasing system adopted by the Department was to award leases to the highest bidder. A lump sum cash bonus was collected at the time the lease was awarded.

The Mineral Leasing Act of 1920 restricted the acreage that could be held by one party in one state. Originally, the law allowed only one lease per person in each state. The limits were raised several times until, in 1964, they allowed a holding by any person of up to 46,080 acres (72 square miles) in one state.

Another feature of the Act was the requirement that leases be issued for an indeterminate period as long as conditions of diligent development and continuous operations were satisfied. These conditions could be waived if operations were interrupted by strikes, the elements, or casualties not attributable to the holder of the lease. Lease terms and conditions became subject to readjustment at the end of 20-year periods. In addition, leases could not be assigned or sublet

without the consent of the Secretary of the Interior.

Other major provisions of the Mineral Leasing Act were:

- Leases could be modified by an additional 2,560 contiguous acres.
- Additional tracts up to 2,560 acres could be leased if workable deposits of coal would be exhausted within three years.
- Single leases could contain noncontiguous tracts.
- Royalties were set at not less than five cents a ton of coal.
- Annual rentals were set at not less than 25 cents, 50 cents, and \$1 for the first, third through fifth, and sixth year onward from lease issuance, respectively.
- Limited licenses or permits could be issued to municipalities (without royalties) if the coal mined was sold without profit to local residents.

1.2.2 1971 Leasing Moratorium

Prior to 1970, the Department's coal leasing policy was reactive in nature. Lease requests were processed on a case-by-case basis. Particularly between 1955 and 1970, there was little consideration given to the total coal reserves under lease or to the need for additional leasing, and environmental impacts of leases were not addressed.

A 1970 Bureau of Land Management (BLM) study [1] reported that leased coal acreage on public lands in six western states – Colorado, New Mexico, North Dakota, Montana, Utah, and Wyoming – rose sharply from roughly 80,000 acres in 1945 to about 788,000 acres in 1970, but that Federal lease production dropped from 10 million tons of coal to 7.4 million tons in those same years. Of the total acreage under lease, over 90 percent was not producing coal. Similar conclusions on leasing problems were reached in a 1974 report by the Council on Economic Priorities [7].

As a result of the 1970 BLM study, the Department took a series of informal actions that resulted in no leases being issued between May 1971 and February 1973.

1.2.3 Short-Term Leasing Since 1973

The informal 1971 moratorium was replaced in February 1973 with a new coal leasing policy that embodied both short-term and long-term actions.

The long-term actions were to develop a comprehensive planning system to determine the size, timing, and location of future coal leases and to prepare an environmental impact statement for the Department's entire Federal coal leasing program.

The short-term actions included a complete moratorium on the issuance of new prospecting permits and a near-total moratorium on the issuance of new Federal coal leases. New leases would be issued only to maintain existing mines or to supply reserves for production in the near future. BLM issued instructions implementing this short-term policy in July 1973. The instructions stated that the decision to issue new leases would be based upon sufficient indications that a prospective lessee needs coal to satisfy an existing market and intends to begin development within three years.

Between 1974 and April 1, 1978, ten leases, covering 30,246 acres, were issued; most were for extensions of existing operations (see Table 1-2). Seven of these leases were producing coal by the end of 1977.

1.2.4 1975 Federal Coal Leasing Environmental Impact Statement

As part of its long-term leasing policy, the Department, in May 1974, issued a draft programmatic environmental impact statement [2].

The focus of the draft statement was on implementation of a new coal leasing system entitled the Energy Minerals Allocation Recommendation System (EMARS I). As described in the draft environmental statement, EMARS I was a three-part system: (1) allocation, (2) tract selection, and (3) leasing. During the allocation process, Federal agencies were to relate inventoried Federal coal resources to projections of coal-related energy needs. Total national energy needs were to be disaggregated into regional demands for coal. In the tract selection phase, Federal coal leasing targets would be established in each coal region. These targets would be derived in part from total national projections for coal-based energy needs. Tracts would be selected to meet the leasing targets. The leasing phase was to begin with detailed pre-planning of the coordinated mining and rehabilitation factors required for reclamation and subsequent surface resource management. This last phase would conclude with pre-sale

evaluations, lease sales, post sale evaluation procedures, and, finally, lease issuance.

Approximately 2,100 sets of the two-volume draft statement were distributed to Federal and state agencies, U.S. Senators and Representatives, industry organizations, conservation groups, and others. Local public hearings were held and 117 formal comments on the draft statement were received.

Comments and testimony were received from a diverse group of individuals, organizations, companies, and agencies. Comments ranged from support of the statement to requests for a complete rewrite. However, two areas of major concern were readily apparent. These were the need (1) for a more detailed description of the proposed Federal coal leasing program, and (2) to further analyze whether additional Federal coal should be leased in light of the large acreage and coal reserves presently under lease but on which no development had taken place.

The Department's final programmatic environmental impact statement [3] was released in September 1975. The proposed action in that statement was changed from that in the draft statement. EMARS I was modified and retitled the Energy Minerals Activity Recommendation System (EMARS II). The three phases of this revised leasing system became: (1) nominations and programming, (2) scheduling, and (3) leasing. While the system envisioned in the draft statement emphasized Interior Department identification of coal reserves to be considered for leasing, the revised EMARS II program involved annual industry nominations and public identification of areas of concern. Nominations would be accepted for any area, with industry providing information on where and how much coal to lease. Based on these nominations, the Department would prepare land use plans and environmental analyses, resolve or mitigate resource conflicts, and hold lease sales if coal development was found to be compatible with the environment. The reasons behind the changes in the program between draft and final statements were not provided.

The following points were offered in the final environmental impact statement to support continued leasing:

- Changing economic conditions made it probable that much of the coal under lease

Note: Does not include leases issued after April 1, 1978.

- in 1975 was no longer suitable for development.
- Diligence requirements extended to existing leases would cause production or relinquishment over a period of a few years.
- Additional leasing might be required to avoid increases in energy costs.
- Some existing leases might be environmentally unsuitable for development, and leasing in new areas might be substituted for leases in unsuitable areas, thereby decreasing the relative value of the latter leases and possibly causing their relinquishment.
- Additional leasing would provide access to Federal coal for firms interested in penetrating new market areas but not currently holding Federal coal leases.

Analysis of the environmental impacts associated with the leasing program was quite brief in the final environmental impact statement.

On October 21, 1975, the validity of the statement was challenged in *NRDC v. Hughes*, in the U.S. District Court for the District of Columbia (see Section 1.2.6 for a discussion of this lawsuit).

1.2.5 *Sierra Club v. Kleppe*

The decision in *Sierra Club v. Kleppe*, 427 U.S. 390 (1976), was the Supreme Court's first extensive treatment of NEPA's environmental impact statement requirements as they concern the Department's coal-related activities. As such, it provides constructive background to the discussion in Chapter 3 of this statement of the Department's policy options for incorporation of environmental analyses into the evolving Federal coal management program.

The litigation began in July 1973. The plaintiffs contended that Federal agencies could not allow further coal development in the Northern Great Plains area (encompassing portions of four states – northeastern Wyoming, eastern Montana, western North Dakota, and western South Dakota) without preparing a comprehensive environmental impact statement for the entire region. The United States Court of Appeals for the District of Columbia Circuit found that there was no Federal regional plan or program for coal development in the Northern Great Plains area. Nevertheless, the court concluded that the involved Federal agencies "contemplated" such a regional plan. The agencies

were ordered to inform the District Court of their role in the further development of the region; if they decided to control that development, an environmental impact statement would be required. The Court of Appeals also enjoined the Department of the Interior from approving the four mining plans analyzed in the multiproject Eastern Powder River Coal Basin Regional Impact Statement, which covered only a two-county area in Wyoming.

The Court further proposed a four-part balancing test for determining when preparation of an environmental impact statement must begin during contemplation of a plan or action. Factors to be considered were:

- Likelihood that the program would soon be initiated.
- Extent to which information is available on the effects of program implementation.
- Extent to which irreversible commitments of resources are being made or options precluded.
- Severity of resultant environmental impacts.

In reversing the Court of Appeals decision, the Supreme Court held that NEPA did not require a "regional" environmental impact statement for the Northern Great Plains area where no proposed action was pending. It also found that an environmental impact statement is not required until the time at which a Federal agency makes a recommendation or report on a proposal for Federal action. Mere contemplation of action does not trigger the need for a statement and, thus, the Court of Appeals balancing test had no statutory authority. The Court further indicated that NEPA may require comprehensive statements where several related projects are pending at the same time, although an individual project may proceed where covered by an adequate statement. Finally, the Court noted that the choice of a region to be covered is largely that of the agency.

1.2.6 *NRDC v. Hughes*

On September 27, 1977, the U.S. District Court for the District of Columbia ruled in *NRDC v. Hughes* (cited previously) that the 1975 final coal leasing programmatic environmental impact statement was inadequate and enjoined the Department from "taking any steps whatsoever directly or indirectly to implement the new coal leasing

program including calling for the nominations of tracts for Federal coal leasing and issuing any leases, except when the proposed lease is required to maintain an existing mining operation at the present levels of production or is necessary to provide reserves needed to meet existing contracts and the extent of the proposed lease is not greater than is required to meet these two criteria for more than three years in the future." The court stated that the standard should be applied to both noncompetitive preference right lease applications (PRLAs) and competitive leases.

The court ordered the Department to issue an official press release, publish a notice in the Federal Register, and take other steps appropriate to receive additional comments on the 1975 statement. The Department was further ordered to prepare a draft supplement to the 1975 statement, receive comments on the supplement, and prepare a new final statement. These documents were to discuss the issues which the court identified as being deficient.

Prior to the entry of the order, the Department had already begun to review its coal management policies and activities and to determine what, if any, coal management program it should adopt. As a result of this internal review process, the Department prepared a series of option papers on the various elements which might comprise a coal management program. In a series of decisions beginning in October 1977 and concluding in November 1978, the Secretary and Under Secretary chose what is described in this statement as a preferred Federal coal management program. Because the Department's preferred program alternative is no longer the EMARS II program described in the 1975 statement and because there have been significant changes in statutory and Presidential policy and in available data, particularly as to the need for new coal leasing, the Department decided not to prepare a supplement to the original environmental impact statement but to write an entirely new statement. Both departmental and public review will be aided by this new statement. To the extent an entirely new integrated statement has been prepared instead of a supplement, the Department has exceeded the court's requirements by preparing an entirely new, comprehensive statement instead of a supplement. This statement responds to all the major concerns

expressed about and corrects the faults previously found in the 1975 statement.

Following the decision in *NRDC v. Hughes* and in accordance with the court order, the Department, in November 1977, solicited comments on the final statement, including the following questions:

- Is there a need for renewed Federal coal leasing?
- If there is a need, how should the leasing program be defined?
- If new Federal leasing should be undertaken, how would different types of Federal leasing programs affect the environment?

Over 100 comments were received from Federal agencies, state and local governments and agencies, coal industry representatives, and private individuals and organizations. Comments included criticisms of the final environmental impact statement and suggestions on preparation of an improved statement, as well as responses to the three questions listed above. Major suggestions offered for an improved statement included:

- Further analyses of the need for renewed Federal coal leasing and a clearer description of the proposed leasing program.
- Detailed analysis of potential environmental, social, and economic impacts of renewed leasing and alternative leasing programs.
- Consideration of current data and recent legislation (e.g., the Surface Mining Control and Reclamation Act of 1977, Federal Coal Leasing Amendments Act of 1976, and 1977 Amendments to the Clean Air Act).
- Consideration of the impacts of processing, transportation, and ultimate use of coal.
- Improved consideration of alternative energy sources (e.g., nuclear, solar, geothermal, wind, and conservation)
- Consideration of state coal-related policies.
- Definition of the role of more detailed regional and site-specific environmental impact statements.

These comments were summarized in Chapter 8 of the draft version of this environmental impact statement and responses to them were integrated into its text, as well as the text of this statement.

Although the Department initially filed a notice of appeal of the court's decision, the District Court approved a settlement of the case on June

14, 1978. The amended order permitted substantially more leasing before issuance of this new programmatic environmental impact statement than would have been allowed under the court's initial standards. The standards will remain in effect until the Department files this programmatic statement and the Secretary decides whether to adopt a program. Utah Power and Light Company has appealed the order to the Court of Appeals for the District of Columbia.

The agreement embodied in the amended order permits leasing under any of the following six standards:

By-pass leases are permitted where Federal coal may be otherwise lost if it is not developed by an existing mine because subsequent costs (either economic or environmental) would be much higher. Up to five years of reserves may be included in a lease issued under this provision. To qualify for a lease, mining operations must have been in existence on September 27, 1977.

Employment leases may be issued in order to maintain production and employment in existing mines on September 27, 1977, which are running short of reserves needed to maintain past production or where additional reserves are needed to meet existing contracts. Up to eight years of reserves may be included in a lease under this provision.

ERDA project leases of no more than 500,000 tons annual production may be issued to support Energy Research and Development Administration (ERDA) projects authorized under Section 908 of SMCRA. Leasing is allowed if the technology assessed cannot be demonstrated on existing leases or private coal holdings.

Lease exchanges are permitted to implement exchanges for Federal leases in alluvial valley floors under Section 510(b)(5) of SMCRA.

Hardship Leases involve seven particular lease applications specified in the agreement as being not subject to the injunction regardless of any other particular standard. The basis for these leases varies, but each has some special circumstance or hardship which justified proceeding with lease issuance in advance of the completion of this statement.

Noncompetitive (preference right) lease applications may be processed but not issued for the 20 PRLAs having the least environmental impact. Other than these 20 (and any applications which

meet one of the court's other standards), the Department may not process any PRLAs. Preference is to be given to PRLAs for tracts containing 90 percent of reserves which can be mined by deep mining and PRLAs for tracts which would not require substantial additional transportation facilities or water storage or supply systems, and would not involve substantial new industrial development, in the region. All activities, including completion of the commercial quantities test and necessary environmental analyses, are permitted under this standard.

In addition to the six standards, the agreement allows the Department to process, but not issue, a lease based on an application by the Edison Development Corporation.

Although the total amount of coal to be leased under all of these provisions cannot be stated precisely, the Department estimates as many as 35 leases involving a total of 275 to 300 million tons of coal reserves could be involved. If these leases were granted, the increased annual production from Federal lands could be as much as 13 to 17 million tons. By comparison, approximately 96 million tons of coal were produced from mines on or including Federal leases in 1977. The original court order would have permitted the issuance of only six leases which would have resulted in approximately 10 million tons of production. As of April 1, 1978, 13 leases have been offered for sale under the amended order covering 6,442 acres and 53 million tons.

The modified order will enable the Department to achieve production in areas where needs are critical and to avoid unnecessary loss of Federal coal resources in by-pass situations. In addition, the settlement allows the Department to continue with the overview portion of the regional environmental impact statements. Although only lease proposals meeting the revised short-term standards will be studied on a site-specific basis, the regional environmental impact statements will address the social, economic, and environmental effects of increased coal production in particular areas, including impacts which could occur under various leasing levels. This information will be useful both to this programmatic environmental impact statement and to subsequent program decisions.

1.2.7 NRDC V. BERKLUND

The rights of holders of PRLAs was recently addressed in related litigation. The issue in *NRDC v. Berklund*, 454 F. Supp. 925 (D.D.C. 1978), *appeal pending*, was whether the Secretary's duty to issue a noncompetitive lease to an otherwise qualified holder of a PRLA is mandatory or discretionary. The United States District Court for the District of Columbia ruled, on June 30, 1977, that the Secretary does not have discretion to reject PRLAs where coal has been found in commercial quantities. It also affirmed the validity of the May 7, 1976, regulations, 41 Federal Register 18848, and, in particular, the point that the cost of complying with lease terms is properly a part of a commercial quantities showing. However, if the issuance of a PRLA would constitute a major Federal action significantly affecting the quality of the human environment, an environmental impact statement must first be prepared. The plaintiffs (Natural Resources Defense Council and three other groups) and intervenor defendants (Utah Power and Light Company and Chaco Energy Company) have appealed this decision to the Court of Appeals for the District of Columbia. The Court is not expected to decide this case until late in 1979.

1.3 FEDERAL CONSTRAINTS ON AND AUTHORITIES FOR COAL MANAGEMENT PROGRAM

This section presents an overview of the major laws and regulations and the programs of Federal agencies which influence the development of Federal coal resources. Primary emphasis is on statutes which directly control leasing and mining activities. Other authorities are cited in less detail to provide a perspective on factors which may indirectly influence the demand for coal resources and the location and intensity of coal development and related activities.

1.3.1 Laws Governing Development of Federal Coal

1.3.1.1 Mineral Leasing Act and Federal Coal Leasing Amendments Act of 1976. The Department's concern in the early 1970's with the efficacy of its coal management program was shared by the Congress, particularly as it related to deficiencies in the coal provisions of the Mineral Leasing Act of 1920. Major deficiencies of the 1920 Act are

discussed below [8,9]. (See also the discussion in Section 1.2.1).

1. Problems with 1920 Act

Speculation. While the 1920 Act provided for lease cancellation, no lease was ever cancelled for failure to develop. In addition, issuance of PRLAs made it possible to gain control of public resources for nominal payments to the Federal government. Slightly less than half of all Federal leases were issued with no competitive bidding [7]. Consequently, holding companies and energy resource speculators had entered the market for Federal coal in large numbers.

Lease Concentration. In 1976, approximately 57 percent of Federal acreage under lease was held by 15 leaseholders [10].

Fair Return to the Public. Under preference right leasing procedures, no competitive sales were held and lessees who discovered commercial quantities of coal had only to pay minimum royalties and rentals. Also, although more than 50 percent of all leases had been offered competitively, 72 percent of the competitive sales had either no bidder or only one bidder [7].

Social and Economic Impacts. When areas were newly opened to large-scale mining, state and local governments had the responsibility of providing needed public services. The 1920 Act provided that monies returned to state government from lease sales were to be used only for schools and roads. This restriction made it difficult for affected areas to meet the needs of their new inhabitants. The attendant problems were exacerbated by the "boom-bust" economic cycle associated with rapid resource development in rural areas.

Maximum Economic Recovery. Some lessees developed only the most easily reached surface deposits which yielded the highest profits. Other resources of coal less easily mined were sometimes left in place.

2. Congressional Response

The Congress responded to these problems with the passage, over President Ford's veto, in August 1976 of the Federal Coal Leasing Amendments Act (FCLAA). The broad purpose of the FCLAA is to provide a more orderly procedure for the leasing and development of coal presently owned by the United States.

Among the most significant requirements of the FCLAA governing the award and development of Federal leases are the following:

- All leasing must be by competitive bidding; no bids can be accepted which do not equal or exceed fair market value.
- Noncompetitive (preference right) leasing is abolished (subject to valid existing rights).
- Leases may be consolidated into logical mining units (LMUs) when needed to insure maximum economic recovery of the coal deposit;¹ all LMU reserves must be mined within 40 years.
- Diligent development and continuous operation is required (except continuous operation may be waived upon payment of advance royalties).
- Leases to a single person are limited to 100,000 acres nationwide (as well as 46,080 acres in a particular state).

Economic, social, and environmental deficiencies inherent in the 1920 Act were also addressed in the FCLAA. The Congress ratified the BLM practice of doing land use plans prior to issuing competitive leases and a comprehensive land use plan or its equivalent was ordinarily required prior to leasing. State shares of royalties were raised from 37 1/2 percent to 50 percent with the new portion of the monies available not just for construction of roads and schools but also for a wide range of public services and facilities in impacted areas. Finally, public bodies were entitled to have reserved a reasonable number of leasing tracts for their own energy production.

1.3.1.2 Federal Lands Policy and Management Act of 1976. Governing the activities of the Bureau of Land Management was a vast number of outmoded public land laws enacted when disposal and largely uncontrolled development of the public domain reflected then-current Federal policy. The Bureau's difficulty in carrying out its land management responsibilities under the statutes was examined in detail in the late 1960's by the Public Land Law Review Commission. After five years of

extensive investigations, the Commission submitted its final report [11] to the President and the Congress. A major recommendation of the Commission was that the policy of large-scale disposal of public lands reflected by the majority of statutes then in force should be revised and that future disposal of public lands should be limited to only those lands which will provide maximum benefit for the general public in non-Federal ownership. Federal ownership should be retained for those lands whose values must be preserved so that they may be used and enjoyed by all Americans. The Commission also emphasized the need to develop a clear set of goals for the management and use of public lands.

The Federal Land Policy and Management Act (FLPMA) enacted in October 1976 embodied many of the Commission's recommendations. The purpose of FLPMA is to provide the first comprehensive statutory statement of purposes, goals, and authority for the use and management of the approximately 448 million acres of Federally-owned lands administered by the Secretary of the Interior through the BLM.

Title II of FLPMA provides BLM with a statutory framework for land use planning for public lands. In the development of land use plans, BLM must:

- Use the principles of multiple use and sustained yield²
- Give priority to the protection of areas of critical environmental concern (such as historic, cultural, or scenic values, fish and wildlife resources, etc.).
- Consider present as well as future uses of public lands.
- Coordinate planning activities with those of Federal, state, and local agencies.

The Act also confirms that the BLM may continue to rely on existing plans.

The Act further liberalized the use of mineral revenues by states and local governments by providing that the entire 50 percent of the funds received by the Federal government for the

¹ An LMU simply stated is an area of land that will be mined as a single unit. The statutory definition is "an area of land in which the coal resources can be developed in an efficient, economical, and orderly manner as a unit with due regard to conservation of coal reserves and other resources. A logical mining unit may consist of one or more Federal leaseholds, and may include intervening or adjacent lands in which the United States does not own the coal resource, but all the lands in a logical mining unit must be under the effective control of a single operator, be able to be developed and operated as a single operation, and be contiguous."

² "Multiple-use" means the combination of resource values that consider changing needs and conditions, long-term needs for renewable and non-renewable resources, land productivity, environmental values, and economic return. "Sustained yield" means the achievement and maintenance in perpetuity of a high-level output of public lands natural resources consistent with multiple use.

development of leasable minerals on Federal land, which the FCLAA had provided to the states and local governments, could be used for any public purpose and by establishing a program to provide low interest loans to states and local governments to be impacted by Federal land mineral development activities. Proposed regulations to carry out the loan program were recently published, 43 Federal Register 49018 (1978).

FLPMA also requires the Department to review all BLM lands for potential designation as wilderness. The major steps in the process are inventory, identification of wilderness study areas, Presidential recommendations, and formal Congressional designation. Proposed procedures and requirements for interior management were published in 44 Federal Register 2699 (1979).

1.3.1.3 Surface Mining Control and Reclamation Act of 1977. The Surface Mining Control and Reclamation Act (SMCRA) was passed in August 1977 in response to concern over the extensive environmental damage caused by all coal mining and to technological and economic changes which now favor surface over underground mining. By 1976, over 60 percent of the coal produced nationally came from surface mines.

Surface coal mining activities have imposed large social and environmental costs in many areas of the country in the form of unreclaimed lands, diminished agricultural productivity, water pollution, erosion, floods, slope failures, loss of fish and wildlife resources, and a decline in natural beauty.

In the western coalfields, many of which are in arid or semi-arid areas, the environmental problems associated with surface mining are significant. Erosion rates on western range lands are among the highest in the United States for upland areas not under cultivation. The arid climate provides minimal moisture for a protective vegetative cover, and once this fragile vegetative cover has been disturbed, its restoration is difficult [12]. Furthermore, in most of the western coalfields the coal beds which lie close to the surface are also aquifers. Removal of the coal by surface mining operations could intersect those aquifers which are the source of water for many wells. Flow patterns in such aquifers could be changed, resulting in reduced availability of water for other uses.

In passing SMCRA, the Congress recognized that many states already had laws to regulate

surface coal mining operations. However, most existing state laws and Federal regulations as well as for surface mining and reclamation were inadequate in that they were tailored to suit ongoing mining practices, and did not require modification of mining practices to meet established environmental standards. Regardless of the adequacy of state mining and reclamation laws, the Congress felt that they were not fully enforced, partly from a lack of funding and manpower to adequately ensure compliance. As a result, violations of the law and regulations were frequent.

SMCRA, therefore, established uniform minimum Federal standards for regulating surface mining and reclamation activities throughout the country on Federal, state, and private lands, and for assuring adequate protection from the environmental impacts of surface mining in all states. The states can assume the primary responsibilities for administration and enforcement of the act under Federally-approved state programs. The Secretary must approve state programs; the Department will assume administrative responsibilities if a state program under the act is found to be inadequate.

The Department is responsible for enforcing reclamation requirements on Federal leases through a Federal lands program. SMCRA also gives a state the right to enforce reclamation requirements on Federal land if it enters into a cooperative agreement with the Department. If this occurs, Federal lessees in that state will have to comply with those requirements rather than those which would be Federally-enforced in the Federal lands program.

The Act has several features directly relevant to the coal management program. While FLPMA and FCLAA are applicable only to Federal coal and surface estates, SMCRA applies to all surface mining operations, whether Federal, state, or private. Thus, many of the prior advantages of developing private coal resources (such as reduced administrative burdens and related environmental and reclamation standards) have been eliminated. Of particular importance to this environmental impact statement are the Act's provisions regarding environmental protection performance standards (Section 515) and designation of areas unsuitable for surface coal mining (Section 522). A synopsis of these sections follows.

Section 515's performance standards are minimum standards applicable to all surface coal

INTRODUCTION AND BACKGROUND

mining and reclamation operations. These standards include:

- Maximum utilization and conservation of the solid fuel resource being recovered.
- Restoration of disturbed land to support the same or better conditions.
- Restoration of the approximate original land contour.
- Stabilization and protection of all surface areas.
- Protection of prime farmlands through specific reclamation techniques.
- Minimization of disturbances to the existing hydrological balance.
- Limitation on mining of steep slopes.

Section 522 of SMCRA establishes a procedure to designate lands unsuitable for all or certain types of coal mining operations. The Secretary of the Interior determines unsuitability on Federal lands. The states have authority to determine unsuitability for non-Federal lands. Areas on both Federal and non-Federal lands may be designated unsuitable if, upon petition, the Secretary determines that reclamation of disturbed lands is not economically or technologically feasible. Areas may also be classified unsuitable if mining operations will:

- Be incompatible with existing land use plans.
- Significantly affect important fragile or historic lands.
- Result in substantial loss or reduction in the productivity of renewable resource lands which produce food or fiber.
- Substantially endanger life and property in natural hazard lands.

Unsuitability designations must be preceded by a report addressing an area's potential coal resources, the demand for these resources, and the impact of designation on the environment, the economy, and the supply of coal. In addition, as part of its obligation under Section 522 of SMCRA, the Department of the Interior must review all Federal lands for unsuitability for all or certain types of coal development, although no formal "designation" of unsuitability is made as part of this lands review.

The environmental impact of unsuitability standards on a broad scale is discussed in the environmental impact statement prepared by the Department of the Interior's Office of Surface

Mining Reclamation and Enforcement (OSM) in connection with its permanent program regulations [13,14]. Section 702 of SMCRA exempts the Federal Lands Program, including the Federal lands review required by Section 522, from compliance with the requirements of NEPA for preparation of an environmental impact statement. Since November 1977, the Department of the Interior has been developing unsuitability criteria for Federal lands. These are discussed in Chapters 3 and 5 and are presented in the proposed regulations (Appendix A). Although these standards are exempt from NEPA's environmental impact statement requirement, the effects of the proposed criteria are discussed in this statement.

Other features of SMCRA relevant to the development of a Federal coal management program are:

- Authority to exchange Federal lands already under lease but which have been included in an alluvial valley floor and are subject to the grandfather clause in Section 510(b)(5) of the Act.
- A requirement for the consent of certain private surface owners before the Department can lease any Federal coal under privately-owned land.

1.3.1.4 Mineral Leasing Act for Acquired Lands. The Mineral Leasing Act for Acquired Lands governs leasing on Federally-acquired lands for coal as well as other minerals covered by the Mineral Leasing Act. The Act requires the consent of the head of the Federal agency having administrative jurisdiction over the lands before BLM can lease for coal. The Federal Coal Leasing Amendments Act grants similar veto authority to the surface managing agency with regard to non-acquired lands. Otherwise, leasing provisions are the same as those for nonacquired lands.

1.3.1.5 Other Relevant Laws. Numerous other Federal laws regulate aspects of coal development and energy conversion. Most pertinent laws are summarized in Table 1-3.

1.3.2 Interagency Relationships in Federal Coal Management

The jurisdictional interrelationships in a Federal coal management program are complex. Many Federal departments and agencies are involved through their specific mandates or related authori-

FEDERAL LAWS AFFECTING COAL DEVELOPMENT AND ENERGY CONVERSION

<u>Popular Name</u>	<u>Public Law/U.S. Code Citation</u>	<u>Purpose</u>	<u>Major Relevance</u>
Antiquities Act of 1906	59-209; 16 U.S.C. 431	*Regulates antiquities excavation and collection (including fossil remains).	*Mitigates potential harm to historical, archaeological, and paleontological resources.
Archaeological and Historical Preservation Act of 1974; Archaeological Salvage Act	93-291, 86-523; 16 U.S.C. 469	*Protects historical values on public land.	*Mitigates potential harm to historical and archaeological, and paleontological resources.
Bald Eagle Protection Act of 1969, as amended	86-70; 16 U.S.C. 668	*Provides for recovery of data from areas to be affected by Federal actions.	*Mitigates potential harm to historical and archaeological resources.
Clean Air Act Amendments of 1977	95-95; 42 U.S.C. 7401	*Provides for preservation of data (including relics and specimens) at every Federal construction project.	*Mitigates potential harm to historical and archaeological resources.
		*Protects bald and golden eagles.	*May make certain coal lands off-limits for development.
		*Establishes requirements for areas failing to attain National Ambient Area Quality Standards (NAAQS).	*Limits industrial development within and adjacent to areas exceeding NAAQS and areas preserving clean air quality.
		*Provides for prevention of significant deterioration of areas where air is cleaner than NAAQS.	*Reduces commercial attractiveness of low-sulfur Western coal as new source standard changed to percent emissions reduction.
		*May require a Federal permit where conflicts with coal development exist.	

TABLE I-3 (Continued)

FEDERAL LAWS AFFECTING COAL DEVELOPMENT AND ENERGY CONVERSION

<u>Popular Name</u>	<u>Public Law/U.S. Code Citation</u>	<u>Purpose</u>	<u>Major Relevance</u>
Clean Air Act Amendments of 1977 (Con't.)		*Modifies 1970 air act provisions regarding Federal facilities; enforcement strategies; coal utilization impacts; and interstate air pollution.	
Clean Water Act of 1977	95-217; 33 U.S.C. 1251	"Establishes effluent limitations for new and existing industrial discharges into U.S. waters. *Limitations set for public treatment discharges; with pretreatment by industrial users. *Provides mechanism to restore and maintain integrity of the nation's waters.	"May reduce development options in areas where anti-degradation policy restricts discharges into high quality waters. *Treatment facilities in areas with rapidly expanding infrastructures must meet water quality standards. *Effluent standards apply to coal mining point sources.
Endangered Species Act of 1973, as amended	93-205; 16 U.S.C. 1531	*Protects endangered and threatened species and critical habitat from Federal activities. Requires prior consultation with Fish and Wildlife Service.	*May make certain coal lands unsuitable for development.
Fish and Wildlife Coordination Act of 1934	85-624; 16 U.S.C. 661	*Requires consultation about water resource development actions which might affect fish or associated wildlife resource.	*Mitigates potential Federal coal development impacts.

<u>Popular Name</u>	<u>Public Law/U.S. Code Citation</u>	<u>Purpose</u>	<u>Major Relevance</u>
Resource Conservation and Recovery Act of 1976 (Cont.)		<ul style="list-style-type: none"> *Creates major Federal hazardous waste regulatory program. *Provides assistance to establish state or regional solid waste plans. 	*Coal industry faced with stringent permit requirements if coal wastes classified by EPA as hazardous.
Safe Drinking Water Act of 1977	95-190; 42 U.S.C. 300	*Establishes mechanism for National Primary Drinking Water Standards.	*EPA conducting study of the impacts of pits, ponds, lagoons, etc. on underground water supplies for public water systems.
Soil and Water Resources Conservation Act of 1977	95-192; 16 U.S.C. 2001	*Requires appraisal by Secretary of Agriculture of information and expertise on conservation and use of soils, plants, woodlands, etc.	*Provides opportunity for expanded data base.
Multiple-Use Sustained Yield Act of 1960	86-519; 16 U.S.C. 528	*Requires management of national forests under principles of multiple use so as to produce a sustained yield of products and services.	*Mandates land management principles similar to those required under PLPMA.
National Forests Management Act of 1976	95-233; 16 U.S.C. 472a	*Provides for a comprehensive system of land and resource management planning for National Forest System lands.	*Key factor in the Department of the Interior's determination of where coal leasing would occur.

TABLE 1-3 (concluded)

FEDERAL LAWS AFFECTING COAL DEVELOPMENT AND ENERGY CONVERSION

<u>Popular Name</u>	<u>Public Law/U.S. Code Citation</u>	<u>Purpose</u>	<u>Major Relevance</u>
Department of Energy Organization Act of 1977	95-91; 42 U.S.C. 7101	"Transfers authority to issue some coal regulations from DOI to DOE, including production regulations.	*Limits coal management authority exercised by the Department of the Interior.
Act of September 28, 1976	94-429; 16 U.S.C. 1908	"DOE determines long-term national coal production goals.	*Requires program to establish proper coordination mechanisms.
		"Provides for the regulation of mining activity within, and to repeal the application of mining laws to, areas of the National Park System, and for other purposes.	*Requires recognition and protection of nationally significant natural areas as they relate to surface mining.

ties. This section summarizes the major points of interaction both within and external to the Department of the Interior.

1.3.2.1 Department of Energy Coal-Related Functions. While many agencies across the Federal structure are involved in coal management activities, the Federal coal management program would be carried out principally by agencies in the Department of the Interior and the Department of Energy (DOE). The DOE was established in October 1977 following enactment of the Department of Energy Organization Act (DOE Act). The DOE Act was passed in response to the Nation's increasing shortage of nonrenewable energy resources and to the national security implications of increasing dependence on foreign energy supplies. Under the Act, many of the energy-related functions of a myriad of agencies were consolidated under a single departmental organization. It was envisioned that the reorganization would foster cooperation among Federal, state, and local governments in the development of national energy programs.

Prior to the passage of the DOE Act, the Department of the Interior had exclusive jurisdiction over Federal coal leasing decisions for public lands administered by the Department. However, the DOE Act transferred to the Department of Energy authority to promulgate regulations for:

- Fostering competition for Federal leases.
- Implementing alternative bidding systems for the award of Federal leases.
- Establishing diligence requirements for coal development operations on Federal leases.
- Setting rates of production for Federal leases.
- Specifying procedures, terms, and conditions for the acquisition and disposition of Federal royalty interests taken in kind.

Activities specified in the DOE Act for which the Secretary of the Interior will remain solely responsible are:

- Issuance and supervision of Federal leases.
- Enforcement of all regulations applicable to leasing of mineral resources, including but not limited to lease terms and conditions and production rates.
- Issuance of all other kinds of regulations.

The Department of the Interior is also required to provide DOE not less than 30 days in which to

disapprove any newly proposed lease term or condition which relates to any matter upon which DOE has authority to promulgate regulations under the DOE Act. No such term or condition may be included in a lease if it is disapproved. Reasons for such disapproval and acceptable alternatives must be furnished in writing to the Department by DOE.

The DOE is required to consider and establish energy production, use, and conservation goals, for periods of 5, 10, and 15 years, necessary to satisfy projected energy needs of the United States. These goals are considered as objectives for the national production of energy resources which are necessary to carry out national energy policy. These production goals are to be included in the proposed National Energy Plan (which is to be transmitted to the Congress no later than April 1, 1979) and are to be reviewed biennially. Section 802 of the Act provides procedures for the Congress to enact legislation regarding the National Energy Plan which may contain appropriate alternatives to, modifications of, or additions to the proposed Plan submitted by the President. Department of Energy and Department of the Interior production goal setting procedures for national energy resources, including coal, from Federal lands between the two Departments have been established in a September 1978 Memorandum of Understanding signed by the two Secretaries. This Memorandum is included in Appendix B.

The Office of Leasing Policy Development manages DOE's responsibilities for participating in Federal energy leasing programs. This office has the responsibility for drafting regulations to implement DOE's leasing responsibilities addressed in the prior section and for fostering close coordination with the Department of the Interior and other agencies.

The Department of Energy's Office of Coal Supply Development was established to monitor, from a broad viewpoint, restraints on coal supply. The office has no direct mandate in coal leasing, but has been reviewing coal supply as a system. Its aim is to isolate potential constraints and attempt to ameliorate them by alerting appropriate policy offices and by drafting corrective legislation. Some subjects currently under study by the office include: the effect of SMCRA on coal production; transportation problems (rising rates, equipment shortages); manpower demand in the mines; coal

leasing (or lack of it) as a potential constraint for competition; and constraints in supply from growing production costs.

1.3.2.2 DOE-Interior Leasing Liaison. A Leasing Liaison Committee was authorized by the DOE Organization Act. This committee has been established and now serves as an executive level coordinating mechanism on Federal energy leasing and other interagency energy programs. Both DOE and Interior are represented by four policy level representatives on the Committee. The Committee meets quarterly and has been used to discuss major policy-level concerns of the two agencies.

1.3.2.3 Department of the Interior's Coal Management Functions. The division of the Department of the Interior's functions and responsibilities concerning management of Federal coal between the Office of Surface Mining Reclamation and Enforcement (OSM), the Geological Survey (USGS), and BLM was set forth in a memorandum signed by the Assistant Secretary, Land and Water Resources, and the Assistant Secretary, Energy and Minerals, in July 1978. Table 1-4 presents the three agencies' extensive coal management responsibilities. The table is divided into three sections—Pre-leasing Functions, Post-leasing Pre-mining Functions, and Functions and Responsibilities During Mining Operations. It indicates the prime responsibility, joint responsibility, consulting, and concurrence requirements of the departmental agreement.

Regulation of coal development on Federal leases is shared by the OSM and the USGS. OSM administers the Department's program to mitigate the adverse effects of surface coal mining and to reclaim land which has been adversely affected. OSM's jurisdiction extends to the surface effects of underground coal mining operations.

SMCRA, OSM's enabling statute, establishes a two-tiered program for the regulation of surface coal mining and the surface effects of underground coal mining on both private and Federal lands. The first phase of this regulatory program went into effect on private lands on December 13, 1977, upon publication of OSM's interim program regulations (30 CFR Part 700, Subchapter B)[15]. These regulations, among other things, put into effect those of the statute's environmental performance standards which the Congress considered to be sufficiently critical to require almost immediate

implementation. Examples of these standards are the requirement to return previously mined land to approximate original contours, to segregate topsoil, and to minimize the disturbance to the hydrological balance of both the mine site and associated off-site areas. These interim performance standards, as well as OSM's inspection and enforcement program, were applied to Federal lands on September 21, 1978, upon publication by the USGS of revisions to its coal mining operating regulations (30 CFR Part 211)[16].

Regulations governing OSM's permanent regulatory program were published in the Federal Register on March 13, 1979, 44 Federal Register 14902-15463 (1979). The permanent regulatory program implements the statute's remaining environmental performance standards, as well as permit application requirements, bonding provisions and provisions for the designation of lands unsuitable for mining on Federal lands.

The USGS determines reserves present on Federal lease tracts, develops coal resource economic evaluations for lease tracts (recommendations for bonus bids and royalty rates), and prepares development and mineral resource recovery requirements for Federal leases. Under its Part 211 regulations, the USGS oversees coal exploration operations, reviews mine plans, and inspects mining operations for compliance with its resource, conservation, development, and recovery requirements. The USGS is currently revising its Part 211 regulations to be consistent with OSM's permanent Federal lands regulations.

In those instances where a mining operation occurs on Federal lands in a state which has concluded a cooperative agreement with the Department under Section 523 of SMCRA, regulatory responsibility for Federal coal development, with respect to reclamation requirements, may be shared with that state. Both SMCRA and the Mineral Leasing Act of 1920, as amended, prohibit the Secretary's delegating to the states his responsibility for protection of the Federal government's proprietary interest in the development of coal resources on Federal lands. Under these cooperative agreements, the states may review and approve mining plans concurrently with the Federal review of those plans and inspect mining operations on Federal lands. To date, the Secretary has concluded and formally proposed cooperative agreements with the States of Utah, Wyoming, and Montana.

NOTE: These agencies will also consult with the U.S. Fish and Wildlife Service, both on a general basis such as during land-use planning and on a specific basis when required by laws such as The Endangered Species Act.

Negotiations are in progress with the States of New Mexico, Colorado, and North Dakota. If these latter three states are unable to conclude successful negotiations with the Department to modify their cooperative agreements, their existing agreements will terminate.

The BLM has the principal responsibility for carrying out the requirements of FCLAA. It prepares the required land use plans and does land use analyses where Federal interests are not sufficient to justify a land-use plan. It has the responsibility to delineate, rank, and select lease tracts and to consult with surface owners over Federal coal. The BLM also conducts hearings on leasing proposals and prepares the necessary environmental analyses. It also carries out certain functions under SMCRA including the initial review of Federal lands to determine which lands are unsuitable for all or certain types of coal mining.

The Department's Office of Coal Leasing, Planning and Coordination serves as the focal point for developing and carrying out the Department's coal policy review and the development of a program for the management and leasing of Federally-owned coal resources in accordance with the President's directives in the National Energy Plan and Environmental Message (see Section 1.4.1). The Office is responsible for developing and coordinating Departmental policies affecting Federal coal management. It assists the Secretary, through the Assistant Secretary for Land and Water Resources, in implementing the Federal coal management responsibilities vested in the Department under the Mineral Leasing Act of 1920 and the Federal Coal Leasing Amendments Act of 1976.

Other Interior Department agencies with lesser coal related responsibilities are the U.S. Fish and Wildlife Service, Bureau of Mines, Bureau of Reclamation, and Heritage Conservation and Recreation Service. The U.S. Fish and Wildlife Service conducts surface mining studies and monitoring work relating to impacts on wildlife in general and on endangered species in particular. These studies are used to assess and predict the affects of coal-related activities on fish, wildlife, and their habitats on Federal, state, and private lands. For particular requirements on Endangered Species Act consultation, see 50 CFR Part 402, 43 Federal Register 870. The division of wildlife

related responsibilities in coal management between the U.S. Fish and Wildlife Service and the Bureau of Land Management was established in a Memorandum of Understanding signed on September 26, 1978, and is included in Appendix B.

Coal activities in the U.S. Bureau of Mines include conducting advanced coal mine health and safety research and demonstration projects on backfilling and subsidence.

1.3.2.4 Other Federal Agencies with Coal Related Responsibilities. Table 1-5 summarizes relevant coal management functions within the Federal structure. Policy and evaluation functions relating to coal, not previously addressed, are assigned within the Executive Office of the President to the Office of Management and Budget, the Council of Environmental Quality, the Domestic Policy Staff, the National Security Council, and the Office of Science and Technology Policy.

The Forest Service in the Department of Agriculture has been given added responsibility relating to coal management functions through the FCLAA. Under the Act, the Secretary of Agriculture has consent authority for Federal leases under his jurisdiction, and may add terms and conditions to coal leases on these lands to protect resource and environmental values. This authority extends to approval of mining and reclamation plans for Federal leases on National Forest System lands.

New responsibilities have also been given to a second Agriculture Department agency, the Soil Conservation Service, including assisting in the identification of prime farmlands within areas that may be surface mined in the future and reviewing and commenting on permits for surface mining which involve prime farmland. The Service is also authorized to review and comment on state reclamation plans.

The FCLAA strengthened the Justice Department's role in preventing anticompetitive and monopolistic practices related to Federal coal leasing. FCLAA requires the Interior Department to consult Justice during rulemaking. It also requires the Justice Department to review whether the issuance, renewal, or readjustment of a coal lease would tend to create a situation inconsistent with the antitrust laws, and limits the Interior Department's authority to issue a coal lease once that finding has been made. Justice is also required

to report to Congress annually on competition in the coal industry.

Legislative organizations with coal management involvement are:

- Library of Congress, Congressional Research Service.
- General Accounting Office.
- Congressional Budget Office.
- Office of Technology Assessment.

These organizations provide research, monitoring, and oversight capabilities for the Congress.

1.4 EXISTING FEDERAL ENERGY POLICIES

1.4.1 Role of Coal in National Energy Policy

In April 1977, President Carter released the Administration's National Energy Plan (NEP), which combines legislative, administrative, and budgetary proposals aimed at solving the Nation's energy crisis. The following seven energy goals for 1985 were announced:

- Reduce total energy growth to below two percent a year.
- Reduce oil imports below six million barrels a day.
- Reduce gasoline consumption by 10 percent from 1977 levels.
- Increase annual coal production by at least 400 million tons over 1976 levels.
- Insulate 90 percent of all buildings.
- Use solar energy in 2.5 million homes.
- Acquire a strategic oil reserve of one billion barrels of oil.

An important element of the NEP is the belief that coal must be the fuel which makes possible a reduction in the U.S. economy's energy related uses of oil and gas. The NEP sets goals for replacing oil and gas with coal and other energy alternatives. Meeting those goals will require increases in the production of coal, with the predicted added production ranging from 400 million more tons per year to 600 million more tons per year, or a possible doubling of 1977 annual production by 1985.

The President also stressed that projected increases in coal production can and must take place without increasing the damage caused by traditional coal mining and consumption practices. In his Environmental Message of May 23, 1977, the President said:

"The newly enacted Coal Leasing Amendments and the Federal Land Policy and Management Act provide the Secretary of the Interior with the necessary authority to carry out environmentally sound, comprehensive planning for the public lands. His duty now is to implement an affirmative program for managing coal lands and associated resources in a manner that fully protects the public interest and respects the rights of private surface owners" [18].

Following this message, the President, by memorandum of May 24, 1977, instructed the Secretary of the Interior to "manage the coal leasing program to assure that it can respond to reasonable production goals by leasing only those areas where mining is environmentally acceptable and compatible with other land uses."

The President further directed that the Department "scrutinize existing Federal coal leases (and applications for preference right leases) to determine whether they show prospects for timely development in an environmentally acceptable manner, taking steps as necessary to deal with nonproducing and environmentally unsatisfactory leases and applications." The memorandum also contained the instruction to review the basis for granting or denying preference right leases and to propose legislation authorizing the Department to condemn outstanding leases upon payment of reasonable compensation, if necessary, to prevent unacceptable environmental damage. Implementation of these Presidential directives are addressed in subsequent chapters of this statement, particularly in Chapter 3.

1.4.2 Congressional Action

Prior Congressional action on legislative proposals directly related to coal management was addressed previously (see Section 1.3). Last year, the Congress focused on the President's proposed National Energy Act.

The National Energy Act was submitted to Congress on April 29, 1977, in response to the President's April 20, 1977, message to a joint session of Congress. The Act was then divided into five major legislative initiatives to correspond to the jurisdictions of appropriate standing committees. On October 15, 1978, Congress passed five bills:

- The National Energy Conservation Policy Act.

- The Public Utilities Regulatory Policy Act of 1978.
- The Natural Gas Policy Act of 1978.
- The Energy Tax Act of 1978.
- The Power Plant and Industrial Fuel Use Act of 1978.

Summaries of these Acts, as passed by Congress and signed by the President follow.

Conservation. The National Energy Conservation Policy Act contains incentives to reduce residential energy use. The Act provides grants for weatherizing lower income homes and a \$900 million three-year grants program to states to improve the energy efficiency of schools, hospitals, and municipal buildings. Grants and government-backed loans are made available for low-income families. The Act also establishes mandatory efficiency standards for 13 major home appliances including water heaters and furnaces. These are to take effect in the mid-1980's. Finally, the Act establishes a program requiring utilities to inform their customers of suggested energy conservation and solar energy measures and to give loans to consumers to install conservation equipment. These measures could indirectly affect coal use by potentially reducing electrical demand from utilities.

Utility Rate Reform. The Public Utility Regulatory Policies Act of 1978 establishes several rate making standards to guide electric utility rate setting policies and practices. To the maximum extent practicable, rates charged by any electric utility should reflect the costs of providing that electric service and encourage conservation through time-of-day rates, seasonal rates, cost of service pricing, interruptible rates, lifeline rates, and prohibition of declining block rates. State regulatory authorities and utilities would be required to formally consider standards within prescribed periods. The Act also requires the Federal Energy Regulatory Commission to prescribe rules favoring industrial cogeneration facilities.

Coal use could be affected by the Act through a leveling of electrical demand, thereby reducing the number and capacity of generating plants needed to supply peaking power.

Natural Gas. The Natural Gas Policy Act of 1978 is particularly significant in that it settles a

39-year confrontation between natural gas producers and consumers over the question of natural gas price controls. It provides continued controls through 1985 with appropriate safeguards beyond that period. The controlled, but escalating, price will substantially increase the incentives for new gas production. Most importantly, the Act will: (1) create a single national market for natural gas production; (2) increase production; and (3) increase producer revenues because of the ability of all producers to help satisfy the demand for natural gas in the interstate market. The one to two trillion cubic feet per year of extra gas that would flow into the interstate market would replace up to one million barrels per day of foreign oil imports.

Coal Conversion. The Powerplant and Industrial Fuel Use Act (FUA) of 1978 prohibits the use of petroleum and natural gas by certain electric powerplants and industrial major fuel burning installations. Effective May 8, 1979, FUA would require the use of coal, synthetic gas derived from coal, or alternate fuels other than oil or natural gas in new utility generation facilities or new industrial boilers, gas turbines, and internal combustion and combined cycle units with a capacity greater than 10 megawatts. For existing powerplants and industrial facilities, DOE can require conversion to coal, other fuels, or coal-oil mixtures.

As with the Department's preferred program, FUA contributes an element to the NEP which advances the use of coal over oil and natural gas. The NEP requirement to increase usage of abundant domestic energy sources is addressed in a November 1978 FUA draft programmatic environmental impact statement prepared by the DOE. The DOE statement evaluates the national impact of the Act based on the assumption that coal will be the primary fuel substituted for oil and gas until 1990. The level of coal production is based on the assumption that no economic exemption would be granted under the Act unless coal is 44 percent more costly than the use of imported oil. Base-case coal production estimates for 1985 and 1990 are indicated by DOE to be 1,098 and 1,255 million tons per year, respectively. These production estimates serve as the basis for the impact quantifications of the DOE statement. Coal consumption attributable to FUA implementation should be only seven percent (72 million tons) of

the total demand in 1985 and over 10 percent (129 million tons) in 1990, according to the statement.

Regional coal production estimates for 1985 and 1990 differ slightly from those used in the Department's preferred program and DOE leasing alternative; however, they are within the high-low estimate range used as the Department's analytical basis. The most obvious reason for the differences is that DOE's coal regions differ somewhat from those in this final environmental impact statement.

The FUA is expected to affect industries which consume large amounts of oil and gas in large boilers, such as food processing, paper and pulps, chemicals, refineries, and machinery. Utilities should be affected less, since new baseload facilities using fuels other than oil or gas are generally anticipated.

According to the FUA draft programmatic ES, the Act will have a major impact in Texas, Louisiana, Arkansas, Oklahoma, and New Mexico, which area accounts for 58 percent of the projected increased coal use in 1985 and 68 percent in 1990. Specific regional environmental impacts as evaluated in the draft programmatic environmental impact statement for the FUA are as follows:

- Air Quality - "negligible impact" from transportation due to the FUA through 1990; "little or no deterioration" in the Northern Great Plains states, northern New England, and Central Appalachia; and "no regional air degradation" from storage and onsite processing of coal.
- Weather and Climate - "...not expected to affect the climatic process..."
- Water Resource Quality - With some exceptions, "Generally, the FUA will not greatly accelerate mining in areas where acid drainage is a major problem"; "... FUA will contribute incrementally to acid precipitation in the eastern United States"; "Acid precipitation is expected to be minimal in the East Texas Gulf area..."; and "minimal" increase in mobilization of trace elements.
- Land Use - 328,000 acres of mostly rangeland, cropland, and some forest land may be disturbed by mining by 2020 as a result of the FUA. Assuming total disposal of ash and sludge by landfill, an additional 108,000 acres would be required for waste disposal; "minimal" land use impacts ex-

pected from FUA-generated transportation, storage, processing, and combustion.

- Terrestrial Biota - Major impact in Texas, Arkansas, Oklahoma, Kansas, Missouri, and Iowa due to loss of deciduous forest/grassland habitats, "increased combustion, emissions due to the FUA are not expected to be large enough to pose a major threat to terrestrial biota."
- Aquatic Biota - "... the FUA may create local impacts . . . resulting from hydrologic alterations, sedimentation, acid mine drainage, alkaline drainage, nutrient enrichment, acid precipitation, and trace metal precipitation."
- Endangered Species "Increased demand for coal under the FUA can . . . increase the potential for deleterious impact upon endangered species and their habitats."
- Social and Economic Impacts - Greatest impacts expected in the Northern Great Plains (25 percent coal production increase due to the FUA); 41 percent coal production increase in Texas.
- Health Effects - 82 fatal and 2500 nonfatal injuries in 1990 expected from increased coal use due to FUA.

Although the FUA draft environmental impact statement and this final environmental impact statement differ in scope and methodology, they are compatible. Both statements address aspects of the NEP which are consistent with increased importance of coal as a domestic energy source. Both statements are based on independently derived regional production estimates which are within close approximation of each other. Moreover, neither program (or environmental impact statement) conflicts with the other because they are directed at distinct and independent phases of the coal cycle.

1.5 STATE POLICIES AND CONSTRAINTS

State policies and legislative actions could act as constraints to development of coal resources in the western coal regions. This section considers the principal potential constraints embodied in the laws and permitting requirements of Colorado, Montana, New Mexico, North Dakota, Utah, and Wyoming. No attempt has been made to compile a comprehensive listing of those laws or permits.

INTRODUCTION AND BACKGROUND

Rather, the purpose has been to indicate the principal constraints to coal development in State legislation. Table 1-6 lists some of these laws and presents a brief statement of their purpose and the state office or agency responsible for their administration and enforcement.

As can be seen from Table 1-6, potential legislative constraints to coal development are quite similar among the six states. Two of the states—Montana and New Mexico—have passed umbrella-type legislation similar to the National Environmental Policy Act (NEPA) of 1969. These laws establish state agencies to serve as general policy-making agencies of the state government. With or without these oversight agencies, however, all six states have developed legislation and established agencies to administer and enforce the legislation in key areas of environmental protection such as air, water, and solid waste management.

In many cases, the standards set at the state level have requirements more stringent than, or in addition to, the corresponding Federal standards. For example, the Wyoming ambient air quality standards are identical to the most stringent national standards except for the annual and 24-hour sulfur dioxide standards. (Wyoming's 60 microgram per cubic meter ($\mu\text{g}/\text{m}^3$) annual and 260 $\mu\text{g}/\text{m}^3$ 24-hour standards are more stringent than the 80 $\mu\text{g}/\text{m}^3$ annual and 365 $\mu\text{g}/\text{m}^3$ 24-hour National Ambient Air Quality Standards.) Also in the area of air quality, New Mexico has added standards for hydrogen sulfide, total reduced sulfur, and suspended particulate trace elements (beryllium, asbestos, and combined total of heavy metals).

State responsibility for enforcement of these environmental standards is considerable. This responsibility is derived either directly from state enabling legislation or indirectly through Federally-authorized transfers of enforcement responsibility as provided by applicable Federal law. For example, Section 107(a) of the Clean Air Act states that, "Each State shall have the primary responsibility for assuring air quality within the entire geographic area comprising such State by submitting an implementation plan for such State which will specify the manner in which the national primary and secondary ambient air quality standards will be achieved and maintained within each air quality control region in such State."

More specifically applicable to coal development, the Surface Mining Control and Reclamation Act of 1977 (SMCRA) states in Section 523(c), "Any State with an approved State program may elect to enter into a cooperative agreement with the Secretary of the Interior to provide for State regulation of surface coal mining and reclamation operations on Federal lands within the State, provided the Secretary determines in writing that such State has the necessary personnel and funding to fully implement such a cooperative agreement in accordance with the provision of the Act." A listing of other relevant Federal legislation is contained in Table 1-3.

Other areas of concern that resulted in Federal legislation have also been addressed by complementary laws enacted by the western coal states. The states have passed antiquities or historic preservation laws to protect paleontological, archaeological, or historic resources within their boundaries. All of the states have adopted a provision that no mining plans or rights-of-way will be approved until the Bureau of Land Management has coordinated professional surveys of cultural resources (including archaeological, architectural, and historical remains) with the appropriate State Historic Preservation Officer and the Advisory Council on Historic Preservation and received their written review and comments.

All of the states have expressed concern over the protection of wildlife and wildlife habitat. In some states, this concern is demonstrated in the legislative approach to reclamation plans. In other states, such as New Mexico (under State Regulation 563), the State Game Commission is specifically authorized to be responsible for endangered species and sub-species in that State.

None of the state legislative measures mentioned thus far represent definite constraints to increased development of western coal resources. Rather, they can be interpreted more as extensions of Federal legislation. Given the high probability of increasing coal development activities throughout the coal regions of the United States in the near future, it is unlikely that state governments will attempt to block this activity unless the quality of the environment or the health and safety of their populations are in clear danger. Although some states have adopted somewhat more stringent environmental standards, a spirit of cooperation is apparent throughout state and Federal legislation.

TABLE 1-6 -- STATE LEGISLATION

COLORADO

Lead State Agency	Legislation	Purpose or Relevance
Colorado Department of Health --Water Quality Control Commission	Colorado Water Quality Control Act	Establishes and administers water quality standards in State waters. Requires site review and permit issuance for projects involving water, sewage, and waste disposal. Establishes criteria for erosion control dams.
--Air Pollution Control Commission	Colorado Air Pollution Control Act	Establishes and administers air quality standards. Would require mines to employ dust preventive measures to all mining procedures including construction activities.
State Land Use Commission	House Bill 1041 Colorado Land Use Act of 1974	Provides for the protection of the utility, value, and future of all lands within the State, including the public domain as well as privately owned land. Local governments have the duty to identify, designate, and administer such areas and activities of State interest, including mineral resource areas and mining activities.
	Colorado Antiquities Act of 1973	House Bill 1041 also establishes areas containing or having significant impact upon historical, natural, or archaeological resources as being of state interest. BLM must coordinate with State Historic Preservation Officer before approving mining plans or rights-of-way.

TABLE 1-6 (Continued)

COLORADO (Continued)

Lead State Agency	Legislation	Purpose or Relevance
Colorado Public Utilities Commission and State Highway Department		Concerned with construction of utility lines, highways and rail- road lines, especially where cross- ing of public roads by a railroad is concerned.
Colorado Department of Natural Resources Division of Mines		Requires the filing of a Notice of Activity for any proposed mining exploration.
-- Land Reclamation Board	Mining Employees Safety Act Colorado Open Mining Land Reclamation Act of 1973	Monitor mine safety practices. Provides for the reclamation of land subjected to surface disturbance by open mining and thereby conserve natural resources, protect wildlife and aquatic resources, and establish recreational, home and industrial sites to protect and perpetuate the taxable value of property.
Division of Labor		Issues permits to acquire, transport, and store explosives and other hazardous materials used in connection with construction or mining.

TABLE 1-6 (Continued)

MONTANA

Lead State Agency	Legislation	Purpose or Relevance
Department of Natural Resources and Conservation	Montana Major Facility Siting Act	Vests in the department the authority to require and review long-range planning by certain utilities, to give approval to energy generation and conversion plant sites and associated facilities, and to require preconstruction certification of such facilities.
Environmental Quality Council	Montana Environmental Policy Act	The purpose of this act is to declare a state policy which will encourage productive and enjoyable harmony between man and his environment; to promote efforts which will prevent or eliminate damage to the environment and biosphere and stimulate the health and welfare of man; to enrich the understanding of the ecological systems and natural resources important to the state; and to establish an environmental quality council.
Montana Department of Health and Environmental Sciences	Montana Water Pollution Control Law Montana Water Quality Criteria Montana Pollutant Discharge Elimination System Permit Montana Solid Waste Manage- ment Act Montana Refuse Disposal Regulations Montana Clean Air Act Montana Air Quality Regulations	All laws and regulations designed to minimize contamination and pollution and maintain the quality of the environment by establishing standards and maximum amounts of deviation of pollutant substances.
Montana Department of Highways		The Montana Department of Highways may approve or disapprove the relocation of roads and railroads across state lands or across existing highways.

TABLE 1-6 (Continued)

MONTANA (Continued)

Lead State Agency	Legislation	Purpose or Relevance
Montana Department of State Lands	Montana Strip and Underground Mine Reclamation Act	The Department of State Lands may grant or deny surface-mining permits.
	Strip Mined Coal Conservation Act	The Act and promulgated rules contain detailed standards regarding the method of mining, blasting, subsidence stabilization, water control, backfilling, grading, highwall reduction, topsoiling, and for the reclamation of lands affected by the proposed mining operations.
	State Antiquities Act Chapter 25 of Title 81, R.C.M. 1947	The intent of the Coal Conservation Act is to prevent waste of marketable coal.
Board of Land Commissioners	Section 81-103, R.C.M. 1947	Administered by the DSL and the Board of Land Commissioners and provides for the registration and protection of historic, prehistoric, archaeologic, paleontologic, scientific, or cultural sites and objects on State Lands.
	Section 81-501, R.C.M. 1947	Requires that the Board of Land Commissioners and provides for the registration and protection of historic, prehistoric, archaeologic, paleontologic, scientific, or cultural sites and objects on State lands.
		Authorizes the Board to grant coal leases.

TABLE 1-6 (Continued)

NEW MEXICO

Lead State Agency	Legislation	Purpose or Relevance
New Mexico Environmental Improvement Agency	Environmental Improvement Act of 1971 NMSA 12-12 through 14	Responsible for environmental management and consumer protection programs, including food protection, water supply and pollution as provided in the Water Quality Act, liquid wastes and solid waste, air quality management as provided in the Air Quality Act, radiation control, noise control, nuisance abatement vector control, occupational health and safety, sanitation of public buildings.
	Air Quality Control Act	Establishes and enforces regulations to prevent or abate air pollution. Requires submission of plans, specifications, and other relevant information prior to issuing a permit for the construction or modification of any new source of air contaminant.
Water Quality Control Commission	Water Quality Control Act	Establishes and administers a comprehensive water quality program and develop a continuing planning process, including adoption of water quality standards as a guide to water pollution control. Also certifies permits to the U.S. Environmental Protection Agency for the discharge of any water contaminant either directly or indirectly into water. Has groundwater regulations pertaining to strip or tunnel mines.

TABLE 1-6 (Continued)

NEW MEXICO (Continued)

Lead State Agency	Legislation	Purpose or Relevance
State Engineer of New Mexico	NMSA Section 75-2-1	Empowered with general supervision, measurement, appropriation, and distribution of the State waters. Responsible for the safety of all State and private dams and providing guidelines to counties for the formulation of local regulations.
State Game Commission	Regulation 563	Responsible for endangered species and sub-species of the State.
State Historic Preserva- tion Officer	Cultural Properties Act, as amended, 1969	Regulates antiquities excavation and collection, and protects historical values on public, Indian Trust, and State lands.
Coal Surfacemining Commission	Coal Surfacemining Act of 1972	Administers the Surfacemining Act, including the setting of standards for mining plans, the procedures for mining plan submission, approval and amendment, and the procedures for permitting and bonding. Issues the necessary permits and licenses to mine after the plan is approved. Responsible for developing reasonable regulations covering the productive reclamation of stripmined land, including grading and revegetation. Administers groundwater regulations pertaining to strip or tunnel mines.

TABLE 1-6 (Continued)

NEW MEXICO (Continued)

Lead State Agency	Legislation	Purpose or Relevance
State Land Office Minerals Division		Responsible for leasing of all mineral rights, excluding oil and gas on State trust lands. Also responsible for issuing rights-of-way signed by the Commissioner of Public Lands, for utility lines or roads which cross State lands.
Bureau of Mines and Mineral Resources		Studies oil, gas, and uranium on State lands.
Public Service Commission		Requires certificates of Public Convenience and Necessity of any public utility plant or system or any extension thereof.

TABLE 1-6 (Continued)

NORTH DAKOTA	Lead State Agency	Legislation	Purpose or Relevance
North Dakota State Department of Health		North Dakota Air Pollution Control Act	Requires plans to issue permit to construct, install, modify, use, or operate any air contaminant source.
--Environmental Health and Engineering Services		Solid Waste Management and Land Protection Act	Required to approve or disapprove permits for solid waste disposal plans. Also enforces North Dakota New Source Performance Standards.
--Environmental Control		North Dakota Water Pollution Control Act	Responsible for establishing and administering standards to prevent or abate pollution of State waters.
		North Dakota Century Code (NDCC 23-25)	Provides means of presenting significant deterioration of state air quality as related to energy development. Involves review of application for permit to construct or operate facilities and monitoring of facilities after operational.
1-48		NDCC 23-29	Requires permits for solid waste disposal facilities
		NDCC 61-28	Responsible for establishing and administering standards to prevent or abate pollution of state waters. Requires application for and receipt of a permit to discharge mine water.

TABLE 1-6 (Continued)

NORTH DAKOTA (Continued)

Lead State Agency	Legislation	Purpose or Relevance
North Dakota State Water Commission	NDCC 61-04	Permit must be secured for all appropriations of water for industrial uses greater than 5000 acre-feet.
	NDCC 61-02 61-16	Permit must be obtained with the approval of the local water management district for construction of dikes or dams for water storage greater than 12.5 acre-feet.
North Dakota State Industrial Commission - State Geologist	NDCC 38-121	Requires a permit for coal exploration and requires the filing of basic coal exploration data with the State Geologist.
1-6 North Dakota State Engineer	NDCC 61-04	Permit must be secured for all appropriations of water for industrial use less than 5000 acre-feet.
	NDCC 61-01	Permit must be obtained with the approval of the local water management district for drainage.
North Dakota Land Development	NDCC 15-05	Responsible for leasing of State coal. Also authorized to coordinate leasing activities with Federal leasing in order to prevent speculation.

TABLE 1-6 (Continued)

NORTH DAKOTA (Continued)

Lead State Agency	Legislation	Purpose or Relevance
North Dakota Highway Commission	NDCC 24-01	Authorized to approve or disapprove granting rights-of-way for communication or power lines, pipelines, etc., along or over state highways. Also controls placement of railroad lines affecting state highways.
North Dakota Industrial Commission		Requires permits for drilling for purposes of coal exploration.
North Dakota Public Services Commission	North Dakota Surface Owners Protection Act NDCC Chapter 38-18	Requires approval of surface owners prior to permitting of mining plans. Issues permits for surface mining activities.
	NDCC 38-14	Requires application for and receipt of a permit for coal surface mining and reclamation activities.
	NDCC 49-22	Regulates siting of conversion and transmission facilities through the North Dakota Facility Siting Act. Requires the application for and receipt of: 1. Certificate of site compatibility; 2. Certificate of corridor compatibility; and 3. Route permit for transmission facility within corridor.
North Dakota Coal Development Impact Office	House Bill 1262, Section 15	Authorized to issue State funds to aid areas experiencing impacts due to coal development.
	NDCC 57-62	Authorized to issue financial grants to impacted taxing districts which demonstrate extraordinary expenditures caused by coal development and the growth incidental thereto.

TABLE 1-6 (Continued)

UTAH

Lead State Agency	Legislation	Purpose or Relevance
Air Conservation Committee	Utah Air Conservation Regulations	These regulations do not officially adopt the NAAQS, but the NAAQS are enforceable in the state. Changes to the Utah regulations are presently under consideration.
Utah Bureau of Water Quality	Water Quality Standards for Utah	Important prescribed standards include those which specify maximum permissible concentrations of dissolved solids, minimum permissible concentrations of dissolved oxygen, and permissible temperatures of State waters. Also establishes anti-degradation policy and effluent standards.
1-51 State Historic Preservation Officer	Utah State Antiquities Act (HB 366, 1977)	Requires a paleontological survey to be undertaken before mining activities can begin. No mining or rights-of-way will be approved until the surface management agency has coordinated professional cultural resource (including archaeological, architectural, and historical remains) surveys with the State Historic Preservation Officer.

TABLE 1-6 (Continued)

UTAH (Continued)			
Lead State Agency	Legislation	Purpose or Relevance	
State of Utah -- Division of Oil, Gas and Mining		This division and the Office of Surface Mining are preparing rules and procedures to implement the applicable initial regulations of SMCRA.	
--Division of Health		Reviews air pollution sources, culinary water sources, water treatment and solid waste disposal areas.	
--Division of Lands		Utility lines, roads, and railroads crossing state lands would require easements from the division.	
I-15 --Division of Water Rights		Authorizes diversion structures, channel modifications, slurry lines and water use.	
Department of Transportation		Requires authorization for relocation of highways, highway access, utility line crossings of State and Federal aid highways, and wide and heavy load requirements.	

TABLE 1-6 (Continued)

WYOMING

Lead State Agency	Legislation	Purpose or Relevance
Wyoming Department of Environmental Quality -- Land Quality Division -- Water Quality Division -- Air Quality Division	Wyoming Environmental Quality Act of 1973 --Land Quality Rules and Regulations, 1975 --Water Quality Standard for Wyoming, 1973 --Wyoming Ambient Air Quality Regulations --Solid Waste Management Rules and Regulations, 1975	Has authority relating to air quality, solid wastes, water quality, and mining and mine-land reclamation. The Land Quality Division issues permits and licenses to mine upon approval of a mining and reclamation plan. Mined-land reclamation provisions of the mining and reclamation plan are administered and enforced by the Land Quality Division. The Air Quality Division issues permits to construct coal mines and permits to operate coal mines after approval of applications with regard to plans for monitoring and controlling air contaminants. The Water Quality Division issues permits to construct settling ponds and waste water systems. They also issue NPDES permits for discharging waste water. The Solid Waste Division issues construction fill permits and industrial waste facility permits for solid waste disposal during construction and operation of coal mines.

TABLE 1-6 (Concluded)

WYOMING (Continued)

Lead State Agency	Legislation	Purpose or Relevance
Wyoming Industrial Siting Administration	Industrial Development Information and Siting Act, 1975	Requires furnishing extensive information and a state permit before certain facilities can be constructed. Affects developments which include gasification or electric generation proposals. Control does not apply to public properties except as provided by law.
Commissioner of Public Lands	Title 36 Wyoming Statute 1977	The Commissioner is responsible for the administration, leasing, and management of lands owned by the State. Utility lines, roads, and railroad spurs crossing state land require easements from the Commissioner.
Land Use Administration	Land Use Planning Act	The Act requires completion of county land use plans by 1978; these plans could conflict with or modify some energy development proposals.
Wyoming Highway Department		Relocation of highways and all utility line crossings of state and Federal aid highways require authorization.
Wyoming State Engineer		Any storage, impoundment, or use of surface or groundwater for mining and coal processing operations requires a permit from the State Engineer. Water pipelines and diversion structures that could affect other users also require a permit.

Difficulties are far more likely to arise at a local level where specific ecosystems and individual lives and lifestyles would be unavoidably affected by coal development. Conflict is possible between some of these laws and Federal authority. These laws must be viewed in light of the Secretary's responsibility for coal leasing decisions and for making unsuitability determinations under Section 522 of SMCRA. In Colorado, for example, House Bills 1023 and 1041 give counties and municipalities authority and funding to develop plans for all lands within their boundaries. A key feature provides authority to designate areas or activities of "state interest" so that they may be maintained or protected to preserve specific values. This could include mineral resource areas, areas of historical significance, and areas around important facilities such as airports, utility facilities, and highway interchanges. Relevant activities that may come under this state interest category include site selection of arterial highways and collector highways, major facilities of a public utility, and development of new communities.

Colorado's House Bill 1041 places primary responsibility for designation of areas and activities of state interest at the local level of government. Permits to develop or undertake activities of state interest in these areas would have to be obtained from local county governments. In addition, Senate Bill 35 gives counties the authority to approve or reject subdivision proposals. As a result, all subdivision plans must be submitted for review by designated agencies and affected municipalities prior to approval.

Colorado presents an unusual situation in that the State has delegated control of mineral resources to local governments. All of the states have authorized local governments to develop their own plans and zoning ordinances. In most of these states, however, localities are specifically denied control over state mineral resources, though individual communities still maintain control over development within their own jurisdiction through local zoning laws.

In New Mexico, local planning and zoning control may extend three miles beyond the boundaries of all cities and five miles for cities with populations over 25,000. Given such a three-mile extension of local control, a small town of ten square miles could have state-authorized develop-

ment control over an area as much as seven or eight times its actual incorporated area.

Housing demands and the need for greater infrastructural capabilities that will result from increased population from coal development activities could place considerable economic strain on communities and local governments.

In North Dakota, the Coal Development Impact Office is authorized to distribute State funds to assist areas experiencing impacts as a result of coal resource development. Wyoming has passed a 50 percent tax on minerals royalties and an 8 1/2 percent severance tax on mining companies. Some of these funds are to be redistributed for schools, water systems, highways, counties, and municipalities. But unless communities and local governments can be guaranteed that they will not suffer the ultimate cost of coal development, they are likely to take a more conservative position toward development than the states or the Federal government. State and Federal officials will have to coordinate closely with local representatives to assure the protection of both the ecological and human environments.

THE NATIONAL ENERGY ROLE OF WESTERN AND FEDERAL COAL

2.1 INTRODUCTION

Fifty-four percent of the coal reserves in the United States are located west of the Mississippi River. Until recently, these reserves played only a limited role as a source of the Nation's coal production, largely because demand for coal was primarily in regions of the East and Midwest which have substantial coal reserves, and which satisfied their demand with coal produced from Appalachian and midwestern coal mines. In the past few years, however, production of western coal has increased rapidly, rising from 60 million tons in 1972 to 166 million tons in 1977 (24 percent of total 1977 coal production in the United States). This upward trend is expected to continue as coal will make an increasingly important contribution to the Nation's energy supplies, especially for electric power generation, and as demand for coal increases in the western states.

Federally owned coal is concentrated in the six key western coal producing states of Colorado, Montana, New Mexico, North Dakota, Utah, and Wyoming, which in 1977 accounted for 71 percent of the production of all western coal. Production of Federal coal in these states was 51.7 million tons in 1977, or 43.7 percent of their total coal production and 7.5 percent of national coal production [5].

Other Federal coal is located in Oklahoma, Alabama, Washington, Kentucky, and in small amounts in other states. Production of Federal coal in these areas could be significant regionally or for specialized types of coal such as metallurgical coal.

Federal coal is expected to have a growing importance in national coal production. Of overall western coal reserves, approximately 60 percent is owned by the Federal government and an additional 20 percent is dependent on the availability of complementary Federal coal for its production.

2.2 COAL RESERVES AND CHARACTERISTICS

In describing the production potential of coal, it is customary to distinguish between coal "resources" and "reserves." The term "resource" describes the estimated total amount of coal for which economic extraction could eventually become feasible. The coal "reserve" is that limited portion of the resource which is judged to be minable at a profit under existing market conditions [19]. The total identified coal resource of the United States is estimated to be 1.7 trillion tons [3]. Of this coal only 438 billion tons have thus far been identified with enough certainty and with sufficient economic prospects to be included in the reserve category.

Reserve calculations for western coal are based in many cases on old geologic data and are probably considerably underestimated. The United States Geological Survey has underway a coal exploration program which will generate improved reserve estimates over the next few years.

For this programmatic environmental impact statement, twelve coal regions were selected as basic units for analysis (see Figure 1-1). The twelve regions contain over 92 percent of the reserve base of the United States and account for over 97 percent of the Nation's current coal production.

The regions shown in Figure 1-1 are used throughout this impact statement as the geographic basis for identifying coal production levels and subsequent impacts. The regions were delineated based on similarities of coal characteristics (as shown on the 1960 USGS map of coal fields of the U.S. [1]) and on opportunities for and the likelihood of new or expanded coal production, both from Federal and non-Federal sources.

As discussed further below, the Federal government administers large amounts of coal in six of these coal regions: the Fort Union, Powder River, Green River-Hams Fork, Uinta-Southwestern Utah, San Juan River, and Denver-Raton Mesa Coal Regions. Smaller but still important amounts

of Federal coal are located in the Western Interior and Central and Southern Appalachian Coal Regions, particularly in the States of Alabama and Kentucky. It is within these geographic areas that the preferred Federal coal management program, described in Chapter 3, would function.

Except for some limited Forest Service-acquired lands, the Federal government owns essentially no coal within the Northern Appalachian, Eastern Interior, and Texas Coal Regions. These regions are included in order to fully present the impacts of Federal coal management actions which might cause coal production to shift from regions with significant Federal coal ownership to regions with high production potential for predominantly non-Federal coal.

Certain areas of the Nation with coal, principally eastern Pennsylvania, southern Michigan, central Texas, northern Montana, Arizona, Washington, and Alaska, are not included in any of the twelve coal regions. Several of the areas – such as eastern Pennsylvania, Washington, and Alaska – were isolated from other regions and did not have enough expected coal production by themselves to form a separate region. Other areas – such as central Michigan and central Texas – are not expected to have any significant production in the near future. The San Juan River Coal Region does not include the State of Arizona because it has little Federal coal and it did not have enough projected production to be a separate region.

Table 2-1 shows the estimated coal reserve base and 1976 production for each of the twelve coal regions. Of the total reserves in the West, a large proportion (66 percent) are located in the Powder River Coal Region. The next most important western coal regions are the Fort Union (11 percent of western coal reserves), Western Interior (seven percent), and Green River-Hams Fork (seven percent) Coal Regions. In the East, reserves are divided almost equally between the Appalachian (54 percent) and the Eastern Interior (46 percent) Coal Regions.

The proportion of surface minable coal reserves in the West is significantly larger than for the Nation as a whole. Seventy-four percent (by weight) of the surface minable reserves shown in Table 2-1 are located west of the Mississippi River. Western surface minable reserves in many cases have less overburden and lie in thicker beds than eastern reserves. This generally results in relatively

lower mining costs, although these lower costs historically were not enough to compensate for higher transportation costs to eastern coal markets. The Powder River Coal Region in northeast Wyoming and southeast Montana contains 40 percent of the United States' surface minable reserves, and has an exceptionally high average seam thickness of 25 feet (eastern seams are typically four to eight feet thick). Another western region, the Fort Union Coal Region, contains 16 percent of the national reserves of surface minable coal, although it is largely comprised of less valuable lignite.

Coal produced by surface mining has increased steadily as a proportion of national production. In the nineteenth century, all mining was by underground methods. However, surface mining in the United States supplied 24 percent of overall production by 1950 and 56 percent by 1976.

There are substantial variations in the heating value (Btus) of a unit of coal [19]. Eastern coal is almost entirely bituminous coal (94 percent) and anthracite, and has a higher heat content than most western coal. Of total western coal, 75 percent is subbituminous and 15 percent lignite, and only 10 percent is the more desirable bituminous. Although western coal reserves represent 54 percent of the Nation's reserves by weight, on a Btu basis they represent only around 45 percent of total national reserves. The overall distribution of coal types by state is shown in Table 2-2.

Sulfur content is a key factor in assessing the value of coal. The sulfur content of coal in the United States generally ranges from 0.2 to 7.0 percent by weight. The presence of sulfur lowers the quality of coke and the resulting iron and steel products. Sulfur also contributes to corrosion and to the formation of boiler deposits. Sulfur compounds may react with water to form sulfuric acid, which is one of the major deleterious substances in acid mine waters contributing to stream pollution. Most importantly, sulfur compounds are a major source of air pollution, particularly in the form of sulfur dioxide.

The percentage of sulfur is highest in the Appalachian and Eastern Interior Coal Regions. Western Interior Coal Region coals are also relatively high in sulfur content. The sulfur percentage is relatively low in the subbituminous coals and lignite of the western states which contain large Federal coal reserves. Because of the

(a) Includes measured and indicated resource categories as defined by the USRM and USGS and represents 100% of the coal in place.

(b) Figures have been rounded.

(c) Quantity undetermined (basic resource data do not provide the detail required for delineation of reserve base).

*Western states including Alaska

different heating (Btu) values of coal, a given sulfur percentage by weight involves varying sulfur content by energy provided. Western coal is also typically low in sulfur content per Btu, although less so than the sulfur percentage by weight would suggest.

Generally, coal with less than one percent sulfur by weight is considered "low sulfur" coal. Only 16 percent of eastern coal is considered low sulfur, compared with 71 percent of western coal (see Tables 2-3 and 2-4). Eighty-four percent of the Nation's low sulfur coal is located in the West. On a tonnage basis, there are nevertheless substantial low sulfur reserves in the East, much of it metallurgical coal.

Within the six western states with major Federal coal ownership, coal mining will be concentrated in areas which are identified by the U.S. Geological Survey as Known Recoverable Coal Resource Areas (KRCRAs) (see Figure 2-1). The total area included within the KRCRAs defined as of March 1978 was 18 million acres (see Table 2-5). It is expected that about 25 million acres will be included in KRCRAs when mapping is completed. Around half of this acreage is expected to have coal of medium or high development potential. By comparison, the total land area of the six western Federal coal states is 396 million acres.

The distribution of coal ownership within KRCRAs is shown in Table 2-5. In many cases, surface ownership differs from subsurface ownership. The largest single ownership category is private surface and Federal coal, which includes 34 percent of the total KRCRA acreage. The second largest category is private surface and non-Federal (usually private) coal, covering 29 percent of the total acreage. Federal surface administered by the BLM with Federal coal and Federal surface administered by The Forest Service with Federal coal cover 21 percent and five percent of total KRCRA acreage, respectively. Finally, state surface and non-Federal (usually state) coal has five percent of the acreage.

Of the total KRCRA acreage, 71 percent of the surface is non-Federally owned. For Federal coal alone, only 44 percent of the surface is owned by the Federal government. Federal subsurface ownership of the coal, on the other hand, covers 66 percent of the total KRCRA acreage. Mainly because the Federal ownership share is unusually

high (80 percent) in the Powder River Coal Region, where coal seams are exceptionally thick and contain large amounts of coal per acre, Federal coal reserves in the West are estimated to be 72 percent of total western KRCRA reserves.

2.3 HISTORY OF NATIONAL COAL USE

Coal was the primary energy source upon which the Nation's early industrial and economic growth was based. Basic industries such as railroads, steel, and, later, electric power generation were developed and rapidly expanded through the production and use of coal. The coal industry reached a 100-million ton level of production by 1880 and 212 million tons by 1900. Stimulated by World War I, coal production reached 579 million tons in 1918. Coal production declined after the war (particularly during the Depression), reaching a low in 1932 of 310 million tons. With World War II, production again rose to new heights, reaching a peak in 1947 of 631 million tons [20].

Once again, however, the coal industry went into decline and reached its post-war low of 392 million tons in 1954. For the next 10 years, while major year-to-year fluctuations sometimes occurred, the basic level of coal use increased only slightly. But by the mid-1960's, the industry had begun an upward trend that by 1977 had reached an annual production level of 689 million tons, the highest ever.

For many years the major coal use categories were railroads, manufacturing and mining industries, retail dealer deliveries, coke plants, and electric utilities. In 1944, railroads consumed 132 million tons of coal. The introduction of diesel locomotives and electrification, however, caused the railroad market for coal to virtually disappear by the early 1960's. Also, the use of coal by ships has been displaced almost entirely by oil. Retail coal deliveries for space heating declined steadily over the years, from more than 122 million tons in 1944 to seven million tons in 1977.

Consumption of coal by coke plants fell from 107 million tons in 1955 to 77 million tons in 1977. The gradual decline in this use resulted from technological changes in the coking processes, including increased injection of supplemental fuels and modification of blast furnace practices. Nevertheless, it is expected that the demand for coking coal will be reasonably steady over the near term,

with relatively small further declines resulting from technological changes.

Industrial uses, other than electric power generation, include coal used for general manufacturing and mining and for cement, steel, and rolling mills. Industrial coal consumption has declined from approximately 270 million tons in 1945 to 60 million tons in 1977.

As recently as 1943, coal contributed more than 50 percent of the Nation's total energy. By 1977, it contributed only 18 percent. Except for coke ovens, the declines in the U.S. domestic coal markets following World War II resulted primarily from the rapid takeover of these markets by oil and natural gas. These fuels were cheap, easy to handle, and relatively clean, and thus provided a competition that coal was unable to meet. Table 2-6 shows the historical pattern of decline of coal in these markets.

Compensating considerably for the loss or decline of all but one of its historical markets, and its exclusion from new markets by the rise of oil and gas consumption, has been the rapid growth in the use of coal for electric power generation. As recently as 1950, less than 100 million tons of coal were burned by utilities. By 1977, use of coal for electric power generation reached 475 million tons (producing 47 percent of the Nation's total electric power) and is expected to constitute the major source of future increases in coal use.

The growth since World War II of coal exports has provided additional coal markets, particularly for coals of metallurgical quality. In 1957, during the Suez Crisis, exports reached more than 76 million tons. In recent years, exports generally have been in the mid-50 million ton level, but rose to over 65 million tons in 1975.

2.4 THE GROWTH IN WESTERN AND FEDERAL COAL PRODUCTION

Before 1972, coal production in the six western Federal coal States (Colorado, Montana, New Mexico, North Dakota, Utah, and Wyoming) never exceeded 40 million tons or seven percent of national production. In 1962, as shown in Table 2-7, these states produced only 14 million tons, or 3.3 percent of national coal production. Production from all western coal regions was still far lower in 1976 than their proportionate share of the Nation's coal reserves, as seen in Figure 2-2.

Production of Federal coal has been even more minimal. Although in the six western Federal coal states more than 70 percent of the coal is Federally owned, in 1972 the amount of Federal coal produced was only 9 million tons or 20 percent of the six states' total production.

This situation has been changing rapidly. Total western production - including that of Texas, Arizona, and the Western Interior Coal Region - reached 165.4 million tons, or 24 percent of national production in 1977 (see Table 2-8). Coal production from the six western Federal coal states was 118.4 million tons in 1977, up from 39.3 million tons in 1971 (see Table 2-7). Production of Federal coal has also been rising rapidly. In 1977, as shown in Table 2-9, Federal coal production in the six western states rose to 51.9 million tons, a five-fold increase over 1971.

As seen in Table 2-9, Wyoming was the leading Federal coal producing state as of 1977. Production of Federal coal in Wyoming grew from only five million tons in 1973 to 28.3 million tons in 1977. Federal coal production in Montana has also grown rapidly, from 1.9 million tons in 1973 to 10.5 million tons in 1977. Almost all the recent growth in Federal coal production in Montana and a large share of it in Wyoming has been from the Powder River Coal Region.

The increasing production of western and Federal coal is attributable to two key factors. The most important is the sharp rise in the price of oil and natural gas, which has made these fuels less economical to use in new utility boilers. Many new western power plants are coal burning, and are using coal mined in the West. In addition, some western plants now burning oil or gas are converting to coal, and this coal is obtained from the western coal regions.

In the East, there is a much greater traditional use of coal for power generation. Because transportation is a substantial portion of the overall cost of coal, eastern power plants traditionally used eastern coal. The economics of eastern power generation were significantly altered, however, by air quality control regulations under the 1970 Clean Air Act Amendments, particularly with respect to sulfur dioxide emissions. Emission standards were set for new plants which were low enough to prohibit use of most eastern coal unless utilities invested in pollution control equipment, but high enough to permit most western coal,

which is lower in sulfur content, to be burned without the installation of control equipment. For many eastern and mid-western utilities, the added cost of building a scrubber was large enough that they preferred to substitute western coal even if its energy content was lower and transportation costs were relatively high. Greater ease of passing increased fuel costs through to customers may also have played a part in this utility preference.

Changes in the emission standards for new power plants are required by the 1977 Clean Air Act Amendments. These new standards are expected to reduce substantially the amount of sulfur which can be emitted. Most western coal, like most coal from the East and Midwest, contains enough sulfur to require that new coal-burning power plants use pollution control equipment to meet the expected new standards. The stricter air quality standards will diminish the economic advantage of western coal over eastern and midwestern coal, and will result in power companies in the East and Midwest using more coal from their own regions instead of transporting coal from the West. However, since power plants coming on line before 1983 will largely be using the old air quality standards, it will be some time before the new standards affect western production. Overall demand for western coal will not be greatly affected by the new air quality standards, because most new demand for western coal will be from power plants and industries in the West. The growth in coal demand is expected to be higher in the West than in any other region of the country. An EPA computer analysis of alternative new source performance standards (published in 43 Federal Register No. 237, December 8, 1978) indicated that new tighter controls would decrease western coal production by two to five percent, depending on the final standard selected.

Western coal is used mainly for electric power generation, with small amounts used for metallurgical and other purposes. Proportionately somewhat greater amounts of eastern coal are used for metallurgical and other purposes than power generation. The use of western and eastern coal by consumer classification is shown in Table 2-10.

In the eastern United States, the Federal government owns the coal rights to 916 thousand acres. Much of this coal lies within national forests. Around three percent of the coal in Alabama is Federally owned. A significant amount of this coal

is interspersed with non-Federal coal and also has non-Federal surface ownership.

Historically, production of Federal coal in the East has never exceeded one million tons per year. In 1977, total eastern production of Federal coal was only 250 thousand tons. However, there is a growing interest in developing Federal coal in the East, especially in Alabama where it could supply metallurgical needs.

2.5 TRENDS IN OTHER SOURCES OF ENERGY

Historically, the United States was able to supply its oil and gas needs largely from domestic sources. However, it now appears that, although world oil and gas supplies might be adequate for some time, continued reliance on these fuels will leave the United States very heavily dependent on foreign nations for its basic energy requirements. The undesirable national security, economic, and other implications of such heavy dependence on foreign energy sources have forced a major national reassessment of future energy directions.

2.5.1 Oil Production Trends

The production of oil in the United States peaked in 1970 and, despite the stimulus of sharply increased prices over the past five years, there has been a continuing domestic production decline. As shown in Table 2-11, the decline in domestic production had to be offset by a large increase in oil imports to meet rising demand. Although overall demand dropped in 1974 and 1975, it again increased in the past two years.

The domestic production decline has been matched by a comparable decline in proven reserves. The discovery of the nearly 10-billion barrel Prudhoe Bay field in Alaska gave a large boost to reserves in the late 1960's. But, by 1975, U.S. crude oil reserves had fallen to a level largely equivalent to the level 10 years earlier (see Table 2-12). Reserves have continued to drop despite the large increase in the number of wells drilled. There were 44,982 completed wells in 1977, the highest level since 1960 [11,30,31].

Sustaining the existing level of domestic oil production will not be easy. At current production rates, more than 25 billion barrels of oil will have to be discovered by 1985 to keep the reserves/production ratio from dropping further. While new discoveries are continually being made,

they are more difficult and expensive to produce as the easier finds are exhausted. The greatest potential for new finds appears to be in costly offshore areas. Recent discoveries also suggest that the Overthrust Belt in the Rocky Mountains may contain major oil reserves.

Stable or declining domestic oil production would have fundamental national security and economic implications. The U.S. payments for foreign oil imports rose from \$2.0 billion in 1965 to \$41.8 billion in 1977 (see Table 2-13). These payments were a principal factor in the U.S. foreign trade deficit in 1977 of \$26.5 billion and the international decline in the value of the dollar. Projections of future oil imports indicate that U.S. payments for foreign oil could be as high as \$60 billion by 1985 [11,30,31].

The huge Mexican oil and gas reserves offer the opportunity to widen the number of nations from which the United States imports oil and to reduce supply instability. The use of Mexican oil and gas of course will not solve balance of payments problems.

The effect of increased coal production, even of modest magnitude, will be significant in terms of reducing dependence on imported oil. By increasing coal production from the 1976 level of 679 million tons to a 1985 production level of 1.2 billion tons as proposed in the President's Energy Plan [12], the importing of around 2.4 million barrels of oil a day, or 803 million barrels a year could be avoided. This would result in reductions in import payments of more than \$10 billion.

The problems of dependence on foreign oil supplies have been underscored by recent instability in Iran and the Middle East generally. Future oil supplies are reduced and prices appear uncertain at this time. If future supplies are reduced and oil prices rise substantially, it may prove necessary to call upon domestic coal production for an even larger energy role than has been expected.

2.5.2 Natural Gas Production Trends

The pattern of domestic production of natural gas has closely followed that of crude oil. Natural gas output peaked in 1973 and has since declined. The proven reserves of natural gas have declined since the mid-1960's, as shown in Table 2-14. Unlike petroleum, natural gas imports amounted to only about five percent of total U.S. consumption in 1977 and have not made up for domestic

production declines. Falling gas supplies have caused gas distributors to curtail and/or interrupt deliveries to industrial customers, restrict the hook-up of new residential and commercial accounts, and limit boiler fuel usage.

The extent to which natural gas will be available to meet future energy requirements is very uncertain at this time. Large foreign supplies of natural gas may be obtained from Mexico or could be transported in liquified form from more distant foreign supply areas. Major Canadian gas discoveries have recently been made in Alberta. Domestically, Alaskan gas could provide substantial supplies or exploration on the outer continental shelf might result in discovery of significant amounts of gas. The recently enacted Natural Gas Policy Act of 1978 aims to stimulate greater production of domestic gas supplies by raising the regulated price and providing for deregulation by 1985. In the short term, the act's most significant consequence has been to abolish the price differential between interstate and intrastate gas. This has resulted in an unexpected increase in the supply of gas which at least temporarily is likely to delay some industrial and utility conversions to coal.

The conversion of coal into synthetic gas is expected to have considerable importance at some time in the future. However, high costs and uncertain technology make it unlikely that large supplies of synthetic gas could be produced before the 1990's [7,30,32].

2.5.3 Nuclear Power Trends

Nuclear power plants produced 11.8 percent of the Nation's electric power in 1977. At that time there were 68 nuclear power plants in operation or in the startup phase with a total capacity of more than 49,000 megawatts. As shown in Table 2-15, 154 other nuclear plants with a total design capacity of 172,000 megawatts were being built, on order, or announced. If all these plants were to be in operation by 1990, they would provide as much as 27 percent of expected national power requirements.

Nuclear plants are currently cost competitive with coal plants and rapid expansion of nuclear power generation could significantly diminish future coal requirements. In recent years, however, the expected growth rate of nuclear energy has been sharply reduced by a number of concerns about its cost and safety. Safety concerns have

involved questions of nuclear proliferation, radiation hazards, spent-fuel storage, and radioactive waste management [7,29,33].

2.5.4. Hydroelectric Power Trends

Hydroelectric plants in 1977 accounted for 68,300 megawatts, or 12 percent of the total installed electrical generating capacity of the United States. This was about 25 percent less than in 1974 and 1975, due primarily to drought conditions in many western states. In the 1930's and 1940's, hydroelectric power provided as much as 30 percent of total domestic electricity needs. Although hydroelectric power is relatively safe, nonpolluting, low in cost, and does not consume fuels, its expansion in recent years has been limited by the lack of good new sites and opposition on environmental and cost grounds. The possibilities for expanding capacity at existing dams and for development of hydroelectric facilities on smaller rivers and streams for more local use are being investigated [7,34].

2.5.5 Nontraditional Energy Sources

Although a number of nontraditional energy sources are under active investigation, these efforts are still mostly in their infancy and these sources are not expected to make a significant contribution to energy supplies by 1990. These sources are briefly described below.

2.5.5.1. Unconventional Sources of Gas. There are four types of gas resources receiving the greatest current attention. The first is gas in geopressured zones of the Gulf Coast in the form of methane-rich waters at depths below 10,000 feet. Although estimated to encompass a vast resource base (3,000 to 50,000 trillion cubic feet), there are numerous technical and environmental problems to be resolved before gas from this resource can be developed [7,36]. The second is gas in "tight" (impermeable) sandstone formations in the Rocky Mountain States. Again, the resource is considerable but the recovery technology has yet to be developed. Gas is also found in Devonian Shales of the Appalachian States. This gas is currently being produced in local areas and efforts are underway to enhance production. Finally, recovery of methane from coal seams in advance of mining operations is technologically possible. Production of this resource would improve mine

safety and make a regionally important impact on gas supply availability [7,37]. Uncertainty about legal ownership of coal seam methane and the right to produce it are currently inhibiting its production.

2.5.5.2 Oil Shale. High grade deposits of oil shale, located primarily in Colorado, Utah, and Wyoming, may contain as much as 600 billion barrels of oil, and lower grade deposits may contain an additional 1.2 trillion barrels. Given favorable economic conditions, as much as 80 billion total barrels of shale oil could be extracted from this resource. A number of optimistic production forecasts were made in the 1973-74 period; it soon became evident, however, that production costs would be much higher than originally expected. Unless there are breakthroughs in technology, shale oil is not expected to be competitive with oil and gas until their prices rise considerably above current levels. Even then, shale development might not be competitive because historically increases in prices have tended to lag behind increases in cost [7,38].

In 1974, the Interior Department awarded four competitive oil shale leases. Construction of in situ experimental systems is now proceeding on two leases in western Colorado.

2.5.5.3 Tar Sands. Although found in at least nine states, the largest known resource of bitumen-bearing rocks (tar sands) is located in Utah, encompassing a resource base roughly equivalent to 28 billion barrels of oil. Because of various constraints and high extractive costs, significant production from this resource is not expected in the United States in the near future [7]. There are much better prospects, however, for development of the major oil sand resources in the Canadian province of Alberta.

2.5.5.4 Alcohol Fuel Uses. Alcohol fuels include methanol and ethanol. Most methanol traditionally comes from natural gas. However, methanol can also be produced from coal or biomass sources.

Ethanol can be produced by the direct hydration of ethylene gas and by the process of fermentation and distillation using various agricultural products such as grain or molasses as feed stock. Ethanol fuel may be a way to effectively use extensive food and grain surpluses in the United States and Canada.

Satisfactory engine operation is possible on existing automobiles that are fueled with up to 15 percent methanol or ethanol gasoline blends and require no carburetor readjustment. Also, the present automobile engine can be retrofitted to run successfully on 100 percent methanol. Brazil has been producing ethanol from excess sugar and is using ethanol gasoline blends as an automobile fuel. However, there is a great deal of uncertainty about the prospects for a nationwide alcohol-gasoline fuel system based on alcohols derived from biomass resources. The principle disadvantages of alcohols are their toxicity, with ethanol being the least toxic. Methanol vapors are more toxic than gasoline vapors. Other methanol disadvantages are its poor cold start capability, aldehyde emissions, and a lower heat of combustion.

An advantage to the use of alcohols in gasoline relates to fuel octane rating. When added to gasoline, both methanol and ethanol boost the octane value of the original gasoline in much the same way as tetra-ethyl lead and no-lead additives in gasoline [21].

2.5.5.5 Geothermal Energy. While it constitutes an enormous potential resource base, the heat of the earth has so far seen limited use as an energy source. Natural hot dry steam at Geysers, California, is the fuel source for a series of plants generating 520-megawatts of electricity. Hot water in Oregon, Idaho, and other western states has been used for local space heating purposes. Other plans are currently being developed to employ hot waters for power production in certain western states and Hawaii and for space heating in several eastern states. However, there is still a great deal of uncertainty about reservoir longevity, since these hot waters are essentially nonrenewable. This feature, combined with technological difficulties and problems of corrosion, has tended to discourage private investment thus far [7,29,39].

2.5.5.6 Solar Energy. The basic solar energy categories are solar heating and cooling of buildings, agricultural and industrial process heat, wind energy conversion, photovoltaic conversion, solar thermal conversion, and biomass. Solar heating and cooling, agricultural and industrial process heat, wind energy, and biomass appear to have potential for significant uses between now and 1990. Technologies need to be developed further for other solar energy sources to attain a reason-

ably competitive level. On an overall basis, solar energy is not expected to contribute more than one to two percent of the total water and space heating energy requirements by 1990. Its impact is more likely to be felt in the period between 2000 and 2020, when forecasts suggest that as much as 10 percent of U.S. energy needs could be met by solar sources. Technological breakthroughs, major subsidy programs, or other developments could cause the earlier use of this resource [7, 29].

2.5.5.7 Energy from the Ocean. The renewable energy sources from the ocean include the following:

- Ocean thermal energy conversion - based on harnessing the thermal differences of at least 17°C between warm surface water and cold deep sea water (found primarily between the Tropics of Cancer and Capricorn).
- Tidal energy conversion - plants proposed for two potential sites in the United States, one in Maine at the Bay of Fundy and the second in Cook Inlet, Alaska. The maximum total capacity of these plants would be 3,600 megawatts and the annual energy output would represent about 1 percent of the electricity produced in the United States.
- Other ocean energy forms that have been the subject of limited study are wave energy, ocean current energy, ocean wind energy, and salinity gradient energy conversion [7, 29].

These sources are not expected to provide significant amounts of energy until the 2000-2020 period at the earliest.

2.5.5.8 Nuclear Fusion. Since it would use low cost, inexhaustible fuels, nuclear fusion is generally considered environmentally more desirable than nuclear fission plants. Although the feasibility of key design principles was recently verified in an important experiment at Princeton University, there are major engineering problems to be overcome before nuclear fusion is a reality. Even if problems are successfully resolved, nuclear fusion cannot be expected to make a major contribution for probably another 50 years [7,35].

2.5.6 Energy Conservation

There are significant possibilities for reducing energy needs through conservation. In many cases, conservation measures might well be more cost effective than development of new energy sources.

The National Energy Plan formally proposed by President Carter in 1977 [12] called for measures such as wellhead taxes on crude oil, phased deregulation of natural gas prices, taxes on industrial use of oil and gas, and selected electricity rate policies, all of which were designed at least in part to dampen and discourage wasteful energy consumption practices. Residential conservation possibilities include weatherization of homes, use of more efficient appliances, and installation of heat pumps. Transportation energy use could be reduced by improvements in operating procedures, new equipment, pumping technologies, and modifications of motor vehicle engine propulsion systems. Possible areas of savings in the industrial sector include waste heat utilization, industrial waste application and process changes.

The various conservation measures could have a substantial impact on energy consumption, reducing it by perhaps as much as 10 percent by 1990 if there are major technology advances. Whether such large scale energy savings will be achieved through conservation efforts still remains, however, an open question [7, 40].

2.6 EXPECTED FUTURE COAL USE

While the precise rate is in considerable doubt, there is little question that the Nation's overall energy requirements will continue to grow. There is little likelihood of supplying that growth from domestic oil and natural gas (see discussion in Sections 2.5.1 and 2.5.2). New technologies and energy forms are still unproven, and cannot be relied on over the next decade or so. Nuclear power could supply large amounts of additional energy, but for the time being its growth is inhibited by concerns about its safety. Given these circumstances, in the next decade the United States will be forced to address the problem of growing energy demands largely through a combination of three basic types of actions: (1) expand use of coal as a domestic energy source; (2) obtain increased foreign supplies of oil and gas; and (3) curb demands by greater energy conservation measures.

2.6.1 Coal in the National Energy Plan

The role of coal in the President's April 1977 National Energy Plan [12] was previously discussed in Section 1.4.1. The National Energy Plan included a reduction in the expected level of imports of foreign oil as a prime objective. It proposed to reduce foreign imports from a projected level of 11.5 million barrels per day in 1985 without the plan, to 7.0 million barrels per day with the plan. This reduction was to be achieved by adoption of additional conservation measures (2.1 million barrels per day of oil saved) and by increased substitution of coal for oil and gas (2.4 million barrels per day).

Under the National Energy Plan, total coal production was expected to rise from 679 million tons per year in 1976 to 1.26 billion tons per year in 1985. This would represent an increase in coal production of about 200 million tons per year more than would have been expected without the plan.

2.6.2 Department of Energy Coal Projections

Projections of future energy production and consumption are based on many assumptions. Inevitably, these assumptions change, sometimes rapidly. Accordingly, it is necessary to use the best projections possible at a given time, while remaining ready to revise the projections as circumstances are altered. Already, the projections in the National Energy Plan are somewhat out of date and are being revised.

In preparing this programmatic environmental impact statement it seemed desirable to have the most current projections of future coal production. A regional breakdown with a fairly high degree of geographic resolution was also needed for the analytical purposes of this statement. Accordingly, the Department of the Interior requested that the Department of Energy (DOE) provide a new set of coal production projections especially developed for use in the preparation of this statement. These projections for 1985 and 1990 were developed by the DOE Leasing Policy Development Office and submitted in a report to the Department of the Interior in June 1978 [13]. This report focuses on projections for the six key western Federal coal producing states. It is available upon request.

The DOE energy and consumption projections incorporate assumptions on future electric power requirements, oil and gas prices, and nuclear power development. Other assumptions involve air

quality controls, transportation costs, and labor cost escalation. Different sets of assumptions were developed for low, medium, and high projections of western coal development. For example, the low oil price assumption for 1985 was \$13 per barrel, the medium assumption \$15 per barrel, and the high assumption \$20 per barrel. The electric power annual growth rate, which is the single most important assumption, was 4, 4.8, and 5.8 percent for the 1985 low, medium, and high projections, respectively. (Electrical growth rates provide an example of the difficulty in selecting assumptions to make energy production projections. They have behaved erratically in recent years, making future rates difficult to predict. From 1969 to 1973, the average annual electricity growth rate was 7.1 percent. Following the OPEC embargo, the growth rate declined to 0.2 percent in 1974 and 2.6 percent in 1975. In 1976 the electricity growth rate rose again to 6.3 percent but then declined to 4.6 percent in 1977 and 3.7 percent in 1978. The average for the past three years was 4.9 percent, slightly above the medium assumption.)

The low modeling assumptions were selected to favor energy sources other than coal and to favor eastern sources for coal produced. The high assumptions favor both higher coal use and western coal production. Low, medium, and high projections were generated for both 1985 and 1990.

The DOE projections were obtained from a large linear programming model and were calculated using a computer. For each coal model demand region, the model user specifies in advance electric power consumption, industrial coal use, and other types of coal use. The model then calculates the lowest cost way of providing for these electric power and coal use requirements for all the demand regions in the United States. Mining, transportation, and air quality control costs are among the costs considered. The model can make decisions to switch among alternative energy sources, to keep old plants operating or to build new ones, and to change the distribution between base, intermediate, and peak load plants. There is no distinction in the model between Federal and non-Federal coal reserves; essentially all reserves are considered available for production.

The assumption that all western reserves are available provides a benchmark production level against which production levels under different policies can be compared. Thus, the impact of a no

leasing policy is shown by comparing production levels likely if all coal reserves are assumed available with production levels likely if currently unleased Federal coal is assumed not available. This use of a with-and-without leasing comparison is similar to the with-and-without techniques commonly employed in benefit-cost studies.

Certain of the assumptions specified by DOE in June 1978 will require revision in making future coal production projections, for example, with respect to predictions of national energy legislation that had to be made before it was actually passed. In addition, assumptions are modified and model refinements are made regularly to improve the predictive accuracy of the DOE projection model. New computer runs thus would show some differences compared with those obtained by DOE. However, the range provided by the use of low, medium, and high projections covers any likely outcome under the changed circumstances and model refinements since June 1978.

Table 2-16 shows the DOE national coal consumption projections for 1985 and 1990, broken down by types of use. Under assumptions of medium use, consumption of coal by utilities is projected to rise by 60 percent between 1977 and 1985, from 475 to 760 million tons a year. The other main increase in coal consumption is in the industrial sector, where coal use is projected to grow by 99 million tons, from 60 million tons in 1977 to 159 million tons in 1985.

Total coal consumption for 1985 is projected to be 1.1 billion tons under medium level assumptions. This is a decline of about 150 million tons per year from the projected 1985 production level under the National Energy Plan, reflecting reduced projections especially for industrial coal use.

The medium level increase in national coal production projected between 1985 and 1990 is 37 percent. Most of this increase is due to greater use of coal by utilities. Industrial coal use has a more rapid rate of growth, but the increase is considerably less in absolute amount.

The projections for synthetic uses of coal assign them a minor role in 1985 (23 million tons). By 1990, synthetics are projected to grow by two and one-half times, but would still not be major uses of coal.

Table 2-17 shows the regional breakdown of total coal production projected by DOE. By 1985, coal production west of the Mississippi River is

projected to reach 42 percent of the national total (medium assumptions). By 1990, projected western production would reach 50 percent of the national total, corresponding roughly to the percentage of reserves located in the West.

The Northern Great Plains (essentially Wyoming, Montana, and North Dakota in the DOE model) would become the largest single producing section of the country if the DOE projections are realized. By 1990, Northern Great Plains coal production would exceed both Appalachian and Midwestern production and would constitute 36 percent of national production. By comparison, in 1977 production from the Northern Great Plains was 13 percent of national production, much higher than only a few years earlier.

In Table 2-18, DOE projections are shown for the western coal regions selected for assessment in this environmental impact statement. As might be expected, considering its huge reserves of low sulfur coal obtainable at low cost by surface mining, the Powder River Coal Region plays a central role in predicted western coal production. DOE projects coal production in the Powder River Coal Region to be 205 million tons per year in 1985 and 396 million tons per year in 1990 under its medium projection. These amounts represent 43 and 52 percent of total western coal production projected for those years, and 18 and 26 percent of national production.

Other major producing regions after the Powder River Coal Region are the Green River-Hams Fork and San Juan River Coal Regions. Assuming medium consumption levels, production of 112 million tons a year in 1985 and 150 million tons a year in 1990 is projected for the Green River-Hams Fork Coal Region, or 24 and 20 percent of total western production projected for those years. The San Juan River Coal Region is projected to have production of 23 million tons per year in 1985 and 58 million tons per year in 1990, or five and eight percent of western production, respectively.

Although not shown in Table 2-18, the great majority of the coal production projected by DOE is expected to be surface mined. In the Fort Union and Powder River Coal Regions, all the coal production is expected to be surface mined, except possibly for some limited production in the Bull Mountains in Montana. Underground mining represents a major share of projected production only in the Uinta-Southwestern Utah Coal Region

(85-90 percent). Of overall western coal production projected for 1985 and 1990, only 6.9 percent and 5.9 percent, respectively, are forecasted by DOE to be mined underground. This low forecast reflects the relatively lower costs of surface mining and the presence in a number of western coal regions of abundant surface minable reserves having low overburden and high seam thickness.

The development of western coal has been stimulated by the greater ease with which low sulfur coal can meet air quality standards, creating a demand in the East for western coal. However, the most important sources of increased demand for western coal are in the West itself. In time, the West is expected to move from its traditional reliance on oil, gas, and hydropower to a new use of coal-fired plants for its electric power. In Table 2-19, the DOE projected transportation of western-produced coal to eastern and western consumption regions is shown. Overall, both for 1985 and 1990 medium forecasts, 18 percent of western production is projected to be consumed in the East and Midwest. While this is not a high percentage, substantial amounts of coal would nevertheless still be shipped east. Under DOE's 1990 high assumptions, which involve low transportation costs, less strict sulfur scrubbing requirements, higher labor costs, and other assumptions designed to promote western production, 299 million tons per year of western coal would move to the East. Table 2-20 provides a detailed breakdown of projected coal flows for the 1990 medium case.

A certain amount of electric power and synthetics production would take place in western producing regions and then be shipped to consuming regions in the East. The consumption of western coal in the East shown in Tables 2-19 and 2-20 thus does not exhaust the use of western coal for eastern energy supply purposes. Similarly, some coal produced in the East will be used to meet western energy consumption needs. The great majority of western production, however, is used to meet western energy needs.

The traditional modeling of the energy sector of the economy, as reflected in the DOE coal model, relates energy use to macroeconomic variables such as income. A new alternative approach currently is being employed in California that projects energy consumption based on a detailed survey of households, businesses, and institutions. To complete the comprehensive inven-

tory on a nationwide basis with the survey method used in California would take considerable time and resources. But the preferred coal management program designed by the Interior Department contains a biennial examination of projections. If it should prove desirable, it will be possible for the Federal government to undertake the kind of end use modeling carried out in California or other alternatives to the DOE methods used for the current projections.

2.7 WESTERN COAL SUPPLY SOURCES

The DOE forecasts of future coal production were based on the assumption that Federal and non-Federal coal reserves would be fully available to meet demands for western coal. The forecasts did not address the questions of which particular reserves might be developed, and whether they were already producing or were likely to be able to enter into production.

2.7.1 Production Potential of Federal Coal

Future production of Federal coal reserves can come either from already issued Federal leases or from new leases. There are currently 534 outstanding Federal coal leases which are estimated to contain 17 billion tons of recoverable reserves (see Table 2-21). Sixty-seven percent of existing lease reserves are surface minable. The Powder River Coal Region contains 58 percent of existing lease reserves, most of which are surface minable and are located in the Wyoming part of the region. Leased surface minable reserves in the Powder River Coal Region represent 82 percent of all surface minable reserves in existing Federal leases. The Uinta-Southwestern Utah Coal Region has the second largest amount of reserves in existing leases, 4.5 billion tons. Sixty-nine percent of these reserves are underground reserves located in the Utah part of the region. The Powder River and Uinta-Southwestern Utah Coal Regions together account for 84 percent of existing lease reserves.

Estimates of recoverable reserves from existing leases were made by U.S. Geological Survey (USGS) mining supervisors (75 percent of lease reserves), by USGS area or district geologists (eight percent), by the lessees (eight percent), or by unspecified parties (four percent). The General Accounting Office has criticized the Interior Department's lease reserve estimates as not sufficiently accurate, particularly on an individual lease

basis [16]. The Department is currently undertaking to improve the accuracy of reserve information, and plans to request lessees to provide new reserve data in order to bring reserve estimates into conformance with the standards for reserves in GS Bulletin 1450B [17].

By 1977, annual production from existing Federal leases reached 51.9 million tons. Substantial further increases in production can be expected from these leases by 1986, both from leases already included in mine plans and from leases which are not currently included in mine plans. After 1986, further expansions in production of Federal coal would have to come either through greater production from already operating mines containing Federal coal or through new Federal leasing. If existing leases issued prior to 1976 are not in production by 1986, under current regulations they would be subject to cancellation for failure to meet diligent development requirements. The Department at present expects that the great majority, if not all, such existing leases would be cancelled if they are not producing by 1986. A few exceptions would be possible to complete work on an advanced technology process, to develop a very large mine, or where there is a firm contract to buy the coal later on (see discussion of diligence requirements for existing leases in Section 3.2.10 and Appendix I).

2.7.1.1 Planned Production from Existing Leases with Mine Plans. As of June 1978, the Department had received 119 mine plans that were approved or were pending approval. The 223 Federal leases included in these mine plans contain 9.3 billion tons of recoverable reserves, representing 54 percent of the reserves in all existing Federal leases. In 1977, production from mines including Federal leases was 96.3 million tons, representing 82 percent of total 1977 coal production in the six western Federal coal states. Only a little more than half of this production represented Federal coal, since a number of the mines also include non-Federal coal. Federal coal is expected to constitute a much larger share of future planned production from mines including Federal leases.

In Table 2-22, planned production from approved and pending mine plans containing Federal leases is shown. These planned production estimates were reported in March 1978 by the U.S. Geological Survey on the basis of lessee an-

(d) Production estimated made during 1978.

nounced plans, submitted mine plans, discussions with lessees, and other information. The total production planned for 1985 from mines including Federal leases is 308.6 million tons. Almost two-thirds of the planned production is expected from the Powder River Coal Region, which is consistent with the large supply of low cost, surface minable reserves in existing leases in this region. Although not shown in Table 2-22, 82 percent of the total production planned in the Powder River Coal Region would come from Wyoming and only 18 percent from Montana.

The production planned for approved and pending mine plans may not all occur. The most important potential constraint is lack of demand; the coal would only be produced if there is a market for it. Some pending mine plans may never be approved (for example, they could be located in an alluvial valley, or require a new transportation system with unacceptable environmental impacts). Planned production may also not materialize if other coal proves to be cheaper to mine or higher in quality. Nevertheless, total production planned from approved and pending mine plans provides a good indication of the production potential of these mines.

2.7.1.2 Likely Production from Existing Leases Without Mine Plans. In addition to the 223 Federal leases included in mine plans, there are an additional 311 Federal leases, representing 46 percent of existing Federal reserves under lease, for which no mine plans have been submitted to the Department. In order to obtain an estimate of the production potential of these leases, the U.S. Geological Survey was requested as part of the Department's coal policy review to give its best judgment as to whether such leases were "more likely than not" to be in production by 1986 in time to meet diligent development standards. These judgments were made in March 1978 by USGS mining supervisors, taking into account demand for the coal type, environmental problems of the lease site, transportation availability, mining costs, lease size, and other factors. Of the 7.8 billion tons of total reserves in existing leases without mine plans, the USGS estimated that leases containing 1.7 billion tons of reserves would likely be in production by 1986 and leases containing 6.1 billion tons of reserves would not likely be in production by 1986. Reserves in leases

believed likely to be producing by 1986 would be sufficient to sustain an annual production rate of 57.3 million tons a year. Leases containing other reserves would be subject to cancellation in 1986 for failure to be diligently developed.

In Table 2-23 the likely regional production from Federal reserves under lease which are not now in mine plans but which are considered likely to be producing by 1986 is shown. The Uinta-Southwestern Utah Coal Region has the largest share, 41 percent of likely production. In other regions, there is only a small amount of likely production from Federal leases beyond that expected from already approved or pending mine plans.

There are many possible reasons why an existing Federal lease might not be put into production by 1986. Many of the leases are small and would require additional Federal leasing or acquisition of other coal rights to form economically viable, or logical, mining units. Others are located far from transportation routes or are in areas with environmental problems. Coal quality is poor and prospective mining costs high in some cases, and there may not be a sufficient demand for the types of coal contained in some leases.

In the Uinta-Southwestern Utah Coal Region, for example, existing leases contain 4.5 billion tons of reserves, most of them for underground mining. These reserves would be sufficient to sustain mines with an annual production rate of 150 million tons per year. However, the DOE 1985 medium production projection for the Uinta-Southwestern Utah Coal Region is only 26.4 million tons (see Table 2-18), some of which would be provided by non-Federal coal. Even if the DOE projections are low, a large part of the reserves in the existing Federal leases in the Uinta-Southwestern Utah Coal Region have very little chance of entering into production by 1986. These nonproducing reserves are likely to be the reserves with higher mining costs, more distant from transportation routes, and with other problems.

Similarly, in the Powder River Coal Region, the one other region with major reserve holdings in existing Federal leases, the 9.5 billion tons of surface minable reserves in existing leases could sustain production of 317 million tons per year. The DOE medium projection for this region in 1985, however, is only 205 million tons and even the high projection is only 232 million tons. The

low 1985 projection is 140 million tons. Hence, a significant amount of existing lease reserves in the Powder River Region also are unlikely to be producing in time to meet the 1986 diligence standard. Nonproducing reserves here would also generally be the ones which are of relatively lower quality, mostly located in Wyoming, where the largest uncommitted reserves are found.

2.7.1.3 Preference Right Lease Applications. Another important potential source of Federal coal production is contained in preference right lease applications (PRLAs). Until preference right leasing was ended administratively in the early 1970's (and statutorily by the Federal Coal Leasing Amendments Act of 1976), the government issued prospecting permits in areas where coal was not known to exist in economically valuable deposits. A holder of a prospecting permit discovering a high quality deposit could apply for and obtain a lease to mine the deposit by demonstrating that it contained commercially valuable coal. Such leases were called preference right leases and were issued on a noncompetitive basis. There are currently 172 outstanding applications for preference right leases remaining from prospecting permits issued mostly in the late 1960's and early 1970's (see Table 2-24).

Total recoverable reserves in PRLAs are 9.9 billion tons, 3.5 billion surface minable and 6.4 billion minable by underground methods. Sixty percent of PRLA reserves are located in the Powder River Coal Region, all in the Wyoming part. Seventy-three percent of Powder River Coal Region PRLA reserves are underground reserves. The Uinta-Southwestern Utah and San Juan River Coal Regions each contain more than one billion tons of PRLA reserves. The Uinta reserves are mostly suitable for underground mining, whereas 55 percent of the San Juan River reserves are recoverable by surface mining methods.

Some PRLA holders may be unable to obtain leases because they have failed to meet all the legal requirements for processing their applications. Initial showings for some PRLAs were never made, or were made after the legal deadline had passed. Other PRLAs were improperly filed including areas containing prior mining claims. PRLAs also may have little development potential

because they are located in areas where coal development is now considered environmentally questionable and where the Department would want to exchange for or purchase any leases which PRLA holders are rightfully due.

As part of the Department's coal policy review, all PRLAs were examined to assess compliance with filing deadlines and other legal requirements and to assess potential environmental problems. Table 2-25 shows PRLA production potential, after excluding PRLAs for which there are legal uncertainties and PRLAs in areas that are considered environmentally questionable.

Total PRLA production potential would be 251 million tons per year. However, 63 percent of this production potential is for underground mining, which has limited prospects in the next decade except in the Uinta-Southwestern Utah Coal Region. Forty-four percent of total PRLA reserves and 57 percent of PRLA reserves without legal or environmental questions are underground reserves located in the Powder River Coal Region, where DOE projections show no underground mining occurring. There are also doubts as to the desirability or feasibility of production from many PRLA surface reserves. PRLAs in many cases are located outside the areas of highest coal development potential, because the Federal government originally issued prospecting permits, which have ripened into PRLAs, only in areas which were outside the known prime coal locations. There also was little attention given to environmental considerations in the issuing of prospecting permits.

2.7.2 Coal Owned by Indian Tribes¹

Indian owned coal reserves in the West are estimated to be 70 billion tons, 30 billion of which are surface minable. These reserves constitute the largest contiguous blocks of non-Federal coal and are a very important potential source of supply for future western coal production. Coal production from Indian lands was 22.9 million tons in 1977, 13.8 percent of total western production. The largest amount of Indian coal production in 1977 took place in Arizona, 11.5 million tons. Indian coal production was 11.4 million tons in the six western Federal coal states; 6.9 million tons in New Mexico, and 4.5 million tons in Montana.

¹Indian coal is considered "non-Federal" coal in this environmental impact statement. This coal would not be governed by the Department's coal management program. Rather, the Department, through the Bureau of Indian

Affairs, exercises trust responsibility over coal development on Indian reservations.

(d) Eliminates reserves under applications which have not met Department procedural or legal requirements — initial showings not made, or filed past deadline, or the PRLA was filed for land already subject to a mining claim.

(e) Eliminates both PRLA reserves with legal problems and reserves which lie in areas judged by Department personnel to be environmentally questionable for mining.

(f) Based on estimates of reserves without legal or environmental questions. Assumes a 30-year mine life.

The most important Indian coal owners are the Crow and Cheyenne Tribes in the Powder River Coal Region in Montana, the Navaho Tribe in the San Juan River Coal Region, and the Three Affiliated Tribes in the Fort Union Coal Region. Except for the Cheyenne, these tribes have indicated an interest in developing their coal reserves. Coal development has the potential for generating a major infusion of income for these tribes. At present, development of the Crow coal is being delayed by a legal battle between the tribe and previous purchasers of leases and holders of prospecting permits.

The Cheyenne Tribe is seeking designation of the Cheyenne Reservation as a Class I air quality area. Such a designation would probably prevent any further construction of power plants in the areas within or immediately adjacent to the reservation. Because of fugitive dust problems, coal mining could also be affected.

In Table 2-26, approximate estimates of surface minable reserves owned by Indian tribes are shown including estimates of reserves not yet fully delineated. The 1977 production level, 1985 planned production from existing and proposed mines, and maximum production potential on Indian lands are also shown. Planned production for 1985 from Indian lands in the six western Federal coal states is 25 million tons. Maximum production potential would be more than 800 million tons per year. However, it would be extremely unlikely that anything like full maximum potential production would occur at any one time.

2.7.3 Non-Federal, Non-Indian Coal

In addition to coal owned by Indian tribes, there are other substantial holdings of non-Federal coal in the West. The states have large reserve holdings, although typically scattered in isolated state sections. Railroads retain large holdings of coal in checkerboard areas which were originally railroad land grants. The Federal Government did not make it a general practice to retain coal rights in its land disposals until the early twentieth century, resulting in large-scale transfers of coal ownership to the private sector in earlier years. In Table 2-27, estimated non-Federal coal reserves and the percentage of total reserves they represent (excluding Indian coal) are shown for the western coal regions. In the six regions shown, which

include 91 percent of western coal reserves, non-Federal reserves are 28 percent of total reserves.

State governments have made large amounts of coal available for development through state leasing. States have issued 2,553 outstanding coal leases for 2.2 million acres of land, almost three times the Federal acreage currently under lease (see Table 2-28). The State of Wyoming has issued the largest number of leases for more than one million acres of state-owned coal. Little production has thus far come from state leases (see Table 2-28), partly due to their small sizes and scattered locations. State leases are most likely to be developed in the future when state coal is located amidst or adjacent to Federal or private coal that is being developed.

Although there are substantial non-Federal reserves, the development potential of these reserves generally is limited by the highly fragmented coal ownership pattern in the West. In checkerboard areas, for example, development would have to proceed one section at a time if the intervening Federal sections were not available. This would impose a high economic cost and would also have undesirable environmental consequences. Therefore, non-Federal coal in checkerboard areas would have a poor development potential without the addition of Federal coal (and vice-versa).

In order to assess the development potential of non-Federal reserves by themselves, these reserves were classified according to three categories: (1) blocks of non-Federal coal possibly large enough by themselves to support a viable mining operation (with the minimum cutoff size set at 2,560 acres); (2) non-Federal coal in checkerboard areas and probably not developable alone; and (3) non-Federal coal in scattered parcels probably too small to support a viable mining operation (less than 2,560 acres). The estimated distribution of non-Federal reserves among these three categories is shown in Table 2-29. Checkerboard areas alone contain more than one-third of all non-Federal reserves. In total, 55 percent of all non-Federal reserves are in fragmented parcels too small to be developed by themselves.

The coal regions with the highest percentages of non-Federal reserves in large contiguous blocks are the Fort Union, Green River - Hams Fork, and Denver-Raton Mesa Coal Regions. The Uinta-Southwestern Utah and the Powder River Coal

San Juan River	14.2	0 ^(d)	8.5	77.3
Denver-Raton Mesa	62.8	0	19.5	17.8
TOTAL	12.1	9.3	5.6	73.0

(a) Estimates based on the distribution of subsurface coal ownership in Known Recoverable Coal Resource Areas (KRCRAs) in the regions shown.

(b) Solid ownership was defined as reserves under non-Federal ownership in contiguous blocks greater than or equal to 2,560 acres. In Regions 2 and 3, a portion of the reserves are found in areas of checkerboard ownership, within which a number of 5-section blocks (3,200 acres) exist where the center section is state-owned and the surrounding sections are privately owned. These sections may be developable only if the center section (640 acres) is leased by the state to a private owner holding development rights to the reserves in the surrounding sections. In Region 2, at least 55 percent of the total solid non-Federal block is composed of these five-section blocks; in Region 3, at least 34 percent of the total solid non-Federal blocks fall in this category.

(c) Scattered small ownership blocks are defined as isolated sections of non-Federal coal ownership less than 2,560 acres in size, outside checkerboard areas.

(d) Some railroad checkerboard lands are located in San Juan River Region. However, as of March 1978 KRCRAs had not yet been defined for these lands.

Regions have relatively much smaller proportions of non-Federal coal contained in large blocks.

Because of the importance of the Powder River Coal Region in future coal production projections, ownership patterns in this region are particularly significant. In the Wyoming part of the region, the areas along the Wyodak seam which are surface minable and which have the highest coal development potential contain almost entirely Federally-owned coal. Other than Indian coal, the Montana part of the Powder River Coal Region is composed of a large checkerboard area and a large area of Federally-owned coal. Only 6.8 percent of the Powder River Coal Region reserves are non-Federal and appear possibly large enough to be efficiently developed.

Most of the coal included in the "possibly developable" category in Table 2-29 is in fact not likely to be developed in the near future. Much of the non-Federal coal is outside the areas of lowest production costs. A large part is suitable only for underground mining. The alluvial valleys of the West are typically privately owned and contain sizeable non-Federal reserves which it may not be desirable to develop. Non-Federal reserves may also have other environmental problems. Even though non-Federal blocks may be of sufficient size to form a viable mining unit, these blocks may have several different non-Federal owners. There is no assurance that all owners would want their coal developed or that it would be possible to assemble the non-Federal coal into a developable package. Finally, non-Federal coal owners may not be able to gain surface owner consent in those cases where there is a different surface owner and consent is needed under state law.

Planned production from mine plans that included Federal leases was shown earlier in Table 2-22. There are also a number of planned mines which do not involve any Federal coal. In 1977, excluding Indian lands, mines with no Federal coal produced 10.7 million tons, or nine percent of total production in the six western Federal coal states.

In Table 2-30, production planned for 1985 from mines that do not involve any Federal leases is shown for the six western coal regions. Total 1985 production planned from these mines is 35.7 million tons. Forty-five percent of this planned production would occur in the Fort Union Coal Region, where there is extensive non-Federal coal ownership.

2.8 THE NEED FOR NEW FEDERAL COAL LEASING

The Department of the Interior imposed a moratorium on further leasing of Federal coal in 1971 (see Chapter 1). At that time, a Department study indicated that Federal reserves under lease were rising rapidly, while production of Federal coal was remaining at low levels. Most previous acquisitions of Federal leases appeared to have been largely for speculative purposes.

Subsequent efforts by the Department to resume Federal coal leasing, including the decision in 1973 to develop a leasing program and the adoption of a leasing program in 1976, were widely criticized on the grounds that the need to resume Federal leasing had not been demonstrated. The failure of the Department to show the need for leasing was cited by the court in *NRDC v. Hughes* as a principal defect in the previous coal leasing programmatic environmental impact statement. (See Chapter 1 for a more detailed discussion of the recent history of Federal coal leasing.)

Certainly, a Federal coal management program is required to govern a range of coal activities other than competitive leasing: the application of planning and land unsuitability requirements to existing leases; the consideration of preference right lease applications; the processing of lease readjustments, relinquishments, cancellations, terminations, and assignments and other transfers; and the exchange of Federal coal and other mineral leases and lease bidding rights for environmentally unacceptable Federal leases and of Federal coal for alluvial valley floor coal. Competitive leasing would be only one, albeit critically important, component of a Federal coal management program. This component would be implemented only if a resumption of competitive leasing is determined to be necessary.

Resumption of Federal coal leasing would have a number of both beneficial and adverse impacts. If the Secretary of the Interior decides to resume leasing, his decision would reflect a determination that the need for leasing and the associated benefits outweigh the adverse impacts.

Resuming leasing would provide to the Nation four important benefits:

- The most important benefit is that it would give the Nation greater assurance of being able to meet its national energy objectives.

TABLE 2-30

1985 PLANNED PRODUCTION FROM EXISTING AND PLANNED MINING OPERATIONS INVOLVING ONLY NON-FEDERAL, NON INDIAN COAL(a)

REGION	1985 PLANNED PRODUCTION (million tons/year)
Fort Union	15.9
Powder River	3.6
Green River-Hams Fork	6.9
Uinta - Southwestern Utah	3.9
San Juan River	2.4
Denver-Raton Mesa	3.0
Total	35.7

(a) Based on DOE Leasing Policy Development Office compilations of planned mine production in 1985 (Reference Number 13).

- New leasing would also provide a means to promote a more desirable pattern of coal development. It may be possible to lower overall production costs and reduce the adverse environmental impacts resulting from coal mining by altering coal development patterns.
- A resumption of leasing would offer significant legal and administrative advantages for the Department of the Interior.
- Finally, the state of competition in the western coal industry would be improved by new leasing.

These benefits must be weighed against adverse environmental consequences of new leasing which are analyzed in Chapter 5.

2.8.1 Leasing to Meet National Energy Objectives

In leasing to meet national energy objectives, the Department is not leasing to meet today's needs but those many years in the future. Forecasts of future energy demands and supplies are subject to many uncertainties. The uncertainties increase the further in the future the forecast is made. It is difficult to predict how energy users and suppliers would respond to greater energy scarcity, new energy and environmental legislation, and changing energy prices, or to what extent users would adopt conservation measures or be willing to change their previous behavior patterns. Information about current and expected future energy reserves often is not very accurate or reliable. Changes in technology may substantially alter the relative economics of different energy sources. The most important factor determining coal demand, electric power demand, is itself subject to great uncertainty. Changes in government regulations can also cause important shifts in the relative desirability of one energy source compared with another. For these and other reasons, when examining the need for western coal it is important to examine a range of possible demand and supply levels, as was done by the Department of Energy (DOE) in the generation of high, medium, and low western coal production projections.

Consideration of forecasts for a range of future years is also required in energy planning. Thus, in evaluating the need for new Federal leasing, western coal production forecasts for 1985 and 1990 were prepared.

After a lease is issued, it would typically be another one to three years before a mine plan is submitted to the government. A government decision on approval of the plan is likely to take up to another year, and in some cases more. From the point of approval, two to three years would then be required to move a major western surface coal mine into full operation. All told, actual production of coal appears likely to occur four to seven years after the sale is held and a lease is issued.

At each of these steps, the potential coal mine could be found infeasible and have to be abandoned because of environmental, geologic, or economic factors. Thus, not only the uncertainty surrounding future levels of demand, but also the uncertainty of any given tract passing through the steps from potential tract to fully operational mine must be taken into account in assessing leasing needs.

If the decision is made to resume Federal leasing, about one to two years would be required to accomplish the full land use and environmental planning for the first round of lease sales under the preferred program. (Some earlier sales could be held under special start-up procedures and later sales would be able to make use of the planning for the first sales.) Taking into account the time after lease issuance, a decision at this time to hold a lease sale is not likely to result in coal production before 1985 to 1990. The planning horizon for this programmatic environmental impact statement includes decisions on whether or not to lease up to as late as 1985. A decision in 1985 to hold a lease sale is not likely to result in coal production until the early 1990s and possibly as late as 1995. Hence, the time horizon for a current assessment of the need for a resumption of Federal coal leasing extends as far as meeting coal production needs in 1995. DOE did not make production projections beyond 1990 and such distant projections would be subject to many uncertainties. The primary focus in assessing leasing needs is on the year 1990. It is unlikely that Federal leasing decisions following completion of this programmatic environmental impact statement could, or need to, have a major influence on 1985 western coal production levels.

Under current regulations, existing Federal leases issued prior to 1976 and not in production by 1986 would be subject to cancellation for failure to be diligently developed. It is expected that, with

a few possible exceptions (see 43 CFR 3520.2-5), existing leases not producing in 1986 will in fact be cancelled. Hence, increases in production of Federal coal after 1986 would essentially have to come either from new Federal leasing or from expansion of mines containing Federal coal which are already operating by 1986. It is hard to know precisely what the expansion potential of these mines would be, or whether rapid expansion would introduce inefficiencies in their operation. But beyond this expansion potential, if Federal coal is to have a role in increases in western coal production after 1986, it would have to be through development of Federal coal that is not now under lease.

In Section 2.7 above, estimates were made of planned and likely western production in 1985 from a number of possible sources. Table 2-31 summarizes these estimates. Total planned production in Table 2-31 includes: (1) planned production from non-Federal, non-Indian mines which do not involve any existing Federal leases; (2) planned production from Federal mine plans currently approved or submitted to the Department; and (3) planned production from mines on Indian lands. Production already planned for 1985 from these sources is 365 million tons. This estimate is reasonably consistent with estimates of 1985 planned production within the six coal regions in Table 2-31 previously compiled by the National Coal Association and DOE's Leasing Policy Development Office. The 1985 planned production estimates obtained by these sources were 420 million tons and 357 million tons, respectively. For comparison, total production in the six coal regions in 1977 was 118 million tons.

As seen in Table 2-31, planned 1985 production is more than the DOE low projection for 1985 of 300 million tons for the six regions located in the six western Federal coal states. On the other hand, planned production is less than the 1985 medium and high production projections of 391 million tons and 439 million tons, respectively.

The addition of likely 1985 production from existing leases currently without mine plans brings the total for 1985 planned and likely production to 422 million tons, above the medium 1985 DOE projection, although still below the high DOE 1985 projection.

As shown in Table 2-31, achievement of any of the DOE 1985 projected production levels appears

unlikely in the Green River-Hams Fork Coal Region. The total of already planned production and likely production from existing leases without mine plans in this region is only half the DOE medium 1985 projected production. As seen in Figure 2-3, the Green River-Hams Fork Coal Region is the only region in which achieving 1985 DOE projected production levels appears to be a substantial problem.

For 1990, which is the more important year than 1985 in assessing the need for new Federal leasing, currently planned production is less than the DOE low, medium, or high projected production levels (see Table 2-32). However, for low 1990 projections, which are actually less than the medium 1985 projections, planned production is just short of projected production. With the addition of likely production from existing Federal leases not now included in mine plans, there would appear to be little difficulty in achieving the DOE low 1990 projected production levels without further Federal leasing if all planned production occurs. As is the case for 1985, there would be major problems in reaching any of the projected production levels in one region, the Green River-Hams Fork Coal Region (See Figure 2-4).

The fact that currently planned and likely production exceeds 1990 low production projections does not resolve the question of the need for new leasing in the low case. Current company production plans are based on demand assumptions that in many cases are undoubtedly more optimistic than the assumptions used by DOE for the low projections. If DOE low assumptions prove accurate, some part of currently planned production would very likely not occur. There would not be enough demand by 1985 to support it, which is the time frame toward which most current plans are oriented. If the planned production does not occur by 1986, plans based on mining of Federal leases would have to be abandoned entirely because of failure to meet diligent development requirements.

Even under low demand assumptions, increases in western coal production would be expected between 1986 and 1990. Significant contributions to this growth in production could not come from Federal coal without new leasing because undeveloped leases would in all likelihood have already been cancelled. In short, the only forecast that leads to a wholly unambiguous

FIGURE 2-4

SUMMARY OF PLANNED, POTENTIAL, AND PROJECTED PRODUCTION, 1990

conclusion that there is no need for new leasing is achievement of 1985 medium or high production projections, followed by a sharp downturn in demand resulting in little if any further increases in production to 1990. If low projections are realized in 1985 as well as 1990, production increases would still be needed between 1985 and 1990 and the only way for Federal coal to make a major contribution to these increases would be through new leasing in the 1980 to 1983 time frame.

Unlike the low 1990 case, currently planned production is far less than the DOE medium 1990 projected production of 660 million tons. The addition of likely production from existing Federal leases without mine plans does little to alter this conclusion. The only regions which would be able to meet 1990 DOE medium projections from currently expected production are the Fort Union and Uinta-Southwestern Utah Coal Regions. These regions have only seven percent of 1990 medium production. The Powder River Coal Region has expected production totaling 226 million tons, far less than the DOE medium 1990 projected production of 396 million tons.

To achieve the DOE 1990 high production projections for all western regions of 922 million tons would require a level of production more than two and one-half times currently planned 1985 production. In the Powder River Coal Region, the 1990 high projection is 603 million tons, compared with 219 million tons in planned production. Planned production is less than the 1990 high projection in all regions except the Uinta-Southwestern Utah Coal Region.

There is not a great likelihood that western coal production would actually reach DOE's high projected levels in 1990. However, the high 1990 production projection represents a reasonable approximation of medium production projections for 1995. Although DOE did not prepare 1995 projections for the purposes of this statement, such projections have been made in the course of other studies. In making an assessment of the need to resume Federal leasing, as indicated above, the time horizon extends beyond 1990 to consideration of coal requirements expected as late as 1995.

It is unlikely that many PRLAs could be processed, leases issued, and production begun from these leases by 1985. The production potential of PRLAs is of importance mainly in considering 1990 production projections. In Table 2-30,

production potential of PRLA surface minable reserves is shown. Because western mining is expected to be almost entirely surface mining except in the Uinta-Southwestern Utah Coal Region, underground PRLA reserves are likely to make an insignificant contribution to reaching 1990 production projections other than in this region. In the Uinta-Southwestern Utah Coal Region, there appears to be little problem in reaching any of the DOE projected production levels.

The addition of PRLA production potential provides a source of new Federal coal development between 1986 and 1990, when current Federal leases either would have already been developed or would have been cancelled. This potential production could play a key role if new Federal coal production is needed during this period to meet 1990 low production projections. Issuance of preference right leases would still leave total production potential from already indicated sources far below medium and high 1990 projected production. Only in the less critical Fort Union and Denver-Raton Mesa Coal Regions does the addition of PRLA production potential raise total production potential above the 1990 medium or high projected production.

An assessment of the need for new Federal leasing based on projections of demand and supply levels thus does not produce an unambiguous picture. For 1985, there appears to be little need for new leasing, except in one region, the Green River-Hams Fork Coal Region. For 1990, there could be some, but probably not a large, need for new leasing to reach low projected production levels. On the other hand, achievement of medium and high 1990 production levels would require extensive development of new sources of western coal production, especially in the Powder River, Green River-Hams Fork, and San Juan River Coal Regions. Because more than 70 percent of the coal in the six western Federal coal states is owned by the Federal Government, new Federal leasing would make a major contribution in achieving such development.

The absolute need for new leasing to meet national energy objectives thus depends on which assumptions about future energy demands and the role of western coal in supplying those demands prove to be most accurate. Uncertainty also exists about planned production estimates. How assured

is production currently planned or considered likely and how much production in fact is likely to occur but may not have been included in planned production estimates? Since it is impossible to know at this time which assumptions and estimates are actually correct, government policy must be flexible. An assessment must be made of the costs of leasing too much Federal coal if current need estimates prove too high, versus the costs of leasing too little Federal coal if higher estimates should turn out to be more valid.

In the past, the cost of leasing too much Federal coal has been to fail to obtain full value for the Federal coal, while also rewarding speculative behavior. Without effective enforcement of diligent development requirements, purchasers of Federal coal leases could hold on to these leases for long periods without developing them. Because expected development was still far off and still uncertain, sales of leases did not obtain prices commensurate with the leases' later development values. Moreover, the Federal Government lost control over the land use and environmental impacts of Federal coal development because the location and timing of such development became largely a matter for private initiative.

These problems would still exist in the future, although in somewhat moderated form, if the Federal Government were to lease too much coal in relation to need. Strict enforcement of diligent development requirements, mandated under the Federal Coal Leasing Amendments Act of 1976, would prevent any future speculative holding of leases for long periods. However, issuance of more leases than can be developed would still act to depress lease sale prices because of the resulting uncertainty about development prospects within the allowed diligent development period. Although more leases would be sold, the lowered prices per lease would probably more than compensate, resulting in reduced overall leasing revenues. The land use and environmental impacts of Federal leasing would depend on which of the excess number of issued leases are developed, making Federal control of these impacts less secure. Finally, a new problem would be introduced, in that strict enforcement of diligent development requirements might cause significant distortions and inefficiencies if many leases were threatened with cancellation. Coal companies might rush leases into production prematurely, offering high

discounts and realigning coal shipments to find a place to ship the early production from the leases.

In considering the possibility of overleasing, it should be recognized that the amount of Federal coal offered is not necessarily the same as the amount actually leased. Fair market value requirements are likely to allow operators, especially the more efficient ones, a certain degree of leeway in their bid levels, but nevertheless would act to discourage marginal operators from acquiring tracts without sound market prospects. By insisting on full fair market value, the Federal Government could end up offering many more leases than are actually issued if there is not much demand. To some extent, the fair market value requirement thus minimizes the risk of the government leasing amounts of coal greatly in excess of market requirements.

In order to assess the impact of no further leasing of Federal coal, a special computer study was made in which future western coal development was limited to non-Federal coal and coal in already issued Federal leases. In addition, non-Federal coal dependent on unleased Federal coal for its development was considered unavailable for future mining. This study can be obtained on request [25].

According to the study, the greatest impact of no further Federal leasing would be experienced in the Powder River Coal Region in 1990. Under medium assumptions, production in this region in 1990 is projected to decline by 27 percent if there is no further Federal leasing. The Wyoming portion of the Green River-Hams Fork Coal Region showed a projected decline of 54 percent under a no leasing policy. Other western regions were either not greatly affected or showed production increases due to displacement of coal production from the Powder River and Green River-Hams Fork Coal Regions to these regions. Nationally, coal production in 1990 was projected to decline by 4 percent under a no leasing policy. For 1985, the study concluded that a no leasing policy would cause only minor impacts nationally and within the West.

National oil and gas consumption was projected to rise in 1990 by 300,000 barrels per day if there were no further Federal leasing (medium assumptions). According to the study, utilities would experience on average an eight percent national increase in delivered coal prices. This

would cause a 1.7 percent average national rise in electric utility rates. The estimated total resource cost to the Nation in 1990 of no further Federal leasing was projected to be \$800 million per year.

The regions most adversely affected by a no leasing policy would be in the West, reflecting the fact that western coal supplies primarily western markets. According to study projections, the Rocky Mountain, West North Central, and Pacific regions would experience increases in delivered coal prices in 1990 of 29, 17, and 27 percent, respectively, if there were no further Federal leasing (medium assumptions). These coal price increases would cause overall electric power rates to rise by 6.4 percent in the Rocky Mountain region, 5.9 percent in the West North Central region and 1 percent in the Pacific region.

The principal consequences of leasing less Federal coal than is needed to meet national energy objectives would likely be to alter patterns of coal development, both at national and regional levels. At least on the basis of computer projections, it appears improbable that total national coal production would be greatly reduced.

2.8.2 Leasing to Promote More Desirable Patterns of Coal Development

The fact that currently planned and likely production, together with the production potential from PRLAs, is not sufficient to reach medium and high 1990 DOE production projections does not mean that these projected levels could not be attained without new Federal coal leasing. As shown in Tables 2-26 and 2-27, there are large amounts of Indian and other non-Federal coal reserves in western regions sufficient to meet almost any conceivable 1990 production requirements.

It is probably not desirable or feasible to emphasize development of this non-Federal coal. Large amounts of it have high production and environmental costs, due to uneconomically small parcel sizes (see Table 2-27), high stripping ratios, distances from transportation, and many other factors. Non-Federal underground coal reserves are not likely to make much of a contribution to western coal for some time, since most western coal is expected to be surface mined. Non-Federal coal is of varying quality, some of it having less desirable chemical composition or a low heat content. The large supplies of non-Federal lignite

in the Fort Union Coal Region, for example, would not experience rapid development without a major expansion in coal use for gasification and liquification. Some non-Federal coal is located in less environmentally desirable locations such as alluvial valleys, which were the first areas to be acquired by early settlers. Indian tribes may oppose major coal development on their reservations or choose to develop their coal gradually over a lengthy period. Private surface owners above non-Federal coal may refuse consent under state surface owner consent laws or owners of non-Federal coal simply may not want to develop it at this time.

The difficulty of relying on non-Federal coal for expanded future production varies from region to region (see Tables 2-27 and 2-28). In the Powder River Coal Region, there is not much potential for production of non-Federal coal alone. In the Wyoming part of the Powder River Coal Region, the high quality, surface minable reserves are almost entirely Federally owned. In the Montana part, the better quality coal is divided among areas of solid Federal ownership, checkerboard ownership, and Indian ownership. It would be difficult to develop non-Federal coal in checkerboard areas without new Federal leasing. The Indian coal reserves would be sufficient for a large expansion of non-Federal coal production (see Table 2-24). However, the Cheyenne Tribe does not currently favor development of its coal reserves and there are many uncertainties about the future development of coal owned by the Crow Tribe.

The Green River-Hams Fork Coal Region contains a large checkerboard area in Wyoming in which expanded production beyond planned levels would be difficult without new Federal leasing. Because coal in the Uinta-Southwestern Utah Coal Region is largely owned by the Federal Government, this region is also relatively more dependent on Federal leasing for expanded production beyond already planned or committed levels. On the other hand, there are major holdings of non-Federal coal which could be developed without Federal leasing in the Fort Union Coal Region. The Denver-Raton Mesa Coal Region similarly has extensive non-Federal deposits. The San Juan River Coal Region appears somewhat less dependent on new Federal leasing because of the presence of Indian coal and some substantial blocks of developable non-Federal coal.

A decision by the Federal government not to lease Federal coal could have a number of impacts on future patterns of coal development. Production might simply be shifted from Federal to non-Federal coal within each region. The western regions more dependent on Federal leasing, especially the Powder River Coal Region, could experience declines in production which are displaced to other western regions less dependent on new Federal leasing, although a similar level of coal development might result in the West as a whole. It is also possible that western coal production would decline significantly, eastern production would rise correspondingly, and there would be little change in overall national coal production. Finally, there could be some declines in total national coal production, with the losses made up either by greater national energy conservation or by greater production from other energy sources.

It is impossible to predict with great confidence to what extent these possibilities would actually materialize. However, it appears that if there were no further leasing of Federal coal by 1990 there would probably be a significant decline in coal production below medium and high DOE projected levels from the Powder River Coal Region in Wyoming and Montana. This could be avoided only by large scale increases in production from Indian lands in that region. Less dramatic declines below projected levels would probably be experienced in the Green River-Hams Fork Coal Region. In other regions, production would be more likely to be displaced from Federal to non-Federal lands within the region, or there would be already adequate production potential for 1990 from mines — some including Federal leases — currently producing or expected to be producing.

If new production within a given region is forced to take place on the more limited non-Federal lands, it becomes likely, although it does not have to be the case, that some non-Federal sites would be devoted to coal production that are inferior to unleased Federal sites in their environmental and economic suitability for coal mining. Simply because the universe of sites to select from would be much smaller, one would automatically expect that it would be harder to find non-Federal sites with the lowest environmental and economic costs. Historically, purchasers of Federal lands and settlers under the Homestead Acts naturally

gravitated toward the better and more productive lands, leaving the least wanted lands to remain in the public domain. Because of this, non-Federal lands are more likely to be used for farming or urban purposes and generally would have a higher current use value and thus a higher opportunity cost for coal mining.

If Federal coal is not available within a region, mines of inefficient sizes and configurations would likely have to be formed from non-Federal coal alone. For example, in areas of checkerboard ownership, pressures would be generated for development of the alternating non-Federal sections and of the five-section non-Federal blocks centered on state sections. If such development occurred, the normal pattern of mining would be distorted, mining costs would increase, and it generally would not represent the most efficient or environmentally satisfactory pattern of coal mining.

Without new Federal leasing, inefficient development patterns could also result from bypassing of unleased Federal tracts which lie in the path of ongoing mining operations (operating on existing Federal leases or non-Federal lands). Because it would usually be easy for an existing operation to mine a tract in its path, the bypassing of such coal foregoes the opportunity to produce relatively low cost coal. The coal bypassed would then generally be uneconomical to produce and would effectively be wasted.

If Federal coal is not available, some existing operations would very likely have to shut down because they could not obtain needed coal. In addition to being socially disruptive, this result might well cause coal development to move elsewhere in the region at higher cost and, by requiring new roads and other mining facilities and new housing and public services, increase the overall area in the region adversely affected by coal mining.

New Federal leasing would be expected to displace development of some existing leases and PRLAs. Existing leases were issued with a minimum of attention to land use planning and environmental considerations. The locations of PRLAs similarly reflect an absence of planning. Displacement of coal development from the sites of existing leases and PRLAs to sites of new Federal leases which would be selected on the basis of comprehensive land use and environmen-

tal planning almost certainly would result in an economically and environmentally improved pattern of development within a region.

A decision not to lease Federal coal would alter development patterns by significantly increasing the pressure to develop Indian lands, offering both potential benefits and costs of coal development to Indian tribes.

If Federal coal is unavailable, interregional shifts in coal development patterns, as well as intraregional shifts, would be expected to occur. The resulting altered pattern of coal development would have different environmental consequences and would represent a different interregional economic efficiency in coal production. For example, because of the unusual thickness of Powder River coal seams, on average more than five acres of land in the East and 3.5 acres in the Southwest would need to be mined and reclaimed in order to obtain the same amount of coal that could be obtained from one acre of land in the Powder River Coal Region. On the other hand, expanded production in the Denver part of the Denver - Raton Mesa Coal Region would minimize socioeconomic impacts, because this area, alone among the western coal regions, already has a large population with a highly capitalized public service base in place.

A decision not to lease could also result in somewhat less total coal production for the Nation. If national energy use is not correspondingly reduced, there would be greater demands on nuclear power, oil imports, and other energy sources. The foreign trade balance would be adversely affected by increasing oil imports and possibly by falling coal exports. The resulting overall national pattern of energy development might be less efficient and environmentally desirable than would the pattern which would result from new Federal leasing.

The discussion thus far has been qualitative. For some of the effects of Federal leasing on development patterns, there is little possibility of making precise quantitative estimates of their magnitude. It would be very difficult, for example, to predict how many bypass situations involving a need for Federal coal might arise or how many existing operations might have to shut down for lack of Federal coal. Shifts within regions to non-Federal coal if Federal coal would not be available are also very hard to predict. The precise manner

in which such shifts would occur would depend on many site specific considerations and the particular requirements of proposed mines. This programmatic environmental impact statement does not attempt to predict exactly how intraregional shifts from Federal to non-Federal coal would occur without new Federal leasing or what the precise effects on coal production costs and environmental impacts within a region would be. An analysis of this nature would require a detailed examination of each region which is more appropriate to land use planning and an environmental impact statement at the regional level. Future Department regional lease sale environmental impact statements would closely examine intraregional impacts of Federal leasing actions.

In general, however, the clear expectation is that new Federal leasing would improve intraregional patterns of development. New leasing will be undertaken only after comprehensive land use and environmental planning is conducted. The much greater availability of lands for development, if Federal coal is available, offers much greater scope for finding the least costly and least environmentally damaging sites for coal development.

In keeping with its focus on interregional concerns, this programmatic environmental impact statement assesses the consequences of Federal coal management policy for the interregional pattern of coal development. In Chapter 5, estimates are shown of coal production in each region under different Federal coal management policies, including no new leasing. The environmental impacts of different interregional production patterns are analyzed. New Federal leasing may be needed if interregional patterns of coal development which result under a policy to resume leasing are judged to be preferable to those which would result if no leasing occurred.

2.8.3 Leasing for Legal and Administrative Purposes

As previously noted, new competitive leasing, whether conducted or not, would be only one component of a Federal coal management program. The Department has little choice legally but to process PRLAs and, for those applicants able to show commercial quantities of coal under appropriate environmental controls, either to issue a noncompetitive lease or to offer an exchange, purchase, or other suitable compensation. A

resumption of Federal leasing, at least to the extent of issuing noncompetitive leases for appropriate PRLAs thus appears necessary. A formal leasing program would be required at a minimum to process the PRLAs, conduct land use planning that is statutorily mandated before leases can be issued, assess environmental impacts of PRLA leasing, and consider whether exchange (where permitted by statute, see discussion in Section 3.2.10 and Appendix I), purchase, displacement through new competitive leasing or other approaches are most appropriate for dealing with environmentally unsatisfactory PRLAs.

As part of its preferred coal management program, the Department would take steps such as exchange or purchase to prevent development of existing leases as well as PRLAs in environmentally unsuitable areas. As has been mentioned, many existing leases and prospecting permits were granted without much attention to their environmental impacts. The pressures for development of both existing leases and PRLAs would be heightened if new Federal leasing does not take place. The likely administrative and financial burdens on the Department to acquire leases in unsuitable areas could therefore be reduced by new leasing.

Federal and state governments would benefit from the added bonuses and royalties which could be obtained from sales of new Federal leases. The Federal Government is under no obligation to preserve private rents and profits by refraining from making alternative Federal coal supplies available to the market.

2.8.4. Leasing to Increase Competition in the Coal Industry

There are certain conditions which must exist in order for private markets to function in the most socially beneficial manner, making the best coal available at the lowest prices. A particularly critical requirement is that there should be a sufficient number of buyers and sellers that the markets are genuinely competitive and that no one or few buyers can influence prices in a monopsonistic or oligopsonistic fashion.

The national importance of the coal industry has generated considerable concern about its competitiveness. Studies of competition in the coal industry have been issued in the past two years by the Antitrust Division of the Department of

Justice, the Federal Trade Commission, and the General Accounting Office [15, 26, 27].

A decision not to lease Federal coal would tend to inhibit competition in the western coal industry. Coal purchasers would have to obtain coal from those companies holding existing Federal leases or possessing non-Federal sources. In regions such as the Powder River Coal Region, where the great majority of mining sites are dependent on the availability of Federal coal, new entry into coal mining could be achieved only by purchases of already existing leases from their current holders. Because of such considerations, the Antitrust Division of the Justice Department, in a 1978 report, *Competition in the Coal Industry* [15], recommended resumption of Federal leasing to promote greater competition in the western coal industry. The report concluded that: "Resumption of the Federal leasing program with all deliberation speed will have beneficial competitive effects."

2.9 OVERVIEW OF THE NEED FOR A FEDERAL COAL MANAGEMENT PROGRAM

The Federal Coal Leasing Amendments Act of 1976, and other recent legislation for the public lands, lay a legal and policy foundation for the Department of the Interior's management of coal owned by the United States Government. The act expresses the intent of the Congress that, through a process of competitive lease sales, Federally owned coal be sold for a fair price from the public domain to coal operators at a rate meeting market needs for new supplies.

The President, in his Environmental Message of 1977 [12], directed the Secretary of the Interior to take certain steps to improve the management of Federal coal reserves, and to operate a coal leasing program capable of responding to reasonable production goals. The President's National Energy Plan, which sets forth the national interest in the substitution of coal for oil and gas as an energy source, and the Power Plant and Industrial Fuel Use Act of 1978 reflect the judgement of the President and the Congress that the Federal Government should encourage and foster the use of coal [22]. The increased demand resulting from the 1978 act would be felt most strongly in the years between 1985 and 1990. The Department, in considering the need for leasing, must plan for the often considerable delay between the time when a

mining company acquires a coal reserve and the time when production begins. Designing a mine plan, assembling equipment and constructing the mine, and studying and designing modifications required to comply with state and Federal laws takes from four to seven years. In some cases, production from new leases may not begin for up to 10 years, which is the maximum delay between leasing and production allowed under the Federal Coal Leasing Amendments Act of 1976.

Because of these time requirements, a leasing program which results in some lease sales in 1980 could not be relied on to have a significant impact on production until after 1985. Existing leases provide an alternative to new leases as a source of coal to meet demand for 1985, because on these leases mining companies can begin now the technical and economic work required to develop production capacity. The consequences of this planning are reflected in production plans reported by those companies (see Table 2-22). Industry plans for development of existing leases and of non-Federal reserves help account for the generally low level of new leasing assessed by the Department's studies as needed to meet 1985 production targets.

To aid in considering alternative programs to implement the President's directive that Federal coal leasing be a tool to help achieve coal production objectives, the Secretary has directed that the Department's Federal coal policy review include an analysis of the demand for Federal coal, and a review of the probable production from existing leases. As was explained, analysis of potential production and analysis of probable demand can not be done with precision because of uncertainties and variables within both the broader economy and the coal industry.

Almost all demand forecasts, however, point to significant increases in the use of coal, with both demand and production increasing at a faster rate in the western United States than in other areas. Such forecasts are reinforced by recent experience. The rate of growth in production of coal in the western states (see Table 2-7) has increased suddenly and substantially over production growth rates in the midwestern and eastern coal fields during the past few years. The rate of growth for production of coal from Federal leases, due in part to diligence requirements, is even higher than the overall western increase, making Federal reserves

the most rapidly growing source of coal in the Nation.

After 1986, however, the Nation would not be able to count on significant additional production from existing Federal leases. The Department's diligent development regulations under the Federal Coal Leasing Amendments Act of 1976 require that pre-existing leases not in production by 1986 be cancelled, with a few possible exceptions. This means that the presently existing leases not in production by 1986 will revert to Federal ownership, and again become part of the general body of unleased Federally-owned coal reserves.

Because actions taken by the Department now will affect the potential for production of Federal coal in 1990 and beyond, the Department must consider present actions in terms of these uncertain future demands. It is clear that, to whatever degree existing Federal coal leases must be considered as an alternative to new leasing in meeting coal production needs, this alternative, already made uncertain by the environmental and economic weaknesses of earlier leasing, virtually disappears when the Department meets its responsibilities to both enforce diligent development and to recognize that today's resource management decisions would determine how much coal is available for production in 1986 and years after.

Currently planned coal production appears likely to be sufficient to meet most 1985 projected needs in the West. However, there is not much additional capacity to meet the considerably larger 1990 expected coal requirements. Unless the DOE low projections for 1990 turn out to be the correct ones, and the DOE medium or high projections for 1985 are met in 1985, a substantial expansion in western coal production would occur between 1985 and 1990.

Because of the dominant Federal share in western coal ownership, it is natural to expect that Federal coal would play a major role in expanding western coal production between 1985 and 1990. As noted, the enforcement of diligent development requirements would mean that, aside from expansions in already operating mines, increases in production of Federal coal after 1986 will have to come from new Federal leases. Because of the substantial time lag between the decision to hold a lease sale and actual coal production, Federal leases expected to come into production from 1986 to 1990 should be issued soon.

It is true that a resumption of significant Federal leasing in the near future runs the risk that, if low 1990 production projections are borne out, there would be more coal under lease than could be developed. However, the Nation's energy and coal leasing policies cannot be predicated on the assumption that future western coal production would be lower than is currently considered likely. The time lags between the decision to lease and the occurrence of actual production are such that an assumption of this nature could well be self-fulfilling.

Besides helping to meet national energy objectives, new Federal leasing is needed to ensure that future western coal development is carried out as efficiently and with as little damage to the physical and human environment as possible. Because of the large Federal ownership of western coal, a major expansion of western production without the availability of Federal coal, even if it were possible, would result in a distorted pattern of coal development, almost certainly a less efficient and environmentally satisfactory one. In many cases, the key consideration in mine site selection would become the ability to avoid the need for Federal coal, rather than the basic economic and environmental desirability of the site.

In many areas, patterns of land and mineral ownership caused by early settlement policies have created a complex division of ownership and jurisdiction, with tracts of Federal coal interspersed with private, state, and Indian coal. Because individual tracts are often not large enough to justify investments, development opportunities for non-Federal coal in many of these areas would be limited unless adjacent Federal coal could also be mined. These ownership patterns add to the uncertainties about production potentials, because theoretical production of much non-Federal coal may not in fact be achievable without development of Federal coal and, conversely, a decision favoring the leasing and development of specific amounts of Federal coal may in fact lead to production of greater non-Federal reserves.

In addition to the planning and resource management requirements of the Federal Coal Leasing Amendments Act of 1976, future management decisions about Federal coal would be governed by the Federal Land Policy and Management Act of 1976 and the Surface Mining Control

and Reclamation Act of 1977. These acts, in combination, create a management and regulatory framework which provides detailed requirements for determining where, and under what circumstances, Federal coal may be leased and mined. Taken as a whole, these laws and related regulations require that the Department of the Interior's decisions about the management of Federal coal reserves conform to, and be integrated with, a broader public land planning and resource management process. The overall planning process considers all Federally-managed resources, and the interests of institutions and people who use the resources or are affected by resource use decisions.

Consideration of these other resources and interests has the effect of placing prohibitions or limitations, some mandatory and some discretionary, on the production of Federal coal. These limitations, designed to protect human communities, agricultural resources, private property rights, wildlife, natural habitats, recreation areas, and diverse other resources and resource uses, are reasonable and flexible enough to assure that Federal coal can, in fact, be produced while the other interests are protected. Most of the protective standards and procedures were put in place within the last two years or less, long after almost all existing Federal coal leases were issued.

This means that all future leasing must not only conform to, but be a product of, a planning and regulatory process designed to be protective of the environment and of other resources and interests. Coal production decisions resulting from this process would be made in compliance with agreed-on land use planning and environmental protection requirements. However, there is no such assurance that past Federal leasing decisions made prior to the adoption of these new standards would, if the leases were produced, meet the planning and environmental requirements.

Hence, the Department, in trying to assess the potential of existing leases to serve as an alternative to unleased Federal coal in meeting future demand, must assign more uncertainty to production potential from existing leases than would be assigned to new leases. It is clear that, from an environmental standpoint, existing leases cannot be presumed to be a preferable alternative to prospective new leases. Neither, of course, can the Department assume that existing leases would fail to meet present environmental standards. To

measure the possible contribution of coal from existing leases toward future energy needs, the Department must receive and review specific lease development proposals, determine if the proposed mines could be operated in conformance with present standards, and forecast the production from existing leases to compare that, and other expected production, with predicted demand for coal. A similar but, in many cases, less comprehensive analysis by state and Federal agencies would precede decisions allowing production of coal from non-Federal reserves. As in the case of already-leased Federal reserves, the Department cannot assume that the production of non-Federal coal would cause less (or more) environmental damage than would be caused by development of new Federal leases.

The decision before the Secretary at this time is whether to adopt the preferred Federal coal management program, or an alternative, as described in this programmatic environmental impact statement, which would be capable of considering specific leasing options, as a part of the Department's responsibility for management of Federal coal resources, within a process which assures that both the need for and environmental impacts of such leasing options are adequately considered prior to a decision to hold lease sales.

Should the Secretary adopt such a program, the need for leasing would be continually assessed through an open, publicly accountable process which compares likely production to likely demand, determines where and when production may fall short of demand, and decides how much Federal coal should, within the limitations of resource management and environmental standards, be leased to assure production sufficient to meet demand. Evaluation of demand would include the use of the best available techniques for analysis of energy use. Evaluation of anticipated production would include all information available to the Department about the production plans for Federal and non-Federal coal reserves.

Such a process would assure that individual proposals for specific coal leasing would be reviewed to determine their consistency with the coal production objectives of the coal management program. While such an assessment at this time shows that some new leasing should be considered now, and that the need for leasing would increase significantly in a few years if coal production

forecasts for 1990 are to be achieved, the need to operate a Federal coal management program does not rest on the current assessment of future coal supply and demand. Forecasts of energy consumption and of available energy sources are based on assumptions which are subject to change. Discovery of additional or alternative energy sources, advances in technology, successes in energy conservation programs, variations in the rate of growth of electric power use, and many other factors could cause coal demand forecasts to be significantly revised, up or down. Sound long run government policy must acknowledge this uncertainty, and not assume that today's forecasts must inflexibly govern resource production decisions of the future.

The Federal coal management program described in Chapter 3 is capable of such flexibility. The process of analysis and review, which incorporates sound land use planning and environmental protection with the identification of those coal reserves most suitable for development, provides both industry and the Department sufficient opportunity to plan for increases in coal demand. Should demand be significantly lower than was projected, diligent development regulations would assure that leases not put into production are returned to Federal ownership. Moreover, regular biennial reassessments of leasing needs as proposed in the preferred program and several other alternatives would allow frequent adjustments in the amount of Federal coal under lease in response to these needs. Any under-leasing or over leasing which results from erroneous facts or assumptions would be compensated by more or less leasing in the next reassessment cycle. And, as the amount of Federal coal under lease increases or decreases in response to local, regional, and national demand for coal, the preferred program would assure that both site-specific and cumulative environmental impacts of Federal coal production are adequately considered.

As important as the consideration of any particular leasing options is the need for the Department to put a coal management program into operation, so decisions about the management of Federal coal can be incorporated into the land use planning systems of the Bureau of Land Management and Forest Service. Just as decisions about Federal coal can not be wisely made in isolation from decisions about wildlife manage-

ment, grasslands, water, community development, and the many other resource management issues which must be considered by the Department, so those other decisions cannot be responsibly made in isolation from consideration of how Federal coal would be managed. As previously noted, these management decisions concern many other actions besides competitive coal leasing. They include decisions on administration of existing leases; the issuance of PRLAs; and the readjustment, relinquishment, cancellation, termination, assignment, and any other transfer of leases.

The preferred coal management program described in this programmatic environmental impact statement, while largely the product of intensive development during the past 18 months, has been in the preparation and review stage for five years. The operation of a complex program designed to integrate Federal coal management decisions with other Federal, state, and local resource decisions is not a simple matter. If the Nation is to be assured of meeting its future energy objectives in the most efficient and environmentally satisfactory way possible, a program for the management of the Federal coal resource is essential.

THE PREFERRED FEDERAL COAL MANAGEMENT PROGRAM AND ALTERNATIVES

The National Environmental Policy Act of 1969 requires the preparation of an environmental impact statement on "any major Federal action significantly affecting the quality of the human environment". A principal task of the one and a half year old interagency Federal coal policy review has been the selection of the proposed action for this programmatic environmental impact statement. A series of issue option papers was prepared on the alternatives and subalternatives which would affect the substance and procedures of a Federal coal management program. Preferences for specific policy options among those presented in the issue option papers were expressed by the Secretary of the Interior or the Under Secretary between October 1977 and March 1979. The procedures followed in the coal policy review to determine the policy option preferences are described in Section 3.2.1 and the various options presented to the Secretary and Under Secretary, the pros and cons associated with each option, and the preferences expressed by the Secretary or Under Secretary are summarized in Table 3-2 accompanying Section 3.2.1. These numerous policy option preferences have been integrated into a complete proposed Federal coal management program which is the proposed major Federal action in this statement. This proposed program, composed of the preferred policy options, is termed the preferred program and is presented in Section 3.1.1 and discussed in greater detail in Section 3.2.

The principal policy options not preferred by the Secretary form the six major alternatives to the preferred program:

- No new Federal leasing until at least 1985.
- Process and lease only outstanding preference right lease applications.
- Lease only bypass coal and coal needed to maintain existing operations (emergency leasing).

- Lease to meet the coal industry's indications of need.
- Allow state determination of leasing levels.
- Lease to meet Department of Energy coal production goals. Other policy options not preferred by the Secretary form the major subalternatives analyzed in Chapter 5, Section 5.4.

Each alternative focuses on a different administrative and policy limitation on the determination of the level of Federal coal leasing to be achieved. They were selected to bracket the range of leasing activity that could result from a Federal coal management program. Because of the stringent statutory and policy restrictions under which the Federal coal policy review is being conducted, any alternative to the preferred program which might be adopted would be similar in most of its details to the structure described for the preferred program. Some of the alternatives would remove certain components of the preferred program (i.e., eliminate new competitive leasing fully for the first two alternatives and effectively for the third alternative), while others would merely shift the responsibility, in whole or in part, for the final decision on how much and which coal will be offered for lease sale (from the Department to the industry in the fourth alternative, to the states in the fifth alternative, and to the Department of Energy in the sixth alternative). Various alternatives also differ from the preferred program in the sequence of, and extent of data required for, decisions in a coal management program. Each of the alternatives is described in Sections 3.1.2 through 3.1.7. Other alternatives not analyzed in this statement and the reasons for excluding them are briefly discussed in Section 3.1.8. The descriptions of the six major alternatives are not as detailed as the description of the preferred program since, as previously noted, most of the components of the preferred program would be incorporated in the various alternatives. The more

detailed description of the preferred program in Section 3.2 contains an explanation of which components of the preferred program are compatible or incompatible with the other major alternatives.

In order to accommodate the reader with a complete visualization of the Federal coal management program, and provide insights on Departmental policy and planning, this document provides in Appendix A, the proposed regulations for that program. If the Secretary upon review of this statement, decides that a program is needed, and actually selects a Federal coal management program that reflects his earlier policy preferences (i.e., preference for the preferred program); then the later regulations that were officially proposed on March 19, 1979 (44 Federal Register 16800-16845) would govern the operation of that program. Both the detailed discussion of the preferred program in Section 3.2 and the proposed regulations in Appendix A should permit the reader to make more specific the comments he or she may wish to offer on this statement and the proposed action. All comments received by the Department on this statement will be considered in the selection by the Secretary of the coal management program the Department will establish and the development of the program's final regulations.

Adoption of any one of these alternatives as the new Federal coal management program would likely result in coal leasing, coal production, and coal-related development activity levels for each coal region different from those which would occur under the preferred program. Taken together, the preferred program and the six major alternatives are intended to cover a full range of coal leasing, coal production, and coal-related development possibilities. The estimated levels of leasing, production, and development which would result from these alternatives are presented in Chapter 5 of this statement and are the basis of that chapter's assessment of the environmental impacts from coal development under each alternative. Chapter 5, Section 5.4 also discusses the impacts of the series of subalternatives which, if adopted, could be incorporated into one or more of the major alternatives.

3.1. DESCRIPTION OF THE ALTERNATIVES

In this section, the preferred program and other alternatives are described.

3.1.1. The Preferred Program

At the outset of the Federal coal policy review, the Secretary established four primary goals the Department must meet for management of the Federal coal resource. These primary goals are:

- Employ land-use planning and effective enforcement of environmental laws to assure that Federal coal is committed to production and produced in an environmentally acceptable manner which is responsive to local communities and land owners affected by Federal coal development.
- Assure that sufficient quantities of Federal coal are produced to help meet the objectives of the National Energy Plan.
- Assure that Federal coal is produced in an economically efficient manner, with a fair economic return to the United States for all coal produced.
- Emphasize consultation and cooperation with state governments in planning the leasing and development of Federal coal.

The preferred Federal coal management program would incorporate these goals; the expressions of preference for certain policy options by the Secretary and Under Secretary; the requirements of the appropriate statutes, principally the Mineral Leasing Act of 1920, the Federal Coal Leasing Amendments Act of 1976, the National Environmental Policy Act of 1969, the Federal Land Policy and Management Act of 1976, and the Surface Mining Control and Reclamation Act of 1977; and the direction provided by the President in his 1977 Energy and Environmental Messages to the Congress.

The preferred program includes eight major elements:

- A planning system, involving close consultation with state and local governments, industry, and the public (1) to decide which areas of Federal coal reserves would be considered acceptable locations for coal production, and (2) to delineate, rank, and select for sale specific tracts of coal.

- A system for evaluating the national demand for coal and for determining production which should be stimulated by the leasing of Federal coal.
- Procedures for conducting sales and issuing leases.
- Post-lease enforcement of terms and conditions.
- Procedures for management of existing leases issued prior to implementation of the new program.
- Procedures for processing existing preference right lease applications.
- A strategy to integrate the environmental analysis requirements of the National Environmental Policy Act of 1969 in the new program.
- Procedures to start-up the new program and to offer lease sales in emergency situations.

Set forth below is a general overview of the eight major elements of the preferred alternative for a Federal coal management program. Figure 3-1 displays a simple flow chart for the preferred alternative.

The draft version of this statement published on December 15, 1978, contained in its Appendix A a set of example regulations for the preferred program. The example regulations were meant to indicate to the reader what type of regulations the Department might propose if the Secretary, after reviewing this final statement, were to select the preferred program. Example regulations were provided in order to respond to one of the principal public and judicial criticisms of the 1975 final environmental impact statement for the last proposed Federal coal management program (see Sections 1.2.4 and 1.2.6), namely, that the preferred program was not adequately described.

Simultaneous with the publication of the draft version of this statement, the Department gave notice of intent to propose rules (43 Federal Register 58776). The example regulations were modified after review of the testimony and written comments received on the draft statement and were published as proposed rules on March 19, 1979 (44 Federal Register 16800-16845). By scheduling the proposed rulemaking between the publication dates for the draft and final environmental impact statements, the Department sought to provide the public with sufficient time to comment

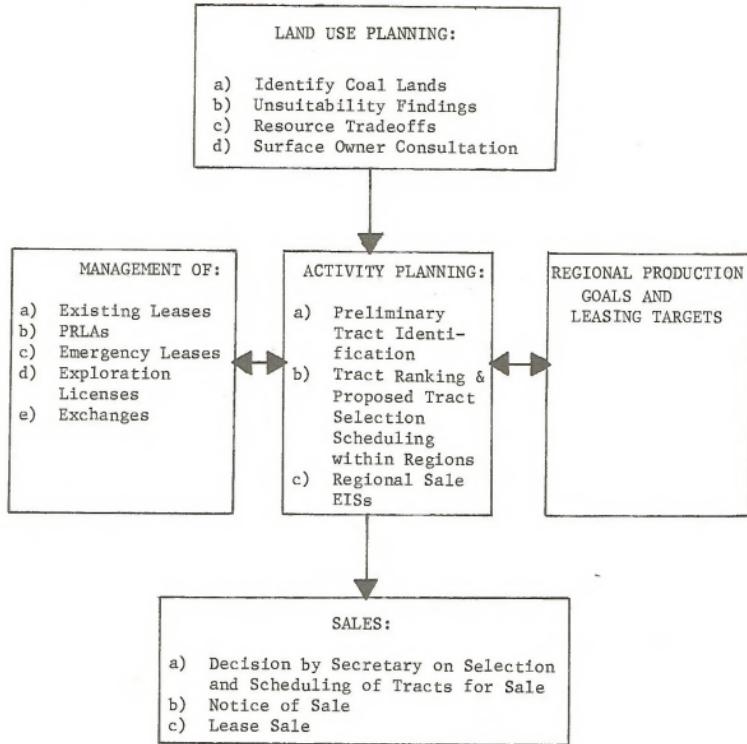

on the proposed rules without the burden of being asked to address simultaneously the varied issues discussed in either the draft or final statement. The lengthy overview of the preferred program in this section, the more detailed discussion of certain aspects of the program in Section 3.2, and the proposed rules set forth in Appendix A should provide the reader with a complete picture of how the preferred program would operate.

For a similarly detailed understanding of all the Department's coal-related activities, the reader may wish to review the regulations of the United States Geological Survey under 30 CFR Part 211, as revised by rulemaking published in 43 Federal Register 37181-37196 on August 22, 1978; the final regulations of the Office of Surface Mining Reclamation and Enforcement under 30 CFR Chapter VII published in 44 Federal Register 14902-15463 on March 13, 1979, and proposed planning regulations for the Bureau of Land Management under 43 CFR Part 1600 published in 43 Federal Register 58764-58774 on December 15, 1978. Finally, the reader may also wish to consult the Forest Service's proposed planning regulations under 36 CFR 219 published in 43 Federal Register 39046-39059 on August 31, 1978.

3.1.1.1 Planning Systems. In the preferred program, the Department would rely on the land management agencies' land use planning processes and the Bureau of Land Management's activity planning process to provide the initial forums for the making of the principal decisions in the Federal coal management program. Activity planning would then take place through an entirely new structure.

Land Use Planning. The critical decision during the land use planning process of the land management agencies (principally the Bureau of Land Management and the Forest Service) would be, under the preferred program, the identification of areas acceptable for further consideration for coal leasing. The areas acceptable would be identified by screening out areas that:

- Are considered not to contain coal reserves of high to moderate development potential.
- Are considered unsuitable for leasing under the provisions of Section 522 of the Surface Mining Control and Reclamation Act (SMCRA) and the President's Environment-

(See Figures 3-2, 3-4 and 3-5 for more detailed presentations of the preferred program.)

FIGURE 3-1
SUMMARY OF THE PREFERRED PROGRAM

- tal Message through the application of lands unsuitability criteria.
- Are considered to be of higher value for other uses as determined by multiple-use, resource management trade-off decisions.
- Include split estate lands where the coal would be recovered by surface mining methods and a significant number of surface owners (as defined in SMCRA) have indicated a preference against surface mining of their land, except in the rare case in activity planning where the Bureau of Land Management determines that no other areas acceptable for further consideration for coal leasing could produce sufficient tracts for lease sale to meet the regional leasing target. The Department is also considering a procedure which would permit an individual surface owner to remove his particular land from further consideration for leasing by means of expressing a firm intent not to provide consent to mine during the lifetime of the land use plan (up to 15 years).

The land use plan could also limit development levels or rates within the areas identified as acceptable for further consideration for coal leasing. This use of development levels or rates is called the threshold concept; it would be an integral part of the land use planning process. As examples of the manner in which this concept could be employed, in acceptable areas a maximum threshold for mining employment might be established in response to state government requests for planning to affect community growth rates, or a minimum threshold on the area of habitat for a particular wildlife specie might be established for resource conservation reasons. Then, the Federal land manager or the responsible official would not lease coal if the additional development could be expected to push total mine employment in the area over, or the total area of the particular species' habitat under, the specified threshold levels. Thresholds would be used to control impacts which depend on an overall development level rather than on site-specific effects.

All potential resource users would be invited and expected to participate actively in the land use planning process. Each potential user — whether a coal company, a livestock operator, or an environ-

mental organization — should voice its opinion concerning the uses to which the land should be put and should provide sufficient information to support that opinion. The land use planning process provides numerous opportunities for such participation. The expertise of, and information available to, the potential users is needed by the land management agency to ensure that an adequate land use plan is prepared. For example, coal company data may show coal which can be regarded as high or medium potential of which the land use planner is not aware; an environmental organization may know of a situation, not disclosed in the planning data, which requires the application of an unsuitability criterion; or the coal company may be able to demonstrate conditions or potential mining techniques, not known to the planner, which qualify for an exception to the application of an unsuitability criterion.

Activity Planning. Activity planning for each Federal resource — coal, timber, forage, etc. — in the planning area follows completion of the land use plan. Under the preferred program, coal resource activity planning would be conducted by the Bureau of Land Management and would involve the delineation, ranking, selection, and scheduling of tracts for lease sale from the land identified in the land use plan as areas acceptable for further consideration for leasing.

The first step in activity planning would be to delineate preliminary tracts from within the acceptable areas. Delineation efforts could take place beginning about 30 to 60 days after a land use plan is filed. The boundaries of the preliminary tracts would be drawn primarily on considerations of technical coal data, resource conservation considerations, and surface ownership patterns. Readjustments of boundaries to reflect environmental or social considerations would occur as the tract ranking and selection process proceeds.

Before tracts are delineated, the Bureau of Land Management would publish a call for submissions by industry of expressions of interest in leasing possible tracts. In addition to the request for industry expressions of leasing interest, the states would be encouraged to suggest possible tracts, particularly tracts of importance to the leasing of state-owned coal. These submittals would be the critical element in the decisions on delineation and subsequent ranking of tracts, since

the interest of companies or the states in those areas would normally reflect important data collected by both parties and market judgements by the companies.

Once the land management agency has identified preliminary tracts, it would begin analyzing the potential environmental impacts and geology related to each tract. The agency would work closely with other Federal agencies, state and local governments, and other interested parties during this process.

All three of the above steps - submission of expressions of leasing interest, tract delineation, and site-specific analysis - are designed to follow the completion of individual land use plans and to be conducted in the land use plan areas. The following steps are designed to precede the setting of a four-year lease sale schedule and to be conducted in multistate regions.

As the next section discloses, the Department has divided the country into coal regions to develop regional leasing targets. In cooperation with all involved land management agencies and the affected state and local governments, the Department would rank all delineated Federal coal tracts within a production region. Generally, ranking would take place every four years. Selected from these ranked tracts would be those tracts to be included in a proposed four-year lease sale schedule. The number of tracts selected and the proposed timing of their sale would be determined by considering the leasing target for the region established by the Department. Should the regional leasing target appear to exceed greatly the producible coal in the more highly ranked Federal tracts, the target itself could be reevaluated and modified. The tract delineation, ranking, and selection decision would be discussed in an environmental impact statement which would consider the site specific impacts and cumulative regional impacts which would ultimately result from the sale of leases for all the selected tracts in the region over the four-year period.

The participation of state and local governments would be sought actively during the tract ranking and selection process, particularly to ensure consideration of social and economic impacts and problems associated with potential coal development. State participation would be ensured by the establishment of regional coal teams composed of BLM personnel and state

governors' representatives to oversee the tract ranking process, to conduct the tract selection and scheduling procedures, and to make the lease sale recommendations to the Secretary. The public would also participate in this process. Regardless of any additional public participation procedures which may be employed, public hearings would be held on the environmental impact statement prepared on the regional tract delineation, ranking, selection, and scheduling process.

From among the tracts selected for lease sale, the Secretary would designate, where appropriate, specific tracts to be offered for sale only to small businesses and to public bodies (Federal and state agencies, municipalities, and rural electric cooperatives and similar organizations, and nonprofit corporations controlled by any of those entities). The decision on these two types of set-aside sales would be made after the Secretary reviews the information provided by public bodies through submissions of expressions of interest in the activity planning process and consults with the Small Business Administration.

Stipulations would be attached to the proposed leases for the tracts selected for lease sale to mitigate adverse environmental and social impacts. These stipulations would incorporate measures which the Department considers necessary as a result of the general environmental analyses conducted in the land use planning and site-specific activity planning processes. It is expected that many of these stipulations would be based on the application of the unsuitability criteria and their exceptions. The leases would also require compliance with the Surface Mining Control and Reclamation Act of 1977.

No tract of Federal coal which includes a surface estate owned by a private surface owner as defined in SMCRA and which, if leased, would be mined by surface mining methods would be offered for lease sale unless that owner has given his or her consent to mine. It would also be removed from any activity planning procedures until the governing land use plan is revised if the surface owner files with the local BLM office a written notice of refusal to give consent.

Before making a final decision on which, if any, tracts to offer for lease sale, the Secretary would formally consult with the governors of states in which tracts are being proposed for sale. Should a governor object to the offering of any proposed

tract within his state, he would be given a period of time in which to prepare and present his arguments to the Secretary.

3.1.1.2 Production Goals and Leasing Targets. The major coal bearing areas of the country have been divided into 12 coal regions. Eight of these regions contain significant reserves of Federal coal and the six westernmost of these regions are expected to play the principal role in any Federal coal leasing scenario. In the preferred Federal coal management program, each region would be managed largely as a separate coal production unit with many of the management responsibilities delegated to regional Department/state teams. Within each of these eight regions, a total regional production goal and, based on an assessment of new leasing needs, a regional leasing target for new logical mining units containing Federal coal leases would be formulated.

Regional production goals and leasing targets would be derived every two years through the following procedure:

1. The Department of Energy would circulate proposed national and regional production goals.
2. The Secretary would provide DOE with his comments, emphasizing possible conflicts between the proposed goals and the Interior Department's missions.
3. The Department of Energy would promulgate its final regional production goals.
4. The regional Department/state coal teams established for activity planning would recommend to the Secretary adjustments to the goals and possible preliminary regional leasing targets after receiving public comments from within their respective regions.
5. On the basis of the teams' recommendations and other information and comments available to the Department and with consideration for the missions of the Department, the Secretary would adjust the DOE goals as necessary and adopt the adjusted goals for the long-term planning guidance of the Department and for the use of states and other agencies. He also would propose the four-year regional leasing targets to be used by the regional coal teams in the formulation or revision of a schedule of sales. (Each schedule would be set for four-years with a revision considered during the second year of its term.)

6. The Secretary would publish his determinations and request comments from the public. He also would consult with the governor of each state to acquire his views of appropriate leasing target levels for the state and region.

7. Finally, on the basis of the comments he receives, the Secretary would adopt regional leasing targets, expressed as tonnages of coal reserves, for the guidance of the regional coal teams. These targets would be made available to the regional coal teams at about the time they begin their task of selecting tracts to propose to the Secretary for lease sale.

In developing its four-year lease sale proposal, a regional coal team may propose a lease sale schedule that does not meet the regional leasing target, but at least one of their alternative schedules should be for the Secretary's regional leasing target. Any recommended divergence from a regional leasing target would not become official unless and until the Secretary formally accepts the recommendation at the time he decides on the lease sale schedule for that region (after completion of the regional lease sale environmental impact statement). Thus, the process of adopting production goals and establishing leasing targets would include consideration of the full range of Federal land management responsibilities and applicable statutory requirements and policies of the states. In considering new regional production goals and leasing targets, the Department would review the analyses in this programmatic environmental impact statement (updated when necessary) and any post-programmatic lease sale environmental impact statements for each region. It would also assess the success of the previous tract delineation, ranking, and selection process in each region; industry surveys; and information developed by other institutions and organizations.

Although the final regional production goals adopted by the Secretary would not be used directly in making Federal leasing decisions during the tract selection process, these regional goals would guide both the Federal and state governments in setting data gathering and planning priorities. These priorities would be established to ensure that a sufficient number of tracts are delineated and enough site-specific information is generated to make the regional tract ranking and selection process workable and to enable the

Department to meet the regional leasing targets derived from those production goals.

The analysis completed on the tracts available but not selected in the previous ranking and selection process for the regions would assist the Department in projecting cumulative impacts of future lease sales. These impacts could then be considered when the Department again considers regional leasing targets. Using this process, the setting of regional leasing targets would supply guidance to the tract ranking and selection process which, in turn, would supply guidance for the next update of the targets.

3.1.1.3 Lease Sales. Each tract selected by the Secretary for lease sale would be analyzed to determine the appropriate fair market value of the coal and the maximum economic recovery requirements. Comments on the fair market value and maximum economic recovery would be taken before the sale.

The method for conducting the sales could vary from sale to sale. One of the main sale differences would be between single tract and intertract sales. In intertract sales, more tracts are offered for sale than would be awarded. The intertract sale is designed to encourage competition over all the tracts when competition for each tract viewed individually may be lacking. At a minimum, this form of sale would be employed for sales involving tracts which would be mined by surface mining methods and which contain a surface estate owned by a surface owner as defined by SMCRA who gave nontransferable consent to mine prior to the enactment of SMCRA.

The responsibility for promulgating regulations concerning the bidding systems to be employed in lease sales belongs to the Department of Energy. In no case would bids for less than fair market value be accepted.

Particular tracts may have been set aside in activity planning for public body or small business special lease sale opportunities. These tracts would be sold in separate sales with only qualified public body and small business firms permitted to bid. In these set-aside lease sales, no bids for less than fair market value would be accepted and no special variation in calculating fair market value would be used. Set aside tracts on which no successful bids are received would be released for the subsequent general sale, if one is scheduled.

The Attorney General would review all successful high bidders for antitrust implications before the leases could be issued. Each lease issued would contain provisions in accordance with regulations promulgated by the Department of Energy to ensure diligent development of the coal and continued operation of the mine.

3.1.1.4 Post-Lease Enforcement of Terms and Conditions. After a lease has been issued, the Office of Surface Mining Reclamation and Enforcement, or, if a cooperative agreement has been signed with the state, the appropriate state agency, would largely be responsible for enforcing the environmental stipulations set forth in the lease and in the mining permit. The mining permit would have to be issued to the lessee jointly by the state agency and the Department of the Interior before mining operations begin. To obtain the permit, the lessee would be required to have a mining plan approved by the Secretary. The lessee would have to file bonds both to ensure that certain financial commitments to the Federal Government are met and to cover the cost of reclamation by the Federal land management agency should the lessee fail to meet all his reclamation requirements. The general post-lease program is discussed in the Final Environmental Statement for the Permanent Regulatory Program under SMCRA [1] and set forth in the permanent regulations of the Office of Surface Mining Reclamation and Enforcement (44 Federal Register 14902-15463, March 9, 1979).

3.1.1.5 Management of Existing Leases. The Department would apply the same land use planning and unsuitability standards to existing nonproducing leases as would be applied to new leases. Such application would respect valid existing rights and substantial financial and legal commitments and other exemptions in SMCRA and other laws. Criteria would be applied to nonproducing existing leases during land use planning. If, however, criteria have not been applied to a nonproducing existing lease prior to submission of a mine plan, they would be applied directly to the lease tract in the mine plan review process.

Under this approach, except where land use planning is conducted, leases on which there is no attempt to achieve production would lapse for failure to meet diligence requirements without the application of criteria. When a mining plan is submitted, the Department would review both

whether the plan is consistent with the reclamation standards of SMCRA and whether coal development is consistent with current planning and unsuitability requirements and stipulations.

Should the review indicate no major problems, the Department would process the mining plan under normal procedures. If major problems exist, however, the Department would seek to work them out with the lessee or reject the mining plan for failure to comply with SMCRA.

Finally, as part of the process of determining the need for new leasing, and in setting the regional production goals and leasing targets, the Department has evaluated, and would continue to evaluate, the production potential from existing producing and nonproducing leases. This evaluation, however, is not as detailed as, nor can it substitute for, the mining plan review for consistency with current planning and unsuitability requirements and reclamation standards.

3.1.1.6 Processing of Preference Right Lease Applications. As with existing leases, the Department would adopt a policy of applying to preference right lease applications the same unsuitability and planning requirements as those applied to new leases. The Department would integrate the determination of consistency with current requirements in the process for determining lease entitlement in which the applicant must show the existence of commercial quantities of coal.

Needed environmental stipulations would be derived after the applicant submits the initial commercial quantities showing. If the final commercial quantities showing is then successfully made, the Department would issue the lease. If not, the application would be rejected.

3.1.1.7 Meeting the Requirements of the National Environmental Policy Act. A regional environmental impact statement would be prepared on a four-year schedule of lease sales in each coal production region shown in Figure 1-1 for which sales of Federal coal are projected. Each regional lease sale statement would include analysis of both the site-specific and intraregional cumulative impacts of the proposed leasing actions. Additionally, mine plan reviews, coal lease exchanges, and other Federal coal management actions might be included where timely and appropriate. The regional leasing target, the tract delineation and ranking process, the proposed selection of tracts to be

leased, and the proposed lease sale schedule would be discussed and analyzed. The tract rankings and sales schedule would be reconsidered two years later when the next biennial process of establishing new regional production goals and leasing targets is completed. If, during this reconsideration in any region, substantial differences are found in tract ranking (because of the preparation of additional land use plans or changed environmental, social, or economic conditions) or if there is a new regional leasing target requiring a major change in the tracts proposed for sale, a two-year supplement to the regional lease sale statement would be prepared. At the time of the second consecutive biennial consideration of regional leasing targets and ranking of tracts, new four-year regional lease sale environmental impact statements would be prepared.

National and interregional impacts of the Federal coal management program are analyzed in this programmatic environmental impact statement. The document would be updated when conditions change sufficiently to require new analyses of those impacts.

It is expected that additional environmental impact statements would also be prepared on the individual land use plans of the Bureau of Land Management and Forest Service. As each land use plan addresses all public land resources and uses, not just coal and coal development, the environmental impact statement on the plan would be comprehensive. Concerning coal, the statement would include an environmental impact analysis of any decision in the plan to identify lands as acceptable for further consideration for coal leasing, including the application of the unsuitability criteria and the resource trade-offs which led to the decision.

Presently, the Department is preparing environmental impact statements on eight regions with high coal development potential. These regions are considerably smaller than the coal regions for which the regional coal lease sale environmental impact statements would be prepared under the preferred program (compare Figures 1-1 and 1-2). These ongoing regional statements discuss mining plans for existing leases and related developments. They do not address any renewed competitive leasing which would result from the determination of a need for leasing under the preferred program. Where, however, the analyses in these regional

statements would be applicable to analyses needed in the new regional lease sale statements, they would be incorporated in the new statements.

3.1.1.8 Emergency Leasing and Start-up of the Program. Should any leasing be contemplated in the near future the entire program would be phased in gradually during the first few sales schedules. This phasing in would be necessitated by budgetary constraints and personnel ceilings. The principal differences between a mature program and start-up procedures would be that, first, the unsuitability criteria would be applied directly to lands which have already been found acceptable for further consideration for coal leasing in existing land use plans and, second, the regional lease sale environmental impact statements would not necessarily include a full four-year sales schedule.

Once the program is in full operation (which could be as early as 1985), situations might arise in which the full planning-through-sale cycle of decisionmaking could not respond quickly enough to avoid causing unfair losses for existing coal operations or the economies of certain locations. To meet these situations, an emergency leasing system, which would develop leases for sale individually, would be a component of the program. This system would use existing land use plans or land use analyses where appropriate and shorten greatly the activity planning stage. No tract, however, would be offered for lease sale under this system that had not been the subject of an environmental assessment, including the application of unsuitability criteria. Emergency lease applications would be considered in cases where Federal coal would be bypassed, where Federal coal is needed to continue existing production or meet existing contract requirements, where failure to lease Federal coal would create a hardship, or where Federal coal would be mined to gain access to other coal deposits. It is expected that the need for emergency leasing would diminish over time. Emergency leasing would not be permitted to substitute for the procedures required in the full preferred program decisionmaking cycle. Emergency applications which are not compatible with existing land use plans would be rejected.

3.1.2 No Federal Leasing

Under this alternative, no new Federal coal would be leased until at least 1985. All preference right lease applications would be rejected where cause for rejection exists, not processed during this period, exchanged for leases for other minerals, or purchased. There would be no leasing for bypass situations or to maintain existing operations. The supply of Federal coal available for development would consist of that coal already under lease, including coal which may have been previously leased under the consent agreement in *NRDC v. Hughes*.

Selection of this alternative implies that the government has decided that leasing is not needed within the planning horizon to 1985. The production under this alternative could reach the same levels as the preferred program or the alternative of leasing to meet DOE production goals since these programs could have outcomes of no leasing in one or more of the study regions.

Compared to the preferred program and other alternatives, the no leasing alternative would likely stimulate the largest number of proposals for development of existing leases for which no mining plans have been submitted. In each such proposal, and after the mining plan is filed, the leasehold would be examined in light of the lands unsuitability criteria. This examination would be carried out through the land use planning system in a fashion similar to that previously described for determining areas acceptable for further consideration for coal leasing. Those leases which are found unsuitable would be revoked using the appropriate, available legal tools. This alternative would also stimulate the largest number of proposals for development of non-Federal coal.

3.1.3 Process Outstanding Preference Right Lease Applications

Under this alternative, the Federal government would process preference right lease applications (PRLAs) and issue leases for those applications which meet the commercial quantities test. However, no other Federal leasing would occur until at least 1985.

Existing leases would be managed as described under the no leasing alternative. The PRLAs would be processed as rapidly as would be administratively feasible. If it were necessary to set

priorities in the processing of PRLAs, the following general guidelines would be applied:

- First, PRLAs in the least environmentally damaging areas.
- Second, PRLAs in areas where coal development needs are greatest as determined by a regional coal needs analysis.
- Third, PRLAs which have been on file for the longest period.

Choice of this alternative would require that those PRLAs in areas which are determined environmentally unacceptable, but which still meet the commercial quantities test (with proper environmental stipulations applied), would either have to be purchased or otherwise acquired (e.g., through lease exchanges permitted by statute).

As with the no leasing alternative, this alternative is not necessarily inconsistent with the preferred program or with the alternative of leasing to meet DOE production goals; leasing level targets under those alternatives could be met with coal from PRLAs.

The surface owner consent provisions of SMCRA do not apply to PRLAs. Environmental analysis to comply with NEPA could be done on a case-by-case basis.

3.1.4 Emergency Leasing

This alternative would provide for limited competitive leasing. Emergency leases would include the relatively small amounts of Federal coal which could be leased to avoid bypassing Federal coal or to maintain existing operations. Bypass situations arise where Federal coal occurs in small blocks which adjoin areas where mines are already operating and which, if not leased, are not likely to be mined at all. Leasing of PRLAs would be permitted only if they meet either the bypass or existing operations criteria. These limited leasing criteria would be similar to current criteria for short-term leasing under the modified order in *NRDC v. Hughes*. The maximum amount of bypass coal eligible for any single lease under this alternative would be that agreed to under the court order (i.e., five years of production at existing rates). Similarly, the maximum amount of coal that would be leased to maintain an existing operation would be defined by that order (eight years of production at existing rates). As with the two previous alternatives, this alternative precludes other new competitive Federal coal lease sales, at

least until 1985, with a review of the need for new leasing anticipated then. Existing leases would be managed as described under the no leasing alternative.

In specifying this alternative, the eligibility of existing operations to lease additional Federal coal to maintain production would have to be restricted. The restrictions decided on were that the mining operation must have been in existence at least five years and must not have previously obtained a new Federal lease in order to maintain the existing operations. This decision, however, will have to be reviewed if the Secretary elects this alternative. It should be noted that these restrictions in some respects are tighter than the comparable short-term leasing criteria under the *NRDC v. Hughes* order, wherein mines must only have been operating by September 1977 to be eligible to lease Federal coal on a short-term basis.

The surface owner consent provisions of Section 714 of SMCRA would apply and, where appropriate, lands unsuitability criteria and general planning analysis would be required. Site specific environmental analysis would be carried out separately and not included in any regional environmental impact statements.

3.1.5 Lease to Satisfy Industry's Indications of Need

This alternative is effectively the Energy Minerals Activity Recommendation System (EMARS II), as proposed by the Department in the September 19, 1975, final environmental impact statement on the Federal coal leasing program. Certain changes must be made to bring the program into compliance with the Federal Land Policy and Management Act of 1976, the Federal Coal Leasing Amendments Act of 1976, and the Surface Mining Control and Reclamation Act of 1977.

Under this alternative, during the early stages of land use planning industry would first be asked to nominate those tracts it is interested in leasing. At the same time, the public would be asked to indicate those areas where leasing should be restricted. Coal demand estimates formed from the sum of the industry nominations would serve as a development restriction. Such information would then be processed through the land management agencies' planning systems to determine whether the specific tracts are environmentally acceptable

and whether coal development represents an efficient and proper use of the land. Tracts which are judged acceptable would then be offered in a future lease sale. Each tract receiving a high bid equal to or above fair market value as determined by the Department would be leased to the high bidder.

Major differences between this alternative and the preferred program are that land use planning would not be required to precede tract delineation, regional environmental and socio-economic concerns would not weigh as heavily in the location of tracts for sale, and more leasing than needed by the market might take place because of speculative interest in leases.

Existing leases and PRLAs would be managed as described earlier. This alternative would also include procedures for emergency leasing of small tracts as described earlier. NEPA compliance could proceed as under the preferred program. The surface owner consent provisions of Section 714 of SMCRA would apply. Regional environmental impact statements would not be prepared, and the tracts would be analyzed in the environmental impact statements on land use plans.

3.1.6 State Determination of Leasing Levels

Under this alternative, the states would have the responsibility to determine the timing and extent of new Federal leasing. There are many procedural structures that could be used to implement this alternative. The states, rather than the Secretary with state consultation, could select and rank tracts from areas acceptable for further consideration for coal leasing as determined through the Federal land management agencies' land use planning systems. States would determine a lease sale schedule; thereafter, the appropriate BLM state office would conduct the sale. The states would have veto power over which leases would finally be issued.

A second possible structure would be to transfer all land use planning and environmental analysis functions to the appropriate state planning office. The Department would retain only the responsibility to conduct lease sales and to issue leases. Both structures would require Congressional action to amend the governing statutes, especially FLPMA and SMCRA.

Existing leases and PRLAs would be managed as described before, but the states could have a

final veto on the acceptability of any area for coal mining and could have responsibility for approval of mining plans for Federal coal. Furthermore, it is assumed that this alternative would include an emergency leasing component. States would be delegated the responsibility to obtain appropriate surface owner consents.

The Department chose this alternative and its variations for analytical purposes only. The alternative and its variations have not been formally requested by the states themselves, although they were consulted to assess the comparative impacts of the alternative. To conduct an environmental impact analysis of this alternative it was necessary to solicit statements of present preferences for leasing levels from the states. The Department requested each western state with substantial reserves of unleased Federal coal to specify what production levels it would like to see analyzed for 1985 and 1990. All but two states provided their own production levels to be used for the analytical purposes of this environmental impact statement. The State of Colorado chose to specify production levels equivalent to the DOE mid-level estimates. The State of Utah preferred not to specify any production levels and indicated that the DOE estimates for Utah are extremely suspect.

3.1.7 Lease to Meet DOE Production Goals

Under this alternative, DOE regional production goals would drive the tract selection system. DOE would select the regional leasing targets. Although the same amount of leasing might result from some of the previously described alternatives, this alternative would focus specifically on the DOE national production projections and would not allow for any adjustment in those projections. Areas acceptable for further consideration for coal leasing would be defined in the land use planning processes as described in the preferred program. New leasing needs in a region would be calculated by first estimating for a future period the difference between DOE production goals and currently committed coal production. Estimates would then be made of the amount of coal needed to fill potential production gaps that could be supplied from existing Federal leases and non-Federal coal. Estimates of the potential production from existing leases and non-Federal coal would take into account the application of unsuitability criteria to existing leases and the relative costs of mining both

sources of production. The remainder of the gap would then have to be met by coal production from new Federal leases.

Under this alternative, PRLAs would be processed as described under the preferred program. The amount of new competitive leasing planned for regions would be adjusted for the amount of reserves in PRLAs expected to be leased. The adjustment would take into account whether PRLA reserves were the least costly to mine, the type of coal needed, environmentally acceptable locations, and other factors.

This alternative would include an emergency leasing component. Environmental impact statements would be prepared as under the preferred program. The surface owner consent provisions of Section 714 of SMCRA would apply.

3.1.8 Other Alternatives Not Considered

The EMARS I proposal is not separately analyzed as an alternative in this statement. The basic principle of EMARS I, that coal development on Federal lands should stem from government interests, is a primary factor in the lease to meet DOE production goals alternative and in the preferred program, which relies on both coal need projections and ways to modify these projections in response to environmental, state government, and other concerns. Other EMARS I elements were either never articulated or superseded by subsequent legislative changes.

The alternative of development of Federal coal resources by the Federal government is not discussed in this statement. Although such an alternative was mentioned in the 1975 programmatic environmental impact statement, it is unlikely the Congress would approve legislation removing the responsibility for developing coal on Federal lands from the private sector. The alternative is unreasonable and does not need to be analyzed.

3.2. DETAILED DESCRIPTION OF CERTAIN COMPONENTS OF THE PREFERRED PROGRAM AND ITS DEVELOPMENT

This section provides a more detailed presentation of certain components of the preferred Federal coal management program. It also includes a discussion of the process of developing the preferred program and certain statutory require-

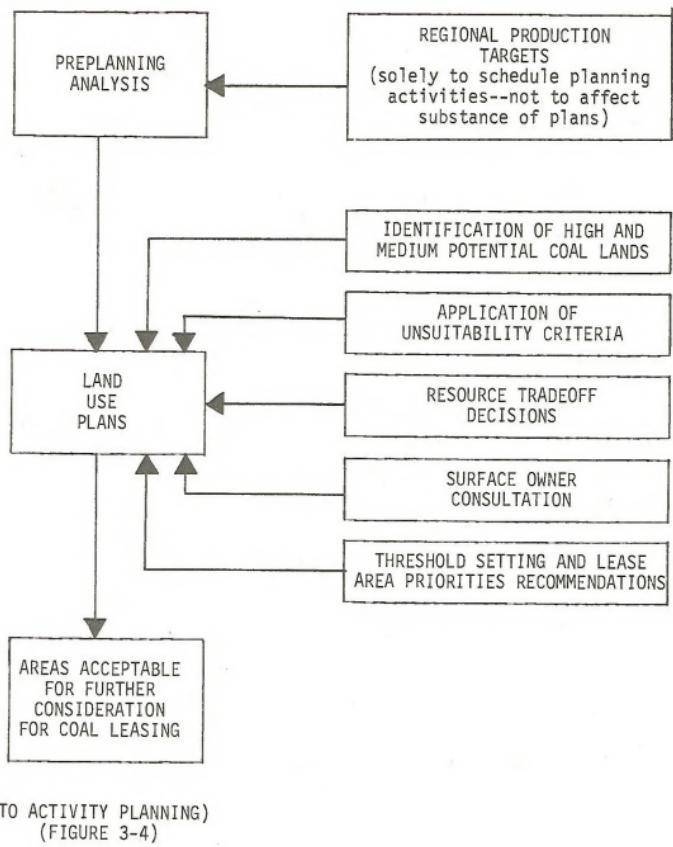

ments which have affected the program's design. Figures 3-2, 3-3 and 3-4 display fully the major steps in the preferred program.

Each discussion of a component of the preferred program in this section notes where the component is unique to the preferred program and where it is compatible with other alternatives.

3.2.1. Development of the Preferred Program

Shortly after assuming the post of Secretary of the Interior, Secretary Andrus requested a review of the status of Federal coal leasing, including the lack of new leasing, the 1975 proposed leasing program, the new statutory base for leasing, and the *NRDC v. Hughes* suit. The reviewers found that the 1975 program had been outdated by the new statutes and, furthermore, was not compatible with the policy objectives of the new Administration; that the plaintiffs' arguments in the law suit were likely to prevail; and that significant, new Federal leasing probably could not and, moreover, should not begin until a new Federal coal management program which complies with the law and meets Presidential and Departmental policy objectives is prepared and the need for renewed leasing is assessed.

Responding to these findings, the Secretary ordered a full-scale interagency coal policy review which, among other things, would assess the need for leasing and initiate the development of a new Federal coal management program. A review committee, composed of the Solicitor and Assistant Secretaries of the Department was formed. The Office of Coal Leasing, Planning, and Coordination was established at the Departmental level to coordinate the review. Three events in 1977 gave impetus to the review: the April 29 publication of the National Energy Plan which emphasized coal as the principal domestic fuel to reduce our dependence on imported oil and gas and called for a doubling of coal production by 1985; the President's May 23 Environmental Message to the Congress and May 24 Memorandum to the Secretary which called upon the Secretary to develop an environmentally sound coal management program; and the September 27 decision in *NRDC v. Hughes* enjoining the Department from engaging in major leasing activity until certain conditions were met (see Chapter I for a discussion of these events).

PREFERRED PROGRAM: SALES PROCEDURES

The process of selecting the preferred new Federal coal management program began in October 1977 and continued through March 1979. The first step in the process was the convening of task forces assigned to specific issue areas. These task forces were staffed with coal, land use planning, and other specialists drawn mostly from the Bureau of Land Management, the Geological Survey, the Fish and Wildlife Service, and the Office of Policy Analysis. Each task force produced a background issue paper which was made public and continues to be available from the Bureau of Land Management upon request. The Office of Coal Leasing, Planning, and Coordination reviewed these papers and from them prepared concise issue option papers which were submitted to the Secretary or Under Secretary. (These issue option papers, listed in Table 3-1, were also made public and continue to be available from the Bureau of Land Management upon request.) The Secretary or Under Secretary circulated the issue option papers to the Assistant Secretaries and the Solicitor for comments and recommendations on which issue options should be selected. After all comments and recommendations were also circulated among the Assistant Secretaries and the Solicitor, they or their representatives met and discussed the comments and recommendations with the Secretary or Under Secretary. The Secretary or Under Secretary subsequently selected the option he preferred under each issue presented to him in the issue option paper or papers then under consideration.

On October 26, 1977, the Secretary considered the general question of when in the planning process should the Department solicit information from the coal industry regarding where they would prefer to have leases offered. On June 30, 1978, the Secretary addressed numerous issues of which the principal one was how should the need for leasing and the levels of leasing be determined and by whom. The six options not preferred by the Secretary became the basis of the six alternatives to the preferred program which are analyzed in this statement. Also selected on that date were options under issues concerning single tract and intertract sale methods, bidding systems, state and public participation procedures, site specific analysis and lease stipulations requirements, the definition of "maximum economic recovery", regulation of the end uses of Federal coal, a program for

public body leasing, and the management of non-producing existing leases and preference right lease applications. The Under Secretary selected options on issues concerning procedures in land use and activity planning on July 28, 1978, and on issues concerning the preparation of environmental impact statements and the implementation of the statutory surface owner consultation and consent requirements on September 15, 1978. On October 3 and November 2, 1978, the Under Secretary selected preferred criteria (and exceptions) for designating Federal coal lands unsuitable for mining. Finally, on March 2, 1979, in response to public comment on the draft version of this statement and further analysis in the coal policy review, the Under Secretary expressed a preference for the use of Department/state regional coal teams in activity planning and for certain changes in surface owner consultation and consent procedures. (The issues and options considered by the Secretary and the Under Secretary, the benefits from and the detriments to each option, the issue option papers which set forth the options and contain the discussion of the benefits and detriments, the option preferred, and the date the preference decision was made are summarized in Table 3-2.)

The preferred program described in Section 3.1.1. and discussed in greater detail below was developed by the Office of Coal Leasing, Planning and Coordination from the policy options preferred by the Secretary or the Under Secretary. Further work in determining procedural details for the preferred program and several of the other alternatives is being accomplished by 23 task forces composed of representatives of various agencies of the Department and of the Office of Leasing Policy Development of the Department of Energy. These task forces were established shortly after the publication of the draft version of this statement on December 15, 1978, and most of their work is already reflected in the proposed regulations set forth in Appendix A and in changes in the text of this chapter from Chapter 3 in the draft statement.

3.2.2. Land Use Planning.

As previously noted, in the preferred program the land management agencies' land use planning systems and The Bureau of Land Management's coal activity planning process are to provide the

TABLE 3-2
POLICY OPTIONS - SECRETARY'S PREFERENCE

ISSUES AND OPTIONS (a)	PROS AND CONS (b)	PAPER AND DATE/COMMENTS
When during the planning process should the Department solicit information from the coal industry regarding where they would prefer to have leases offered?		
1. Before multiple-use tradeoff and unavailability decisions are made.	(+) Incorporates market information into land use planning. (+) Incorporates industry's resource information into land use planning. (-) Multiple-use decisions areas which otherwise would pass unavailability and tradeoff screens but in which industry is not interested. (-) Overbalanced tradeoff decision in favor of coal.	
2. No not solicit any information.	(-) Government would have access to resource and market information industry has already. (-) More likely to be located at sites that are not efficient for the industry. (-) Could bias BLM planning toward noncoal surface resources.	
3. No not use industry information until areas acceptable for further consideration for leasing have been identified, then use industry information in tract delimitation, ranking, and selection process.	(+) Industry will have strong voice in selection of tracts, but only in areas known to be acceptable for further consideration for leasing. (-) Incorporates market information into activity plan. (-) BLM multiple-use resource decisions cannot be made for coal without coal "denom" estimate.	
In new coal leasing needed; if so, what should be the referral structure of a new Federal coal management program?		
1. No Federal leasing until at least 1985.	(+) Low administrative burden. (-) Low assurance of meeting WEP goals. (-) Low assurance of leasing least-cost coal. (-) Low capability to incorporate environmental impacts to non-Federal lands. (c) Shifts coal production to East.	
2. No Federal leasing, but process preference right lease applications.	(+) Moderate to low administrative burden. (-) Low assurance of meeting WEP goals. (-) Low assurance of leasing least-cost coal. (-) Low capability to incorporate environmental considerations. (c) Shifts coal production to East.	
3. Preference leasing only (business and maintain existing production) (No option would allow limited new mine leasing).	(+) Moderate to low administrative burden. (-) Low assurance of meeting WEP goals. (-) Low assurance of leasing least-cost coal. (-) Low capability to incorporate regional environmental considerations. (-) Restricts new entrants to coal industry. (+) High assurance of meeting WEP goals. (+) High assurance of leasing least-cost coal. (+) Low administrative burden. (-) Low capability to incorporate regional environmental considerations. <td></td>	
4. Lease to satisfy industry needs.		
(a) The options have been edited to clarify their presentation in this Table. (b) Note the pros and cons have, in some cases, been reduced by deleting redundant arguments, i.e., where an advantage of one option is a disadvantage of another. In some cases it is lacking from them. Also in a few cases where the comments of the Assistant Secretaries developed pros or cons which were not in the original papers but that weighed significantly in the decision, those arguments have been added. Readers are requested to refer to the papers cited for a full description of issues, options, and pros and cons. Papers are available upon request to the Department of the Interior. (c) Neutral, neither pro nor con from a national perspective.		

TABLE 3-2
(Continued)

POLICY OPTIONS - SECRETARY'S PREFERENCE

<u>ISSUES AND OPTIONS</u>	<u>PROS AND CONS</u>	<u>PAPER AND DATE/COMMENTS</u>
5. Let States determine level of leasing directly through final veto.	<ul style="list-style-type: none"> (-) High administrative burden. (-) No assurance of meeting national priorities without central decision maker. (-) Secretary abandoning resource responsibilities. (D) High weight mitigating local fiscal and social impacts. 	
6. Lease to meet or exceed DOE production projections.	<ul style="list-style-type: none"> (+) High assurance of meeting NEP goals. (+) High assurance of leasing least-cost coal. (-) Moderate ability to mitigate social, fiscal, and environmental impacts. (-) Secretary abandoning resource responsibilities. 	
7. Merge DOE production projections with inputs from States, local governments, industry, and interest groups to derive NRI regional production targets.	<ul style="list-style-type: none"> (+) High assurance of meeting national NEP goals. (+) High assurance of leasing least-cost coal. (+) High ability to mitigate social, fiscal, and environmental impacts. (-) Moderate-to-high administrative burden. 	
What sale system should the Department adopt?		
1. Lease using single tract system (require separate sales for each tract).	<ul style="list-style-type: none"> (+) Easiest system to administer. (+) Allows for more definitive activity planning and sale schedule proposal. (+) Greater assurance of leasing where the Department feels it needs to. (-) Where little competition involved, puts heavy reliance on fair market value. 	Paper: "Bidding Systems," June 23, 1978. Decision: Option 3; June 30, 1978.
2. Lease using intertract system (offer several tracts in a sale, lease only those with highest bid).	<ul style="list-style-type: none"> (+) Maximizes revenue by maximizing competition. (+) Offering large number of tracts lessens chance of appearing to favor any one party. (+) Greater opportunity for operation of industry in area. (-) More complex to administer. (-) Proposal action difficult to define for MIS. (-) Time, money, and manpower spent on tracts not sold, but these tracts can be used in later sales. 	
3. Retain discretion to use either.	<ul style="list-style-type: none"> (+) Allows Department to gain experience with intertract concept. (+) Offers Department means to deal with various ownership patterns. (-) Department expends effort on developing two systems rather than one, complicates program. 	
Should the current deferred bonus bidding system be used exclusively or should the Department experiment with other bonus bidding systems?		
1. Continue to use deferred bonus bidding system exclusively.	<ul style="list-style-type: none"> (+) Administratively simple. (+) Department has experience with system. (-) Risk factor in coal not as great as in PCS. (-) Might increase front end cost burden on coal companies. (-) Current bonus bidding may favor large over small companies. 	Paper: "Bidding Systems," June 23, 1978. Decision: Option 2; June 30, 1978.
2. Experiment with alternative bidding system and adopt those successful.	<ul style="list-style-type: none"> (+) Allows greater flexibility to meet varying situations. (-) Complicates administration of program. 	
What form of final pre-sale State consultation should the system adopt (choices in addition to consultation occurring during planning and tract selection)?		
1. Only consult if tract is for surface mining in National Forest (statutory requirement).	<ul style="list-style-type: none"> (+) Easiest option to administer. (+) Follows letter of statute. (-) Would reduce consultation from current practice. (-) Artificially stresses National Forest coal. 	
2. Consult on all tracts with an optional response period of from 30 to 60 days except for mandatory period on National Forest.	<ul style="list-style-type: none"> (+) Allows Secretary to respond when serious concern seems likely, but otherwise to proceed with timely sale. (-) Assures States will be allowed to present case to Secretary. (-) Creates administrative burden when #1. (-) Introduces delay into sales. 	Paper: "State and Local Government Participation," June 23, 1978. Decision: Option 2; June 30, 1978.

TABLE 3-2
(Continued)

POLICY OPTIONS - SECRETARY'S PREFERENCE

ISSUES AND OPTIONS	FROB AND OWN	PAPER AND DATE COMMENTS
3. Extend statutory privilege to all lands.	(+) Provides state opportunity for participation. (-) Potential to introduce delay into system (great (up to 8 months) end would have delayed even if States did not desire it.	
<u>What should be the role and scope of the site specific analysis and the resulting stipulations?</u>		
1. Analyses and stipulations based only on baseline data should be included at the time of lease sale. Rely on lease plan to develop specific site stipulations.	(+) Applicant bears data cost. (+) May shorten time to go from land use plan to sale. (-) Increases risk to bidder of non-operable or expensive leases. (-) Could result in FOB being needed for mining plan.	
2. Develop sufficient information prior to leasing to answer basic environmental and economic questions (i.e., what is the most profitable tract that will meet SWRA standards) but may proceed with less information than needed for mining plan. Stipulations are to be detailed, must require compliance with SWRA, and be subject to change in response to new information from mining plan.	(+) Reduces risk of offering for sale deficient tract. (+) Allows pre-lease and mining plan analysis objectives. (-) Imposes additional cost and time on system. (-) May inhibit mining plan manager from adding needed additional stipulations.	
3. All lease stipulations should be formulated at the time of lease sale and detailed data must be available then.	(+) Gives industry greatest assurance that mining will be permitted under lease without new costs to meet later stipulations. (-) Very tight data costs before certain tract will be sold. (-) Lengthens time for tract selection significantly.	
<u>When should mandatory public hearings occur in system?</u>		
1. Prior to adoption of land use plan, and/or		
2. After draft regional environmental assessment, and/or	Generally, the Department should maximize public involvement opportunity. Lower effectiveness of public hearings increases as more hearings are held. Probability of comments causing change in material presented declines the further into the process the hearing is held.	
3. After final environmental impact analysis and before sale.		
<u>How should the Department define and apply the phrase "maximum economic recovery" (MER)?</u>		
1. Calculate maximum economic recovery on a seam-by-seam basis (if seam is profitable it must be mined).	(+) Bonus bids will be higher than for Option 2 since less cost per acre. (-) Increased susceptibility to coal price decrease. (-) May "lose" marginal seams from supply. (-) More acreage leased. (-) Increases potential for double opening of same ground.	
2. Calculate maximum economic recovery on basis of all seams in land (all seams which collectively are profitable must be mined) with consideration for social and environmental costs.	(-) Less acreage disturbed. (-) Greater conservation of resources. (-) Potential for subsidence is high because of deep mining that may be required. (-) Increased economic cost to society. (-) High administrative burden.	
3. Use engineering practice to guide determination.	(+) Uses expertise of mining supervisor. (+) Pre-lease analysis is simplified. (-) May increase costs of production rates. (-) Could result in litigation. (-) Judgments could be of varying quality and probably not consistent.	
<u>Should stipulations on the end uses for the coal be part of the process?</u>		
1. Use stipulations to restrict technology or location of final use permitted for coal mined from Federal tracts.	(+) Gives program additional means to mitigate social/environmental impacts. (-) Legal basis has not been adequately researched. (-) Greater administrative burden.	
2. Use end-use stipulations only in support of special opportunity bidding programs.	(+) Strengthens statutorily required program without extending into new areas of regulation. (-) Legal basis has not been adequately researched.	
3. Refer for further study.	(+) Allows for more study needed of this question. (-) Poses some risk to programmatic XIS.	

TABLE 3-2
(Continued)

POLICY OPTIONS - SECRETARY'S PREFERENCE

ISSUES AND OPTIONS	PROS AND CONS	PAPER AND DATE/COMMENTS
What policy posture should the Department take toward public body leasing?		
1. Keep "public body" leasing program to the minimum size possible while still satisfying the Federal Coal Leasing Amendments Act of 1976.	<ul style="list-style-type: none"> (+) Least program cost and complexity. (+) The larger operations of private coal operators are easier to adapt to environmentally desirable operations. (-) Less participation of public body participation. (+) Preserves competition for private coal operators. (+) Can be accomplished without any major adjustments to system timing. (-) Leases would have to maintain two separate leasing systems and continually audit public body coal use. 	<p>Paper: "Public Body Leasing," June 23, 1978. Decision: Option 2; June 30, 1978.</p>
2. Treat "public body" leasing as a major component of the system and encourage "public body" participation, but do not modify fair market value requirements or provide other financial incentives.	<ul style="list-style-type: none"> (+) Ensures relatively low cost coal to "public bodies." (-) Riskier in terms of favoring "public body" leasing without adequate mandate. (-) Higher administrative costs. 	
3. Treat "public body" leasing as a major component of the coal leasing program and encourage use.		
How should the Department manage preference right lease applications (PRLAs)?		
1. Continue current practice (no review for consistency with land use plans or unsuitability criteria).	<ul style="list-style-type: none"> (+) Least administrative burden. (+) Avoids possible controversy. (-) Could result in leases in areas that would be unsuitable under new coal management program. (-) Preserves feasibility question to mining plan stage. (-) Does not satisfy President's request to scrutinize PRLAs. (-) Would develop better understanding of how much coal would be forthcoming from PRLAs. (+) Meets President's request. 	<p>Paper: "Management of Preference Right Lease Applications," June 23, 1978. Decision: Option 3; June 30, 1978.</p>
2. Reclassify PRLAs in light of land use planning and unsuitability criteria <u>prior</u> to engaging in commercial quantities determination.	<ul style="list-style-type: none"> (+) Meets President's request. (-) By combining work should be less costly than under Option 2. (-) Adds administrative complexity of coal management program. (-) May study applications that cannot make showing. 	
3. Reprocess PRLAs and determine commercial quantities simultaneously. Review each application individually to determine if it meets current planning and unsuitability criteria. Use appropriate tools to avoid undesirable development.	<ul style="list-style-type: none"> (+) Meets President's request. (-) By combining work should be less costly than under Option 2. (-) Adds administrative complexity of coal management program. (-) May study applications that cannot make showing. 	<p>(The Secretary also indicated that the Department should proceed to identify the least harmful twenty PRLAs and proceed to process them under the <u>NRD v. Hughes</u> agreement.)</p>
How should the Department manage non-producing existing leases?		
1. Review all non-producing leases (regardless of production plan) to decide if the leases could be operated in an environmentally acceptable manner. Use appropriate tools to avoid undesirable development.	<ul style="list-style-type: none"> (+) Gives the Department best estimate of how much coal might be produced and need for new leases. (-) High administrative costs. (-) May process some leases that would not be developed. (-) Uncertain legal environment. (+) Maintains consistency with new leasing where possible. (+) Moderate administrative costs. (-) Does not resolve planning uncertainty surrounding existing leases. (-) High cost to lessee. 	<p>Paper: "Management of Existing Leases", June 23, 1978. Decision: Option 2; June 30, 1978. Expanded by:</p>
2. The Department would await the fulfillment by the lessee of the legal obligations required to initiate mining (submission of a mining plan) before reviewing the desirability of lease development. This does not preclude evaluation of the needs of the lessee. The new planning requirements and unsuitability criterias would be applied to all non-producing leases. The mining plan would be evaluated in light of the unsuitability criterias to determine if the lessee may apply. If any criterion applies, the specific criterion and any exception to it which the conditions permit to be made would be applied. If the specific criterion does not apply and the conditions do not permit an exception, a further decision would be made on whether the land is exempt from the criterion because of the source of the authority for the criterion.		<p>Paper: "Land Unsuitability Criterias", September 22, 1978. Decision: October 3, 1978.</p>

TABLE 3-2
(Continued)

POLICY OPTIONS - SECRETARY'S PREFERENCE

ISSUES AND OPTIONS	PROS AND CONS	PAPER AND DATE/COMMENTS
<u>How will regional targets be used in the management system?</u>		
1. Targets under planning process at MFT stage and serve as constraint for resource tradeoffs.	<ul style="list-style-type: none"> (+) Provides explicit guidance for tradeoff planning decisions. (+) Makes coal consistent with planning for other resources being managed. (-) May reflect political tradeoffs. (-) Makes least use of industry information. (-) Might require more frequent cycling of land use plans. (-) Intertract sales would not be possible. 	Paper: "Intraregional Matters Affecting Design of a Coal Leasing Process"; July 18, 1978; Decision: Option 2; July 26, 1978.
2. Targets used at point of regional tract selection.	<ul style="list-style-type: none"> (+) Allows maximum flexibility for intraregional tradeoff. (+) Does not require frequent recycling of land use plans. (+) Allows intertract bidding. (-) Places heavy emphasis on untried unsuitability concepts. (-) Changes ELM resource decision process. 	
3. Targets with safety factor multiplier enter at land use plan level and goals used at regional level.	<ul style="list-style-type: none"> (+) Target available for guiding land use plan decision. (+) Develops pool of possible tracts for possible use in intertract sales. (-) Could be seen as developing unneeded tracts. (-) Elimination of targets to planning unit level difficult. 	
<u>How should industry tract interest information be used?</u>		
1. Used to delineate tract boundaries only after "best" areas are identified.	<ul style="list-style-type: none"> (+) Department could not be seen as reacting to industry. (-) Ignores opportunity to use valuable industry information. (-) May result in development of tracts that are not least cost or that are of no interest to industry. 	Paper: "Intraregional Matters Affecting Design of a Coal Leasing Process"; July 18, 1978; Decision: Option 2; July 26, 1978. (See also decision of October 26, 1978)
2. Need to select "best" leasing tracts from areas acceptable for further consideration for leasing.	<ul style="list-style-type: none"> (+) Allows the party who ultimately will be mining a bigger role in identifying areas for leases. 	
<u>Should lands unsuitability criteria be adopted by Department?</u>		
1. Criteria should be adopted by Department.		
2. Criteria should not be adopted so that maximum discretion is exercised at field level.	<ul style="list-style-type: none"> (+) Assures consistency among field units. (+) Provides local land managers a standard. (+) Provides a mechanism for assessing cumulative impacts of statutory regulation and policy. (+) Higher level of public regulation and policy. (+) Provides greater compatibility with State programs. (-) Decreases flexibility at legal level. (-) Provides unnecessary changes and costs. (-) Rigid application might restrict tract availability. 	Paper: "Intraregional Matters Affecting Design of a Coal Leasing Process"; July 18, 1978; Decision: Option 1; July 26, 1978. (See October 3, 1978, Decision).
<u>Should regional comparisons be based on areas or specific lease tracts?</u>		
1. Rank by areas.	<ul style="list-style-type: none"> (+) Ranking process is more meaningful with larger geographic area. (+) Less open to charge of favoritism to any one company. (-) More divers information to assess. (-) Requires all plans on same schedule. (-) Allows use of industry information. 	Paper: "Intraregional Matters Affecting Design of a Coal Leasing Process"; July 18, 1978; Decision: Option 3; July 26, 1978.
2. Rank by tracts.	<ul style="list-style-type: none"> (+) Ranking should cost less. (-) Requires all plans on same schedule. (-) Closer identification with specific coal companies. 	
3. Rank by both areas and tracts "Ranking factors will include many values, including environmental".	<ul style="list-style-type: none"> (+) Does not require all planning to be on same schedule. (+) More flexibility to field managers. (-) Some loss in consistency of ranking. 	

TABLE 3-2
(Continued)
POLICY OPTIONS - SECRETARY'S OPTIONS

ISSUES AND OPTIONS	PARKS AND COWS	PAPERS AND DATES/COMMENTS
<u>Should coal leasing be restricted to areas identified in CDO/CDF maps?</u>		
1. Require only that coal leases be issued within KNRAs.	(+) Would make the widest area available for consideration. (-) Department might end up trying to lease tracts with inadequate knowledge of value of coal deposit. (+) Ensures consistent coal data. (-) Pressure would be applied to increase CDO/CDF effort, increasing costs. (+) Makes widest area available for consideration. (-) Encourages use of CDO/CDF data for consistency. (-) Possibility for inconsistency in coal data use.	Paper: "Intraregional Matters Affecting Design of a Coal Leasing Process," July 18, 1978. Decision: Option 3; July 28, 1978.
2. Lease only in areas identified as high or medium coal development potential by the CDO/CDF maps.		
3. Requires only that coal leases be issued within KNRAs but ranks coal quality as a ranking factor and use CDO/CDF maps for information.		
<u>Should the Department adopt a policy of preferring either clustered or dispersed leasing patterns within a region?</u>		
1. Adopt policy preference prior to leasing for either (a) clustered lease pattern or (b) dispersed lease pattern.	(+) Ensures Secretary that possibility for strategic arrangements of tracts will be studied. (+) Ensures Secretary regional and local "carrying capacity" will be studied. (-) Does not allow for dynamic approach and reduces flexibility. (-) Concerns mentioned in the two "progs" above can be met in ranking process and, therefore, flexibility is surrendered without gain. (+) Maximum flexibility for local land managers. (+) Maintains integrity of ranking system design and of leasing process. (-) Moves this decision from programmatic EIS to regional EIS, lowering visibility.	Paper: "Intraregional Matters Affecting Design of a Coal Leasing Process," July 18, 1978. Decision: Option 2; July 28, 1978.
2. Leave decision to local land managers, requiring only that social impacts be one of the factors considered in ranking tracts and that local land managers consider interdependence of tracts on ranking.		
<u>Should assured access to Federal lease tracts be obtained prior to sale?</u>		
1. Lease only those tracts with known assured access.	(+) Avoids manpower and dollar costs of how access program would be implemented. (-) Extra competition. (-) Confines access to existing corridors or corridors government has strong control over. (-) Provides unit to companies interested in areas that would not qualify and to consenting surface owners. (-) Eliminates an unknown number of tracts. (+) Likely to increase the number of bidders and level of bids on certain tracts. (+) Would allow better job of planning for individual tracts. (-) Would involve new program and new costs. (-) Benefits of guaranteed access are not clear yet. (-) Could add time to leasing schedule and lower number of available tracts.	Paper: "Intraregional Matters Affecting Design of a Coal Leasing Process," July 18, 1978. Decision: Option 3; July 28, 1978.
2. Adopt full-scale access acquisition program.	(+) No additional manpower or costs. (+) No waste of outside bid programs. (-) May lower competition on certain tracts. (-) May risk post-sale failure to mine where access blocked.	
3. Status quo (access responsibility of winning bidder).	(+) Department could ascertain benefits of program without committing manpower and costs. (-) Adds to complexity of program management.	
4. Offer assured access on an experimental basis.	(+) Gives lessees assurance of access. (+) Would integrate with split-estate program, taking advantage of conceptual similarities. (-) Would require more time to implement directly acquire surface owner consents. (-) Adds complexity to very delicate split-estate program.	
5. Attempt to "acquire" access together with surface owner consent, otherwise proceed as for Option 1.		

TABLE 3-2
(Continued)

POLICY OPTIONS - SECRETARY'S PREFERENCE

ISSUES AND OPTIONS	PROS AND CONS	PAPER AND DATE/COMMENTS
<u>What approach should the Department adopt for an ongoing environmental analysis strategy?</u>		
1. Prepare a national coal sales EIS covering all proposed sales to occur in a specified period of time in all prospective regions. The EIS would cover all potential site-specific, regional, interregional, and national impacts.	<ul style="list-style-type: none"> (+) No update of programmatic needed. (+) All possible levels of impact in one document. (-) Administratively complex. (-) Delays capability to make specific comments. (-) If statement challenged entire program may be delayed. <ul style="list-style-type: none"> (+) Better compatibility with existing EIS (+) Takes maximum advantage of existing analysis in programmatic. (+) Regional schedules could be adopted to reduce administrative burdens. (-) Several statements would have to be prepared instead of one. (-) Possible controversy over when a programmatic update is needed. 	Paper: "Environmental Analysis Strategy," August 31, 1978. Decision: Option 2; September 13, 1978.
2. A regional, site-specific EIS would be prepared on a five year schedule of lease sales in each region. Delays in preparing a programmatic EIS. Each regional EIS would include analysis of both the site-specific and intraregional cumulative impacts of the proposed leasing actions. Lease sales schedule would be revised if too many leases were issued before the time of establishing new regional production targets is completed. If, in any region, substantial differences are found in tract ranking (because of the presence of surface owners or because of changes in environmental, social, or economic conditions) or the relevant new regional production target which requires a change in the lease sales schedule for that region, a statement to the regional statement would be prepared. National and interregional impacts of the Federal coal management program would be analyzed in the programmatic EIS. The EIS would be updated annually to reflect any changes sufficiently to require new analysis of those impacts. (Suboption: Include all pending mining plan approval actions in regional statement.)		
<u>Should the Secretary condition his decision to proceed with leasing based on existence of split estate (surface/minerals under different ownership) in lease areas?</u>		
1. Do not lease where "surface owner" restrictions of Section 714 of SMCRA apply.		
2. Same as Option 1, but encourages coal companies to purchase split estates.		
3. Attempt to lease all coal regardless of ownership but decline to lease where compensation payments exceed a standard amount.		
4. Attempt to lease all coal regardless of surface ownership with passive compensation safeguards through fair market value computation.		
5. Lease all coal regardless of surface ownership and compensation.		
<u>Who should acquire surface owner consents and when?</u>		
1. Industry would acquire consent or options during the development of their expressions of interest and file them with the expressions. Options would be transferable. Terms of the consent options would have to be presented to the Department with the expressions of interest in an area.		
2. Industry would have the responsibility in the Federal coal management program of acquiring surface owner consent. Consents would have to be filed with the BLM prior to the sale announcement. The contracts would be removed from the lease sales if no filing of consent is made on a tract prior to the sale announcement, the tract would be removed from the sale schedule (and, if necessary, another tract substituted). The lease sale would be delayed until such a determination is made, the successful bidder on that tract in the sale would be given a period of time after tract sale to obtain consent.		
NOTES: Under Secretary added option to have consent acquired after sale.		
	<ul style="list-style-type: none"> (+) Avoids adverse social impact. (+) Implementation easy. (0) Shifts location of environmental damage away from Northern Great Plains. (-) By restricting supply of coal may raise cost to consumer. <p>(Same as Option 1, moderated somewhat)</p> <ul style="list-style-type: none"> (+) Outright purchase costs may raise price of coal. (-) Dislocates surface owner permanently. <ul style="list-style-type: none"> (+) Minimizes cost to consumer. (-) Difficult implementation. (-) Subject to legal challenges. <ul style="list-style-type: none"> (+) Tends to minimize cost to consumer. (+) Implementation straightforward. (+) Should not inhibit development of split estate leases permanently. (-) Fair market value not easily determined. <ul style="list-style-type: none"> (+) Minimal cost for implementation. (-) Possibly raises cost to consumer. (-) Loss of government income. 	Paper: "Coal Leasing: Surface Owner Consent," June 23, 1978. Decision: Option 4; June 30, 1978.
		Modified by: Paper: "Split Estate Leasing Implementation," August 31, 1978. Decision: Option 4; September 13, 1978.
		(Subject to Solicitor's review) (Suboption considered would have to be filed for split estates compensation in fair market value computation to zero.)
		Paper: "Split Estate Leasing Implementation," August 31, 1978. Decision: Option 2; September 13, 1978.

TABLE 3-3
(Continued)

POLICY OPTIONS - SECRETARY'S PREFERENCE

ISSUES AND OPTIONS	PROS AND CONS	PAPER AND DATE/DECISIONS
<p>1. Industry would acquire consents after lease sale announcement but consents must be filed before the actual sale. Consents would be transferable to a third party and consent payments would be contingent on successful sale. Date of actual sale may be held up pending receipt of indication of consent or need to be offered.</p> <p>4. Company would acquire consent after it is successful in lease sale; the consent would have to be filed before lease is executed.</p> <p>5. At the time the surface owner is consulted by BLM in the planning process, he or she would be offered the opportunity to agree in writing consent to avoid surface mining, to agree to no option for a consent. The terms of the contract, including all payments at the time of lease execution. If consent were not given, the lease would be suspended from further lease acquisition until the next round of planning 5 to 10 years later. Alternatively, if consent were not forthcoming, but the surface owner indicated a preference for alternative uses, the lease would be withdrawn from the leasing process and a second opportunity would be given the surface owner by BLM prior to offering the tract for lease sale.</p> <p>6. BLM would begin to directly seek surface owner consents at the time of tract ranking and would continue to acquire consents through completion of site-specific analyses. Payment would be made to the BLM at time of lease execution. Third party consents would be negotiated.</p> <p>7. BLM would negotiate surface owner consents following completion of site-specific analyses and before tracts are offered for sale.</p>	<ul style="list-style-type: none"> (+) Direct government involvement not required. (+) Industry will be aware of terms of sale before paying for consent. (-) Short time allowed for negotiation. (-) Continuous uncertainty regarding consent for lease sale at least moment, putting all government at risk. (-) Puts cost burden on industry. <ul style="list-style-type: none"> (+) Direct government involvement not required. (+) Avoids question of who should negotiate. (+) Avoids unneeded consents. (+) Surface owner has full information. (-) Puts previous expenditures of time and funds in preparing tract in jeopardy. (-) Surface owner is very strong bargaining position. (-) Uncertainty of acquiring consents may reduce competitiveness of sale. (-) Puts cost burden on industry. (-) Government could not know if split-intertract tracts would be mined until after costs of sale. <ul style="list-style-type: none"> (+) Possible reduction in costs of program. (-) Leasing program could proceed without necessarily having surface owner. (-) May be seen as unfair to split estate owner. (-) Makes consultation more complex. (-) Relatively lower chance of successfully getting consent. (-) Government bears cost of consent. 	
<p><u>What should the Department's policy be toward pre-existing consents?</u></p> <p>1. Offer tracts which are covered by nontransferable consents in intertrack sales only.</p> <p>2. Decline to lease tracts with pre-existing consents that are not transferable.</p> <p>3. (Combination of 1 and 2) Tracts which are selected for lease sale and which include areas covered by pre-existing consents would be offered for sale if the consents are determined to be transferable. If any pre-existing consent is determined to be nontransferable the tract would not be offered for sale unless it is included in an intertrack sale.</p> <p><u>Should the Department require compensation be paid to companies for consents they acquire?</u></p> <p>1. A surface owner consent agreement would be considered transferable only if it provides that (A) the payment for the lease sale is made to the BLM and (B) the lease sale after the lease sale in which the lease for the tract to which the consent applies is sold or (2) after the lease sale, the successful bidder is permitted to release the company which first obtained the consent for the purchase price of the consent.</p> <p>2. Foster the sharing of risk of losing consent costs by encouraging the development of industrial groups for the purpose of acquiring consent options.</p> <p>3. Take the position that loss of consent costs is a normal business risk in which the government should not be involved.</p>	<p>Same as Option 2 except government bears cost of consent acquisition.</p> <p>(+) Government could keep program more in phase with tract ranking process.</p> <p>(-) May require new authority to pay for consent.</p> <p>Same as Option 3 except government bears cost of consent acquisition.</p> <p>(+) Surface owner gets maximum information.</p> <p>(-) BLM would be in difficult negotiating position because of costs sunk in tract analysis end selection.</p> <p>(+) Meets Secretary's policy regarding transferability of consents.</p> <p>(-) Requires BLM to institute new program.</p> <p>(+) Minimizes administrative cost of pre-existing consent process.</p> <p>(-) Subject to possible legal challenge.</p> <p>(+) Processes greater number of consents.</p> <p>(-) Greatest administrative burden.</p> <p>(+) Low administrative costs.</p> <p>(+) Encourages companies to acquire consents by ensuring they would not be forced to pay cost of consent on the tracts they do not obtain.</p> <p>(-) Complicates negotiations between coal companies and surface owners.</p> <p>(-) Reasonably low administrative costs.</p> <p>(-) May be seen as anti-competitive by encouraging grouping of would-be lessees in future sales.</p> <p>(-) No administrative costs.</p> <p>(-) Would discourage industry from acquiring consent unless they had competitive edge.</p> <p>(-) One company could end up paying for another's consent acquisition.</p>	<p>Paper: "Split Estate Leasing Implementation," August 31, 1978. Decision: Option 3; September 15, 1978.</p> <p>Paper: "Split Estate Leasing Implementation," August 31, 1978. Decision: Option 1; September 15, 1978.</p> <p>Paper: "Split Estate Leasing Implementation," August 31, 1978. Decision: Option 1; September 15, 1978.</p>

<p>Should the discretion granted the local land manager to exclude an area in the process if a firm preference against leasing is expressed during consultation be dropped and the resulting local land manager's input consideration be made mandatory? The owner would have to indicate on the consultation form that he has not given an earlier consent and will not consent for the life of the plan.</p> <ol style="list-style-type: none"> 1. Agree. 2. Agree as modified. 3. Disapprove. 4. Defer. 	<p>(+) Answer argument advanced by many commentors that discretion at this point was not intended.</p> <p>(+) Extends the coverage of the "definite no" rule to areas excluded by local land manager.</p> <p>(-) Confuses consultation and consent processes.</p> <p>(-) Presents possibility of having to process plan amendments when ownership changes.</p> <p>(-) Introduces rigidity into process by going from a policy preference to firm direction to local land manager.</p>	<p>Paper: "Surface Owner Consent Procedures", February 27, 1979. Decision: Option 4 (but publish in preliminary rulemaking and request comments); March 2, 1979.</p>

initiative and the forums for making decisions in the Federal coal management program. This emphasis on planning is fully consistent with statutory requirements. Section 3(A)(i) of the Federal Coal Leasing Amendments Act of 1976, amending Section 2 of the Mineral Leasing Act of 1920, directs that "no lease sale shall be held unless the lands containing the coal deposits have been included in a comprehensive land-use plan and such sale is compatible with such plan." The Federal Land Policy and Management Act of 1976 established the basic planning authority for the Bureau of Land Management (BLM) and the Multiple-Use Sustained-Yield Act of 1960 and the National Forest Management Act of 1976 provided planning guidance for the Forest Service. The guidelines for planning in the Federal Land Policy and Management Act include:

- Inventory public lands, their resources, and other values.
- Apply an interdisciplinary approach.
- Give priority to the designation and protection of areas of critical environmental concern.
- Consider present and potential uses of the land.
- Consider the relative scarcity of the values involved and alternative means and sites for realization of those values.
- Consider both long-term and short-term benefits.
- Provide for compliance with applicable pollution control laws.
- Coordinate inventory, planning, and management with other Federal agencies and state and local governments.

The products of both the Bureau of Land Management's and Forest Service's land use planning processes are comprehensive, multiple-use land use plans for discrete areas of Federal lands. These plans are now called Management Framework Plans (MFPs) by the Bureau and Unit Plans by the Forest Service. The planning systems of the two land management agencies are broadly similar and are expected to be even more closely related when new planning regulations under the Federal Land Policy and Management Act of 1976 and the National Forest Management Act of 1976 are promulgated.

The Forest Service's proposed National Forest System Land and Resource Management Planning

Rules were published on August 31, 1978 (43 Federal Register 39046-39059). The BLM's proposed planning regulations were published on December 15, 1978 (43 Federal Register 58764-58774). Under the proposed regulations, the unit plans of the Forest Service would be renamed National Forest Plans and the Management Framework Plans of the BLM would be termed Resource Management Plans.

Both sets of proposed regulations would permit the continued use of existing plans as bases for resource development decisions until new plans are developed under the new procedures. Therefore, both existing plans under present procedures and new plans under changed procedures may be used in future coal management decisions. However, as a matter of practice and program policy, the Department of the Interior will give considerable priority to preparation of new Resource Management Plans in the most critical high value coal areas. Some Resource Management Plans may be finished as soon as late 1984. In the meantime, existing Management Framework Plans would be examined closely and modified as necessary to ensure compliance with the proposed unsuitability criteria and surface owner consultation procedures (see Sections 3.2.2.2 and 3.2.2.4). The results of this examination and modification would be published in supplements to the Management Framework Plans.

The BLM planning system, under the proposed regulations, will call for the completion of nine required steps. These are the same steps prescribed in the proposed Forest Service planning system. This should enhance common understanding of these processes. There will be substantial differences in how these steps are accomplished and documented, both between the BLM and Forest Service and from plan to plan within each agency, based on variations in issues, concerns, data, and legal authorities.

The required steps in each agency's proposed new land use planning system are listed in the left-hand column below, in the general sequence they are to be initiated. The existing BLM planning system components are listed in the right-hand column below to indicate which components of the existing system include the same general objectives and scope as the steps in the proposed system. The new steps are designed to improve substantially the quality of land use plans and are explained in

detail in the proposed planning regulations. (The existing BLM system procedure was described in more detail in the draft version of this statement.)

Steps in the New BLM Planning System Presented In the Proposed Regulations	Existing BLM Planning System Components Including the Same General Objectives and Scope as the Steps In the Proposed Regulations
1. Identification of issues, concerns, and opportunities.	Portions of the Planning Area Analysis
2. Development of planning criteria.	Portions of the Preplanning Analysis.
3. Inventory data and information collection	No comparable requirement, since existing system uses available information.
4. Analysis of the management situation.	Portions of Unit Resource Analysis, Planning Area Analysis, and first step of the Management Framework Plan.
5. Formulation of Alternative Plans.	Management Framework Plan Step Two.
6. Estimation of the effects of alternatives.	Management Framework Plan Step Two.
7. Selection of Preferred Alternative and filing the draft EIS.	MFP Step Two (no requirement in existing system for preparation of an EIS).
8. Selection of preferred plan and filing the final EIS.	MFP Step Three (no requirement in existing system for preparation of an EIS).
9. Monitoring and evaluation of plan.	No similar requirement in existing system.

The manner in which the Forest Service's planning process will relate and contribute to the coal management program will be set forth in Memoranda of Understanding now being negotiated by the Forest Service and the BLM. The first of these is to be on unsuitability criteria. (As the Secretary is required by section 522 of the Surface Mining Control and Reclamation Act to make the determination of which land is unsuitable for surface coal mining on all Federal lands, in order for the Forest Service to conduct the application of

unsuitability criteria on national forest system lands, the Secretary must delegate the authority to do so to that agency.) It is expected that the Forest Service will adopt the unsuitability criteria which the Secretary selects when he makes his program decisions except where modifications are necessary to reflect the Forest Service's missions and programs and the Secretary approves such modifications. The land use plans which are the products of both the existing and proposed land use planning systems identify preferred land uses, or combinations of uses, for the planning areas and serve as guides to the Federal land managers. The land use plans establish the nature, extent, and objectives for future actions and programs on lands administered by the two agencies. Under the Secretary's preferred alternative, the principal coal resource decision in the land use plans would be the determination of which areas are acceptable for further consideration for coal leasing (see Figure 3-2). These areas would be identified after placing all lands in a planning area through four screens, integral to the planning process:

1. Areas would be eliminated from any further coal development consideration if they do not have high to medium coal potential (see Section 3.2.2.1).
2. Additional coal areas would be eliminated if they are judged unsuitable under the Department's unsuitability criteria (see Section 3.2.2.2).
3. Additional coal areas may be eliminated on multiple use grounds if other Federal resource values are determined to be superior to coal (see Section 3.2.2.3).
4. Additional coal areas where the Federal government owns the coal, the coal would be surface mined, and the surface is owned by ranchers or farmers may be eliminated after consultation with those surface owners (see Section 3.2.2.4).

The remaining areas after application of these screens would be identified in the land use plan as areas acceptable for further consideration for coal leasing, subject to areawide constraints and multiple use coordination requirements to guide coal program activities. (Note: Any leasing which is conducted would not involve all the land in these areas. Those lands not leased would, of course, continue to be available for any other uses, (e.g., livestock grazing) permitted by the land use plan.) These constraints and requirements could include such actions as: (a) establishment of threshold

development levels over the planning area (see Section 3.2.2.5); (b) identification of unique stipulations to be placed in any potential coal lease on an area which the land use plan might identify as acceptable for further consideration for leasing; and (c) recommendations of preferred coal leasing areas if the areas acceptable for further consideration for coal leasing clearly are larger than may be needed for leasing (see Section 3.2.2.6). The proposed planning regulations would require review of a plan every five years, and full revision of a plan in 15 years, or earlier if necessary.

All potential resource users — ranchers, coal companies, timber purchasers, environmental organizations, etc. — should participate actively in the land use planning process if the process is to allocate uses of the Federal lands in the best possible manner. For example, the coal industry would be expected to help identify high and medium potential coal resources and no area would be excluded in the first screen that is shown by a company to contain coal which possesses a medium or high potential for development. Industry would also be expected to argue forcefully in favor of coal development over other uses in the resources trade-off screen and provide any data it might have which would permit the making of exceptions to the application of unsuitability criteria. Environmental organizations would be expected to assist the planning team in identifying situations which require the application of unsuitability criteria, critique information which suggests exceptions may be made, and advocate non-commodity uses of the land. Ranchers, timber purchasers, and other users should voice their desire to see sufficient land allocated to their respective uses, provide the planning team with information as to their needs, and argue forcefully for the allocation to their uses of specific areas for which other users are competing in the resources trade-off screen. Throughout the land use planning process, opportunities are provided for this type of participation and public participation is given special emphasis in the proposed new planning regulations of the Bureau of Land Management (43 Federal Register 58764-58774) and the Forest Service (43 Federal Register 39046-39059).

3.2.2.1 Coal Potential. Only a portion of the coal resources within a land use planning area is likely to be potentially economic to mine or to become so

over the life of the land use plan. Rather than apply all the screens in the land use planning process to uneconomic coal, the first screen to be applied would identify high or moderate development potential coal. Lands with less than moderate development potential would be dropped from further consideration until their potential for development is judged to be higher, perhaps the next land use planning cycle.

The major source of information for this screening would be the coal resource occurrence/coal development potential (CRO/CDP) maps and other related coal potential analysis of the U.S. Geological Survey. Where CRO/CDP maps are not available, other sources of information such as information from the Geologic Survey of the states and other available U.S. Geological Survey data would be used. It should be emphasized that this screen is only the first of four in the land use planning process and its application does not have as its result the designation of any land as an area to be included in a lease sale (a decision taken only later in activity planning after land use planning has been completed) or even to be determined acceptable for further consideration for possible leasing (a decision to be made at the end of land use planning after all four screens have been applied). With this in mind, coal companies, the states, or members of the public may submit non-confidential coal geological and economic data during the earlier inventory phase of planning. Where such information is determined to indicate significant development potential for an area not shown to be of medium or high potential in the CRO/CDP maps, the area would not be excluded from further consideration and application of the remaining screens in the land use planning process.

3.2.2.2 Unsuitability Criteria. The key activity added to the land use planning process as a result of the requirements of Section 522 of SMCRA and other policy directives is the application of lands unsuitability criteria. It is the second of four screens applied to Federal coal lands in the land use planning process.

The President, in a May 24, 1977 memorandum implementing his Environmental Message of May 23, 1977, instructed the Secretary of the Interior to lease "only those areas where mining is environmentally acceptable and compatible with

other land uses." The President further directed that the Department "scrutinize existing Federal coal leases (and preference right lease applications) to determine whether they show prospects for timely development in an environmentally acceptable manner, taking steps as necessary to deal with nonproducing and environmentally unsatisfactory leases and applications."

In addition, on August 3, 1977, the President signed into law the Surface Mining Control and Reclamation Act (SMCRA). Section 522 of this Act requires the Secretary to review Federal lands to determine whether they contain areas which are unsuitable for surface coal mining operations. SMCRA also contains a requirement for the states to undertake a similar program for non-Federal lands if they wish to assume primary regulatory authority under the Act. A list of standards to be used by the states is identified in Section 522(a)(3) of the Act. These same standards are also required to be applied to Federal lands (private surface lands overlying Federal coal are considered to be Federal lands for the purposes of the application of the standards).

Under the preferred program, unsuitability criteria have been developed in response to Section 522 of SMCRA and the directives in the President's Environmental Message. The criteria are to be applied to medium and high potential coal lands in the land use planning process to identify those areas with key features, principally environmental, which make them unsuitable for all or certain methods of coal mining and thus should not be leased for that purpose. Accordingly, these areas would be removed from the activity planning process of delineation, ranking, selection and scheduling of tracts for lease sales or continued for only certain stipulated methods of mining. A principal purpose of the unsuitability criteria is to ensure that the responsibility of determining Federal lands unsuitable for coal mining is fulfilled in as consistent, uniform, and objective a manner as possible so that all parties—public officials, coal companies, environmentalists, and the public—can have confidence in the unsuitability decisions. As Federal land planners have not had to follow any such national standards before, their very existence would fulfill the purpose of limiting the incidence of divergent, subjective land use decisions. Certainly, because of the vast differences in topography and other conditions in Federal coal lands, no

set of criteria can be designed to eliminate entirely the necessity, or indeed the advisability, of subjective, site-specific decisions by the planners. However, the proposal to include the procedures for applying the criteria and the criteria themselves in regulations (see Appendix A), and the proposed application procedures which emphasize public accountability for application decisions and limit the situations in which exceptions to criteria are to be considered, would greatly reduce the range and number of subjective judgments the planners might otherwise make lacking firm policy guidance.

Section 522 does not require that the Federal lands unsuitability review be completed prior to leasing or even prior to issuance of a mining permit, although several individual criteria selected by the Under Secretary incorporate mandatory requirements of section 522 of SMCRA and other statutes and would have to be applied prior to permit issuance. However, the Department has proposed to apply all the criteria at the mining plan stage. In addition, the Secretary chose to apply the criteria not just at the mine plan stage late in the coal management decision making process but also at the beginning of the process in land use planning. He expressed this preference for several reasons: to provide greater predictability for all interested parties in the coal management program, to ensure that lands which clearly should not be mined are excluded from leasing consideration as promptly as possible, and to avoid the costly situation for both a coal company and the Federal government of taking a tract all the way through lease sale and mine plan development only to find it is either unminable or would require such restrictive stipulations in the mine plan or mining permit as to make mining uneconomic.

An intensive Department-wide effort was made to develop the 24 unsuitability criteria and their exceptions selected by the Under Secretary for inclusion in the preferred program and set forth in Table 3-3. Between November 1977 and March 1978, a task force representing ten agencies and offices in the Department of the Interior and the Forest Service, Department of Agriculture, conducted a comprehensive review of existing legislation, Presidential and Secretarial Orders, and Departmental policy and prepared a set of draft unsuitability criteria with, in many cases, alternative criteria and exceptions. These criteria (set

TABLE 3-3

PROPOSED CRITERIA FOR ASSESSING
AND DESIGNATING FEDERAL LANDS UNSUITABLE FOR
ALL OR CERTAIN TYPES OF COAL MINING OPERATIONS*

	<u>CRITERION</u>	<u>EXCEPTIONS & EXEMPTIONS</u>
<u>(a) Federal Land Systems</u>	<p>All Federal lands included in the following land systems or categories and an appropriate buffer zone, if necessary, as determined by the land management agency, shall be considered unsuitable for coal mining: National Park System, National Wildlife Refuge System, National Systems of Trails, National Wilderness Preservation System, National Wild and Scenic Rivers System, National Recreation Areas, lands acquired with money derived from the Land and Water Conservation Fund, Custer National Forest, and Federal lands in incorporated cities, towns, and villages. All Federal lands which are recommended for inclusion in any of the above systems or categories by the Administration in legislation proposals submitted to the Congress of which are required by statute to be studied for inclusion in such systems or categories shall be considered unsuitable.</p>	<p>Exception: A lease may be issued and mining operations may be approved within the Custer National Forest with the consent of the Department of Agriculture as long as no surface coal mining operations are permitted.</p> <p>Exemptions: The application of this criterion to lands within the listed land systems and categories is subject to valid existing rights. The application of the buffer zone portion of this criterion does not apply to lands: to which substantial financial and legal commitments were made prior to January 4, 1977; on which operations were being conducted on August 3, 1977; or which include operations on which a permit has been issued.</p>
<u>(b) Rights-of-Way and Easements</u>	<p>Federal lands that are within rights-of-way or easements or within surface leases for residential, commercial, industrial, or other public purposes, or for agricultural crop production on Federally owned surface shall be considered unsuitable.</p>	<p>Exception: A lease may be issued, and mining operations approved, in such areas if the surface management agency determines that:</p> <ul style="list-style-type: none"> (i) all or certain types of coal development (e.g., underground mining) will not interfere with the purpose of the right-of-way or easement; or (ii) the right-of-way or easement was granted for mining purposes; or (iii) the right-of-way or easement was issued for a purpose for which it is not being used; or (iv) the parties involved in the right-of-way or easement agree to leasing; or (v) it is impractical to exclude such areas due to the location of coal and method of mining and such areas or uses can be protected through appropriate stipulations. <p>Exemption: This criterion does not apply to lands on which mining would result in substantial loss or reduction of long-range productivity of food or fiber products, and it does not apply to lands: to which the operator made substantial financial and legal commitments prior to January 4, 1977; on which operations were being conducted on August 3, 1977; or which include operations on which a permit has been issued.</p>

*See Table 5-88 for the draft unsuitability criteria field-tested in the summer of 1978.

TABLE 3-3 (continued)

<u>CRITERION</u>	<u>EXCEPTIONS & EXEMPTIONS</u>
(c) <u>Buffer Zones Along Rights-of-Way and Adjacent to Communities and Buildings</u>	<p>Federal lands affected by section 522(e) (4) and (5) of the Surface Mining Control and Reclamation Act of 1977 shall be considered unsuitable. This includes lands within 100 feet of the outside limit of the right-of-way of a public highway or within 100 feet of a cemetery, or within 100 feet of an occupied public building, school, church, community or institutional building or public park or within 300 feet of an occupied dwelling.</p> <p>Exceptions: A lease may be issued and mining operations approved for lands:</p> <ul style="list-style-type: none"> (i) used as mine access roads or haulage roads that join the right-of-way for a public road; (ii) for which the Office of Surface Mining Reclamation and Enforcement has issued a permit to have public roads relocated; (iii) for which owners of occupied buildings have given permission to mine within 300 feet of their buildings. <p>Exemption: The application of this criterion is subject to valid existing rights.</p>
(d) <u>Wilderness Study Areas</u>	<p>Federal lands designated as wilderness study areas shall be considered unsuitable while under review by the Administration and the Congress for possible wilderness designation. For any Federal land which is to be leased or mined prior to completion of the wilderness inventory by the surface management agency, the environmental assessment or impact statement on the lease sale or mine plan must consider whether the land possesses the characteristics of a wilderness study area. If the finding is affirmative, the land shall be considered unsuitable.</p> <p>Exception: A lease may be issued and mining operations approved if authorized by the Federal Land Policy and Management Act of 1976.</p> <p>Exemption: The application of this criterion to lands for which the Bureau of Land Management is the surface management agency is subject to valid existing rights.</p>
(e) <u>Scenic Areas</u>	<p>Scenic Federal lands designated by visual resource management analysis as Class I or II (an area of outstanding scenic quality or high visual sensitivity) but not currently on the National Register of Natural Landmarks shall be considered unsuitable.</p> <p>Exception: A lease may be issued and mining operations approved if the surface management agency determines that mining operations will not significantly diminish or adversely affect the scenic quality of the designated areas.</p> <p>Exemption: This criterion does not apply to lands to which the operator made substantial financial and legal commitments prior to January 4, 1977; on which operations were being conducted on August 3, 1977; or which include operations on which a permit has been issued.</p>

TABLE 3-3 (continued)

<u>CRITERION</u>	<u>EXCEPTIONS & EXEMPTIONS</u>
(f) <u>Lands Used for Scientific Studies</u>	<p>Federal lands under permit by the land management agency for scientific studies involving food or fiber production, natural resources, or technology demonstrations and experiments shall be considered unsuitable.</p> <p>Exceptions: A lease may be issued and mining operations approved:</p> <ul style="list-style-type: none"> (i) with the concurrence of the principal scientific user or agency; or (ii) where it would be stipulated that the mining would be done in such a way as not to jeopardize the purpose of the study as determined by the surface management agency. <p>Exemption: This criterion does not apply to lands to which the operator made substantial financial and legal commitments prior to January 4, 1977; on which operations were being conducted on August 3, 1977; or which include operations on which a permit has been issued.</p>
(g) <u>Historic Lands and Sites</u>	<p>All districts, sites, buildings, structures, and objects of historic, architectural, archaeological, or cultural significance which are included in or eligible for inclusion in the National Register of Historic Sites, and an appropriate buffer zone around the outside boundary of the designated property (to protect the inherent values of the property that make it eligible for listing in the National Register) as determined by the land management agency, in consultation with the Advisory Council on Historic Preservation or by procedures approved by the Advisory Council, shall be considered unsuitable.</p> <p>Exceptions: A lease may be issued and mining operations approved if the surface management agency determines:</p> <ul style="list-style-type: none"> (i) with the concurrence of the state, that the site, structure, or object is of regional or local significance only; or (ii) in consultation with the Advisory Council on Historic Preservation, that the direct and indirect effects of all or certain stipulated methods of coal mining on a property in or eligible for the National Register of Historic Sites will not result in significant adverse impacts to the site, structure, or object. <p>Exemption: The application of this criterion is subject to valid existing rights.</p>
(h) <u>Natural Areas</u>	<p>Federal lands designated as natural areas or as National Natural Landmarks shall be considered unsuitable.</p> <p>Exceptions: A lease may be issued and mining operations approved in an area or site if the surface management agency determines that:</p> <ul style="list-style-type: none"> (i) with the concurrence of the state, the area or site is of regional or local significance only; (ii) the use of appropriate stipulated mining technology will result in no significant adverse impact to the area or site; or (iii) the mining of the coal resource under appropriate stipulations will enhance information recovery (e.g., paleontological sites). <p>Exemption: This criterion does not apply to lands to which the operator made substantial financial and legal commitments prior to January 4, 1977; on which operations were being conducted on August 3, 1977; or which include operations on which a permit has been issued.</p>

TABLE 3-3 (continued)

	<u>CRITERION</u>	<u>EXCEPTIONS & EXEMPTIONS</u>
(i) <u>Federally Listed Endangered Species</u>	Federally designated critical habitat for threatened or endangered plant and animal species, and habitat for Federal threatened or endangered species which is determined by the Fish and Wildlife Service and the surface management agency to be of essential value and where the presence of threatened or endangered species has been scientifically documented, shall be considered unsuitable.	Exception: A lease may be issued and mining operations approved if, after consultation with the Fish and Wildlife Service, the surface management agency determines the species and its habitat will not be adversely affected by all or certain stipulated methods of coal mining operations.
(j) <u>State Listed Endangered Species</u>	Lands containing habitat deemed critical or essential for plant or animal species listed by state pursuant to state law as endangered or threatened shall be considered unsuitable.	Exception: A lease may be issued and mining operations approved if, after consultation with the state, the surface management agency determines that the species will not be adversely affected by all or certain stipulated methods of coal mining.
(k) <u>Bald and Golden Eagle Nests</u>	A bald or golden eagle nest that is determined to be active and a buffer zone of land in a 1/4 mile radius from a nest area which shall be considered unsuitable. Consideration of availability of habitat for prey species shall be included in the determination of buffer zones.	Exception: (i) A lease may be issued and mining operations approved if: (A) they can be conditioned in such a way, either in manner or period of operation, that eagles will not be disturbed during breeding season; or (B) golden eagle nest sites will be moved with the concurrence of the Fish and Wildlife Service. (ii) Buffer zones may be decreased if the surface management agency determines that the active eagle nests will not be adversely affected.

TABLE 3-3 (continued)

	<u>CRITERION</u>	<u>EXCEPTIONS & EXEMPTIONS</u>
(1) <u>Bald and Golden Eagle Roost and Concentration Areas</u>	Bald and golden eagle roost and concentration areas used during migration and wintering shall be considered unsuitable.	<u>Exception:</u> A lease may be issued and mining operations approved if the surface management agency determines that all or certain stipulated methods of coal mining can be conducted in such a way, and during such periods of time, to ensure that eagles shall not be adversely disturbed.
(m) <u>Falcon Cliff Nesting Sites</u>	Federal lands containing falcon cliff nesting sites with active nests and a buffer zone of Federal land in a 1/4 mile radius from the nest to provide needed prey habitat shall be considered unsuitable. Consideration of availability of habitat for prey species shall be included in the determination of buffer zones.	<u>Exception:</u> A lease may be issued and mining operations approved where the land management agency, after consultation with the Fish and Wildlife Service, determines that all or certain stipulated methods of coal mining will not adversely affect the migratory bird habitat during the periods when such habitat is used by the species.
(n) <u>Migratory Birds</u>	Federal lands which are high priority habitat for migratory bird species of high Federal interest on a regional or national basis, as determined jointly by the surface management agency and the Fish and Wildlife Service, shall be considered unsuitable.	<u>Exception:</u> A lease may be issued and mining operations approved where the surface management agency, after consultation with the Fish and Wildlife Service, determines that all or certain methods of coal mining will not adversely affect the migratory bird habitat during the periods when such habitat is used by the species.
(o) <u>State Resident Fish and Wildlife</u>	Federal lands which the land management agency and the state jointly agree are fish and wildlife habitat for resident species of high interest to the state and which are essential for maintaining these priority wildlife species shall be considered unsuitable. Such lands may include appropriate buffer zones as determined jointly by the surface management agency and the state. Such lands shall include: <ul style="list-style-type: none"> (i) active dancing and strutting grounds for sage grouse, sharp-tailed grouse, and prairie chicken; (ii) the most critical winter ranges for deer, antelope, and elk; and (iii) migration corridors for elk. 	<u>Exception:</u> A lease may be issued and mining operations approved if the surface management agency, in consultation with the state wildlife agency, determines that: <ul style="list-style-type: none"> (i) complete mitigation is possible; or (ii) the species being protected will not be adversely affected by all or certain stipulated methods of coal mining. <u>Exception:</u> This criterion does not apply to lands to which the operator made substantial financial and legal commitments prior to January 4, 1977; on which operations were being conducted on August 3, 1977; or which include operations on which a permit has been issued.

TABLE 3-3 (continued)

	<u>CRITERION</u>	<u>EXCEPTIONS & EXEMPTIONS</u>
(p) <u>Wetlands</u>	<p>Federal lands containing:</p> <ul style="list-style-type: none"> (i) inland lakes, impoundments, and associated wetlands; (ii) inland shallow, predominantly vegetated wetlands; or (iii) riverine wetland systems, lower and upper perennial systems with flow greater than 5 cubic feet per second, and riparian zones in a "relatively undisturbed" state that are larger than one linear mile along a riverine system shall be considered unsuitable. 	<p>Exceptions: A lease may be issued and mining operations approved where the surface management agency determines that:</p> <ul style="list-style-type: none"> (i) the use of appropriate stipulated mining or reclamation technology will not significantly affect the wetlands or will provide for complete restoration; or (ii) the wetlands contain no significant values for groundwater recharge, fish and wildlife habitat, recreation, or scientific study. <p>Exemption: This criterion does not apply to lands to which the operator made substantial financial and legal commitments prior to January 4, 1977; on which operations were being conducted on August 3, 1977; or which include operations on which a permit has been issued.</p>
(q) <u>Floodplains</u>	<p>Riverine, coastal, and special floodplains (100-year recurrence interval) shall be considered unsuitable.</p>	<p>Exception: A lease may be issued and mining operations approved where the surface management agency determines that:</p> <ul style="list-style-type: none"> (i) leasing a particular tract and approval of mining operations is the only practicable method of access to coal lands outside the floodplain which are not unsuitable under any other criterion; and (ii) potential for harm to people or property and natural and beneficial values of floodplains can be minimized through stipulated use of demonstrated and available mining and mitigation measures. <p>Exemption: This criterion does not apply to lands to which the operator made substantial financial and legal commitments prior to January 4, 1977; on which operations were being conducted on August 3, 1977; or which include operations on which a permit has been issued.</p>

TABLE 3-3 (continued)

	<u>CRITERION</u>	<u>EXCEPTIONS & EXCLUSIONS</u>
(r) <u>Municipal Watersheds</u>	Federal lands which have been committed by the land management agency to use as municipal watersheds shall be considered unsuitable.	<p><u>Exception:</u> A lease may be issued and mining operations approved where:</p> <ul style="list-style-type: none"> (i) the surface management agency determines that all or certain stipulated methods of coal mining will not adversely affect the watershed to any significant degree; and (ii) the municipality or water users concur in the issuance of the lease. <p><u>Exemption:</u> This criterion does not apply to lands to which the operator made substantial financial and legal commitments prior to January 4, 1977; on which operations were being conducted on August 31, 1977; or which include operations on which a permit has been issued.</p>
(s) <u>National Resource Waters</u>	Federal lands with National Resource Waters, as identified by states in their water quality management plans, and a buffer zone of Federal lands 1/4 mile from the outer edge of the far banks of the water, shall be unsuitable.	<p><u>Exception:</u> The buffer zone may be eliminated or reduced in size where the surface management agency determines that it is not necessary to protect the National Resource Waters.</p>
(t) <u>Prime Farm Lands</u>	When the surface management agency, with the concurrence of the Secretary of Agriculture (Soil Conservation Service), identifies Federal lands having prime farmland soils, such lands shall be considered unsuitable.	<p><u>Exceptions:</u> A lease may be issued when:</p> <ul style="list-style-type: none"> (i) conditions such as soil rockiness, angle of slope or historic or other conditions leading to a negative determination under the permanent regulations of the Office of Surface Mining Reclamation and Enforcement are present; or (ii) scientific studies show that crop yields equivalent to pre-mining crop yields on non-mined prime farmlands in the surrounding areas under equivalent levels of management could be obtained and that an operator or potential operator complies with soil reconstruction standards in section 515(b)(7) of the Surface Mining Control and Reclamation Act of 1977 (30 U.S.C. 1265 (b)(7)), and the permanent regulations of the Office of Surface Mining Reclamation and Enforcement.

TABLE 3-3 (continued)

(u) <u>Alluvial Valley Floors</u>	Federal lands identified by the surface management agency, with the concurrence of the State in which they are located, as alluvial valley floors according to the definition and standards in the permanent regulations under the Surface Mining Control and Reclamation Act of 1977, and the final alluvial valley floor guidelines of the Office of Surface Mining Reclamation and Enforcement, and approved state programs under the Surface Mining Control and Reclamation Act of 1977, where mining would interrupt, discontinue, or preclude farming, shall be considered unsuitable. Additionally, when mining Federal land outside an alluvial valley floor would materially damage the quantity or quality of water in surface or underground water systems that would supply alluvial valley floors, the land shall be considered unsuitable.	Exception: A lease may be issued where all or certain methods of coal mining would not interrupt, discontinue, or preclude farming on land to which the first sentence of the criterion applies.
(v) <u>Reclaimability</u>	As information regarding reclaimability on a local or regional basis becomes available, the surface management agency shall use such information to determine if areas of Federal land are reclaimable to the standards of the Surface Mining Control and Reclamation Act of 1977, the regulations, and applicable state laws. Examples of information on reclaimability would be soil studies, hydrologic studies, and studies concerning re-vegetation. If any area is determined not to be so reclaimable, such area shall be considered unsuitable.	Exception: A lease may be issued upon presentation of information which contains results of studies showing that reclamation is possible to the standards in the permanent regulations of the Office of Surface Mining Reclamation and Enforcement, and an approved state program, including state regulations.
(w) <u>State Lands Unsuitable</u>	Federal lands in a state to which is applicable a criterion (i) proposed by the state, and (ii) adopted by rulemaking by the Secretary of the Interior, shall be considered unsuitable for coal mining.	<p>Exceptions: A lease may be issued when:</p> <ul style="list-style-type: none"> (i) such criterion is adopted by the Secretary less than 6 months prior to the publication of the draft land use plan, or supplement to the land use plan, for the area in which such land is included, or (ii) the surface management agency, in consultation with the state, determines that, although the criterion applies, mining will not adversely affect the value which the criterion would protect. <p>Exemption: This criterion does not apply to lands to which the operator made substantial financial and legal commitments prior to January 4, 1977; on which operations were being conducted on August 3, 1977; or which include operations on which a permit has been issued.</p>

TABLE 3-3 (concluded)

<u>(x) State Proposed Criteria</u>	A buffer zone of Federal lands necessary to provide protection for any adjacent area designated as land unsuitable for mining by the state shall be considered unsuitable.	Exception: The buffer zone may be modified or eliminated where the surface management agency, in consultation with the state, determines that all or parts of the zone are not necessary to protect the designated area. Exemption: This criterion does not apply to lands to which the operator made substantial financial and legal commitments prior to January 4, 1977; on which operations were being conducted on August 3, 1977; or which include operations on which a permit has been issued.
------------------------------------	--	---

forth in Table 5-88) were then field tested by three task force teams on Federal lands in four test areas in Montana, Utah, and Wyoming during the summer of 1978. After completion of the field tests, the task force reconvened to review the field test results and, on the basis of those results, to recommend to the Department which criteria and exceptions should be altered, added, or deleted. The field test results and recommended criteria and exceptions appear in the task force's September 12, 1978, final report, Land Unsuitability Criteria (available upon request from the Department) [2]. The Under Secretary expressed a preference for the twenty-four criteria and their exceptions set forth in Table 3-3 after extensive discussions in the manner described in Section 3.2.1. with the Assistant Secretaries for Land and Water Resources; Fish, Wildlife and Parks; Energy and Minerals; and Policy, Budget and Administration; and the Solicitor. Each Assistant Secretary and the Solicitor proposed new language for many of the task force's recommended criteria and exceptions and either deletions or additions to those criteria and exceptions. Certain criteria and exceptions were more tightly drawn to ensure that their application would not result in the screening out of lands not necessary for the protection of the values reflected in the criteria. On the other hand, a number of new criteria were added by the Under Secretary to provide protection to values other than those which the task force's recommended criteria were intended to protect. Finally, one criterion recommended by the task force was deleted by the Under Secretary. (See Section 5.4.8 and Table 5-89 for a discussion of field test results and changes made in the draft field test criteria (Table 5-88) before their adoption as the proposed criteria for the preferred program (Table 3-3).)

Because the criteria and exceptions selected by the Under Secretary for the preferred program are changed significantly from the criteria and exceptions originally field tested by the task force, the Department determined that they should be field tested anew before any final decision on them is made by the Secretary. Furthermore, the Department designed procedures for these field tests to ensure that the criteria and exceptions would receive attention not only from the land management agencies' planners, but also from interested user groups and the public. The field tests are being conducted in a four-county area in Alabama

and on 540,000 acres in nine planning units in Colorado, Montana, Utah, and Wyoming. The preliminary results have been made available to the public in the form of draft supplements to existing land use plans and public meetings have been held on the documents. The draft supplements and public comments on them will be fully considered by the Secretary prior to making any final decision on a Federal coal management program. Any changes in the preferred criteria and exceptions adopted by the Secretary would be subsequently incorporated in the final supplements which would be published after the Secretary's decision. (The procedures for conducting the field tests and preparing the supplements were published on December 8, 1978, in 43 Federal Register 57662-57670.)

These 24 preferred unsuitability criteria can be divided into four categories: those which are required under Section 522 of SMCRA (e.g., Federal land system, buffer zones along rights-of-way and adjacent to communities and buildings, and reclaimability criteria), those which are discretionary under Section 522 (e.g., land used for scientific studies, municipal watersheds, and flood-plains criteria); those which embody requirements under other statutes which the Department chooses to enforce through the application of unsuitability criteria (e.g., federally-listed endangered species and bald and golden eagle criteria); and those which are not required by statute but which the Department has decided to apply in its discretion as good public policy (e.g., scenic areas, state resident fish and wildlife, state lands unsuitable, and state proposed criteria). In short, some of the criteria involve interpretation of legal requirements within circumscribed limits; others represent an attempt to set broader limits on field-level resource management judgments that have previously been entirely discretionary. (Table 3-4 sets out the authorities for each unsuitability criterion.) Each criterion in all four categories of criteria, including the two discretionary categories, would be fully applied during land use planning; the responsible official would not have the discretion to refrain from applying any criterion. The only remaining discretion, either permitted by law in the required criteria or inherent in the discretionary criteria, is incorporated in the exceptions and the decision whether to apply an exception. The combination of, first, taking issues that have been

TABLE 3-4

PROPOSED UNSUITABILITY STANDARDS:
THEIR SOURCES AND LIMITATIONS

CRITERION (Proposed Rule Section)	STATUTORY SOURCE <u>1/</u>	NATURE OF CRITERION	EXEMPTIONS	DERIVATION OF EXCEPTIONS
1-1. Lands in federal land preservation systems (National Parks, Wildlife Refuges and Trails)	a. 522(e)-SMCRA;	a. mandatory	a. valid existing rights; surface coal mining operations existing on 8-3-77	
	b. 16-FCLAA	b. mandatory	b. none	
1-2. Buffer zones around such land	522(a)(3)- SMCRA Clean Air Act	discretionary	522(a)(6)-SMCRA <u>2/</u>	
1-3. Lands in Custer National Forest [3461.2(a)]	522(e)-SMCRA	mandatory	valid existing rights; existing surface coal mining operations	operations that involve no surface coal mining operations (522(e)(2)(B) proviso-SMCRA)

1/ Statutory sections are cited if clear. SMCRA means the Surface Mining Control and Reclamation Act of 1977, 30 U.S.C. § 1201 *et seq.*; FCLAA means the Federal Coal Leasing Amendments Act of 1976; FLPA means the Federal Land Policy and Management Act of 1976, 43 U.S.C. § 1701, *et seq.*

Section 2 of the Mineral Leasing Act, as amended, 30 U.S.C. § 201, contains the Secretary's ultimate discretion to lease or not to lease in the public interest. It applies to all the criteria. Similarly, sections 201 and 202 of FLPA, the Secretary's resource inventory and land use planning authorities, apply to all criteria on all lands administered by the Bureau of Land Management. These sections are cited only when they are relied on as authority for the criterion.

- 2/ In every case, section 522(a)(6) exempts: (a) operations approved under SMCRA; (b) surface coal mining operations existing on August 3, 1977; and (c) operations to which substantial legal and financial commitments were made prior to January 4, 1977.
- 3/ The general authority for the exception is found in the coverage or limitations on the coverage of the statutory policies and protections.

considered within varying degrees of specificity at various stages of Federal coal management and requiring that they receive some attention at the earliest stages of planning, and, second, providing that attention through a process that requires site-specific, for-the-record determinations of the applicability of those criteria would, the Department believes, have two beneficial results. It would make all land use planning decisions more sensitive to the resource values covered by the unsuitability criteria and would permit a level of public review and accountability not previously associated with that kind of field-level decision.

The unsuitability criteria would, in some form, be applied to all new leases, including emergency leases and preference right lease applications. The criteria would be applied directly to the tract areas for emergency and preference right lease applications. For all other new leases, the procedures set forth below would be followed.

The responsible official of the Federal land management agency would describe in the land use plan the results of the application of each of the unsuitability criteria to the medium and high potential coal lands in the planning area. He would state each instance in which a criterion is found to be applicable and show the area which is excluded from further coal development consideration or, should he determine that the conditions for an exception exist, describe the area to which the exception applies and discuss in detail the reasons why the exception is made and what type of stipulations will be required in the lease or mining permit to assure compliance with the exception. In applying the criteria and exceptions, the responsible official would first publish a composite map showing full application of all criteria prior to consideration of any of the exceptions. The map would be part of the formal documentation to be made available to the public. Only after the map has been prepared and made public would the exceptions be applied; however, the responsible official would consider using an exception only when a small area: (1) has applicable to it a criterion; (2) is in a larger area to which no criteria otherwise apply; and (3) would likely preclude the designing of any lease tracts within the larger area. This procedure deters aggressive application of the exceptions and places a distinct burden of proof on the responsible official to carefully and forcefully

document any application of exceptions which he would make.

Where the quality of the data available for the application of a particular criterion or exception is high, the responsible official would decide on the basis of that data whether the area is unsuitable as set out above. Where data are unavailable or where the best available data are not of sufficient quality to allow a decision on the application of the criterion or exception to be reached with reasonable certainty, the responsible official would continue the land affected in the process and state in the land use plan when in activity planning, lease sale, or post-lease activities the additional, necessary data might be obtained. At such time as the data become available, the responsible official would be required to make public his determination concerning unsuitability, and the reasons therefore, and provide opportunity for public comment before that determination is made. Any changes which either result from petitions for designating lands unsuitable or for removing unsuitability designations or are warranted by additional data acquired in the activity planning, lease sale, or mine plan review process would be made without formally revising the plan.

All lands not identified unsuitable for coal mining would be considered further in the land use planning process. Lands with coal that would be mined by underground mining methods would not be considered unsuitable for coal mining where the mining would result in no hydrologic or surface effects. Where underground mining of Federal coal would produce hydrologic or surface effects to which an unsuitability criterion applies, those lands would be considered unsuitable unless the conditions exist to permit an exception. In predicting surface effects, the responsible official would consider surface occupancy and the potential for subsidence, fire, or other environmental impacts of underground mining which may be manifested on the surface.

As previously mentioned, the Secretary's decision to apply unsuitability criteria at the land use planning stage, as well as the post-leasing mine plan stage, was based on both public policy and economic considerations. By this policy preference, the Secretary hopes to avoid the unfortunate and possibly frequent occurrence of the following scenario: the Federal government expends considerable sums of money on a site-specific analysis for

lease sale preparation; a mining company also incurs large expenditures to determine whether it wishes to bid on the tract and (if successful in purchasing the lease) to prepare a mine plan; application of the criteria at the time of mine plan submission may suddenly make the foregoing tract unmineable or require the insertion of so many stipulations in the mine plan or mining permit as to make mining of the tract uneconomical. This scenario could be almost entirely avoided by the application of criteria first in the land use planning process. Although the criteria would be applied again at the mine plan stage, the application of most of them in the land use planning process could be done with a degree of certainty which makes any changes as a result of the second application unlikely. However, certain criteria, most notably the reclaimability and alluvial valley floor criteria, would require so much costly, site-specific data—data which would not be collected until after the land use planning is finished (in activity planning or prior to submission of the mine plan)—that the application of them in the land use planning process could only serve to screen out the most obvious areas. In the case of these few criteria, there would remain an unavoidable possibility that significant changes could occur when the criteria would be applied again after the lease has been issued at the time of mine plan submission. Note also that there are other potential criteria that might be applied at the mine plan stage but not earlier, most specifically criteria related to geologic hazards.

The unsuitability criteria would also be applied to each existing non-producing lease upon submission of a mine plan by the lessee (should an existing lease be within a land use plan area to which unsuitability criteria are being applied in land use planning the criteria would be applied to the lease at that time if a mine plan has not already been submitted.) The mine plan would be reviewed in light of the unsuitability criteria to determine which, if any, apply. If a criterion applies, the Department would evaluate whether, under an exception to the criterion, the plan could be changed to eliminate the harmful effects to the value which the criterion is designed to protect. If no change could be made and some or all types of mining could not take place consistent with the criterion, a decision would be made whether the Department has the authority to apply that

criterion to the lease. If the lessee has valid existing rights and has made substantial legal and financial commitments, he may be exempted, by statute, from complying with certain of the criteria depending on the source of authority for the criteria and the dates of his commitments. If the Department is found to possess the authority to apply the criterion, the mining would not be permitted. For some criteria, the Department would have to formally designate the lands as unsuitable to prevent mining; for others, formal designation would not be needed.

Section 522(b) of SMCRA mandates the Secretary of the Interior to review all Federal lands for unsuitability and it allows citizens to petition for and against designation of lands as unsuitable. Consequently, under SMCRA, the Department must have procedures to apply unsuitability criteria both as part of a comprehensive Federal lands review and as part of a petition process.

Section 522(b) requires the Secretary to review all Federal lands even though many local areas are under the land managing jurisdiction of another agency, principally the Forest Service or the Corps of Engineers. By expressing a preference for the application of the unsuitability criteria to Federal lands in the land use planning conducted by each Federal surface management agency, the Department has proposed a course for the Federal lands review that would allow other surface management agencies to enter into cooperative agreements with the Department to carry out the Federal lands review on lands they administer just as the Bureau of Land Management will on land it administers. (The BLM is presently negotiating a memorandum of understanding with the Forest Service on how the latter agency would apply the criteria on national forest system lands.) For any agency that does not have the resources to accomplish such a review for lands under its jurisdiction, the Secretary would remain obligated to conduct a review on those lands.

With respect to lands administered by BLM, the Under Secretary on July 5, 1978, approved a delegation of authority that gives BLM the responsibility to administer the Federal lands review through its land use planning system and the Office of Surface Mining Reclamation and Enforcement (OSM) the responsibility to administer the statutory petition process. (Appendix B to

the Federal Register Notice of December 8, 1978; 43 Federal Register 57662, 57666-57668).

The Federal lands review under Section 522(b) of SMCRA would be conducted in accordance with the procedures discussed above for application of the unsuitability criteria during land use planning or upon submission of a mine plan. The Federal lands review is not a program for the designation of lands as unsuitable for mining. Formal designation of Federal lands as unsuitable would occur only in response to a petition to designate under Section 522(c) of SMCRA. Petitions would be filed with OSM under the division of responsibility established on July 5. Section 522(c) requires the petitioner to be adversely affected by potential mining of the lands in question, and requires each petition to "contain allegations of facts with supporting evidence" to establish the truth of the allegations. Because of these threshold requirements, it is assumed that the public lands will not be blanketed by petitions. On those petitions that do pass the threshold requirements, designation as unsuitable, rejection of the petition, or termination of a prior designation would have to occur within one year. The year provides the time in which the BLM (or other land management agency) would substantively review the petition and, if necessary and possible, examine the tract, and in which a public hearing on the petition would be held and a written decision rendered. The OSM would refer each petition to the BLM or other appropriate land management agency for its review and the results of that review would be presented at or before the hearing. The BLM or other agency would also be able to petition OSM on its own behalf to designate Federal lands as unsuitable.

While the criteria applied in the Federal lands review and the petition process are the same, it is important to note that OSM, not the land management agency, controls the outcome of the petition process. It may be that certain lands which would not be found to be unsuitable in land use planning might be designated unsuitable upon petition, and, conversely, lands deemed unsuitable by the land management agency might not be designated unsuitable upon petition. This is possible because the unsuitability criteria themselves, and their exceptions, are, in origin and function, designed to ensure environmental protection and establish mitigation of adverse impacts, while the formal

designation process requires consideration of coal demand and the socio-economic impacts in carrying out the environmental purposes served by the criteria. Section 522(d) of SMCRA requires OSM to prepare, prior to designating Federal land unsuitable, a "detailed statement on (i) the potential coal resources of the area; (ii) the demand for coal resources, and (iii) the impact of such designation on the environment, the economy, and the supply of coal." In order to assure the greatest consistency between OSM's unsuitability designations and BLM's or other land management agency's land use planning unsuitability assessments, the BLM's proposed coal management regulations (Appendix A, Section 3461.4-3) require that the same "detailed statement" be made by BLM to document its unsuitability assessments when it adopts a land use plan.

3.2.2.3 Multiple Use Resource Management Decisions. Although it is likely that most major conflicts between coal and other resources would be addressed during the application of the unsuitability criteria, significant resource balancing decisions could remain. These other resource trade-offs would be considered and acted upon after application of the unsuitability criteria. The adjustments at this stage in the land use planning process would be made to accommodate unique, site-specific resource values clearly superior to coal but which are not included in the criteria. A prime recreation site or campground might be an example. The responsible official would balance these values against the value of possibly offering additional coal from the planning unit.

3.2.2.4 Surface Owner Consultation. Section 714 (d) of the Surface Mining Control and Reclamation Act of 1977 requires the Secretary to consult during the planning process with certain owners of the surface estate overlying Federal coal resources being considered for leasing. This forms another screen for identifying lands that should not be leased.

In order to minimize disturbance to surface owners from surface coal mining of Federal coal deposits and to assist in the preparation of comprehensive land use plans required by Section 2(a) of the Mineral Leasing Act of 1920, as amended, the Department would consult with any surface owner as defined in Section 714(e) of SMCRA whose land might be included in a leasing

tract and ask the surface owner to state his preference for or against the offering of the deposit under his land for lease. It would also request disclosure of any consent for mining already given by the surface owner. The Department would, to the maximum extent practicable, refrain from leasing coal deposits for development by methods other than underground mining in areas where a significant number of qualified surface owners state a preference against the offering of the deposits for lease. Although portions of these areas might still be designated as acceptable for further consideration for coal leasing, the land use plan would contain the recommendation that no leasing take place in the areas unless there are no acceptable alternative local areas available to meet the leasing target for the entire coal region.

The Department is considering an additional policy applicable to the surface owner consultation process and is soliciting public comment on that policy, in particular comments on the proposed regulations (see Section 3420.2-3(d) in Appendix A). Under this policy, the Department would provide on the consultation form a place for the qualified surface owner to register not only his preference for or against surface mining of his land but also whether he has a firm intent not to consent to such mining during the life of the land use plan (a maximum of 15 years in the BLM's proposed planning regulations). After the surface owner consultation screen has been applied and the local land manager (1) has determined each general area in which a significant number of qualified surface owners has expressed a preference against leasing and (2) has made a determination concerning the removal of those preference areas from the areas which the land use plan will identify as acceptable for further consideration for leasing for the surface mining of coal, the disclosures of firm intent not to consent would be considered. Those specific lands covered by firm intent disclosures would be removed from any further consideration for leasing for the surface mining of coal in the land use plan.

As a consequence of these procedures, any land covered by a firm intent disclosure on the consultation form would not be considered for leasing again if the coal were to be developed by surface mining methods for the life of the land use plan even if a preference area encompasses it and the BLM decides to lease in that area under the

limited exception discussed above. The only exception would be when the ownership of the land changes and the new owner either is not a qualified surface owner or is willing to file a written consent to surface mining, and the land management agency elects to amend the land use plan.

Should the surface owner not be willing to make a decision at this point, he would still be able to exercise his surface owner protection rights under the subsequent consent acquisition procedures of the preferred program (see Section 3.2.5.1).

3.2.2.5 Threshold Development Levels. Although many land use decisions can be made on a site specific basis (as previously suggested, such a decision might be that a particular area should be developed as a recreation site rather than leased for coal), other decisions may be oriented more toward impacts dependent on levels or rates of development. Although any one of several given potential coal development sites under consideration might have an acceptable impact by itself, the total impact to the area of developing all sites could be intolerable. As an example, the crucial habitat area for a particular species might have been removed from further consideration for leasing. The species do, however, use additional areas within the land use planning unit. Coal development in these areas might adversely affect the species' population. During the land use planning process, a decision might be made that a 10-percent decrease in the population would be an acceptable trade-off. Given the protection of the crucial habitat area, it might not make a difference what other areas would be temporarily lost to coal development as long as the total would not exceed a certain acreage or decrease the population more than the agreed upon amount. In this situation, no additional land would be removed from further consideration for coal leasing. Instead, a threshold constraint would be established in the land use plan to specify the total level of habitat reduction within the acceptable areas identified in the plan.

This threshold concept is particularly appropriate when considering socio-economic impacts. The social and economic infrastructure which coal development in the land use planning area would affect might, over a certain time period, only be able to support a particular developmental level.

Also, the rate of development might be critical. If this information is available, a recommended threshold leasing or development level and rate could be specified in the plan.

It is not necessary to establish thresholds in the land use plan. The later steps in the activity planning process supply opportunity for the Department, other Federal agencies, state and local governments, and others to discuss and agree upon regional and subregional thresholds. If, however, the land use planning process reveals the need for a particular threshold on the scale of a planning unit, then the decision could and should be made at that point.

In a March 8, 1979, memorandum to the Director of the Bureau of Land Management, the Assistant Secretary, Land and Water Resources, requested that the Bureau undertake as a high priority task the further intensive development of the threshold concept. The study is to be conducted in the context of the Bureau's land use planning system, and is to consider use of the threshold concept not just for the coal resource but also for the other resources addressed in the planning process. The Bureau was further requested to incorporate the threshold concept into its final planning regulations.

3.2.2.6 Preferred Coal Leasing Areas. Within the areas identified as acceptable for further consideration for coal leasing, the land use plan could delimit preferred coal leasing areas. This would be done only when available coal demand data suggest that the areas acceptable for further consideration for coal leasing clearly could yield more coal than would be needed for leasing before the land use plan would be reviewed (five years in the BLM's proposed planning regulations). Preferred areas would be identified by employing available socio-economic, environmental, and economic data. These preferred area identifications would be advisory only to the regional coal teams and not a plan commitment.

All of the land use planning steps in the preferred program could be made a part of any of the alternatives since land use planning must be done even if the Department decides not to adopt a coal management program. This component is least compatible with the lease to meet industry needs alternative particularly as it requires the land use planners to set threshold development levels.

Under the lease to meet industry needs alternative, the Department would rely on the market place to set the various threshold levels. Application of the unsuitability criteria would be postponed until the mine plan stage. Planning would focus only on those areas for which there had been nominations.

3.2.3 Activity Planning.

Two consecutive processes would be undertaken in activity planning in the preferred program: tract delineation and tract ranking, selection, and scheduling (see Figure 3.3). The first process would take place in each land use plan area; the second would be conducted over the entire coal region encompassing many land use plan areas.

3.2.3.1 Tract Delineation and Industry Expressions of Interest. As previously noted, the land use plans would disclose areas which are considered to be acceptable for further consideration for coal leasing. These areas would *not* be lease tracts and would be much larger than any acreage which might be needed for leasing over the next 10 years (the lengthiest period which would be used for setting regional leasing targets (see Section 3.2.4)). The purpose of activity planning is to delineate and select a sufficient number of tracts for sale from the areas designated in the land use plans as acceptable for further consideration for leasing to meet the regional leasing target. The first step after publication of the land use plan is to preliminarily delineate potential lease tracts. In delineating the preliminary tracts, the land management agencies would consider the following factors:

- Expressions of interest and existing or planned operations on adjoining lands.
- Technical coal data, including reserve tonnage, rank, sulfur content, seam thickness, and ratio of recoverable coal to reserves.
- Conservation considerations, including calculation of preliminary maximum economic recovery, land ownership patterns, and the formation of logical mining units.
- Surface ownership, including the results of surface owner consultation, and the existence of surface owner consents and their terms.
- Prior regional leasing targets and guidance from the regional coal teams.

Although preliminary tract delineation would be done by the Department, the first step in the

delineation process would be to request submissions by industry of expressions of interest for leasing. As previously discussed, a call for expressions of leasing interest would be made only after areas acceptable for further consideration for coal leasing have been identified in the Bureau of Land Management or Forest Service land use plans. In areas where state or other agency plans have been adopted, unsuitability criteria would be applied before a call would be made. The call would be made before any tract boundaries would be delineated and the expressions of leasing interest would be the most significant information employed in delineating the tracts. It is expected that any tract proposed in expressions of leasing interest would be preliminarily delineated as proposed, unless it was necessary to not delineate it, delineate it differently, or delineate other tracts to ensure competitive interest in the eventual lease sale, conserve Federal coal, or meet other largely economic objectives in the coal management program.

In addition to industry, any individual, state, or public body would be able to respond when the Secretary issues a call for expressions of leasing interest. All calls would provide a description of the kind of information required, including but not limited to location and quantities of coal desired, date lease would be desired, proposed use of coal, technical coal data, commitments with private surface owners and adjacent landowners or lessees, and basic development proposals. Expressions of interest against leasing which were possible under the 1975 proposed program (EMARS II) would not be accepted; however, a similar purpose would be served by unsuitability petitions in the present preferred program. Public inspection and copying of information submitted with the expressions of leasing interest would be permitted in accordance with Departmental regulations.

Notice of each request for expressions of leasing interest would be published in the Federal Register and in the general circulation newspaper(s) in the coal region. This notice of request would specify the area or areas involved, information required, the period of time within which expressions may be submitted, where to write for further information, and where to submit the expressions.

The fact that a specific request for expressions of interest would be part of the activity planning

system would not preclude industry, the states, or other parties from participating in the earlier land use planning efforts. General comments and interests could be submitted during the planning process or whenever any party might wish to indicate an interest in Federal coal in a particular area. Such general comments and interests could be in the form of a letter or public testimony. The Department would use this information for planning purposes or to aid in setting the regional production goals and leasing targets.

Tracts would not be identified as special opportunity lease sales for public bodies or small businesses during tract delineation. However, if special leasing opportunity sales are contemplated in the region, an effort to identify tracts of an appropriate size and location would be made at this stage of the process. In order to initiate Departmental action to identify potential public body lease sale tracts, interested public bodies would have to submit formal expressions of leasing interest in response to the notice calling for expressions of leasing interest. Although potential small business candidates would be encouraged to submit formal expressions of leasing interest, they would not have to initiate tract identifications for small business special leasing opportunities. Rather, in consultation with the Small Business Administration, the Department would delineate tracts to go into the ranking process which could meet the needs of small businesses. The Small Business Administration proposed a definition of a small business for Federal coal lease sale set-aside purposes on March 14, 1979 (44 Federal Register 15513-15514).

In the months before the schedule is established, all available preliminary tracts would be reviewed for the adequacy of the tract information profile. Data insufficiencies would be noted and, where time permitted, remedied so that each tract would have as complete a coal resource, socioeconomic, and environmental profile as possible. Also, unsuitability questions left unresolved in general planning would be analyzed and tract-specific stipulations written at this time.

3.2.3.2 Regional Tract Ranking, Selection, and Scheduling. If a regional leasing target established for any given region suggests the need for Federal coal leasing over the up-coming two or four years, a proposed lease sale schedule would be prepared.

Every two or four years, the Director of the BLM would formally begin the regional tract ranking and selection process. Ranking would be on a coal region-wide basis and not separately within each land use planning area. In the ranking process, factors relating to coal economics, ease of reclamation, proximity to existing transportation facilities, class of surface ownership (Federal or non-Federal), and socioeconomic and other environmental concerns would be employed. Ranking would be for general levels of acceptability only. The regional coal team would be expected to emphasize those factors of importance to the region. The ranked tracts would be compared with the regional leasing target and a set of tracts would be selected for a proposed lease sale schedule. Since the potential environmental and social impacts resulting from development of any tracts in the same area would be cumulative, the selection of the first tract might preclude selection, or lower the priority of, other highly ranked tracts. Accordingly, as selections are made of individual tracts, the original rankings of the remaining tracts might be altered and the final, selected tracts would not necessarily directly correspond to the relative order in which the individual tracts were originally ranked. The number of tracts proposed would be dependent on the type of bidding system to be used (intertract or single tract bidding) and the tonnage targeted for lease. The selected tracts would be placed in a proposed regional lease sale schedule.

The tract ranking and selection process would be conducted in close coordination with the governors of the states comprising the region and in consultation with all affected Federal land management agencies and other Federal and state agencies with expertise of relevance to the process. To facilitate this coordination and consultation, a Department/state regional coal team would be established for each of the major multi-state coal regions. The team would consist of a BLM field representative and a state government representative from each state within the region. An additional member appointed by, and directly responsible to, the Director of the BLM would be assigned to each team and serve as its director. In addition, procedures would be established to ensure that the Federal land management agencies and the other Federal and state agencies with expertise would participate during the ranking process.

Each regional coal team would consider and suggest policy for regional production goal and leasing target setting, tract delineation, and site-specific analysis in the coal region. It would guide and review tract ranking, and conduct the tract selection and sale scheduling procedures that develop the alternatives which are analyzed in the regional lease sale environmental impact statement and are recommended to the Secretary. If any state representative should disagree with the Federal team members' ranking decisions or selection and scheduling recommendations and a compromise could not be reached, his opinions would be documented and his alternative recommendation would be treated equally in the regional lease sale environmental impact statement sent through the Director, BLM, to the Secretary for his decision. The ultimate decision-making authority for the selection and scheduling of tracts for lease sale resides in the Secretary.

A notice of intent to rank and select tracts to be included in a proposed regional lease sale schedule would be published in the Federal Register and selected general distribution newspapers within the coal region no less than 30 days before the ranking process begins. The notice would contain a description of the tracts to be ranked and procedures under which any interested parties are to be involved in the process. Also a final call for surface owner consent filings would be made for the tracts to be ranked.

Detailed profile information on each of the tracts ranked would be available for inspection in the Bureau of Land Management offices in the coal region. Those parties interested in commenting on the results of the tract ranking and selection process would have the opportunity to do so in the regional lease sale environmental impact statement process before any final decision would be made by the Secretary to accept the proposed lease sale schedule or hold a lease sale encompassing any of the selected tracts. It is the intent of the Department that the development of the regional sale schedule and the environmental impact statement for the regional sale be closely integrated. This would be done by integrating the decision and analyses documents used for sale schedule development with the statement. Some special efforts will be needed for the statement alone after preliminary identification of a sale schedule, but this work would be limited. This procedure would

be in accord with the new Council on Environmental Quality regulations for preparation of environmental impact statements.

The tract ranking and selection decisions would normally be reconsidered every two years in accordance with the updating of the national and regional production goals and leasing targets. The Secretary might, in consultation with the governors of the affected states, initiate or postpone the tract ranking and selection process to respond to considerations such as major planning updates, new preliminary tract delineations, and increases or decreases in the level of leasing.

To establish planning and inventory-related priorities, the Secretary might include in the ranking process areas recently identified in new land use plans or plan updates, or recently designated, as areas acceptable for further consideration for coal leasing which have not yet been delineated as preliminary lease tracts. All tracts subsequently identified for lease consideration would be formally entered into the ranking and selection process before they are included in a lease sale proposal.

Activity planning would not occur under the no new leasing alternative and would have relatively little importance under the preference right lease application and the emergency lease only alternatives. Under the lease to meet industry indications of need alternative, activity planning would take place only in response to industry nominations, and regional tract ranking and selection would not occur. The process described here would be consistent with the lease to meet DOE production goals alternative. Under the state determination of leasing levels alternative, the control over activity planning would be transferred from the Bureau of Land Management to the states.

3.2.4. Setting Regional Production Goals and Leasing Targets.

Over the past several years the question of the need for leasing has been a focal point of much of the controversy surrounding the Department's efforts to manage the Federal coal resource. Considering the several years' lead time needed for developing mines to the point of production and the similar time frames for planning and constructing coal-consuming power plants, precise determinations now of the tonnage of Federal coal which

should be leased to meet the Nation's future energy requirements are not feasible, although estimates can be made on the basis of available information and projections.

Chapter 2 of this document provides an examination of the national energy role of Federal coal, including an assessment of the need for leasing. The need for leasing involves both meeting national energy objectives and improving coal development patterns for a given amount of coal production. This analysis, together with the overriding consideration that the Department requires a coal management system in place to respond promptly to leasing needs when they are determined, is the basis for the Secretary's preference for a Federal coal management program which has the capability to initiate new competitive lease sales. However, the Secretary realizes that, no matter how good the analysis of need for leasing may be in Chapter 2, circumstances seldom remain sufficiently constant, and forecasts are not often precise enough to permit the competitive leasing component of a coal management program to function continuously on the basis of a single assessment of leasing needs. Accordingly, the Secretary chose to make a continual reassessment of leasing needs an integral and very public part of the preferred program. The preference is for a process which merges DOE production goals with advice from state and local governments, the coal industry, and other interest groups to determine leasing levels. This process of continual reassessment of future regional coal needs would permit modification of leasing activity in response to changes in projected demands for coal.

The major coal bearing areas of the continental United States have been divided into 12 coal regions as shown in Figure 1-1. Eight of these regions contain significant reserves of Federal coal (see Appendix H). Under the preferred program, these eight coal regions would serve as the basic units both on which the assessment of desired levels of leasing would be centered and in which tracts would be ranked, selected, and scheduled and lease sales conducted. The Department of Energy (DOE), pursuant to the responsibilities assigned to it by the Department of Energy Organization Act, would establish and biennially update five, 10, and 15-year regional coal production goals which would guide the Department of

the Interior in its decisions on the number and timing of lease sales.

Under the terms of the Memorandum of Understanding between the Departments of the Interior and Energy set out in Appendix B, the Secretary of Energy would submit proposed DOE regional production goals to the Secretary of the Interior. The supporting material for these proposed goals might include an indication of probable need for coal by major type; however, in determining regional goals for specific types of coal, the Secretary of the Interior would be guided mainly by industry indications of interest submitted at the start of the activity planning process. The Secretary of the Interior would, within 60 days, comment to the Secretary of Energy on any potential conflicts or problems which the Interior Department foresees in the DOE regional production goals as proposed. These comments would be based on the Interior Department's responsibilities for the management, regulation, and conservation of natural resources; the capabilities of Federal lands and Federal coal resources to meet those goals; and the national need for the coal balanced against the environmental consequences of developing it.

These comments would, of necessity due to the short comment period, focus on immediately perceivable problems and conflicts and would not include in-depth analyses of issues which can only be undertaken after consultation with field personnel, the states, industry, and the public. It is expected that, during the preparation of the regional production goals, the Department of Energy would focus mostly on macroeconomic issues concerning the energy needs of a healthy national economy and would consider comments from diverse sources on the formulation of national energy goals and the role of coal production in meeting those goals. Within 30 days after receiving the Secretary of the Interior's comments, the Secretary of Energy would transmit to him final DOE national and suggested regional production goals.

The Secretary of the Interior would then look to the expertise and viewpoints of the regional coal teams (see Section 3.2.3.2) as the major source of information and comment on the final DOE regional production goals and how they might affect leasing strategies and decisions. The Secretary would transmit the relevant DOE goal to each

team. The team, in turn, would analyze the goal on the basis of its tract ranking and selection experience, its detailed knowledge of the region, and public comments it receives on the goal from publication in the Federal Register and a hearing in the region. The team would report back to the Secretary any adjustments it feels are necessary in the relevant DOE regional production goal and the reasons for those adjustments. The team would also provide the Secretary with its suggestion for a regional leasing target (on a reserve tonnage basis) for the next four year period.

Based on the recommendations of the teams and other information available to him, the Secretary of the Interior would adopt the final DOE regional production goals either without change or after making adjustments to them. He would transmit the final DOE goals, as adopted with or without adjustments, to the Secretary of Energy and publish them in the Federal Register. The goals adopted would be used by the Department for long range coal management program planning and would be made available to the states, local governments, and other bodies for their use.

The Secretary of the Interior would also adopt preliminary regional leasing targets for logical mining units which would be composed of or include Federal leases, again after consideration of the teams' recommendations and other information available to him.

These preliminary regional leasing targets would reflect primarily the difference between desired levels of production in the region and the estimated production without new Federal leasing. They would include the Federal and non-Federal coal that enters production because of Federal leasing. Among other factors which might be affected by leasing decisions and which the Secretary would consider in establishing preliminary regional leasing targets would be competition within the industry and environmental problems associated with the existing pattern of leases and mines in the regions.

The Secretary would publish the preliminary regional leasing targets in the Federal Register and transmit them to the regional coal teams.

Among the sources of information which the Secretary would consider in making any adjustments to the final DOE regional production goals and in establishing the preliminary regional leasing

targets would be statutory requirements; Departmental policies; land management requirements in land use and activity plans; the analyses in this programmatic environmental impact statement; environmental impact statements on the delineation, ranking, and selection of tracts; and reports and studies by governmental agencies, trade associations and companies, universities, and other institutions and organizations. The Secretary might also call a national conference of the regional coal teams to discuss their individual recommendations and the sum effect of those recommendations. After publishing the final DOE regional production goals and the preliminary regional leasing targets, the Secretary would consult directly with the governors of the affected states to learn their views, particularly with respect to the relationship between the preliminary regional leasing targets and potential social and economic effects on the states and regions. Based on the information he receives through all of the above procedures, the Secretary would publish in the Federal Register and transmit to the regional coal teams, final regional leasing targets.

The final DOE regional production goals, as adopted by the Secretary, and the preliminary and final regional leasing targets would be used by the Federal and state governments to set data gathering and planning priorities to ensure that a sufficient number of tracts would be delineated in the future, and that adequate site-specific information would be available, to make the coal management process workable. The final regional leasing targets would specifically guide the regional coal teams in the selection and scheduling of ranked tracts for the four-year proposed lease sale programs in their respective regions.

The regional tract ranking and selection process would consistently indicate the optimum tracts for the desired level of development and lead to thorough analyses of the impacts of at least one but usually several alternative lease sale schedules at the target level. These analyses could include an alternative or alternatives of choosing a combination of tracts for leasing which would result in a leasing level above or below the level called for in the final regional leasing target for a particular region. Among the reasons for proposing leasing above or below the final target during the scheduling process might be the results of the analysis contained in the regional lease sale environmental

impact statement; expressed industry interests not taken into account earlier; the interest of communities or regions in promoting or avoiding coal development in the near future; interest in special opportunity sales; sales experience with the ongoing regional lease schedule; or an expressed desire on the part of a state to shift or disperse coal development patterns. Any proposed divergence above or below the final regional leasing target would be discussed and explained in detail by the regional coal team in the draft regional lease sale environmental impact statement, and public comment would be specifically requested on the proposal in the public participation process on the draft statement. The Secretary would specifically consider the analyses and comments on the proposed divergence from the leasing target at the time he makes his decision on a lease sale schedule.

In the regional tract ranking and selection process, the possibility of trade-offs in production goals and leasing targets between regions could not be adequately analyzed. This must be considered during the next biennial process in which the production goals and leasing targets are set or revised. The first time the process of determining regional leasing targets would be conducted, the interregional analysis included in this programmatic environmental impact statement would be used as a basis for the decisions on the targets after providing for state consultation and public comment.

In the subsequent biennial revisions of regional production goals and leasing targets, the information and analyses generated in the preceding regional tract ranking and selection process would provide useful information for the goal and target decisions. In the previous tract ranking and selection process, alternative tracts to the ones finally chosen would have been analyzed. Those highly rated but previously unselected tracts would most likely serve as an important pool of tracts for the selection of tracts to meet the new regional production goals and leasing targets. If the unchosen tracts remaining in one region are clearly superior to most of those remaining in another, consideration of interregional trade-offs in the setting of the new regional production goals would be appropriate. This overall interregional analysis of the tracts makes the development or update of the regional production goals at this stage quite important. The biennial regional leasing targets

derived from the production goals would be used for either guiding new four-year lease sale schedules at the end of the existing schedules or amending existing lease sale schedules after the first two years of their four-year terms.

These procedures for setting regional production goals and leasing targets would be followed only under the preferred program. Under the no new leasing, preference right leasing, and emergency leasing alternatives, the procedures would not be needed. They are incompatible with the lease to meet industry indications of need alternative which relies on industry nominations to resolve the question of leasing levels. Similarly they are unneeded with the lease to meet DOE production goals and the State determination of leasing levels alternatives which rely on DOE and the states, respectively, to set the levels of development for Federal coal.

3.2.5. Pre-Sale and Sale Procedures

From the time a tract is selected for sale at the conclusion of the activity planning stage, until a lease can be issued, a series of actions would be required to meet various statutory and administrative requirements (see Figure 3-4).

3.2.5.1 Split Estate Leasing and Surface Owner Consent. Under the original homestead laws, ranchers and farmers were granted both the surface and mineral rights to their land, but later homestead laws provided for retention of the mineral estate by the Federal government. The majority of split estates involving federally-owned mineral rights originated out of entries made under these later homestead laws. The retained mineral estate included the right to enter and mine at any time in the future. The private owner of the surface estate did not have the power to prevent mining, though he or she was guaranteed some degree of indemnification for damage. The most important of these homestead laws is the Stock-Raising Homestead Act (30 U.S.C. 299) which states at section 9:

Any person who has acquired from the United States the coal . . . in any such land, or the right to mine and remove the same, may reenter and occupy so much of the surface as may be required for all purposes reasonably incident to the mining or removal of the coal . . . first, upon securing the written consent . . . of the homestead . . . patentee; second, upon payment of the damages to crops or other tangible

improvements . . . ; or, third, . . . upon the execution of a good and sufficient bond.

Section 714 of the Surface Mining Control and Reclamation Act of 1977 (SMCRA) provides that, in cases where Federal coal is overlain by private surface owned by a special class of owners, the Secretary may not issue a coal lease for surface mining purposes unless the surface owner has granted, in writing, valid consent to conduct such mining operations. Members of this special class of surface owners are defined as persons who:

- Hold legal or equitable title to the land surface; and
- Have their principal places of residence on the land or personally conduct farming or ranching operations on the land or receive a significant portion of their income from farming or ranching the land; and
- Have met these two conditions for at least three years prior to granting their consent.

The section further provides that valid consents granted prior to the date of the Act (August 3, 1977) will be deemed sufficient for complying with the section regardless of the consent terms.

Section 714 also requires that surface owners be consulted during land use planning. The provision reads:

In order to minimize disturbance to surface owners from surface coal mining of Federal coal deposits and to assist in the preparation of comprehensive land-use plans required by section 2(a) of the Mineral Lands Leasing Act of 1920, as amended, the Secretary shall consult with any surface owner whose land is proposed to be included in a leasing tract and shall ask the surface owner to state his preference for or against the offering of the deposit under his land for lease. The Secretary shall, in his discretion but to the maximum extent practicable, refrain from leasing coal deposits for development by methods other than underground mining techniques in those areas where a significant number of surface owners have stated a preference against offering the deposits for lease.

This consultation requirement differs sharply from the consent requirement. Whereas the consent requirement is related to the activity planning process, is mandatory, and concerns an individual's authority to prevent surface mining on his specific land, the consultation requirement is related to the land use planning process, provides limited discretion to the responsible Federal official, and concerns the authority of a group of individuals to influence surface mining on a wider area encompassing their individual properties. The

consultation step under the preferred program is described in Section 3.2.2.4.

Several issues were raised in considering how Section 714 might affect the structure and implementation of a Federal coal management program. The questions are not trivial; of the 9.7 million acres of Federal lands classified as containing technically recoverable coal in the six principal western coal states, 6 million acres are overlain by private surface (see Table 2-5). Of course, the amount of private surface owned by surface owners as defined by Section 714 will be much less than the full 6 million acres, but is still expected to be significant.

The legislative history of Section 714 was stormy. The measure was proposed to protect the property of farmers and ranchers who face the risk of being moved off their land to make way for surface mining. The Congress considered amendments expressly limiting compensation paid for surface owners' consents, and the Senate version of SMCRA empowered the Secretary to override the surface owner if leasing would be in the national interest. The provision agreed to by the conference committee, and signed by the President, however, included no compensation limitation or override.

SMCRA does stipulate that Federal coal underlying the private surface is to be leased in accordance with the Mineral Leasing Act of 1920, as amended. This law prohibits the government from accepting any bid which is less than the fair market value of the coal, as determined by the Secretary, and requires, with only minor exceptions, that all Federal coal be sold competitively. According to the Department's Office of the Solicitor, "... the conflicts between surface owner consent and the Secretary's obligations under the Mineral Leasing Act are ... subject to reasonable regulation under the terms of Section 32 . . . , 30 USC 189, which provides, 'The Secretary ... is authorized to prescribe necessary and proper rules and regulations and to do any and all things necessary to carry out and accomplish the purposes of this (Act) "[3]. The Act, therefore, is interpreted as giving the Secretary the authority to regulate the leasing process to meet the two purposes of ensuring that leases are sold on a competitive basis and that fair market value is received for the coal. Specifically, the Secretary may monitor surface owner consents to ensure their form and financial terms do not substantially

affect fair market value or the competitive nature of the lease sale and, should these terms threaten the public interest, decline to proceed with that lease sale or to execute the lease.

Therefore, the guiding principal in interpreting the possible consequences of Section 714 is that, even if consent has been given, the section does not prohibit the Secretary from exercising his discretion not to lease.

Tracts would be delineated and ranked regardless of the ownership of the surface. In the selection of tracts for sale, a preference would be accorded tracts where the surface is federally owned in favor of tracts where the surface is in private ownership (other factors being nearly equal). For tracts where the surface is owned by qualified surface owners, a preference would be given to those tracts where BLM has received evidence of consent by the time of ranking over tracts which still require consent.

Two interrelated issues considered by the Secretary in selecting issue options for the design of the preferred program were when during the tract delineation, ranking, and selection process surface owner consents would be acquired, and who should acquire consents—the Federal government or industry. These two questions are set out below in a matrix of possible program choices:

WHEN	INDUSTRY	WHO	BLM
1. Contemporaneous with surface owner consultation (planning)	Not feasible	Yes, passively for those willing to volunteer	
2. Adjunct to obtaining industry expressions of interest	Yes, as part of interest submission	Not applicable	
3. Beginning with tract ranking and continuing through tract analysis	Feasible	Feasible	
4. Prior to offering for sale	Feasible	Feasible	
5. After sale, but before executing lease	Feasible	Not feasible	

In studying these two issues, the following factors were considered:

- The later in the process surface owner consent is obtained, the less would be the administrative costs of obtaining consent

no matter who acquires it. Administrative costs would be somewhat mitigated by tying them to steps in the coal management program where contact must be made for reasons other than surface owner consent; that is, during surface owner consultation in land use planning and during submissions of industry expressions of leasing interest at the beginning of activity planning.

- The later in the process, the more information the surface owner would have available to make his decision and, presumably, the stronger would be his bargaining position.
- The later in the process, the greater would be the risk to the government of loss of the time and money spent on evaluating and analyzing coal leasing tracts.
- The less direct involvement the BLM has, the agency's administrative costs would be lower and its vulnerability to charges of government interference would be less.
- The less direct involvement the BLM has, the less capable would be government to monitor compensation for the purposes of complying with the fair market value requirements of the Mineral Leasing Act of 1920.

The Secretary preferred that industry be responsible for acquiring surface owner consent for the surface mining of tracts of Federal coal whenever such consent is required by Section 714 of the SMCRA before a lease can be executed. Consents would be required to be filed with the BLM prior to the sale announcement. Industry (as well as the states and the public) would be supplied with the preliminary tract ranking to give potential bidders an indication of the likelihood certain tracts would be scheduled for sale in the coming four years. Industry would be encouraged to advise the BLM when consent negotiations fail so that unnecessary site specific analyses would not be undertaken. If no filing of consent is made on a tract before the notice of sale, the tract would be removed from the sale schedule (and, if necessary, another tract substituted for it).

If a qualified surface owner who firmly intends not to provide consent to surface mine his land could prevent the leasing of his land for surface mining only by withholding his consent, the result could be unnecessary interference in his life and unnecessary costs for the Federal government. If

the surface owner simply withdraws his consent, no lease could be sold; but he might have to watch a tract containing his land go entirely through tract delineation, ranking, and selection and scheduling for sale. This would certainly result in continued presence on his land of Federal and perhaps, private company, employees conducting site-specific analyses and might cause him to continue to receive unwanted overtures from potential consent purchasers. The Federal government would continue to expend time and resources in fruitlessly planning that surface owner's land for leasing for coal surface mining.

In order to avoid this situation, a qualified surface owner who owns land in an area identified in the land use plan as an area acceptable for further consideration for leasing and, if leased, would be surface mined, could submit a statement to the local office of his refusal to provide consent. The statement would have to be in writing and confirm that the surface owner has not previously given consent to mine and that he will not for the expected future life of the land use plan (a maximum of 15 years under the BLM's proposed planning regulations). Upon receipt of that statement, the BLM would remove the Federal coal underlying the surface owner's land from further consideration in the ongoing activity planning process or any such processes conducted in the future until the land use plan is revised or until the ownership of the surface estate changes. Upon revision of the land use plan, the surface owner would be notified that his prior written submission has expired and he would be given the opportunity to submit another statement. Also, whenever industry or other groups notify the BLM of a surface owner who has refused to provide his consent to a potential consent purchaser, that owner would be given an opportunity to submit a statement of refusal to consent.

If the price of surface owner consent remains unlimited and the government makes no effort to receive fair payment for its coal, the cost of obtaining consent could easily reduce the amount which a lessee is able and willing to pay to the government for the opportunity to recover coal. If the cost of consent is sufficiently large, bids submitted for Federal coal leases arguably would not provide the fair return which the Congress intended to flow to the public from the development of the coal. To ensure receipt of fair market

value for Federal coal, the Department, in calculating the fair market value figure above which bids must be made if the lease is to be sold, would assume a ceiling cost of obtaining surface owner consent based on losses and costs to the surface estate and operation. This procedure could indirectly limit the amount paid to a surface owner for consent to mine underlying coal unless the company can find other ways to absorb the cost of exceeding the ceiling.

Requiring industry to negotiate consents not only transfers the negotiation costs to industry from the government, but also imposes on one company (the holder of the consent) the risk of bearing the surface owner consent costs for the lease of another (the successful bidder). The effect of this policy would be to discourage coal companies from negotiating consents except in cases where they felt they might have a strong competitive edge. This problem would be resolved by requiring that any tract containing an area to which applies a surface owner consent negotiated after the enactment of SMCRA could be placed in the sale only if the consent is transferable to a third party. A surface owner consent agreement would be considered transferable only if it provides, in part, that after the lease sale (1) the payment for the consent is to be made by the successful bidder directly to the qualified surface owner or (2) the successful bidder is automatically permitted to acquire the consent by reimbursing the company which first obtained the consent for its original purchase price.

Consents given prior to the enactment of SMCRA (often under state laws) were validated under Section 714 regardless of the consent terms. Therefore, the Department cannot require that these consents contain provisions which provide for their transferability. To ensure competitive sales, the Secretary expressed a preference for an issue option which provides that tracts which are selected for lease sale and which include areas covered by consents given prior to the enactment of SMCRA would be offered for sale individually only if the consents are determined to be transferable. If the consents are determined to be non-transferable, the tract would not be offered for sale unless it is included in an intertract sale (see section 3.2.5.4).

3.2.5.2 Environmental Analysis and Lease Stipulations. The BLM would conduct an environmental analysis for each tract proposed for lease sale to develop and refine lease terms and stipulations. In general the information on which this report would be based must be sufficiently detailed so that the Department could be reasonably certain that the lease would be economically and environmentally acceptable, but in less detail than would be required of a lessee at the time a mining plan would be approved.

Certain environmental considerations, such as hydrology, archaeology, and reclamation require intensive drilling or field surveying which are more easily and cheaply conducted as part of a lessee's pre-mining plan permit approval activities. The Department would make preliminary decisions on these environmental considerations at the time of lease sale based on modelling or less intensive surveys and would stipulate the detailed data which would be collected as part of the mining plan approval process.

3.2.5.3 Fair Market Value. The Mineral Leasing Act of 1920, as amended by the Federal Coal Leasing Amendments Act of 1976 (FCLAA), specifically mandates that, "No bid shall be accepted which is less than the fair market value, as determined by the Secretary, of the coal subject to the lease."

The basic methods for evaluating fair market value would be comparable sales analyses and discounted cash flow analysis. The discounted cash flow analysis involves calculating annual costs and income resulting from the development of a property under realistic conditions. This method is currently being used by the Department to determine fair market value for those tracts being leased under the NRDC v. Hughes agreement.

Before the Department makes any determination on fair market value on a tract, the public would be given the opportunity to comment. Comments would be solicited on fair market value consideration for any tract being offered (especially on the values that should go into the fair market value determination), as well as on the related decision of maximum economic recovery.

3.2.5.4 Sale and Bidding Methods, Due Diligence Requirements. For the preferred program, the Secretary has recommended that sale and bidding

method regulations be kept flexible, permitting the choice of method to be on a case-by-case basis.

Coal leases would usually be sold using the individual tract sale method in which bidders compete against one another for any given tract. The Department would choose which tracts it feels are the best tracts, both economically and environmentally, and which cumulatively contain the amount of coal reserves desired for lease. These tracts would be offered for sale over the four year period of the regional sale schedule. The highest bidder in any sale would be offered the tract provided his bid meets fair market value, passes the Attorney General's anti-trust review, and meets all other requirements of the laws and regulations.

Coal leases could also be sold using the intertract sale method in which bidders compete between tracts as well as over individual tracts. Competition would be enhanced because more tracts would be offered than are intended to be awarded. The high bids for each tract would be compared, and only those tracts with the highest bids above fair market value which are needed to meet cumulatively the sale's target would be awarded. As under individual tract bidding, the tracts for the sale offering would be selected on the basis of land use planning, site specific analysis, and tract ranking. The intertract sale method would be used at least in all cases where tracts are offered for sale which would be mined by surface mining methods and which involve non-transferable surface owner consents given before the enactment of SMCRA.

Regardless of whether the individual tract or intertract sale method is used, the type of bidding method must also be determined. Optional methods tentatively identified by the Department of Energy as acceptable include:

- Direct or deferred bonus bidding: cash payment is offered for the lease. (Note, the Federal Coal Leasing Amendments Act of 1976 requires half of all sales to be by deferred bonus bid.)
- Variable royalty bidding: bids are placed in the form of royalty rates based on a percentage of the value of the coal recovered (usually a small cash down payment is also required).
- Sliding scale royalty bidding: cash payment is offered for the lease, but the amount of

the royalty paid is varied in proportion to the value of the coal produced.

In addition, DOE has stated it intends to study very closely possible use of a profit sharing method (British system). Here the government essentially becomes a partner in the coal enterprise and receives a bid offering a percentage of profits, if any.

The potential bidder in the lease sale will wish to know what diligence and continued operations requirements he will have to meet if he purchases the lease. The current regulations (43 CFR 3500.05), which have been carried over to the new proposed regulations, define diligent development for any coal lease issued after August 4, 1976, as the timely preparation for, and initiation of, coal production from a logical mining unit (LMU) of which the lease is a part so that the coal is actually produced at the rate of one percent of the reserves in the LMU by the end of the tenth year from the effective date of the lease. Diligent development for any lease issued prior to August 4, 1976, is defined as the timely preparation for, and initiation of, coal production from the LMU so that the coal is actually produced at the rate of one-fortieth of the LMU reserves before June 1, 1986. Under the regulations, the period of time for the latter leases may be extended.

Timely production of coal is further assured through the current "continued operation" regulations. Under these regulations, coal equal to one percent of the reserves of the logical mining unit must be produced for each of the first two years following achievement of diligent development. Thereafter, an average amount of one percent of the reserves associated with the lease must be produced. The average amount is computed over a three-year period consisting of the year in question and the preceding two years.

Although the authority to promulgate regulations concerning bidding methods, diligent development, and continued operations was transferred to the Department of Energy in the Department of Energy Organization Act, should DOE not promulgate new regulations before a Federal coal management program is established, the current regulations would remain in force until superseded by DOE regulations.

3.2.5.5 Consultation with the Governors. Prior to setting a regional coal lease sale schedule, the

Secretary would consult with the governor of each state in which tracts to be leased are located. The Secretary would ask each governor to comment in a specified period of time, not less than 30 days nor more than 60 days, before issuing the final schedule of sale. Section 3 of the Federal Coal Leasing Amendments Act of 1976 provides a specific procedure for consultation with a state when a lease proposal would permit surface mining within the boundaries of a National Forest within that state. The governor would be notified by the Secretary. If the governor fails to object to the lease proposal in 60 days, the Secretary could issue the lease. If, within the 60-day period, the governor notifies the Secretary, in writing, of an objection to the lease proposal, the Secretary would not approve the lease for six months from the date the governor objects to the lease. The governor could, during this six-month period, submit a written statement of the reasons why the lease should not be issued, and the Secretary would, on the basis of this statement, reconsider the lease proposal.

These pre-sale and sale procedures are compatible with all alternatives, although they would have no applicability to the no new leasing and preference right leasing only alternatives.

3.2.6 State, Local, And Industry Participation.

A variety of methods have been developed to provide state, local, and industry participation in the preferred alternative Federal coal management program.

3.2.6.1 State Participation. The preferred program is designed to offer as significant a role for the state governments in the Federal coal management process as possible short of providing them with veto power over Federal decisions. The states would be offered the opportunity to sign cooperative agreements to enable them to participate directly in the land use planning process. The States could nominate unsuitability criteria to be added to the list of Federal unsuitability criteria. They could also submit expressions of interest in potential coal tracts. The states would be expected to participate actively and directly through membership on regional coal teams in the activity planning procedures of tract ranking, selection, and scheduling. Furthermore, a special consultation step would be provided to the states in setting regional production goals and leasing targets. The

governor would also be informally consulted prior to any final decision to offer a tract for sale. Although the states would be expected to provide their views over the full spectrum of issues, the Department would particularly need the states' comments on the interregional and cumulative regional social and economic impacts of coal development in the regional leasing target-setting process and on intraregional and site-specific social and economic impacts in the tract ranking and selection process. The states would also have the lead for many post-sale lease management actions.

Whenever possible, the regional coal teams (see Section 3.2.3.2) would serve as the general forums in which state participation would occur. In particular, as noted in Sections 3.2.3.2 and 3.2.4, these teams would be the focal points for developing proposals for Secretarial decision on the tracts selected and scheduled for sale and on regional production goals and leasing targets.

The activities of these teams would provide the state governors with an opportunity to discuss any potential significant Federal decisions *before* they are made and not just in the formal consultation which occurs after the decision-making and would provide to the citizens of each state, through their elected officials, an authoritative forum for the airing of their interests and concerns.

3.2.6.2 General Public Participation. The public would have several opportunities to participate directly throughout the coal management decision making process. Hearings would be held on the land use plan recommendations before the final land use plan decisions would be made. Comments would be solicited from the public at the beginning of the regional tract ranking, selection, and sale scheduling process. The public would have the opportunity to submit written comments and to participate in a hearing on the regional sale environmental impact statement. The Secretary could also hold additional hearings in the area of the proposed sale if there were a general interest in the proposed sale and any issue existed which had not been thoroughly discussed at previous hearings. Besides the general public participation steps, there would be opportunities for participation during the surface owner consultations, surface owner consent, and indications of leasing interest stages of the coal management program.

In addition to these formal opportunities for public participation, anyone could submit general comments at any time in the process. The Department would schedule meetings for public comment whenever it has reason to believe that it would serve the public's interest.

3.2.6.3 Industry Participation. Industry is a critically important actor in the preferred program not only because it supplies the bidders in the lease sales and the technology and capital to extract the coal, but also because it provides the information needed in the determinations leading to the delineation of tracts. The three principal sources for coal information in the United States are the Federal government, through the Geological Survey and other agencies; the state governments, through the state geological surveys or mining bureaus; and the coal industry. Industry is in a special position to make the Federal government aware of the type, quality, quantity, and location of coal which it believes should be considered for leasing.

Industry would be able to participate in the land use planning and regional production goal and leasing target setting processes through all the same formal and informal channels available to the general public. During land use planning, industry could contribute information on existing operations and on the location of resources. During the setting of regional production goals and leasing targets, industry could supply information on the overall demand for coal and the production potential from previously leased Federal reserves and non-Federal reserves for meeting that demand. In addition to these general participation opportunities, industry would continue to have the opportunity to indicate tracts it would like to see leased and supply site-specific data. Indeed, such industry indications are critical to the functioning of the leasing component of a Federal coal management program. In the preferred program, this step would be scheduled to occur as the first formal step in the activity planning process.

As previously noted, the activity planning process for coal would involve the delineation, ranking, and selection of tracts within areas identified as acceptable for further consideration for coal leasing in the land use plan. Information derived from industry data would be required to

assist in determining need and to facilitate lease tract delineations and economic evaluations. To obtain these data, industry would be requested through formal notices to submit expressions of leasing interest for coal within the areas acceptable for further consideration for leasing set out in the land use plans. To the extent these indications define potential tracts, they would be relied on for the preliminary delineation of tracts, unless it is determined that different tracts or different tract boundaries would be necessary to ensure competitive interest in the eventual lease sale, conserve Federal coal, or meet other largely economic objectives in the coal management program. The types of information which might be requested and used in the tract delineation and ranking process would be:

- Written descriptions of land by legal subdivision and a map with a scale of one-half inch to the mile or larger.
- Amount of coal desired including such geologic data on the area as bed thickness, overburden depth, and thickness of coal seam(s).
- Method of mining anticipated, with proposed mining sequence and rate of production.
- Relationship, if any, between the anticipated mining operations and existing or planned mining operations or supporting facilities on adjacent Federal or non-Federal lands.
- Anticipated method(s) of transportation and status of existing or proposed transportation system.
- Evidence of qualifications.
- Intended "end use" of coal.
- Consent certification if the surface is not owned or controlled by the Federal government.
- Description of adjacent coal reserves under ownership or control of the company providing the expression of leasing interest.

These participation components would not be compatible with the no leasing or preference right leasing only alternatives and would be used only to a limited extent under the emergency leasing alternative. Under the lease to meet industry indications of need alternative, greater emphasis would be placed on obtaining, at an early stage,

industry nominations and less emphasis would be placed on state consultation. Under the state determination of leasing levels alternative, the role of the states would obviously be pre-eminent. On the other hand, in the lease to meet DOE production goals alternative, the roles of industry and the states would both be reduced.

3.2.7 Special Leasing Opportunities.

In response to the requirements in the Federal Coal Leasing Amendments Act of 1976 and the Small Business Act of 1953, as amended, the Department would reserve and offer a reasonable number of coal lease tracts as special leasing opportunities. The special opportunities would be provided through special lease sales where public bodies would bid only against other public bodies and small businesses only against other small businesses. No special determinations of maximum economic recovery or other possible financial incentives would be proposed.

Public bodies are non-profit consumer-owned utilities, principally rural electric cooperatives, municipally owned utilities, and Federal agencies. The Secretary would designate and schedule one or more coal lease tracts for special opportunity lease sales for public bodies after the ranking and selection process only if a public body has, through submission of an expression of leasing interest, requested that a special opportunity lease sale be held. With the submission of this request, the public body would have to provide evidence of its qualifications to participate in a special opportunity sale.

Small business would be required to meet the qualifying standards set forth in 13 CFR 121. The Small Business Administration proposed qualification requirements for small businesses to participate in Federal coal lease special opportunity sales on March 14, 1979 (44 Federal Register 15513-15514). To qualify, the business would have to be independently owned and operated, not be dominant in its field, and, together with its affiliates, employ not more than 250 employees. Although it would be advisable and to its advantage to do so, a small business would not be required to notify the Department of its desire for a special opportunity sale. The Secretary's decision to hold a small business special opportunity sale would be made in consultation with the Small Business Administration.

The Department has under consideration various methods of encouraging minority business participation in the Federal coal management program. This could be accomplished administratively or through legislation and by means of a separate set-aside sale or through the assistance of the Small Business Administration in the small business set-aside sales.

These special leasing opportunity procedures would be employed in all but the no leasing and preference right leasing only alternatives.

3.2.8 Emergency Leasing System.

The preferred program would contain an emergency leasing system which would enable the Department to provide for urgent needs for Federal coal when those needs could not be met in a timely manner through the general, long-term leasing process (by pass, production maintenance, or hardship situations). The emergency leasing system would differ from the general, long-term leasing process only with respect to (1) the method of tract identification and (2) the breadth and scope required in the planning and environmental assessment process. This system would be administered tightly, so as to maintain the integrity of the general, long-term leasing process.

To qualify for production maintenance or bypass emergency leases, an operation that has been producing for at least two years prior to the application would be required to show that:

- The Federal coal is needed within three years to maintain an existing mining operation at the average annual level of production or new contracted level of production on the date of application, as substantiated by the proposed production levels stated in a mine plan or a complete copy of the supply or delivery contract, or both; or
- If the coal deposits are not leased they will be bypassed for the reasonably foreseeable future, and if leased, some portion of the tract applied for will be utilized within three years, as substantiated by the proposed production levels stated in a mining sequence plan; and
- The need for the coal deposits resulted from circumstances that were beyond the control of the applicant or for which he could not have reasonably foreseen and planned.

The extent of coal reserves covered by bypass and production maintenance emergency leases could not be more than that which could be mined over eight years at the average annual production level or new contracted level of production on the date of the application.

An applicant not qualifying for an emergency lease under the above conditions could still qualify as a hardship case if his operations are:

- Outside of a coal region;
- Inside a coal region in which activity planning has not yet begun; or
- Of a size, quality, or end use that is not significantly related to meeting the regional leasing target.

The applicant would also be required to show a hardship of the following type:

- A locality has lost or will lose its alternative sources of domestic coal supply;
- A mine which has been closed will be reopened, and local unemployment will be alleviated;
- The mine will test new technology supported by a Federal agency;
- Mining and reclamation of the tract will promote a program or policy of another surface management agency, such as rehabilitation of lands scarred by past uses; or
- Similar reasons that the Secretary, after holding a hearing, determines are substantially in the public interest.

The terms of hardship emergency leases would be determined on a case-by-case basis.

The tract to be offered for the emergency lease sale would only be so much of the land applied for as would be necessary to meet the emergency need of the applicant without violating the integrity of the general, long-term leasing process.

No coal lease would be issued unless a comprehensive land use analysis has been conducted on, and the Department's unsuitability criteria have been applied to, the land to be included in the lease. All emergency leasing decisions would have to be consistent with the appropriate land use plan or analysis and the unsuitability criteria.

Before a lease sale would be held in response to an emergency lease sale application, an environmental analysis would be completed on the potential effect of such a coal lease on the resources of the area and its environment, includ-

ing fish and other aquatic resources, wildlife habitats and populations, and visual, recreation, cultural, and other resources in the affected area. Should the Department determine an environmental impact statement is required, one would be completed.

The pre-sale and sale procedures, including public participation procedures, of the general, long-term leasing process would be followed in all emergency leasing situations.

This would be the major component of the emergency leasing alternative. It could also remain a component of the lease to meet DOE production goals, lease to meet industry indications of need, and state determination of leasing level alternatives.

3.2.9 Post-Programmatic Environmental Analysis

The National Environmental Policy Act of 1969 requires each Federal agency proposing a major action which might significantly affect the quality of the human environment to prepare a statement of the environmental impacts of that action and its reasonable alternatives. The Department, in formulating the preferred coal management program, considered which key leasing decision points could represent major Federal actions within the meaning of the Act.

The preferred option is to maintain two separate levels of environmental impacts analysis, one to consider interregional and national impacts and one to consider site-specific and cumulative intraregional impacts. The first level of analysis would be contained in this programmatic environmental impact statement, updated when necessary, and the second level of analysis would be made in environmental impact statements for each region covering the four-year sales periods and discussing the tract delineation, ranking, and selection process. These environmental analyses procedures in the preferred program are discussed in greater detail in section 3.11.1.7 and set forth in Section 3420.3-4 and 3420.4-5 of the proposed coal management regulations in Appendix A.

3.2.10 Administration of Existing Leases and PRLAs

A significant element of the Department's federal coal management program is the administration of existing coal leases and preference right lease applications. The amount of coal involved is

considerable. As of October 1978, there were 533 federal coal leases estimated to contain 17 billion tons of coal and 172 preference right lease applications excluding Alaska which cover land estimated to contain 9.9 billion tons of coal.

Because the United States owns a large percentage of coal in the United States (nearly 60 percent in the West) and because demand for coal is expected to increase significantly, Federal policies toward coal and, specifically, toward existing leases and preference right lease applications will have a significant impact on energy production in the United States. In 1977, 50 million tons of coal were produced from existing leases. The Department calculates, however, from data chiefly supplied by lessees themselves, that they are likely to produce 360 million tons annually from Federal leases by 1985. The Department uses this data in setting the regional leasing targets for coal leasing, taking into account environmental, social, and economic impacts in each region. The following discussion of issues summarizes the matters set forth in depth in the memorandum of March 20, 1979, from the Director, Office of Coal Leasing, Planning and Coordination to the Under Secretary (Appendix I in this statement).

The proposed coal management program is the major program for conducting the Federal lands review to identify lands unsuitable for coal mining pursuant to Section 522(b) of the Surface Mining Control and Reclamation Act, 30 U.S.C. 1272. There are 24 criteria set forth in Table 3-3 and Section 3461.2 of the proposed regulations (Appendix A) which may result in the assessment or designation of certain lands as being unsuitable for mining.

There are, however, certain limitations on assessing or designating lands involving existing leases or preference right lease applications as unsuitable for coal mining. First, under many criteria even if the criterion were otherwise applicable, if mining operations were being conducted on an existing lease on August 4, 1977, the lands are exempt from the criterion. Second, if substantial financial and legal commitments had been made to a mining operation before January 4, 1977, those lands are also exempt. Finally, under other criteria any unsuitability designation may not prejudice valid existing rights. The memorandum of March 20, 1979 (Appendix I) discusses the

issues arising out of the exemptions from the application of unsuitability criteria to existing leases and preference right lease applications. Table 3-4 in this environmental impact statement, which is taken from the memorandum, sets out in detail the sources of authority for each criterion and the exemptions attached to its application.

The process of applying these criteria is also significant. The Director of the Bureau of Land Management has instructed Bureau offices how to incorporate the criteria into existing and future land use plans. Essentially, the 24 criteria will be applied to all coal lands. Lands in existing leases and preference right applications will be checked for exceptions (that is, any possible alternative mining method which is not unsuitable in the particular area, or any method of mitigating the adverse impact) and exemptions (that is, where the substantial commitments and valid existing rights provisions of SMCRA prohibit application of specific criteria.) All of the studies conducted for unsuitability will include public hearings before final assessments are adopted as part of a land use plan or environmental analysis on a mine plan.

The possibility of exchanging coal lands and leases to shift the impacts of operations from unacceptable to acceptable lands has always interested the makers of Federal coal development policy. One complex of issues discussed at length in Appendix I is the Secretary's authority to exchange coal leases or lease interests, and the Secretary's policies toward implementing that authority to prevent or mitigate unacceptable adverse social or environmental impacts of coal mining. Two propositions stand out from the discussion in Appendix I. First, the Secretary's authority to exchange coal leases is quite limited. Second, the Secretary, consistent with the Department's stance on S. 3189 in the 95th Congress, does not currently intend to consummate exchanges in cases where the unsuitability criteria or other provisions of the Surface Mining Control and Reclamation Act, or other Federal law, lawfully apply to prevent or adequately mitigate the threatened adverse impacts.

The first proposition can be quickly documented. To start with, what authority the Secretary does have is entirely voluntary; both the Secretary and the lessee or preference right lease applicant must be satisfied by the terms of the exchange. The Secretary does not have condemnation authority,

nor does he have purchase authority even if a lessee were willing to relinquish a lease for value. Prior to the Federal Coal Leasing Amendments Act of 1976, the Secretary did have the authority to exchange coal leases, but that Act repealed that authority. The Congress reestablished such authority in Section 510(b)(5) of the Surface Mining Control and Reclamation Act, 30 U.S.C. 1260(b)(5), only for a limited class of holders of coal leases in alluvial valley floors. In addition, the Department has provided by regulation, under its general authority in the Mineral Leasing Act that, in exchange for voluntary relinquishment of a coal lease, a lessee may receive 1) a lease for certain minerals other than coal, (2) bidding rights to future coal leases, or 3) additions to other existing coal leases. The Department is not now seeking to broaden its authorities in this area, but it does appear that eventually the Department may reconsider asking Congress for new, broader, or more clarified coal exchange authority.

The second proposition above, that exchanges should not be consummated where mining operations on lands in the lease or preference right lease application can be lawfully prevented or adequately mitigated, states present Departmental policy. That policy is derived from three principles discussed at greater length in Appendix I. First, the existing exchange authority should not be exercised for the purpose of relieving lessees of their diligent development obligations under the lease. If a lessee has violated the diligent development requirements or appears not to have made any effort toward development, the lease should expire under its own terms or be cancelled rather than be exchanged. Second, exchanges should not be used to undermine the proper implementation of the environmental and reclamation standards newly established by and under the Surface Mining Control and Reclamation Act. If unsuitability criteria derived from Section 522(a) of that Act or from the statutory mining prohibitions in Section 522(e) of that Act can lawfully prevent the mining of a certain area or prevent mining an area in a certain manner, then the would-be exchange proponent has no property right to mine that area or to mine it in a certain manner that required recognition or "compensation" through an exchange. Third, if mining an area can lawfully be prevented, then there must be deducted from the value of the lease that includes that area for

purposes of an exchange any value that would have been attributed to the unsuitable or otherwise unmineable acreage. If the Department used the value of the coal the lessee could *not* mine in finding a tract of equal value to lease in exchange, the Department might be giving something for nothing; coal with little or no economic value for coal with substantial economic value. These three points are all important in understanding that the exchange concept may not be easily converted into a viable management tool, and that the Department may have to seek Congressional clarification or resolution of these issues before exchanges become a significant component of the Federal coal management program.

The Department intends vigorously to enforce the diligence provisions, the provisions requiring diligent development and continued operation, applicable to existing coal leases. Such an effort will be a major impetus toward the timely development of the federal coal reserves already under lease. Under the regulations promulgated in May 1976 that apply to existing leases, production is to begin by June 1, 1986 or ten years after lease issuance, whichever is later. In order to be ready for that date, and in order to have firm diligence enforcement policies for the interim, the Department is examining a series of questions on this subject to determine (1) whether there are any enforcement actions that could or should be taken prior to 1986 for violations of any lease terms related to diligence, and (2) whether there are any limitations in the Mineral Leasing Act or the existing leases themselves that might in any way limit the complete application of the May 1976 regulations and their June 1, 1986, production requirement to all existing leases.

The Federal Coal Leasing Amendments Act of 1976 (FCLAA) generally applies only to leases issued after August 4, 1976. The diligence standards for new leases in the FCLAA are in many ways derived from the Department's own regulations on diligence which were published in May 1976, so the Department's December 1976 regulations to implement the FCLAA contain many parallel requirements for leases issued after the FCLAA was passed on August 4, 1976. Each lease is by regulation automatically a logical mining unit LMU. Production in commercial quantities (2.5 percent of the reserves for pre-FCLAA leases, one percent of the reserves for post-FCLAA leases)

must be achieved by the tenth lease year. The lessee must also continue operations at the rate of one percent of the reserves per year. Finally, upon application by the lessee, the Department may consider private lands or separate Federal leases to be part of a logical mining unit. Extensions in the period for achieving production or suspensions of the continued operation obligation of leases can be ordered by the Secretary to accommodate events not within the control of the lessee, including strikes.

All existing leases are also subject to readjustment every 20 years after their issuance. In addition to expressly imposing due diligence requirements at the time of readjustment, the Department will also raise royalties to at least 12.5 percent for coal mined by surface methods and eight percent for coal mined by underground methods. Current rates are as low as 5¢ per ton with the rates of 10¢ to 15¢ per ton being fairly common. Prior to the enactment of the FCLAA, 51 leases had had their 20-year anniversary, but had not yet been readjusted. More leases are now subject to readjustment, and the Department is now aggressively moving to readjust those leases to bring them into conformity with its May 1976 regulations and the FCLAA. On March 16, 1979, the Under Secretary endorsed the policy of systematically readjusting leases which are now pending readjustment or will become due for readjustment prior to June 1, 1979, to the prescribed minimum royalties, rather than attempting to establish possibly higher royalties on a case-by-case basis. This policy was adopted in order to complete the backlog of readjustments promptly.

The sale and sublease of existing leases presents a potential opportunity for the Department to impose the policies and requirements discussed above on existing leases. Up to this point, proposed assignments have been examined only to check the assignee's qualifications to hold the lease or to determine whether the assignor had been fully complying with the terms of the lease. Partially in response to assertions that there is an undesirable speculative market in the resale of coal leases, the Department is examining whether, in exercising its authority to approve assignments, the lease may be readjusted by the express imposition of due diligence requirements, consent to a plan of development, or other stipulations. A further question is whether the proposed lease assignment

should be referred to the Attorney General for antitrust review.

Another important set of questions with regard to existing leases concerns the strategy to pursue in performing environmental studies. After the Department completed its programmatic environmental statement on the Energy Minerals Activity Recommendation System in 1975, it divided Federal coal areas into eight regions for the purpose of preparing environmental impact statements. Each regional statement was designed to study the site-specific impact of both operations on existing leases and new leases, in the framework of an analysis of the regional, cumulative impacts of the specific proposals. As a result of the decision in *NRDC v. Hughes*, 437 F. Supp. 981 (D.D.C. 1977), modified, 454 F. Supp. 148 (D.D.C. 1978), appeal pending, the Department stopped considering possible new leasing, and continued specific study only of the 27 mine plan approval and other coal-related applications then pending. The Department is now studying all possible options on a regional level, including a no new leasing alternative. If no new leasing is found to be necessary, the Department will then consider site-specific mine plans for existing leases. These studies would be keyed into the completed regional environmental statements. If new leasing is found to be necessary, the Secretary's preferred alternative is to establish the need for leasing region by region, and then proceed to study and rank tracts within each affected region. While specific new environmental studies would have to be prepared for approval of mine plans for existing leases, specific environmental studies for new leases will be performed as part of the regional tract delineation, ranking, and selection, and sale scheduling processes.

Most of the program requirements and policy issues just discussed apply to both existing leases and preference right lease applications. However, a few additional points should be made with respect to preference right lease applications. In determining whether a preference right lease applicant has discovered coal in commercial quantities and is thus entitled to a lease, the Department must take into account quantifiable environmental costs and must consider what stipulations should be imposed to mitigate environmental damage. (See *Natural Resources Defense Council, Inc. v. Berklund*, 458 F. Supp. 925 (D.D.C. 1978), appeal pending.) While a preference right lease applicant has a valid existing

right to have his lease application adjudicated even though the law has changed, he does not necessarily have a valid existing right to mine, as the term is used in applying unsuitability criteria. It is, rather, the right to have his application fairly acted upon by the Department. In addition to considering the provisions of the National Environmental Policy Act, the Department must, when adjudicating an application, also consider the provisions of the Surface Mining Control and Reclamation Act and the Federal Coal Leasing Amendments Act of 1976.

The Department has the same authority, and the same problems, with exchanges involving preference right lease applications as it does with existing leases, with one added twist. Does the Secretary have to make the crucial determination of discovery of commercial quantities of coal before he can make an exchange? If the applicant is found to be entitled to the lease, he may have no incentive to complete the exchange. If the determination is not made, the Secretary risks exchanging something of value for nothing. A task force in the Office of the Assistant Secretary, Land and Water Resources, has been formed to consider this and other issues related to exchanges.

Another likely problem occurs because coal prospecting permits could be issued only on lands which are unclaimed and undeveloped. Some study has been done by the Bureau of Land Management indicating that the land in some of the preference right lease applications is covered by mining locations. Thus, these conflicts will have to be eliminated; the procedures for the resolution of these conflicts have yet to be fully defined.

Another issue in the adjudication of the pending applications concerns the proper royalty rate to be charged on leases issued to preference right lease applicants. Section 7 of the Mineral Leasing Act, as amended, 30 U.S.C. § 207 (1976), sets a minimum royalty, but not a maximum. Thus, the royalty rate can apparently be varied to capture the fair market value of the coal, and prevent a lessee from garnering undue profits. At the same time, however, the royalty rate in many private leases that can only be developed in conjunction with Federal lands is tied to that of the adjoining Federal leases. Therefore, a boost in the Federal rate may well boost the private rate on significant quantities of coal.

Finally, the due diligence requirements of the December 1976 regulations implementing the Federal Coal Leasing Amendments Act of 1976 will be imposed on every new lease issued to preference right applicants. While the preference right applicant may have the right to a lease, he is not entitled to any particular terms that he may specify, but rather those required by law and policy in effect at the time of lease adjudication and issuance.

Appendix I to this environmental impact statement discusses these issues in depth. As that Appendix and this summary make clear, the administration of existing leases and preference right lease applications will require a significant share of the Department's coal management efforts. While the discussion in Appendix I can serve in part as a guide in the administration of certain matters, especially application of the unsuitability criteria, the rest of that Appendix sets out the significant legal and policy issues which the Department will have to resolve before routine administration of existing leases and PRLAs is realized and before the Department can predict with full confidence future production from existing leases and PRLAs without relying primarily on lessees' intentions.

3.2.11 Special Start-up Considerations

The preferred program, if adopted, would be a major effort for the Department. The administrative tasks would begin with pre-planning inventory efforts and proceed all the way through post-mining land use monitoring. The program would touch on a myriad of other Federal and state programs with a degree of interrelationship varying from slight to mutual dependence. To put such a program in place without causing severe disruptions either to the management of Federal coal resources or to other important programs requires careful and prudent planning. This section presents the major considerations that will control the start-up of the Federal coal management program if the preferred program is selected. Assuming that, upon review of this statement, the Secretary, first, decides that a new Federal coal management program is needed; second, selects a program substantially similar to the preferred program described in this statement; and third, determines that lease sales should be held in one or more regions during 1980 or 1981, the new program

would be established and integrated into existing programs, most notably the land use planning process, as follows:

- Much of the general resource inventory and land use planning required under the procedures described above would be adopted from work already completed or work that is underway at the time of the publication of this final environmental impact statement.
- In all areas for which plans have never been prepared, the inventory process, the first step in land use planning, would begin under the normal scheduling for BLM. It is estimated that about 15 percent of the coal areas are in this class. The proposed BLM planning regulations would be applied to these areas. Planning areas would be selected for inventorying based on the anticipated need for the leasing of coal in the particular areas or on other high resource demands.
- In certain priority areas for which land use plans have been completed, the land use decisions would be reexamined on areas identified in the existing plans as appropriate for coal development. This reexamination would be in the form of application to these areas of the unsuitability criteria that are selected by the Secretary as a result of his decisions on the program. Also, if surface owner consultation had not taken place earlier, this step would be taken. Those areas which remain acceptable for further consideration for leasing after application of the criteria and consultation with qualified surface owners would, following opportunity for public comment, be identified in a published supplement to the existing plan. These areas would then be entered in the activity planning process and could be considered for lease sale. A call for industry expressions of leasing interest in the areas identified in the supplement as acceptable for further consideration for leasing would be the first step taken in activity planning after publication of the supplement.
- As discussed in Sections 3.2.2 and 5.4.10, the Department would use land use plans supplemented as necessary until new plans could be prepared under proposed BLM regulations (43 Federal Register 58764-58774).
- The first lease sales may not be conducted in all regions for which the regional leasing targets suggest leasing is needed and might be insufficient to fully meet the targets for the regions in which they are held.
- Notice of intent to rank tracts would be issued immediately prior to initiation of ranking.
- The first regional lease sale environmental impact statements would likely address a two-year rather than a four-year lease sale schedule.
- The regional targets, if any, for the first sales would be selected by the Secretary after reviewing all the comments received as a result of the publication of this statement and after consulting with the state governors and with the Secretary of the Department of Energy.

The Department anticipates that, should the Secretary elect to start up the preferred program as quickly as possible, a lease sale schedule would be prepared for 1980-1981 under these start-up considerations. Subsequent schedules would be prepared substantially as set out in the preferred program. However, land use plans prepared wholly under the proposed BLM planning regulations would not begin to appear in the process until 1984 or 1985. It might be several more years before a sufficient number of new land use plans are prepared to identify enough areas acceptable for further consideration for leasing to permit coal leasing decisions to be based entirely on land use plans which fully conform with the proposed planning regulations.

3.2.12 Other Aspects of the Preferred Program

Two other aspects of the preferred program considered by the Secretary were maximum economic recovery and end use controls.

3.2.12.1 Maximum Economic Recovery. In Section 3 of the Federal Coal leasing Amendments Act of 1976 (FCLAA), the Congress introduced the concept of Maximum Economic Recovery (MER). The Congress has indicated that MER is of considerable importance and should be treated in a consistent and formal manner. The statute requires MER to be considered at two stages - - lease issuance and mine plan approval. Specifical-

ly, Section 3 of FCLAA, requires that: "Prior to issuance of a lease, the Secretary shall evaluate and compare the effects of recovering coal by deep mining, by surface mining, and by any other method to determine which method or methods or sequence of methods achieves the maximum economic recovery of the coal within the proposed leasing tract. This evaluation and comparison by the Secretary shall be in writing but shall not prohibit the issuance of a lease; however, no mining operating plan shall be approved which is not found to achieve the maximum economic recovery of the coal within the tract."

The issue forwarded for the Secretary's expression of preference was what definition of MER should be adopted. Five different definitions were considered; the Secretary prefers that MER be calculated so as to require that all coal seams which are collectively profitable be mined, taking into consideration social and environmental costs. For any scale of development (annual production rate), this definition would tend to minimize the area disturbed from surface mining; deeper seams would be substituted for the broadening of areas of operation.

An interagency task force is presently devising the methods for determining MER in accordance with the Secretary's preference and at least two other alternatives. At the request of the Council of Economic Advisers, the task force will conduct an economic analysis of the Secretary's preference and other alternatives to determine their cost of administration and their effects on individual lessees and the overall coal market.

3.2.12.2 End-Use Considerations. Another issue considered by the Secretary was whether the Department should condition new coal leases with stipulations which specify how, where, or by whom coal would be consumed. The goals of such restrictions would be to:

- More actively control the location and extent of environmental degradation.
- Promote the entry of economically and socially disadvantaged groups to the coal industry.

- Allow more active integration of Federal actions with state and local government planning, and otherwise control socioeconomic impacts.
- Encourage new energy technologies.

Coal leases have not in the past limited how lessees could dispose of mined coal. A lessee can sell the coal for a minemouth power plant, ship coal short or long distances, or use the coal for gasification. Specifying the end-use of coal from new leases could give the Department greater control over the environmental and economic effects of mining and could be used to encourage new technologies. There is, however, a very real possibility end use conditions could infringe upon other agencies' responsibilities, such as state regulation of power plant siting and the Environmental Protection Agency's Clean Air Act regulations. In addition, the Department's legal authority to regulate end-uses is unclear.

Options for resolution of this issue ranged from not adopting end-use stipulations (except as mandated in the FCLAA for public bodies and as required for railroads in the Mineral Leasing Act of 1920) to an active policy of conditioning leases to meet all the goals specified above. The Secretary preferred not to adopt end-use stipulations pending a Solicitor's opinion on the Department's authority for such action. The Solicitor's opinion is being developed.

DESCRIPTION OF REGIONAL ENVIRONMENTS

This chapter contains descriptive discussions of the environments of the twelve coal regions specified in Chapter 1 (see Figure 1-1). The components of each region are discussed cumulatively due to their physical continuity and their similar environments. Each regional description is subdivided into a discussion of the environment and a discussion of the environment and man. The sections on the environment contain descriptive information on the regions' topography, geology, resources, climate, air quality, water quality, and biota. Supportive ecological descriptive data are contained in Appendices D and E. The sections on the environment and man contain descriptive information on history, resource development, economics, infrastructure, and demography. The descriptions are limited to only those environmental features which are pertinent to the environmental impact analyses described in Chapter 5. For a list of counties that are contained either totally or partially within each region's respective boundaries, refer to Appendix J.

4.1 THE APPALACHIAN COAL REGION

The Appalachian Coal Region is in the Appalachian Mountain range of the eastern United States. The region encompasses 111,637 square miles in two Maryland, 31 Ohio, 49 West Virginia, 32 Pennsylvania, 34 Kentucky, 21 Tennessee, seven Virginia, 24 Alabama, and four Georgia counties. For purposes of discussion, this region has been divided into three regions: the Northern Appalachian, Central Appalachian, and Southern Appalachian Coal Regions. The Northern Appalachian Coal Region covers 53,120 square miles in 94 counties of Pennsylvania, Ohio, West Virginia, and Maryland. The Central Appalachian Coal Region covers 35,292 square miles in 69 counties of West Virginia, Kentucky, Tennessee, and Virginia. The Southern Appalachian Coal Region covers 23,225 square miles in 39 counties of Tennessee, Georgia, and Alabama.

4.1.1 The Environment

The dominant topographical feature of the region, the Appalachian Mountain Range, reaches elevations of up to 5,000 feet in the Central Region. Elevations in the Northern and Southern Regions are much lower, although large changes in relief do exist. The steep-sided plateaus of sandstone bedrock on the eastern side of the range give way to broad open folds dipping gently to the west.

This difference in the topography of the eastern and western sides of the Appalachians reflects the two different physiographic provinces involved. The Valley and Ridge Province to the east consists of rocks that have been greatly disturbed by faulting and folding. The Appalachian Plateaus to the west have not been subject to such severe disturbance and the gently folded rocks are nearly flat. Unique or significant geologic features, such as caverns and karst areas, are numerous.

Sandstones, shales, limestones, conglomerates, and beds of coal are characteristic of the three Appalachian Coal Regions. Coal-bearing rocks are of Pennsylvanian age and include the Monongahela, Conemaugh, Allegheny, and Pottsville Formations. The total estimated coal reserve base for the entire Appalachian Coal Region is 103 billion tons.

The rank of coal in the Appalachian Coal Region varies with physiographic provinces, reflecting the differing amounts of deformation the rocks received. The coal in the Appalachian Plateaus (on the western edge) is high-volatile bituminous, with some coal being as high in grade as anthracite.

In general, the Appalachian Coal Region has moderate to hot, humid summers and moderate to cold, humid winters with an average annual precipitation of 40-50 inches. Growing seasons (periods of frost-free temperatures) vary from 120 to 210 days. The mean annual relative humidity is about 70 percent. The most distinctive climatic difference between the subregions is the monthly distribution of precipitation.

The Northern Appalachian Coal Region has coldest temperatures; the average annual temperatures are 54°F, with minimum January temperatures of 20°F and maximum July temperatures of over 70°F. Summer is the season of maximum precipitation. Light wind speeds are common, with an average of 9.5 miles per hour (mph) at ridge level and 6 mph in the valleys.

The Central Appalachian Coal Region has a more moderate climate with mild, damp winters and hot, humid summers. The mean annual temperature is 57°F. The annual precipitation is 45-50 inches, though some sheltered valleys receive less than 40 inches and higher elevations in some areas of Tennessee receive over 55 inches. The Central Appalachian Coal Region has two seasons of maximum rainfall, spring and summer; fall brings the least precipitation. The winds are similar to those in the Northern Appalachian Coal Region: 8-9 mph on the ridges, 50-60 percent less in the valleys.

The Southern Appalachian Coal Region has mild, wet winters and hot, humid summers. The annual mean temperature reaches 65°F, while precipitation averages 54 inches annually. The maximum precipitation is received in late winter and early spring. Fall has the least rainfall.

In none of the regions do extremes in meteorological conditions occur often enough to restrict habitation, land use, or physical resource development. Seasonal flooding along river, stream, and creek banks, occasional hurricanes in the southern areas and more rarely in the northern areas, severe winter storms ("northeasters" in the Northern Appalachian Coal Region), and infrequent droughts or tornadoes may have temporary local adverse effects on land use.

Land use, however, can affect local climates. Large quantities of heat and moisture or disruption of surface features can alter temperatures and moisture conditions, and thus affect local growing seasons. Major surface disturbance can also lead to loss of ground cover (which provides shade and soil stability), which could result in changes in relative humidity, soil temperature, soil moisture, and susceptibility to flash flooding. Solid particulates in the air can weaken intensity of solar insulation, while sulfur dioxide in the air can lead to acid rain which will corrode limestone, marble, etc.

Various meteorological parameters, such as speed, persistence, and direction of winds, can affect the significance of the negative impacts of land uses on air quality. Frequency and persistence of atmospheric inversions can be considered a limiting factor to pollution-creating land uses in the Appalachian Coal Region. In the Northern Appalachian Coal Region, surface-based inversions occur 35-45 percent of the time in winter and up to 70 percent of summer mornings. Poor dispersion also occurs frequently in late summer and fall in the other regions. This creates a high potential for stagnation of poor quality air throughout the region, particularly in the summer.

This combination of particular types of land use and climatic conditions had obvious effects on air quality in some parts of the Appalachian Coal Region. In heavily industrialized and mined areas in Pennsylvania, Ohio, and West Virginia, such as the Steubenville-Weirton-Wheeling Interstate Air Quality Control Region (AQCR), the national primary ambient air quality standards for sulfur dioxide and suspended particulate matter are not being attained. In most other counties and AQCRs in the Appalachian Coal Region, however, the air quality is good. In Maryland, Virginia, Kentucky, Tennessee, Georgia, and Alabama, measurements of sulfur dioxide and suspended particulate matter are generally better than the national standards.

Unlike most of the other regions to be discussed in this statement, the Appalachian Coal Region has an abundant supply of surface water. Severe droughts are uncommon and, in fact, many areas are flood prone. The Ohio River and its tributaries are major streams in the Northern Appalachian Coal Region, and the average annual stream flow from the Upper Ohio River Basin (as measured at Sewickley, Pennsylvania) is 23.3 million acre-feet. In the Central Appalachian Coal Region, the Big Sandy and Kanawha Rivers provide the upper Ohio and upper Tennessee River systems with the most abundant surface water flow of the three regions — 49.7 million acre-feet.

Use of surface water is constant throughout the year in all the regions, with industry and municipal entities being the dominant consumers. Annually, 1.3 million acre-feet is used in the Northern Appalachian Coal Region, 1.5 million in the Central Appalachian Coal Region, and only 23,000 in the Southern Appalachian Coal Region. Agricultural use of surface water is unimportant.

Topography has an important influence on both quantity of runoff and quality of surface water. Runoff is higher in the steep areas of the Valley and Ridge Province to the east than in the more gently sloping Appalachian Plateaus in the west. Likewise, sediment load and total dissolved solid content are greater in the eastern areas than in the western ones. Average sediment load ranges from 250-280 milligrams per liter in the western areas, and can jump to 2500 mg/liter in high runoff areas on the eastern rim. Likewise, total dissolved solids can vary from 100-350 mg/liter in the west to over 1200 mg/liter in small areas of the east. Surface water quality is also significantly influenced by land uses. Many of the nation's acid-mine drainage pollution problems are in the Northern Appalachian Coal Region. Other industrial and municipal wastes also plague surface water quality throughout the region.

Groundwater in the Appalachian Coal Region is most prevalent in some carbonate rocks, sandstones, and shoestring deposits of sand and gravel occupying flood plains along the principal streams. Well yields range from only a few gallons per minute to 500 gal/min., depending on the permeability of the rock. Groundwater quality is generally poor in the Appalachian Coal Region, with hardness and local excesses of iron, manganese, and hydrogen sulfide being the primary problems. Mining, industrial, and municipal wastes cause local adverse effects on groundwater quality.

Due to an abundance of surface water in the Appalachian Coal Region, groundwater does not play as significant a role in the survival of man, plants, and animals as it does in much of the West. Groundwater use is relatively low with a high of 190,000 acre-feet per year in the Central Appalachian Coal Region and a low of 11,500 acre-feet in the Southern Appalachian Coal Region.

Geology, topography, and climate are important factors in determining soil type. Generally, the soils in the Appalachian Coal Region are a mix with weakly differentiated horizons that exhibit the alteration of various parent materials. Soils are low in organic matter with subsurface horizons of clay accumulations. Most of the soils in the Appalachian Coal Region are well-drained with low natural fertility. Moderate to severe erosion hazard is common.

There are two major native vegetation communities in the Appalachian Coal Region, the eastern

deciduous forest (primarily in the Northern and Central Appalachian Coal Regions) and the southeastern mixed forest (Southern Appalachian Coal Region). The wide variety of forest and understory vegetation, good interspersing of terrestrial and aquatic habitat types, and the abundance of water resources give the region the cover, water, space, and forage needed to accommodate a multitude of wildlife species. Over 300 species of fish, 96 species of reptiles and amphibians, 110 species of birds, and 200 species of mammals, as well as innumerable invertebrates, inhabit the region on either a permanent or seasonal basis. It is impractical to identify all the plant and animal species in the subregions so only some of the major or characteristic species will be noted.

In the Northern and Central Appalachian Coal Regions (from Ohio and Pennsylvania south to West Virginia and Kentucky, and along lower slopes of mountains extending into the Southern Appalachian Coal Regions), beech and maple are the predominant species. Closely associated oaks, sweetgum, tulip, hornbeam, basswood, wild cherry, dogwood, hedge maple, hawthorne, and alder are also present. From Tennessee south into the Southern Appalachian Coal Region, the character of the eastern deciduous forest changes somewhat, with oak becoming the dominant species. Tulip, sweetgum, and shagbark hickory are common. Typical animal species in these areas of the deciduous forest include such game and furbearing species as the whitetail deer, black bear, wild turkey, eastern cottontail, raccoon, opossum, gray squirrel, and gray and red fox, and such birds as woodpeckers, thrushes, warblers, vireos, and owls.

The Southern Appalachian Coal Region contains some immature sandy soils overlain by pine forests. Loblolly, shortleaf, pitch, Virginia, longleaf, and slash pines are the most widespread varieties. Typical animals in these forests include such game species as black bear, whitetail deer, and ruffed grouse, and such birds as nuthatches, chickadees, woodpeckers, and warblers.

Aquatic and riparian vegetation throughout the Appalachian Coal Region includes such species as loosestrife, arrow arum, pondweed, water lilies, plaintains, and cattails. The rivers, streams, and lakes in the region support many aquatic insects and mollusks, as well as game fish such as bass, trout, crappie, bluegill, pike, pickerel, muskellunge, and catfish, and non-game fish such

as carp, shad, shiners, chubs, and sculpins. These same water sources and the riparian habitat near them accommodate turtles, lizards, muskrat, otter, beaver, and many species of snakes, frogs, and salamanders.

Agricultural crops are varied and numerous in the region. The animal species which prefer agricultural land habitat and can live in relatively close association with man are whitetail deer, robin, crows, mourning dove, bobwhite, red fox, raccoon, hawks, and owls.

Currently, there are at least 26 species of animals within the Appalachian Coal Region that are listed as endangered under the Endangered Species Act of 1973. These include the bald eagle, peregrine falcon, Bachman's warbler, red-cockaded woodpecker, eastern cougar, gray bat, Indiana bat, watercress darter, and 17 species of mussels. Although there are no Federally listed threatened or endangered plants within the region, there are a large number proposed for listing. These are presently under consideration by the U.S. Fish and Wildlife Service.

There are numerous local variations (due to topography, soil, and climate) in vegetation and wildlife that will require site-specific assessments to identify exact distributions of vegetative species. In the coal basin region of Alabama, the uplands plantlife is dominated by Virginia, shortleaf, longleaf, and loblolly pines; turkey and red oak; sweetgum; and winged elm, because they are tolerant of shallow, dry, nutrient-poor soils. Lower slopes, however, are occupied by larger, deciduous hardwoods and a great variety of shrubs that require more water. The valley bottoms with deep soils are lush with an even wider variety of vegetation including agricultural crops. The wildlife species present vary according to the habitat preferences defined earlier.

Land uses have reduced vegetative quantity and diversity in the past few hundred years, but of the various coal regions, the Appalachian Coal Region maintains the highest diversity. Natural primary productivity is moderate to high (8.9 tons per acre per year in forests to 17.8 tons per acre per year in floodplain areas). Forest cover can return naturally within 10 to 30 years after severe disturbance. This natural productivity, combined with excellent climatic conditions, gives the Appalachian Coal Region higher potential for reclamation than the western coal areas. Currently, coal

mining rehabilitation can rapidly establish a ground cover of grasses and legumes and restore suitable fish and wildlife habitat for many species. Research has not been oriented towards recreating original composition and diversity of native forests, and therefore it is not yet possible to evaluate whether current reclamation will be able to restore land to original or better productivity for tree growth in this region. Harvesting of forest products is possible within 30 years after reclamation.

4.1.2 The Environment and Man

The history of mankind in the Appalachian Coal Region can be divided into the Paleo-Indian period (prior to 8000 B.C.), the Eastern Archaic tradition (8000 to 1200 B.C.), the Woodland tradition (1200 B.C. to 900 A.D.), the Mississippian period (900 A.D.-1650 A.D.), and the proto-historic and historic cultures.

The Paleo-Indian occupation is reflected in the Meadowcroft Rock Shelter site in Washington County, Pennsylvania, dated at 14,200 B.C. These Indians were nomadic hunters who used hunting implements, pebble-choppers, hand axes, and scrapers.

The loss of traditional food sources at the end of the Pleistocene is thought to have led to the development of the Archaic tradition. Hunting continued, but fishing and plant gathering became more common. Populations increased and life became more sedentary. Earliest pottery in the southeastern U.S. is thought to have been made in Georgia in approximately 2000 B.C.

During the Woodland tradition, pottery manufacturers flourished, villages grew in size, and social organization became more formal; burial mounds were a distinctive feature of this tradition. The Mississippian culture, with large, permanent villages, riverine agriculture, and ceremonial mounds, was the next major influence, most evident in the Southern Appalachian Coal Region. During the proto-historic period, riverine agriculture, hunting, and fishing continued to provide subsistence. The dominant aboriginal groups included the Chickasaws, Choctaws, and Creeks.

Approximately 40 archaeological sites throughout the Appalachian Coal Region, remnants of prehistoric and proto-historic cultures, are listed on the National Register of Historic Places. The potential remains for discovery of more values

during future site-specific surveys, particularly in sparsely inhabited areas near lakes and streams.

The beginning of the historic period is commonly defined by the arrival of Hernando deSoto (who explored parts of the Appalachian and Gulf of Mexico areas in the 1500's), but the major influx of Europeans did not start until the early 1700's. The first white settlements were built in the early 1800's as the British and French competed for land. The settlers were primarily farmers (raising corn, hogs, cattle, cotton, and tobacco) with secondary occupations as blacksmiths, cobblers, and millers. Slavery was important in the Southern Appalachian Coal Region and parts of the Central Appalachian Coal Region. Railroads, wagon trains, and steamboats helped the settlers penetrate into the frontier and displace the native Americans.

As early as the 1830's, coal mining had begun to rival the cotton industry in some areas. By 1860, factories (producing lumber, carriages, cotton and wool products, and machinery) and coal mines were active throughout the Appalachian Coal Region.

The Civil War sparked mineral activity (smelting and casting furnaces) throughout the Appalachian Coal Region. During the War, many industries, particularly in the Central and Southern Appalachian Coal Regions, were damaged. Cotton production gave way to new industries such as iron and steel manufacturing in the late 1800's. As these industries grew, so did the need for coal.

There was steady economic progress after the turn of the century. Coal production was booming in the 1920's. Other industries that began to grow included steam, natural gas, oil, and electricity.

Over 600 historic sites (houses, covered bridges, iron furnaces, railroad buildings, battle-fields, land-mark oil wells, and other structures), reminiscent of the Appalachian Coal Region's varied and colorful history, are listed on the National Register of Historic Places. This comprises one third of all the National Register sites in the coal regions.

There is wide variance in the socio-economic characteristics of the three regions. The Appalachian Coal Region, as a whole, is very distinct from the Western regions. Tables 4-1, 4-2, and 4-3 show population, employment, and other socio-economic characteristics of the three regions.

The Northern Appalachian Coal Region is the most densely populated with a population of over 8,019,000 in 1975 and a density of over 150 people per square mile. The Central and Southern Appalachian Coal Regions both have populations over 2,000,000, but the density in the Central Appalachian Coal Region is slightly less than 60 people per square mile, while in the Southern Appalachian Coal Region it is almost 100 people per square mile. All three regions experienced high out-migration rates during the 1960's. In the 1970's, out-migration in the Northern Appalachian Coal Region slowed considerably and the other two regions gained population.

In the region as a whole, manufacturing and wholesale and retail trade have replaced agriculture and mining, important occupations in earlier history, as the major employment sectors. In 1975, these sectors employed from 36 to 53 percent of the populations of these regions.

In 1975, coal mining employment ranged from only 1 percent in the Southern Appalachian Coal Region to 12 percent in the Central Appalachian Coal Region. Development of other minerals employed less than 4 percent of the regions' populations, while agriculture employed 4 to 10 percent. In small localized areas throughout the region, however, minerals development or agriculture may provide the dominant employment opportunity.

Land uses are varied. Most farms are small (averaging less than 160 acres each), and the major crops include cotton, soybeans, corn, wheat, sorghum grain, hay, and fruit. Some of the best farm land is along the Ohio River, as it was in prehistoric and historic times. Beef cattle, sheep, and hogs remain important products of the agricultural sector.

As mentioned previously, there is active mining throughout the region. Federal leaseable minerals include oil, gas, and coal. The greatest potential for development of federally owned oil, gas, and coal is found in the Southern Appalachian Coal Region. Saleable minerals in the Appalachian Coal Region include sand, gravel, shale, and clay. The most important hardrock minerals are iron, zinc, and copper.

Most of the federally-owned coal reserves of the Appalachian Coal Region are located in various National Forests, which are scattered throughout Alabama, Kentucky, Ohio, Pennsylvania,

(a) Demographic information which is based on all counties either totally or partially within regional boundaries.

nia, Virginia, and West Virginia. National Forest coal reserves total approximately 679,000 acres. The largest concentration of Federally-owned coal on both Federal and private surfaces occurs in Alabama, where about 40 percent of all Federal reserves of the Appalachian Coal Region are located. Federal coal reserve acreages on state surface, private surface, and National Forests are 80,878; 91,980, and 506,126 respectively.

In the Appalachian Coal Region, coal is transported by waterway, railroad, conveyor belt, and truck. There are no coal slurry lines. The Appalachian coal is closer to demand centers, and transportation costs are lower than those involved in development of western coal. Some problems in transport of coal in the region exist, however. Inadequate lock systems and congestion in the waterway system (which includes the Mississippi, Ohio, Greer, Warrior, and other rivers) are causing bottleneck delays in some areas. Abandonment and deterioration of railway lines are making transport by rail more difficult in areas like West Virginia. The use of trucks is growing as coal production increases. This results in increased noise and air pollution, road congestion, and safety hazards. Some counties have resorted to levying taxes to correct environmental damage caused by coal trucks.

Other land uses include urban and suburban development, communication sites, powerlines, gas pipelines, sand and gravel pits, and sanitary landfills. Access to most federally owned coal is afforded by county or state owned and maintained, all-weather, paved or gravel roads of varying quality.

Recreation is an important land use to be considered. The Appalachian Coal Region has over 138 state parks, 10 state forests, and 10 other state-owned recreational facilities, covering over 511,000 acres and attracting over 56 million visitors a year. Camping, hunting (deer, turkey, and small game are most popular), fishing (bass, blue gill, trout, and catfish primarily), boating, spelunking, hiking, rockhounding, and skiing are just a few of the opportunities available.

The region contains many rivers presently included in the Wild and Scenic Rivers System (e.g., 45 miles of the Obed River in Tennessee, 33 miles of Little Beaver River in Ohio). Others are being considered for inclusion (e.g., parts of Pine Creek in Pennsylvania; Sipsey Fork River in

Alabama). There are also four wilderness areas, totaling nearly 48,000 acres, in the Central and Southern Appalachian Coal Regions. Three trails (North Country, Kittanning, and Potomac Heritage) are being considered for inclusion in the National System of Trails.

About 23 billion tons of coal had been extracted from the beginning of mining in the region until 1965. One-third of this was from the Pittsburgh coal bed, making it one of the most valuable beds in the U.S. The number of coal beds in the region varies from 10 in Pennsylvania to 62 in West Virginia.

4.2 EASTERN INTERIOR COAL REGION

The Eastern Interior Coal Region is located within the Central Lowland and Interior Low Plateaus of the United States. This region encompasses approximately 59,000 square miles in 85 Illinois, 23 Indiana, 18 Kentucky, and two Iowa counties.

4.2.1 The Environment

The Eastern Interior Coal Region is a combination of smooth and irregular plains within the Mississippi and Ohio River watersheds. The Illinois, Indiana, and Iowa portions of the plains are smooth almost to Kentucky, due to the influence of the Illinois glacier. The remainder of the region is unglaciated and its topography is therefore hilly. In this portion of the region, local relief varies from 100 to 500 feet with steep bluffs occurring along many of the rivers. The elevation of the entire region does not exceed 1,000 feet above sea level.

The region's geological formations are primarily sedimentary rocks from the Upper Paleozoic Era of approximately 300,000,000 years ago. Rock strata are dominated by sandstones, limestones, conglomerates, and shales. Various paleontological formations are associated with these strata, as well as the region's coal deposits.

The principal coal bearing formations are the Lower Pennsylvania, Pottsville, and Allegheny Formations. The coal deposits are composed almost entirely of low-volatile bituminous. A three-county area of southern Illinois, however, contains high-volatile bituminous deposits. In addition to coal, the mineral resources of the region include petroleum, clay, crushed stone, gravel, and sand.

The region's total reserve base is estimated to be 88.9 billion tons.

To a great extent, soils in the northern half of the region have derived from glacial drift and windblown deposits. Soils from two to five feet deep predominate in this portion of the region. Top soil is generally black, friable, and high in organic content. The unglaciated southern portion of the region has soils with a thinner layer of top soil. Soils in this area are derived from windblown deposits overlaying glacial till. These soils have a gray-brown surface layer that is medium to highly basic. This surface soil often overlies an impermeable clay pan that produces poor internal drainage. Soils of the entire region are fertile. Those in the northern portion are the more productive.

A temperate climate prevails throughout the region. Annual mean temperatures range from 48°F in the north to 60°F in the south. Seasonal extremes range from -20°F to 110°F.

Precipitation volumes also increase from north to south; the northern areas receive about 30 inches a year, while the southern areas receive 40 inches per year. The region has snowfall, although it is generally less than 10 inches annually. Storms are most frequent in the winter and spring months. Summer storms generally track from the north and are weaker. Autumns are often dry with little storm activity until November. Although short dry periods do occur, the region is not vulnerable to sustained droughts.

The region is subjected to a variety of winds from Canada, the Great Plains, and the Gulf Coast. Wind speeds average approximately 10 miles per hour, which is above the nation's average. The lack of topographic barriers permits continual ventilation and air quality is good. There are generally less than 20 days a year during which the region is subjected to high levels of air pollution. These episodes are generally short-lived. Certain urban centers do create some localized air quality problems. These problems are restricted to Evansville, Indiana, where high particulate and moderate sulfur dioxide levels occur; Terre Haute, Indiana, where high particulate levels occur; Springfield, Illinois, where moderate particulate levels occur; and Peoria, Illinois, where moderate particulate levels occur.

With its precipitation patterns and two major waterways, the Eastern Interior Coal Region generally has plentiful supplies of water. A dendri-

tic drainage pattern is formed by the Mississippi and Ohio Rivers, their major tributaries such as the Illinois and Wabash Rivers, and the smaller tributaries of these. During heavy rains and spring thaws, these rivers are prone to damaging floods.

Water quality varies throughout the region. For most uses, it is generally satisfactory or can be treated. Agricultural runoff causes localized problems with bacterial contaminants, nitrogenous pollutants, and suspended solids. Additionally, various industrial pollutants are found in the region's scattered urban centers.

It is estimated that 42.3 million acre-feet of fresh to slightly saline groundwater is in storage in the region, and some towns and cities have had difficulty obtaining wells yielding good water at reasonable costs. Over most of the region, however, fresh groundwater, at least in small to medium quantities, is not difficult to develop. Some local overpumping has resulted, since only about 4.1 million acre-feet of fresh groundwater is recharged to the system each year. Some municipalities have found it less expensive and more satisfactory to discontinue their poor groundwater sources and develop treated surface waters. Over most of the region, the depth to saline groundwater is less than 500 feet.

The above-described environmental aspects have created an ecotone-type ecology in the region. This means that the region is situated in the transition zone between the eastern deciduous forest and the Great Plains grasslands. An oak-hickory forest dominates the natural vegetation of the Kentucky, Indiana, and southern Illinois portion of the region. The remaining portion is dominated by farmland and an oak savannah ecosystem. Intensive agricultural practices occur in the region, so much of the natural vegetation has been removed. Only about 15 percent of the region is now forested.

Where natural forests exist, dominant tree species include fir, white and swamp oaks, hickory, ash, poplar, and sweet gum. Associated ground cover includes shrubs (such as mountain laurel, rhododendron, dogwood, wisteria, sumac, buckthorn, alder, and hawthorn), numerous forbs, and grasses (such as winged pigweed, bishopcap, love grass, panic grass, and morning glory). Net primary productivity for forested areas is about 8.9 tons per acre per year.

Relict prairie areas exist in limited portions of the oak savannahs that have not been disrupted by agriculture. They are vegetated by mixed grasses, legumes, and other herbaceous species. Typical species are bluestem, switchgrass, and Indian grass (representative of tall grass prairie); little bluestem, needlegrass, and western wheat-grass (representative of mid-grass prairie); and buffalo grass, blue grama, and side-oats grama (representative of short grass prairie). There is a general tendency for the short grasses, more typical of western prairies, to push eastward onto the heavier soils of this region, and the tall grasses (typically eastern) to push westward onto the lighter soils. Net primary productivity of the remaining prairie in the region is about 6 tons per acre.

Typical vegetation of the wetlands and bottom areas includes spike rush, sedges, milkweed, water primrose, cattails, pondweeds, and lizardtails. These wet areas are highly productive and are valuable habitat to waterfowl using the Mississippi flyway.

The forests and prairies of the region serve as habitat for a wide variety of other wildlife species. Due to extensive farming, most wildlife within the region is compatible with man's activities. Some even depend on the farmer's fields for food and cover. Typical forest mammals include whitetail deer, eastern cottontail, gray squirrel, gray fox, and raccoon. Species typical of the prairie areas and edge habitat between forest and prairie include whitetail deer, woodchuck, red fox, and coyote. Small mammals, such as mice, shrews, and bats are numerous in both prairie and forest areas. Fur-bearers, such as mink, beaver, and muskrat, occur along waterways and in marshy habitats.

Major upland game birds found in the region include ring-necked pheasant, ruffed grouse, mourning dove, bobwhite, and wild turkey. Wetlands and waterways provide habitat for waterfowl using the Mississippi flyway, such as bluewinged and greenwinged teal, pintails, wood ducks, lesser scaup, black ducks, mallards, and lesser snow and Canada geese. Among the principal non-game birds are redtailed hawk, turkey vulture, great horned owl, green heron, chimney swift, cardinal, indigo bunting, crow, bluejay, brown thrasher.

Among the 15 species of game fish in the region, largemouth bass is the most popular. Other gamefish of local importance include bluegills,

crappie, northern pike, catfish, yellow perch, white bass, and yellow bass.

Reptiles and amphibians found within the region include box turtles, soft-shelled turtles, snapping turtles, copperhead snakes, king snakes, cricket frogs, bull frogs, and a variety of lizards and salamanders.

Although most species have adapted to man, a few have not. Their habitats have diminished with agricultural advancement to the point where populations are very restricted and are threatened or in danger of extinction. Federally listed endangered species of wildlife within the region include the Indiana bat, bald eagle, tuberculated-blossom pearly mussel, Sampson's pearly mussel, and peregrine falcon. There are no Federally listed endangered plants within the region's boundaries, but numerous plant species are presently under consideration for threatened or endangered designation by the U.S. Fish and Wildlife Service. The plants in the relict prairies are not endangered, as they are common in other prairies in the West.

The ecosystems within the Eastern Interior Coal Region are capable of recovery after human disturbances. With proper soil conditions, natural succession can return a grassland to a near original state within a decade. Forest lands require much longer to return to a stage similar to virgin timber. Natural succession, however, can return a cleared forest to an immature forest in less than 50 years, given proper conditions. With adequate management, the lands of this region could be reclaimed after coal mining operations.

4.2.2 The Environment and Man

The agricultural opportunities of the Eastern Interior Coal Region have historically been its major attraction for human beings. Timber and other natural resources have also been attractive but to a lesser degree. Original Indian populations were primarily village farmers. Tribes of Illinois, Miami, and Shawnee Indians produced maize and grains from the fertile soil. White men did not arrive until 1672, when two French explorers, Joliet and Marquette, led an expedition up the Mississippi and Illinois Rivers. Their journey initiated the education of the European colonists to the region's abundant agricultural opportunities. Eventually, settlers were drawn westward from the deciduous forests of the original 13 colonies to the agricultural advantages of the prairie fringe. The

acquisition of the Northwest Territory by the United States in 1787 provided for this colonial expansion. In 1820 settlement was limited to the Ohio Valley, but shortly thereafter settlements were found scattered throughout the entire region.

In 1836 a blacksmith's apprentice named John Deere was drawn to Grand Detour, Illinois, from Vermont. In 1837 he built the world's first steel moldboard plow. His invention became famous as "the plow that broke the plains." Thereafter farming became the primary regional activity and most of the land was cleared. Agriculture is still the primary land use over the entire region and is a significant contribution to the area's economic base. Most farmers grow corn, soybeans, grains, and hay for export or livestock feed. Individual farms vary in size up to 500 acres.

The timber production of the southern portion of the region has added to the region's economy. Oil is another natural resource that was found in moderate abundance in the region. It also contributes to the area's economic base.

Twentieth century industrial development has added greatly to the region's economy, but is essentially limited to urban centers. The major cities that support most of the industry are Peoria, Springfield, and Decatur, Illinois; Burlington, Iowa; Evansville, Indiana; and Owensboro, Kentucky. Coal production has played an important role in the region's industrial development; together with oil, it provides most of the energy supply. Manufacturing is the major contributor to employment, involving 26 percent of the total workforce. Table 4-4 provides additional economic data, illustrating the relative importance of specific sectors of the economy.

Surface transportation via water and rail was instrumental in urbanization. Water carrier service is available on the Mississippi, Ohio, and Illinois Rivers. Major railways serving the region include the Chessie System, Norfolk and Western, Illinois Central Gulf, Louisville and Nashville, Southern, and ConRail. In addition to these modes, a modern highway network is used for commercial and private transportation. The primary highways used for bulk commodity transportation are the interstate highways. The region is traversed by Interstate Highways 24, 64, 70, 74, 55, and 57. Oil and gas pipelines are also located in the region. Coal slurry pipelines are not present.

Historic agricultural development and recent community development have been instrumental in creating a large population growth in the Eastern Interior Coal Region. Presently, there are over 5 million inhabitants within the region. The 1975 population density was approximately 85 persons per square mile. The rural sector of the region is fairly stable, while the urbanized centers are experiencing mild growth. The area has never been exposed to any major boom town phenomena. Cultural development within the region is highly varied. Indian artifacts from cultures dating to 2000 B.C. have been discovered in Greene County, Illinois. Remnants of the Wabash and Erie Canals of the mid 1800's still remain. Historical sites relating to Abraham Lincoln's past are found in numerous locations. Over 200 individual historic sites within the region are identified for preservation by the National Register of Historic Places.

Most federally-owned coal reserves are located in the National Forests within the boundaries of the Eastern Interior Coal Region. National Forest coal reserves for this region total nearly 117,000 acres. The region's largest concentration of Federal coal ownership under Federal and private surface occurs in Illinois, where some 95,499 acres are located. Federal coal reserve acreages for private surface and National Forests are 7,645 and 116,809 respectively.

4.3 WESTERN INTERIOR COAL REGION

The Western Interior Coal Region is in the central plains of the United States. This region encompasses approximately 98,000 square miles in eight Arkansas, 53 Iowa, 36 Kansas, 56 Missouri, nine Nebraska, and 25 Oklahoma counties.

4.3.1 The Environment

The Western Interior Coal Region contains a wide variety of topographic features, from irregular glaciated plains in the north to steep-sided ridges and mountains in the south. Elevations vary from 500 feet in the northeast portion of the region to 2,000 feet in the southern highlands. The region is situated within the Central Lowland physiographic province and has a generally flat to rolling topography. There are some eroded mountains in eastern Oklahoma and western Arkansas known as the Ouachita and Boston Mountains.

TOTAL	1,956,540		19,731,603	

(a) Demographic information which is based on all counties either totally or partially within regional boundaries.

Present topography and land forms are largely a result of surface rocks. Resistant rocks, such as granite, sandstone, and limestone, generally form high ridges, hills, and mountain peaks, whereas nearby outcrops of shale and other easily eroded rocks form valleys and lowland areas.

In the past, forces within the earth have caused portions of the region to alternately sink below and rise above sea level. Large areas were often covered by shallow seas, and thick layers of sediments were deposited and subsequently lithified into shales, limestones, and sandstones. Later, these areas were uplifted and the sedimentary rocks were exposed and eroded.

The gently sloping hills of the northern portion of this region are composed of alluvium, glacial drift, and loess, underlain by Paleozoic sandstones, limestones, shales, and coal seams in horizontal or nearly horizontal beds with isolated faulting and gentle folding. The east-west trending ridges and valleys of the Ouachita province were formed during the early Paleozoic Age through extensive folding and faulting.

The coal beds of the region are Upper Carboniferous (Pennsylvanian) in age and mostly high-volatile bituminous in rank. They are generally of better quality than the coals of the West, but are also higher in sulfur content. The principal coal-bearing formations throughout most of the region are the Lower Pennsylvanian, Pottsville, and Allegheny Formations. They comprise a lower series, that contains most of the coal, termed the Des Moines Group, and an upper series termed the Missouri Group. The region's estimated reserve base is 16 billion tons.

Most of the Federal coal in the region is in the southern part, in Oklahoma. In this area, and in western Arkansas as well, mountain-building forces of the Ouachita disturbance sufficiently devolatilized the coal beds to raise their rank to low-volatile bituminous and some localized semianthracite deposits. The coal is mostly of coking quality and is contained in rocks of the Hartshorne Sandstone and the McAlester Shale. The most important beds are the Lower Hartshorne, 2.5 to 6 feet thick; the Upper Hartshorne, 1.75 to 5.5 feet; and the McAlester Shale, 1.75 to 4 feet thick.

Most hard rock minerals are formed as a result of igneous activity. Ore mineral such as silver, lead, and zinc occur within the tri-state area of Arkansas-Missouri-Oklahoma. "Common variety" min-

eral materials, such as sand and gravel, building stone, crushed stone, and common clay, are abundant in most of the region. Building stone and crushed rock are quarried from sandstone and limestone. Sand and gravel are obtained from river alluvium, and clay is obtained from shale.

Coal is plentiful in the region, but production is principally in eastern Oklahoma. Oil and gas producing horizons occur principally in Oklahoma and Kansas in several different formations at a wide range of depths. Fossil-bearing strata occur throughout the region. The only ones of significance in the Federal coal reserves are those associated with coal seams of the Middle Pennsylvanian Hartshorne, McAlester, Savanna, and Boggy Formations.

The climate of the Western Interior Coal Region is characterized by hot summers and cold winters. Ranges in temperature and precipitation are pronounced. The area tends to be dominated by cold air from the Canadian arctic in winter and warm air from the southwest in summer. Temperatures in the southern portion average 40°F in January and 80°F in July. In the northern portion, they average 20°F in January and 70°F in July. The mean annual freeze-free days range from 150 in the north to 210 in the southwest.

Most of the area receives between 32 and 48 inches of precipitation per year. Months with the highest precipitation are March, April, May, and June, at the start of the growing season. Parts of the area receive over 4 inches per month during this time although they are also exposed to occasional short-lived droughts. Fall rains may average over 2 inches per month. Winter snows, particularly in the north, are common. The humidity averages between 60 and 70 percent most of the year, with some portions having a higher average in the fall and winter. The relatively high amounts of rainfall and seasonally warm temperatures combine to provide very favorable conditions for plant growth.

The area is generally windy. Average speeds near the ground are 11-14 mph. When precipitation has been sparse fugitive dust and dust storms are common. The winds are typically out of the west and northwest in the winter and out of the south the rest of the year. This area is subject to many tornadoes every year.

Air quality, in terms of particulate, sulfur dioxide, and nitrogen dioxide content, is good in

most areas of the region. Some variation does exist, particularly in urbanized areas of the region. These variations are located in Kansas City, Missouri, where moderate particulate matter and sulfur dioxide levels occur; Omaha, Nebraska, where moderate particulate matter and sulfur dioxide occur; and Tulsa, Oklahoma, where low particulate matter and moderate nitrogen dioxide occur.

Most of this region has abundant supplies of water, including a considerable number of lakes and reservoirs. However, most industries and municipalities must treat surface water and some groundwater before use. The quality of surface water ranges from low dissolved solids and high sediment concentrations during high flow periods to high dissolved solids and low sediment content during low flows.

Surface-water runoff averages about 7 inches over most of the region, ranging from 3 inches in the northwestern to extremes of 30 inches in the southern mountains. Where standing bodies of water exist in the region, evaporation ranges from about 36 inches in the north to 54 inches in the southwest. Devastating floods resulting from thunderstorms are not uncommon.

The quality of the surface water is generally good, especially in the east where the total dissolved solids are generally moderate. In the western part of the region, particularly in the northwestern and southwestern areas, the rivers not only carry a greater concentration of total dissolved solids but a much heavier load of suspended solids. The Des Moines, Iowa, Missouri, and Arkansas Rivers have the poorest quality water. In some streams, oil-field wastes and other industrial and municipal wastes have created serious problems.

Groundwater conditions vary widely with respect to quantity and quality. In the Iowa and northern Missouri portion of the region, well yields vary, but wells are generally less than 250 feet deep. Groundwater supplies in the unglaciated southern portion of the region can be obtained from river alluvium, shale, sandstone, limestone, and dolomite aquifers. The river alluvium generally yields moderate to large supplies of water of good quality. The shallow sandstone and limestone bedrock aquifers generally yield less than 25 gallons per minute of medium to poor quality water. In some parts of the area wells over 1,000 feet deep which penetrate the Cambrian and

Ordovician carbonate aquifers underlying the coal bearing strata yield over 500 gallons per minute of good to medium quality water. The dense slaty shale and hard sandstone that largely make up the Ouachita Mountains yield a poor supply of groundwater in that area.

The soils of the region vary considerably but are mostly sedimentary in origin. Soils range from organic rich bottomland to sandy hillside loams. The dominant soils in the northern part of the region are black organic rich soils that often have a brown clay subsoil. These soils developed from glacial till or loess and are generally quite fertile. The prevailing soil in the south is a dark red loam, made up of decomposed sandstone and limestone. The river valleys often have rich deposits of alluvium.

The Western Interior Coal Region includes a portion of the continent where the eastern deciduous forests merge with the prairies and plains of the west. Accordingly, there is a transition between the vegetative communities typical of both biomes. The deciduous forest, tall-grass prairie, and transitional zones, including the savannahs, make up the major habitat types. This mixture of habitats within the region provides suitable food, shelter, and cover for a variety of wildlife.

The mixed oak-hickory forest association is common in the eastern portion of the region, grading to oak-hickory-pine forest in the southeastern portion. Associated understory vegetation includes dogwood, redbud, holly, sassafras, winged elm, wild grape, spicebush, sumac, and numerous native grasses and forbs. On well-shaded slopes, mosses, liverworts, and fruticose lichens form a continuous mat over the surface of the ground. Few mammalian species develop large populations in these forest associations. Whitetail deer, raccoon, red fox, gray fox, eastern gray squirrel, fox squirrel, brush mouse, eastern woodrat, eastern cottontail, striped skunk, and opossum are typical mammals. Typical birds include those that prefer the upper canopy layers, such as vireos and warblers, and those occupying the lower canopy and the forest floor, such as thrashers, wood pewee, rufous-sided towhee, cardinal, wild turkey, and ruffed grouse.

The bottomland forest association occupies fertile bottomland soils of alluvial origin. This vegetative association is found along water bodies and stream courses. The more common species are

willow, cottonwood, American elm, sycamore, and sweet gum. Boggy areas support a heavy cover of herbs and ferns. Understory vegetation consists of numerous small trees, shrubs, and lichens. As the forests diminish to the west, and the prairies become extensive, the relative amount of grassland and woodland varies greatly in different parts of the region. For the most part, grassland vegetation consists of a mixture of such dominants as big bluestem, little bluestem, Indian grass, silver beard grass, and switch grass. Wildlife typical of prairie areas and agricultural lands within the region include whitetail deer, eastern cottontail, red fox, and coyote. Typical birds in these open habitats include horned lark, crow, cowbirds, grasshopper sparrow, bobwhite, mourning dove, and ring-necked pheasant. The greater prairie chicken may be found in the savannah type.

Distribution of water plants usually is not controlled in the same way as occurrence of the plants growing in adjacent terrestrial habitats. Many aquatic species rely on the various lakes, ponds, or streams throughout the region. Some are restricted to small areas or special types of lakes. Species which are common to the aquatic vegetation community of the region include water willow, cattails, spikerushes, duckweeds, watervelvet, water chinquapin, waterlilies, spatterdock, smooth water primrose, and a wide variety of submerged aquatic aggregations.

Water bodies within the region are generally highly productive and support a variety of fish including bullheads, yellow perch, bluegills, large mouth bass, crappie, shiners, and minnows. Fur-bearers associated with these aquatic habitats include mink, muskrat, beaver, otter, and raccoon. Typical birds include red-winged blackbird, herons, gulls, wood ducks, mallards, scaup, snow and Canada geese, and bald eagle.

Some of the amphibians and reptiles common in the region include cricket frog, bullfrog, collared lizard, sixlined race runner, box turtle, spiny soft-shelled turtle, ringnecked snake, kingsnake, gartersnake, and ground snake.

There are 10 species of animals occurring within the Western Interior Coal Region that now have protected status as endangered species: These include the red wolf, Indiana bat, gray bat, peregrine falcon, Eskimo curlew, bald eagle, red-cockaded woodpecker, and Bachman's warbler. Presently, there is only one plant species in this

region listed as endangered. This is the northern wild monkshood, with known distribution in Iowa. However, there are numerous other plants under consideration for designation as endangered or threatened. These may be given protection by the U.S. Fish and Wildlife Service.

The above-described ecosystems within the Western Interior Coal Region's boundaries are capable of natural reoccurrence after human disturbance. Prairie grasses can reoccur through a natural succession process within a few years of disturbance. Oak-hickory forests, however, require a much longer period to regenerate, although they too can naturally reoccur. These ecosystems would be reclaimable following coal mining operations; however, proper attention would be necessary to assist the reclamation process.

4.3.2 The Environment and Man

Evidence has been found that man existed in the Western Interior Coal Region more than ten thousand years ago. Artifacts reveal that wandering tribes of hunters and gatherers were the first inhabitants of the region. Gradually, some of the tribes became sedentary and agricultural communities developed. The region is rich in archeological sites dating from many periods. Over 60 of these sites are included in the National Register of Historic Places.

Recorded history began in 1541 when Francisco Vasquez de Coronado crossed the region in his search of the fabled city of Cibola. In the seventeenth and eighteenth centuries, French trappers and hunters wandered down the Missouri River and settled on its tributaries. The Missouri River was the principal travel route for the explorers of the early 1700's, and became the standard route for the traders travelling between St. Louis and the Mandan Indian villages in the northern Great Plains during the 1780's and 1790's. By 1800 some towns and forts were established and some areas in the eastern part of the region along the Missouri were settled.

A new era in the development of the region commenced with the Louisiana Purchase of 1803. Expeditions were sent by the U.S. Government to explore this newly acquired territory for its resources. Following further explorations, important trade routes and eventually cattle trails became established during the nineteenth century. The Texas Road, the Butterfield Stage Line, the

Chisolm Trail, and the California Road stimulated the founding of trading posts and then settlements along these routes.

At present, there are over 450 sites or districts from this region included in the National Register of Historic Places. These listings include sites similar to those in the other eastern regions (houses, churches, and courthouses), together with a range of sites associated with early travel in the area, new settlers, contacts with the American Indians, and events of the Civil War.

The region has a long history related to agriculture as the dominant land use. Present day agriculture in the region includes the enormously productive feed-grain and livestock producing areas of central Iowa, much less productive general farming in eastern Oklahoma, and poultry production in the Arkansas portion. In the northern portion of the region, over 75 percent of the land area is in cropland, and a substantial part of this area is prime farm land. In the Kansas and Missouri portions, cropland represents from 50 to 70 percent of the land area. In the Oklahoma and Arkansan portions, only 15 to 30 percent of all land is used for crops but a higher percentage of farm land is used as pastures. Principal crops are corn, soybeans, peanuts, cotton, grain sorghums, hay, and fruit. Along the Arkansas River, the cropland is devoted to commercial vegetable production for local canneries because of a plentiful year-round water supply and excellent soil for pasture.

Although cropland is decreasing in many areas and improved pastures are increasing, the size of farms shows a decided increase in acreage as mechanized farming is now the rule and better fertilizers and land management give greater yields with less labor.

In the southern part of the region, where the climate is warm and humid, timber is an important resource. In recent decades, much of the cleared land has been replaced by second and third generation forests. Presently, trees are harvested for timber and wood products, furniture and fixtures, and paper and allied products.

The presence of coal in the region has been known since the 1820's. Mining was not done on a commercial scale until the Missouri, Kansas, and Texas Railroad was built through McAlester, Oklahoma, in 1872. At first, the coal was mined for use as domestic and locomotive fuels. As branch

lines were built out into the various coal fields of the region, mining expanded and began producing coal for shipment to distant markets. The steadily rising production continued and reached an all-time high in 1920. However, annual production declined after 1920 as railroads began using diesel-powered locomotives. Production rose again in the late 1940's and 50's, then declined rapidly again as industry switched to oil and natural gas for fuel. The energy problems of the 1970's triggered a new increase in production, with present production nearing the production figures of 1920.

The first natural gas in the region was discovered in the Arkansas portion of the Arkoma Basin in 1902. The first productive well in the Oklahoma portion of the Arkoma Basin was drilled near Poteau, in 1910. This discovery spurred the drilling of numerous shallow wells in the 1910's and 1920's. Many of the zones are still productive or are being used for gas storage. Presently, the only oil and gas producing States in the Western Interior Coal Region are Arkansas, Oklahoma, and Kansas. In 1955, rising natural gas prices encouraged a new wave of drilling activity. Development was hampered at first by the absence of an adequate pipeline network, but new pipelines were built and drilling activity boomed through the mid-1960's. By the late 1960's, however, rapidly increasing drilling costs coupled with stagnant or slowly rising gas prices discouraged new, large-scale drilling activity. In 1973, the energy crisis forced natural gas prices upward and drilling activity increased again. Higher gas prices and steadily advancing drilling technology have encouraged drillers to seek pay zones at ever increasing depths, and new wells in a number of fields are more than 12,000 feet deep.

The tourist and recreation industry is of moderate economic importance, but the region has always been an area of high recreational use. Good roads, proximity to population centers, and publicized recreation resources result in heavy tourist traffic. Two national wilderness areas are located in national forests that are partially in this region. They are Caney Creek with 14,344 acres in the Ouachita National Forest, and Upper Buffalo, encompassing 10,182 acres of the Ozark National Forest. In addition, more than 66 state parks, 40 state recreational areas, 26 state forests and preserves, and 20 other recreation areas lie within the region. Combined annual attendance for these

facilities is over 19 million and their present area is 260,850 acres.

Principal manufacturing, retail and wholesale trade centers in the region are in Des Moines, Iowa; Omaha, Nebraska; Kansas City, Missouri; Kansas City, Kansas; Tulsa, Oklahoma; Fort Smith, Arkansas; and Topeka, Kansas. These large cities are also executive centers for large business such as major oil companies, large corporations, financial and banking institutions. Total employment and earnings in each employment class during 1974 is presented in Table 4-5 along with percentage distribution.

Transportation systems have historically been an influential factor in the development of the region. The Missouri River provided the principal means of access to the west during the early portion of the nineteenth century. Later that century, development was spurred by the advent of the railroads. Today the region is served by eight major railways, barge lines, and by truck service over a widespread highway network including six Interstate Highways. Major air terminals are located in all major population centers and several cities around the region within relatively easy driving distances. Various electrical transmission lines, water lines, microwave paths, telephone lines, gas lines, and oil lines form a network throughout the region. There are no coal slurry pipelines in the region.

Socioeconomic data for the Western Interior Coal Region are presented in Table 4-5. The population totaled over 5.8 million in 1975 with a density of 55 persons per square mile. Farm populations vary from 11.3 to 28.1 percent among the counties of the region, with urban dwellers comprising another 58.5 percent of the total. The population was relatively stable during the 1960's with a slight gain between 1970 and 1976.

Land use development and settlement in the region occurred in such a manner that there are no major tracts of land under the Bureau of Land Management's jurisdiction. The only significant Federal lands in this region are the Ouachita and Ozark National Forests, which are under the jurisdiction of the U.S. Forest Service; the DeSoto, Squaw Creek, Swan Lake, Flint Hills, and Sequoyah National Wildlife Refuges, which are under the jurisdiction of the U.S. Fish and Wildlife Service; and scattered reservoirs and military bases, which

are under the jurisdiction of the U.S. Department of Defense.

In summary, the region can be described as predominately rural, with numerous farms and ranches; a variety of second growth timbered areas varying from small farm woodlots to managed forest tracts; numerous small rural communities and large metropolitan industrial centers; and an extensive road network which permits mobility and accessibility between them.

4.4 TEXAS COAL REGION

The Texas Coal Region is located entirely within the Gulf Coastal Plain. The region encompasses 37,000 square miles in 51 Texas, four Louisiana, and one Arkansas counties.

4.4.1 The Environment

The Texas Coal Region has major resources, in the form of natural resources, agriculture, and industry. Topographically, it consists of gently sloping, irregular plains and tablelands. Elevation does not exceed 1,000 feet above sea level. The area is underlain with sedimentary rock of the early Cenozoic Era of about 70 million years ago. The soils have never been glaciated. These prehistoric conditions have enabled the preservation of numerous fossil formations which are scattered throughout Texas. Many formations are closely associated with the lignite deposits.

In terms of historical geology, lignite constitutes an early stage of development. It is a low grade coal and contains separable pieces of plant material. The relatively low value of the coal is directly correlated with its recent geologic occurrence. Today's lignite deposits resulted from accumulations of plant material in river deltas, flood plains, and lagoons in the early and middle Cenozoic Era. Subsequent sedimentation compacted this organic matter to its present state.

The region's lignite reserves are estimated to be 3.3 billion tons. Both surface and subsurface deposits exist in most counties. Generally lignite is associated with three major seams which parallel the northeast-southwest boundaries of the region. Surface lignite is associated with the Wilcox or the Yegua-Jackson Group, while subsurface lignite is associated with a seam commonly referred to as the Texas Deep-Basin deposit. Surface deposits are usually less than 90 feet deep and are often found in seams that are 10 to 20 feet thick. Many seams,

TOTAL	2,365,214		23,827,964

(a) Demographic information which is based on all counties either totally or partially within regional boundaries.

however, are thinner and are thus presently unattractive for development. Texas Deep-Basin coal is found up to 5,000 feet below the surface. Most of the subsurface deposits are found in the northeastern half of the region.

Other significant mineral resources are located within this area of Texas and Louisiana. This region is a very major contributor to the nation's petroleum and natural gas production. In addition, ample iron ore, clay, sand, and gravel reserves are available to supply regional construction needs.

Soils of sandy, silty, or clay loams overlay the mineral deposits throughout the region. Soil conditions vary from acidic to basic at varying locations. The soil's organic content also varies among locations, depending not only on natural conditions but also on the particular land use. Soil moisture and consequently soil productivity varies extensively from northeast to southwest according to the degree of precipitation and irrigation.

Climatic conditions are such that the region receives about 48 inches of precipitation in the northeast but only 16 inches in the southwest. This variance is due largely to the variability in the influence of the Gulf of Mexico. The northeastern area is more heavily influenced by the sub-tropical winds from the Gulf. The result is a more humid climate. Proceeding southwesterly, the Gulf's influence diminishes and the region is subjected to the wind currents from interior Mexico and the Southwest. The result is thus an increasingly arid climate in the southwestern portion of the region. These conditions create periodic droughts in the southwestern portion. They do not, however, permit any measurable quantities of snowfall.

Winters are cool with daily mean temperatures ranging from 64°F in the northeast to 70°F in the southwest. Summers are hot. Record temperatures throughout the region exceed 100°F. Temperatures in excess of 100°F occur every summer.

Average wind speeds are approximately 10 miles per hour and are generally southerly or southeasterly. An outstanding characteristic is their steadiness and persistence. The region is continually and consistently ventilated so that no major concentrations of air pollutants (sulfur dioxide, nitrogen dioxides, and particulates) are found within its boundaries. Minor concentrations of particulates do, however, occur at Waco, Tyler, Austin, and San Antonio, Texas.

Like the climate, the region's water characteristics change from northeast to southwest. Runoff is substantial in the northeast (up to 16 inches a year), but is essentially nonexistent in the southwest (down to 1 inch a year). Potential evapotranspiration in the area is highest of all the regions, averaging 42 inches a year over most of the region and exceeding 54 inches a year in the extreme southwest.

Numerous streams, including the Sabine, Brazos, Red, Neches, Trinity, Colorado, and Nueces Rivers, drain the region and empty into the Gulf of Mexico. The combined flow of these rivers and their tributaries is 61.5 million acre-feet per year. Stream sediment levels decrease to the northeast as precipitation and runoff increase. Total dissolved solids range from 270 to over 1,900 milligrams per liter in streams in the western part, and from less than 350 to over 1,200 milligrams per liter in eastern parts of the region. Streams in the area may carry up to several thousand milligrams per liter in areas affected by salt seeps and oil-field activities. Of the total surface water withdrawn, 15.5 million acre-feet are consumptively used each year, primarily for irrigation and industry.

Groundwater is abundant and of good quality. Very high yields, over 1,000 gallons per minute, have been reported from both bedrock and alluvial aquifers. The water generally contains less than 500 milligrams per liter of total dissolved solids, but quality deteriorates with increasing depth. In the southwestern part of the area, some natural groundwaters contain high levels of trace metals and fluoride. Additionally, groundwater quality has been affected in some areas by oil-field activities. Groundwater use in the region is approximately 75,000 acre-feet per year, primarily for public and industrial water supply.

The interplay of these environmental factors contributes to considerable ecological diversity within the region. From northeast to southwest there is a transition in natural vegetation from oak-hickory-pine forest, to oak-hickory forest, to mesquite-oak savannah, and lastly to mesquite-acacia savannah. Of the deciduous forest species, blackjack oak, post oak, and shagbark hickory associations are the more prevalent. Much of the natural vegetation is presently thriving, as approximately 30 percent of the total region is forested.

The primary tree species in the coniferous forests are loblolly pine, shortleaf pine, and

longleaf pine. The vegetation of the region's flood plains differs, however. Cypress, sweetbay, maidencane, cattails, pondweeds, alligator weed, and watermilfoil are dominant plant species in these locations. Mixed shrubs and grasses are the most common types of flora in the mesquite savannahs. In addition to mesquite and acacia, major species include yucca, juniper, little bluestem, gramma, wheatgrass, needlegrass, and buffalograss.

The diverse associations of flora serve as habitats for a variety of wildlife populations. For example, populations of raccoon, fox squirrel, wild turkey, and red-eyed vireo thrive in the forests while populations of bobwhite, ringtail cat, eastern cottontail, and fulvous harvest mouse thrive in the savannahs. Species common throughout the region include armadillo, coyote, peccary, and whitetail deer. Major fish include catfish, minnows, shiners, and various gamefish such as black bass, crappie, spotted bass, and sunfish.

Most of the species that exist in the region have proven to be somewhat compatible with man. Some species, however, are more adaptable to human habitation. They are, therefore, common in areas that border agricultural, natural resource, or community developments. Other species are more sensitive to human activity. Their populations have diminished to the point where they are rare or in danger of extinction. Federally listed endangered species of wildlife include the Houston toad, Mexican duck, whooping crane, peregrine falcon, bald eagle, red wolf, American alligator, and fountain darter. Presently, there is only one species of plant listed as endangered by the U.S. Fish and Wildlife Service. This is Texas wild rice. Numerous other plants are under consideration for designation as endangered. They may eventually be listed as threatened or endangered.

The ecosystems within the Texas Coal Region are not particularly fragile. The forests and savannahs can sustain a degree of disruption and eventually return to a natural state. This is presently being demonstrated in areas where there was earlier widespread clear-cutting of deciduous and coniferous forests. Within decades these lands became reforested through natural successions. Disturbed vegetation may take many years to mature to an oak-hickory climax forest similar to original virgin timber. Nevertheless, immature oak-hickory-pine associations can reoccur naturally within 50 years. Mesquite savannahs can

regenerate even more quickly. Additionally the gently rolling topography is not overly vulnerable to erosion, although localized erosion problems exist, particularly in the southwestern portion of the region. In summary, the ecosystem within the Texas Region could be reclaimed with proper management, should the surface be disturbed by coal mining.

4.4.2 The Environment and Man

The natural resources of the Texas Coal Region have historically attracted man. Prior to the European colonization of North America, the region supported Indian populations from the Caddo, Wichita, Tonkawa, Lipan, and Desert Tribes. Hunting was the main means of survival. Bison, deer, and smaller birds, mammals, and reptiles were primary food sources.

The land was not visited by Europeans until the sixteenth century. In 1542 a Spaniard named Mosoco, who had been a member of de Soto's party, entered the Texas Region from the northeast, proceeded southwesterly to about the center of the region, and then returned by the same route. Mosoco's exploration initiated Spanish colonization of the area.

Over the next three centuries Spanish colonists settled the area and missions and small farms were established. By the nineteenth century, the productivity of the land also proved attractive to the westward expanding states. English speaking people began migrating to the area. Conflicts resulted between the Spaniards from Mexico and the citizens of the United States. War eventually resulted with troops lead by Sam Houston and Santa Anna. The Mexicans were defeated, and the U.S. obtained possession of the land. After 10 years as an independent republic, Texas joined the Union in 1845.

By 1850, the northeastern half of the region had been settled by westward migrating pioneers. The area's flood plains were settled first because of their agricultural productivity and proximity to water. Timber and clay resources were more than adequate to supply all needs for construction materials. By 1890 cities and towns were scattered throughout the region. The region proved especially attractive to ranchers and farmers. The vast grasslands of the southwestern portion could readily support cattle or sheep, and extensive ranches were developed in this area. In the wooded

territory of the northeast, some of the land was cleared for pasture or the cultivation of cash crops. The central ecotone between the grassland and forestland (mesquite-oak savannah) supported both farming and ranching. Environmental conditions permitted the widespread cultivation of cotton in the northeastern central areas. Much of the land still supports cattle and sheep production and the cultivation of cotton and other cash crops. Currently, approximately 70,000 persons, or about 10 percent of the total regional work force are employed in the agricultural sector.

The vast stands of virgin timber in the northeast continue to be highly productive. Extensive lumbering operations began about 1880. The economics of the industry, at that time, required the harvesting of only large diameter trees. Within decades, however, construction material and paper demands grew with the population, and all timber stands became valuable. By 1930, all virgin timber stands had been harvested. Presently, timber demand still is high particularly for pulpwood production in the northeast; however, primarily second and some third generation timber is being harvested.

In addition to timber, numerous other resources were developed for use as twentieth century construction material. Clay for brick manufacturing is plentiful in the area. Ample sand and gravel supplies are available for use as cement for buildings or concrete for highways. Large deposits of iron ore are found throughout the northeastern portion. The ore is a low grade brown ore, but is being actively mined for use as a highway construction material.

Perhaps the most attractive natural resources within the Texas Coal Region are the energy minerals. In addition to lignite, oil and gas are abundant. Texas became the leading State in the country for production of both oil and gas. Much of these resources are produced within the boundaries of the Texas Coal Region. The region is presently producing more oil and gas than it consumes, and contributes significantly to the country's energy demands. The low grade lignite found within the region has not been economically competitive with oil and gas. Until recently, the higher grade bituminous and anthracite coals were of greater economic value to industry. Accordingly, no major development of the region's lignite deposits has occurred to date. Scattered localized

development of lignite, however, is occurring for intraregional industrial use. Industries are, nevertheless, becoming interested in lignite development.

The demand for the region's numerous resources also created a demand for a transportation network with the capacity to accommodate the movement of bulk commodities, as well as people and their necessities. The entire region is crisscrossed by a diversified network of rail main lines and branch lines operated by the Missouri Pacific, Southern Pacific, St. Louis Southwestern, Atchison Topeka and Santa Fe, Louisiana and Arkansas, Texas and Pacific, and Missouri-Kansas-Texas railways. The region's highway network is composed of numerous county, State, and Federal highways, all of which can lead eventually to access to the major Interstate Highways. The pipeline system is composed of oil and gas lines. No coal slurry pipelines are located in the region.

Natural resource development has led to dramatic socioeconomic changes for the region during the twentieth century. Table 4-6 presents pertinent socioeconomic data which provides information on the relative importance of specific sectors of the region's economy. In addition to rural development, community and urban growth has been inspired by resource-dependent industry. Industrial growth has been and still is a dynamic phenomenon in the region. Currently, approximately 150,000 workers, or about 17 percent of the total regional labor force, is in the manufacturing sector. Industrial growth concentrations include Tyler, Longview, Bryan, and San Antonio, Texas, and Shreveport, Louisiana. These cities are absorbing growth in a relatively organized manner.

The resource-oriented economic base of the region has brought prosperity to the Texas Coal Region. Surplus resources are exported, thereby resulting in an influx of revenues. Regional capital, together with an adequate labor pool, has been capable of supporting industrial development. They are available for continued resource development.

Cultural development within the Texas Coal Region provides the area with an interesting history. Indian artifacts can be found throughout the region. Historical sites from the Alamo to Lyndon Baines Johnson's boyhood home are located within its boundaries. Approximately 150 such sites are listed on the National Register of

(a) Demographic information which is based on all counties either totally or partially within regional boundaries.

Historic Places. The Chisholm and Old Cattle Trails, currently proposed for the National System of Trails, are being considered for protection and preservation.

The region's population growth and settlement patterns have been such that no surface land ownership is presently under the Bureau of Land Management's jurisdiction. The major Federal lands in the region are Camp Swift and the Sam Rayburn Reservoir and the Sommerville Reservoir, which are under the jurisdiction of the U.S. Department of Defense and portions of the Sabine, Davy Crockett, Sam Houston, and Angelino National Forests, which are under the jurisdiction of the U.S. Forest Service.

4.5 POWDER RIVER COAL REGION

The Powder River Coal Region is the southwest portion of the Northern Great Plains. The region encompasses about 31,300 square miles in eight Montana and eight Wyoming counties.

4.5.1 The Environment

The region is on a broad plain bordered by the Rocky Mountains on the west, the Black Hills uplift on the east, and the Missouri River on the north. The area is covered primarily with the thin stony deposits characteristic of a semi-arid area, with recent alluvial deposits and terrace gravels in the floodplains. These alluvial deposits of sand and silt with lenses of gravel usually occur in thicknesses up to 15 feet along the major rivers of the area and 10 to 15 feet along the tributaries.

Rocks are mostly sedimentary, and rest nearly horizontal except along the flanks of the Bighorn Mountains where they turn up sharply. The sedimentary rocks consist of several thousand feet of sandstone, shale, limestone, conglomerate, and beds of sub-bituminous coal. Some of these beds were deposited on the floors of ancient seas that extended across the continent; others were deposited in deltas or tidal areas along the margins of the seas or inland in broad basins. Coal formed in tidal swamps and marshes along the marine shores, and also in swamps and lakes on the flood plains of major drainage systems of inland basins which developed after the continents were uplifted and the seas retreated. Coal of commercial interest is contained in the Tongue River member of the Fort Union Formation and the overlying Wasatch Formation.

In general, the coal beds are thickest in the northern parts of the region and across the gently dipping northern and eastern sides of the Powder River basin in Wyoming. A large proportion of this coal lies in near-surface beds that are readily available to surface mining. The region contains approximately 142.5 billion tons of sub-bituminous coal resources.

The thickness of these beds is unsurpassed anywhere in the U.S. The Wyodak seam in the Wyoming portion of the basin is as much as 120 feet thick, and contains 212,400 tons of coal per acre within a few feet of the surface. In the central parts of the region, south of the Yellowstone River in Montana, there are several beds with equally abundant coal in near-surface seams.

In addition to coal, extensive deposits of oil and gas are found in the Wyoming portion of the region and in Montana around the Bull Mountains. Uranium is also found in the Wyoming portion. Underlying the entire Powder River Coal Region south of the Yellowstone is the Madison Group, which is considered the top part of the major aquifer of the basin. This aquifer dips very steeply off the flanks of the Bighorn Mountains to a point about 15,000 feet below the surface. The Madison Group rises gently from this point toward the Yellowstone River and the Black Hills where it outcrops. The Madison Group is about 200 feet thick near the south end of the basin and gradually thickens toward the Yellowstone where it is up to 1,400 feet thick.

The regional climate is continental and semi-arid. Frontal systems from the Pacific regularly cross the area, but have dropped most of their moisture on the western slopes of the Rocky Mountains. About a dozen times a year, winter storms from the north swing through the area, bringing windy and often intensely cold weather with rarely significant moisture. These cold waves are often modified by periods of milder weather created by "chinook" winds. These winds, warm and dry, frequently reach 25-50 mph and may persist for several days. Spring and summer bring some moisture; however, the area is considered dry.

The average annual temperature varies little throughout the area, with most points averaging 45°F. Maximum temperatures occur in July when 100°F temperatures are recorded. The arctic outbreaks in winter bring extreme cold in January

and February, with record lows in many areas of -50°F.

Seventy-five percent of the average annual precipitation of 14 inches falls between April and September. At least half occurs during late spring and early summer, at the start of the growing season. Despite the region's aridity, flooding is common in the spring when rapid snow melt produces heavy runoff.

Perhaps the most important climatic feature in shaping the region is the recurrence of drought cycles. Though this region is characterized as semi-arid, it varies from humid in some years to arid in others and is never predictable.

The region is windy, with average speeds of 12 mph. The prevailing direction is westerly, but directions near terrain features may vary considerably. Surface-based inversions occur on 75-85 percent of the mornings, summer and winter; and on winter afternoons, surface based inversions occur about 35 percent of the time. Stable conditions are prevalent in spite of generally windy conditions, and these circumstances contribute to the high summertime afternoon mixing heights.

Air quality in the region is generally good. Some variations do exist around populated areas and even more so in areas where coal surface mining is presently taking place. In Montana, the particulate air quality is very good except for the Colstrip area in Rosebud County and the Billings area in Yellowstone County. The Colstrip area, where surface mining and electric generation are taking place, is not meeting the primary standard for particulates. The Billings area is not meeting the secondary standard. Particulate air quality in the Wyoming counties is better than the national standards. However, in areas where substantial coal surface mining is taking place (such as Campbell and Converse counties in Wyoming), the air quality in the immediate area of the mine site may not be as good. Sulfur dioxide air quality is better than the national standard throughout the region, with the exception of Billings.

The major streams of the region are the Yellowstone, Big Horn, Powder, Tongue, Belle Fourche, and Musselshell Rivers. Surface reservoirs for regulation of streamflow have a combined capacity of about 2.5 million acre-feet. Surface water runoff is low, about half an inch per year. Potential evapotranspiration over most of the area

is less than 24 inches a year, but in the Yellowstone River lowlands it rises to as much as 36 inches.

Surface water quality is variable. The Powder and Big Horn Rivers commonly carry concentrations of dissolved solids in excess of 1,000 mg/liter. Streams with heavy sediment load are the Powder and the Yellowstone, ranging from a low of about 270 mg/liter to a high 1,900 mg/liter. Over the remainder of the area, the sediment loads are variable and can exceed 1,900 mg/liter.

The occurrence of groundwater in the region is far from uniform. In Montana, there are large areas where shallow wells will yield only 2 to 4 gpm, but wells drilled into the bedrock aquifers, such as the Hell Creek and Fox Hills Formations (Cretaceous) or the Fort Union (Paleocene) may yield more than 50 gpm. Many wells drilled in the Powder River and Yellowstone River Valleys flow under artesian pressure, but lowering of artesian pressures sometimes necessitates pumping. Much of the southern and southeastern region is underlain by several thousand feet of non-productive shales. Groundwater can be produced at a rate of up to several hundred gpm from wells in permeable valley fills along major streams. The greatest development of these alluvial deposits is along the Yellowstone River and its tributaries.

The Madison Limestone Formation underlies the region at considerable depths, and is currently being tested by the U.S. Geological Survey as a potential source of water supply for the coal industry. Recent studies indicate that the water is chemically suitable, but the quantity available for withdrawal is unknown.

Groundwater quality is variable. Generally, at depths greater than 500 feet, all groundwater has more than 1,000 mg/liter of total dissolved solids. The amount of groundwater withdrawn in 1975 for consumptive uses was about 124,000 acre-feet, of which about 34,000 acre-feet was actually consumed. The largest use was for irrigation, and the second largest use for self-supplied industries.

Groundwater in storage is about 1.4 million acre-feet in the near-surface alluvial aquifer material. Estimated reserves from the deep Madison limestone, however, are unknown, although estimates range up to over one billion acre-feet.

Topographically, the region can be divided into three general areas: the Powder River drainage in Wyoming, the Tongue River drainage in Montana, and the area north of the Yellowstone

River. The Wyoming area drained by the Powder River has gently undulating topography with clay and loam soils that have a large amount of sodium in the clays. These soils are dry much of the year and their relative productivity is poor. Exceptions are the locally important and more productive soils associated with flood plains of the Powder River, Little Powder River, and lesser tributaries. These flood plains with alluvial soils are often broadly terraced and have high water tables. Typical flood plain vegetation includes cottonwood, willow, green ash, boxelder, chokecherry, greasewood, salt grass, and western wheatgrass. Wildlife ranging over many miles of the adjacent plains rely on these flood plains for critical resource needs.

The remainder of the Wyoming portion of the region can be generally classed short-grass prairie, grassland-sagebrush, and sagebrush steppe. These vegetation types may seem monotonous and unproductive. They are, however, a complex assemblage of plants that are well adapted to the extremes of weather which occur in the area. Lying dormant during periods of drought, they are capable of quick response to precipitation, producing significant quantities of foliage of high nutrient value. Besides the common grasses and sagebrush, there is an abundance of forbs that increase the species diversity and resilience of the vegetative community, which in turn supports a diverse assemblage of animals.

North of the Wyoming border in the Tongue River basin and the lower reaches of the Powder River there is a change in topography and an associated change in soils, vegetation, and wildlife. The dominant soil in the Tongue River basin is loam with fair to very good productivity. The area is highly dissected by numerous small drainages dominated by two major vegetation types, grassland-sagebrush and ponderosa pine. The ponderosa pine type occurs on uplands, ridges, and north slopes that have shallow loam soils. Prominent species of plants are ponderosa pine, snowberry, bluegrasses, fescues, and June grass.

North of the Yellowstone, the Powder River Coal Region is dominated by soil types not found south of the river. The undulating to hilly land has shallow to moderately deep loamy soils that are nearly always dry and hence have low productivity. These lands are vegetated by the mid-to-short-grass prairie type, characterized by such species as western wheatgrass, needle-and-thread grass, and

blue grama grass. On the northern border of the region along the Missouri River are the "Breaks", highly dissected land forms similar to the Badlands in North and South Dakota.

In general, the region can be considered part of the short-grass prairie. The high annual turnover of net primary production in its grasslands and sagebrush steppe communities provides a food base for a wide variety of mammals. Grazing animals, burrowing mammals, and ground-nesting birds are characteristic of the grasslands. Insect life is abundant, varied, and heavily utilized as food for many secondary consumers. Sagebrush is prominent in the vegetation composition in parts of the grassland, especially in the southern part of the region, and is important to pronghorn antelope and Brewer's sparrows and virtually essential to sage grouse. Large herbivores such as bison and antelope were present in great number during presettlement times. Today, bison have been replaced as the primary grazing animals by domestic livestock as horses, cattle, and sheep often compete with herbivores.

Practices used in livestock production have sometimes disrupted the grassland ecosystem to the detriment of various wildlife species. Examples are predator and rodent control programs and sagebrush eradication in antelope or sage grouse wintering areas. Antelope are still numerous in the grasslands; investigations have shown that they are highly dependent on the brush and forb components of the grassland for survival. Typical smaller mammals include the masked shrew, white-tailed jackrabbit (northwest), black-tailed jackrabbit (southeast), desert cottontail, black-tailed prairie dog, northern pocket gopher, the plains pocket gopher (south), coyote, long-tail weasel, badger, and prairie spotted skunk. Reptiles include the prairie rattlesnake and eastern short-horned lizard. Birds include the ferruginous hawk, sharp-tailed grouse, mountain plover, burrowing owl, horned lark, western meadowlark, lark bunting, savannah sparrow, grasshopper sparrow, vesper sparrow, and McCown's longspur. Drought and severe winter storms occur periodically, and some animal populations can fluctuate widely from year to year.

In the ecotone area between the montane coniferous forest and the grasslands, animal species characteristic of the coniferous forest and of the forest edge will often be found. Some of these animals, such as mule deer and elk, also

occur in extensions or scattered islands of coniferous forest and related subtypes within the grassland. Typical mammals of the coniferous forest and forest edge include the golden-mantled ground squirrel, least chipmunk, red squirrel, bushy-tailed wood rat, boreal redback vole, porcupine, mule deer, elk, and bobcat. Birds include the golden eagle, Clark's nutcracker, mountain chickadee, mountain bluebird, and pygmy nuthatch.

The deciduous forest edge extends into the shortgrass plains along stream drainages. As the interior of the continent grew arid in prehistoric times, many species of deciduous trees together with their associated animals were able to persist along the stream. These tongues of forest greatly extend the forest edge, increasing the number of species that can live in the grasslands. Some species are common to the deciduous forest edge over most of its range, and others are found only in the western portion of this type. Typical mammals in these areas include the fox squirrel, eastern cottontail, whitetail deer, red fox, striped skunk, and raccoon. Reptiles include the blue racer, milk snake, and red-spotted garter snake. Birds include the turkey vulture, sharp-shinned hawk, Cooper's hawk, red-tailed hawk, Swainson's hawk, mourning dove, common nighthawk, red-shafted flicker, violet-green swallow, common crow, black-billed magpie, loggerhead shrike, and Brewer's blackbird.

Aquatic wildlife includes a variety of invertebrates, fishes, birds, mammals, reptiles, and amphibians associated with the stream, lake, and pond-marsh communities. Typical inhabitants of stream riffles and sand-bottom pools are caddisfly larvae, mayfly naiads, stonefly naiads, crayfish, and snails. Characteristic species include the longnose dace, flathead chub, goldeye, river carpsucker, black bullhead, channel catfish, stonewall, plains topminnow, plains killifish, and white sucker. Rainbow and brown trout are found in suitable larger streams. Other stream-associated wildlife include the tiger salamander, plains spadefoot toad, great plains toad, leopard frog, and snapping turtle. Muskrats use burrows in stream banks and feed on streamside vegetation. Beaver feed on the aspen, willow, and cottonwoods along stream courses and in some localities build dams creating pools.

Species characteristic of the few lakes in the region include yellow perch, largemouth bass, black crappie, and carp. In deeper, cooler lakes

rainbow trout are often planted and maintained by man. A number of birds commonly inhabit the lakes and subsist mainly on fish. Common mergansers, California gulls, bald eagles, white pelicans, and osprey are among them. Swallows consume great numbers of emerging midges and other insects.

Wildlife species in this region that are classified as endangered are the black-footed ferret, whooping crane, bald eagle, and American peregrine falcon. Some species, while not endangered throughout their range, have remnant populations in danger of being eliminated in local areas. This has prompted some states to develop "rare and endangered" species lists. Wyoming's list includes such species as the shovelnose sturgeon, sturgeon chub, kit fox, upland plover, and western smooth green snake, all of which occur within this region. There are no plant species currently listed as endangered or threatened; however, some species found in this region currently are being considered for inclusion.

4.5.2 The Environment and Man

The earlier dwellers of the plains are believed to have been the Paleo Indians of the Big-Game Hunting Tradition.

Although not well documented within this region, the Paleo-Indian big game hunting tradition of the pre-8000 B.C. period can be characterized by sites such as Brewster and Hell Gap immediately to the east and southeast of the region. The Hell Gap site in Niobrara County, Wyoming, produced evidence of several occupation levels to approximately 9000 B.C. This region is in the transition area from the Eastern Archaic to the western Desert Culture, occupied in the pre-1000 B.C. period by the Middle Prehistoric cultural complex. The final cultural development produced the Plains Bison Hunter complex that was ancestral to the tribal groups encountered by early European explorers. The most common evidence are the piles of buffalo bones found at the base of small cliffs. The area is rich in archeological resources but remains largely uninvestigated with no major systematic program having been undertaken. Most identified sites were found by accident or were attempts to salvage sites being developed for mining, industrial, or urban uses.

The first non-Indians to enter the region were seeking beaver. Men like Jim Bridger and Will

Sublette came into the land as explorers and trappers and became trail blazers who led pioneers across the great American Desert to the California gold fields and the lush Willamette Valley in Oregon Territory. Most of the early pioneers passed through the region believing that it was unsuitable for their agrarian culture. Settlers headed for California and Oregon passed through during this period. The gold rush to California started in 1849 and persisted until 1870. The Montana gold strike was in 1865 and it attracted more people through the area.

The influence of the non-Indian culture in the plains grew rapidly. The development of the telegraph, railroads, cattle drives, and the passage of the first Homestead Act in 1862 began the process which eliminated the vast buffalo herds. Two tribes, the Crow and Northern Cheyenne, occupied the region beginning in the 17th Century. Both tribes were a mobile society depending on the buffalo for a significant part of their consumptive needs. Both tribes signed the Friendship Treaty of 1825 and the Ft. Laramie Treaty of 1851, both of which were violated by non-Indians. These violations led to conflict. The most famous of this period is the 1876 Battle of the Little Big Horn where General Custer and his troops were killed. Many historic remnants of this period have been preserved. In addition to the Custer Battlefield, there are many U.S. Army Forts still found in the area.

The Northern Cheyenne and Crow were unsuccessful in their attempts to retain the lands granted to them in the earlier treaties and eventually agreed to move onto their present reservations. The Northern Cheyenne Tongue River Reservation, consisting of 371,200 acres, was established in 1884. The name of this reservation has been changed to the Northern Cheyenne Indian reservation and has been expanded by Tribal land purchases to 444,308 acres.

The treaty of Ft. Laramie granted the Crows a hunting reservation of 38,883,174 acres in Montana and Wyoming. In 1868 the Federal Government reduced this to 9 million acres which lie primarily in Big Horn County, Montana. Sales by the Crows and further reductions by the U.S. Government reduced the Crow reservation to 1,569,288 acres.

Stock raising in the Powder River Coal Region became a booming business which grew rapidly

between the civil war and the 1880's. At first it was based on a free open range with the only constraint being the number of head a group could put together and the availability of stock water. The scarcity of water was immediately evident. Development of springs, small retention dams on intermittent streams, and the windmill are still the critical links in the chain that makes the region's grazing lands useful. Conflicts over the use of western water continue to this day even at the national level.

In the early days of ranching most cattle were left on the range year round. Although winter feed was limited, most cattle survived and reproduced in sufficient numbers to maintain a viable economy. Records show that the period from the end of the civil war until the end of the 1880's was a period of unusually high precipitation. The condition of the range and the availability of winter forage were significantly higher than could be normally expected. However, in the late 1880's, particularly the winter of 1886-87, the growing cattle empires suffered devastating losses. Severe cold and high winds killed hundreds of thousands of animals.

Cattlemen partially addressed this problem by insuring a good supply of winter feed. They accomplished this by converting bottomlands to irrigated hay meadows, the mainstay of the industry yet today. Simple one-man stream diversions grew to cooperative efforts between neighbors to large ditch companies that not only built and maintain diversion and delivery facilities but also reservoirs to store the spring runoff for use during the summer and late fall. By the 1890's irrigation systems could be found in most of the areas where their development was practical and economical. The opportunity to develop irrigated haylands was not as available in the southern part of the region. Therefore, many ranchers in this region still depend on the range for winter feed often supplemented by hay purchased from other areas.

The cattle industry of today is essentially the same as it was at the turn of the century. The ranches as they now exist in the area are large. Average size for Campbell and Converse Counties, Wyoming, is over 7,000 acres. Most of these ranches are self-contained, but some ranchers move cattle and sheep from their base ranches to summer ranges on public lands located some

distance away. Most units utilize some state or Federally owned surface rights. Machinery has replaced much of the hand labor; smaller outfits have been absorbed by larger ones; and local owners have in some instances been bought out by corporations. For those people on the land their life is much the same as those of their grandfathers and grandmothers who settled the land. Hay is irrigated and cut and stacked in the summer and fall. Cattle are rounded up in the fall, fed on the home place over winter, and transferred to the range for the summer where they feed and grow on native vegetation.

Many of the settlers who began to enter the region after the turn of the century came to farm. As a result, much of the land in the region has been used to produce dryland crops, particularly wheat. However, the soils and the rainfall are marginal at best and, except for those farms that are irrigated, like those along the Yellowstone River. A cycle of boom and bust has been the rule. During periods of drought, wind erosion starts and tons of soil, developed over thousands of years, are lost in a matter of days.

The last few decades have shown a variability in amount of dryland farming, crop yields, and crop failures. During the 1920's, drought drove many homesteaders off the land. The Federal Government, operating under the National Industrial Recovery Act of 1933, Emergency Relief Act of 1935, and the Bankhead Jones Act of 1937, reacquired many of these eroded lands and replanted them with forage plants. Some of these lands have been included in the Thunder Basin National Grasslands in the southern part of the region.

Many of the above described events are being preserved for posterity's sake by historic designations. Sheridan and Johnson Counties alone, for example, contain more than 65 historic sites eligible for or enrolled in the National Register of Historic Places.

Although ranching and farming are the life style, and constitute the economic activity generally associated with the region, the exploitation of oil, gas, and uranium have made significant economic contributions, particularly in the Wyoming portion of the region. Table 4-7 presents an overview of comparative data for the various sectors of the region's economy.

Oil and/or natural gas have been discovered in more than 200 fields within the Wyoming portion of the region, and active exploration continues. Most of the fields produce from either the Muddy Sandstone of Cretaceous age or the Minnelusa Formation of Pennsylvanian age. The Cloverly Formation of early Cretaceous age is also an important producing horizon and lesser amounts of oil and/or natural gas come from Sundance, Morrison, Mowry, Turner, Niobrara, Shannon, Sussex, Parkman, Ferguson, and Teapot Sandstones.

From the first significant oil discovery at Big Muddy Field in 1916 until January 1, 1973, production has been more than 400 million barrels of oil and about 400 billion cubic feet of gas. The remaining recoverable reserves in the region are conservatively estimated at more than 200 million barrels of oil and more than 500 billion cubic feet of natural gas.

Of the known fields, 66 are actively producing and 44 are classified as temporarily nonproductive. A majority of the nonproductive fields are shut in, waiting for secondary or tertiary recovery procedures or reactivation to be implemented.

The average area used by oil well facilities including pumper, separator, ponds, pipelines, and access roads, does not exceed 15 acres per square mile. Where several wells share land facilities or are developed with spacing, the area required is less than 5 acres per square mile.

Uranium ore occurs in two mining districts in the Wyoming portion of the region: the Pumpkin Buttes district in Campbell, Converse, and Johnson Counties, and the Southern Powder River Basin district in Converse County. Host rocks for uranium ore in the Pumpkin Buttes district are sandstones in the Wasatch Formation. In the Southern Powder River Basin district the ore occurs in sandstone in the upper part of the Fort Union Formation and in the sandstones in the Wasatch Formation.

The uranium industry of Wyoming began in the Pumpkin Buttes district with the discovery of ore-grade uranium in 1951, and the first commercial production began in 1953. Early mining was for high-grade deposits at or near the surface, from pits generally less than 100 feet deep and less than 5 acres in extent. Between the years 1953 and 1967, 36,737 tons of ore containing 208,143 pounds of uranium were mined from 55 mines in Campbell

TABLE 4-7

POPULATION AND ECONOMIC CHARACTERISTICS IN THE
POWDER RIVER REGION (a)

1975 Total Population ^a	228,418

(a) Demographic information which is based on all counties either totally or partially within regional boundaries.

County. By the late 1960's accelerated exploratory activity resulted in discovery of significant ore bodies in the Southern Powder River Basin district.

Uranium is not presently being mined in the Pumpkin Buttes district, but three mines are producing in the Southern Powder River Basin district from open pits. One company has begun development of underground mines.

The Powder River Region is surrounded by recreational resources of unique national significance. The Black Hills, Teton Park, the Bridger Wilderness, the Dakota Badlands, and Yellowstone Park annually attract millions of people. These tourists frequently travel through the Powder River Coal Region and experience its natural resources. Its primary attributes are clean air, open vistas and a kind of solitude not found in many areas. The region is sparsely populated; population density is about 5 people per square mile. Many of these are concentrated in major trade centers like Billings, Sheridan, Gillette and Casper. The low population levels enhance the quality of the recreational activities of camping, fishing, and hunting. Many farmers and ranchers become guides and this kind of part-time tourist industry has had small but important economic benefits to ranchers. The major economic benefits, however, accrue to the motel and restaurant operators who provide services to the tourists as they pass through the region to the parks and forests on the edges of region.

The lifestyle of the area is clearly western; cowboy boots, pick-up trucks, and big hats are the practical symbols of this lifestyle. As the rest of the nation is characterized by the mobility of the people, this area's common attribute is the stability of large segments of the population. A ranch, drug store, or farm equipment dealership may have been operated by the same family for several generations.

Overall population growth has been very slow during the last several decades. There have been local booms in towns like Gillette and Sheridan and some counties have experienced population losses, but overall the population can be considered stable. The influx of oil and gas developers has disrupted this stability in certain local areas, such as Gillette in the late 1960's and early 1970's, but the net regional effect has been relatively minor.

In recent years, coal and uranium developments have begun to accelerate. These types of development activities are much more extensive. They require more people, more land, and more water. New mines have opened around Gillette and increased its population. In addition to coal mining, coal conversion plants are being built, like those at Colstrip, Montana. With this kind of population influx the stability of the old structure is being radically changed.

Control of the political and economic system is shifting from the rural citizens to the new urban population. Many new private and public facilities are being constructed, increasing the opportunities and services available, but for the established residents of the area they are different and they are controlled by a new establishment. Regional development has occurred in such a manner that most of the land is in Federal ownership, with the Bureau of Land Management and the U.S. Forest Service being the primary administering agencies. Within Federal land areas, some state and private lands occur. Of particular interest are the tracts of alternating private and Federal lands (interspersed with some state-owned sections), which create a checkerboard pattern of land ownership. These are scattered in various locations throughout the region.

4.6 GREEN RIVER - HAMS FORK COAL REGION

The Green River - Hams Fork Coal Region is in the Middle Rocky Mountain Province of the western United States. This region encompasses approximately 37,500 square miles in five Colorado, 12 Wyoming, five Idaho and three Utah counties.

4.6.1 The Environment

The Green River-Hams Fork Coal Region is part of the Middle Rocky Mountain province, characterized by complex mountains with many inter-mountain basins and plains. The area is a series of parallel mountain ranges and valleys. Local relief may be as much as 2,000 feet, but is more commonly less than 1,000 feet.

The Green River subregion encompasses an area of about 17,000 square miles in southwestern Wyoming and northern Colorado, and includes several separate structural units. The Green River basin occupies the western section, separated from

the Great Divide basin to the east by the large Rock Springs anticline. Coal-bearing rocks here are the Mesaverde group, including the Rock Springs and the Lance Formations; the Fort Union Formation; and the Wasatch Formation. In the Colorado portion of the field, the Iles and Williams Fork Formations contain the Mesaverde Group coal beds. The coal-bearing section of rocks is several thousand feet thick and is composed mainly of sandstone with beds of siltstone, shale, and coal.

Coal beds range in thickness from a few inches to 42 feet and rank from sub-bituminous C to high-volatile bituminous C, with coals of higher rank occurring locally in areas of igneous intrusives and intense structural deformation. In past years, the high quality coals of the Mesaverde Group have been the most extensively mined and the most important in the area. Coal beds in most parts of the region are deeply buried and may never be of economic potential.

A total of 130 coal beds has been mapped in the coal-bearing Mesaverde and Medicine Bow Formations, the Ferris Formation, and the Hanna Formation. The beds are sub-bituminous C to high-volatile bituminous C in rank. They range in thicknesses from 8 feet in discontinuous beds in the lower formations to 35 feet in the Hanna Formation. The Hanna Basin area is characterized by rugged surface features. The Rock Creek coal field adjoins the Hanna Basin field on the southeast and contains coal beds ranging in thicknesses of 9.5 feet in the Hanna Formation and 8 feet in the Mesaverde Formation. Large areas of the surface are covered with gravel, and the coal-bearing rocks are difficult to trace.

The Hams-Fork portion of the region is in the extreme western part of Wyoming and includes small parts of Utah. The coal-bearing rocks crop out in long narrow belts extending from the mountainous region in the north to the less rugged southern region near the Utah-Wyoming border. The area lies in the highly complex Wyoming overthrust belt, an area of current interest for its high potential for oil and gas development. The coal-bearing formations exposed in the region are the Bear River Frontier, Adaville, and the Evanston. The Frontier Formation, the main coal-bearing unit, forms north-trending outcrop bands generally less than two miles in length.

The coal beds in the Hams Fork portion range in rank from high volatile bituminous A in the Frontier coals to sub-bituminous B in the Adaville Formation. Thicknesses greater than 100 feet are reported for coal beds in the Adaville Formation. The higher quality Frontier coals attain thicknesses as great as 20 feet. The steep dips make mining difficult in most parts of the region. The total coal reserve base is estimated to be 15.5 billion tons.

Coal is presently produced in several counties in this region, but is the leading mineral commodity in only three of these counties. Other important commodities include oil, gas, phosphate rock, stone, cement, vanadium, and trona (sodium carbonate). Sweetwater County, Wyoming, is the nation's principal source of trona. In addition, the area is endowed with paleontological and archaeological remains.

Of major geological interest in the region are the Como Bluff Fossil Area and the Petrified Fish Cut, areas of dinosaur and fish fossils, respectively. The Como Bluff Fossil Area is located in the northeastern section of the region, on the boundary line between Carbon and Albany Counties, Wyoming. This designated natural landmark is the site of the famous "Dinosaur Graveyard", where paleontological excavations since the 1870's have uncovered a great number of dinosaurs of various types. In the Kemmerer area of Lincoln County, Wyoming, the famous Petrified Fish Cut was discovered when the Union Pacific Railroad cut through the shale hills west of Green River in the late 1860's. Middle Eocene fish fossils from this area are in museum collections throughout the world. Principal fossiliferous formations in the region which contain paleontological resources are the North Park, Bridges, Green River, Hanna, Ferris, Fort Chriion, Lance, Lewis, Almond, Rock Springs, and Morrison.

The region has a primarily continental climate. Fronts generally originate in the Pacific and deposit moisture in the mountains as wind currents pass over increased elevations. Average annual precipitation is more evenly distributed in the mountains than in the basin areas. General flooding potential is low, although flash floods do result from intense summer thunderstorms. Evaporation potential far exceeds the total precipitation usually received.

The average annual temperatures range from 37°F to 46°F, with variations due mostly to differences in elevation and exposure. Growing seasons range from 28 days at Steamboat Springs, Colorado, to 130 days at Rawlins, Wyoming.

Pervading winds for most of the area are generally out of the southwest. Most of the harsh winter storms are out of the northwest. The wind patterns are typically funneled through some of the mountain passes and canyons. The winter winds out of the north typically bring cold dry air with velocities sometimes exceeding 40 mph. Wind directions change regularly, and tend to be less persistent in any one direction than in many other portions of the U.S. The region has surface-based inversions on 85 percent of the mornings, during both summer and winter. They tend to be intense, but not particularly deep.

Overall regional air quality is very good. Areas not meeting the national standard for particulates are Craig, Colorado and the trona industrial area of Sweetwater County, Wyoming. The entire region is better than the standard for sulfur dioxide air quality.

Major drainage basins in the region are the Green and Yampa Rivers. Average annual runoff varies from less than 1 inch to over 30 inches in some of the high mountains. Many of the large streams in the area are perennial, obtaining most of their runoff from the higher mountainous areas; however, most of the tributaries originating in the lower area are intermittent. The region is vulnerable to droughts.

The quality of surface waters in the region ranges from good in the higher elevations to poor in the lower elevations. During low-flow periods many tributary streams have over 1,000 milligrams per liter of dissolved solids. The suspended-sediment content of surface waters is generally high, and during high flows exceeds 30,000 parts per million in many tributaries.

The average annual stream flow in the Green River Basin is 5.26 million acre-feet. Fontenelle and Flaming Gorge reservoirs are the largest in the region, storing about 4.3 million acre-feet. Such stored water is used to satisfy current water rights. About 2.5 million acre-feet of surface water is withdrawn per year, of which about 1.1 million acre-feet is consumptively used, primarily for irrigation.

Groundwater is found in the aquifers of alluvial deposits and bedrock strata. Alluvial deposits are good aquifers and are capable of yielding moderate amounts of groundwater. Pumping from alluvial aquifers is restricted in some States because of effects on appropriated water rights or nearby stream flow. Water in the alluvium aquifers has generally acceptable quality for most uses, but in some areas is highly mineralized.

Yields of most sandstone aquifers are low to moderate, while the highly variable limestone aquifers may yield up to 1,000 gallons per minute in wells. In general, where the aquifers are highly permeable, good quality water is obtained to depths of 1,000 feet or more. However, where the aquifers have low permeability, highly mineralized water is obtained even at shallow depths. Water quality throughout the region has not been fully explored.

The most common soils throughout this region have a sandy loam, loam, or silty surface and a calcium carbonate accumulation at depths usually greater than four feet. Permeability is moderate to low and, due to climate conditions, these soils seldom retain moisture for three consecutive months. Shallow, poorly developed soils consisting mainly of rock fragments occur along the mountains of the region. Dominant soil limitations of the region are shallowness, erosion, stoniness, and salinity.

The Green River-Hams Fork Coal Region is part of the cold desert biome, and is comprised primarily of sagebrush or saltbush-greasewood dominated communities. Other communities of local importance include mountain shrub, evergreen, and broadleaf forest, and barren areas. Approximately 24 percent of the total regional land area is forest.

The sagebrush community is composed of a mixture of low-growing shrubs dominated by sagebrush with a variable understory of perennial grasses and forbs. Understory vegetation includes bluebunch wheatgrass, thick wheatgrass, Indian ricegrass, prairie junegrass, cheatgrass, brome, lupines, rabbitbrushes, broom snakeweed, and goldenweeds.

Where the salt content of the soil is relatively high, sagebrush dominated communities are replaced by saltbush-greasewood associations. Dominant species are Nuttal saltbush, shadscale salt-

bush, fourwing saltbush, and black greasewood. Associated understory includes Alkali sacaton, bottlebrush, squirreltail, and thickspike wheatgrass, in addition to many of the same understory species of the sagebrush community.

Shrub communities of the higher elevation are dominated by serviceberry-snowberry-mahogany associations with understories that include thickspike wheatgrass, prairie junegrass, bluegrasses, western yarrow, asters, and milkvetch. On well drained, poorly developed, shallow, gravelly soils, shrub woodlands, dominated by rocky mountain and Utah juniper, predominate. Associated species include big sagebrush, low sagebrush, rabbitbrushes, mountain mahogany, prickly pear, and a variety of grasses, phloxes, and goldenweeds.

Depending upon slope, aspect, and elevation, forested mountain areas may contain associations of pinyon-juniper, spruce-Douglas fir, ponderosa pine-lodgepole, or a mixture of evergreen-aspen. Understory species include snowberries, blueberries, mountain mahogany, pine readgrass, lupines, mountain brome, and various grasses. Broadleaf forest, consisting principally of willow and cottonwood with grass understories, are limited primarily to floodplains along perennial streams. Barren areas associated with rock outcrops have a limited vegetation cover provided by mountain mahogany, serviceberry, wild buckwheats, big sagebrush, saltbushes, and prairie junegrasses.

Primary productivity estimates for the major vegetative communities of the region range from about 1.8 tons per acre per year for sagebrush to approximately 5.4 tons per year for forested areas.

The region has 53 species of mammals including big game such as elk, mule deer, pronghorn antelope, moose, and Rocky Mountain bighorn sheep; and small game and non-game species such as whitetail jackrabbit, red squirrel, white-tailed prairie dog, longtail weasel, badger, coyote, and red fox. Twenty percent of the world's pronghorn antelope population and a major portion of the world's sage grouse population may be found within the sagebrush-grassland areas of this region. These areas also provide critical winter habitat for elk and mule deer, particularly in the northern section of the region. In addition to these mammals, the sagebrush biome is a winter concentration area for golden and bald eagles.

Species found in the conifer-aspen forest include the Canada lynx, snowshoe rabbit, red

squirrel, porcupine, and the great horned owl. The Shiras moose occurs in the conifer-aspen forest and along the willow-dominated river bottoms. Rocky Mountain bighorn sheep prefer higher elevations where the coniferous forests are broken by alpine openings.

In the woodland-bushland communities, mule deer, mountain lion, and coyote commonly occur in the woodlands during the fall, winter, and spring and range into adjacent habitats during summer. Rocky hillsides and cliffs within the woodland-bushland community provide habitat for the bobcat, rock squirrel, cliff chipmunk, desert and bushytailed woodrats, and pinyon mouse. Common birds of the woodland area include pinyon and scrub jay and bandtailed pigeon. Rattlesnakes, lizards, and horned toads may invade from adjacent desert areas, but are not particularly characteristic of woodland communities.

A number of game and non-game fish species are typical of the region's waterways. Principal game fish native to the region include mountain whitefish and cutthroat trout. Fish introduced into some lakes of the region include largemouth bass, smallmouth bass, and crappie. Non-game species found in the region include speckled dace, mountain sucker, Utah chub, redbanded shiner, and longnose dace. Pond-marsh biotic communities are limited in extent, but have local significance. The most widespread type of aquatic or semi-aquatic situation is provided by beaver ponds which are numerous on small mountain streams throughout the region. Also found in the pond marsh communities are mallards, pintails, teal, Barrow's golden eye, Great Basin Canada goose, marsh hawk, bald eagle, and osprey.

In the region one species of fish (the Kendall Warm Springs dace), three species of birds (the peregrine falcon, bald eagle, and whooping crane), and two species of mammals (the black-footed ferret and Rocky Mountain wolf) are presently officially listed as endangered species. There are no endangered plants listed for the region, although 18 species are proposed for such listing.

Wild horses are found in several parts of the region. Herds of approximately 4,500 are estimated to exist in Wyoming and in northwestern Colorado, and are estimated to increase between 15 percent and 30 percent annually.

The potential for reclamation of disturbed areas varies considerably within the region. By

using the best available technology for reclamation, many of the limitations of soil and precipitation can probably be overcome. Each specific location for disturbance will require separate evaluation.

4.6.2 The Environment and Man

The earliest cultural traditions of this region were divided between big-game hunting in the eastern half of the region and gathering and hunting activities of the desert. During later periods, the entire region was under the influence of the Desert Culture, which persisted with little basic change up to the end of the historic period. The Desert Culture was predominated by hunter-gatherers who inhabited caves from about 9,000 B.C. to 4,000 B.C.

Astorians returning to St. Louis passed through the northern part of this region in 1812, but it was not until the mid-1820's that this area was extensively traveled. This was the era of the American fur traders, the mountain men who opened up the area of the central Rockies. Jedediah Smith in 1824 rediscovered the South Pass through the Rockies which was later used by thousands of immigrants heading for Oregon and California. By 1835, the Oregon Trail was well established and the reconnaissance work of Fremont and other Army explorers helped to map the land west of South Pass. The Union Pacific Railroad was built across southern Wyoming in 1868-1869. By 1890, one-fourth of the area was settled, and the Pony Express, the Overland Stage, and the railroad had established routes through the area.

There are approximately 50 listings from this region in the National Register of Historic Places, including stage line stations, Army forts, Oregon Trail sites, and a variety of buildings and historic districts.

Today, the region is still typically western with a low population covering vast areas of public lands and large ranches. The primary source of employment in the region is wholesale and retail trade. The construction industry accounts for five percent of the employment. Agricultural employment in the region is 10 percent, and mining and mineral industry in the region is 12 percent of the employment. The Government employs 23 percent of the workforce. Table 4-8 shows a breakdown by

each economic sector for employment and earnings.

While agriculture is not large in terms of the number of people employed or the total income, it is the most visible activity throughout the region. The agricultural economy has developed in the area since the 1800's and continues to play a major role. To some extent, farming and, to a large extent, grazing of domestic livestock persist throughout the region. Farming is limited by rainfall and temperature. Cattle and sheep ranching are the leading agricultural activities.

This region has an array of recreational resources. Parts of Rocky Mountain National Park, the Mt. Zirkel and Rawah Wilderness areas, and the Denver and Rio Preservation Areas within Routt and Roosevelt National Forests, are located within the region. Five National Wildlife Refuges (National Elk Refuge, Seedskadee, Pamforth, Hutton Lake, and Arapahoe) with a combined area of approximately 37,600 acres, are also located here. The Fossil Butte National Monument in Wyoming is in the area. The Mormon, Oregon, and Continental Divide Trails are under consideration for the National System of Trails. Three state recreational areas, three state parks, and twelve state historical sites are in the region. These facilities have a total area of over 76,200 acres and have an annual attendance of more than 693,000. Camping, fishing, and hunting are the most popular recreational activities.

Counties in the region are characterized by sparse population with densities of about 2.6 persons per square mile. The total population is approximately 126,900. The decade of the 1960's recorded high rates of out-migration ranging from 8 to 34 percent. This trend reversed, however, between 1970 and 1976 when over 33,000 persons in-migrated. Population and general economic data are shown on Table 4-8.

Major transportation in the Colorado section of the region is provided by the east-west Denver and Rio Grande Western railroad. The southern Wyoming region is served by Interstate 80 and by the Union Pacific railroad. There are many other paved highways and unpaved roads existing throughout the region which provide access into the major areas of economic development.

Adequate housing is in short supply, especially in the larger communities such as Craig, Colorado, and Rock Springs, Green River, and Rawlins,

TOTAL	48,757		516,753	

(a) Demographic information which is based on all counties either totally or partially within regional boundaries.

Wyoming. Many smaller communities within the region such as Meeker, Colorado, are experiencing housing problems. The number of mobile homes and mobile home parks has increased in many communities. Increased population in many communities has also produced increased school enrollments, resulting in overcrowded classrooms in understaffed schools.

Health care facilities are generally adequate for the region, although some areas are experiencing a shortage of physicians. Mental health care facilities, where they exist within the region, are receiving a disproportionate number of cases from energy related rapid growth. Fire protection service is generally provided by the volunteer departments, and only Rawlins, Sinclair, Rock Springs, Green River, and Evanston, Wyoming, have fire insurance ratings which are considered adequate. Expansion of water and sewer systems are of highest priority for most local officials. Nearly all water systems are publicly owned. Telephone, electricity, and natural gas systems are generally adequate for the region, with some exceptions where local shortages may occur.

Prior to the current industrial development of both coal and trona, the region's lifestyle was primarily ranching with very little industrial development. In the last six years, rapid development of coal and trona, and expanding oil and gas exploration have brought about higher prices, more crime, housing shortages, and other boomtown characteristics which have altered and are continuing to alter this rural lifestyle.

Most of the land is Federally owned and administered by the Bureau of Land Management and the U.S. Forest Service. Within the Federal land area, some state and private lands occur. Of significant interest in the southern portion of Wyoming is the checkerboard pattern of alternating private and Federal lands interspersed with some state-owned sections.

4.7 FORT UNION COAL REGION

The Fort Union Coal Region is in the Northern Great Plains of the western United States. This region encompasses about 60,214 square miles in 12 Montana, 26 North Dakota, and seven South Dakota counties.

4.7.1 The Environment

The sedimentary rocks of the Fort Union Coal Region were deposited in the Williston basin, a sedimentary and structural depression that lies in western North Dakota and extends into Canada, Montana, and South Dakota. The combined thickness of the sedimentary rocks exceeds 15,000 feet in the deepest part of the basin southeast of the city of Williston, North Dakota. The surface formations generally dip toward the basin's center at rates of 10 to 20 feet per mile, but dips may decrease to about one degree near large structures, such as the Nesson anticline. Local departures from the regional dip, especially in the coal beds, may be the result of differential compaction of the underlying sediments rather than a deep-seated earth movement.

Most of the coal is contained in the Lebo, Tongue River, and Sentinel Butte (in North Dakota), members of the Fort Union Formation of Paleocene age. The coal beds are discontinuous and vary greatly in thickness. More than a hundred coal beds have been identified by the North Dakota State Geological Survey, but in any one section no more than three beds of commercial thickness have been found. The Fort Union Formation ranges from 425 to 775 feet thick in South Dakota to 1,500 feet thick in Montana and contains an estimated 440 billion tons of lignite. The coal throughout most of the Fort Union region is lignite in rank; however, westward from the Montana-North Dakota state line, the rank of the coal increases to subbituminous C near Miles City, Montana and subbituminous B further to the west. Estimated subbituminous reserves in the aforementioned areas total approximately 23 billion tons of surface-mineable coal.

The Fort Union Coal Region is within the glaciated and the unglaciated Missouri Plateau sections of the Great Plains Physiographic Province, except for a small area at the northeastern boundary which is part of the Central Lowland Province. The Missouri Escarpment which is the eastern boundary of the Great Plains Province is a northeastward facing escarpment, commonly 200 to 300 feet high. It extends from the northeast corner of North Dakota diagonally to near the center of the south boundary and beyond into South Dakota.

The Drift Prairie section of the Central Lowland east of the escarpment includes a large

part of eastern North Dakota. Glacial deposits, such as ground moraine and outwash plains, are characteristic of the gently undulating land surface. They may be as much as 200 feet thick, but generally, the relief is 20 feet or less. In the part of the area north and east of the Missouri River, channels cut into the glacial drift by meltwater from the ice are common. They are generally 20 to 50 feet deep, and range in width from 100 feet to as much as one-half mile. Most are partly filled by glacial outwash and alluvial material. Some coincide with deep preglacial valleys.

Southwest of the Missouri River, glacial deposits are thin or absent, natural ponds are absent, and the boundary of the Glaciated Missouri Plateau is poorly defined. The maximum extent of glaciers is marked by the locations of glacial erratics. The major streams and their tributaries are in preglacial or interglacial valleys. The general character of the terrain is similar to that of the unglaciated region to the south.

The unglaciated Missouri Plateau in southwest North Dakota, northwest South Dakota, and eastern Montana, is a gently sloping plateau. The present surface consists of rolling prairie, isolated buttes and mesas, and badlands. It has been mostly carved since the ice age by intermittent erosion of the nearly flat-lying easily-eroded rocks at the surface.

Clinker, formed when heat from the natural burning of coal baked the overlying rocks, has been a factor in the formation and development of badland topography. The level of the surface above the burned coal bed is lowered by a number of feet equal to the thickness of the burned coal bed. The clinker strongly resists weathering and erosion, and it forms a cap-rock that adds to the irregularity and roughness of the land surface.

Badlands are found along the Little Missouri River, along the lower reaches of the Powder River, and the area surrounding Fort Peck Reservoir on the Missouri River.

The Fort Union Coal Region has a semi-arid continental climate. Winters are long and cold; summers are short and warm. Considerable frontal activity passes through the area, but being distant from major sources of moisture, precipitation is not plentiful. A dozen to 15 times a year, arctic air breaks into the region, causing severe winter cold. The extreme cold is often moderated in the western and southern portions of the area by chinook

winds that develop on the eastern slopes of the Rocky Mountains.

The mean annual temperature varies from 38°F in some locations in the northeast part of the region to 45°F in the southeast portion. This area is subject to the dominant path of arctic generated storms crossing the Canadian-U.S. border, as well as the chinook winds that moderate the cold temperatures in the western portion of the region.

Annual precipitation varies from slightly less than 12 inches in northeastern Montana to 16 inches in the eastern portion of the region. A few points near prominent terrain features cause slight aberrations in the otherwise smooth increase in average precipitation from west to east. Most precipitation occurs in the growing season, occurring as showers or thunderstorms. Rainfall, therefore, tends to be spotty and local flooding may occur not far from places that are enduring drought.

Floods along the main stem of the Missouri River are generally caused by spring snow-melt and are aggravated by ice jams. Major rainstorms sufficient to cause widespread flooding are rare. Drought effects usually appear in this semi-arid region soon after the precipitation drops much below the long-term mean. The windy, sunny conditions that prevail in the area cause evaporation to exceed normal precipitation by a factor of two or more.

The region is windy; average speeds for the year are 10 mph. The prevailing direction is northwest, but southerly winds are common during warm months.

Surface-based inversions occur on about 65 percent of winter mornings and 80 percent of summer mornings. Forty to 50 percent are accompanied by winds of 5 mph or more. On summer afternoons, surface-based inversions are rare; on winter afternoons, they occur 25-30 percent of the time. Morning mixing depths tend to be lowest in summer in the eastern part of the region and in the winter in the western part.

The Fort Union Coal Region's air quality is very good for both particulates and sulfur dioxide. This holds true for all portions of the region.

Surface water resources are very limited in the Fort Union Coal Region except for those areas adjacent to the Missouri and Yellowstone Rivers. The Little Missouri River, which runs north through the middle of the region to the Missouri,

and all of the tributaries to the Missouri downstream from that point have highly variable flows.

Surface water runoff is very low (less than one inch over most of the area) and quality is poor. Total dissolved solids exceed 350 million parts per liter nearly everywhere. Hardness levels are mostly within the 180-240 mg/l range. These tributaries generally carry a sediment load in excess of 1,900 mg/l. Sediment loads have been greatly reduced in the Missouri River since it has been extensively dammed, with each reservoir acting as a sediment trap.

Groundwater is available in small to moderate quantities almost everywhere, but only in large amounts locally, particularly in the alluvial valley fills along the perennial streams. The greatest potential for groundwater development in the region is from glacial outwash sands and gravels and valley alluvium, particularly along the Missouri River and, in lesser amounts, along the Yellowstone River. Groundwater may also be developed in dependable supplies from the Fort Union Formation and the deeper Fox Hills and Hills Creek Formations. Most of these deeper groundwaters are moderately mineralized at depths of less than 500 feet.

Soils in the northeastern half of the region have been derived from glaciated materials. These soils are generally loamy soils with good productivity and stability. The area northeast of the Missouri escarpment is rolling mid-tall grass prairie characterized by wheat grass, big and little bluestem grasses, and needle grass. The remainder of the region is dominated by the mid grass and mid-short grass prairie type, except for the floodplains along the major streams and the badlands on the Little Missouri, Lower Powder, and around Fort Peck Reservoir.

The mid-grass prairie which covers the mid-section of the region is characterized by loamy to clayey loamy soils from east to west. Dominant plants are needle grass, wheat grass, and blue stem grasses. No short grasses are dominant. The mid-short grass type is found in the extreme western portion of the region north of the Yellowstone River. These rolling prairies have loam to clay loam soils and are dominated by western wheat grass, needle-and-thread grass, and blue grama grass.

Badlands are characterized by breaks along rivers and streams with steep south-facing slopes of

exposed shales, sandstones, scoria, and clays. Soils are dry much of the year. Dominant plant species are arid-land shrubs and grasses associated locally with scrubby ponderosa pine forests.

The floodplains have alluvial soils with high water tables. Vegetation is predominantly hard-wood trees and shrub species.

With proper soil and vegetative management, most lands can be reclaimed to a near-original state following surface mining. It should be noted, however, that much of the prime farmlands, alluvial valley floors, and natural areas would require a high degree of attention during reclamation.

Wildlife occurring in the Fort Union Coal Region is similar in composition to that of the Powder River Region. The various habitats support 87 species of birds, approximately 70 species of mammals, 200 species of fish, and 20 species of amphibian and reptiles, as well as numerous insects and other invertebrates.

Principal big game animals include mule deer, whitetail deer, and pronghorn antelope. While ranges may occasionally overlap, each is associated with a preferred habitat. Primary mule deer habitat is provided by the rough breaks and badlands where browse species, such as buckbrush, skunkbrush, yucca, chokecherry, and mixed grasses occur. Whitetail deer, while widespread throughout the region, prefer river bottoms and other areas where dense vegetation provides adequate cover. Preferred food items include buckbrush, chokecherry, rose, cottonwood, willow, aspen, and green ash. Prime pronghorn antelope range occurs on the rolling or broken grasslands interspersed with large sagebrush flats. Where available, big sagebrush and silver sagebrush provide critical winter browse.

Principal small game animals within the region include eastern cottontail, desert cottontail, snowshoe hare, gray squirrel, and fox squirrel.

The eastern cottontail is widely dispersed through the area, while the desert cottontail prefers shrubland habitat. Snowshoe hare, fox and gray squirrels are typically associated with woodlands.

Furbearers and other small mammals associated with this region include typical grassland species such as Richardson ground squirrel, thirteen-lined ground squirrel, blacktailed prairie dog, western harvest mouse, deer mouse, meadow vole, prairie vole, and blackfooted ferret; woodlands

and shrubland species, such as gray fox, raccoon, badger, skunk, bobcat, opossum, least chipmunk, wood rat, and southern red backed vole; and wetland and semi-aquatic species, such as beaver, mink, and muskrat.

Gamebirds of the region include sharp-tailed grouse, ring-necked pheasant, Hungarian partridge, and wild turkey. Both sharp-tailed grouse and the introduced pheasant prefer large expanses of undisturbed native grasslands interspersed with brush for food, cover, and nesting. The Hungarian partridge is widely dispersed but prefers areas of limited agriculture where shelterbelts are available for cover. Wild turkey are more limited in distribution and tend to be associated with river bottom woodlands, or around ranches and farms where they have become accustomed to human activity.

Wetlands, occurring primarily as scattered potholes along the Missouri River and other drainages within the region, are of primary value as nesting and feeding habitat for waterfowl of the Central Flyway. Breeding species include mallards, green-winged and blue-winged teal, pintail, red-head, canvasback, gadwall, American widgeon, shoveler, and wood duck. Shorebirds and other non-game birds associated with these wet areas include cranes, grebes, sandpipers, terns, and gulls.

The large areas of open terrain found throughout much of this region provide both seasonal and year round habitat for a variety of predator birds. These include golden and bald eagles, osprey, marsh hawk, sharp-shinned hawk, rough-legged hawk, Swainson's hawk, Cooper's hawk, red-tailed hawk, prairie and peregrine falcon, barn owl, long-eared and short-eared owl, burrowing owl, and great horned owl.

Open areas, woodlands, and edges are utilized by a wide variety of song birds, warblers, and woodpeckers. At least 145 species of non-game birds occur within the region, including black-billed cuckoo, belted kingfisher, red-headed and red-bellied woodpeckers, catbird, robin, eastern and mountain bluebirds, yellow warbler, tree and chipping sparrows, cowbird, and cardinal. Principal species of game fish stocked in reservoirs and lakes include walleye, sanger, northern pike, white bass, yellow perch, largemouth bass, channel catfish, and black bullheads. Non-game species common to most streams and rivers include a variety of minnows, shiners, and suckers.

There are at least seven species of endangered animals that occur or have been reported in the region. These include the northern kit fox, peregrine falcon, black-footed ferret, whooping crane, bald eagle, and Tule white-fronted goose. Presently there are no endangered or threatened plants in the region, although a number are proposed for inclusion in the Federal list. They may eventually be given protection under the Endangered Species Act of 1973.

4.7.2 The Environment and Man

The Fort Union Coal Region has experienced many changes in climate since the Paleo-Indian crossed a land or ice bridge from Asia to the Western Hemisphere. There is evidence that the region has a prehistory much like the Powder River Coal Region. The distinctive culture of the Fort Union Coal Region was agriculturally oriented along both sides of the Missouri River in North Dakota. The region's history is marked with Indian-settler interactions both peaceful and non-peaceful. Evidence of these events still remain such as Fort Union Trading Post and Fort Dilts.

The historical development of the region left most of the land in Federal ownership, with the Bureau of Land Management and the U.S. Forest Service being the primary administering agencies. Within Federal land areas, some state and private lands occur. Of particular interest are the scattered tracts of alternating private and Federal lands (interspersed with some state-owned sections), which create a checkerboard pattern of land ownership.

Agriculture in this region consists primarily of spring wheat farming in the northern and eastern portions, and cattle ranching with some irrigated crop production in the southern and western portions. Farms tend to be large, averaging over 1,000 acres in commercial wheat growing areas in the region.

Cropland constitutes over 75 percent of the total land area along the northeastern border of the region decreasing to under 5 percent in the southern portion (Montana and South Dakota). Irrigated cropland represents less than 1 percent of the farmland over most of the region, with some counties in Montana and North Dakota having from 1 to 4 percent of cropland irrigated.

Principal agricultural crops grown within the region include soybean, hay, wheat, oats, barley,

flaxseed, and sugarbeets. Yields per acre for these crops are 17.3 bushels for soybeans, 1.4 tons for hay, 24.6 bushels for wheat, 42.1 bushels for oats, and 19.3 tons for sugarbeets. Cash-grain farms, along with livestock farms and general farms, are found in the northern and eastern portions of the region, while livestock operations predominate in the other areas of the region.

Table 4-9 shows the employment and earnings for the Fort Union Coal Region. Federal, state, and local governments employ 28 percent of the population. This is significantly higher than the national average which is 17 percent. Federal employment is 3 times greater than the national average. Agricultural employment is the second strongest sector, employing 25 percent of the population. This is five times the national average. This statistic emphasizes the dependence of the region's people on the biological productivity of the region.

The region's transportation network is composed primarily of railroads and highways. The Burlington Northern is the primary rail carrier of the region, although the Soo Line and Chicago, Milwaukee, St. Paul, and Pacific also provide a degree of service. The area's access to the interstate highway network is provided by I-94. A variety of U.S., state, and county roads connect with I-94. There are no coal slurry pipelines in this region.

The infrastructure of the region is similar to most of the rural West. Businesses that supply the needs of farmers and ranchers are located in trade centers across the region. These trade centers are small and, along with the rural population, are relatively stable. Public services in these towns are limited and not usually amenable to significant expansion. Medical facilities are limited and those in need of special care usually travel to Denver, Colorado, or Rochester, Minnesota. Bismarck, North Dakota is the exception to the rule. It is a growing urban center that is developing many of the social and cultural services not found in the smaller towns of the region.

Due to the rural nature of the region most of the recreation is outdoor oriented. Fishing, hunting, and site-seeing are common activities. Hunting also draws people from outside the region.

4.8 SAN JUAN RIVER COAL REGION

The San Juan River Coal Region is in the Colorado Plateau of the southwestern United

States. The region encompasses approximately 57,000 square miles in one Utah, seven Colorado, and 11 New Mexico counties.

4.8.1 The Environment

This region is part of the Colorado Plateau physiographic province with high plateaus of stratified rock cut by deep canyons. Elevations generally range between 5,000 and 7,500 feet. Topographically, it is a basin with mesas, rolling plains, badlands, and canyons that are lower than the surrounding mountain ranges: the San Juan Mountains to the north, the San Pedros to the east, the Zunis to the south, and the San Francisco Peaks to the west.

The region's variety of landforms has resulted from its geology and the forces of erosion. Mesas and ridges are held up by caps of sandstone, whereas the adjacent lowlands have formed by erosion of the softer shales. The Menefee Formation, which is mostly shale, lies beneath relatively thick sandstone and forms the lowlands and valleys. Steep-walled canyons form where the resistant sandstone is thick. Badlands form in thick shale sequences imbedded with thin lenses of sandstone. The Fruitland Formation, which is composed of shale, minor amounts of sandstone, and some coal, has been carved by water and wind into distinctive badland shapes.

The San Juan River Coal Region contains sedimentary rocks ranging in age to 500 million years. The Paleozoic formations, chiefly marine limestones, sandstones, and shales, do not crop out in the region, although they underlie it. In places along the southern part of the region, this formation forms an aquifer capable of yielding water for irrigation, industrial, and municipal use. The Triassic and Jurassic formations are chiefly non-marine sandstones, and claystones. The Entrada Sandstone and the Westwater Canyon Member of the Morrison Formation form important aquifers that may be utilized for coal development.

The formations of greatest interest are those of Upper Cretaceous age. In addition to containing coal, some form important aquifers, and many contain important fossil assemblages. When these formations were deposited, the shoreline of a large interior sea was moving back and forth in a general northeast to southwest direction through the region, so the deposits vary considerably in thickness and lithology. Most of the coal formed in

backshore swamps along the seacoast. The Crevassee Canyon, Menefee, and Fruitland Formations are the principal coal-bearing units.

Coals within the region rank from high-volatile A to B bituminous, to discontinuous and dirty coals that are high-volatile C to B bituminous with high ash content. Most coals are sub-bituminous. The region's estimated reserve base is 4.2 billion tons.

The region lies south of the major storm belt from the Pacific across the Rockies. The general climate is semi-arid, with variations resulting from elevation and topography. The Pacific fronts that trail across the region deposit most of their moisture on the mountains to the west. In the colder season, storms that develop off southern California move through the region once or twice a year and produce some precipitation, mostly on higher terrain as snow. During the summer, widely scattered showers and thunderstorms occur but coverage is spotty and erratic, often leading to drought in many areas of the region.

Annual mean temperatures vary from 48°F to 52°F. Temperatures exceeding 100°F occur throughout the region, while subzero temperatures are uncommon except in the mountains. A distinctive feature of the climate is the large variation in the daily high-low temperatures.

Annual precipitation averages less than 10 inches for most of the region, though points in northern New Mexico and southwestern Colorado receive 20 inches or more. At lower elevations, about half the precipitation falls between May and August. At higher elevations, a greater proportion is received from winter storms. Summer rainfall is mostly from intense local thunderstorms that frequently cause flash floods. Potential evaporation exceeds normal precipitation by a factor of 6 or more.

Wind direction tends to show the effect of local topography. Generally, winds are westerly during the day and easterly during the night, but terrain features complicate the wind field and cause significant deviations. For example, uneven cooling of the air results in downslope drainage of cold dense air during calm, clear nights; and the heating of valley walls and hills causes air to flow upslope and out of the valleys on calm, fair days. These terrain-induced circulations are common with the complex topography in all sections of the region.

Mixing heights and transport winds in the region have seasonal and diurnal variation. Generally, mixing heights are higher in the afternoon than in the morning. Seasonally, morning mixing heights are lowest during winter months, due to radiation inversions and afternoon mixing. Surface-based inversions occur 80-90 percent of the mornings throughout the year but are uncommon during afternoons. Stagnations are very prevalent. Ventilation values are highest in the spring because of the strong transport winds and lowest during the winter because of long nights, short days, snow cover, and persistent high-pressure systems. These various conditions result in a rather poor potential for pollution dispersion during certain periods of the year.

Nevertheless, for the most part, the region's air quality is considered good and better than the national standards. High winds can pick up dust which can cause or result in high particulate content in local areas for several days at a time. Areas generally not meeting the standards for particulate content include the industrial areas around the Four Corners and San Juan generating stations in San Juan County, New Mexico. Sulfur dioxide air quality is generally better than the national standards except near the generating stations about 15 miles west of Farmington, New Mexico. The region is now primarily rural except for the towns of Gallup and Farmington, New Mexico and Durango, Colorado. Most industrial, commercial, and population growth is expected to be in these urban areas. As this occurs, the air quality will probably deteriorate.

Major rivers draining the region are the San Juan, the Colorado, and the Little Colorado. The region encompasses headwaters of the San Juan, the only stream that receives flow from outside the area. Potential evapotranspiration ranges from less than 24 to about 35 inches per year. Runoff in the Little Colorado and its numerous dry washes is almost nil. Average annual stream flow for the region measured at the confluence of the San Juan and Colorado Rivers is approximately 2.6 million acre-feet. Surface reservoirs of the region store 27.1 million acre-feet.

Only in the upper reaches of the higher tributaries of the San Juan, in Colorado, is the sediment concentration low or medium. Over most of the San Juan River Coal Region the sediment concentration exceeds 1,000 milligrams per liter.

Summer thunderstorms and spring snowmelt often create floods of damaging proportions that carry tremendous loads of sediment. During such high-flow periods, the suspended-sediment content of the San Juan River and many of its tributaries may exceed 50,000 parts per million. Hardness of the surface water throughout most of the region exceeds 240 mg/liter, and all three major streams average at least 1,000 mg/liter of total dissolved solids. Approximately 1 million acre-feet of surface water is withdrawn each year for consumptive use, mainly irrigation.

Groundwater in the region is generally good where it is available. Nearly all sandstone formations in the region yield water, which is generally sufficient for livestock and domestic purposes. Wells developed in riparian deposits or in sandstone aquifers deliver 50 to 500 gallons per minute. Groundwater withdrawals for consumptive use in the region are approximately 50,000 acre-feet per year. The heaviest groundwater pumping is in the Gallup, New Mexico, area, which is part of the Little Colorado drainage. There pumpage to meet the demands of industry associated with coal and uranium is removing more water from the aquifers than can naturally be replaced.

In general, the San Juan River Coal Region is characterized by steep slopes covered with only sparse vegetation and a semi-arid climate with an extremely variable precipitation. Formation of top soil is slow because parent materials are predominately sandstone and shale for all soils in the region. Permeability is slow to moderate, and the soils are used primarily for grazing. Rich alluvial soils occur along the floodplains and alluvial fans, but these make up only a small percentage of the region. The major limitations of the region's soils are shallowness, salinity, and erodability.

The region contains three major vegetative communities: grassland and grassland-shrub (lower altitudes), pinyon-juniper (5,000-7,000 feet), and montane coniferous forest (above 7,000 feet). Wildlife within the region includes at least 100 species of mammals, 116 species of birds, and 28 species of amphibians. Several species are unique to this region.

Many of the grassland-shrub areas in the region have been severely overgrazed by livestock. Dominant plant species within this habitat type include green joint fir at higher elevations and rubber rabbitbrush, greasewood, and pale wolfber-

ry along the dry washes and arroyos. Fourwing saltbush and snakeweed may be locally abundant. Typical grasses include galleta, blue grama, sand dropseed, and Indian ricegrass. Russian thistle and cheat grass are common on overgrazed areas. Much of the region is dominated by big sagebrush. Common mammals in these areas include pronghorn antelope, black-tailed jackrabbit, desert cottontail, sagebrush vole, northern grasshopper mouse, Ord's and Great Basin kangaroo rats, prairie dog, badger, coyote, and western spotted skunk. Common birds include Gambel's quail, sage grouse, mourning dove, loggerhead shrike, sage thrasher, sage sparrow, Brewer's sparrow, red-tailed hawk, ferruginous hawk, and great horned owl. Reptiles, particularly lizards and snakes, are well represented. Common species include sagebrush lizard, leopard lizard, side-blotched lizard, bullsnake, plateau whiptail, racer, and western rattlesnake. This habitat is heavily populated by rodents adapted to dry conditions.

The woodland-bushland community supports wildlife from grassland and grassland-shrub associations plus some additional species. Typical trees and shrubs include pinyon pine, juniper, big sagebrush, Utah serviceberry, oak, fourwing saltbush, antelope bitterbrush, mountain mahogany, and cliffrose. Characteristic mammals include mule deer, rock squirrel, cliff chipmunk, desert woodrat, pinyon mouse, bushytailed woodrat, coyote, and bobcat. Birds include the ash-throated flycatcher, scrub jay, pinyon jay, blue-gray gnatcatcher, western bluebird, and acorn woodpecker.

Typical species of coniferous forest and forest edge communities include Douglas-fir, blue spruce, Englemann spruce, aspen, and oak. Typical mammals include mule deer, elk, snowshoe rabbit, red squirrel, golden-mantled ground squirrel, deer mouse, porcupine, black bear, marten, and cougar. Birds include the mountain bluebird, varied thrush, western tanager, common raven, gray jay, blue grouse, pygmy owl, flammulated owl, saw-whet owl, great horned owl, and golden eagle.

Numerous plant species proposed for endangered or threatened status exist in the San Juan River Coal Region. Presently, however, no plant species in the region are classified as endangered. Endangered fauna includes the whooping crane, Mexican duck, bald eagle, peregrine falcon, thick-billed parrot, and gray wolf.

All areas within the region can probably be reclaimed after disturbance, provided that topsoil is replaced as a plant medium and adequate moisture is available for plant germination and emergence. The fragile nature of the area's soil and the relatively low precipitation, however, would require a high degree of attention during reclamation.

4.8.2 The Environment and Man

The San Juan River Coal Region is one of the most interesting historical and archaeological regions in North America. The earliest known use of the region, dating back as far as 10,000 B.C., was by mobile hunter-gatherers. This subsistence pattern continued until about two and three thousand years ago, when the Anasazi people began a more settled existence and started raising domestic plants, such as squash, corn, beans, amaranth, and chili. Large multi-storyed pueblos developed, reaching a peak of elaboration at about 1,000 to 1,100 A.D. Their locations appear to have been determined primarily by the availability of water for floodwater farming and controlled irrigation. Recent evidence indicates that major pueblos were linked by a complex road network; and it is possible that the entire San Juan River Coal Region was organized into a regionwide economic and political system. During the 1300's the area along the San Juan River was abandoned for unknown reasons.

The earliest Navajo materials are found in the north-central part of the region, along the Colorado-New Mexico border. After acquiring sheep from the Spanish, the Navajos spread quickly, and by about 1800, herding and limited agriculture were dominant economic patterns throughout the region.

Spanish explorers and missionaries ventured into the northern Southwest in the 16th, 17th, and 18th Centuries, but it was not until the early 1800's that non-Indians arrived with any frequency. Trappers, miners, and traveling merchants began arriving regularly during the early to mid-1800's. During the period between 1850 and 1890, Army expeditions extensively mapped the region, restricted Indian activities, and established forts; and traders greatly increased the level of Indian contact when the Atlantic and Pacific Railroad crossed the southern portion of the region. By 1890, about one-fourth of the area was settled. At

present, there are approximately 30 listings in the National Register of Historic Places for this region, many associated with Indian tribes.

The economic patterns of the region are closely related to energy development. The three economic sectors that supply the majority of jobs are commercial and professional services, wholesale and retail trade, and mining. These three sectors accounted for 75 percent of all employed workers as of 1974. Table 4-10 provides an overview of pertinent economic and demographic data for the San Juan River Coal Region. Economic development has been relatively orderly, although some localized problems have resulted.

Commercial and professional services are largely limited to the population centers. Most services are related to the oil, gas, and mining industries. The expansion of urban areas, as distribution, transportation, and communication service centers, has been simultaneous with the growth of light industry. The expansion of government services is related to the vast holdings of Federally controlled lands within the region. Approximately 42,803 workers, or about 43 percent of the total work force is involved in services.

Mining has been important to all the states in the region. Much of the growth of the transportation, communication, and utilities sectors of the economy has stemmed from mining activity. Coal has been mined historically in all states of the region, but only recently have these reserves received national interest. Oil and gas are produced in half of the counties and are the leading commodities in one-quarter of the counties. The most common mineral produced in the region is sand and gravel, but a wide variety of metals (uranium, copper, zinc, lead, vanadium, gold, silver, and iron) and nonmetallic (crushed stone, clay, gypsum, lime, potassium salts, and salt) are also mined.

Historically, agriculture was the principal employment sector until the early 1950's, when energy-related development started to increase. With population increases, urban expansion moved to the prime agricultural valleys.

Agriculture in this area consists of irrigated farming along water courses and the grazing of cattle and sheep. Dryland farming is important locally, especially in the Colorado portion of the basin. The value of farm products sold is less than \$1 per acre of land throughout the region; most

(a) Demographic information which is based on all counties either totally or partially within regional boundaries.

income is derived from sales of cattle and sheep. Principal agricultural crops grown within the region include corn, hay, wheat, cotton, and sugarbeets.

Relatively low population, remoteness, and breathtaking scenery combine to make recreational opportunities almost unlimited. Two rivers in Colorado, the Dolores and Los Pinos, are under consideration for inclusion in the Wild and Scenic Rivers System. There are six National Monuments in the region and twelve state recreational facilities. The most popular recreational activity in this region is camping, followed by fishing, picnicking, and hunting. Recreation is showing significant economic growth in all areas.

Land ownership throughout the region is primarily Federal. Federal lands are National Forest and public lands (administered by BLM). Indian land also is prevalent. Only a small percentage of the land is private. This has made urban expansion expensive and difficult.

The region is well supplied with energy by the Colorado River Storage Project of the Bureau of Reclamation, by municipal, private, and cooperative power companies, and by natural gas distributors. Recent growth in demand for electricity has been rapid. Demand for natural gas has been increasing at a lesser rate, due to rising prices. Transportation facilities are best developed in urban areas. The major transportation network within the region are highways, but neither construction nor maintenance has kept up with the expanded use. Railways are almost non-existent, although an east-west main-line of the Santa Fe Railway traverses the region.

Water may be one of the most stringent limits on future growth. Water supply and wastewater treatment require advanced technologies in what is essentially a desert environment. Few rural communities in the region possess the water supply systems and wastewater treatment facilities that are features of urban areas. Surface water is scarce; groundwater often has a large quantity of minerals and salts and must be processed.

4.9 UNTA-SOUTHWESTERN UTAH COAL REGION

The Uinta-Southwestern Utah Coal Region, is in the Colorado Plateau and Uinta Basin of the southwestern United States. This region encom-

passes about 57,000 square miles in six Colorado and 14 Utah counties.

4.9.1 The Environment

The general area is characterized by extremes in both topography and climate. The higher peaks and plateaus rise above the adjacent lowlands which, in turn, are from about 3,000 to over 5,000 feet above sea level. Extremely steep slopes and narrow, vertically walled canyons prevail throughout much of the region. Many of the coal deposits are in the flanks of the major peaks and plateaus at intermediate elevations.

The Uinta portion of this region, the northern majority of the region in Utah and Colorado which contains the south slope of the Uinta mountains, is a structural basin with rocks on the southern flanks of the basin dipping gently toward the center. Rocks on the northern and northeastern flanks are steeply dipping with overturned beds and major faults. The remaining Southwestern Utah portion of the region includes a series of plateaus in a shallow structural basin. Many of those areas are separated by a series of major faults, including the Hurricane, Sevier, and Paunsaugunt Faults. A number of geologically significant areas within this region have been included in the National Park System as parts of Zion, Bryce Canyon, and Capitol Reef National Parks, and Cedar Breaks National Monument. A number of areas, less known to the general public but almost equally spectacular and geologically unique, have been designated by the Bureau of Land Management as outstanding natural areas. For examples, the canyons of the Escalante River and its tributaries contain numerous natural bridges and arches, towering rock monoliths, and sheer sandstone cliffs.

Principal minerals are coal, petroleum, natural gas, copper, zinc, lead, vanadium, gold, silver, and iron. Oil shale and tar sands, as well as conventional petroleum sources, are extensive.

The geological age of the coal deposits date back to the Cretaceous and Paleocene ages. Coal seams are primarily deep deposits of medium to high volatile A and B bituminous. The region's coal reserve base is estimated to be approximately 6 billion tons.

Fossils of prehistoric plants and animals are widespread. One of the nation's major concentrations of dinosaur remains is in the Utah portion of

Dinosaur National Monument. Other deposits occur throughout the region.

Pervading southwest winds, that move across the Colorado and Mohave Deserts, give most of the region an arid climate with a very high evapotranspiration rate. However, rugged topography and great differences in elevation and orientation cause great variations in temperature and moisture within short distances. The result is a mosaic of microclimates with significant differences between north and south facing slopes, and between sheltered canyon bottoms and exposed ridges. At higher elevations subzero winter temperatures are common. Summers are cold and growing seasons are short. The higher peaks and mountain ranges are covered with snow, often several feet deep, several months of the year.

The lower elevations are characterized by hot summers, with temperatures frequently exceeding 100°F, especially in southern portions of the region. Even at lower elevations subfreezing temperatures occur frequently in the winter.

The clear, dry air typical of much of the area is conducive to rapid temperature changes. It is not unusual to have temperatures in the eighties at midday and frost at night within the same 24-hour period.

In spite of the prevailing general movement of air from west to east many local wind variations result from the rugged topography. Warm air rises from the valley floors and plains during the day and cold air drains down from the higher elevations at night. Local wind flows created by these factors can be quite strong. As a rule, however, their persistence is not great.

Throughout rural portions of this region, air quality is generally very good. There are no major concentrations of particulates, sulfur dioxide, or nitrogen dioxide. Occasionally, however, air quality problems occur in the closed valleys where temperature inversions trap and hold urban and industrial emissions.

Because of the high evapotranspiration rate during summer months, winter precipitation is usually more effective in providing soil moisture and groundwater recharge.

Water from much of the region drains east and south into tributaries of the Colorado River. Principal Colorado tributaries include the Green, White, Duchesne, Price, Dirty Devil, Escalante, Paria, and Virgin Rivers. The Yampa River,

though just outside the region, contributes significantly to flows of the Green. The remainder of the region, including the Provo and Sevier Rivers, is in the Great Basin hydrologic region.

Most precipitation occurs on the high mountains and plateaus. Watersheds at lower elevations contribute little to base stream flows because of low precipitation and high evapotranspiration rates. Therefore, most streams diminish rather than grow in size after leaving the mountains. This natural tendency is intensified by extensive diversions and consumptive use of water by man. The Sevier River is subjected to extremely heavy use with much of the water rediverted and reused several times along its course, and is largely depleted by the time the river reaches Sevier Dry Lake.

Most streams originate in the high timbered country of the headwaters. As they descend, they accumulate sediments and salts from the highly erosive watersheds at lower elevations. This natural trend is intensified by diversion of water, primarily for irrigation. Water returning to the stream as drainage from irrigated agriculture carries an increased loading of salts and sediments. Tributaries originating at lower elevations are usually intermittent. Stream flows and surface water use have not been quantified for this region specifically, and flows are probably less than 6 million acre-feet per year.

Dissolved solids in streams of the region range from 120 to 350 milligrams per liter in the western base of the Wasatch Mountains, and tributaries to the Upper Strawberry, which drain the south face of the Uinta Mountains. Over the remainder of the region, total dissolved solids values are greater than 350 mg/l. In some basins total dissolved solids exceed 1800 mg/l. Sediment concentrations are variable, but are greater than 1900 mg/l in the larger perennial rivers. Suspended sediment concentrations vary extensively throughout the region.

The region is underlain by low permeability rocks that generally yield less than 50 gallons per minute to wells. However, in some of the alluvial valley fills, particularly those containing gravels and sands, yields of several hundred gallons a minute can be obtained. The quality of bedrock water supplies is generally poor.

Over much of the region soils are poorly developed. The combination of steep slopes and semi-arid to arid climate, with highly variable

Precipitation, results in a naturally high rate of erosion. Wind erosion is significant in southern portions of the region. Formation of top soil is quite slow. In the geologic past, much of the region was covered by a shallow sea which contributed salts to the land. In much of the region the high evapotranspiration rate has caused further concentration of salts in many areas. Salts are generally more concentrated in soils of flat valley floors and closed basins. The more productive soils frequently occur on benches, alluvial fans and gentle slopes, where there is sufficient drainage to minimize the accumulation of salts.

In addition to soil problems inherent to the topography, climate, and geological history of the region, severe range and watershed abuse by the early settlers caused loss or degradation of much of the limited and fragile original top soil. Continued heavy grazing has limited recovery of damaged areas in many cases.

Soils of the eastern part of the region generally are sandy loam, loam, or silty loam with a calcium carbonate accumulation usually occurring at depths greater than four feet. The soils of the central portion of the region are generally steep, shallow, and poorly developed, often with many rock fragments. In the southern portion of the region, the soils are a mix of the rocky soils found in the central part of the region and soils with sandy loam to silty clay loam texture with a calcium carbonate zone at one to three feet.

Vegetation is largely a manifestation of climate and soils. Plantlife within the region forms a mosaic closely conforming to the pattern of climates caused by the rugged topography. In this arid environment, moisture is by far the most vital factor in determining what vegetation will grow in a given site. Native flora ranges from cold desert through pinyon-juniper woodland to montane coniferous forest often within a few miles. Narrow belts of streamside vegetation transect all the major vegetal communities.

Numbers and kinds of wildlife present are, in turn, determined primarily by the habitat created by existing vegetation. The great diversity of vegetation supports a corresponding diversity of wildlife including approximately 90 different mammals, 270 birds, 26 reptiles, 9 amphibians, and a great many insects and other invertebrates.

The montane forests of the higher elevations contain ponderosa and lodgepole pine, Douglas-

fir, and spruce. Aspen is interspersed throughout much of the conifer forests.

Wildlife representative of the montane coniferous forests include small mammals such as snowshoe rabbit, red squirrel, flying squirrel, and porcupine; game species such as elk, black bear, mule deer; and predators such as bobcat, cougar, and marten. Moose have recently been transplanted into the region. Characteristic birds include Clark's nutcracker, grayheaded junco, mountain bluebird, mountain chickadee, hairy woodpecker, ruffed grouse, blue grouse, goshawk, great horned owl, pygmy owl, and flammulated owl. Wild turkey occur in limited areas.

The woodland-brushland, at intermediate elevations consists of juniper, pinyon pine, mountain mahogany, and oakbrush with interspersions of sagebrush and grasses.

Representative mammals of the pinyon-juniper woodland-bushland communities include rock squirrel, cliff chipmunk, desert woodrat, pinyon mouse, bobcat, bushy-tailed woodrat, mule deer, and elk. A free-roaming bison herd occurs in this vegetal type on the Henry Mountains of Utah. Birds include the ash-throated flycatcher, gray flycatcher, pinyon jay, plains titmouse, western bluebird, and the black-throated gray warbler.

Vegetation of the cold desert is dominated by salt-bush and greasewood, indicating saline soil, in lower, poorly drained areas. Sagebrush with associated grasses and forbs predominate on slopes and benches that are better drained and less saline.

In cold desert communities, typical mammals are the black-tailed jack rabbit, desert cottontail, Nuttall's cottontail, desert woodrat, least chipmunk, Great Basin pocket mouse, Ord's kangaroo rat, northern grasshopper mouse, pronghorn antelope, coyote, kit fox, skunk, and desert bighorn sheep. Characteristic reptiles are the leopard lizard, sagebrush lizard, side-blotched lizard, short-horned lizard, bullsnake, plateau whiptail racer, and western rattlesnake. Birds include red-tailed hawk, Gambel's quail, sage grouse, mourning dove, great-horned owl, loggerhead shrike, sage thrasher, sage sparrow, and Brewer's sparrow.

Streamside vegetation consists mainly of cottonwood, willow, and herbaceous wetland plants. The narrow belts of riparian woodlands are vital to many wildlife species and support a greater diversity of wildlife than any other single habitat type. This is especially true in lower and more arid

areas where the riparian vegetation is literally an oasis in the desert. The cottonwoods and other trees often provide the only nesting and perching sites in many miles for raptors and other birds.

Throughout the region, much of the vegetal cover has changed considerably since the coming of settlers and the grazing of domestic livestock. Prior to this time, grasslands were more extensive and sagebrush and pinyon-juniper more limited in area. Heavy grazing of grasses favored an increase in shrubs and woodland. This caused an increase in numbers of deer and a decrease in numbers of elk, antelope, and desert bighorn.

Reclamation of land, to the point where it supports the same vegetation and fauna that was there before disturbance, is a slow process in much of the region. In the more arid areas, the probability of seeding success without irrigation is approximately one year out of three. In a drought cycle several years may pass before suitable moisture conditions occur for reseeding success. Proper soil management and irrigation practices may, however, mitigate the adverse reclamation effects of droughts. Transplanting of seedlings is sometimes required for some desirable shrub species. Trees grow slowly, and 100 years or more may be required to replace a mature stand of timber.

In some cases, predominant existing vegetation represents a deteriorated watershed condition resulting from long-term overuse by livestock and big game animals. Therefore, restoration of the exact existing vegetation might not always be desirable.

The numerous habitat areas isolated from one another by barriers of terrain and climate have encouraged the evolution of a number of unique plant species. Eighty-four plants in the region have been proposed for Federal endangered or threatened status; however, only the Rydberg milk-vetch has been designated as threatened. None are Federally considered to be endangered. The remaining 83 may not eventually receive this status.

A number of Federally-listed endangered or threatened animals inhabit the region either year-round or seasonally. These include the bald eagle, peregrine falcon, Utah prairie dog, black-footed ferret, and whooping crane. Endangered and threatened fish include the endangered Colorado squawfish, humpback chub, and woundfin. The Virgin River spinedace and Virgin River roundtail

chub have been recommended for endangered classification. The razorback sucker is on the Colorado endangered list. Additionally, Colorado cites the river otter as endangered and Utah cites the spotted bat as unique.

4.9.2 The Environment and Man

The prehistory of the region includes several distinct archeologically defined cultural periods: the Paleo Indians (big game hunters-12,000 B.C. to 500 B.C.), Archaic (hunter/gatherers-12,000 B.C. to 500 B.C.), Desert Anasazi (sedentary agriculturalistic-A.D. 700 to A.D. 1250), and Paiute (hunter/gatherers-A.D. 1250 to the historic period). Numerous small groups of cliff dwellings and other archeological sites are scattered throughout canyons, mainly in southern portions of the region. Indian artifacts are scattered throughout the region. Modern Indians still occupy considerable areas.

The first documented non-Indian passage through southern Utah and western Colorado was by the Dominguez-Escalante expedition of 1776-77. The somewhat later, trade-oriented Spanish Trail also passes through the region. The region was visited in the earlier 1800's by the government explorer John C. Fremont, the famed trapper Jedediah Smith, and other trappers, fur traders, and mountain men.

Very soon after their arrival in the Salt Lake Valley in 1847, the Mormons initiated exploration and colonization missions on a substantial scale. Initial thrusts were along the western base of the Wasatch Plateau and in the Sevier River Valley where snow-fed streams from the mountains provided water for irrigation. The region was originally settled primarily for agriculture and stock raising. However, discovery of minerals soon brought about considerable mining activity in some areas. The Mormons established settlements as rapidly as possible in almost every location which the resources could conceivably support. The Colorado portion was settled in a more typical fashion. The White River Basin, somewhat isolated from the main travel routes through the mountains, was occupied by white settlers later than much of the region.

Mining of coal began in numerous locations at an early date. The coal enterprise prospered for many years supplying primarily the railroads and local domestic and industrial needs. Replacement

of coal-burning railroad locomotives with diesel-electric engines and conversion from coal to natural gas and fuel oil for home heating and industrial use caused a drastic decline in coal mining activity. Many mines were inactive until recently when the construction of several large coal-fired power plants created a greatly increased demand.

The uranium boom following World War II brought thousands of prospectors and miners into the more rugged and remote areas of southern Utah and western Colorado. This influx was temporary and most uranium seekers left after the market for uranium declined. Roads and jeep trails established or improved during the uranium boom have had a lasting impact by increasing accessibility to many areas.

Uranium mining and processing, which have been at a low level for a number of years, are beginning to accelerate in response to the increase in nuclear power plants.

Coal is produced in almost half the region's counties and is the leading value mineral in six of them. Of those counties reporting actual dollar volume of production, 60 percent had total production valued at greater than \$1 million; and 45 percent had values greater than \$10 million.

Petroleum, natural gas, and natural gas liquids were produced in half of the counties and were the leading commodities in one-quarter of the counties, including two counties that had a total mineral production of \$340 million. Although sand and gravel were the most common minerals in the region, being produced in 95 percent of the counties, production value was low, accounting for only one percent of Utah's total mineral production. A wide variety of metallic minerals were produced in the region, the most common being uranium. Other metallic minerals included copper, zinc, lead, vanadium, gold, silver, and iron. In addition to sand and gravel, the nonmetallic minerals produced in the region included crushed stone, clay, gypsum, lime, potassium salts, and salt. The demand for limestone and lime is increasing as these materials are used for dust suppression in coal mines and in wet scrubbers for emission control at power plants.

Even though much of the region is sparsely populated and rural in nature, it supports localized urban centers. Price, Richfield, Vernal, St. George and Cedar City, Utah, and Grand Junction and

Montrose, Colorado, are some of the principal trade centers within the region. Page and Fredonia, Arizona, and Salt Lake City and Provo, Utah, are within the area of economic influence. Nearly all communities are dependent on Salt Lake City or Denver for some goods and services.

Total population for the Uinta-Southwestern Utah Coal Region was approximately 406,600 in 1975, with a density of approximately seven persons per square mile. Forty-four thousand persons migrated into the region between 1970 and 1976. Public school enrollments totaled over 100,000 students in 1975. Table 4-11 provides an overview of pertinent demographic and socioeconomic information.

Approximately 26,400 workers, or about 19.2 percent of total regional employment, are in the service sector. Combined with 29,900 workers in the wholesale and retail trade sector and 16,700 workers in the manufacturing sector, these three sectors represent over 52 percent of total employment. Approximately 13,460 persons are employed in the agricultural sector in the region.

Livestock grazing in some form occurs over much of the region. The limited area of farm land, less than 5 percent of the land area, is largely used for production of hay and feed grains in conjunction with range livestock operations.

Pastureland represents more than 75 percent of farmlands. Over 75 percent of harvested cropland is irrigated. In some counties, as much as 20-29 percent of the total farm land and most of the irrigated land was used for the production of hay to support livestock operations.

Cultivated crops produced within the region include hay, wheat, sugarbeets, and corn. Average yields per acre for these crops are 2.5 tons for hay, 23.3 bushels for wheat, 18 tons for sugarbeets, and 96 bushels for corn.

Military and other U.S. government installations and operations in and adjacent to the region make a significant contribution to the economy. In recent years the service sector related to tourism and outdoor recreation has become important. Hunting, fishing, camping, plus other recreation-oriented out-of-doors activities are significant elements of the regional economy. Five national parks, five national monuments, one national recreation area, one wilderness area, one national forest primitive area, several BLM outstanding natural areas, numerous ski resorts, and river-

(a) Demographic information which is based on all counties either totally or partially within regional boundaries.

running opportunities on the Colorado River, all within or immediately adjacent to the region, draw recreationists from throughout the nation.

A significant characteristic of the region is that existing population centers are far apart and often considerable distances from the natural resources that are being developed. Also, availability of land suitable for expanded municipal and residential development is sometimes physically limited by rugged terrain or inadequate water supply.

School districts range from over 13,000 students in 34 schools at Grand Junction, Colorado, to less than 100 students and one school in some smaller rural communities.

In many communities little vacant housing is available to accommodate any substantial population increase. In towns currently experiencing rapid growth there has been a marked increase in mobile homes.

Most towns have small administrative staffs which have few resources for planning future developments. Also, land use control mechanisms to manage growth are frequently lacking.

Police and fire protection range from full time professional departments to part time services of the county sheriff's departments in the smaller communities.

Except for the few major highways most roads were designed a number of years ago to handle relatively light traffic and would require upgrading to accomodate heavy coal hauling. Some coal deposits are accessible only by primitive roads and major road construction would be required if coal were developed. Only a few active railroads exist in the region. Interstate Highway 15 skirts the western edge of the region linking the major trade centers of Utah with Las Vegas and Los Angeles to the southwest and with Boise, Portland, and Seattle in the northwest. Interstate 70 links central Utah with Grand Junction and Denver on the east. Interstate 80, just outside the region, links the Wasatch Front population centers of Utah with the San Francisco Bay area and industrial centers of the Great Lakes and northeastern regions.

Major railroads are the Union Pacific and Denver and Rio Grande Western (D&RGW). The D&RGW begins at Ogden, Utah, passes through Salt Lake City and Provo, crosses the Wasatch Plateau and parallels US 6 to Grand Junction and Denver, Colorado. A segment of the D&RGW extends southward through the region to Richfield,

Utah. The Union Pacific links the region to other population centers of the nation.

A preponderance of the land is in public ownership. Portions of nine National Forests are included in the higher, timbered portions of the region. These are the Wasatch, Uinta, Ashley, Fishlake, and Dixie National Forests in Utah and the White River, Routt, Grand Mesa, and Uncompahgre National Forests in Colorado. The Uintah-Utah Indian Reservation is located in the Uinta Basin portion of the region. Lands at lower elevations are largely public lands administered by the Bureau of Land Management. Typically, bottom lands and gentle slopes suitable for agriculture are privately owned and the more rugged terrain is in public ownership.

4.10 DENVER - RATON MESA COAL REGION

The Denver-Raton Mesa Coal Region is in the Colorado Piedmont and Great Plains of the west central United States. This region encompasses approximately 24,000 square miles in 14 Colorado and one New Mexico counties.

4.10.1 The Environment

The Denver Basin occupies a north-south trending basin characterized by gently dipping strata to the east and by steeply dipping upturned beds along the foothills to the west. Except along the foothills where crystalline rocks outcrop, the surface rocks are sedimentary. The Laramie Formation contains coal beds of sub-bituminous B and C rank. Although these beds range up to 17 feet thick, most are thinner, lenticular, and discontinuous. A number of small mines have extracted coal from this formation, particularly in Boulder and Weld Counties, Colorado, and near Colorado Springs. In addition, the Denver Formation contains extensive beds of sub-bituminous coal in an area about 75 miles long by 25-35 miles wide. Placer gold was recovered from portions of the area in the latter part of the nineteenth century, but gold is not actively mined now. Numerous producing oil and gas wells are located in the region. Production is from the Dakota Sandstone and is spread over a number of small scattered fields.

The Raton Mesa area of this region occupies a broad trough that runs north-south from northern New Mexico into southern Colorado. This basin is

also characterized by gently dipping rocks on the eastern flank and steeply dipping to overturned rocks along the flanks of the Sangre De Cristo Mountains to the west. The area contains many igneous intrusions that alter the coal beds. Coal occurs throughout the sandstones and shales of the Vermejo Formation and the conglomerate, sandstone, and shale of the Raton Formations. The entire region is estimated to contain 3.9 billion tons of demonstrated coal reserves. The coal is high-volatile A to B bituminous and of coking quality throughout most of the region, except in the Walsenburg Field in the northern part. The coalbearing rocks are up to 2,400 feet thick and contain coal beds mostly 2 to 5 feet thick, but ranging up to 15 feet thick in the New Mexico section of the region. Much of the coal outcrops at the surface on hillsides and along hogbacks. Some surface-mineable coal reserves are reported, but a number of major coal beds of the Vermejo Formation are buried by overburden as thick as 1,000 to 3,000 feet. Sand and gravel are extracted in all counties of the region.

The climate of the Denver-Raton Mesa Coal Region is highland continental. It is characterized by low relative humidity, light rainfall, abundant sunshine, moderate to high wind movement, and a large daily range in temperature. Precipitation generally ranges from 13 to 18 inches a year, the greater amounts falling at the higher elevations. Precipitation is heaviest in spring and early summer and lowest in the winter months.

Prevailing storm patterns across the region are west-to-east. The storms provide little moisture to the area, however, because they deposit most of it on the western slopes of the Rockies. Similarly, storms from the north that bring some of the coldest weather are rarely accompanied by significant precipitation. In spring, when storms tend to develop in the panhandle of Texas and Oklahoma, moisture is deposited on the eastern slopes of the mountains and the area receives the heaviest and most general rains. These taper off to shower and thunderstorm activity in the summer period.

The mean annual temperature in the region ranges between 48° and 52° F. However, daily temperatures vary by 27°F to 39°F, indicative of the high, semi-arid nature of the area and climate.

Surface wind speeds average 10 miles per hour. However, winds through the vertical mixing zone are less than average for the nation as a whole.

Frequent night-time surface inversions and relatively high afternoon mixing heights are prevalent features of the region. The terrain and the considerable daily range in temperature tend to create local valley-mountain circulations, so that winds are not very persistent in direction except when chinooks occur. There is a tendency for regular reversals of flow, a situation that is not conducive to dispersing pollutants.

In spite of these factors, overall regional air quality is quite good. However, in the more heavily populated areas along the Front Range, and particularly in the South Platte River Valley, air quality frequently fails to meet national standards. The principal cause is automobile emissions coupled with atmospheric temperature inversions. These conditions are more frequent in the fall and early winter though they may occur at any time of the year.

The region is part of three major drainage basins: the Upper Missouri, the Upper Arkansas Red, and the Western Gulf. The major rivers draining the region include the South Platte and its tributaries, and tributaries to the Arkansas River. Headwaters of these streams lie to the west in the Rocky Mountains where most of the runoff originates as winter snows. Streams originating within the region are ephemeral; any runoff in them is generally from spring and summer thunder showers. Surface-water flow in the region is about 5.4 million acre-feet per year, of which over 4.5 million acre-feet are consumptively used, primarily for irrigation and self-supplied industry.

Aquifers are found both in the alluvial deposits of the Denver and Raton Basins and in the underlying sandstones. Wells drawing from alluvium in the Denver Basin primarily supply water for irrigation and yield 400 to 2000 gallons per minute. The Foxhill Sandstone is the most notable bedrock aquifer in the Denver Basin; it lies at the base of the coal zone of the Laramie Formation. Most wells in the sandstone yield water under artesian pressure, although heavy pumping has lowered the artesian head about 600 feet in some areas. Recharge areas of this aquifer are in the foothills to the west and the Black Forest area near Colorado Springs. In the Raton Basin, the Dakota Sandstone is the principal bedrock aquifer, though water is recovered from other sandstones also. Wells into these sandstones generally yield 10 to 100 gpm, and some yield over 200 gpm.

Water quality in the perennial streams entering the region is quite good, with total dissolved solids averaging less than 100 milligrams per liter. However, ephemeral tributary streams often add water containing 1800 mg/liter or more. Due to this and to return flows water quality deteriorates progressively downstream. For example, the South Platte contains about 1000 mg/liter of dissolved solids where it leaves the region. Similarly, the perennial streams entering the region start with little sediment, but tributary streams, particularly during peak flows, contribute very heavy loads, with the result that, in the eastern part of the region, sediment loads may exceed 1900 mg/liter.

Groundwater quality in alluvial aquifers also tends to deteriorate downstream, increasing from 1300 mg/liter of total dissolved solids near Denver to about 1800 mg/liter near the state line. Quality of water from the sandstone varies but generally is lightly mineralized with a high fluoride concentration and some is slightly corrosive.

Due to a shortage of available water to meet municipal, irrigation, and industrial needs of the region, extensive importation of water from western Colorado has been undertaken.

Within the Denver section of this region, the soils generally have an organic-rich surface horizon and are high in bases. These gently sloping soils usually have a thin clay accumulation in the subsurface horizon and are intermittently dry for long periods during the summer. This portion of the region is on the western edge of the prairie biome and the predominant vegetation is buffalo grass and blue grama. Associated vegetation includes yucca, western wheatgrass, needlegrass, fringed sage, and prairie globemallow. Other plants of local importance include cottonwood, willows, and fourwing saltbush along drainage systems; saltgrass on saline or alkaline soils; and prairie sand reed and plains prickly pear in sandy areas. Ponderosa pine is found in areas southeast of Denver generally on northerly and easterly aspects, in the Black Forest north of Colorado Springs, and where the grassland grades to a coniferous forest of ponderosa pine and Douglas fir along the southwest border of the region.

The predominant soils of the Raton Mesa section have a grey to brown surface horizon with a subsurface accumulation of clay, and are medium to high in bases. These soils are usually moist but have steep slopes and many areas with

rock outcrops. Soil limitations in this section include erosion, shallowness, and slope. Vegetation is primarily montane coniferous forest of ponderosa pine, Douglas-fir, and Englemann spruce. Pinyon-juniper stands grading into short-grass prairie similar to that in the Denver section are found in the eastern portions of the Raton section.

A high annual turnover and production in the grasslands of the Denver section provide a food base for large variety of animals. Populations of many wild animals can fluctuate widely because of periodic droughts and severe winter storms. Riparian habitats along drainage bottoms extend the forest edge into the grasslands. This greatly increases the variety of habitat available for animals; those requiring heavy cover, shade, browse, tree nesting, etc., are able to survive within the grassland.

Except for a few remaining pronghorn antelope, the original grazing animals have been replaced by domestic livestock. Mule deer are resident where ponderosa pine is found and in the fingers of riparian habitat along stream beds. Whitetail deer are found in the South Platte River bottoms and the deer population is increasing in this section.

Animal life of the Raton-Mesa section is typical of the montane coniferous forest and forest edge habitats. Typical species include mammalian yellow-bellied marmot, golden-mantled ground squirrel, least chipmunk, red squirrel, bushy-tailed woodrat, boreal redback vole, bobcat, mule deer, elk, and porcupine. Typical birds include the western flycatcher, Clark's nutcracker, mountain chickadee, mountain bluebird, and pygmy nuthatch.

There are five animal species in the region whose populations have diminished to the point that they are currently on the Federal list of endangered species: the bald eagle, peregrine falcon, whooping crane, black-footed ferret, and greenback cutthroat trout. There are no plant species presently listed as threatened or endangered, although a number are under consideration.

After disturbance, most areas of the Denver-Raton Mesa Coal Region could probably be reclaimed with proper land management. The principal limiting factor is the uncertainty of precipitation and, in some areas, erodibility of soils.

4.10.2 The Environment And Man

Both sections of the Denver-Raton Mesa Coal Region are associated with important Paleo-Indian life. East of the Raton Mesa section is the Folsom site in Colfax County, New Mexico, the first site to be positively identified as Paleo-Indian. Folsom points, a particular style of projectile point identified with this site, were found in direct association with the remains of an extinct species of bison. North of Denver is the Lindenmeier site, in Larimer County, Colorado. Extensive excavations of this site uncovered over 20,000 artifacts, primarily stone blades and projectile points, and helped to produce a better understanding of Paleo-Indian life. Cultural developments following the aforementioned Paleo-Indian period included the San Jose complex of the Desert Culture in the Raton Mesa section and a transition phase between the Archaic and Desert Cultures in the Denver section. Further developments continued to divide the two sections between eastern and western cultural influences. In the period following 500 A.D., the Denver section was within the cultural sphere of the Plains Bison Hunters, and the Raton Mesa section was part of the Anasazi complex of the southwestern Farmers Tradition. The National Register of Historic Places provides cultural protection for many of these and other important archeological and historical features within the region. Within historic time, eastern Colorado and northern New Mexico were the domain of several successive Indian nations. When the white man arrived in the Denver-Raton Mesa Coal Region, the Arapaho and Cheyenne occupied the plains north of the Arkansas River and the Kiowa and Comanche occupied the land to the south.

Although Spain was the first European nation to claim what is now the Denver-Raton Mesa Coal Region, that nation never established any settlements there. Both soldiers and friars from the settlements near Santa Fe, New Mexico, visited the area beginning in the early 1700's. They generally followed a route over Raton Pass; the same route followed by present day Interstate 25.

Within three years of the Louisiana Purchase, General Pike visited the region on his explorations in 1806. However, it was not until after the Mexican War and the treaty of 1848 that settlement began in the Raton Mesa section. Settlers came to this area primarily from New Mexico beginning in the 1850's and 1860's. By 1850, John

Fremont had passed through the Denver section on two of his expeditions, and the Santa Fe Trail had been established through the Raton Mesa section. The discovery of gold near what is now Denver in 1858 brought settlement to that area, primarily from the East. Following the Civil War, the plains Indians were removed to reservations in Oklahoma.

Railroads from Cheyenne and Kansas City both reached Denver in 1870, greatly accelerating the settlement of that part of the region. Denver is the largest city in the region. Of the 110 historic sites within the region that are listed on the National Register of Historic Places, half are within the City of Denver.

Dominant economic activities in the region reflect the position of Denver as a financial, trade, and manufacturing center for the whole Rocky Mountain area, as well as a western government center. Federal, state, and local governments employ 24 percent of the work force. Wholesale and retail trade (23 percent), services (16 percent), and manufacturing (14 percent) together employ 53 per cent of the workers. Table 4-12 describes the major sector socioeconomic characteristics. Agriculture employs about 2 percent and mining less than 1 percent of the workers. The total labor force, expressed as a percentage of total population, provides an estimate of the labor force participation rate. The estimated 1975 labor force participation rate in the Denver-Raton Mesa Coal Region was 72 percent.

Per capita income for the region in 1975 was \$5,787, some 14 percent above the national average of \$5,077. Income ranged from a low of \$3,228 in Huerfano County, Colorado, to a high of \$6,858 in Denver County.

Beyond the metropolitan areas, the principal industry is agriculture. In rural counties, as high as 55 percent of the workers are employed in agriculture. Regional agricultural sales were \$908 million in 1975 with over 68 percent of that being livestock, mostly beef cattle. Agriculture of the region can be divided into three separate categories. In northern Colorado, particularly along the South Platte River, there is substantial irrigation and beef production. Principal crops include sugarbeets and grains. In this area, farm products valued at \$50-\$150 per acre are produced. South of this area there is a shortage of irrigation water, and agriculture is about equally divided between

(a) Demographic information which is based on all counties either totally or partially within regional boundaries.

dryland wheat and livestock ranching. In this area, the value of farm products sold per acre of farm land is between \$10 and \$30. In the Raton Mesa section, cattle and sheep ranching predominate and there are few cultivated crops. The average value of farm products here is less than \$10 per acre of agricultural land.

Principal crops grown within the region include wheat, hay, corn, sugarbeets, and cotton. Yields per acre for these crops are approximately 23 bushels of wheat, 3 tons of hay, 101 bushels of corn, 19 tons of sugarbeets, and 380 pounds of cotton. Agriculture employs about 18,576 persons in the region, about half of these being in the livestock industry.

Mining is a relatively minor part of the local industry, with coal mining employing less than one percent of the work force. Historically there have been a number of smaller coal mines both in Boulder and Weld County, Colorado, and in the Raton Basin. Oil and gas production has been the source of greatest extracted wealth with numerous small fields throughout the area. Production of sand and gravel is the most universal of the mineral industries with activity found in every county of the region. Sand and gravel are used almost exclusively for local roads and building construction.

The Denver-Raton Mesa Coal Region is not an area of outstanding outdoor recreation opportunities. It contains no national parks, wild and scenic rivers, or wilderness areas. The region does include eight state recreation facilities and one state park, all in Colorado. These nine areas comprise some 22,000 acres and receive about 2.7 million visits annually.

Upland bird and waterfowl hunting are important fall activities, particularly in the irrigated agricultural lands north of Denver. Similarly, deer are hunted in the forested areas of the Raton Basin. Both sections of the region are on access routes to the Rocky Mountains to the west where many people, both resident and non-resident, travel for recreational activities (hunting, fishing, skiing, hiking, jeeping, mountain climbing, etc.). The most popular recreational activities within the region are camping, fishing, and picnicking.

Because of Denver's historical role as an industrial and trade center and the nearby cities of Colorado Springs and Fort Collins, facilities in the Denver section of the region are well developed.

This section is served by good highway and rail systems and a major regional airport.

The area has been one of rapid growth for the past 15 years. Net immigration to the region between 1970 and 1976 was 162,000 persons. Despite this growth, the capacity of most community facilities has kept pace and public services are generally adequate. Some shortages of classrooms are noted in rapid growth portions of the metropolitan areas, but older sections of these same areas are experiencing declining public school enrollments and are facing the prospect of closing schools.

Domestic water supplies are a critical factor in the metropolitan areas. All are dependent to one degree or another on water imported from the western slope of the Rocky Mountains.

To a large extent, the size and nature of community facilities are a function of population density. This is reflected in the contrast between the metropolitan areas of the region and the more rural areas. In the Raton Mesa section of the region, the smaller communities have limited capacity to deal with a population explosion.

Life styles of the Denver-Raton Mesa Coal Region can be logically divided into three main types. First is the metropolitan life style of the Denver metropolitan area which is not unlike other large cities. Many people live in the suburbs and commute to regularly scheduled jobs in the city. The city also offers a full range of cultural activities, from museums to plays and symphony concerts to professional sports events. Because of the relative proximity of the mountains, many metropolitan residents maintain an active interest and participation in outdoor recreational pursuits. Each weekend the highways to the mountains are congested with residents traveling to favorite hiking, camping, skiing, or fishing areas.

Small towns are relatively stable communities where ranchers and merchants know their neighbors. Many cultural activities and spectator-type entertainments are lacking in these areas. Residents are generally quite independent and proud of their chosen way of life.

Between these types of life styles are the small cities such as Colorado Springs and Fort Collins. These communities are large enough to support a reasonable level of cultural and educational services, yet retain much of the small town atmo-

sphere and attitudes, particularly among the long-time residents.

Federal land surface ownership in the region is minimal and widely scattered, amounting to only about 97,000 acres. Over half of this is in Huerfano County, Colorado.

REGIONAL IMPACTS OF FEDERAL COAL MANAGEMENT PROGRAM ALTERNATIVES

The environmental impacts of the preferred Federal coal management program and six major alternatives as described in Chapter 3 are presented in this chapter. The impacts are evaluated across the major activities related to the entire coal development cycle: coal extraction; beneficiation; transportation; conversion and utilization; and transmission, distribution, and delivery. Impact levels vary by alternative according to changes in regional coal production and consumption levels.

The first section of this chapter (5.1) presents a general discussion of the methodologies used for the determination and analysis of impacts. The second section (5.2) gives a summary comparison of the regional impacts of the alternatives. Detailed data used to quantify the various impacts are provided in a series of appendices at the end of this statement. Section 5.3 describes the impacts by resource category that could occur under each of the alternatives. Finally, Section 5.4 discusses the impacts of several issue subalternatives which could affect the structure of any Federal coal management program. These subalternatives are based on the issues summarized in Table 3-1.

5.1 IMPACT ANALYSIS METHODOLOGIES

Chapter 3 of this programmatic environmental impact statement identifies seven Federal coal management program alternatives. The factors which most influence the varying levels of impact of the coal management program alternatives are the changes in regional coal production and consumption levels. These levels are used to estimate corresponding distributions of coal throughout the various activities related to coal development. For each activity, quantitative estimates for various environmental, social, and economic factors are then derived by region. Analysis of the impacts is done by assessing the influence of these factors on selected features of the environment. Where quantification of an

environmental, social, or economic factor is not feasible, a qualitative discussion is presented.

It should be emphasized that the programmatic nature of this impact statement precludes site-specific analyses. Such analyses will be developed in subsequent regional environmental studies. The focus of this statement, therefore, is on the national and interregional impacts of the coal management program alternatives.

The coal development activities which form the basis of the quantification of the environmental, social, and economic factors are described in Section 5.1.1. General methodological assumptions and guidelines for analysis of impacts are found in Section 5.1.2. Specific assumptions are stated with each impact discussion to ensure appropriate textual interpretation. In Section 5.1.3, a summary of the methodology used to calculate the environmental, economic, and social factors is given. The methodology is described in full detail in Appendix H. In this statement the term "environmental impact" is used interchangeably with "environmental effect." When reference is made to a quantifiable change in some individual feature of the environment, the term "impact factor" is used. When such a change is expressed in terms of a quantified amount (or normalized in the mathematical sense), the term "environmental loading factor" or "impact multiplier" is applied (e.g., pounds of solid waste produced per 100,000 tons of coal mined, or fatalities resulting per billion ton-miles of coal transported). Using the environmental loading factor as a multiplier (i.e., multiplying it by the number of appropriate units involved, such as 100,000 tons of coal mined or billion gross ton-miles of movement) results in a quantitative estimate of the impact.

5.1.1 Coal Development Cycle Activities

The activities that form the basis for analysis of impacts are those which occur from the time the coal resource is identified until the energy in the

coal is used by the consumption sector. As shown in Figure 5-1, the coal development cycle or sequence of coal development activities consists of six major activity areas. The figure also indicates which activities were analyzed with the aid of a computer program developed expressly for this purpose and those analyzed apart from the computer program. Associated with the major activities are a number of subactivities or phases in the coal development cycle. The major subactivity areas and phases are described briefly below. A more detailed discussion is contained in Appendix C, which also includes other information about coal such as how it was formed, its characteristics, and how it is used to meet energy demands. Figure 5-1

5.1.1.1 Coal Extraction. There are two major methods of extracting coal - underground mining and surface mining. Until about 1950, most underground mining was done by the conventional room and pillar technique. This entails mining coal in a series of rooms with the room separations serving as pillars to support the strata above. After a block, panel, or section has been mined, part of the coal in the pillars can be recovered as a retreat is made toward a main entry to the mine. Since 1950, continuous mining has become widely used. By this technique, an electric-powered machine rips the coal from the entire length of the working face while permitting the excavated sections to collapse behind it. This technique avoids the need to provide separate entries to undercut, drill, place explosives, blast, load, and roof bolt required by the conventional underground method.

Where coalbeds are relatively flat and near the surface as in much of the West, the surface mining method is employed. Here, overlying material is removed in long narrow cuts and the topsoil is segregated by distinct layers termed "horizons." The overburden material is placed into parallel cuts from which the coal has been removed and the topsoil is placed on top. In the East, where the terrain is steep, surface mining is generally accomplished by contour stripping. The overlying materials are removed by proceeding around the hillside, with the overburden cast down the hill. The exposed coal is then removed. This process continues until the overlying material becomes too thick to economically remove.

5.1.1.2 Coal Beneficiation. Two processing options were examined in this activity area of the coal development cycle: (1) crushing and screening and (2) mechanical cleaning. In the context of this analysis, crushing and screening refers to the removal of impurities such as clay, rock, shale, and pyrite. Mechanical cleaning includes operations beyond crushing and screening such as cleaning by pulsating air or by water to separate the coal and impurities [1]. Sometimes only crushing and screening is performed; sometimes both techniques are employed in tandem. Some coal is supplied to consuming areas without being processed, for example to plants which have their own cleaning facilities or which accept run-of-mine coal. Factors used to estimate impacts from crushing and screening and mechanical cleaning, and the amounts of coal to be processed by the two techniques, are discussed in Appendix H.

5.1.1.3 Coal Transportation. This activity area of the coal development cycle addresses conveying coal from the mine to conversion or utilization facilities (e.g., fossil fuel power plants or synthetic fuel plants). The four transport modes considered in the analysis are slurry pipeline, truck, railroad, and barge. In certain instances several transport modes are used for a given coal movement. For example, coal may be hauled from the mine area by off-road vehicles to a unit train and then to a barge loading point. As shown in Appendix H, loading factors to determine environmental impacts are developed for each type of transport.

5.1.1.4 Coal Conversion and Utilization. This part of the coal development cycle includes the conversion of coal for consumptive use. In order to expand the future use of coal, it is anticipated that certain existing gas and oil consuming facilities must convert to coal, and certain new facilities would be built to convert coal into substitutes for oil and gas. The subactivity options considered are use of coal as feedstock for electric power and industrial plants (steam electric option), conversion to substitute natural gas or oil (synthetic gas or synthetic liquid option), and production of coke for industrial processes (coke option). The rationale for allocating consumption to each of these options and the development of the loading factors used to estimate environmental impacts associated with the use of coal in each option are presented in Appendix H. Appendix C contains a more detailed

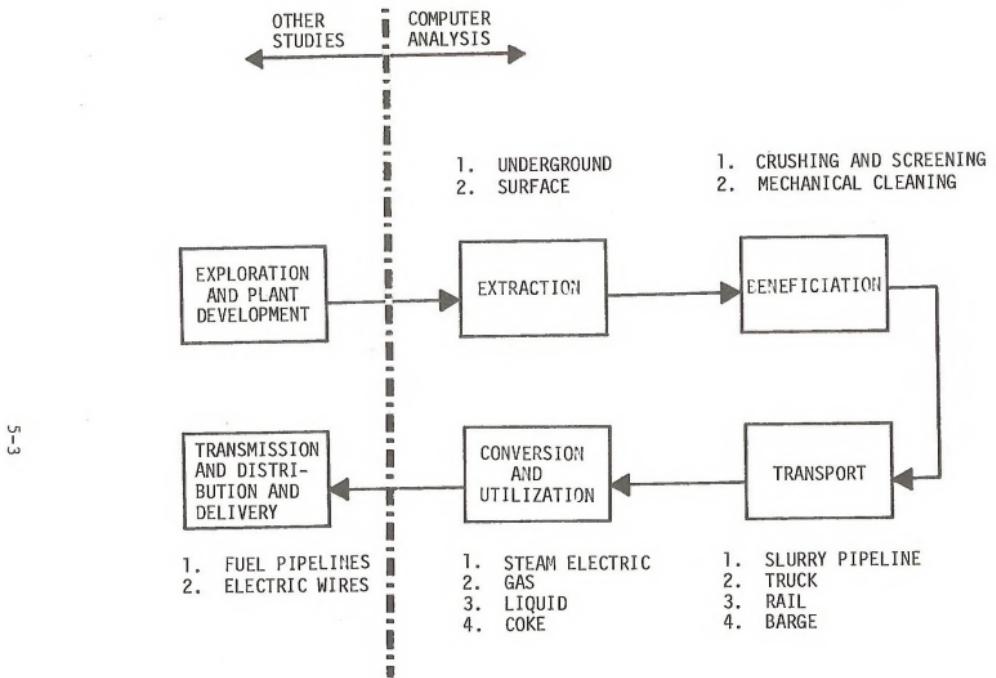

FIGURE 5-1
THE COAL DEVELOPMENT CYCLE

discussion of the processes involved in converting coal to satisfy these options.

5.1.1.5 Transmission, Distribution, and Delivery. This is the final major activity area in the coal development cycle. It involves the delivery of the electric power and substitute natural gas and oil to distribution centers. The two phases considered are the use of electric power lines and fuel pipelines. Factors were used to estimate the environmental impacts associated with constructing additional power lines to tie into an existing grid system and constructing additional pipelines to connect to existing interstate and intrastate pipelines. Appendix H provides the rationale for the loading factors used in this analysis.

5.1.2 Assumptions and Analysis Guidelines

Assumptions used to establish the limits and guidelines for analysis of programmatic impacts are presented in this section. The assumptions are set forth to aid in interpreting the magnitudes of the impacts that are forecasted. They also provide a base for future regional impact analysis forecasts.

5.1.2.1 Assumptions. The assumptions used in this analysis are as follows:

- Coal demand will encourage additional development of coal reserves.
- Coal energy requirements, on a Btu basis by coal consuming states in 1985 and 1990, are based on the Department of Energy's National Coal Model (NCM) demand assumptions (see section 5.1.3 and Appendix H).
- Coal mining and preparation technologies will not change significantly by 1990.
- Conversion of coal to synthetic gas and oil will be a commercial reality by 1985, but on a limited scale. Conversion on a large scale basis is not expected until after the year 2000.
- Labor, equipment, and capital shortages will not significantly distort the projected levels or timing of the Federal coal management program.
- No extensive delays will be encountered in obtaining required Federal, state, and local clearances for the Federal coal management program.
- Reclamation technology will not change significantly by 1990 and the major thrust

of reclamation would be to return disturbed land to the contour and use specified in the approved reclamation plan.

- Current best practicable pollution control technology will be used to minimize the emission of air pollutants by 1985.
- Current best available control technology will be used to minimize the release of water pollutants by 1985.
- Development of other resources in the Federal coal regions will not significantly interfere with coal resource development under the Federal coal management program.
- Coal energy demands projected by the Department of Energy for 1985 and 1990 for the high, medium, and low production levels will be met for all Federal coal management program alternatives. If, under a given strategy, production decreases in one or more regions, it would be compensated by increases in other regions.

5.1.2.2 Analysis Guidelines. The following guidelines were used in the analysis of impacts:

- There are twelve basic coal supply regions. For analysis purposes, the Appalachian Coal Region has been divided into three regions—Northern, Central, and Southern.
- Programmatic impacts for these twelve regions are analyzed for two points in time, 1985 and 1990.
- The impacts associated with the no new leasing program alternative closely approximate those of a no-action program alternative.
- The high and low coal production estimates associated with the preferred and no new leasing coal management program alternatives adequately include the possible ranges in coal production levels to be achieved in the 1985 and 1990 time periods.

5.1.3 Impact Estimation

The impact estimation performed in this programmatic statement for the several Federal coal management program alternatives is based to the maximum extent possible on quantification of environmental changes which would result from the operation of the various activities of the coal development cycle.

By necessity, some impacts can only be stated in general terms because of: (1) the absence of knowledge of the exact locations where coal mining and other activities would occur; (2) the lack of adequate methods to perform quantification; or (3) the absence of consistent regional base case information which can be applied uniformly among the twelve coal regions analyzed. A detailed accounting of pollutant-related impacts on specific air sheds or water bodies falls within the first class. Quantification of aesthetic impacts or changes in ecological community composition and diversity are examples of the second class of impacts which may be projected only in a general way.

In order to provide information on the anticipated impacts of a Federal coal management program, several analytical tools have been employed. Output from the Department of Energy's National Coal Model (NCM) has been used as the departure point for determining the quantities of the coal involved in the various activities of the coal development cycle [2]. This model is described in Appendix H.

An allocation methodology (i.e., algorithm) has been employed to adjust the NCM output for use in the present analysis. This algorithm (1) translates the 30 NCM coal production areas and 35 consumption areas to the 41 production areas and 53 consumption areas used in this environmental impact statement; and (2) estimates interregional flows from the 41 production areas to the 53 consumption areas.

The third analytical tool employed in the impact analysis is a computerized program developed for this statement, the Coal Impact Estimation Program (CIEP). This program is summarized below and a detailed description of the procedures employed is presented in Appendix H together with the program's basic inputs (coal production levels, coal transportation flows, coal consumption points and quantities, and environmental loading factors).

5.1.3.1 Derivation of Coal Production and Consumption Levels and Coal Flows. In June 1978, the Department of Energy (DOE) provided the Department of the Interior with the results from the NCM for low, medium, and high levels of coal production in 1985 and in 1990. These computer runs are starting points for the analysis of the

seven Federal coal management program alternatives.

The NCM uses a least economic cost methodology to estimate the level of coal production by surface and underground methods within 30 geographic areas. It further allocates this production by type of end use using the most economic transport routes to 35 geographic consuming areas. The primary model outputs are the production and consumption levels in each region and a 30 by 35 origin/destination coal flow matrix (i.e., a table in which the 30 coal producing areas from which the coal originates appear as rows, and the 35 consuming areas to which it is destined appear as columns; the number in each row-column intersection denotes the amount of coal produced in region A that is consumed in region B).

Since the NCM runs address different geographic coal production and consumption areas than used in this statement, it was necessary to translate the NCM outputs into this statement's 41 production areas and 53 consuming areas. In performing this redistribution, it was assumed that neither the proportionality of surface and underground mining nor the split between crushing and screening and mechanical beneficiation would vary from those in the NCM model and that the distribution among end uses of the coal would be a function of the coal energy demand assumptions included in the NCM. The translation and redistribution was manually and judgmentally performed for each of the six DOE projections (low, medium, and high for 1985 and 1990). The results of this effort are six separate 41 by 53 origin/destination coal flow matrices. The row totals of these matrices indicate regional production levels while the column totals represent regional consumption levels.

Given the supply, demand, and coal flow data on a 41 by 53 matrix basis, it was necessary to determine what differences would exist for each of the Federal coal management program alternatives: no new Federal leasing, the preferred program, processing of PRLAs only, emergency leasing, lease to meet DOE production goals, lease to satisfy industry indications of need, and state determination of leasing levels.

The low, medium, and high western regional coal production levels for each alternative management program for 1985 and 1990 were derived from the low, medium, and high 1985 and 1990

DOE production projections and a number of other sources of information. In the absence of an established procedure for estimating these regional production levels, decisions have been made based on the information available, including:

- DOE projections.
- Department of the Interior regional environmental impact statements on expansion of existing coal mines and development of proposed new coal mines.
- Coal industry and government forecasts.
- Expected production from approved and pending mine plans.
- Likely production from Federal leases without mine plans.
- Current coal production levels.
- Contractually obligated coal production.
- Coal lands ownership patterns.
- Indian coal ownership.
- Non-Federal coal ownership.

As an example of the judgmental considerations included in this adjustment process, projected production under the no new Federal leasing alternative took into account the amount of coal already available in existing Federal leases and the production potential of these leases. Many existing Federal leases are not expected to be in production by 1985 because of small size, environmental problems, high mining costs, poor quality coal, poor location, or other factors. If any of those leases would not be producing by 1986, it was assumed that they would be cancelled for failure to be diligently developed.

Another important consideration used in estimating the impact of a no new Federal leasing policy is the availability and production potential of non-Federal reserves in a given region. In many instances, non-Federal reserves would not be developed if complementary Federal reserves are not available. Significant portions of the reserves in the western coal regions are contained in checkerboard lands or in scattered blocks where the non-Federal coal holdings are often too small to form mines of economically efficient size without including adjacent Federal coal.

Special computer runs which used the DOE's NCM were made for the no new or restricted leasing alternatives. These runs were made by modifying the supply curves used in the NCM to correspond to the estimated reduced regional coal supplies that would be available under these

alternatives. Federal coal not in existing leases and non-Federal coal which requires new leasing of complementary Federal coal to be developed were eliminated from the supply considered available for regional coal development. The NCM was then rerun with this restricted coal supply in order to estimate the impacts on coal production by coal region.

One result obtained from the computer runs is that a number of western coal regions would show increases in coal production as a result of a no new Federal coal leasing policy. These regions already have major supplies of non-Federal coal or coal in existing Federal leases. Hence, when coal production is reduced in other western regions that are more dependent on new Federal leasing to sustain or increase production, some of the loss is displaced to western regions less dependent on new Federal leasing. In particular, the region in which achieving projected production levels is most dependent on new Federal leasing is the Powder River Coal Region in Wyoming and Montana. This region tends to lose production relative to projected levels while other western regions tend to gain production when Federal coal availability is tightly restricted. Production under a no new leasing policy also tends to be displaced to midwestern and eastern regions that have little Federal coal.

There are large reserves of Indian coal in the West. These reserves appear large enough that, were they to be rapidly developed, they could make up for virtually all production deficiencies caused by a no new leasing policy. However, there are many uncertainties relating to development of tribal coal reserves. For example, in Montana, the Cheyenne Indian Tribe has resisted expanded coal development and the Crow Indian Tribe recently cancelled existing coal leases in part on the basis of inadequate royalties. In estimating regional coal production levels for this environmental impact statement, it is assumed that there would not be a large expansion of Indian coal production to make up for production declines caused by a Federal decision not to lease additional Federal coal until at least 1985. However, already planned production from mines on Indian lands is considered part of the available coal supply under a no new leasing policy.

An additional factor complicating projections for the no new leasing and other Federal coal

management program alternatives is the extent to which existing operations could or would expand capacity in response to unsatisfied demands. While it is assumed that this would happen to some extent, the resulting additional production is not specifically quantified.

The distribution of western coal production under each program alternative was determined by the above process. An origin/destination matrix for each alternative was developed. The coal demand in each consuming region was specified by DOE for its runs on a Btu basis for the low, medium, and high DOE production projections for 1985 and 1990. The DOE production projections in each western region are similarly analyzed on a Btu basis, which then allows calculation of the flows in the origin/destination matrix.

Next, for each Federal coal management program alternative, a comparison was made between the Btus of energy produced in each region and that required to meet the DOE established consumption projection for each consuming region. Where differences existed, coal flows in terms of Btus of energy delivered were modified such that the net flow of coal-derived energy into each consumption region was held constant. After a supply-demand Btu equilibrium was again attained, the Btu production and consumption levels and Btu flows were converted back to coal tonnages. The result of this procedure was the generation of new coal flow origin/destination matrices for each alternative.

The last remaining task prior to the calculation of environmental impact factors for each alternative was a split of coal flows by transport mode from each origin (production area) through intermediate transshipment or transfer points to each destination (consumption area). Assumptions were made that the majority of coal movements between states would be by rail, a smaller volume of intrastate shipments within a state would be transported by rail, and the remainder by barge, highway, or slurry pipeline depending on existing and projected transportation facilities of these types.

In contrast to the other activities in the coal cycle (i.e., production and consumption), the characterization of coal flows in terms of tonnage does not result in a clear presentation of environmental impact factors. The measure chosen to determine transportation environmental impact

factors was gross ton-miles generated as a result of transporting coal. In this context, gross ton-miles is obtained by summing the following components:

- Net ton-miles - weight of coal times distance moved.
- Tare ton-miles - weight of transportation equipment utilized times round trip distance from mine to destination and return.

The inclusion of tare weight gives recognition to the fact that trains, trucks, and barges which haul coal also generate environmental impacts during the return trip to the coal mine or loading facility.

For each Federal coal management program alternative and production level, the methodology developed to estimate the level of gross ton-miles generated consisted of:

- Development of the origin/destination matrices for the gross tonnages of coal flows from producing regions to consuming regions.
- Identification of probable routes and length of route within each state between origin and destination.
- Calculation of the number of trips and coal tonnage flows within each state.
- Combination of volume of coal flow, distance, and transport mode to estimate gross ton-mileage generated per state and per region.

All of the above information formed the basis for estimation of environmental impact factors generated by the several Federal coal management program alternatives. The factors were enumerated through the use of another computerized procedure developed specially for this programmatic environmental impact statement. The outputs of this program, the Coal Impact Estimation Program (CIEP), were employed to determine the potential environmental impacts described later in this chapter.

5.1.3.2 Overview of the Coal Impact Estimation Program. The CIEP is designed to be highly flexible and reactive to the Federal coal management program alternatives for which impact estimates are required. As presently contemplated, it could be a major component of the Federal coal management program, and would employ specific levels of coal production and consumption in separate geographic areas. These levels are combined with the distributions of coal flowing into

each major activity in the coal development cycle and the results are multiplied by impact multipliers which correspond to environmental impact factors per 100,000 tons of coal or billion gross ton-miles. The impact factors treated in the CIEP are presented in Table 5-1.

An overview of the major modules within the CIEP is presented in the following sections. A more detailed description of the CIEP assumptions and structure is presented in Appendix H. The CIEP consists of the three major modules described below.

Main Impact Estimation Module. The Main Impact Estimation Module uses coal production and consumption estimates for each region of the country to produce numerical estimates of the resulting major environmental impacts. This is done by expressing coal production and consumption levels as flows through the coal development cycle. Once quantities of coal flowing into each activity in the coal cycle are determined for each geographic area, the environmental impact multipliers are applied to produce the following estimates:

- Air pollution – total suspended particulates (TSP), hydrocarbons (HC), carbon monoxide (CO), sulfur oxides (SO_2), nitrogen oxides (NO_x) and carbon dioxide (CO_2).
- Water use – makeup (effluent and evaporative loss).
- Disturbed acreage.
- Operational and construction employment.
- Solid wastes – active and inert.
- Accidents/Fatalities.
- Operating energy.

Estimates of the level of change of environmental impacts in each category for each geographic area and activity in the coal development cycle are produced by this module. These estimates are then used as input into either the socioeconomic or the ecological impact estimation modules of the CIEP.

Socioeconomic and Ecologic Impact Estimation Module. There are two major modules in the CIEP. The first makes use of estimates of the requirements for construction and operational workers at each activity of the coal development cycle to produce estimates of total population, infrastructure demands, and fiscal requirements on a regional basis. The second uses the acreage

disturbed throughout the coal development cycle, on both a long and short term basis, to produce estimates of agricultural productivity losses and decreases in wildlife habitat and total carrying capacity. Both modules produce impact estimates on an activity-by-activity basis for the production, transportation, and consumption elements of the coal development cycle. This feature identifies the estimated impact effects of mining and beneficiation, of transportation, and of consumption of coal by geographic area.

5.1.3.3 Coal Impact Estimation Program Inputs. The five major classes of coal-related information required to operate the CIEP are:

- Production levels.
- Transportation levels.
- Consumption levels.
- Coal development cycle flow distribution.
- Environmental impact multipliers.

The first four classes of information have been described in the foregoing sections. They are discussed in greater detail in Appendix H. The remaining input is presented below.

Environmental Impact Multipliers. Environmental impact multipliers are used to identify and quantify the social, economic, and environmental factors related to coal extraction, beneficiation, transportation, conversion, and utilization. These impact multipliers relate specific impacts to a 100,000 ton unit of coal. This approach is used in all activities in the coal development cycle with the exception of transportation. In the transportation area, estimates are made per billion gross ton-miles. By generally expressing all impacts in terms of tons of coal, impact estimates are made once coal production and consumption levels are determined. Even though some states would have no coal production, they could have transportation, conversion, and utilization flows resulting in environmental, social and economic impacts. Impact multipliers used as input to the main portion of the Coal Impact Estimation Program are defined for the major categories shown in Table 5-1. These multipliers vary for the 41 producing regions, overlain with 53 consuming regions. Additional multipliers are used for a broad range of social, economic, and environmental parameters incorporated into the subroutines of the CIEP.

5.1.3.4 Program Output. The CIEP produces estimates of impacts that can be reported according to analytical needs. The output reports can be presented geographically, by category, or by activity in the coal development cycle.

The program has the capability of subtotaling impact estimates for several distinct geographic areas, and aggregating and displaying the results on a regional basis. Examples of this capability include the aggregation of the separate portions of Colorado in the Green River-Hams Fork, Denver-Raton Mesa, San Juan River and Uinta-Southwestern Utah Coal Regions into estimates for the State of Colorado. The program also produces aggregate estimates for a total coal region (e.g., the Powder River Coal Region made up of the Powder River, Montana, and Powder River, Wyoming geographic areas). An additional optional report generated by the CIEP presents the level of coal flows into each activity in the coal development cycle.

The flexibility of the CIEP is demonstrated further by the ability to incorporate additional options in the output reports. The first feature allows estimates of impact levels accompanying various Federal coal management program alternatives to be compared to one another at a given point in time. The program output, when this feature is selected, represents the difference between the impact levels generated by the two alternatives. Program reports based on this output can be used for a rapid comparison of the broad effects of the alternatives in question. The second feature of the program is that it produces estimates of the change in environmental impacts for a specific program alternative between two points in time. The output feature of the CIEP is currently structured to produce impact estimates for the periods 1976 to 1985 and 1985 to 1990.

5.1.4 Other Impacts

The variability of potential impacts associated with certain resource categories precludes analysis in these areas on a quantitative basis. Because elements that influence the degree of impacts on these resources vary at individual locations, impacts at the programmatic level can only be described in general for each of the various activities of the coal development cycle. The resource categories in this case include topography, geology, minerals, soils, archaeological and

historical resources, and recreation. In addition, several resource impact categories can only be described generically.

5.2 REGIONAL IMPACTS SUMMARIES

This section contains summaries of the environmental, social, and economic impacts associated with the various Federal coal management programs. Section 5.3 contains a more detailed analysis of program effects, organized by impact area. This section presents a comparison of the effects of 10 representative impact areas for each of the 12 Federal coal regions. The 10 impact areas selected are as follows:

- Coal Production.
- Coal Consumption.
- Land Committed (independent of reclamation).
- Agriculture (value of crops lost).
- Population (coal-related only).
- Disabling Accidents (those resulting in man-days lost).
- Water (required to support the Federal coal management program).
- Game Animal Losses.
- Particulate Emissions (total suspended particulates).
- Sulfur Oxide Emissions.

Each of the above impact areas is examined on an annual basis for 1985 and 1990. For purposes of summarizing, each impact is presented as the percent change between the no new leasing (base case) alternative and the other six Federal coal management program alternatives.

A positive percent change (+) means that the impacts forecast for a Federal coal management program alternative exceed those forecast for the no new leasing base case. A negative percent change (-) means that the impacts forecast for a Federal coal management program alternative are less than those forecast for the base case. The percent changes thus signify the extent to which developments under a Federal coal management program alternative relate to those developments, under the no new leasing base case, from ongoing or prospective coal mining on private and public land already leased for, or otherwise committed to, coal mining. Whereas Section 5.3 (below) addresses impacts as a function of three coal production levels (low, medium, and high), only impacts associated with the medium coal produc-

tion level are addressed in this summary section. The medium level impact projections for the 10 impact areas are presented in a single table for each of the 12 coal regions. Percent changes in the ranges 10 to 19, 20 to 29, and greater than 30 percent between the no new leasing baseline and the six program alternatives are highlighted in these tables. As in Section 5.3 that follows, the differences between program alternatives are based on regional coal production and consumption projections derived from the NCM and on quantified estimates of environmental, social, and economic impact factors provided for each region by the Department of the Interior's Coal Impact Estimation Program (CIEP). The environmental impacts of each alternative in each region will be a function of the combination of effects attributable to the production, transportation and use of coal and site-specific factors in each region. Accordingly, the reader of this summary section should refer to Section 5.3 (and related appendices) for details about the impact assessment process.

The material contained in the 12 regional summary tables has been aggregated to permit the reader to observe how differences for the 10 impact areas vary across the coal regions. Tables 5-14 to 5-17 (following Section 5.2.10), display these differences.

5.2.1 The Appalachian Coal Region

As discussed in Chapter 4, Description of Regional Environments, the Appalachian Coal Region extends over nine eastern states and contains an estimated 103 billion tons of coal reserves. For purposes of the presentation in this environmental impact statement, the region has been divided into three regions which are referred to as the Northern, Central, and Southern Appalachian Coal Regions.

Tables 5-2, 5-3, and 5-4 provide estimates of the ten impact areas selected for discussion in this summary section. As shown in these tables, impacts projected for 1985 will generally decrease under the six Federal coal management program alternatives as compared with the no new leasing base case. In 1990, the trend is reversed and the impacts tend to increase. For the preferred alternative, coal production and consumption in 1985 and 1990 does not vary from the baseline case in the Northern Appalachian Coal Region and

varies only slightly in the Central and Southern Appalachian Coal Regions.

The socioeconomic characteristics of the three regions differ widely. The Northern and Southern Appalachian Coal Regions currently employ a very small portion of their total labor forces in coal-related industries (about six percent). Thus, more significant impacts in terms of numbers of persons involved would be anticipated in the Central Appalachian Coal Region as coal production and/or consumption caused coal-related populations to change.

No significant impacts are projected for the Northern Appalachian Coal Region in 1985 for any of the program alternatives considered. In 1990, for all alternatives considered, with the exception of the preferred program and the lease to meet DOE goals alternative, related population levels are projected to increase by more than 11 percent (+11.3 to +23.3 percent). These population increases are anticipated primarily as a result of shifts from surface mining to more labor-intensive underground mining techniques.

Significant changes in population are projected in the Central Appalachian Coal Region in 1985 under the lease to meet industry needs alternative, the lease to meet DOE goals alternative and the state determination of leasing levels alternative (-59.3, -10.2 and +24.9 percent, respectively). These population changes are projected to occur as a result of anticipated production changes (increased production for the meet industry needs and meet DOE goals alternatives, decreased production for state determination alternatives). In 1990, only the lease to meet industry needs and lease to meet DOE goals alternatives are projected to result in significant impacts in the Central Appalachian Coal Region. Population changes under these alternatives are projected to vary by +11.2 percent and -13.7 percent, respectively, from 1990 base case conditions. These changes are anticipated as a result of projected production changes for the two program alternatives identified.

The increase in coal-related population in 1990 under the preferred alternative for the Southern Appalachian Coal Region primarily results from a shift from surface mining to underground mining, the latter being more labor-intensive.

For the lease to meet industry needs alternative, significant increases in coal production are estimated for the Southern Appalachian Coal

Region (+14.9 percent in 1985 and +15.1 percent in 1990). This is attributed to an industry preference for expanding production for both underground and surface mining in this region. For the lease to meet DOE production goals and state determination of leasing levels alternatives, significant decreases in production are estimated in both 1985 and 1990 for the Southern Appalachian Coal Region; associated directly with the production decreases are the forecasted population decreases.

As addressed in Section 4.1.1 above, the frequency and persistence of atmospheric inversions in the Appalachian Coal Regions tends to aggravate air quality problems. National Ambient Air Quality Standards for sulfur dioxide and suspended particulate matter are being currently exceeded in the heavily industrialized and mined areas in the regions. As shown in the tables, air emissions associated with the six Federal coal management program alternatives for 1985 and 1990 should have a negligible impact on ambient air quality in the regions as compared with the impacts associated with the base case for the same years.

Since the three coal regions have an abundant supply of surface water, and groundwater does not play as significant a role in the survival of man, plants, and animals as in the West, water use under the Federal coal management program is not an important consideration. Natural primary productivity (what the land produces without human intervention) is moderate to high in the three coal regions (8.9 tons per acre per year in forests to 17.8 tons per acre per year in flood-plain areas); this productivity rate in combination with excellent climatic conditions results in a high potential for reclamation of coal-disturbed land within the regions.

5.2.2 The Eastern Interior Coal Region

This coal region is primarily located in Illinois with smaller portions in Indiana, Kentucky, and Iowa. The Eastern Interior Coal Region contains an estimated 88.9 billion tons of coal reserves which are predominately low-volatility bituminous in rank. As shown in Table 5-5, percent changes in impacts associated with the Federal coal management program alternatives over the no new leasing (base case) alternative are slight. All of the program alternatives except for the lease to meet industry needs and the state determination of

leasing levels alternatives show little or no real change.

With its favorable precipitation patterns and two major waterways (Mississippi and Ohio Rivers), the coal region generally has plentiful supplies of water. Although some communities have had difficulty obtaining wells yielding quality water supplies at reasonable costs, fresh groundwater in at least small to medium quantities is not generally difficult to develop. Additional water required to support implementation of any of the Federal coal management program alternatives is not considered a significant problem.

The region has supported extensive agricultural development in the past. Much of the natural vegetation has been removed and only about 15 percent of the region is forested. Accordingly, most wildlife in the region is compatible with man's activities. Little impact on land use, agriculture, and wildlife is thus forecast as a result of any of the Federal coal management program alternatives. Furthermore, the ecosystems within the region should adequately recover from program impacts. With proper soil conditions, natural succession is expected to return grasslands to a near original state within a decade.

A minor increase in production is forecast for the preferred program in 1985 (1.7 percent increase over the no new leasing basecase). This is paralleled by a minor increase in the coal-related population (two percent increase). These impacts should not cause major problems for the region's existing economy and social structure since coal production has traditionally played an important role in the region's industrial development. In point of fact, these trends are shown to reverse in 1990, indicating that coal-related activities in the Eastern Interior Coal Region are not dependent upon the Federal coal management program; the extent of these activities is dependent upon what has been forecast for the no new leasing base case.

5.2.3 Western Interior Coal Region

Major portions of this coal region are located in Missouri, Iowa, Kansas, and Oklahoma; minor portions are located in southeast Nebraska and northwest Arkansas. The Western Interior Coal Region has an estimated coal reserve base of approximately 15.6 billion tons. This reserve base is mostly high-volatility bituminous coal. There is

some coking coal located in Arkansas and Oklahoma.

Following general trends exhibited in the other eastern coal regions, impacts associated with the Federal coal management program alternatives are shown, with one exception, to be less than those associated with the no new leasing (base case) alternative. As shown in Table 5-6, impacts associated with the state determination of leasing levels alternative are projected to exceed the base case significantly. This is a reflection of the increased coal production in 1985 (+11.2 percent) and in 1990 (+37.3 percent).

The region has traditionally supported agriculture as the dominant land use. However, although coal is plentiful in the region, production is principally in eastern Oklahoma where the region's less productive agricultural areas are currently located.

Due to the nation's energy problems of recent years, coal production which had been steadily declining has revived and is now near the maximum annual production rate reached in 1920. Both water and land based transportation systems used by coal mining activities are adequate to support increased demands in this regard. Thus, the region has already initiated many of the changes (i.e., labor force, social structure, transportation systems) needed to accommodate increasing dependence on coal as an economic base. Environmental impacts associated with the implementation of the preferred Federal coal management program would thus be minor. Since the region has an adequate water supply and the climate is generally favorable, ecosystems native to the region are able to regenerate well. This is a desirable feature of this coal region; it implies that land that has been disturbed due to coal-related activities will rapidly regain natural primary productivity.

5.2.4 The Texas Coal Region

This region consists mostly of a portion of east Texas and a small portion of northwest Louisiana. Currently, the region's lignite reserves are estimated to be 3.3 billion tons. Other significant mineral resources such as petroleum and natural gas are also present.

As indicated in Table 5-7, all key impact areas for the preferred program alternative and most impact areas for the state determination of leasing levels alternative are shown to increase in 1985; in

1990, all six program alternatives show a decrease in impact areas as compared with the no new leasing base case.

With respect to 1985, impacts for the preferred program due to increased production may be significant. Although the region receives about 48 inches of precipitation per year in the northeast, only 16 inches are received in the southwest. As a result, the southwest is relatively arid and periodic droughts are experienced. Generally, groundwater is abundant and of good quality; very high yields (over 1,000 gallons per minute) have been obtained from both bedrock and alluvial aquifers. The ecosystems within the region are not particularly fragile so that a fair degree of disruption can be tolerated with an eventual return to a natural state. Finally, the region has a gently rolling topography which is not especially vulnerable to erosion. For these reasons, the land disturbed as a result of a Federal coal management program can be adequately reclaimed.

No major development of the region's lignite deposits has occurred to date. Thus, forecasts of production increases in the region in 1985 under the preferred program will require changes in the region's industrial development pattern. The region currently exports more oil and gas than it consumes, and this export demand has stimulated development of a transportation network accommodating the transport of bulk commodities, as well as people and the necessities of life. Industrial growth has been termed phenomenal and an adequate labor pool is considered to be available to support the demands of a Federal coal management program.

5.2.5 The Powder River Coal Region

This coal region includes portions of Montana and Wyoming. The region contains about 142.5 billion tons of sub-bituminous coal. The beds are thickest in the northern parts of the region (Montana). Most of this coal lies in near-surface beds that are readily amenable to surface mining.

As shown in Table 5-8, significant impacts are forecast for the region in 1990, with one exception, for all Federal coal management program alternatives. Except for the state determination of leasing levels alternative, where a decrease in production is projected, percent changes in production range from +3.6 percent (emergency leasing only) to +47.5 percent (lease to meet industry needs).

Impacts associated with the preferred program are especially significant (31.1 percent production increase and 78.3 percent population increase, for example).

Several features of the region magnify the severity of the impacts shown in the table for 1990. Seventy-five percent of the region's average annual precipitation of 14 inches falls between April and September; flooding is common in the spring when rapid snow melt produces heavy run-off. Though the region is classified as semi-arid, it varies from humid in some years to arid in others and is never predictable. Thus the climate of the coal region militates against attempts to minimize the consequences of disturbing the land and to maximize its subsequent reclamation.

Air quality in the region is generally good. However, the changes in 1990 in particulate emissions projected for the preferred program (+24.1 percent), lease to meet industry needs alternative (+36.7 percent), and lease to meet DOE production goals alternative (+23.3 percent) indicate that air quality in this coal region may be severely degraded should any of these alternatives be implemented.

Surface water and groundwater quality are both variable. Although such water may be chemically suitable to support Federal coal management program activities, the quantity of water available for such activities may be limited.

Ranching and farming are the predominant lifestyles in the region; however, exploitation of oil, gas, and uranium resources has spurred mining developments in recent years. Although population growth has been generally slow in recent years, stability has been disrupted on a local basis by the boom town phenomenon, with Gillette and Sheridan, Wyoming, being notable examples. As a result of increased demands for water, labor, and land associated with developments under the Federal coal management program, the stability of existing lifestyles and socioeconomic structure in the coal region is threatened.

5.2.6 The Green River-Hams Fork Coal Region

This coal region is composed of two contiguous coal regions (Green River and Hams Fork) in extreme western Wyoming, northwestern Colorado, and small portions of Utah and Idaho. Total reserves are estimated to be 15.6 billion tons in the Green River-Hams Fork Coal Region. The coal

beds in southwestern Wyoming and northern Colorado range in thickness from a few inches to about 40 feet. Most of this coal is deeply buried and it is not considered economical to extract it using current mining technologies. The coal beds in the rest of the region (western Wyoming, Utah, and Idaho) range up to 100 feet thick with some high quality coals up to 20 feet thick. Steep dips, however, make mining of these beds difficult.

As indicated in Table 5-9, coal production in 1990 in this region due to implementation of the preferred program is forecast to increase substantially (+21.5 percent) over the no new leasing (base case) alternative. Correspondingly significant increases in population (+51.3 percent), land committed (+16.7 percent), and particulate emissions (+12.9 percent) are also indicated for 1990. The impacts associated with the preferred program in 1985 are not as large as those in 1990 (+5.2 percent for production, +7.3 percent for population, for example), but they still pose a threat.

There is wide variation in the magnitudes of impacts forecast for the region in both years among the Federal coal management program alternatives. Under the state determination of leasing levels alternative, coal production in the region would be severely constrained. For the lease to meet industry needs and lease to meet DOE production goals alternatives, the reverse is true; production would be greatly emphasized and all impacts would be correspondingly magnified. In terms of coal production and impacts, the preferred program strikes a balance between the extremes associated with these three alternatives.

Although overall regional air quality is very good, there are localities like Craig, Colorado; Sweetwater County, Wyoming; and Soda Springs, Idaho, where particulates concentrations exceed national standards. It is difficult to relate the particulate emission increases forecast for 1985 and 1990 to particulate concentrations without being site-specific and performing detailed air quality studies. However, it can be stated that the increases in particulate emissions shown for the preferred program will degrade air quality; air quality in localities that are near to or exceed national standards for particulates may be further degraded.

A serious problem is expected in supplying the water needed to support preferred program activities. Though many of the large streams in the

region are perennial (like the Green and Yampa Rivers), most of the tributaries are intermittent. The region is thus subject to droughts. Groundwater found in alluvial deposits is of good quality and moderate yields can be obtained. However, pumping from these aquifers is restricted by the states because of appropriated water rights or interference with nearby stream flows. Yields from sandstone aquifers and limestone aquifers are highly variable depending upon permeability. In general, water quality throughout the region has not been fully explored. Not only is the water impact forecast a very real concern because of the water availability and water quality issues, but also because of the constraints it may impose on other non-coal related development activities in the region.

The region contains vast public lands and large ranches, and a low population density (2.6 persons per square mile (1975 data)). Construction of additional housing has not kept pace with demand and there is currently a housing shortage in many of the region's communities. The large increase in coal-related population for 1990 (+51.3 percent over the no new leasing base case) will aggravate this situation unless appropriate measures are taken.

The agricultural sector currently accounts for 10 percent of the region's work force. The value of agricultural crops lost due to mining is forecast to be significant in 1990 (+17.1 percent increase over the base case). Serious changes in the lifestyles of residents in the region have occurred in some areas. These changes will continue whether or not local workers leave agricultural employment for employment in activities related to a Federal coal management program.

There have been recent increases in the levels of development of natural resources in the region, particularly coal, trona, oil, and gas, which have influenced the creation of new communities. The lifestyles of the new residents and their reliance on industry for employment opportunities have combined to alter the typically western character of the region. Since forecasts associated with implementation of the preferred program show increases in coal production, population, water demands, and land committed over the no new leasing base case, it is expected that the character of the region will be altered even more.

Considerable land area is projected to be disturbed for roads, utility corridors, and coal facilities. Since the region consists of a series of parallel mountain ranges and valleys, reclamation of coal-disturbed lands is highly site-specific. Because of the varying topography, soil types, and precipitation rates in the region, the reclamation process is further complicated.

5.2.7 The Fort Union Coal Region

The largest coal region in the Northern Great Plains Province, the Fort Union Coal Region, includes portions of eastern Montana, northwestern South Dakota, and western North Dakota. Significant amounts of coal are located in this region. Reserves of 440 billion tons of lignite, ranging to 1500 feet thick, are estimated in the South Dakota and Montana portions of the region. About 23.1 billion tons of subbituminous reserves are estimated to be surface-mineable from North Dakota westward into Montana.

Table 5-10 indicates the extent of the impacts projected for the Federal coal management program alternatives. The table shows that, in 1985, coal production under the preferred program would not change from the level of the no new leasing base case. The other impact areas (except for disabling accidents) are shown to increase in 1985, some significantly. The explanation for these seeming inconsistencies is that although coal production remains constant under the preferred program, coal consumption in the coal region increases significantly (+11.6 percent); the increases in population, water, air emissions, and other impacts are associated with the projected operation of a modest-sized synthetic fuels high-Btu coal gasification plant within the region. By 1990, coal production in the region under the preferred program is forecast to be much less (-17.8 percent) than that associated with the no new leasing base case, while coal consumption remains the same as the base case. As a result, in 1990 the impacts in other key areas are much less than the base case. These may or may not be desirable impacts, however, depending upon the economic stimulation generated and the stresses that the local social and economic structures would have to endure.

Under the state determination of leasing levels alternative, production is slated to be greater in 1985 over the preferred program (+17.2 percent).

This is due to the preference of North Dakota to intensify development of its coal resources. Relative increases in population under the program alternatives reflect a move towards greater overall industrialization in the region. For the lease to meet industry needs alternative, the same general comments apply. The situation reverses itself for the lease to meet DOE production goals alternative where coal production is forecast to be reduced significantly as compared to both the no new leasing base case and the preferred program. As regards these three alternatives (lease to meet industry needs, lease to meet DOE production goals, and state determination of leasing levels), the preferred program strikes a balance between the impact extremes.

Air quality in the region is well within National Ambient Air Quality Standards, especially for particulates and sulfur dioxide. Increased air emissions in 1985 resulting from greater coal consumption under the preferred program will degrade this air quality. However, since these impacts cannot be quantified until specific sites have been studied, it cannot be said that air quality in the region will reach or exceed National Ambient Air Quality Standards.

Groundwater is available throughout the region but only in small to moderate amounts. Surface water is limited throughout the region, except for those areas adjacent to the Missouri and Yellowstone Rivers. Water availability could cause severe problems depending upon where the coal-related activities are sited. The greatest potential for groundwater development is along the Missouri and Yellowstone Rivers and from the deep coal bearing formations themselves.

The infrastructure of the region is typically rural western. Increases in social demands associated with the preferred program due to the population influx projected for 1985 will strain limited service facilities. Agriculture, presently a dominant pursuit in the region, may have to give way to coal-related industrial developments. The lifestyles of the older residents may be adversely affected by coal resource developments and new residents.

5.2.8 The San Juan River Coal Region

This region covers the Four Corners area of the southwest including portions of New Mexico, Colorado, and Utah. The total estimated reserve

base in the San Juan River Coal Region is 4.2 billion tons. Coals within the region rank from high-volatile A to B bituminous, to discontinuous and dirty coals that are high-volatile C to B bituminous with high ash content.

As presented in Table 5-11, percent changes in key impact areas for the preferred program as compared with the no new leasing base case are essentially negligible in 1985 and significantly lower in 1990. This indicates that the major coal-related impacts to be felt in the region in these years would result from mining on existing Federal leases and from mines not dependent on Federal coal. There is some variation in projected impacts among several of the other Federal coal management program alternatives. Under both the lease to meet industry needs and the state determination of leasing levels alternatives, significant production increases from additional mining are indicated for 1985 (+20.9 percent and +29.0 percent, respectively, over the base case). As expected, production increases result in additional land disturbed, an influx of people for the region, and more particulate emissions due to fugitive dust from the surface mining activities. To the opposite extreme, the lease to meet DOE production goals alternative would result in a large decrease (-10.8 percent) in coal production. Other key impact areas for this alternative decrease accordingly.

The quantity and quality of water required to support any additional developments in the region, let alone the demands projected under the no new leasing base case, are a crucial issue. The region is essentially a desert environment. The quality of groundwater, where it can be found, is only fair. Currently, pumping to support coal and uranium mining in the Gallup, New Mexico area exceeds aquifer replacement capabilities. Annual precipitation is generally less than 10 inches for most of the region. An aggravating factor is that potential evaporation exceeds normal precipitation many times over. Only the San Juan River receives flow from outside the region. Surface reservoirs have been constructed to store the region's water and to control the floods created by summer thunderstorms and spring snowmelt. From a water consumption viewpoint, the preferred program requires less water in 1990 than the no new leasing base case.

Impacts of the preferred program on the region's air quality and its lifestyles are forecast to

be negligible. Any undesirable impacts associated with the preferred program in these impact areas or any of the others will be relatively equivalent to those projected for the no new leasing base case.

5.2.9 The Uinta-Southwestern Utah Coal Region

Included within this region are portions of Colorado and Utah. The region is characterized by extremely steep slopes and narrow vertically-walled canyons. At least 7.2 billion tons of coal reserves are estimated to be in the region, with most deposits in the flanks of major peaks and plateaus. Coal mining, which until recently had declined because of competition from natural gas and fuel oil, has become active again after being spurred by energy shortages. Several large coal-fired power plants have been constructed in the region.

Table 5-12 presents comparative data on key impact areas for the Federal coal management program alternatives and the no new leasing base case. Production projected for the preferred program is shown to be slightly greater (+1.3 percent) than the base case in 1985. This greater production is accompanied by increases in other impact areas. In 1990, the impacts associated with the preferred program are much less than those for the base case because of the lower coal production (-15.8 percent).

Several of the program alternatives show wide swings in impacts as compared to the preferred and no new leasing alternatives. For the lease to meet industry needs alternative, an increase in production of five million tons in 1985 (+18.2 percent change over the base case) is forecast to be accompanied by large impacts in land disturbance, population growth, and air quality. Conversely, the lower production (-10.8 percent) associated with the lease to meet DOE production goals alternative is accompanied by much less severe impacts in these other areas.

Air quality is currently well within National Ambient Air Quality Standards in rural areas of the region. Problems do exist, however, in closed valleys where industrial and urban emissions become trapped. Although the emissions impacts for the preferred program are forecast to be slight in 1985 (+2.3 percent change over the base case for particulates and +2.6 percent for sulfur oxides), there will be some degradation of air quality. The other Federal coal management

alternatives are also forecast to adversely affect regional air quality. Since coal operations will take place where adverse temperature inversions are expected to occur, localized problems are likely to be experienced in 1985. In 1990, air quality impacts associated with the six Federal coal management program alternatives are forecast to be negligible.

As regards water impacts, most streams in the region diminish in size as they flow from the mountains. This seeming contradiction is due to a combination of low precipitation coupled with high evaporation, and diversions for irrigation. Tributaries originating at lower elevations are intermittent. As compared with the no new leasing base case, the six Federal coal management program alternatives are forecast not only to draw down more of the existing short supplies in the region in 1985 but, also to further degrade water quality by subjecting more land to erosion. Similar impacts on water quality and quantity in 1990 are estimated to be negligible as compared with the base case.

The region experienced a uranium boom following World War II. When the demand eased, the uranium-induced population left the area. The increase in coal-related population under the preferred program is nominal (+2.4 percent change over the base case), but in a region so sparsely populated and rural in nature the impact could be significant. Housing stocks used by the uranium boom-induced population have deteriorated such that existing, habitable stocks of vacant housing are inadequate to meet the needs of projected coal-induced population increases. Existing population centers are far apart and distant from the coal deposits. Many communities have housing shortages and social services are limited.

The availability of facilities to transport coal to markets is limited in the region. Highway and rail systems must undergo extensive development by 1985 to support increased coal-related development activities associated with a Federal coal management program.

5.2.10 The Denver-Raton Mesa Coal Region

This coal region consists of portions of Colorado and New Mexico. The Denver Basin part of the region contains coal beds up to 17 feet thick in the Laramie Formation; extensive coal beds also exist in the Denver Formation in an area about 75 miles

long by 30 miles wide. In the other part of the region, Raton Mesa, coal beds are mostly two to five feet thick, ranging to 15 feet. Much of this coal outcrops but surface-mineable reserves are low. A number of the beds are under overburden 1,000 to 3,000 feet thick. The region is estimated to contain about 3.9 billion tons of demonstrated reserves.

In 1976, the region's consumption of coal far surpassed its production (5.2 million tons consumed, 1.9 million tons produced). As presented in Table 5-13, this trend is forecast to continue in 1985 and 1990 under the preferred program but at much higher absolute levels. In 1985, 20 million tons are estimated to be consumed and five million tons produced. In 1990, 30.3 million tons would be consumed and 10 million tons produced. Whereas the same tonnage would be produced in 1985 as the no new leasing base case, positive impacts greater than the base case are shown because of the increase in consumption. These impacts are considerably less than those associated with three of the other Federal coal management program alternatives (lease to meet industry needs, lease to meet DOE production goals, and state determination of leasing levels). The impacts may be significant depending upon where site-specific activities take place. The increases in air emissions and land committed for the preferred program are attributable to greater coal consumption within the region than are associated with the base case. In other words, the preferred program forecasts greater industrial development that depends upon coal as an energy source.

Overall regional air quality is quite good; however, there are areas where it fails to meet National Ambient Air Quality Standards. This degradation is primarily due to automotive emissions coupled with temperature inversions. Under the preferred program, air quality would be degraded in the region. Without knowing the location of the pollutant sources it cannot be said that resulting air quality on a regional basis would be bad.

Water is in short supply in the region. Water is imported from western Colorado to meet regional municipal, irrigational, and industrial needs. The demands for water to support a Federal coal management program in 1985 would aggravate the situation.

The region has seen rapid population growth during the last 15 years (about a 35 percent

increase). Public and service facilities in the Denver portion of the region are well-developed and probably can be expanded to meet coal development requirements. However, this is not the case in the Raton Mesa section of the region where communities are small and less able to handle rapid growth.

5.3 PROGRAM IMPACTS

This section discusses in greater detail than the summaries in Section 5.2 the impacts that could result from implementing the various alternatives for a Federal coal management program. To provide a proper perspective, the analysis first examines how much coal will be produced and consumed in each region under each of the program alternatives. This introductory material is then followed by detailed analyses of impacts in the following categories: physical, ecological, socioeconomic (urban effects), transportation system, and operating energy requirements. Each subsection discusses a particular category of impact for the various regions and a particular category of impact under the different program alternatives. Although impacts are discussed individually, they are interrelated. For example, land disturbance results in habitat loss, productivity loss, and other physical impacts. Likewise, population changes frequently lead to impacts on employment, health and safety, recreation, and income accruing to local governments through taxation.

Impacts are analyzed for two program time frames, 1985 and 1990, and are related to a base year, typically 1976. For each Federal coal management program alternative, the effects of a medium-level projection of coal production are examined; for two alternatives, the no new leasing and the preferred alternatives, the impacts resulting from the high and low coal production projections are also considered. The no new leasing alternative represents the "no-action" alternative and the other six program alternatives are compared to it. In this regard, it must be emphasized that the impacts attributable to the Federal coal management program would be only a small fraction of those resulting from meeting national coal requirements. Finally, except in the discussion of water impacts, impacts attributable to normal economic growth projections are not addressed. Growth which would normally occur in the 12 Federal regions and be considered due to

non coal-related developments has not been considered in this impact statement.

5.3.1 Coal Production and Consumption

This section presents an overview of the broad interregional shifts in coal production and consumption associated with the Federal coal management program alternatives. Much of the discussion is based on the analysis of the role and need for Federal and western coal presented in Chapter 2 and the description of the impact methodology in Section 5.1.3 of this chapter. This section concludes with a discussion of the implications of the methodological approach employed for this programmatic environmental impact statement.

5.3.1.1 Regional Coal Considerations. The amount of coal produced and consumed in each region is summarized in Tables 5-18 and 5-19, respectively. For comparative purposes the differences in coal production between the no new leasing alternative and each of the other alternatives is shown in Table 5-20. For the preferred program and for the no new leasing alternative, data are presented for the high, medium, and low production estimates. For the other alternatives, only the medium production level is tabulated. For all alternatives the medium level is the only production level regularly addressed in the textual discussion.

The no new leasing alternative is considered as a base case against which the other alternatives are compared, as in Table 5-20, for example. Under this alternative, the supply of Federal coal available for development would be limited to coal already under lease or coal which may be leased under the consent agreement in *NRDC v. Hughes*. This could, nevertheless, result in a significant increase in Federal coal production, as already existing leases alone now have a 1985 planned production of 308.6 million tons (see Table 2-20). Adding in other likely production (see Table 2-21), total planned and likely production from existing Federal leases in 1985 is 366 million tons. With the addition of planned production from Indian and other non-Federal lands, total 1985 planned and likely production in the western states comes to 422.2 million tons (see Table 2-29). Essentially none of this production depends on new leasing. In 1985, western coal production under the no new leasing alternative would be 34 percent of total U.S. production (compared to 16 percent in 1976) as shown in Table 5-18. For most alternatives, the

differences in western coal production are less than one percent of this base case projection. An exception is the lease to meet industry needs alternative under which western coal is estimated to increase (at the medium level of production) by 20 percent to over 450 million tons.

By 1990, however, the western production projections would show more pronounced changes among the alternatives. For example, western production under the no new leasing alternative would be 38 percent of U.S. production, compared to 43 percent under the preferred program, 49 percent under the lease to meet industry needs alternative, and 34 percent under the state determination of leasing levels alternative. Within the western regions, the greatest fluctuations in absolute terms would be experienced within the Powder River Coal Region. The lease to meet industry needs and lease to meet DOE production goals alternatives project 1990 production from this region at 450 million tons and 396 million tons, respectively. The medium projection under the no new leasing alternative would result in the production of 305 million tons.

Given the Powder River Coal Region's land ownership patterns and the economic desirability of the coal resources, this disparity is to be expected. The coal industry, as any private enterprise, seeks to maximize profits in part by minimizing costs. Producers are attracted to the Powder River Coal Region's fields in Wyoming and Montana with their thick coal seams and relatively low ratio of seam thickness to overburden. The NCM production projections are based on a least cost linear programming model. A program of leasing to meet industry needs would emphasize production of this economically attractive coal. On the other hand, a policy of no new leasing would restrict available production both by preventing expansion of the Federal coal lease reserve base and by affecting the economic viability of private coal dependent upon adjacent Federal reserves for their development. The Powder River Coal Region is highly dependent on Federal leasing to expand production beyond currently planned levels. Between the two alternatives there is a difference in medium level projections for Powder River production of over 20 million tons in 1985 and 145 million tons in 1990.

Changes in western production from one alternative to another would lead to reactive

(a) Land required for facilities and coal production (mining) in 1985 and 1990 under the No New Leasing Alternative.
Remaining columns represent differences from the No New Leasing Levels.

changes in eastern and midwestern coal production. This result follows from the assumption that total regional energy demands (on a Btu basis) remain invariant under the program alternatives analyzed (for given low, medium, or high demand assumptions). Thus, when the supply of western coal is assumed to decline under a given leasing alternative (for example, state determination of leasing levels), greater output from other coal fields is projected to take up the excess. The adjustments resulting from different western production levels create the greatest supply fluctuations in regions that are geographically close to the western coal supply areas, namely the Texas, Eastern Interior, and Western Interior Coal Regions. For example, should the supply of coal in the Powder River Coal Region projected to flow to the Texas Coal Region markets be restricted under the no new leasing alternative, the energy shortfall would not be expected to be made up with coal supplied from the East, but from elsewhere in the West and Midwest.

5.3.1.2 Implications of Methodological Approach. As discussed in Section 5.1, in defining production levels and flow distributions for the Federal coal management program alternatives, it was assumed that Btu demand in each of the 53 geographical consumption areas analyzed would be specified at a constant level for each of the production levels in 1985 and 1990. For example, the Btu demand in the Northern Appalachian Coal Region at the medium production level would be constant for all mid-level production program alternatives analyzed. The specified area demand levels (in terms of total Btus of energy) correspond to the lease to meet DOE production goals levels as derived from the NCM output. Because the Btu content of coal from various sources differs, the projected tonnage will also vary under these alternatives where differing amounts of coal from each region are projected. The Btu consumption, however, is assumed to remain constant for each level (i.e., high, medium and low).

The primary advantage of this assumption is that it enables a rapid redistribution of coal flows in response to projected changes in the level of future western coal production. Other approaches were not available to generate comparable data essential to the timely completion of this environmental impact statement. Major implications of

the constant demand and related methodological assumptions are discussed below.

The first implication relates to the general acceptability of the NCM high, medium, and low coal demand estimates. The NCM projects a 1985 medium level demand of 1.1 billion tons, a 64 percent increase over the 1976 production of 674 million tons. Many believe growth of this magnitude is overly optimistic, particularly in view of the myriad of uncertainties involved in estimating coal demand at such high levels over the relatively short time between 1979 and 1985. A new iteration of the NCM, may, with updated assumptions such as competing fuel costs, transportation rates, and environmental control standards, produce total United States coal demand projections which would be more generally accepted by governmental and industry spokesmen. Nevertheless, for the purposes of this environmental impact statement, the projections derived from NCM output effectively bracket the range of regional coal demand in 1985 and in 1990.

The methodology also assumes that the proportional split between underground and surface mining would remain constant for a given production level for a given year for all alternatives analyzed. The proportional split does, however, vary between production levels (high, medium, and low) and between years (1985 and 1990). It is likely that the relative economics of extraction could shift slightly to favor one extractive method over another for incremental changes in production in a given year between the program alternatives. However, any inaccuracies resulting from this approach appear to be minor. Also, the coal regions experiencing the greatest production variations among the alternatives (i.e., Power River and Texas) are not projected to produce any underground mined coal.

Another assumption in the projections derived from the NCM output is related to the use of coal. These projections assume a constant proportional allocation of coal in a region among various coal conversion and utilization technologies for a given national coal production level (low, medium, or high). For example, the proportional split among coal-using sectors (i.e., steam electric generation, coke production, synthetic fuels) does not vary between alternatives at any specified production level. The proportional split does, however, vary between production levels (low to medium, medi-

um to high, etc.) and between years (1985 versus 1990).

A final consideration concerns the constant regional demand assumption. The economics of coal use are such that a change of only a few cents per million Btus of energy could influence both the consumptive demand for coal and the relative economic desirability of developing regional coal reserves. To a considerable extent, this fact is considered in the projections by the NCM, which reports the interrelationship between the price of coal and the quantity demanded at each production level. A more sophisticated methodology would have been possible, taking into account the interaction between various substitutes for coal (e.g., oil and gas, nuclear generation of electricity, etc.) such that a change in the relative prices of these alternative energy sources would result in a shift in demand. Such a methodology might have yielded more precise estimates of the amount of coal demanded, but it is questionable whether it would be more useful. For one thing (as discussed in Section 2.5), coal substitutes such as oil and gas are of limited availability in the long term. Also, the NCM uses a least cost linear programming approach. To assume restricted availability of the most economically recoverable coal reserves (private or Federal) would invariably lead to higher fuel costs, with potentially serious national economic growth implications.

5.3.2 Physical Impacts

This section analyzes the environmental impacts of the Federal coal management program alternatives on selected physical resources. Topography, geology, minerals, and soils impacts are treated rather broadly on a regional basis; the specific effects are highly dependent on the physical setting of individual mines and other coal-related activities. Land disturbance, water quality, and air quality also depend to a considerable degree on conditions at each specific site. However, to the extent feasible, these are discussed quantitatively in more detail. These factors, however, are highly significant in any comprehensive consideration of physical impacts of the Federal coal management program alternative.

5.3.2.1 Land Disturbance and Reclamation. This section addresses the amounts of land in each coal region that would be temporarily and permanently

disturbed during the periods from 1976 to 1985 and from 1986 to 1990 for each production level of each alternative. Land requirements for mining, coal beneficiation, conversion, and utilization plants and development to support coal related population increases are considered.

Land area that would be required for coal development activities in the specific years 1985 and 1990 (exclusive of land to support coal related population increases) under the no new leasing alternative is listed by coal regions and coal projections in Table 5-21. Land required to implement the other six alternatives is tabulated according to its variation from the no new leasing values. For example, under the preferred program at the medium level of production, 311 fewer acres would be required in the Southern Appalachian Coal Region than under no new leasing program alternative, whereas in the Eastern Interior Coal Region, 135 more acres would be required. Acres tabulated represent land required for coal operations during the relevant time period, without regard to how much could be reclaimed. In terms of total land required at these discrete periods in time, midwestern coal regions (Eastern and Western Interior and Texas) would be impacted substantially more than the eastern or western regions regardless of the Federal coal management program alternative implemented. Maximum differences among alternatives at the medium production level would occur under the leasing to meet industry needs and leasing to meet DOE goals alternatives; the land requirement for 1985 in the Green River-Hams Fork Coal Region is about 35 percent greater under these than for the base case of no new leasing. In 1990, increases in land requirements under these alternatives and under the lease PRLAs only alternative may also be deemed significant for the Powder River Coal Region. Decreased land requirements under leasing to meet industry needs and leasing to meet DOE goals alternatives in both 1985 and 1990 would be experienced in the Texas Coal Region. Significant increases in the Western Interior and Texas Coal Regions would occur in 1985 under the state determination of leasing levels alternative whereas in 1990 this alternative would slightly decrease land requirements in these regions. Changes in other regions, and particularly in the East under all alternatives, reflect only small percentages of the base case values.

The accumulative amounts of land that would be required under the preferred program (medium level of production) for each region between 1976 and 1990 are listed in Table 5-22. Land requirements for coal production (mining), facilities (coal cleaning, conversion, and consumption, and mine site facilities) and coal-related population increases are considered. Total land required (column 4) represents the sum of land requirements by 1990 without regard for reclamation, and includes both long-term and short-term commitments. Figures enclosed in parentheses show in each column the percent of the total land represented by each category of usage.

It can be seen that greatest land requirements under the preferred program would occur in the Eastern Interior Coal Region (approximately 170,000 acres). The Northern Appalachian (150,000 acres) and Texas (138,000 acres) Coal Regions would rank second and third respectively. The largest percentage of land required for non-mining purposes, 82 percent, occurs in the Uinta-Southwestern Utah Coal Region, followed by the Denver-Raton Mesa (75 percent), Western Interior (68 percent), and Texas (60 percent) Coal Regions. In terms of total acreage, the greatest land area for coal-related facilities is required in the Texas Coal Region (36,000 acres).

Land requirements for coal production under the preferred program would be greatest in the Central Appalachian (79,000 acres) and Northern Appalachian (71,000 acres) Coal Regions between 1976 and 1985. Between 1986 and 1990 the land required for mining would be greatest in the Green River-Hams Fork and Powder River (both approximately 33,000 acres) Coal Regions.

Estimates of the amount of land that would remain actively disturbed (including land subject to a major change of land use) as of 1990 under the preferred program at the medium level of production are shown in Table 5-23. The estimates have been derived in the following way. It was assumed that on the average 40 percent of the land actually required for coal-related purposes would be preempted from any other use. For example, much of the land purchased for a power plant may be left in its wooded state. Similarly, transmission lines frequently occupy land devoted to other purposes. Thus, the figures in the first column of Table 5-23 represent 40 percent of the corresponding values in Table 5-22. The second column lists acreage

estimated to be disturbed due to coal-related population increases. It was assumed that all land required to support this increase in population would remain in intensive usage throughout the life of the project, and would not be subject to reclamation in the same sense as land actively mined. The third column lists acreage disturbed due to active mining. These figures represent twice the estimated annual production rate assumed for 1990, based on the assumption of a two-year lag between mining and reclamation; thus, land which had been mined three or more years before 1990 would be in the process of being reclaimed. The fourth column sums these figures to give estimates of land disturbance in 1990. Column 5 estimates long term (beyond 1990) disturbance based on the assumption that all land actually mined between 1976-1990 will be reclaimed and could put in a different land use while the component of land committed to facilities or coal-related population increase would likely remain the same use. The Texas (73,000 acres), Eastern Interior (68,000 acres) and Powder River (54,000 acres) Coal Regions would have the largest amounts of land disturbed by 1990, and, on a long-term basis (beyond 1990). Comparatively speaking, and considering only total numbers, more land would be disturbed by 1990 and over the long term in the Eastern and Interior Coal Regions than in the West. These relative impacts would not be significantly changed under any of the other alternatives, as tabulated in Table 5-21, although the amount of land under long-term commitment would increase for the Powder River and Green River-Hams Fork Coal Regions under those alternatives (such as leasing to meet industry needs and leasing to meet DOE production goals) in which total land usage increases over the no new leasing base case.

Reclamation Potential. The basic purposes of SMCRA that pertain to reclamation are to assure that surface mining operations are not allowed if the required reclamation is not feasible, to assure that reclamation be as contemporaneous with mining as possible, and to promote reclamation of abandoned mine areas. The unsuitability criteria (Section 522 of SMCRA) relate to reclamation in a general way in that mining would not be allowed if it caused a substantial long-range production loss of renewable resource lands and such a loss would occur if it were not possible to reclaim the mined

TABLE 5-22
ACRES OF LAND REQUIRED BY COAL REGION FOR THE PREFERRED PROGRAM
MEDIUM COAL PRODUCTION PROJECTION BETWEEN 1976 AND 1990

REGION	LAND REQUIRED FOR COAL PRODUCTION (a)			LAND REQUIRED FOR COAL-RELATED FACILITIES (b)	LAND REQUIRED FOR COAL-RELATED POPULATION INCREASES (c)	TOTAL LAND REQUIRED
	1976-1985	1986-1990	Total (1976-1990)			
Northern Appalachian	70,605	26,405	97,010 (65%) ^(d)	25,296 (17%)	27,480 (18%)	149,786

Total	68,221	259,140	92,156	419,517	327,361

- (a) Assumes 40% of the total land required for coal cleaning conversion and consumption facilities and mine site facilities (Table 5-6) is put into buildings or other hard surface areas and would not be reclaimable during the life of the project.
- (b) Assumes all land required to support coal related population increases remains man-influenced for the life of the project (From Table 5-6).
- (c) 1990 mining rate time two. Assumes a two year lag between mining and when land is ready for seeding/revegetation.
- (d) Land disturbance includes land actively being disturbed (e.g. mining) and land committed to a major land use change (e.g. building, pavement).
- (e) Assumes all mined land is reclaimed without regard to success of reclamation effort or future land use.

land. The primary reclamation requirements are contained in the environmental protection performance standards (Section 515 of SMCRA) which require that mined land be restored to equal or better uses compared to its premining condition.

All of the surface coal operations associated with each of the program alternatives being considered in this environmental impact statement, including the no new leasing alternative, would be covered by the reclamation requirements of SMCRA. The only variations in reclamation requirements among the different program alternatives would be the number of acres requiring reclamation and the differences in degree of intensity of reclamation efforts as they relate to the various types of land being disturbed.

This section addresses the reclamation potential and problems likely to be encountered in the coal producing regions. Since specific sites to be mined or reclaimed are not known at this level of analysis, the discussion is necessarily generic in nature. Actual reclamation potential is highly dependent on detailed information specific to the sites to be reclaimed. Since each of the alternatives project some coal development in all of the coal regions, all of the alternatives could affect lands with varying potentials for reclamation. Therefore, variation among alternatives at this non-site specific level of analysis will be in the differing amounts of land that will require reclamation as a result of coal development.

Reclamation potential is dependent upon climate, inherent chemical and physical properties of the spoils, and to a lesser extent, upon the biological character of the area. Among the factors that would affect reclamation success are type, toxicity, depth, and fertility of the spoils, amounts and frequency of precipitation, erosion potential, slope and aspect of the land, choice of plants used in revegetation, timing of seeding or planting, and proposed use of the reclaimed area.

Water availability would have a direct influence on revegetation potential in all of the coal regions. Generally speaking, water availability is not a major problem in the eastern (Appalachian) or midwestern (Eastern and Western Interior and Texas) coal regions. In the western coal regions, however, rainfall patterns are extremely variable

and in some areas, consistently low. Arid and semiarid lands, particularly in the southwest (e.g. San Juan River Coal Region), have areas with average rainfalls of eight inches or less a year. While the amounts of water needed to sustain revegetation will vary with species requirements, areas receiving less than 10 inches of annual precipitation will likely require supplemental water. The question of whether initially irrigated plant communities can achieve and maintain densities similar to undisturbed native areas on reclaimed land has not been answered. Additionally, plant communities established under irrigation systems may be severely impacted if a drought year occurs after irrigation is terminated [14, 15]. Revegetation success may also vary according to techniques used for irrigation. Dense stands of vegetation established under sprinkler irrigation may not establish dense root systems. Drip irrigation, on the other hand, may encourage a more concentrated root system around the water source, but may not encourage the development of dense stands [105]. Water harvesting methods⁵ may prove successful for arid and semiarid land reclamation [104,105]. However, when ditching is used for water harvesting, periods of exceptionally heavy runoff may create enough siltation to destroy established vegetation [105]. Water rights and legal claims to water may also limit the amount of water available for mined land irrigation, particularly in the San Juan River Coal Region [105].

Soil conditioning and amendment may be required in any of the regions. Included among the most common conditioning techniques are topsoiling, fertilizer addition, spreading chemical additives for soil neutralization, and mulching. Topsoil addition may be required to overcome specific problems or to provide a proper medium for plant growth. In areas naturally subject to leaching, underlying soils may contain more nutrients than native topsoil. Segregation and replacement of native topsoils in these cases could produce less favorable results than mixing spoils. The amounts of topsoil required to overcome saline or sodic soils in western coal regions, or acid conditions in eastern and mid-western coal regions, are variable. Barth [102] indicates that while the depth or topsoil

⁵An example of water harvesting is a method under investigation in Washington state which involves smoothing tops and sides of spoil banks and seeding "valleys" between banks. Experiments are being conducted to provide

more effective waterproofing of spoil slopes to allow more of the runoff water to reach the planted area.

required for successful revegetation has yet to be precisely determined, as much as one foot may be required over saline or sodic spoils in the western regions. Sandoval et al. [98] found that as little as two inches of topsoil placed over sodic soils in portions of the Northern Great Plains increased the water infiltration rate several fold, reduced runoff, and vastly improved plant survival and growth. It is preferred, however, to apply a greater thickness of topsoil [96]. A topsoil layer of up to two feet or more may be required in extremely acid sites in the Appalachian Coal Region [97]. Unless handled properly, toxic spoils would severely limit or totally negate any revegetation effort.

A number of plant species have been tested and appear to be useful for revegetation on spoils of varying quality [99, 100, 101, 103]. Care must be taken that proper species (and in many cases proper strain of the species) be selected for revegetation that will best serve the intended land use objective. Reseeding efforts, however, will likely produce areas with different species and densities from surrounding natural areas. Reclamation efforts in the southwest currently emphasize late successional species which are difficult to establish under low water availability [105]. Plantings with earlier successional stages may prove a benefit to long term success. Plantings with introduced species may be established quicker and be more productive, but they also require more skillful management to achieve and maintain this production [96]. Long term stability of revegetated areas is not known.

Success of revegetation is also highly dependent on timing and method of planting. Generally speaking, arid and semiarid regions of the southwest may show greatest results from plantings in late summer since this is just prior to normal periods of greatest precipitation. Similarly, fall plantings in intermountain areas of the West and spring plantings in the Plains areas and in the interior and eastern coal regions should give more favorable results.

Land use planning and objectives will play a major role in determining the success of reclamation. Forage, pasture, and agricultural crops may grow well on mine spoils, but would be less practical in regions where agriculture contributed little to the economy [97]. Packer [4] lists several rehabilitation options available for the Northern

Great Plains which would also be applicable to other regions. These are:

- Return as nearly as possible to original range/forest condition.
- Return to previous agricultural cropland condition.
- Convert from previous range/forest condition to agricultural cropland.
- Convert from previous agricultural crop land to range/forest condition.
- Take advantage of such specialized features as water for ponds or lakes to develop unique recreation and/or wildlife habitat areas.
- Develop such intensified land uses as airports, industrial or residential areas, solar energy sites, etc.

In western coal regions, postmining land use would likely be limited to grazing as the dominant land use. Because of difficulties associated with overcoming precipitation deficits, this dominant land use should not change.

In the midwestern regions, extensive mining and postmining reclamation would probably decrease forest land acreage while increasing the amount of grazing land. For example, presently approved reclamation plans in Illinois may cause a 20 percent increase in pastureland and a 19 percent decrease in forest land in affected areas. Carter et al [11] and Kennedy et al [12] attribute the increase in pastureland to its much lower cost of reclamation. Cropland would remain about the same [5]. Surface coal mining in midwestern areas has encroached on valuable prime agricultural lands. In 1976, for example, three-year permits were issued to surface mine 17,230 acres within the State of Illinois. Of this total acreage, 12,954 acres, or about 75 percent, is classified as prime agricultural land by the U.S. Soil Conservation Service [5]. An increase in surface mining activity would undoubtedly advance the disturbance of prime agricultural lands and affect both the economies and environments in midwestern surface mining areas. A major concern of mining prime agricultural lands is whether or not the technology or knowledge exists which would allow the successful reestablishment of those soil factors which are conducive to successful crop production.

In the Texas Coal Region, reclamation to the current dominant land use of grazing probably would not change appreciably. In the Appalachian

Coal Regions, a reduction of forest land (the dominant land use) is anticipated. Due to the close proximity of numerous densely populated cities to coal areas in the Appalachian Regions, an opportunity would be provided for increased land values and stimulation of local economies by establishing recreational facilities and second home communities. Coal companies have recently given more emphasis to reclaiming surface-mined land to recreational and housing developments [13]. However, these have been isolated endeavors, primarily because marketability has not been thoroughly investigated.

Packer [4] developed a method for predicting the rehabilitation potential success on large tracts of land in the Northern Great Plains. This method expresses rehabilitation potential using a scale from -9 to +9, with the latter representing areas where success is expected to be greatest. The scale considers: (1) the productivity and stability characteristics of surface soil materials; (2) the suitability and availability of native plant species for plant cover re-establishment and their availability; and (3) the amount and distribution of rainfall. The predictive capacity of Packer's method is not expected to be useful on a site specific basis, but is useful in predicting potential rehabilitation success on larger tracts of land which may be characterized by soil associations, broad vegetation types, and average annual rainfall characteristics [4]. The length of time required to successfully rehabilitate surface mined sites can also be expected to depend on essentially the same environmental factors that determine rehabilitation potentials. These times similarly should not be applied to specific sites.

Reclamation potential in the Northern Great Plains is highly variable even between broad areas. Higher rated response units (+3 to +9) which occur predominately in North Dakota, may require as little as one year to restore to agricultural cropland and five years to restore to mixed-grass range [4]. Medium-rated (+3 to -3) response units which dominate the moister areas of southeastern Montana and northeastern Wyoming may vary from five to 10 years, depending on whether the rehabilitation objective is to return the land to short-grass prairie, grass-shrub steppe, a mixture of these types or ponderosa pine. On lower response units (-3 to -9), such as those in northeastern Wyoming and northeastern Montana, from five to 15 years may be required to return the land to

short-grass and/or shrub-steppe range. These time frames would be heavily influenced by rainfall patterns.

Assuming a direct correlation between the rehabilitation potential scale and time estimates, Table 5-24 estimates years to reclaim mined land to rangeland and cropland. Of importance here is the relative nature of time. Generally speaking, and assuming that the best technology available is applied, it would take longer to achieve reclamation in the San Juan River, Uinta-Southwestern Utah, and Denver-Raton Mesa Coal Regions. Revegetation to native species may require a much longer time period. It may not be possible to restore mixed native vegetation in the Northern Great Plains in less than 30 to 40 years [96]. Natural succession to coniferous and hardwood forest on old abandoned fields averages about 60 to 150 years, respectively, although present commercial forestry techniques have reduced this period by about 50 percent for both conifer and hardwood stands [9, 10]. Whether long-term postmining productivities can equal premining levels is unknown due to the relative infancy of timberland reclamation practices [10]. Reestablishment of ponderosa pine and mountain shrub types in areas where rainfall is favorable for plant growth and where deep fertile soils have developed (intermediate elevation zones in parts of Uinta-Southwestern Utah, Green River-Hams Fork, Powder River, and Denver-Raton Mesa Coal Regions) may not present a revegetation problem. Growth of pine trees and shrubs could reasonably be expected within 10 to 20 years in these areas [14].

In desert areas of the West, natural regeneration of the dominant plant species occurs only every five to seven years, and only when two better than average years occur in succession [14]. Natural ecological succession in deserts even when a seed source is close by and the disturbed areas are not extensive, requires from 20 to 50 years [14]. The National Academy of Science [14] indicates probabilities of reaching rehabilitation objectives for desert, sagebrush foothills mixed grass plains and ponderosa pine and mountain brush in the western region. These probabilities depend on the land use objectives, characteristics of the site, available reclamation technology, and the skill with which this technology is applied.

TABLE 5-24

ESTIMATED TIME REQUIRED TO RECLAIM MINED-LAND
(Western Regions) (a)

COAL REGION	RECLAMATION POTENTIAL(b)		TIME TO RECLAIM (years) (e)	
	WEIGHTED AVERAGE(c)	RANGE	RANGELAND	CROPLAND
Powder River	0.9	-2 to 5	10.0	5.0
Green River-Hams Fork	0.2	-2 to 4	10.0	8.0
Fort Union	3.4	1 to 8	8.0	5.0
San Juan River	-6.9	-8 to 3	14.0	14.0
Uinta-Southwestern Utah	-5.0	-5	14.0	13.0
Denver-Raton Mesa(d)	-5.0	-5	14.0	13.0

(a) Source: Reference Numbers 3 and 4.

(b) Based on scale of -8 to +8 developed in Reference Number 3.

(c) Based on total acres which would be mined through 1980 and reclamation potential of active mines.

(d) Same value as Uinta-Southwestern Utah Coal Region due to regional productivity and latitudinal similarities.

(e) In the Appalachian and Eastern Interior Coal Regions reclamation to the equivalent of rangeland could occur in 1-2 years and to prime cropland in 5-15 years.

In general, if sites are reshaped and left to natural succession, only sites in ponderosa pine and mixed grass plains have a moderate chance of revegetating in a short time. Successful revegetation in the desert is low even when existing technology is applied properly, and sagebrush revegetation is moderate. The chance of approaching the original ecosystem is moderate even on the best sites, and there is no probability of *complete* restoration anywhere.

5.3.2.2 Topography. An impact on the topography of an area would occur if a permanent change in the general configuration of the land surface were to result from coal related development. The concept of permanent change is a key factor in determining the topographic impacts of surface mining under the provisions of the Surface Mining Control and Reclamation Act (SMCRA). The environmental protection performance standards of that law (section 515(c)(3)) operate to mitigate the significance of topographic changes compared with those changes that would occur under conditions of no control.

During early activities in developing a coal mine, topographic changes would be limited to the grading required for access roads and for the preparation of the drill sites used to determine the overburden and coal-deposit dimensions. Holes are drilled at quarter-mile intervals; this involves approximately 35 holes per 1,000 acres of leasehold. Except in very rugged terrain, grading for access roads and drilling sites would involve a negligible portion of the leasehold.

Topographic impacts could also occur during premining site preparation and facilities construction. Cuts and fills could be required for coal haul roads and some surface grading might be needed for mine-support facilities such as offices, warehouses, shops, and equipment parking or storage areas. The amount of such changes would be highly dependent on the characteristics of a particular site. However, the topographic changes resulting from these activities would not generally be extensive enough to significantly impact the topography of the area or any sizeable portion of it.

The extent of topographic disturbance due to coal extraction operations differs considerably between surface mining and underground mining. By far, the greater disturbance is associated with

surface mining. Surface mining involves the removal of the overburden and the extraction of the exposed coal seam or seams. The primary impact of this activity would be the lowering of the surface in the area mined to depths that vary from a few feet to hundreds of feet, depending on the combination of overburden depth and coal seam thickness. If left in its surface-mined form, the area would suffer a significant topographic impact. However, SMCRA (section 515(b)(3)) requires that all overburden material be backfilled and graded to restore the approximate original contour of the land.

Section 515(b)(3) also covers provisions in SMCRA for instances where insufficient or excess overburden does not allow restoration of original contours. The geological nature of the overburden and the ratio of overburden thickness to coal seam thickness are factors that would determine whether there is excess or insufficient overburden. During excavation, the overburden material would be broken up and expansion of its volume, known as bulking, would occur. This overburden bulking (from 10 to 20 percent) could vary between regions, within regions, and even within a particular leasehold depending on the geological materials encountered. If a 20-foot coal seam were to be mined in an area that required the removal of 200 feet of overburden material having a 10 percent bulking factor, backfilling and grading of the overburden could restore the approximate original contour of the land with all highwalls, spoil piles, and depressions eliminated. If the ratio of overburden to coal seam thickness ratio were greater than the percent of overburden bulking, there would be excess overburden. Conversely, if the overburden to coal ratio were less than the percent of bulking, there would be insufficient overburden and a depression would remain after mining reclamation. Among the various coal regions, the Powder River Coal Region, with its 26-foot average seam thickness, would have a much higher proportion of lowered topography than the other regions. Surface lowerings of 25 to 40 feet have been experienced at some present mining operations in this region involving coal seams up to 70 feet thick with overburden thicknesses averaging 150 to 250 feet. The conditions of both hill and depression formation are covered under SMCRA, which requires that the overburden material be backfilled, graded, and compacted (where advisable) to the lowest

practicable grade but not more than the angle of repose.

Another area of topographic impact resulting from surface mining operations involves the general shape of the restored land. Regardless of whether the restored area is at the same elevation, raised, or depressed relative to the original elevation, the landforms resulting from restoration activities would have more smoothly contoured surfaces than the original landscape; most of the microrelief features, such as small ledges, rock outcrops, and natural steep banks, would be eliminated.

Underground mining could impact surface topography through deformation of the geologic strata above the coal extraction area. This could lead to lowerings of the surface, cracks due to tension, or bulges resulting from compression. These types of impacts could have a major effect on future use to which the land surface above the mine workings can be put. The type and magnitude of such surface changes is highly site-specific and cannot be generalized for any region. Conditions which affect subsidence include the nature of the rock formation and thickness of the overburden, the geometry of mine workings, coal-bed thickness and the rate of mining, and the direction in which any coal bed dips as seen at the point where it is exposed at the surface [17]. Underground mining activities can be designed to take into account those factors which influence subsidence processes. New techniques, such as the use of remote sensing imagery, are being developed to provide better information for evaluating mine ground stability and potential areas of subsidence [17,18,19].

Other activities associated with the coal development cycle such as plant construction, utility and transportation corridor construction, and employment-related factors might also produce topographic changes. New roads or rail lines might require cuts or fills; coal-conversion and electric-generation facilities would generally require site preparation in the form of some degree of surface grading or leveling; and community-development activities (housing, utilities, schools, etc.) associated with coal development would also involve a certain amount of surface grading. These changes would also be site dependent and the magnitude of such changes from a topographical basis should not be significant. The overall effect on topogra-

phy would be moderate alterations in land contours of the acres involved.

It is not anticipated that the impacts in the topography of any region will differ significantly under any one of the program alternatives as compared with the other alternatives. In general, mining more coal increases the potential for topographic impact, especially when surface mining techniques are used. Hence, the chance of lasting topographic effects for each region is greatest under that alternative in which coal production from that region is maximum. As noted in section 5.1.3, it was assumed that the split between underground and surface mining (i.e., the percentage of coal extracted by each method) in each region would be the same for all alternatives. Therefore, when coal production in a given region varies as a result of interregional shifts, the amount of coal extracted by each method will change by a proportional amount. In each coal region, the alternative for which surface extraction is maximum will be the same as that for which overall production is maximum; minimum production by each method will also correspond with the alternative for which overall production is minimum.

5.3.2.3 Geology. Mining is the only activity in the coal development cycle in which significant geological impacts could occur. Although coal processing, transport, conversion, and use might produce minor topographic changes, the impacts of such changes would not be great enough to significantly alter the geologic character of an area.

In the mining phase, surface mining operations would produce significantly greater geologic impacts than underground operations. The exact extent of surface mining impacts would be directly related to the geological characteristics and thickness of the overburden, and cannot be generalized for a particular region. When overburden is broken up, removed, and later replaced, the geological structure and natural stratification of the overburden is destroyed and its physical and chemical properties are altered. Although such structural alterations would prevent any future scientific study of the original nature and structure of the overburden, much of the needed information would be collected during earlier development activities. Exploratory drilling includes the collection of core samples for mineralogical, physical, and chemical testing and also includes bore hole

testing to collect data on the seismic, gravimetric, and magnetic characteristics of the different underground strata. The breaking up of the overburden and the mining of coal could also affect groundwater through the disruption of any aquifers in the overburden material or in the coal itself. This area of impacts is described in detail in Section 5.3.2.6.

Paleontological resources could be affected by the disturbance, destruction, or removal of fossil material from overburden during stripping and backfilling operations. The exposure of fossiliferous rocks that might occur in association with conjunctive activities could also lead to losses resulting from unauthorized fossil collecting and vandalism. The significance of impacts on paleontological resources from stripping operations cannot be meaningfully assessed without data collection guidelines, assessment procedures, and evaluatory criteria. The Bureau of Land Management and the U.S. Geological Survey are currently developing a mechanism to provide for the protection of paleontological resources on Federal lands. The overall impacts from a geological standpoint would be minimal. Likewise, paleontological resources in any coal region should sustain only minimal impacts, although some specific sites might be adversely affected.

Another category of potential geological impacts involves the Department of the Interior's Natural Landmarks Program that affects other Federally designated scenic and natural areas. A certain number of these areas would be considered as unsuitable for coal mining under the lands unsuitability criteria set forth in Table 3-1 above. Scenic Federal lands designated by visual resource management analysis as areas of outstanding scenic quality and/or of high visual sensitivity - Class I or II - but not currently on the National Registry of Natural Landmarks would, in general, also be considered unsuitable for coal mining. An exception is that a lease may be issued in a scenic area only if the land management agency determines that: (1) the area or site is only of regional or local significance and the state concurs that leasing may be permitted; (2) the use of appropriate mining technology would result in no significant adverse impact to the area or site; and (3) the mining of the coal resource would enhance information recovery (e.g., paleontological sites). The extent of the areas that would be considered as

unsuitable for coal mining because of their natural or scenic qualities cannot be determined at the programmatic level.

The objective of the Natural Landmarks Program is to assist the preservation of the various categories of significant natural areas which would illustrate the diversity of the country's natural history. The types of nationally-significant geological features that could qualify for natural landmark designation are outstanding formations significantly illustrating geologic processes, significant fossil evidence of the development of life on earth, and examples of the scenic grandeur of our natural heritage [20]. Efforts to inventory significant landmarks of all the natural regions are continuing through a variety of natural-region theme studies. It is not possible at present to determine the magnitude of potential impacts on these landmarks without specific data on all of the sites where mining will occur. The nature of the landmark would be a factor in determining whether coal development activities would cause a significant impact. For example, a landmark which owed part of its significance to the ability to view it from a particular vantage point could be impacted by the visual intrusion of man-made structures or terrain alterations while a significant fossil area could remain unaffected by such activities so long as they did not physically disrupt the fossil formations.

In general, all of the activities in the coal development cycle contain elements which could possibly affect natural landmarks. However, surface mining activities would present the highest probability of potential impacts. Thirteen landmarks currently included on the National Registry of Natural Landmarks have been reported to be threatened by various types of surface mining [21]. Although only one of these sites specifically involved coal mining, these cases are illustrative of potential coal development impacts on designated natural landmarks. Coal development activities could also alter a site so as to preclude its possible designation as a natural landmark. Other activities which would have potential for landmark impacts include uncontrolled fossil collection due to mine-related population increases and community developments which could preempt the designation of an area as a natural landmark.

As with topographic impacts, increasing the amount of coal mined heightens the potential for

significantly affecting an area's geology. The greatest potential for adverse impacts in paleontology and natural landmarks exists in the West. This section has long been known for its diversity of natural formations and unusual geologic features; with its low population density, many scenic attractions remain open to uninterrupted view. While fossil remains are found throughout the U.S., the likelihood of still undiscovered remains is greater in the abundant open spaces of the West. On judgement, then, the potential for unanticipated adverse geologic impacts is greatest for those alternatives that call for mining the largest amounts of western coal.

5.3.2.4 Minerals. Mineral resources would be impacted by their extraction, by the establishment of conditions which preempt any future development, or by conditions which delay their development. The major impacts of any Federal coal management program would be the permanent depletion of coal as a nonrenewable resource through the production and consumption of the tonnages of coal associated with each of the alternatives. Additional minor impacts would occur through the use of sand and gravel or other materials for road-base material and as construction aggregate. These materials would be required in varying quantities in all activities of the coal development cycle and in any community development that would occur due to coal development. Although the requirements are not known at this time, regionally significant impacts would not be expected because of the widespread availability of these construction materials. Hence no region is likely to experience significant depletion nor would major differences occur under the various alternatives.

Both surface and underground mining have the potential to preempt future development of other mineral resources. The magnitude of any preemption cannot be estimated for any region. The factors that determine what and how much of a mineral is thus preempted depend on the specific sites chosen for mining coal. These factors include the mineral-resources in a surface mine overburden and the location of any deep coal bed relative to other mineral commodities above or below it. An example of potential preemption by surface mining operations can be illustrated by the Wasatch and Fort Union Formations in the

Wyoming portion of the Powder River Coal Region. Uranium and coal have both been found in these formations. The stripping of overburden to reach a coal seam would intermix any uranium with the rest of the overburden and eliminate the possibility of any future uranium extraction. The uranium occurring under such conditions usually consists of deposits that are presently uneconomical to recover. However, if future uranium market conditions or uranium extraction technology were to change to make recovery of this deposit economically attractive, such recovery would have been preempted by the intermixing with the rest of the overburden. The extent to which this might occur for uranium or other minerals cannot be projected for any of the coal regions since it is dependent on the specific mineral characteristics of individual leases. Mineral development preemption could also occur with the development of new communities or the expansion of existing communities if such development were to occur above mineral deposits so that they could not feasibly be mined.

Coal mining operations could also conflict with oil and gas recovery operations, either by preempting development or by delaying development for the life of the coal mining project. In a few instances, coal deposits occur below or at the same approximate level as a commercial oil or gas deposit. Simultaneous operation of a coal mine and a producing oil or gas field have presented some difficulties. Regulations [30 CFR 211] have been established by the Geological Survey to deal with these situations. Standard drilling procedures would not interfere with underground coal operations if coal seam intersections were properly cased. Standard casing would seal underground workings so that no hydrocarbon vapors could enter the coal seam from the well to create safety problems.

There is sometimes a particular sequence in which the extraction of two resources from the same area should occur. Where a mining operation follows the extraction of petroleum products, for example, the location of oil and gas wells would have to be determined by the mining company in order to leave safety pillars around the wells. It should be noted that in cases of coal mining requiring sequential extraction, it is generally more prudent, for technological reasons, to extract the coal resource before the oil and gas resource.

5.3.2.5 Soils. Coal mining activities could cause soil impacts ranging from minor, short-term disturbances to significantly adverse, long-term alteration of soil characteristics. Stripping or grading operations could drastically alter soil characteristics through the mixing of the soil with the subsoil and underlying rock material. However, distinct strata of topsoil could be saved for use in reclamation, thereby increasing the productivity potential of mined lands in the postmining phase. The natural soil structure would be broken up, soil compaction would cause lower permeability, soil microorganism would be buried, and nutrient cycling and established soil climate relationship could be completely altered. Overburden removal could also bring to the surface and mix with the soil those elements that are either toxic to plant growth or toxic to animal life that feed on the plants.

All land disturbances would result in the exposure of a range of soil materials of varying particle size to the action of wind and water. Soil productivity, permeability, and rates at which moisture infiltrates would be reduced, thereby increasing runoff, soil erosion, and sedimentation. Wind action, which is variable both among the regions and within a single region, would cause fine soil particles (silt and clay) to be lifted into the atmosphere, reducing air quality and increasing soil loss. However, estimates of impacts on soils can only be made for each site on an individual basis after haul roads, plant facilities, utility corridors, and other mine development activities have been identified.

Because of the provisions of Section 406(a) and Section 508 (a)(5) of the Surface Mining Control and Reclamation Act that pertain specifically to topsoil handling and restoration, potentially adverse soil impacts such as removal of too much topsoil and improper soil substitution and compaction can be minimized. The mining and reclamation plan for a particular leasehold must include soil surveys provided by the lessee. Such surveys would identify physical and chemical characteristics together with the geographic extent of the leasehold soils to provide the basis for an effective reclamation plan. The wide variability of soil types is well illustrated by the proposed mining and reclamation plan for a Powder River Coal Region mine. This plan included a soil survey that

identified 28 different soil types within a 5,800-acre leasehold [22].

5.3.2.6 Water Impacts. Water requirements in the 12 coal regions reflect the degree of coal development in each region. The total water withdrawal required yearly under the no new leasing alternative would range (depending upon the level of production assumed) from 3.1 million acre-feet to 3.7 million acre-feet in 1985. By 1990, the range would be from 3.4 million to 4.8 million acre-feet (Tables 5-25 and 5-26). Not all of this water would be lost to further use; much of it would be returned to the source, as, for example, after it had been used in washing coal or for cooling purposes at a power plant. The amount of water used up in coal-related activities represents what is termed consumptive-use and is shown for the 12 coal regions under the no new leasing alternative in Table 5-28.

Both water availability and water quality would be affected by a Federal coal management program. Water to meet mining, cleaning, and conversion needs would be drawn from available surface water and groundwater sources. Depending on local conditions, these water sources may or may not be adequate to support the increase in coal development activities projected for 1985 and 1990. Following its use, some volume of water would be discharged to the environment. The quality of this fluid would have been changed during its use. Such quality changes may include the addition of total dissolved solids, including heavy and trace metals as well as the more common cations and anions (electrically charged particles in solution), the lowering of pH (i.e., of alkalinity so as to make the water more acidic), and the addition of heat. Even with controls, some release of these substances would occur either directly into surface or ground waters or indirectly by being leached from solid waste or disposal sites. Use of water could also increase salinity and concentrations of pollutants downstream from the point of where the water was diverted for use. Additional water degradation may occur as a result of mine drainage and runoff from storage, overburden, and spoil piles.

Coal seams are frequently found in close proximity to usable aquifers. In some cases, the coal beds themselves may constitute an aquifer. Disruption of rock strata during mining may therefore cause substantial changes in groundwater

flow conditions with potentially important impacts on drinking water supplies and receiving surface water bodies.

An increased population and industrial growth associated with coal development would exert additional water demands and would introduce quantities of salts, nutrients, organic materials, bacteria, pesticides, trace elements, heavy metals, etc. into surface waters, and could overtax existing sewage treatment facilities. Actual impacts on both water supply and quality would depend on features of the individual situation, such as streamflow characteristics and present water quality. Depending on the local characteristics, the impacts at a specific site where water is used may be more or less severe than the effects on the region as a whole, which reflect usage at many different locations. For conversion facilities and mines located near the upper reaches of streams where the flow is low, impacts on water quality could be significant.

This analysis of water availability is based on preliminary data on water flow and consumptive water use compiled by the U.S. Water Resources Council [23].

Each water system, consisting of a major river and its tributaries, drains a particular area of the United States. The runoff from rainfall and melting snow, as well as the streamflow from smaller moving bodies of water such as those fed from underground springs, finds its way into the river as it moves through that area. This drainage area is termed a watershed (sometimes also called a "basin"), usually named for the principal body of water draining it. Examples of major watersheds include the upper Missouri River Basin in the Northern Plains states and the Ohio River Basin in the East. Watersheds are defined by the conditions of stream flow, which in turn reflect geologic and topographic features of the land, and do not correspond to the coal regions into which the country has been divided for purposes of this statement. Data of the Water Resources Council (WRC), like most information on water availability and use, are organized in terms of watersheds. Each major watershed in the United States is divided into subunits, called aggregated subregions (ASR). The ASRs are listed in Appendix E. These are, in general, smaller than the coal regions and provide the best basis for relating water data to the regions, through the ASRs which most nearly

match or overlap with the latter. For example, the Uinta-Southwestern Utah Coal Region spans both ASRs 1401 and 1402. The amount of water available to that region can be obtained by summing the data from these two ASRs.

Since water supply and water quality in a region is affected by all upstream uses, it is also necessary to identify the regions which are located in the lower or central areas of watersheds. In order to obtain a realistic analysis of future water supply in such regions, the future upstream consumptive demands must also be determined. For instance, the Green River-Hams Fork Coal Region is also contained in ASR 1401, upstream from the Uinta-Southwestern Utah Coal Region. Therefore, any future increases of consumptive water requirements in the Green River-Hams Fork Coal Region (including coal development under any of the alternatives) would deplete the water supply flowing through the Uinta-Southwestern Utah Coal Region. Additionally, parts of the San Juan River Coal Region (contained in ASR 1403) are downstream from both the Green River-Hams Fork and Uinta-Southwestern Utah Coal Regions. As a result, any future increases of consumptive water requirements in ASRs 1401 and 1402 would decrease the water flow, and hence, availability, to those parts of the San Juan River Coal Region. This means that water consumption for coal development and for nonenergy-related developments in the Green River-Hams Fork and Uinta-Southwestern Utah Coal Regions must be deducted from future supplies in the San Juan River Coal Region. The ASRs used in the analysis of each coal region are listed in Table 5-27. The points in the ASRs at which the flows are measured are shown in Figure 5-2 and are listed in Appendix E.

The total stream flow, estimated present and future water requirements (without coal development), and the description of the ASRs used in this analysis are contained in Appendix E. The water flows that are shown in the tables of Appendix E are not necessarily readily available for consumption. Much of it must remain available for supporting fish and wildlife habitats, insuring navigability, and maintaining water quality. Additional amounts are held in reserve under the separate systems of water rights law within each state and within appropriate interstate water compacts. In addition, the location of the point at which water is required within a basin may affect

FIGURE 5-2
STREAM FLOW MONITORING POINTS

the water availability. Even though there may be a net water surplus in the basin as a whole, local areas within the basin may experience water shortages while others have surplus supplies.

Some of the most important limiting factors on water use in western states are legal constraints. Since water is relatively scarce in these western states, an intricate system of compacts and water laws has been developed to divide the existing water both between states and within states. This system is quite complex and subject to many interpretations of key issues [24,25,26,27,28,29]. Major issues include the extent of Indian and Federal water rights,¹ the amount of water available for division among the states, and the ease with which water rights may be changed from one use to another.

Indian water rights represent a particularly complex issue which in some coal regions could play a critical role. Indian claims of title to groundwater should be noted as representing an issue which affects coal development, in particular in the San Juan River Coal Region. In general, water rights in the western states are governed by the doctrine of prior appropriation, in which the first water user in a basin has the first right to use the water during periods of shortage. Many of the streams in the West are already over-appropriated, or appropriated to the extent that users with new rights are not guaranteed a water supply during periods of low flow. Procedures for transferring water rights with early priority dates vary in complexity from state to state. In many cases the rights may be transferred without excessive difficulty as long as all parties are willing [25]. However, most western states have provisions designed to protect the rights of other water users which could complicate transfer proceedings if another appropriator in the basin objects to the transfer [30].

One other consideration in the evaluation of water availability is that the calculated future flows determined by the Water Resources Council (WRC) are based on historical flows and, therefore, contain the implicit assumption that the amounts available would continue in the same pattern as they did during the period of record upon which the total stream flows are derived. As

water supply needs change, reservoir operations would likely be modified to meet these needs. Maintenance of in-stream flow requirements could also necessitate changes in current operating patterns. New reservoirs may be built in an attempt to ensure more constant water supplies for coal or other developments, although it should be noted that proposals to build new reservoirs often produce extensive opposition on environmental grounds. In addition, some existing reservoirs in the coal regions already have significant amounts of unused water storage reserved for industrial purposes. For example, the U.S. Bureau of Reclamation has approximately 650,000 acre-feet in the Yellowtail Reservoir (Big Horn Lake) adjacent to the Powder River Coal Region that are reserved for industrial options, but are not currently used [31]. Although optional management of existing reservoirs or additions of new reservoirs should allow more even distribution of runoff through the year, no new water is "created." In semi-arid regions open water evaporation may dramatically decrease total supplies, but the water that remains can be used more efficiently, due to the water containment and storage structures.

In order to compare the regional amounts of water that will be used up in coal-related activities with the available supply, the estimates of regional consumptive requirements (as given in Table 5-28) have been converted to requirements in each of the watersheds which will furnish the water. Table 5-29 expresses these requirements for the no new leasing alternative. The interrelationships between coal regions and watersheds shown in Table 5-27 were used to provide estimated requirements at each level of production. The results in Table 5-29 were then compared with estimates from the WRC as to water availability in 1985. However, there was a complication in using WRC data as is discussed next.

The future flows calculated by the WRC represent the amount of water that will discharge from the watersheds in 1985 after all consumptive uses have been accounted for. The Council's figures on consumption already include estimates of water used in the production of energy, including the mining and utilization of 1.1 billion tons of coal in 1985. This independent estimate for

¹The Indian tribes of the Northern Great Plains have claimed prior and paramount rights to all waters which flow through, arise on, or border their reservations. These claims are based on the United States Supreme Court

decision in the case, *Winters vs. United States*, 207 U.S. 564 (1908). The claims and similar competing interests between the state and Indian water rights in other regions will have to be resolved in the courts.

(b) See Appendix E.

coal use is close to that projected for the no new leasing alternative at the medium level of production. An attempt was therefore made to use the WRC watershed data as surrogates for assessing the impact of this alternative.

In seven of the 10 watersheds and watershed combinations, estimates by WRC, as shown in Table 5-30, for all energy-related activities exceed the projections in Table 5-29 for coal-related activities alone. Therefore, the WRC estimates for these watersheds may reasonably be assumed to encompass the consumptive water requirements in 1985 for coal development under the alternative of no new leasing at the medium level of production. The results are shown in Tables 5-33 through 5-38 and in Table 5-40.

For three of the watershed combinations, however, the demand calculated for coal alone (as given in Table 5-29) exceeds WRC estimates of demand for all energy-related activities. These three watershed combinations are the Upper Ohio and Upper Tennessee, the Upper Mississippi and Ohio, and the Green River and Upper Mainstem Colorado River. Several options for dealing with this problem exist. The safest approach, in that it minimizes the danger of underestimation, is to add the consumptive requirements projected for coal alone (as given in Table 5-28 and 5-29) under the no new leasing alternative to those calculated by WRC for all energy sources. This approach will overstate the total water requirements by an unknown amount, because the WRC estimates have already included some requirements related to coal. The actual amount overestimated is unknown, however, and cannot be subtracted out. The comparison of water needs with water availability will represent, therefore, a worst-case estimate.

The results of using this approach are shown for the three combined watersheds in Tables 5-31, 5-32 and 5-39. In these tables, estimates of annual water production, based on the no new leasing alternative at the medium level of production, were divided by 12 to obtain average monthly values.

It will be noted in Tables 5-31 through 5-40 that monthly predictions of water flow (after accounting for all consumptive uses) are given in terms of both the mean or average level and the 95 percent level. The latter figure is based on the estimated 20-year low flow and represents the volume of water that is expected to be exceeded

during the specified month in 19 years out of 20. It is, of course, not possible to predict from past records in what year the low flow would occur nor to guarantee that values below the 95 percent level would occur only at 20-year intervals.

As can be seen from the tables, demand exceeds supply for six of the ten combined watersheds. All of these are west of the Mississippi River. The only western watersheds for which deficits are not predicted are the Upper Missouri and the Green River and Upper Mainstem Colorado (already noted). These deficits would occur during the summer months when the patterns of precipitation and runoff result in minimum stream flow. While many Western streams also experience low flows in the winter, this condition apparently does not result in as severe a regional depletion of supplies as low flows in the summer. Except in the Texas and Denver-Raton Mesa Coal Regions (Tables 5-18 and 5-40), these deficits would occur only at the 95 percent level and would not exist during most years. The deficits would not be eliminated under any of the alternatives which call for less consumptive use of water in some of the regions, as shown in Table 5-41. On a monthly basis, none of the reductions from the no new leasing alternative are enough to offset the deficit. Indeed, the water impact expected under any given alternative (at the medium level of production) are not appreciably different from those expected under any other.

Before discussing impacts on a geographical basis, several of the uncertainties inherent to the methodologies should be highlighted. One of the most important is the lack of information on the probable margin of error in WRC estimates. The percent change in water consumption from one alternative to another, which can be considered as statistically significant, is therefore difficult to address. As stated earlier, while a deficit may not be predicted for a given watershed (therefore, water should still physically flow in the major streams) under coal development, other constraints may affect water availability. Legislatively mandated flow requirements for pollution control and conservation needs, interbasin allocation agreements, and recreational considerations will all affect how much water can be taken from the streams and consumed for coal development. These constraints are exceedingly difficult to address on a region basis; however, other supplies

TABLE 5-30

WATER RESOURCES COUNCIL PROJECTED CONSUMPTIVE WATER REQUIREMENTS IN 1985
(1000 acre-feet/year)

Watershed ^(a)	Fuels Mining	Petroleum Refining	Steam Electric Generation	Total ^(b)

June	6,350	2,890
July	4,540	2,220
August	3,960	1,840
September	3,160	1,520
October	3,200	1,420
November	4,640	1,780
December	8,020	2,190
Annual (b)	96,500	62,800

* See Appendix E.

Note: Flow after all uses including irrigation.

(a) Calculated flow is the difference between the water entering and the total water depletions in the watershed(s) that contain the region. It is the estimated amount of water that would flow out of the basin as measured at the point of discharge. Negative values indicate water deficits which would necessitate at least temporary reduction in upstream consumption. Positive values do not necessarily imply that the water is available for use, since water availability also depends on such factors as minimum in-stream requirements; water quality; and water law as determined by each state and by compacts between the states (see text).

(b) Annual totals may not equal the sum of the individual months due to accumulated round-off error. The annual 95 percent flow does not equal the sum of the monthly 95 percent flow.

Source: Adapted from Reference Number 23.

may become available in the future through conservation efforts in the highly consumptive irrigation sector, properly managed lease sale groundwater developments, and through effective surface water storage systems.

Impacts - No New Leasing Alternative. The total regional water requirements reflect the degree to which coal development is supported by each region. The 1985 consumptive water requirements for the no new leasing alternative high option range from a low of 59,000 acre-feet per year in the San Juan River Coal Region to a high of 453,000 acre-feet per year in the Eastern Interior Coal Region (see Table 5-28). The requirement for 588,000 acre-feet shown for other areas is due to coal consumption in nonproducing areas and is distributed throughout the remaining areas of the United States.

Based upon predicted water flow data in Table 5-31, the water supply in the Northern, Central, and Southern Appalachian Coal Regions (the Upper Ohio and Upper Tennessee River Basin) is more than sufficient to support projected coal related development. The yearly requirement in 1985 for the high option (about 927 thousand acre-feet, see Table 5-12) is less than two percent of the extreme low flow (95 percent low flow or the flow which is exceeded during 19 out of every 20 years, on the average) for the watershed (about 63 million acre-feet). The 20-year low flow for October is about 1.4 million acre-feet and the average monthly requirement is about 8,000 acre-feet. Even under such low-flow conditions, the monthly flow is not expected to go below 1.3 million acre-feet per month. In addition, the Southern Appalachian Coal Region may be able to obtain water from the Black Warrior and Coosa River systems and the Northern Appalachian Coal Region may obtain some water from the Susquehanna River, none of which has been included in this analysis. Although estimates of water flow in 1990 are not available, it appears that the additional requirements for the no new leasing alternative (as shown in Table 5-29) would not present any significant problems at the regional level. About 80 percent of the water withdrawals in the Appalachian Regions would be consumptively used (Tables 5-26 and 5-28). The remainder (between 190 and 210 thousand acre-feet) would be discharged as waste fluid to surface water. Even if discharges would meet Federal and state regulations, local pollution problems may

develop. These could be of particular concern when summer low flows are insufficient for waste assimilation. Additional controls may then be required to maintain ecosystem health and productivity during times of critical flow.

The situation is similar for the water requirements of the Eastern Interior Coal Region, which is supported by the Upper Mississippi and Ohio River Basins (see Table 5-32). Since the Ohio River Basin also supports the water requirements for a large portion of the Appalachian Coal Regions, the water requirements for all three Appalachian Coal Regions were combined with those of the Eastern Interior Coal Region in Table 5-32. This results in the presentation of a worst-case situation since at least some of the water supply for the Northern and Southern Appalachian Coal Regions would be developed from sources not included in the table. However, even this extra demand could be supplied. The 1985 annual requirement for the combined regions is estimated to be 1.4 million acre-feet for the high option. This is less than 1.2 percent of the calculated 20-year low flow of the two basins (about 121 million acre-feet). In no case would the monthly requirement exceed 10 percent of the monthly low flow. Some local problems, however, may occur where stream flow of individual rivers may not be able to support the coal mining demands. Large supplies of groundwater are available to meet these localized demands [32,33], though groundwater quality may not be adequate for some uses, such as steam conversion. High consumptive use of the water (over 80 percent) will result in relatively low effluent discharge. Some pollution problems may, however, exist in smaller streams.

The Missouri and Arkansas River Basins support the water requirements of the Western Interior, Denver-Raton Mesa, Powder River, and Fort Union Coal Regions. Table 5-33 summarizes the impact of coal development in these regions on the Missouri and Arkansas River Basins. There is one month (August) during which water demand may exceed surface water supplies in the Arkansas River Basin based on a 20-year low flow. At present, this demand is met by extensive ground water mining, and by flow averaging using the numerous reservoirs contained in the region. Additional coal development such as is predicted with the high production projections would further add to these deficiencies; however, even the

expected water requirements in 1990 would not cause net regional deficits in other months. On a local level, surface supplies from smaller subwatersheds may be insufficient to meet the seasonal needs of coal mining and utilization facilities. This maximum demand would equal less than 20 percent of the unused mean monthly flow in all months except August. On an annual basis, less than one percent of the average flow and less than three percent of the 20-year low flow would be required for the high option in 1985.

Consumptive use of water withdrawals for the no new leasing alternative is close to 90 percent in the Missouri and Arkansas River Basins (as can be seen by Tables 5-26 and 5-28 for the regions affected). During periods of low flow, local streams may not be able to provide sufficient flow to dilute the effluent discharges to meet water quality standards in many local areas.

Several rivers, including the Lower Red, Sabine, Neches, Trinity, Brazos, Colorado, and Nueces Rivers can be used to support the water demands of the Texas Region. Even though the mean annual flow of these rivers (46.7 million acre-feet) is sufficient to meet the yearly 1985 water demand of 474 thousand acre-feet (high option 1985 withdrawal), as shown in Table 5-34, the 20-year monthly low flows would not be able to support the mean monthly water consumption (35,000 acre-feet) during four months of the year.

Increasing water consumption by up to 85 percent in 1990 would exacerbate the water deficit, though it will not increase the number of months with net water deficits. Tables in this analysis do not reflect water supplies derived from groundwater. The WRC estimates that groundwater reservoirs currently supply about 7.7 million acre-feet per year to the watersheds aggregated in Table 5-34. Baker and Wall [34] report that the three principal aquifers underlying the Texas Coal Region are the Sparta, Queen City, and Carrizo-Wilcox aquifers, and that these reservoirs could supply a steady-state yield of 130, 120, and 560 thousand acre-feet per year, respectively. (In some places, these formations overlap or are contained within the lignite deposits and may be locally removed or dewatered during surface mining.) The impact on surface water supplies from aquifer alteration and intensive use is therefore an important issue. Additionally, this region contains numerous large surface reservoirs which help

distribute the water flows more evenly throughout the year. As with most surface mining projects, water quality impacts from sediment erosion will have to be addressed on a site by site basis.

The Yellowstone River Basin would provide water for the coal mining and processing facilities located in the Powder River Coal Region. Table 5-35 summarizes the impacts of the Powder River Coal Region requirements on the water supply in the Yellowstone River Basin. The high development option would require one percent of the average annual flow, and about two percent of the 20-year low annual flow of the Yellowstone River. Deficiencies are expected to occur during August and September at the 95 percent low-flow level. No additional months would experience net deficits due to coal development at any level, though existing deficits would be exacerbated. The monthly demand under this high option in 1985 would equal less than four percent of the unused regional flow in all months other than August and September. This demand would increase to five percent in 1990, assuming other water requirements remain constant.

Several additional constraints affect water availability in the Powder River Coal Region, some of which have implications affecting the other western regions as well. The Montana Water Use Act of 1973 amended the State of Montana water law structure to allow the designation of water reservation for maintenance of in-stream flow. In 1974, the State enacted "the Yellowstone Moratorium," suspending action on all applications for changes in beneficial use of existing water rights, as well as all applications for new water rights for the appropriation of more than 14 cfs or 14,000 acre-feet in the Yellowstone Basin.

The Moratorium was lifted upon the December 15, 1978 issuance of an "Order of Board of Natural Resources establishing Water Reservations." A principal result of the Order is the recognition that instream reservations for maintaining water quality and aquatic life are beneficial uses of water. The largest applications during the Moratorium under this category were submitted by the Montana Fish and Game Commission. The Order accepted portions of their applications. These included reservations of Yellowstone River water at Miles City and Sidney, Montana tied to the 80th percentile flow (minus other consumptive reservations). This category of flow is approxi-

mately equal to 5,578,900 and 5,492,300 acre feet per year at the respective locations. The reservations are less than the mean flow of the Yellowstone River, projected for 1985 and 2000 (see Appendix E). The reservations are greater than the 95% projected flow. However, as a result obtaining new water rights for coal mining and utilization facilities may be difficult. Insuring adequate supplies for drier years will likely foster competition between water users for older, established water rights. The December 15th Order also set down numerous other reservations which will affect available water supplies on a site-specific basis. Following the President's National Water Policy, water conservation in non-energy-related activities could make water available for energy users.

As mentioned previously, the Yellowtail Reservoir has a large, presently unused storage reserved for industrial uses [31]. Use of this water in the Powder River Coal Region would require pipelines or some other form of transport. The Montana Department of Natural Resources and Conservation has an application pending to increase the dam height on the Tongue River Reservoir (in eastern Big Horn County, in the middle of the coal region) to provide more storage for both irrigation and industry [36]. This application is also pending approval by the State Water Board. Approval of the full reservation would provide about 29,000 acre-feet per year for industrial use. This application conflicts in part with the application of the Montana Fish and Game Commission.

The Yellowstone River Compact of 1950 divided the waters of the Yellowstone River and its interstate tributaries (Clarks Fork, Big Horn River, Tongue River, and Powder River) between Montana and Wyoming. The compact applied only to those waters not appropriated at that time. Further, it contained a provision specifically prohibiting export of water from the basin without the unanimous consent of all signatory states, including North Dakota. Wyoming's share of this water could range from about 2.4 to 2.9 million acre-feet (mostly from the Big Horn Basin, which contains only marginal coal supplies), depending on the exact interpretation of the compact provisions. This compact could therefore affect the distribution of development within both the Powder River and Fort Union Coal Regions and could also affect the feasibility of coal slurry pipelines, though

they might be more allowable if supplied by groundwater.

Groundwater is available in the Powder River Coal Region both from shallow aquifers (ranging in depth to several hundred feet) and from the deeper Madison aquifer system. The Madison has lately been the subject of much interest and is currently being studied by the U.S. Geological Survey [38] to determine its potential as a water source for coal development in the Powder River Basin. It has been estimated that large diameter wells drilled to depths of 1,000 to 5,000 feet and open to all aquifers through which they pass could yield up to 500 gpm [37]. However, available information is not sufficient to determine the ability of the shallow aquifers to support large well fields at this rate without causing excessive drawdowns and local depletions. In addition, the mixing of overlying aquifers could adversely affect both water levels (requiring deeper wells) and water quality. The inadvertent mixing of saline and fresh water aquifers is an issue of particular importance. Due to the low permeabilities of many bedrock aquifers, well fields producing significant amounts of groundwater would have to spread out over tens of square miles. Potential for high yield wells does exist in some areas of secondary porosity, where partings or small faults induced in the rock strata provide paths along which the water could move with less resistance. Wells placed to take advantage of these underground patterns might produce quite high sustained yields. These concepts are presently being tested by the U.S. Geological Survey [38]. Even so, it is possible that withdrawal rates on the order of 20,000 acre-feet per year from one well field would greatly exceed the rate at which groundwater is recharged. An overall loss in the resource would then occur. Land subsidence might also develop at depths which could hinder aquifer recharge and recovery.

Excessive groundwater withdrawals and consumption may also affect the flow of surface water bodies and springs which are supported by groundwater discharge. During times of low surface water flow, groundwater may be the primary water source. Disruption of aquifers may therefore cause ecologic as well as water supply impacts. While this condition is obviously a concern for shallow aquifers, modifications to deeper groundwater zones could foster adverse

surface water impacts at considerable distances from the point of groundwater use.

The Fort Union Coal Region has the advantage of being able to draw on the supplies of the upper mainstem of the Missouri River as well as water from the Yellowstone River system. Also, two large reservoirs, Fort Peck Lake and Lake Sakakawea, located on the Missouri River have combined active storage in excess of 24 million acre-feet [37] and can help distribute the water flow more evenly through time, saving the peak flows for release during dry periods. With proper planning, the reservoirs of the region would be able to reduce or prevent low-flow problems in the future. The aquatic life of the reservoirs could be affected during irregular fluctuations of the water level. Comparison of Table 5-20 with Table 5-13 shows that even at the high production level less than four percent of the annual 20-year low flow is required. The average monthly requirement for the high option (about 15 thousand acre-feet) amounts to 10.5 percent of the lowest monthly low flow (February). As previously discussed, these calculations apply only to the net water balance in the basin. Shortages could occur locally that would not be reflected by the stream flows out of the basin. Additionally, water rights and other legal considerations could affect actual water availability.

The Upper Colorado River Basin would be the primary source of supply for the Green River-Hams Fork, Uinta-Southwestern Utah, and San Juan River Coal Regions. The supply and demand estimates for this basin are summarized in Table 5-37. This basin along with several others in the western states has been extensively studied from both water quantity and quality standpoints. Significant contributions to resource knowledge emerged from Federal and state efforts in the Water for Energy Management Program [26,37]. Numerous laws and agreements are of particular importance to the Colorado River Basin. According to the Colorado River Compact of 1922, the states of the Upper Colorado River Basin must supply an average flow over any consecutive 10-year period of 7.5 million acre-feet per year to the Lower Basin at Lee's Ferry, Arizona. In addition, the states are obligated to support the U.S. agreement to release 1.5 million acre-feet per year to Mexico, though the exact extent of their obligation is a point of dispute between the states in the Upper and Lower Basins. Assuming the

Upper Basin states contribute one half of the water for Mexico (a maximum case), they would be required to release a mean flow of 8.25 million acre-feet per year to the Lower Basin. The estimated mean total stream flow for the Upper Basin is 13.93 million acre-feet per year (including evaporation, see Appendix E). Therefore, the amount of water available for use in the Upper Basin averages at most 5.68 million acre-feet per year. The estimated consumptive requirement in the basin by the year 2000 is nearly four million acre-feet. Based on a supply of 5.7 million acre-feet, a maximum of approximately 1.7 million acre-feet would remain for additional development.

Meeting required releases to the Lower Colorado Basin may be difficult during low flow conditions, due to excessive demand and limited supplies. According to Table 5-37, projected demands would exceed supply for three months and be only marginally below demand for an additional two months.

Several large reservoirs and numerous smaller ones are currently in operation in the Upper Colorado Basin. The Flaming Gorge Reservoir is located in the Green River-Hams Fork Coal Region and its releases affect stream flow in the northern portion of the Uinta-Southwestern Utah Coal Region. Its active storage is about 3.7 million acre-feet. The Blue Mesa Reservoir, just east of the Uinta-Southwestern Utah Coal Region, has an active storage of 830,000 acre-feet. The San Juan River Coal Region contains the Navajo Reservoir, with an active storage of about 1.7 million acre-feet, much of which is committed to a Navajo Indian irrigation project [39]. Under appropriate circumstances, some of the water demands for coal development could be supplied from these reservoirs, even though they distribute flows only and, due to evaporation, could decrease the total water supply.

Groundwater is available in the Upper Colorado Basin (Green River-Hams Fork and Uinta-Southwestern Utah Coal Regions), though not to the extent it is in the Eastern Interior and Appalachian Coal Regions. It has been estimated that the Upper Colorado Basin contains between 50 and 115 million acre-feet of recoverable groundwater in storage in the upper 100 feet of saturated rocks. The cost of pumping deeper aquifers and mitigating such potential impacts as subsidence may be considerable, however. Rec-

charge rates are believed to be about four million acre-feet per year [40]. Any long-term diversion of groundwater, over and above natural recharge, could cause a proportionate decrease in the groundwater influx to streams. In addition, although the total volume of groundwater in storage is rather large, about 85 percent of it occurs in sedimentary rocks characterized by low permeability which yield water to wells quite slowly. Well yields in the vicinity of the San Juan River Coal Region rarely exceed 50 gallons per minute. In places, especially around the San Juan River Coal Region, groundwater levels may be more than 1,000 feet below the land surface [40]. Indian claims to groundwater in the San Juan River Coal Region have already been noted. No final determinations have been made as to who owns the water underlying much of this coal. Disposition of the issue will critically affect the development of the coal in the San Juan River Region. In some areas of Arizona and New Mexico, notably near urban areas south of the San Juan River Coal Region (such as Phoenix and Tucson, Arizona), groundwater withdrawals are causing large drawdowns of the water table. It is estimated that the groundwater overdraft in Arizona is about two million acre-feet per year [41]. Such overdrafts can lead to land subsidence as the pore spaces in the rock which were formerly filled with water collapse. It may be concluded that, although groundwater supplies may be sufficient to support individual plants, depending on their location, groundwater reservoirs are not in themselves sufficient to supply the additional water to support the commitment to the Lower Basin.

The 1985 discharge of about 25,000 acre-feet of effluent from the Green River-Hams Fork, Uinta-Southwestern Utah, and San Juan River Coal Regions in the Colorado River Basin may result in regional as well as local water quality impacts. The Colorado River Basin is already characterized by high salinity. To minimize the deleterious impacts on the Colorado River of saline drainage waters resulting from operation of mines and coal-using facilities, these facilities should operate in accordance with the policy, adopted by the seven-state Colorado River Basin Salinity Control Forum and the states of the Colorado River Basin, of no-salt returns in industrial discharges, wherever practicable. This policy has been followed by the states and the Environmental Protection Agency in the

issuance of National Pollution Discharge Elimination System permits in the Colorado River Basin. Adherence to this policy will minimize the salinity deterioration below Hoover Dam.

The water requirements for the Green River-Hams Fork and Uinta-Southwestern Utah Coal Regions can also be examined based on smaller sub-basins contained within the Upper Colorado River Basin. The Green River-Hams Fork Coal Region is contained entirely within the Green River Basin (ASR 1401). The Uinta-Southwestern Utah Coal Region spans the lower part of the Green River Basin, as well as a large fraction of the Upper Colorado River Mainstem (ASR 1402). Table 5-38 compares water supply data for the Green River with the water requirements for coal development in the Green River-Hams Fork Coal Region alone.

Table 5-38 summarizes the impact of coal development in the Green River-Hams Fork Coal Region on the predicted water flow in the Green River Basin. Coal development in this region would require up to 61 thousand acre-feet of water annually by 1985, and 63 thousand acre-feet annually by 1990. Even at the high option, this is less than two percent of the mean annual water flow and less than four percent of the 20-year low flow in the Green River. On a monthly low-flow basis, it is estimated that water demand during one month (August) would exceed supply by the year 1985 even without coal development. No additional months would experience net deficits as a result of coal development at any of the options presented here, and except for that one month, the high option water consumption would be less than 15 percent of the unused stream flow during any monthly low flow.

Table 5-39 compares the combined supply data for the Green and Upper Colorado Mainstem Systems with the requirements for coal development in both the Green River-Hams Fork and the Uinta-Southwestern Utah Coal Regions. The extent to which these sub-basins would be required to support the Colorado River Compact and associated commitments is not clear. Although the water in the Upper Basin as a whole is divided between the states, it is not divided according to watershed, so neither coal region's share of the commitment can readily be estimated. However, the total mean annual stream flow of the Green River alone (as shown in Appendix E) constitutes

38 percent of the total flow in the Upper Basin, and the combined flows of the Upper Colorado Mainstem and Green River constitute 84 percent of the total mean flow of the Upper Colorado River at Lee's Ferry, Arizona. It can therefore be assumed that the Green River-Hams Fork and Uinta-Southwestern Utah Coal Regions' share of Upper Basin commitments are significant. In addition, the water rights to most free-flowing water in the Upper Colorado Basin are already allocated and could have to be transferred in order to support additional development with assured water supplies. As discussed for the other regions, future minimum flow requirements for insuring fish and wildlife productivity may add other surface water supply constraints.

Table 5-39 summarizes the impact of coal development in both the Unita-Southwestern Utah and Green River-Hams Fork Coal Regions on the projected combined waterflows in the Upper Colorado Mainstem and Green River. Coal development in both of the aforementioned regions would require up to 120 thousand acre-feet of water each year by 1985, and up to 127 thousand acre-feet by 1990. At the high option level, this is about 1.3 and 3.0 percent of the mean and 20-year low annual flows (respectively) of the combined river systems. Even on a monthly low-flow basis, it is estimated that the water flow in the basin would be sufficient to supply the water requirements for both coal development and all other users by drawing heavily on the Upper Colorado Mainstem during periods of drought. Coal development would require up to about 7.5 percent of the lowest 20-year monthly flow in 1985.

However, in order to obtain sufficient and reliable water supplies to support normal regional development, the compact commitments, and coal developments in the Upper Colorado Basin, it would probably be necessary to obtain existing water rights and transfer them to industrial purposes. Such procedures would be significantly affected by the disposition of existing and future court cases involving the extent of Indian and Federal water rights. The ability to acquire and transfer existing water rights is governed by state law and varies with each state in the region. Although such transfers may be somewhat complicated, they are generally possible in all the Upper Basin states [30]. Such transfers would decrease the amount of water used for other purposes, notably

irrigation, and could have considerable socioeconomic impacts.

The Upper Platte and Upper Arkansas River Basins would be the source of water supply for future development in the Denver-Raton Mesa Coal Region. Coal development at the high option level would require 65 and 79 thousand acre-feet of water per year in 1985 and 1990, respectively. Table 5-40 indicates that even without additional demands for coal development, the projected monthly mean flow during July and August would not meet the normal water requirements of the two basins. At the low flow level, net deficiencies would occur during September as well, and local deficiencies would probably occur during other months. With limited available stream flow for assimilation, point source discharges from coal utilization facilities and non-point pollution from coal mining operations may develop as important water quality constraints.

The water shortages of this region are compounded by its rapid rate of urbanization. In a situation similar to that discussed for the Upper Colorado and Upper Missouri River Basins, virtually all dependable natural water supplies of the region were claimed long ago under the doctrine of prior appropriation [42]. Rapid urbanization on the eastern slopes of the front range of the Rocky Mountains has resulted in intense competition for existing water rights and has led to several condemnation proceedings being brought against irrigation companies to secure agricultural water rights for municipal use [43]. The prospects of developing new water rights for coal development in the prevailing political climate of this region are not good.

Impacts of Other Alternatives. Table 5-41 presents the relative water consumption of the other alternatives, as compared to the no new leasing alternative. The information is presented in acre-feet per year, and aggregated in the same watersheds used in the preceding analysis. In order to compare these estimates with the expected water flows in Tables 5-31 through 5-40, the numbers must be divided by 12 to yield monthly consumption. Even considering the annual values, most of the differences are small, and many are almost negligible.

Preferred Program. In 1985, the consumptive water requirements for the low option of the

(a) Represents absolute water consumption under the no new leasing alternative production projections. All other columns represent changes from the no new leasing base case. Refers to coal-related activities only.

preferred program are practically indistinguishable from those of the low option of the no new leasing alternative. The only difference is an additional demand for about 550 acre-feet per month in the Fort Union Coal Region. This could result in a slight increase in local shortages in that region during times of drought. However, due to the large reservoir storage capacity in the region, the significance of this increased demand is minor.

Similarly, all other options for this alternative in both 1985 and 1990 would not greatly increase the water demands over those discussed with respect to the no new leasing alternative. Except for a few regions in the case of the 1990 high option, consumptive water demands would not increase more than 2,000 acre-feet per month.

In 1990 the high option for the preferred program would increase the consumptive water demand in the Mississippi, Ohio, and Tennessee River Basins by a total of 544 thousand acre-feet per year. This increased demand can be supplied relatively easily in the Appalachian, Eastern Interior, and Western Interior Coal Regions, although the associated effluents could somewhat decrease local water quality. The increased demand of about 10,000 acre-feet per month in the Western Interior Coal Region for this option represents a 13 percent increase over the no new leasing alternative, and could exacerbate the supply problems in that region accordingly. Similarly, the 36 percent increase projected for the coal regions of the Upper Colorado River Basin (Green River-Hams Fork and Uinta-Southwestern Utah) would serve to increase competition for water. Although, subject to the constraints discussed previously, this increase could be met on an annual basis without violating any of the regional water compacts. Local shortages would probably be an important constraint on this option.

PRLAs Only Alternative. In 1985, the water requirements for this alternative would decrease water consumption by less than as 2,000 acre-feet per month (relative to the no new leasing alternative) in any of the watersheds addressed in this analysis. In 1990, relative water consumption would change by as much as 1,000 acre-feet per month in four of the watersheds addressed in this analysis. The effects of this alternative would, therefore, closely parallel those discussed for the no new leasing alternative.

Emergency Leasing Only Alternative. The 1985 consumptive water requirements for this alternative are nearly identical to those of the PRLAs only alternative. The 1990 water consumption would decrease relative to the no new leasing alternative in all but one watershed (Upper Missouri River) by less than 1,000 acre-feet per month. This alternative thus represents a slight improvement in most watersheds relative to the impacts described previously for the no new leasing alternative. However, due to the small differences, the improvements would be minor.

Meet Industry Needs Alternative. The net effect of this alternative would be to slightly increase western water consumption (relative to the no new leasing alternative) in both 1985 and 1990. The maximum increase would be 3,000 acre-feet per month in the Missouri and Arkansas River Basins (Western Interior, Denver-Raton-Mesa and Uinta-Southwestern Utah Coal Regions). Water demand in the East would be less than that of the no new leasing alternative in 1985, and greater in 1990. Water shortages and pollution problems in the West would be slightly increased by this alternative, relative to those discussed previously.

Meet DOE Goals Alternative. The 1985 water demands for this alternative are identical to those of the no new leasing alternative. The 1990 demands differ by less than 500 acre-feet per month in all watersheds except the Upper Missouri (Western Interior Coal Region), which decreases by about 900 acre-feet per month. Thus, the impacts of this alternative would be very close to those of the no new leasing alternative. Shortages would be somewhat exacerbated in the Yellowstone, Green, Upper Colorado Mainstem, Upper Platte, and Upper Arkansas River Basins in 1990.

State Determination of Leasing Levels Alternative. The results of this alternative would be to decrease 1985 water consumption in the Appalachian, and Eastern and Western Interior Coal Regions, and increase consumption in the Fort Union and Texas Coal Regions, relative to the no new leasing alternative. Changes in these regions would be less than 2,000 acre-feet per month, while consumption in other regions would be changed by less than 2,000 acre-feet per year. The 1990 demands for this alternative would be slightly greater than those of the no new leasing alternative

in the Appalachian and Fort Union Coal Regions, and less in all others. The reservoirs of the Texas and Fort Union Coal Regions should be sufficient to supply the additional demands in both years, though local shortages may occur. More extensive aquifer disruption in these regions may create additional problems. Otherwise, the impacts of this alternative would be similar to those discussed previously. The water availability problems projected for the Western Interior Coal Region, and to a lesser extent in the Denver-Raton Mesa Coal Region, would be somewhat reduced.

5.3.2.7 Air Quality. This section addresses air emissions so as to compare the region by region totals, as well as the emissions associated with the Federal coal management program alternatives against the no new leasing base case. This section begins with a discussion of the sources of air emissions associated with the entire coal development cycle. Next, the legislative status of the control of air emissions is addressed. Finally, the data associated with total emissions for each coal region and for each alternative is presented and discussed.

The regional emissions for each alternative represent the aggregated emissions from coal mining, transportation, and conversion and utilization. Gaseous streams, composed primarily of carbon dioxide (CO_2), oxides of sulfur (SO_2), oxides of nitrogen (NO_x), and particulate matter, would be emitted to the environment because of coal development even though best available emission control technologies (BACT) were employed and air quality standards were enforced. Hydrocarbons (HC), carbon monoxide (CO), and trace elements are also emitted, although in smaller quantities. Coal conversion and utilization would contribute the largest single amount to the totals; however, significant amounts of particulates would be emitted by coal mining.

The aggregated emissions do not directly represent measures of air quality degradation. The quality of the air is measured by the concentration of pollutants in the atmosphere, typically expressed in micrograms per cubic meter ($\mu\text{g}/\text{m}^3$). Models of varying degrees of sophistication are available that convert, under specified circumstances, the point or area source emissions into estimates of ambient air concentrations. The use of these models requires detailed information regard-

ing the nature of the source as well as meteorological and geographic characteristics of the surrounding area. The alternatives for a Federal coal management program cannot be compared on the basis of ambient concentrations because there is not enough specific data available from which to make the model calculations. A comparison of the total emissions for each alternative is the most meaningful measure of relative air quality impact available.

Potential Air Quality Impacts. In estimating the total dust emissions from a coal mine, it is preferable to identify the dust-producing activities present and estimate emissions from each activity separately rather than to use a single emission factor for the entire mine. This allows direct determination of the major emission sources and their contribution to the overall emissions from the mine.

Potential sources of dust associated with coal mines are as follows:

- Haul roads.
- Access roads.
- Topsoil removal.
- Overburden removal.
- Reclamation.
- Drilling.
- Blasting.
- Shovel/truck loading.
- Transfer and conveying.
- Front-end loading.
- Truck dumping.
- Open storage.
- Coal crushing (after truck dumping).
- Coal cleaning.
- Train loading.
- Waste disposal.
- Fly-ash dump at mine mouth plants.
- Coal fires.
- Wind erosion of exposed areas.

These sources are not always noticeable at every mine site. For example, only the transfer, conveying, and access road sources are normally found at underground mines. Recent studies have shown that of the sources listed above, haul roads and access roads are most often the largest contributors to ambient particulate concentrations at and near the mine sites [44]. Other major sources of particulates are wind erosion from exposed areas and topsoil and overburden removal.

The impact of mining operations on existing particulate air quality at and in the vicinity of an active mine would depend on a number of variables: climatology, type of dust-producing operations, and size of the mine. Any one of these factors could greatly add to or reduce emissions from a mine site. For example, a small underground mine could contribute greatly to the ambient particulate concentration in the surrounding area because of an extremely long unpaved access road leading to the mine which mine employees travel every day.

The impacts on air quality would be greatest at the mine site where generation of airborne particulates would take place and at areas closely surrounding the mine site. Air quality impacts from mining operations generally would decrease markedly with respect to distance from the site.

The addition of particulates to the atmosphere could also reduce visibility at the mine site and in surrounding areas. Table 5-42 presents four examples of visibility reduction that could happen as a result of increased atmospheric total suspended particulates.

Another air pollution source at coal mines is exhaust emissions from employees' motor vehicles and diesel-powered haul trucks and equipment. The major gaseous emissions from these sources are carbon dioxide, carbon monoxide, hydrocarbons, nitrogen oxides, and water vapor. The amount of these pollutants generated at even the larger coal mines would not be significant, as indicated by recent studies of the impact of vehicle emissions associated with western coal mines. [16].

Air pollutants associated with transportation of coal by rail or barge would result primarily from coal cars and barges and from the exhaust of train and tug engines. Estimates of wind blown coal dust range from 0.2 to two percent of the volume of coal transported [2]. These estimates assume that the coal is transported dry. If transported wet, dust emissions could be reduced to negligible amounts.

Any large-scale construction activity would generate essentially the same types of air pollutants. The major emissions would include fugitive dust, exhausts from motor vehicles and construction equipment (primarily carbon dioxide, carbon monoxide, hydrocarbons, nitrogen oxides, and water vapor), and smoke from the burning of cleared vegetation. The magnitude of the emissions would depend on the size of the construction area,

the method of construction, the project duration, the type of terrain, and the type of control measures employed. In low areas in narrow, steep-sided valleys, where the build-up of polluted air would be greater than in surrounding areas, concentrations of nitrogen oxides from construction equipment could exceed the National Ambient Air Quality Secondary Standards. The actual concentrations would depend upon such factors as wind and temperature conditions, atmospheric mixing conditions, pollutant production rates, and duration of operations.

Coal combustion to generate steam and electric power for internal use by synthetic fuel plants and electric power plants would release both gaseous and solid (particulate matter) pollutants. The chemical and physical characteristics of the gases leaving the boiler primarily are a function of the fuel composition and boiler design. The major gaseous pollutants produced during fossil fuel combustion would be sulfur oxides, nitrogen oxides, carbon monoxide, hydrocarbons, and aldehydes. The particulate matter produced during combustion would leave the boiler as fly ash.

Sulfur oxides would be produced in the greatest quantity during coal combustion. About 95 percent of the sulfur in the coal would be converted to gaseous sulfur oxides; the balance would remain in the fly and bottom ash, or slag. The weight of the sulfur dioxide is essentially twice the weight of the sulfur in the gas. For coal with a sulfur content of two percent (by weight), approximately 76 pounds of sulfur dioxide would be produced for each ton of coal combusted.

Nitrogen oxides are produced from high temperature reactions of nitrogen and oxygen present in the combustion atmosphere and the combustion of nitrogen-containing compounds in the fuel. The concentration of nitrogen oxides in the exhaust during coal combustion would be affected by the amount of nitrogen in the coal, the air-to-fuel ratio, and the way the temperature of the combustion gases changes with time as the gases pass through the boiler. Dry bottom pulverized coal-fired units would emit about 18 pounds of nitrogen oxides for each ton of coal fired, wet bottom pulverized coal units (operating at higher temperatures) would emit 30 pounds, and wet bottom cyclone units would emit 55 pounds [45].

Presently there are no national primary or secondary standards or new source performance

TABLE 5-42

- (a) Expected visibility for the hypothetical situations presented in this table were calculated from the formula presented in Reference Number 77.
- (b) Represents a hypothetical annual average ambient particulate concentration that would exist without the mining activity.
- (c) Represents a hypothetical annual average visibility that would exist without the mining activity.
- (d) That additional portion of the ambient particulate concentration that would be contributed to the TSP as a result of mining activity. Note that the higher contributions such as, 60 and 30 $\mu\text{g}/\text{m}^3$, would normally occur in very close proximity to the mine site.
- (e) The TSP concentration that would result from the background concentration plus the contribution from the mining activity.
- (f) The average visibility that would result from the resultant ambient concentration.
- (g) The reduction in visibility that is directly attributable to the additional particulates from the mining activity.

standards for carbon dioxide. In fact, general practice currently is to convert pollutants such as HC and CO to CO₂ and H₂O and discharge them to the atmosphere. However, there are indications that the rising CO₂ levels in the atmosphere could pose a serious problem, commonly referred to as the greenhouse effect¹. Therefore, CO₂ is addressed here as a potential pollutant.

Carbon dioxide is produced from complete combustion of carbon or carbon-containing compounds. During coal production, CO₂ is generated from the burning of coal at the mine site for power as in well as in the combustion of diesel fuel needed to run mining equipment. During the cleaning of coal, CO₂ is emitted from thermal dryers, while, during transportation, CO₂ is emitted from the combustion of liquid fuel used by the transportation facility. Finally, coal conversion and combustion would result in large quantities of CO₂ emissions. The combustion of one ton of carbon would produce about 3.67 tons of CO₂. The National Research Council [112] concluded that the primary limit on energy production from fossil fuels during the next few centuries may be the climatic effects associated with the release of carbon dioxide. Generally there are uncertainties about the carbon cycle, the net sources of carbon dioxide in the atmosphere, and the net effects of carbon dioxide on temperature and climate. Generally, about 40 percent of the carbon dioxide released to the air is absorbed by the land organic pool, about 20 percent is absorbed by the oceans, and about 40 percent remains in the air. Some experts feel that a doubling of carbon dioxide in the atmosphere will cause about a 2° to 3°C rise in the average temperature of the lower atmosphere at middle latitudes.

Other gaseous pollutants such as carbon monoxide, hydrocarbons, and aldehydes would occur in relatively small quantities during fuel combustion. They would result from incomplete combustion of the organic portion of the coal. Careful control of excess air rates, the use of high combustion temperature, and provisions for more

complete fuel-air contact could minimize these emissions.

The particulates in the exhaust gases of coal combustion would be composed primarily of silica, alumina, and iron present in the inorganic portion of the coal or ash. The size distribution of particles leaving the unit would primarily be a function of unit type. Particulates from a pulverized coal unit would generally be larger than those from a cyclone unit. Particle size distribution would vary from one boiler to the next. These variations are important as they affect the formation of fine particulates that are not only more difficult to control but also considered a greater risk to health.

In addition to the major gaseous and particulate pollutants of concern, coal combustion would also result in emissions of a variety of toxic trace elements which, in sufficient quantity, could cause adverse environmental and health effects. During combustion, these trace elements could vaporize to exit the boiler in a gaseous state, or they could form particulates that would be entrained in the exhaust. High efficiency particulate control could greatly reduce these emissions. However, despite the low concentrations of these pollutants in coal and the high efficiency of present particulate control systems, the sheer volume of coal consumed in the United States makes coal combustion a major air emission source of these pollutants.

The Environmental Protection Agency [45] has estimated the average trace element emissions associated with coal combustion in domestic utility boilers. These estimates and the assumed emission factors are presented in Table 5-43. The atmospheric concentration of each element is shown in parts per million (ppm) whereas the emission factor is expressed as grams per million Btu consumed. (Approximately 453 grams equal one pound).

Coal also contains traces of uranium, thorium, and radium; consequently, during combustion, low levels of radionuclides would be emitted from coal-burning facilities. Studies of radioactive releases from 1,000-megawatt electric power plants employing eastern coals have indicated that the observed levels of radioactive releases did not

¹Carbon dioxide, although transparent to shortwave solar radiation (visible light), strongly absorbs the earth's long-wave radiation (heat) at certain wavelengths. Carbon dioxide molecules absorb infrared radiation emitted by the earth's surface that otherwise would escape into space. Just as glass in a greenhouse traps the sun's heat, so also CO₂ absorbs heat (the long-wave

radiation from the earth's surface) and produces what is known as the greenhouse effect. Thus, high levels of carbon dioxide could upset the balance of incoming solar radiation and outgoing heat from the earth causing a net increase in temperature on the earth's surface. This increase may cause climatic changes.

constitute a public health problem [46,47]. It is not known how radioactive releases from coal gasification or liquefaction plants would compare with those from fossil fuel power plants. Furthermore, a recent Environmental Protection Agency study has indicated that the lung dose from a 1,000-megawatt electric power plant employing western coal could be significant (see U.S. Environmental Protection Agency comments in Appendix E of Reference 39).

In general, because of the dispersion of coal combustion throughout the United States, air concentrations of trace elements from coal firing should not accumulate to levels likely to be associated with known adverse health effects. However, the long-term health effects of these emissions and their overall impact on the environment have not been well defined.

Emission Control Standards. Application of fugitive-dust control measures as required by OSM's proposed regulations will contribute to the achievement and maintenance of National Ambient Air Quality Standards and other applicable Federal and state air quality standards. Production facilities using fossil-fuel steam generators must meet Environmental Protection Agency (EPA) new source performance standards (NSPS). The baseline regulation is summarized in Table 5-44. The Clean Air Act Amendments of 1977 require EPA to revise the current standards of performance for fossil fuel-fired stationary sources. The intended effect of recent EPA proposed standards is to require new, modified, and reconstructed electric utility steam generating units to use the best demonstrated systems of continuous emission reduction and to satisfy the requirements of the Clean Air Act Amendments of 1977.

The principal issue associated with the proposed standards is whether electric utility steam generating units firing low-sulfur coal should be required to achieve the same percentage reduction in potential sulfur dioxide emissions as those burning higher sulfur content coal. Resolving this question of full versus partial control is difficult because of the significant environmental, energy, and economic implications associated with each alternative. The Administrator of EPA has not made a decision on which of the alternatives should be adopted in the final standard.

The proposed standards would apply to electric utility steam generating units that are capable of firing more than 73 megawatts (250 million Btu/hour heat input of fossil fuel) and for which construction is commenced after September 18, 1978.

The proposed sulfur dioxide (SO_2) standards would limit emissions to 1.2 lb/million Btu heat input for solid fuel (except for three days per month) and 0.80 lb/million Btu for liquid and gaseous fuel (except for three days per month). Also, uncontrolled SO_2 emissions from solid, liquid, and gaseous fuel would be required to be reduced by 85 percent regardless of the sulfur content of the fuel burned. Credit would be given, however, for sulfur removed in fuel pretreatment or removed in bottom ash. The percent reduction requirement would not apply if SO_2 emissions into the atmosphere would be less than 0.20 lb/million Btu heat input without pollution controls.

The proposed particulate matter emission standard would limit emissions to 0.03 lb/million Btu heat input. The proposed opacity standard would limit the opacity of emissions to 20 percent (six-minute average).

The proposed NO_2 emission standards vary according to fuel characteristics as follows:

- 0.50 lb/million Btu heat input from the combustion of subbituminous coal, shale oil, or any solid, liquid, or gaseous fuel derived from coal.
- 0.60 lb/million Btu heat input from the combustion of bituminous coal.

Several states within the coal regions have promulgated sulfur oxide and particulate emissions limitations for the combustion of coal that are stricter than the proposed Federal standards. The stricter standards are noted in Table 5-45.

Under the Clean Air Act of 1970, EPA was directed to establish National Ambient Air Quality Standards (NAAQS) to protect public health (primary standards) and public welfare (secondary standards). As of October 1978, EPA has established NAAQS for specified pollutants at particular levels determined by what are termed "episode criteria." These pollutants are known as criteria pollutants and are sulfur oxides, particulates, carbon monoxide, photochemical oxidants, nitrogen oxides, and hydrocarbons. The NAAQS and the recommended Federal episode criteria established by the EPA are given in Table 5-46.

(a) $\mu\text{g}/\text{m}^3$ - micrograms of pollutant per cubic meter of air.

mg/m^3 - milligrams of pollutant per cubic meter of air.

$[\mu\text{g}/\text{m}^3]^2$ - product of the concentration of one pollutant measured in micrograms per cubic meter and the concentration of a second pollutant measured in micrograms per cubic meter.

(b) National secondary ambient air quality standards are, in the judgment of the EPA Administrator, requisite to protect the public welfare from any known or anticipated adverse effects associated with the presence of pollutants in the ambient air.

(c) National primary ambient air quality standards are, in the judgment of the EPA Administrator, requisite to protect the public health.

(d) The Federal Episode Criteria specify that meteorological conditions are such that pollutant concentrations can be expected to remain at these levels for 12 or more hours or increase; or, in the case of oxidants, the situation is likely to reoccur within the next 24 hours unless control actions are taken.

(e) Maximum concentration allowed once yearly.

Source: 40 CFR 50-99.

By August 7, 1977, EPA was required to identify those portions of the country that were not meeting the primary or secondary NAAQS for particulates, sulfur oxides, nitrogen oxides, hydrocarbons, photochemical oxidants, or carbon monoxide. Areas for which sufficient data existed to permit their being identified as exceeding standards were designated as nonattainment areas for the pollutant(s) considered. Other areas were designated as attainment areas. Under the 1970 legislation, all states were to have attained the NAAQS by mid-1977. Under the 1977 amendments to the Clean Air Act, all NAAQSs must be attained by 1983, with special provisions for extending the primary NAAQS attainment dates for photochemical oxidants and carbon monoxide until 1987 at the latest. Thus, according to plan, all areas of the country should be attainment areas by 1987. Table 5-47 shows the number of Air Quality Control Regions (AQCR) that lie wholly or partially in each coal region and the number that are designated as nonattainment areas.

Under the amendments to the Clean Air Act, unless a state implementation plan (SIP) is approved, EPA is empowered to prevent or halt the construction of any new emission source which would seek to locate either in a nonattainment area or in an area from which the source could potentially exacerbate a NAAQS violation in a nearby nonattainment area. At the present time, EPA is moving to establish a uniform litigation-oriented approach to enforcing the act. Violation of the standards, criteria, or guidance of an EPA approved SIP would be sufficient basis for Federal (civil and criminal) enforcement. Inadequate administration of a SIP would permit EPA to displace the state authority and assume enforcement responsibilities.

In attainment areas, a specific EPA program to prevent significant deterioration of ambient air quality is in effect. Under EPA's regulatory scheme for prevention of significant deterioration (PSD), areas of the Nation having attained both primary and secondary NAAQS, which should include all areas of the country by 1987 at the latest, could be designated under any of three "classes." Specified numerical "increments" of particulate matter are permitted up to a level considered to be significant for areas designated within a particular class. The allowable PSD increments are presented in Table 5-48. By August

7, 1979, EPA must promulgate PSD regulations for hydrocarbons, photochemical oxidants, carbon monoxide, and nitrogen oxides which would become effective one year later. States must submit SIP revisions within 21 months of EPA's promulgation of the increments. All areas subject to PSD have been initially designated as Class II, with the exception of certain Federal lands which are mandatory Class I areas, such as national parks. The highly restrictive Class I numerical increments were designed to severely limit industry in order to protect pristine areas. All sources must be analyzed not only for air quality impact in their immediate area, but also for their impact on neighboring areas. In order to prevent deterioration of air quality in areas in which the most restrictive PSD numerical increments are applicable, it is necessary to control emissions from sources both within the geographic boundaries of the most restrictive areas and from sources located in less restrictive areas if the sources in less restrictive areas could cause significant air quality deterioration in the more restrictive areas. For example, construction of a power plant in a Class III PSD area could be prohibited if an air quality analysis for the specific facility found that emissions were sufficient to violate the permitted increments of a Class II area several miles away. The allowable PSD increments are increases in pollutant levels over a baseline concentration as of January 6, 1975. The baseline concentrations represent a status quo point against which air quality is measured. Regardless of the allowable increments, the NAAQSs represent ceilings above which ambient concentrations will not be allowed to rise. All sources planning to locate in a given area are required by EPA to demonstrate that their emissions, in conjunction with the effects of growth and emission reductions occurring since the end of 1974, would not violate the applicable NAAQS or the allowable PSD increments in that area.

Although approval or disapproval of a source permit would be based on the emissions directly related to the source, the indirect or secondary emissions resulting from growth associated with the action, such as community expansion, must also be considered in the PSD increments. Temporary emissions such as those associated with construction are specifically exempt from consideration even if they would contribute to air quality

degradation in excess of an ambient air quality standard.

Program Alternatives Analyses. The following discussion addresses the aggregated air emissions associated with each region and each alternative. In order to put these estimates in perspective, Table 5-49 contains the most recent EPA estimates of criteria pollutant total emissions on a national basis.

Tables 5-50 through 5-55 present data comparing the emissions associated with the low, medium, and high production projections of the no new leasing alternative with current (1976) emissions. The data represent estimates of emissions from all sources associated with the coal cycle. The three columns showing emissions at low, medium, and high production for 1976-1985 represent increases over the base case 1976 values. The three columns showing emissions at low, medium, and high production for 1990-1985 represent increases or in a few cases decreases over 1985 estimates.

Although differences occur from region to region and from pollutant to pollutant, the following general and well established trends can be seen from the totals for all regions for every pollutant:

- The 1985 emissions of any pollutant for the low production level would be about 50 percent greater than the base case.
- The 1990 increases for the low production level would only be from about one-third to one-half of the 1985 increases.
- The total emissions associated with the medium production projection in 1985 would be only slightly smaller than the emissions for the high production projection in 1985. In both cases they represent about a 75 percent increase over the 1976 base case.
- Relative to 1976 levels, total emissions by 1985 would increase by about 75 percent and by 1990 would double or triple under the high production projection.
- In general, this magnitude of increase could conceivably be large enough to prevent growth in the eastern or the western regions. In the industrialized East, the NAAQS could be exceeded and in the pristine West, the PSD requirements could be exceeded.

- On a percentage basis, the Texas Coal Region would experience the greatest increase. A tenfold increase would occur by 1990 in that region for all pollutants except hydrocarbons where a fivefold increase would occur over 1976 levels. The Uinta-Southwestern Utah Coal Region would experience the next highest increase.
- The Central Appalachian, Eastern Interior, Green River-Hams Fork, and Fort Union Coal Regions would experience the smallest increase, although, in general, a doubling would still occur.

Tables 5-56 through 5-61 show, for 1985 and 1990, the total emissions which would result under the no new leasing alternative together with the incremental change of the other alternatives measured against the no new leasing base case. Negative values indicate smaller amounts of emissions.

In the methodology employed to estimate emissions (the Coal Impact Estimation Program), power plant energy consumption on a Btu basis did not change from alternative to alternative within a given year and within the high, medium, or low production projection. Therefore, any differences in emissions would come from interregional shifts in coal mining, beneficiation, and transportation. Emissions from these sources would be minor compared to those from coal conversion or steam electric power plants and the small differences between the numbers in the table are to be expected.

Only two differences in sulfur oxides emissions in 1985 and 1990 (Table 5-56) are significant; both occur in the Western Interior Coal Region where about a six percent increase is forecast under the high case for the preferred program alternative and about a five percent decrease is forecast for the state determination of leasing levels alternative.

Particulates in 1985 and 1990 (Table 5-57) would generally decrease in the eastern regions for each alternative when compared with the no new leasing base case. For the western regions these values would generally increase. In both cases, however, the changes would rarely be greater than 10 percent and never more than 15 percent above the no new leasing alternative.

Since 1850, the amount of carbon dioxide in the atmosphere is estimated to have increased by 40 ppm from 290 ppm. A fourth of this total

increase has occurred within the past 10 years [109]. Most of the 40 ppm increase is attributed to the increased use of fossil fuels as the result of the industrial revolution. The impacts of increased coal utilization should be studied on a world-wide basis since even a 2° to 3°C global temperature rise could have profound climatic effects. For example, resultant warming of ocean waters could disrupt marine life and ocean circulation. In addition, changes in temperature distribution in the atmosphere could cause changes in other climate variables such as precipitation, cloud cover, winds, and humidity [110]. World-wide agriculture production and distribution could be detrimentally affected. The accuracy of predicting future carbon dioxide levels in the atmosphere is limited by uncertainty about its final destination (fate). The amount of carbon dioxide released to the atmosphere each year is speculative on a global basis because of uncertainties about factors like the effects on carbon dioxide production of forest clearing and the mechanisms for carbon dioxide removal from the atmosphere. Predictions about the extent to which greater utilization of fossil fuels, especially coal, will contribute to atmospheric carbon dioxide levels adds another factor of uncertainty to the prediction process.

Table 5-55 shows that carbon dioxide emissions in 1976 due to coal production totaled about 1,197 million tons (the sum of the 1976 base case column). As shown in Table 5-61 for the no new leasing medium level alternative, emissions are projected to be about 2,152.7 million tons in 1985 and 2,929 million tons in 1990. These estimates represent increases of 955.7 million tons and 1,732 million tons, respectively, over the 1976 base case. The preferred medium level alternative is projected to contribute 948.3 million tons and 1,768 million tons in 1985 and 1990, respectively, over the 1976 base case. The preferred alternative for the proposed Federal coal management program is estimated to produce less carbon dioxide in 1985 than would be produced under the no new leasing base case; in 1990, the preferred alternative program is estimated to produce 36 million tons (or 1.2 percent) more emissions than would be produced under the no new leasing base case. Presently, the atmosphere contains about 700 billion metric tons of carbon. Annual global carbon dioxide emissions in 1976 were about 20 billion tons, primarily due to fossil fuel burning

[110]. The total carbon dioxide emissions estimated for 1976 resulting from U.S. coal development activities (1,197 million tons) represents about 5.9 percent of the 1976 global carbon dioxide emissions. Assuming that the only contributions to global carbon dioxide emissions were from coal development activities, then the U.S. share of these emissions would be about 9.6 percent and 12.8 percent for 1985 and 1990, respectively.

The 1985 and 1990 values for carbon monoxide emissions (Table 5-58) show a general decrease for the eastern regions and a general increase for the western regions under other alternatives. Carbon dioxide in 1985 and 1990 (Table 5-61) would generally decrease in the eastern regions for each alternative when compared with the no new leasing base case. For the western regions these values would generally increase. For the eastern regions the decrease is not more than six percent, while for the western regions the increase is less than 90 percent.

Increases in nitrous oxides in 1985 and 1990 (Table 5-59), would be generally less in the eastern regions for the other alternatives than for the no new leasing alternative although these other values are still usually only a few percentage points below the no new leasing base case. For the western regions in 1985, no change larger than about two percent is projected.

For hydrocarbons (Table 5-60) in 1985, only two alternatives would lead to an increase of as much as one percent over the no new leasing base case; both increases would occur in the Denver-Raton Mesa Coal Region. Similar results would be obtained in 1990.

5.3.3 Ecological Impacts

Ecosystems in each coal region would experience a number of impacts from increased coal development activity. These impacts would include primary disturbance and destruction of vegetation and wildlife populations and introduction of hazards to biota.

Secondary impacts resulting from induced growth, changes in plant and animal communities, and adjustment of ecosystems would also occur. Disturbances and modifications of habitats adjacent to the areas of principal impacts would diminish with distances but this "area of influence" could encompass as much as five times the

area directly disturbed, depending on species affected and type of impact [48].

Since the specific tracts which might be leased are presently unknown, it is not possible to indicate exact habitats which would be lost. Existing legislation and/or the criteria which establish some land areas as unsuitable (see Section 3.2.2 and Section 5.4.8), however, protect sensitive habitats, such as endangered species critical habitat, alluvial valley floor habitat, wetlands, National Wildlife Refuges, National Wilderness Areas, Federally-designated wilderness study areas, high priority migratory bird habitat, raptor nests and roosts, and habitat for resident high interest wildlife species.

The severity of impacts on regional ecosystems under the program alternatives would be affected by the frequency of disturbance, which depends in part on the rate of growth in coal related activities and whether the activities would be concentrated or dispersed. In general, the ecologic harm done to a region will increase under those alternatives which involve the largest amounts of coal production and coal consumption and the most land disturbance.

Off-road vehicles (ORVs) would be frequently used during the exploration phase of coal development as well as for recreation. The immediate impact of ORV travel would be to the surface where low growing vegetation might be injured and destroyed. Repeated travel over the same route could result in soil compaction, decreased water infiltration, and interference with root growth [49]. Increased runoff resulting from a reduced capacity of the compacted soils to absorb rainfall could lead to erosion, the formation of ruts, and increased sediment loadings in adjacent waterways. Concentrated ORV travel and frequent disturbances (noise and man's presence) in a given area might affect wintering big game, upset breeding behavior of animals and birds, and result in direct loss of some wildlife.

Vegetation removed during site preparation would result in loss of natural site productivity for wildlife. Indirect or secondary impacts would include an increase in the potential for site erosion, sedimentation, and introduction of pollutants into adjacent waterways, as well as disturbance of adjacent vegetation, habitat, and wildlife. Animal life would be adversely affected by losses of food, cover, and habitat. The initial impact would be

greatest to soil micro- and macro-organisms, arthropods, small burrowing mammals, ground nesting birds, and slowly moving forms such as amphibians and reptiles. However, due to their relatively rapid population turnovers and high reproductive rates, these same groups of animals would likely be the first to repopulate reclaimed areas. Insects and other arthropods would begin to repopulate disturbed areas during and after re-vegetation. Diversity, however, could be lower than before development.

While direct mortality of larger, more mobile wildlife species would be rare, loss or disturbance of habitat would cause increased competition for food, cover, nesting sites, and territory, thereby potentially reducing wildlife populations over time. Comparatively speaking, fewer numbers of predators and large game mammals would be affected by habitat loss as both generally range over a larger territory than do smaller creatures. The losses which might occur, however, would tend to be more long-term due to slower population turnovers and lower reproductive rates.

Wildlife dependent upon specific seasonal habitats would be affected by activities which removed or reduced these habitats. If development were to reduce habitats which presently limit the size of a particular migratory wildlife population, that population would also be reduced in other habitat areas. Further secondary impacts could then be felt by predators, prey, or other links in the food chain of that species. Lands undergoing coal development would decrease the total area available for wildlife and, initially, create increased crowding of adjacent habitats. Populations in excess of a habitat's carrying capacity would, however, eventually diminish to a level equal to or lower than that carrying capacity.

Ecosystems beyond the immediate development area could be temporarily or permanently disturbed by noise, air, and water emissions from community expansion; increased human presence and activity; and plant and mine operations. Most species tolerate human intrusions only to a certain point. Others, such as pronghorn antelope, are very wary of human presence [50]. The extent of these impacts would be dependent on the tolerance of a given species.

Coal development would result in the introduction of additional hazards into the environment. Fences constructed along rights-of-way, or around

areas under construction and areas under rehabilitation, would reduce some populations such as antelope [51]. Increased vehicular traffic would result in higher numbers of roadkills of various species. The presence of mining operations and support facilities could change migration patterns and grazing movements through changes in the quantity and quality of forage and water, as well as physically restricting movements by erecting impenetrable barriers, such as tall fences, deep ditches, and heavily travelled roadways.

Factors which limit distribution of aquatic organisms include temperature, turbidity, pH, (acidity or alkalinity), water velocity, oxygen supply, conductivity, and substratum. Any one of these factors could be changed in adjacent streams and downstream rivers by effluents, accidental spills, impoundments, and/or erosion. Sufficient amounts of leached substances and saline groundwater released to surface waters from excavations or overburden piles could cause a shift in pH and conductivity into a range that would interfere with the vital functions of aquatic organisms. Acid drainage is a potential problem particularly in the East, while salinity poses more of a problem in the West.

Sediment introduced into surface waters by runoff could affect aquatic life in many ways; it could clog fish gills, bury eggs of both fish and insects, bury food sources, smother aquatic vegetation, and alter habitat. In addition, there are many indirect ways in which sediment could disrupt an aquatic system. For example, turbidity would decrease light penetration, thereby decreasing photosynthetic activity of aquatic plants and phytoplankton. This effect, in turn, could result in a reduction of dissolved oxygen concentration.

Development activities near surface water systems might also affect aquatic life through the introduction of various materials into the water body by overland runoff. Runoff frequently contains inorganic and organic matter originating from decayed vegetation and from the soil itself. Overland runoff could also leach minerals from exposed soils or might carry residues (oils, grease, pesticides, etc.) which are used during the construction period or which are present in the soil. The exact quantities of various pollutants which would enter a given water body would depend, to some extent, on the care taken to minimize their entry.

Any change in the physical characteristics of the stream substratum could result in extensive alteration in benthic composition (stream bottom communities). Species dependent on running water for food supply and on hard attachment surfaces for maintaining their position could be replaced by organisms which typically live in the substratum rather than on it.

Alteration of benthic composition would affect species dependent upon these organisms as a food source. The number of different species of large invertebrates and fish in an impounded pool is usually substantially lower than in the pool's former unimpounded, free-flowing status [52]. Game fish would be replaced by more tolerant species, such as carp.

Large volumes of water would be required in all of the regions for mining and reclamation activities, coal conversion and use plants, conjunctive developments, and population increases (see Section 5.3.2.6). Water withdrawals could affect aquatic systems by reducing habitats and by changing the physical regimes (principally dissolved oxygen and temperature) of the remaining water.

5.3.3.1 Productivity Loss. Table 5-62 presents potential losses in thousands of tons of natural primary production (biomass) for the no new leasing alternative at low, medium, and high production projections in 1985 and 1990. The table also compares the no new leasing with the other program alternatives. These potentials are based on the product of unweighted averages of the amount of material produced by acre (excluding agriculture) for each region and the surface area disturbed in each region. Potential losses weighted by major natural vegetation types are given in Appendix D, Tables D-4 through D-25. While such actual productivity losses will vary, until specific sites are determined this comparison provides the most feasible way to indicate differences between alternatives and between regions.

Comparison between the no new leasing and the preferred alternatives at the medium coal production projection in 1985 shows that coal related development under the preferred program would remove less natural productivity in the Appalachian and Western Interior Coal Regions and would remove up to eight percent more in the Eastern Interior, Texas, and all western coal

regions. In 1990, medium level coal production under the preferred program would result in a lower loss in primary production in comparison to the no new leasing alternative in all regions except the Northern Appalachian, Powder River, Green River-Hams Fork, and Denver-Raton Mesa Coal Regions. The largest increase would be a 23 percent higher loss in the Powder River Coal Region; the Fort Union Coal Region would lose about 17 percent more primary production of biomass.

Comparison of the lease PRLAs only and the no new leasing alternatives at the medium production levels in 1985 indicates that lower primary productivity under the lease PLRAs only alternative would occur in the West except in the Powder River and San Juan River Coal Regions; losses in the East would be consistently lower. In 1990, all regions except the Central and Southern Appalachian and Powder River Coal Regions would experience lower losses in productivity than under the no new leasing alternative; the loss in the Powder River Coal Region would be about 12 percent higher.

Under the emergency leasing alternative in 1985, moderate increases in productivity lost would result in the western coal regions compared to the no new leasing alternative. In 1990, losses in productivity would be lower or would increase only slightly above those which would result under the no new leasing alternative.

The leasing to meet industry needs alternative would generally remove slightly less natural productivity (on a percentage basis) in the East and considerably more in the West during both time periods. The lease to meet DOE production goals alternative would cause considerably higher losses in some of the western regions.

Under the state determination of leasing levels alternative at the medium coal production projection, a general amelioration of the western impacts would occur when compared to the lease to meet industry needs or lease to meet DOE production goals alternatives. In the near term, this alternative, however, would create higher losses in the Fort Union and Green River-Hams Fork Coal Regions than those which would occur under the no new leasing alternative. Over the long term, no significant differences would be noticed.

5.3.3.2 Habitat Losses.

Habitat losses are dependent on the amount of land disturbed during program-related coal development activities. The degree of surface mining in a given region would be a major factor contributing to habitat loss. Land for community expansion, rights-of-way, and conversion and consumption plants would also reduce habitat.

Surface mining disturbances typically clear a land tract of vegetation and remove the area of overburden. The removal of vegetation with soils causes a loss of food, cover, and breeding sites for resident wildlife populations, as well as livestock herds. This would ultimately result in net reductions of these populations in the affected coal regions. Cattle and sheep herds would be removed from western grazing lands or eastern pastureroads, where surface mining occurs. Populations of burrowing mammals, ground nesting birds, reptiles, and soil organisms would be reduced by the elimination of both individuals and habitat due to coal-related excavation. More mobile wildlife, such as deer, songbirds, and predators, would flee to the surrounding areas, where they would create additional interspecific competition for food, cover, and nesting sites. Where such competition is at a maximum, but the existing wildlife can still be supported, the habitat is said to be at its carrying capacity. If habitats in surrounding areas are already at their carrying capacities, which is generally the case with a stabilized ecosystem, the habitat will not be able to sustain any long-term population increases. Thus, in addition to losses on lands directly disturbed, wildlife would also be subject to losses on other lands which already support populations at the carrying capacity. Table 5-63 presents estimates of potential big game population reductions which would occur due to habitat loss as a result of the no new Federal leasing alternative at low, medium, and high production projections. Table 5-63 also presents a comparison of potential big game population reductions of the no new Federal leasing versus other program management alternatives. Carrying capacity information for typical types of wildlife common to the 12 coal regions is given in Table D-1 of Appendix D. In addition, Appendix D provides estimates of potential wildlife losses by region per alternative that would occur as a result of habitat losses.

5.3.3.3 Endangered Species. Endangered and threatened species and their habitat are protected under the Endangered Species Act of 1973 for their aesthetic, ecological, historical, recreational, and scientific value. Regardless of which coal management alternative is adopted, any site selected for mining would require specific analysis to determine the presence of protected species or their habitat. If it is determined that such species or habitat does occur, the surface area may be designated as unsuitable for coal mining under lands unsuitability criteria (see Sections 3.2.2 and Section 5.4.8). (The unsuitability criteria proposed in the preferred program (see Table 3-1) would also protect threatened species designated under the 1973 Act and state listed threatened or endangered species).

Table 5-64 provides a summary list of endangered species found within the coal regions together with the developments that most severely threaten their continued existence. Included in this listing are animal and plant species with formal endangered or threatened status as identified by the U.S. Fish and Wildlife Service's List of Endangered and Threatened Wildlife and Plants, January 17, 1979. Of the 22 plant species which have been formally accepted as endangered or threatened, only four (Texas wild rice, northern wild monkshood, Rydberg milk-vetch, and *Phacelia argillacea*) have been reported to occur in the coal regions. Proposed listings of plants such as the Smithsonian listing of 1975 are not included. The "Distribution" column lists general drainages or states where the species occur. Where the species occurs in several regions, these species are discussed once in the region most commonly inhabited. The major types of developments which adversely impact these species are listed in the "Most Serious Threat" column. However, as all new construction and mining would affect habitats, these also must be considered in planning for coal related development.

Guidelines for Section 7 of the Endangered Species Act of 1973 were issued to all Federal agencies by the U.S. Fish and Wildlife Service on April 22, 1976. On January 4, 1978 in 43 Federal Register 870, the U.S. Fish and Wildlife Service issued final rules establishing the procedures governing interagency consultation under Section 7 of the Endangered Species Act of 1973. Accordingly, before the Bureau of Land Management

would consider a new coal lease, it would consult with the Fish and Wildlife Service regarding potential impacts to endangered species or their habitats.

The following is a brief discussion, by region, of potential impacts on Federal endangered species. The main problem in the future regarding actions at specific sites would be determination of whether or not an endangered species (either as a resident or an occasional migrant) or its habitat is present. Appendix Table D-3 lists the number of species by major category (i.e., mammals, birds, etc.) which occur on the state listings of protected species. Site specific information would also be required to determine their presence.

Northern Appalachian Coal Region. While Appendix D lists 26 species of endangered animals for the Appalachian Coal Region, few are actually permanent residents in the Northern Appalachian Coal Region. Much of this region is man-dominated and many species have already been eliminated. Reintroduction of the peregrine falcon is occurring in the Northeast, and it is possible that it could eventually spread to this region. Nesting habitat which could be provided by rock outcrops and cliffs would be impacted by mining in the Northern Appalachian Coal Region. However, released birds are known to nest on man-made structures.

The gray and Indiana bats may be found in limestone caves, which could be affected by mining that removed the caves or impaired entrances. An occasional eastern cougar could be found in remote mountain areas. Because of the large territories established by this predator, any reduction of habitat either by mining, urbanization, or other conjunctive development would threaten the cougar.

No endangered plant species occur in the Northern Appalachian Coal Region.

Central Appalachian Coal Region. The statements for the Northern Appalachian Coal Region also apply to the Central Appalachian Coal Region. Since the Central Appalachian Coal Region is more remote, the potential for impacts to cougars and bald eagles would increase. As mountain tracts are stripped or opened to urbanization, these species might disappear. The gray and Indiana bat are less rare in Central Appalachia.

TABLE 5-64
POTENTIAL THREATS TO ENDANGERED SPECIES OF COAL REGION

Common Name	Scientific Name	Distribution	Habitat	Most Serious Threat
FISHES				
Woundfin	<u>Plagopterus</u> <u>argentissimus</u>	Virgin River below Hurricane, Utah	swift rivers	reservoirs
Greenback cutthroat trout	<u>Salmo</u> <u>clarki</u> <u>stomias</u>	Blackhollow Creek Cache la Poudre River, few possible streams in Boulder & Larimer counties, Colorado	fresh, cold streams & rivers	reservoirs
Arizona (apache) trout	<u>Salmo</u> <u>apache</u>	Arizona	streams	reservoirs
Humpback chub	<u>Gila</u> <u>cypha</u>	Green & Colorado Rivers, from Grand Canyon Area Northward to vicinity of Flaming Gorge Dam on Utah-Wyoming border	flowing streams & rivers	reservoirs
Colorado squawfish	<u>Ptychocheilus</u> <u>lucius</u>	middle and lower Green River, main Colorado River above Lake Powell, and Salt River; spawning in Yampa and Green River	turbid, swift warm rivers	reservoirs
Kendall Warm Springs dace	<u>Rhinichthys</u> <u>osculus</u> <u>thermalis</u>	Kendall Warm Springs, tributary to the Green River in Wyoming	warm springs fed streams	reservoirs
Fountain darter	<u>Etheostoma</u> <u>fonticola</u>	Comal & San Marcos Springs in Hays and Comal Counties Texas	spring out-flow	habitat change
Watercress darter	<u>Etheostoma</u> <u>nuchale</u>	Glen Springs at Bessemer, Jefferson County, Alabama (Black Warrior River drainage)	springs with watercress	habitat change
HERPTILES				
Texas blind salamander	<u>Typhlonolge</u> <u>rathbuni</u>	Hays County Texas	deep wells, underground streams	probably none
Houston toad	<u>Bufo</u> <u>houstonensis</u>	southcentral Texas	loblolly pine forests	habitat loss
American Alligator	<u>Alligator</u> <u>mississippiensis</u>	North Carolina, South to Texas, Florida, Louisiana, Georgia, Arkansas, Southeast Oklahoma	fresh wetlands, salty estuaries	habitat loss
BIRDS				
Eskimo curlew	<u>Numenius</u> <u>borealis</u>	Alaska, migratory through Central U.S.	grasslands and tundra	habitat loss

TABLE 5-64 (continued)

Common Name	Scientific Name	Distribution	Habitat	Most Serious Threat
Whooping crane	<u>Grus americana</u>	winters on Gulf Coast, Texas; migrates through westcentral U.S. from Canada to Texas	wetlands, coast, grain farmlands	probably none
Attwater's greater prairie chicken	<u>Tympanuchus cupido attwateri</u>	coastal prairie counties, Texas (primarily Refugio and Colorado Counties)	prairie, grasslands	habitat loss
Arctic peregrine falcon	<u>Falco peregrinus tundrius</u>	migrates through eastern and middle North America to Gulf	breeds in treeless tundra; migrates along coasts and waterways, feeds in marshes	habitat and wetland removal
American peregrine	<u>Falco peregrinus anatum</u>	breeds Alaska south to Baja Calif., Arizona to Rocky Mts. (most western states)	coniferous forests and wetlands and along rivers	habitat and wetland removal
Bald eagle	<u>Haliaeetus leucocephalus</u>	Atlantic & Gulf coasts, resident of Florida, may be found all over U.S. wandering	wetlands, cliffs, forests, estuaries, freshwater lakes	transmission lines, habitat removal
Red-cockaded woodpecker	<u>Picoides borealis</u>	Oklahoma, Arkansas, Kentucky, Virginia-South to Gulf of Florida	mature pine forests	habitat removal
Ivory-billed woodpecker	<u>Campephilus p. principalis</u>	Texas, Louisiana	mature hardwoods	habitat removal
Bachman's warbler	<u>Vermivora bachmanii</u>	Virginia, South Carolina, Alabama	swamp forests bottomlands	habitat removal
Thick-billed parrot	<u>Rhynchositta pachyrhyncha</u>	Arizona & New Mexico	mountains	probably none
Kirtland's warbler	<u>Dendroica kirtlandii</u>	breeding area--lower Michigan, migrates south to Bahamas	Jack pines brushy undergrowth	probably none
<hr/>				
<u>MAMMALS</u>				
Gray bat	<u>Myotis grisescens</u>	central, southeastern, midwestern, and eastern states.	limestone caves	habitat loss
Indiana bat	<u>Myotis sodalis</u>	central and southeastern states	limestone caves	habitat loss

TABLE 5-64 (continued)

Common Name	Scientific Name	Distribution	Habitat	Most Serious Threat
Black-footed ferret	<u>Mustela nigripes</u>	Western United States and Canada	shortgrass prairie	habitat loss
Utah prairie dog	<u>Cynomys parvidens</u>	Utah	grassland & cropland	habitat loss
Eastern cougar	<u>Felis concolor cougar</u>	Eastern United States (Canada to Carolinas)	remote woodlands and mountains	community expansion
Red wolf	<u>Canis rufus</u>	Texas, Louisiana (Gulf regions)	coastal prairie marshes, swamps, lands	community expansion
Gray wolf	<u>Canis lupus</u>	Texas, New Mexico, Mexico, Wyoming, Montana, South Dakota (Black Hills), Idaho, Oregon and Washington	remote arid prairies; remote mountain regions & open lands & forests	community expansion
<u>CLAMS</u>				
Birdwing pearly mussel	<u>Conradilla caelata</u>	Powell & Clinch Rivers in Virginia and Tennessee; Duck River in Tennessee	river	reservoirs
Dromedary pearly mussel	<u>Dromus dromas</u>	Powell & Clinch Rivers in Virginia and Tennessee	river	reservoirs
Green-blossom pearly mussel	<u>Epioblasma torulosa gubernaculum</u>	Clinch River in Virginia and Tennessee	river	reservoirs
Tubercled-blossom pearly mussel	<u>Epioblasma torulosa torulosa</u>	Lower Ohio River in Kentucky and Illinois, Nolichucky River in Tennessee and Kanawha River in West Virginia	river	acid drainage, reservoirs
Fine-rayed pigtoe pearly mussel	<u>Fusconaia cuneolus</u>	Clinch River in Virginia and Tennessee, Powell River in Virginia and Tennessee, and Paint Rock River in northern Alabama	river	reservoirs
Shiny pigtoe pearly mussel	<u>Fusconaia edgariana</u>	Powell and Clinch Rivers in Virginia and Tennessee, Paint Rock River in Alabama and Holston River in Virginia	river	reservoirs

TABLE 5-64 (concluded)

Common Name	Scientific Name	Distribution	Habitat	Most Serious Threat
Pink mucket pearly mussel	<u>Lampsilis orbiculata</u> <u>orbiculata</u>	Green River, Kentucky Kanawha River in West Virginia, Tennessee River (Tennessee and Alabama); Muskingum River, Ohio	river	acid drainage, reservoirs
Alabama lamp pearly mussel	<u>Lampsilis virescens</u>	Faint Rock River System in Alabama	river	reservoirs
White warty-back pearly mussel	<u>Plethobasis</u> <u>cicatricosus</u>	Tennessee River in Tennessee and Alabama	river	reservoirs
Orange-footed pearly mussel	<u>Plethobasis</u> <u>cooperianus</u>	Tennessee River in Tennessee and Alabama, Duck River in Tennessee	river	reservoirs
Rough pigtoe pearly mussel	<u>Pleurobema plenum</u>	Tennessee River, Tennessee; Green River, Kentucky; Clinch River, Virginia and Tennessee	river	acid drainage, reservoirs
Cumberland monkey-face pearly mussel	<u>Quadrula intermedia</u>	Powell and Clinch Rivers in Virginia and Tennessee Duck River, Tennessee	river	reservoirs
Appalachian monkeyface pearly mussel	<u>Quadrula sparsa</u>	Powell and Clinch Rivers in Virginia and Tennessee; Duck River, Tennessee	river	reservoirs
Pale lilliput pearly mussel	<u>Toxolasma cylindrella</u>	Duck river, Tennessee; Paint Rock River, Alabama	river	reservoirs
Cumberland bean pearly mussel	<u>Villosa trabilia</u>	Cumberland and Rockcastle Rivers, Kentucky	river	acid drainage, reservoirs
Yellow-blossom pearly mussel	<u>Epioblasma florentina</u> <u>florentina</u>	Duck River, Tennessee	river	acid drainage, reservoirs
Turgid-blossom pearly mussel	<u>Epioblasma turgida</u>	Duck River, Tennessee	river	acid drainage, reservoirs
<hr/>				
<u>Endangered Plants</u>				
Texas wild rice	<u>Zizania texana</u>	San Marcos River, Texas	warm spring-fed waters	habitat loss
Hydberg milk-vetch	<u>Astragalus perianus</u>	Utah	grasslands	habitat loss
Northern wild monkshood	<u>Aconitum</u> <u>noveboracense</u>	Iowa	moist woodlands	habitat loss
Unnamed phacelia	<u>Phacelia</u> <u>argillacea</u>	Utah	wetlands	habitat loss

The rivers of the Central Appalachian Coal Region support 16 endangered mussels. These species could be threatened by mining which adds acid mine drainage or sediment to regional streams. In addition, reservoirs which change river habitat to lake habitat would eliminate some populations. The species residing in the following rivers would be most impacted by coal developments and industrialization: Powell, Clinch, Duck, Lower Ohio, Nolichucky, Kanawha, Holston, Muskingum, Green, Tennessee, Cumberland, and Rockcastle Rivers.

No endangered or threatened plant species are known to occur in this coal region.

Southern Appalachian Coal Region. Three endangered bird species are found in the Southern Appalachian Coal Region. The bald eagle nests there, as well as the red-cockaded woodpecker and Bachman's warbler. All of these species are found in other southern states where coal development would not occur, so extinction would not occur if the habitats in this coal region were removed.

Conjunctive developments, such as roads, pipelines, plant construction, and urbanization, and sediment from land clearing, could reduce watercress darter populations. If Glenn Springs (Jefferson County, Alabama) were to be affected drastically as well, this species could become extinct.

The Paint Rock and lower Tennessee River systems support seven endangered clams. Sediment and reservoirs would reduce certain populations of these mussels.

No endangered or threatened plant species are known to occur in this coal region.

Eastern Interior Coal Region. At least eight species of endangered animals are found in the Eastern Interior Coal Region. Few of these are permanent residents. The peregrine falcon migrates through this coal region along waterways. Bald eagles are found along the Mississippi River. The gray and Indiana bats are residents of limestone cave areas, which could be adversely affected by mining. Modification of caves would eliminate critical habitat.

Two endangered species of mussels which are distributed in Eastern Interior Coal Region rivers would be affected by acid mine drainage and sedimentation.

No endangered or threatened plant species are known to occur in this coal region.

Western Interior Coal Region. At least 10 endangered animal species are found within this region, and many more are unique to the Ozarks. Bald eagles, whooping cranes, peregrine falcons, eskimo curlews, and Bachman's warblers are all migrants of this region. The red-cockaded woodpecker is a probable permanent resident in mature pine forests, particularly where suitable cavity trees exist (generally overmature pines infected with red heart disease). While development would not likely eliminate the species, population within this region would be reduced where development removed these forests.

Northern wild monkshood (a threatened plant) occurs in moist woodlands in Iowa, and would be adversely affected if coal development removed or encroached on its habitat.

Texas Coal Region. The Texas Coal Region provides habitat for 12 endangered species. The fountain darter in Hays and Comal Counties, Texas, could be affected by water withdrawals and water disturbances due to developments associated with coal production. If Comal and San Marcos Springs were to be eliminated, the fountain darter could become extinct.

The Houston toad could be eliminated from central Texas if pine forest were cleared and surface mined. The ivory-billed woodpecker may occur in mature bottomlands such as the Big Thicket. This bird and the red wolf would be affected if remote woodlands were altered.

Wetlands for the whooping crane are well protected. Drier prairie sites, which could be used for coal conversion and utilization plant sites or for strip mining, provide habitat for Attwater's greater prairie chicken.

The San Marcos River provides habitat for Texas wild rice. Water withdrawals, sedimentation, and water pollution would adversely affect this plant species.

Powder River Coal Region. At least four endangered species occur in this region. The whooping crane, bald eagle, and American peregrine falcon are all migrants of the region. Wherever prairie dog towns and resident black-footed ferrets are found, surface mining, industrial development,

or urbanization would lower or possibly cause loss of the ferret population.

No endangered or threatened plant species are known to occur in this coal region.

Green River-Hams Fork Coal Region. At least six endangered animal species are present in this coal region. The Kendall Warm Springs dace occurs in Kendall Warm Springs Creek, a tributary of the Green River. The black-footed ferret occurs in the Green River - Hams Fork Coal Region. As prairies are surface-mined and communities expand into remote areas, animal numbers would be reduced.

No endangered or threatened plant species are known to occur in this coal region.

Fort Union Coal Region. In addition to species mentioned for the Powder River Coal Region, the Tule white-fronted goose is a potential migrant into the Fort Union Coal Region. This species would be impacted if development adversely affected critical lake or wetland habitats. The northern kit fox is an occasional wanderer into the region from Canada.

No endangered or threatened plant species are known to occur in this coal region.

San Juan River Coal Region. In this coal region, the Arizona (Apache) trout would be affected by any water development, water withdrawals, reservoirs, or water pollution. The American peregrine falcon is more dependent upon upland habitats which could be strip mined or subject to urbanization. The thick-billed parrot would probably remain unaffected by coal development since it exists principally south of the coal fields.

No endangered or threatened plant species are known to occur in this coal region.

Uinta-Southwestern Utah Coal Region. This region has at least 10 threatened or endangered species. The woundfin, humpback chub, and Colorado squawfish are all associated with flowing river habitat and would be affected by reservoir construction, mining pollution, and water withdrawal.

Rydberg milk-vetch (a threatened plant) and *Phacelia argillacea* (an endangered species of the waterleaf family) would be adversely affected by strip mining, urbanization, and other land clearing activities.

Nesting areas for golden eagles and winter roosting concentration areas for bald eagles would also be potentially affected.

Denver-Raton Mesa Coal Region. At least five endangered species occur in this region. Whooping cranes, peregrine falcons, and bald eagles are migrants through the region. The black-footed ferret would be affected where strip mining and urbanization removed habitat or reduced prairie dog populations. A small population of the greenback cutthroat trout also remains within this coal region.

No endangered or threatened plant species are known from this coal region.

5.3.4 Socioeconomic Impacts

The purpose of this section is to assess socioeconomic impacts which are likely to occur within each coal production region due to production activities under a Federal coal management program. Community impacts can be anticipated within broad geographic areas by quantitative analysis of inter-regional population changes induced by coal-related activities. Program decisions would have consequences for:

- Population and lifestyle
- Employment opportunities
- Agricultural productivity
- Public services and community fiscal stability
- Tax revenue time lag
- Coal development cycle accidents and fatalities
- Cultural resources
- Recreation resources

The following section reviews what can be determined for each of these areas of impact using regional data. The location and intensity of impacts with respect to specific communities is dependent upon the form taken by the Federal coal management program which is finally adopted.

One purpose of the Federal coal program is to delineate tracts, if necessary, for coal leasing. The size and location of these tracts will be determined under an approved program through a land-use planning process, by application of suitability criteria after consultation with state and local government, industry, and the public. In the future, after tracts have been delineated, the

impacts associated with leasing and mining will be the subject of intra-regional impact assessments. Decisions on the tracts and on regional assessments will not be made until after adoption of a Federal coal management program. The regional assessments will include:

- Cumulative site-specific analysis of all impacts for each tract within a given region.
- Site-specific urban impact analysis and assessment of effects on rural and community development. A special situation may exist in some western localities where population increases occur adjacent to Indian communities in which English is not spoken and traditional life styles of the inhabitants predominate. The problem of expanding educational facilities would be complicated, particularly because of the linguistic difference and because children of the newcomers would have different school needs from those of the native pupils. The situation would be the reverse of that encountered in other parts of the country, where it has been necessary to establish bilingual instruction to serve non-English speaking groups that move in. As means have been found to meet the educational needs in this latter situation, it can be assumed that satisfactory provision will also be made in communities where children of both Indian and non-Indian parents will require instruction.

The difficulties inherent in a potential conflict of traditional and transplanted lifestyles are more difficult to predict; however, both as to the form they will take and as to the means that could prevent or mitigate them. The problems discussed above in regard to impacts on existing social patterns could be aggravated by the language barrier to communications. As a minimum, careful advanced planning will be required, initiated by state and local government authority and supported by the industry involved. Within this planning framework, it will be essential for leaders of both existing and incoming elements of the community to hold a continuing series of meetings with a view to anticipating and averting potential problems, providing the necessary expanded or additional community services, and establishing the mutual cooperation necessary for different lifestyles to exist harmoniously in close contact.

5.3.4.1 Population. Socioeconomic impacts are addressed in this section by analyzing the relationships between population changes that might be stimulated by coal management decisions and the baseline population data presented in the regional descriptions in Chapter 4. Population change is emphasized because it is one of the most important indicators of other kinds of change which often result in social and economic problems in communities affected by sudden increases or decreases in coal production. The Department recognizes that the real impacts of Federal coal management decisions are felt directly by individuals and families. It also recognizes that some impacts are easier to measure than others. The change from a stable rural environment to a more diverse and unpredictable setting, which combines both rural and urban activity, creates losses for some individuals which are real but difficult to quantify. Such changes may also intensify social tensions, such as those between Indians and non-Indians where coal development occurs near Indian reservations and between the resident ranchers and farmers and the new families attracted by the coal development employment opportunities. These losses and tensions are also the least likely to be avoided or minimized through mitigation efforts.

Quantitative analysis can help predict the needs for housing, education, health care, utilities, public safety, recreational facilities, and other services and facilities required to assure that a population of a certain size can be accommodated in a specific area without causing overcrowded schools, inadequate health care, substandard living conditions from housing shortages, or similar problems. The cost of providing facilities and services can also be measured. This means that by analyzing the probable population impacts of the Federal coal management alternatives, the state and local governments in impacted regions can work with local citizens, Federal agencies, and the coal industry to determine what kinds of facilities and services will be needed, where such facilities and services should be located, when they are needed, and who should pay for them.

Where data in this section indicate large population changes or rapid population growth rates, social and economic problems would likely result unless corrective actions are planned in advance by responsible state and local governments. The possible impacts of such changes can

be further measured by comparing the socioeconomic data in Appendix G with the regional descriptions in Chapter 4. The comparison will illustrate the range of facility and service demands which could be generated by population changes.

Population changes might occur in any of several specific locations within a broad geographic area, and regional data can not be used to predict impacts on an individual community or locale. Only a more project-specific and site-specific analysis could provide information of meaningful value to local planners. The impact of rapid increases in coal-related employment will also vary greatly from community to community, depending on the level of existing services and facilities in specific areas. A given amount or rate of coal development-induced demand for services would have one effect in an area that is already relatively industrialized as compared to the impact of introducing the same demand in a predominantly agricultural area. For this reason, increases in demand for specific facilities and services can not necessarily be considered as an economic threat, or an economic benefit, without more specific analysis of local conditions and capabilities. It should be noted in those areas with high rates of unemployment, such as Indian reservations, energy development will have both positive and negative effects. As noted above, the probability of social and cultural conflicts is high. Further, seemingly impossible demands upon existing infrastructures will strain the ability of local communities to deliver essential services. Positive effects will include substantial increases in the demand for labor, and, over time, generation of significant levels of public revenues derived from energy resources.

In general, social and economic change can be projected to have different impacts, requiring consideration of different mitigation measures, in three broad categories of impacted communities. In areas that have previously experienced industrial development, and that have both private and public facilities and services in place to support an existing urban or industrial population, an increase in mining and related activities may lead to increased occupancy of existing housing, increased employment among existing local or area workers, higher enrollment in existing schools, and corresponding increases in the use of other facilities and services. Population changes resulting from the

increased activities, in terms of both the absolute numbers and the numbers relative to the community's existing population, may be minimal. Where changes would take place, local and state government agencies with existing budgets and staffs designed to deal with social services, planning, and land use can address the population-related problems; in these cases, the need to increase the size and complexity of local government might be minimal.

However, where neither the private economy nor local governments have previously been required to respond to needs created by relatively large numbers of industrial workers, the changes required may seriously conflict with existing patterns of residential and commercial development, transportation systems, and priorities for government activity and spending. Some problems would be physical and financial, others more social and political.

Housing shortages could be severe, resulting in the rapid establishment of mobile home parks in areas with inadequate zoning regulations. This development often leads to haphazard growth, substandard living conditions, and a general deterioration of the social structure. In more severe situations, there could be an increase in violent and property crimes, alcoholism, prostitution, and drug abuse. Lack of a full array of recreational, education, social services, and cultural opportunities for personal enrichment might become evident. A sharp increase in demand for building sites, construction materials, and other goods and services could cause serious local inflation. New employees in coal development-related industries would usually be more highly paid than the established residents who work in other enterprises, with the result that people who have lived in a community for years may find themselves paying more to live, without a commensurate increase in personal income. The need to decide where to develop new housing, to protect community health and safety by building new sewage treatment plants and hiring more police and fire employees, and to build new schools and employ more teachers could put strains and pressures on the resources of a small community. Divisive political struggles for control of local government and the feeling of loss of community control could develop.

Long term planning problems are also likely in the public sector. Demand for public facilities and services would rise rapidly once development began. The need to find public funds to pay for roads, sewers, schools, and other government services might also increase the tax burden for all local residents, particularly where tax collections from the new industry and its workers would not bring in new revenues fast enough to finance the new services and facilities needed. Repair and maintenance costs for old facilities would also increase. For example, increased use of public roads by mining or industrial equipment would shorten repair and maintenance intervals.

A municipal or county government which has not previously had to address such questions may be forced to consider substantial changes in budget, structure, and priorities. In summary, the process of considering serious changes in the size, cost, and authority of local government may cause considerable social and political conflict within a community.

The third category of impacted communities includes those areas so far removed from existing communities that, with the exception of often unsurfaced rural roads and occasional general stores, only the most minimal commercial or government facilities and services exist. Residents make infrequent trips to distant urban centers for most supplies and materials. Medical care, commercial entertainment, and other services available only in larger communities are equally distant. Self-reliance and interdependence among neighboring families establish community relationships which provide cooperative approaches to dealing with common problems. Rather than feeling isolated or deprived, many residents of such rural areas are satisfied with the quality of their lives and feel threatened by changes that would result from the introduction of mining and industrial development in their areas. Others who welcome employment and other economic opportunities that could be generated by coal development retain, at the same time, a strong interest in maintaining what they consider to be the benefits of life in a rural, agricultural area. Few residents of these rural areas, even among that segment of the population which favors coal development, want development to take place in a manner which would seriously disrupt traditional community values and patterns.

On Indian reservations these feelings are augmented by the desire to maintain unique cultural values.

Introduction of coal development-induced populations into such areas would have significant social and economic consequences. The goal of maintaining a physical and social environment consistent with tradition or culture would not be realistic. Residents who cherish this way of life would be forced to tolerate changes. At the same time, because there are few existing financial and institutional commitments to housing, transportation, and government services, these facilities and services could be designed and installed without causing the conflicts and disruption which could result from trying to match the new needs to existing private and public support existing in an established community. The benefit of being able to avoid such temporary social and financial conflict by locating new communities in undeveloped areas may be offset, however, by the higher economic costs of building a complete new community in a remote and undeveloped area.

Basically, the degree of impact in any region would be directly related to the incremental growth of the area. Communities in semirural areas could generally absorb a five percent annual growth rate without experiencing severe strain. However, rapid urban growth or "hyperurbanization" could occur if average annual increases approached the seven to 10 percent range, i.e., boom-town development. Population growth rates above 10 percent would require detailed advance planning and possible considerations of new town designs. If growth rates exceed the hyperurbanization levels, (i.e., were much above 10 percent), many of the impacts discussed above would likely intensify. Quantification of population change in the following discussion should, therefore, be related to these ranges of growth. It should be noted, however, that the following analysis assumes that total population would grow at a constant rate. It does not reflect the specific variations between types of coal related activities nor does it reflect short-term growth fluctuations. For example, the different impacts which would result from the rapid rise and fall of a labor force required for the construction of a steam electric power plant as opposed to the long-term build-up of operational-related populations are not addressed separately. The total population discussed in the remainder of this section is derived from

both the construction and operational workers for all activities in the coal development cycle. The workers directly employed in coal development activities and their families are included as well as the indirect or service sector related population. The latter reflects the fact that additional goods and services required to meet the needs of the direct workers and their families will create new business opportunities, which attract additional people to the vicinity.

The total population related to the no new leasing alternative is presented in Table 5-65 for the low, medium, and high coal production projections. Data shown for 1985 represent the change in coal related population that could occur between 1976 and 1985. More specifically, it is the difference between the population which existed as a result of coal related activity in 1976 and the population related to coal production and consumption levels projected for 1985. It is this change in coal related population over time, compared to the regional baseline populations shown in Table 5-65, that provides the basis for addressing population growth rates and the significance of socioeconomic impacts. Similarly, the 1990 numbers represent coal related population changes that could take place between 1986 and 1990. The numbers do not necessarily mean that regional populations would increase or decrease by these magnitudes. The numbers are directly related to employment associated with coal development cycle increases and represent positions which might be filled by unemployed or underemployed workers within the region or new local entries into the labor market. In situations of this type, little if any population influx would occur. This is the probable case in Appalachian regions where coal related population increases would comprise a very small part of the total regional population base. Conversely, when these increases would be significantly greater than the baseline population, as in the Powder River Coal Region, considerable immigration of workers and their families would be expected. While detailed socioeconomic impact analysis must be conducted on a more site-specific level, the relative magnitudes of the coal-related populations and regional baseline populations presented here are indicative of potential impacts at the regional level.

On this basis, socioeconomic impacts of the no new leasing alternative would be greatest in the

Powder River Coal Region for the low, medium, and high production projections for both time periods. Population related to the 1985 production level would range from approximately 80,000 for the low projection to about 157,000 for the high projection (see Table 5-65). This represents 35 to 69 percent of the 1975 regional baseline population of about 228,000. Comparable numbers for the 1990 time period for the medium production projection are approximately 91,000, or about 40 percent of baseline. A total change of 89 percent over the 15-year period from 1975 to 1990 would result for the medium production projection.

Associated with these population data are comparable impacts on other socioeconomic characteristics as shown in Appendix G. For example, the 157,000 people at the 1985 high production projection in the Powder River Coal Region relate to approximately 35,000 public school children and 52,000 housing units. These compare to baseline figures of 54,000 enrollments and 82,000 year-round dwellings; this is about a 65 percent increase over baseline for the same time period. Also, while there were only an estimated 257 patient care physicians in the entire Powder River Coal Region in the base year, coal-related demand for doctors would reach approximately 160 at the 1985 high production projection. Requirements for 330 law enforcement officers compare to a base force of about 550.

It is apparent that coal related population in the Powder River Coal Region would reach levels at which rapid growth would be likely to occur during both time periods under the no new leasing alternative.

Although some of the absolute population figures shown in Table 5-65 would reach considerable levels in other regions under the no new leasing alternative, their relative magnitudes are much less significant when compared to baseline populations. The projected growth rate in the Green River-Hams Fork Coal Region in 1985, however, ranges from just under 20 to nearly 40 percent of the 1976 baseline. There are also significant differences between the program alternatives which cannot be analyzed quantitatively at this level of aggregation. For example, although the no new leasing alternative data may in some cases suggest lower levels of impact when compared to other alternatives, the distribution and timing of related population influx within the

(c) Change in coal related population between 1985 and 1990.

region could result in more severe problems that are not apparent in the numbers. Demand for coal would require significant levels of production and consumption even without additional Federal coal leasing. Leasing might encourage changes in the rate and location of this activity away from areas least capable of accommodating the development.

For example, under the no new leasing alternative, the future unavailability of new Federal coal would accelerate development of other coal reserves in a region. As a general proposition, a coal company develops its resources by choosing to mine the most profitable reserves it owns. The Federal government, on the other hand, directly and indirectly controls vast amounts of western coal reserves. In developing future regional production targets and in acting on mine plans for existing leases, the Department of the Interior has the ability to encourage the development of those reserves which best balance energy needs with other social, environmental, and economic values and objectives.

Another consideration is the degree to which the ability of local communities to react to infrastructure demands related to accelerated coal development is considered in future coal management decisions. The preferred program would include establishment of formal procedures for the exchange of information, concerns, and desires between the Department of the Interior and state and local agencies. The planning elements of the preferred program are also incorporated into the lease PRLAs only, emergency leasing, and lease to meet DOE production goals alternatives. While the extent of any new Federal leasing would vary among these alternatives, the ability to recognize and minimize associated economic dislocations could be assured. The state determination of leasing levels alternative would achieve similar results, but with many management responsibilities transferred from the Federal Government to the states.

Comparing the no new leasing alternative to the other six alternatives provides insight into the relative magnitude of expected impacts between alternatives. Data in Table 5-66 show the coal-related population increase related to the no new leasing alternative and compare the increases which would result under the other alternatives to that level. Positive numbers shown for the other alternatives indicate a higher level of coal-related

population change than under the no new leasing alternative; negative numbers indicate a lower level.

The preferred program medium level in the Powder River Coal Region reflects a population change of approximately 71,000 over the no new leasing alternative by 1990. This amounts to an increase of about 162,000 people over the baseline population of 228,000 or an annual growth rate of approximately 14.2 percent. While adverse socioeconomic impacts would arise if there were no new leasing, they would be more severe under alternatives in which coal production in that region significantly increases.

There are also several other alternatives which suggest severe problems in the Powder River Coal Region under the 1990 projections. While the no new leasing alternative reflects an annual growth rate of about eight percent, the lease PRLAs only, lease to meet industry needs, and lease to meet DOE production goals alternatives would each stimulate growth above that level. These alternatives would result in annual population growth rates of approximately 11 percent, 16 percent, and 14 percent, respectively. Population changes related to these alternatives would be considerably higher than for the no new leasing alternative.

In summary, the Powder River Coal Region would experience the greatest socioeconomic impacts for the no new leasing alternative for both the 1985 and 1990 forecasts. These impacts would be even more severe in 1990 if production is increased to levels projected for the preferred programs, the lease PRLAs only, lease to meet industry needs, and lease to meet DOE production goals alternatives. Data indicate that population growth rates in the Powder River Coal Region would probably be excessive and result in too rapid urban development or "hyperurbanization"; the occurrence of the variety of adverse socioeconomic impacts discussed earlier would be likely. While growth rates in other regions appear to be within manageable levels, any concentration of population change in the more sparsely populated areas of the western regions would have the potential for similar adverse impacts.

5.3.4.2 Employment Impacts. The increased production and use of coal would create more jobs. The rate of increase in coal-related employment would depend on the level of total energy demand and

(a) Represents change in coal related population between 1975 and 1985 and between 1985 and 1990.

the percentage of that demand supplied by coal-using facilities. Increases would be for jobs needed to mine, beneficiate (crush, grind, wash, and otherwise treat coal to make it usable), transport, and use coal.

Whether from surface or underground mining, increased coal production would result in significant new demands for labor. While all coal mining creates jobs, fewer jobs are created by surface mining than by underground mining, because the massive draglines and shovels used in surface mining require much less labor for each ton of coal recovered than do the smaller and relatively less productive machines used in underground mining. Although demand for labor would increase in all parts of the country where coal is mined, and the greatest growth rate in the coal mining industry is expected to take place in the western states (where coal mining now occurs at a relatively low level), the resultant increase in western demand for coal miners is not expected to cause a significant westward migration of mine workers. Increasing employment opportunities in eastern and midwestern mines, the high percentage of eastern miners trained in underground mining skills different from those required in those western surface mining regions experiencing high growth rates, and reluctance to give up established homes and living patterns in the East for difficult new living conditions in western coal "boom towns," would cause many eastern miners, even underemployed or unemployed mine workers, to remain in their established communities.

The principal source of labor for western coal production would be western workers in agriculture, and, to some degree, in the construction industry. Workers skilled in heavy equipment operation could easily transfer their skills to surface mining. Operators of small farms and ranches may supplement their incomes by working part time in the mining industry. It is expected that many agricultural workers would respond to the higher income opportunities created by coal mining, and so reduce the supply and increase the cost of agricultural labor. However, the severity of economic conflicts between the needs of agriculture and the needs of coal-related employers cannot be accurately predicted without more specific information about individual projects, rates of growth, and whether jobs are filled by local workers or by workers who have migrated

into the region to seek employment in the coal industry.

Impacts of the high employment demands of coal-using facilities would vary according to the location of the power plants, gasification or liquefaction plants, and other facilities. For several reasons, it cannot be assumed that coal-based energy facilities would be located near the mines which supply them. Utilities which once planned to build mine-mouth power plants in the intermountain West to provide electricity for distant consumers are now considering other more advanced technologies. These could result in coal being transported by rail or slurry pipeline to conversion plants located in or near the major energy consumption centers. The relative scarcity of water in those western states with abundant coal supplies, and the desire of those states to ensure that their own industrial growth potential is not limited by pollution from plants which export power elsewhere, are stimulating more interest in techniques for converting coal in plants close to the industries and the consumers who use the coal-based energy. These factors and uncertainty about which new technologies and which coal feedstocks would be used in the manufacture of coal-based synthetic fuels mean that assumptions of national demand for those products cannot be translated into specific projections showing where the conversion plants and resulting employment demand would be located. Because of the specialized construction and operational skills required, it can be expected that to the degree conversion plants are located in remote rural areas or near communities without existing industrial workforces, significant interregional population movement would occur, as discussed in Section 5.3.4.1.

Because coal transportation systems are not labor intensive, the growth in employment required to transport coal would not be as dramatic as for the mining or use of coal. Overall numbers of coal transportation jobs are not likely to be changed by alternatives, although the selection of rail, slurry, or waterway transport could affect the location of job opportunities. A secondary consequence of transporting coal by truck, the need for significant increases in road repair, may create substantial localized demands for public works maintenance workers.

Projected employment increases in 1985 and 1990 under the no new leasing and other coal

management alternatives are presented in Tables 5-67 through 5-72 on the basis of employment type (construction or operation), and by major activity area of the coal development cycle (mining, beneficiation, conversion, or use).

Estimates for construction employment in the coal mining and beneficiation activity area are presented in Table 5-67 for the low, medium, and high production projections in 1985 and 1990 for the no new leasing alternative. Current (1976) coal-related employment is also presented. In 1985, employment in this component of the coal development cycle is projected to increase by 21 to 33 percent (low to high production projections) over 1976 levels. Major increases in the eastern regions are projected to occur in the Eastern Interior Coal Region (26 to 41 percent increase over 1976 levels) and in the Texas Coal Region (108 to 156 percent increase over 1976 levels). In the western regions, a substantial increase in construction employment is projected in the Powder River Coal Region for all production levels. Medium and high production projections would cause substantial construction employment increases in the Green River-Hams Fork Coal Region (85 to 123 percent), San Juan River Coal Region (82 to 158 percent), and Uinta-Southwestern Utah Coal Region (84 to 149 percent).

By 1990, the high growth rates observed in the earlier periods would generally decrease. Western coal mine and beneficiation plant construction is projected to provide an additional 21,000 to 42,000 jobs over the number estimated for 1985. This represents a national increase in construction employment in the mining and beneficiation sector of approximately 10 percent. The primary reason for the decline in the demand for construction workers is that the rate of growth of coal production would be generally higher between 1976 and 1985 than it would be between 1986 and 1990. By 1990, western coal demand would reach high levels but the relative increases would be small.

Projected levels of construction employment in the mining and beneficiation sector for all other program alternatives are presented in Table 5-68. In 1985, major variations from employment levels for the no new leasing alternative are projected in the Eastern Interior, Powder River, Green River-Hams Fork, and San Juan River Coal Regions. By 1990, major changes from the no new leasing

alternative are predicted for several alternatives. For the Powder River Coal Region, a decrease is projected under the state determination of leasing levels alternative. In all other other alternatives, increases are estimated for this region which ranges from a low of 2,889 (about four percent) under emergency leasing to a high of about 38,000 (nearly 49 percent) for the leasing to meet industry needs alternative. These increases are at the medium level of production. Under the projection of high coal production, the increase in the Powder River Coal Region would exceed 80 percent of the corresponding baseline employment estimate. The Green River - Hams Fork Coal Region would also experience significant increases over the no new leasing alternative of from 5,452 to 12,965 (from about 20 to 50 percent) under the preferred program, and under the alternatives of lease to meet industry needs, and lease to meet DOE production goals. In other western regions, employment in 1990 is projected under other alternatives to be less than that estimated for the no new lease alternative or to show relative increases well under 10 percent. Projected relative decreases are especially striking for the Texas Coal Region, where employment under the lease to meet industry needs alternative would be less than half that estimated for the baseline level of employment.

One of the largest increments in actual numbers (19,514) is projected for the Eastern Interior Coal Region under the state determination of leasing levels alternatives. This increase represents over 15 percent of the baseline employment level. This alternative is also associated with an increment in the Western Interior Coal Region which is about one-third of the employment projected with no new leasing. Under most alternatives, employment in the East would in 1990 show little change from the baseline or would decrease relative to it. These relative decreases may exceed 45 percent for the Southern Appalachian Coal Region and 59 percent in the Western Interior Coal Region, both regions where comparatively small amounts of coal are projected to be mined.

Employment projections for the operation of coal mining and beneficiation facilities are presented in Table 5-69. The data indicate the additional employment (in excess of 1976 baseline estimates) projected under the various no new leasing production levels for 1985 and 1990. Major

increases are projected to occur in the Northern Appalachian, Eastern Interior, Texas, Powder River, Green River-Hams Fork, and Uinta-Southwestern Utah Coal Regions. The number of workers needed in the western regions would be fewer than those required for the labor intensive eastern mines, but the socioeconomic changes caused by the new western coal-related employment would be more significant. This would occur both because the relative the labor force required here generally exceeds the 1976 level and because there is a shortage of industrial workers in western mining regions.

Table 5-70 presents the level of projected increase or decrease from baseline conditions for each of the other program alternatives analyzed. As with the level of construction workers projected to accompany each alternative, the number of additional operational workers projected is dependent on both the baseline level of coal development cycle employment and the rate of projected coal production increases.

Estimates of the 1976 construction employment in coal-using facilities indicate approximately 387,000 workers are employed in this activity of the coal development cycle. By 1985, demand for an additional 230,000 workers is projected. Projections of construction employment, in 1985 and 1990, at the low, medium, and high production levels for the no new leasing alternative are presented in Table 5-71. Analysis of projected construction employment in this activity of the coal development cycle for other program alternatives indicates that no substantial variations from the no new leasing alternative are projected to occur by either 1985 or 1990.

As shown by Table 5-72, development of new coal-using facilities and an increase in the number of workers employed in such facilities would occur, even if no additional Federal coal reserves are leased. The 69 percent increase shown for 1985 reflects a nationwide surge in construction of new combustion facilities, and the data assumes the possibility of subsequent development of significant numbers of coal-based synthetic fuels plants by 1990. As noted earlier, neither the number nor the geographic distribution of synthetic fuels plants can be reliably projected, principally because of uncertainties about economic and technolo-

logical factors which would influence the development of the synthetic fuels industry.

5.3.4.3 Agriculture. The adoption of any of the program alternatives would impact lands which are presently used for agricultural purposes. Surface mining, right-of-way construction, and power plant construction are coal-related activities that could require the use of agricultural lands. Without knowing the specific agricultural lands which may be disrupted by program-related coal development, this agricultural impact analysis is necessarily limited to a general discussion.

Table 5-73 provides an interregional comparison of agricultural values using the no new leasing alternative as a basis. Dollar values were determined from the average value of all crops per acre times the estimates of potential cropland for each region. While actual values and acres may vary, Table 5-73 provides a means for comparing agricultural impacts among the regions on a general basis. In addition, estimates of potential agricultural production loss for the program alternatives are presented in Appendix D, Tables D-5 through D-26.

In general, the relatively larger impacts in the Appalachian, Eastern Interior, Western Interior, and Texas Coal Regions reflect more eastern land being devoted to cropland with a higher productivity value per acre than in the western regions.

The amount of land allocated to cropland for regional comparative purposes does not necessarily imply that a similar amount of prime farmland exists. This can only be determined after the completion of soil surveys for the designation of prime farmlands are completed. Once actual mining sites are identified and surveyed for prime farmland, specific options for mining would be available. Impacts on prime farmland would be minimized pursuant to the prime farmland and alluvial valley floor provisions of the Surface Mining Control and Reclamation Act of 1977 (SMCRA) and the land unsuitability criteria (see Table 3-1 and Section 5.4.8). Section 5.10(B)5A of SMCRA includes provisions for the protection of alluvial valley floors.

5.3.4.4 Fiscal Impacts. Coal-induced population shifts would change the level of demand for public services provided by states and local governments. The services required would include education, health care, welfare services, police protection, fire

(a) Agricultural productivity values were calculated by multiplying the percent of total Land Disturbed (Section 5.3.2.1) devoted to cropland times an average value of all agricultural products sold per acre of land (Appendix H, Section H-6). Positive numbers represent greater productivity loss compared to the No Leasing Alternative.

protection, and the provision of water and sewage systems, recreational facilities, libraries, and highways. The fiscal impacts of the change in demand would depend on the change in the size of the population and of the levels and types of services currently provided. Capital expenditures to provide the needed social service facilities as well as funds to operate and maintain these facilities would also be required.

No estimates of the magnitude of the capital expenditures required are made in this statement since capital costs are a function of specific characteristics of the communities affected. For example, a community may have under-utilized school facilities and a part of the increase in the student population may be readily absorbed, thus reducing the per capita capital expenditure required. A public water system may require modification for which the capital expenditure is not proportional to the increase in population. On the other hand, current per capita annual expenditures are a measure of services provided and it is assumed that the level of service they represent would continue.

Estimates of additional "net" annual expenditures that would be required in 1985 and 1990 of the state and local government agencies in each state have been prepared. These estimates have been prepared on a "worst case" basis in the sense that it has been assumed that all coal-induced population shifts would represent migration between states. To the extent that population shifts are intrastate movements of people from one location to another or from one industry to another, the estimates represent an overstatement of additional state level expenditures. The estimates represent the net effect in terms of government revenues generated from sources within the state and expenditures required. State population changes would increase expenditures but would also increase revenues from individual income taxes, sales taxes, property taxes, various excise taxes, etc. The estimates of net additional expenditures and of the proportionate impact on total expenditures for coal producing states are presented in Tables 5-74 and 5-75. These data represent ranges based on the population shifts projected for the low and the high coal production projections for the no new leasing and preferred program alternatives. These options bound the upper and

lower limits of all other alternatives addressed in this environmental impact statement.

Table 5-76 presents estimates for 1985 and 1990 of the changes which would occur in state and local government expenditures in non-coal producing regions. The magnitude of these changes is relatively small, representing no more than one percent of total expenditures and, therefore, these changes have not been offset against changes in revenue.

The difference between state and local expenditures and internally generated income represents that portion of revenue received from the Federal government through revenue-sharing and Federal-aid programs, such as Federal aid for highways or urban renewal funds. The total of the net changes—in the range of \$153 to \$445 million under the no new leasing alternative and of \$146 to \$655 million under the preferred program—represents the national increase in revenue sharing and Federal aid associated with the coal-related population. It does not represent an absolute increase in these revenues as it has been assumed that Federal policies in these areas would not change. The state-by-state net changes shown in Tables 5-74 and 5-75 may be construed as shifts in revenue sharing and Federal aid funding. However, due to the nature of the specific Federal programs, such changes might not be wholly realized. Therefore, the more severely impacted states such as Wyoming and Montana could seek to raise revenue by other means, for example, through the imposition of an increased coal severance tax.

5.3.4.5 Tax Lead Time. The ability of a region to absorb the impacts on the demand for public facilities and services from interregional population shifts depends on the size of the existing infrastructure and the magnitude of the impacts. Regardless of the Federal coal management program alternative finally selected, many areas in the western coal producing states would experience substantial increases in coal-related activities accompanied by significant increases in population. As a result, state and local governments having jurisdiction in these areas would experience significant fiscal impacts where existing public facilities and services systems are either currently deficient or are already at capacity. In other words, large highly developed infrastructures would be

better able to absorb a given level of development than small underdeveloped infrastructures.

Overall estimates of fiscal impacts on a state-by-state basis are presented in Section 5.3.4.4. These estimates pertain to impacts on public services. The extent to which an individual community is impacted depends on the specific conditions that characterize it. The acquisition of funds to expand public service systems in order to meet coal-induced population increases is a major problem facing many communities. This problem is the result of:

- Time lags between the identification of specific public service needs and the operation of facilities to meet those needs, i.e., the time required to plan, design, and construct facilities.
- Time lags between the need to fund the development of the infrastructure and the generation of tax revenues from the additional population served.
- Geographic difference between the location of coal development and the jurisdiction receiving increased infrastructure demands.

Although prospective revenues (from royalties or severance taxes) resulting from the Federal coal management program may be more than adequate to cover that portion of the costs of local government operations not met through regular tax revenue services, as well as to cover the additional debt service and capital repayments for infrastructure development, they are not likely to be available when needed. This deficiency can be met in a number of ways.

If revenues generated by energy development are sufficient over the long run to meet the costs of expanding public facilities and services, loans provide a logical front-end funding mechanism. Alternatives under this category include:

- Loans through the Federal government—either in the form of a direct loan program or a guaranteed loan program.
- Prepayment of taxes (severance, property, income, sales, or use taxes) or royalties by coal producers over a period, for example, of two or three years before the intensive coal production activity begins. These prepayments would, in effect, be short-term, no interest loans by industry to the local or state governments.

Another revenue source involves direct financing assistance. This funding source presumes either that energy development would not normally provide sufficient long-term revenues to pay for needed community facilities, or that impacted communities should not have to pay, even if they can afford to over the long-term. Alternatives under this category include the following:

- Direct financial assistance from the Federal government through new or existing programs. There are a number of existing Federal grant programs of this type.
- Direct financing of needed community facilities by coal developers, voluntarily or as a condition for approval of state permit applications. Such financing could be provided under lease-purchase or lease-with-option-to-purchase agreements, under which the coal developer finances construction and the local jurisdiction leases the facilities with an option to purchase.

Various uncertainties plague coal developments. Stable and continued operation of mines and associated facilities can be threatened by contingencies over which neither the industry nor state government has control. Plant production could be cut-back or halted during the operation phase causing layoffs, migration out of the region, and loss of local and state government revenues. Second, even after major project permits are issued, legal, political, or financial contingencies may make it difficult or impossible to predict exactly when or whether plant production (and revenue generation) would occur.

Assuming that the anticipated development of coal results in a stable and continuing situation, state and local governments would receive revenues through taxes from the increase in population and through severance taxes or royalties. Revenue from the latter source could be used for debt repayment. Severance taxes, however, are not imposed by every coal-producing state (for example, Utah) and where they exist, the rate varies. Table 5-77 presents the current levels of severance taxes. These taxes apply to coal extracted from non-Federal land. The comparable source of revenue from coal extracted from Federal land is coal royalties. In August 1976, an amendment to the Federal Coal Leasing Amendments Act and the Federal Land Policy and Management Act increased the state share of lease and royalty

TABLE 5-77
SEVERANCE TAXES - COAL PRODUCING STATES

STATE	SEVERANCE TAX
Alabama	33.5¢ per ton for all coal mined.
Colorado	60¢ per ton on surface-mined coal. 30¢ per ton on underground-mined coal.
Montana	30 percent of gross value of coal produced.
New Mexico	38¢ per ton (steam coal). 18¢ per ton (metallurgical coal).
North Dakota	60¢ per short-ton (current rate); to rise 1¢ per ton for each one-point increase in Wholesale Price Index using 1977 as the base year.
Utah	No severance tax. Several taxes have been proposed; none have passed. The State now finances coal development impacts from Federal leasing royalties.
Wyoming	10.5 percent of gross value of coal produced.

Source: Reference Number 87.

payments for minerals extracted from Federal lands from 37.5 percent to 50 percent of total royalties paid to the Federal government, and relaxed restrictions on the use of these revenues, providing that they be used as the state legislature directs, giving priority to energy impacted communities.

Table 5-78 presents estimates of potential levels of royalties and severance taxes that might accrue to the various states under the Federal coal management program. The precise mix of Federal and non-Federal coal production for each of the western states is not known. However, the range of funds flowing to the states is calculated assuming 100 percent production on Federal lands (for royalty payments) and 100 percent on non-Federal lands (for severance tax payments). In this manner, the range of severance tax and royalty funds is effectively bracketed.

Mitigation of future tax lead time impacts can only be achieved through implementation of planning programs prior to energy resource development. Because of the general nature of the tax lead time problem, a concerted state and Federal approach with private participation would be required.

5.3.4.6 Coal Development Cycle Fatalities and Disabling Accidents. Fatalities and accidents can occur in all activities of the coal development cycle. They are caused by human error, structural and mechanical failures, and natural phenomena. This discussion considers those fatalities and accidents associated with coal mining, beneficiation, conversion, transportation, and use.

A number of observations are useful to place the discussion that follows in a proper perspective.

- Coal mining is a high-risk occupation. This is especially true for underground mining and, to a lesser degree, for surface mining.
- Due to these risks, increased coal production, whether by underground, surface, or some combination of the two mining methods, would result in increased levels of fatalities regardless of which Federal coal management program alternative is adopted.
- Increased levels of coal production would result in increased levels of disabling accidents and fatalities related to the coal development cycle. There would also be an

increase in man-days lost due to disabling accidents.

Estimates of the fatalities associated with the no new leasing and preferred program alternatives (mid-level coal production) are presented in Table 5-79. The increases for the three regional groupings in this table are a function of the level of coal production and the method of mining. Thus, the proportionately larger production effort in the western regions results in a significant fatality increases in 1985 despite the predominant use of lower-risk surface mining techniques. The fatality increase in the midwestern regions is not as great as in the western regions because production is less. However, the fact that about half the coal produced is by underground mining tends to keep the fatality level high.

Estimates of the level of disabling accidents associated with the no new leasing and preferred program alternatives (mid-level coal production) are presented in Table 5-80. As with the level of fatalities, the level of accidents and total man-days lost are a function of the level of coal production and the extraction technology used. Despite generally lower accident rates associated with surface mining, increases in western coal production would be accompanied by substantial increases in the level of disabling accidents.

In the Appalachian Coal Regions, the increase in fatalities in 1985 over 1976 can be attributed primarily to use of underground mining methods (higher risks) with only a slight increase in production.

With regard to the 1990 figures, analysis is much more difficult. Although total coal production is projected to increase by about 28 percent over 1985 levels, the fatality level increases by over 60 percent. On a national basis, the same mix of mining methods is used in both years i.e., about 27 percent more coal is mined by surface than underground methods. The Appalachian Coal Regions show little differences between the no new leasing and preferred program alternatives, while the midwestern and western coal regions indicate a noticeable shift in fatality levels. Since the no new leasing alternative compared to the preferred program results in a greater emphasis on eastern production over western production, and increases in eastern production would cause a greater dependence on underground mining than on surface mining, it is probable that the fatality levels

DISABLING ACCIDENTS
COAL MINING (SURFACE AND UNDERGROUND)

REGION	1976 BASE CASE	1985		1990	
		NO NEW LEASING	PREFERRED PROGRAM	NO NEW LEASING	PREFERRED PROGRAM
Appalachian	9,045	11,276	11,242	12,050	11,957
Midwest	1,558	3,290	3,337	6,111	6,018
West	407	1,349	1,319	2,092	2,067
Total	11,010	15,915	15,898	20,253	20,042

between eastern and western coal regions would differ accordingly for the alternatives. A greater fatality level is forecast under the no new leasing alternative in the Midwest where the increase in production is to occur (more underground mining) whereas the preferred program, which results in greater western production, forecasts just the opposite.

The projected level of disabling accidents in 1990 is approximately 27 percent higher than the projected 1985 level. This increase is attributable to increased coal production in both the western and midwestern coal regions. In 1990, only minor variations (less than 1 1/2 percent) are projected between the no new leasing alternative and the preferred program. Mining sector disabling accident levels projected to accompany other leasing alternatives are expected to vary in a similar manner. A discussion of projected levels of disabling accidents throughout the coal development cycle is presented in Appendix H, Section H.5.

Data for the other five program alternatives considered are not shown. The significant variations in the levels of projected fatalities for 1985 were estimated compared to the no new leasing alternative. In 1990, under the lease to meet industry needs alternative, one significant shift in fatalities was estimated, i.e., a decrease of 16 fatalities in the Eastern Interior Coal Region was balanced by an increase of 16 fatalities in the Powder River Coal Region. The probable explanation for this relates to coal production shifts to the West which tends to increase fatalities there, and a de-emphasis of underground mining in the Midwest.

A measure of the overall impact of projected fatalities and disabling accidents is the level of man-days lost due to accidents. In 1975, an average of 141 man-days were lost for every disabling accident in the mining sector of the coal development cycle. Fatalities in this sector are equated to 6,000 man-days lost. Based upon these assumptions of man-day losses per accident, Table 5-81 presents estimates of total man-day losses associated with coal mining. An expanded discussion of projected man-day losses throughout the coal development cycle is presented in Appendix H, Section H.5.

5.3.4.7 Cultural Resources. Due to the site-specific nature of potential impacts, programmatic effects on cultural resources can best be described generically for the various activity sectors of coal development.

Archaeological Resources. It is not possible, at present, to estimate the extent of potential archaeological resource impacts due to various levels of coal development. Present levels of archaeological site information are based primarily on localized general surveys or on surveys performed prior to specific construction projects (e.g., mines, highways, or power plants). The concept of archaeological site density for a particular coal region cannot be used to determine potential impacts except in a very general sense, since impacts depend on the exact location of a particular leasehold and on the activities associated with coal development in the leasehold.

Coal development activities, particularly those related to surface mining, produce surface disturbances which may affect archaeological resources. In general, archaeological sites might be affected by the disturbance of artifacts or other evidence of a surface site, by grading or excavation that destroys a subsurface site, by destruction of site integrity through alteration of the adjacent landscape setting, or by the exposure of a site to vandalism and unauthorized artifact collecting. It is not only the comparatively massive excavations associated with surface mining that could adversely affect an archaeological site, but even lesser activities such as vehicle parking and open storage of materials. Vehicle movement in an ungraded, unsurfaced parking area could easily disturb surface evidence or destroy a surface site. Similarly, the excavation and reclamation of a 6,000-acre surface mine may not encounter and thus not disturb any archaeological sites while a cut for a short section of 40-foot wide, employee-access road leading to this mine could completely destroy a site. A site-specific survey is absolutely necessary to determine any potential archaeological impacts due to coal development. Because of this variability of potential impacts, there is no direct correlation between interregional or intraregional coal production levels and the extent of potential archaeological site impacts.

A 1976 amendment to the National Historic Preservation Act of 1966 (16 U.S.C. 470) now requires that a Federal agency take into account

TABLE 5-81

PROJECTED MAN DAY LOSSES^a

Source: From Tables 5-78 and 5-80.

the potential impact of an undertaking not only on sites included in the National Register of Historic Places, but also on sites eligible for inclusion in the Register, and an executive order of 1971 (E.O. 11593, 16 U.S.C. 470) directs Federal agencies to locate, inventory, and nominate to the National Register properties under their jurisdiction or control. The National Register criterion used in determining the eligibility of archaeological sites is any site that has yielded or may be likely to yield information important in prehistory or history (36 CFR 800.10). The Department of the Interior, together with the Advisory Council on Historic Preservation, will take appropriate steps (site survey, evaluation, eligibility determination, impact analysis, etc.) to minimize potential archaeological disturbances.

Historical Resources. Although the number of historical sites presently on the National Register is far greater than the number of archaeological sites, there is still a need to protect important historical sites, particularly certain types of sites in the western areas. Historical sites and certain architectural styles are not as well represented in the West as in the East, with ranches and windmills particularly needing to be assured of adequate representation [56].

Any urban changes that occur because of coal development could affect the older, historic cores of existing communities. Representative architectural styles as well as buildings of local historical significance could be lost to make room for new structures. The historical integrity of a group of structures could similarly be affected by new construction. Although it can be postulated that some adverse impacts to historical resources would occur, it is not possible to estimate the extent or magnitude of such potential impacts at the level of this environmental impact statement or to determine how these impacts would differ among the program alternatives. However, as is the case with archaeological resources, the Department of the Interior, together with the Advisory Council on Historic Preservation, will take appropriate steps to minimize potential historic site disturbances.

5.3.4.8 Recreational Impacts. The greatest impact on recreation facilities would be the increase in the recreation demand caused by population increases. In addition, the areas being mined would be unavailable for any potential recreation activities

until after reclamation efforts have been initiated or perhaps completed. Overcrowding and overuse of existing facilities, a decrease in the quality of recreation activities requiring facilities or solitude, increased administrative costs, and increased vandalism could result [57]. The increased demand for recreation facilities would also cause more conflicts between private land owners and people desiring to use land for recreation. The increased number of people going to the country for hiking, camping, and other outdoor experiences could reduce the quality of wilderness type recreation on large areas of public lands, particularly in the western coal regions.

While the Surface Mining Control and Reclamation Act of 1977 (Section 522(e)) prohibits new surface mining on certain types of recreational land systems, or within 300 feet of any public park, these areas could still be adversely affected by nearby mining operations.

Wildlife for viewing and hunting could be reduced through displacement of species distressed by noise, dust and human activities around mine sites, loss of habitat due to surface mining and pressure from increased urbanization. The increased hunting pressure could necessitate reductions in hunting seasons and bag limits. Demand already exceeds supply for deer and elk hunting permits in parts of western Colorado, reducing hunting opportunities in that portion of the Uinta-Southwestern Utah Coal Region [58]. Increased fishing pressure could also reduce the present capabilities of many areas to attract and sustain recreational fishing.

Workers brought into expanding coal development areas would tend to be younger and desire more recreational opportunities than the permanent residents. If long-term recreation facilities were built for the peak coal-related population, these facilities could become a tax burden when the peak level changes.

Expansion of coal mining could also have some beneficial impacts on recreation. Part of the greater tax revenue generated by the increased activities and population could be used to help alleviate pressure on existing municipal facilities. Mining operations could open up new roads and trails to off-road-vehicle use [59]. Recontouring and replanting of land during reclamation could sometimes increase habitat for small game, waterfowl, and migratory birds.

A detailed determination of the extent of potential coal-development-related recreation impacts is highly dependent upon a variety of regional and sub-regional specific recreation data. These data from the regional, county, and municipality level include the present use levels of all area recreation facilities and an analysis of these use levels in terms of capacity. This would provide the basis for determining which facilities have excess capacity, which are at capacity, and which are overused. The recreation characteristics of projected population increases would be needed to indicate what types of facilities or activities would be the focus of additional recreation pressures. The location of new mines would have to be known before the data required for such a recreation impact determination could be meaningfully collected. There cannot be at this time any substantive determination of how potential management program alternatives differ in this respect, except to the extent that the alternatives emphasize development of western region coal reserves particularly in the Powder River and Green River-Hams Fork Coal Regions. Accordingly, the lease to meet industry needs alternative would create the greatest stress on resident population lifestyles while the no new leasing alternative would reduce the stress. The determining factors are the potential changes in the coal-related population (see Section 5.3.4.1).

5.3.5 Transportation System Impacts

This section identifies and discusses the major impacts on the national transportation system due to the increase in coal production anticipated in the near-term (by 1985). For the purpose of quantifying some of these impacts, the medium level coal production projection has been used, i.e., 1.1 billion tons in 1985 and 1.5 billion tons in 1990. Production levels of this magnitude are substantially higher than the current (1976) production level of 674 million tons [59a]. Coal transportation requirements would, proportionately, increase even more as "coal from the West, where most U.S. reserves are located, will become more important . . . the transportation system will be required to accommodate both a substantial general step-up in the quantity produced and a dramatically sharp increase in western production, with the attendant longer hauls required" [60]. However, the proportionately greater increase in transporta-

tion requirements would be mitigated to some degree through an increase in intrastate movements due to the shifts in population into coal producing areas and to whatever extent the trend in minemouth consumption (about 12 percent in 1976) continues. Interregional coal flows are depicted in Figures 5-3 through 5-5.

The Department of the Interior was furnished with DOE computer outputs of the National Coal Model. These outputs were for the low, medium, and high production levels of the lease to meet DOE production goals alternative. Included in the data was an origin-destination matrix which formed the basis for identification of coal flows, transport routes and estimates of gross transportation ton-mileage by state for mid-level production. All other alternatives in this statement use this matrix as a basis for distributing coal production as no other comparable coal distribution patterns were available. Accordingly, impacts quantified in this section are generally presented in terms of comparing the DOE production alternative to the no new leasing alternative.

In terms of the modes of transportation used for coal movements, the railroad industry would have to assume the predominant burden of increased transportation of coal. Factors influencing these increases are:

- The pattern of coal flows could substantially differ from the current pattern which emphasizes flows from the western coal regions eastward.
- Western coalfields would, for the most part, be inaccessible to water transportation although movements involving different modes via the Great Lakes and the Mississippi River system could increase.
- Truck transportation would be limited to short-haul movements, generally movements within a state of 50 to 75 miles [61].
- Slurry pipelines would increase in significance as a coal transportation mode, provided certain major issues such as water availability and right-of-way access over rail lines are resolved. (However, as a transportation mode, they have limited application in the near-term. Total thriput capacity of all pipelines, operational or in the developmental stage, would be limited to 100-150 million tons per year in the period 1985 to 1990).

FIGURE 5-5

REGIONAL COAL PRODUCTION AND CONSUMPTION FLOWS - 1990
MILLIONS OF TONS (M)

In terms of net ton-miles of transportation service, the division among different modes, across all states used in this analysis is as follows:

- Rail - 77 percent
- Pipeline — 13 percent
- Waterway — 9 percent
- Trucks — 1 percent

This section, therefore, focuses on the railroad industry and treats the other modes more briefly.

5.3.5.1 Railroads. As noted above, coal transportation by rail would increase due to both increased tonnage to be moved and the greater distances involved. Impacts on the railroads as an overall system or institution will both depend on, and in turn, be affected by:

- The physical capacity of the railroad system. This includes rights-of-way, railroad plant, and railroad equipment (freight cars and locomotives).
- The financial capability of the industry to secure the investments required to expand its physical capacity.

In addition, there are a number of operational impacts to be considered; the more significant of these include air emissions, operating energy requirements, fatalities, and problems relating to shipment by two or more transportation modes, such as transferring coal from rail to barge or truck.

For the purpose of considering institutional impacts on a "worst case" basis, it has been assumed that all interstate coal tonnage would be moved by rail and that 75 percent of the intrastate tonnage would move by rail, i.e., a total of 1,044 million tons of coal in 1985 and 1,456 million tons in 1990. Industry-wide impacts are considered as they affect the needs of the railroads to move all freight, not just coal.

System Capacity. The capacity of a transportation system is a complex concept involving both rights-of-way and transportation plant and equipment. System capacity may be defined as the volume of traffic that can be moved without undue delay because of traffic congestion. In this sense, capacity is a function of the type and condition of the right-of-way available, equipment availability, and operating conditions. Plant only affects capacity indirectly in terms of equipment availability, i.e., down time during car repairs, and operating

conditions, and is not considered further with respect to the railroad industry.

In terms of rights-of-way, there are no comprehensive estimates of how much can be transported by the railroad industry [62]. The amount depends on miles of railroad lines (i.e. connection between two locations), the number of tracks per line, the length and spacing of sidings (to permit the passing of trains on the same single-track line), the type of signalling system and train control, and track conditions. It is also affected by how well the traffic load is distributed over time. When the volume of traffic to go from one terminus to another is fairly even, it moves much more easily than when it alternately peaks and drops off, especially if the occurrence of heavy traffic loads is unpredictable [63]. The condition of the track is of particular concern as this dictates the type of equipment and the loads that could be hauled, and influences capacity by affecting train speed. Therefore, it is recognized that many rights-of-way would have to be upgraded to accommodate major increases in coal traffic [60]. Rails would need upgrading to endure the heavier weight of coal trains—not merely by laying heavier rail sections but by concentrating on drainage, ballast, and ties [64].

Other means of increasing capacity, and thus eliminating potential bottlenecks, are available. These means include:

- Double tracking of existing single track line.
- Alternating single- and double-track.
- Increasing the length and frequency of passing sidings.
- Upgrading traffic control systems to automatic block signals or even to Centralized Traffic Control (CTC).

Among these means, double tracking with CTC would have the greatest effect on line capacity—raising it to 125 trains per day on a typical line [65]. Such measures could increase the railroad's capacity to handle increased coal and other traffic, and, in fact, extensive plans for improving rights-of-way have been formulated by some railroads concerned, e.g., the Burlington Northern and the Seaboard Coast Line. It has been stated that all required rights-of-way to transport the increased coal traffic projected for 1985 are in place and that plans exist to construct at least a further 300 miles of rail line to meet coal

needs [60]. This construction is estimated to cost \$300 million.

Other estimates include 1,000 miles of new construction contemplated in the western coal regions. One estimate includes: 1) the completion of the line connecting Gillette and Douglas, Wyoming; 2) an extension of the existing Burlington Northern (BN) Decker spur northwest to the Colstrip, Montana spur and north along the Tongue River to the BN and the Milwaukee Railroad mainlines at Miles City, Montana; 3) completion of the BN Gillette north spur; 4) two extensions of the Sante Fe Railroad mainline north to the Star Lake and the Four Corners, New Mexico, area; and 5) an extension of the Union Pacific Railroad mainline to the Kaiparowitz Plateau [67].

Potential transportation impacts would be a regional issue due to the shift in the pattern of coal flows. Only 23,000 miles of railroad lines or 11 percent of the national totals (derived from Reference 66) lie within the borders of seven western states (Arizona, Colorado, New Mexico, Montana, North Dakota, Utah, Wyoming) in which over half the recoverable coal reserves are located; only 6,900 miles of railroad lines (three percent) are in Montana and Wyoming which contain the Powder River Coal Region (37 percent of recoverable reserves) as well as portions of the Green River-Hams Fork Coal Region.

The coal flows projected in this statement were analyzed on a state-by-state basis and compared to the capacities of the transportation system links over which they would move. This analysis took into account the increase in non-coal traffic projected at a compound annual growth rate of one percent. Based on assumed link capacities of 25 trains per day for single-track lines and 70 trains per day for double-track lines, it was determined that capacity would be exceeded in 1985 on five of the 215 coal routes examined. The sections of the rail network that may become overloaded are presented in Table 5-82. Expected capacity shortfall has been characterized as:

- Moderate — not more than 100 percent of capacity
- Severe — over 100 percent of capacity.

Given the above factors, and the expressed willingness of the railroad industry to expand line capacity as evidenced by their current plans, impacts on rights-of-way of projected increases in

coal traffic would either be relatively small or could be mitigated through additions to or upgrading of the existing network.

Equipment needs to provide transportation service depend on the ton-miles of freight movements and the speed with which these movements are completed, i.e., trip turnaround time. In 1976, revenue freight movements of all Class I railroads were approximately 791 billion ton-miles [66]. Coal traffic is estimated to account for 15 percent of this total or about 110 billion ton-miles based on historical data [60, 68]. The average haul distances (based on the medium production projection for the lease to meet DOE production goals alternative) used are as follows:

- Interstate movements of coal — 700 miles
- Intrastate movements of coal — 75 miles.
- Movements of other freight — 700 miles (derived from Reference 66).

Estimated freight transportation services would be as follows:

- Interstate coal movements — 574 billion ton-miles in 1985 and 854 billion ton-miles in 1990.
- Intrastate coal movements — 17 billion ton-miles in 1985 and 18 billion ton-miles in 1990.
- Noncoal movements — 738 billion ton-miles in 1985 and 775 billion ton-miles in 1990.
- Total movements — 1,329 billion ton-miles in 1985 and 1,647 billion ton-miles in 1990.

Freight transportation services of this order of magnitude would be substantially higher than the current level. Equipment requirements — hopper and other freight cars and locomotives — have been estimated for both coal and noncoal movements. Freight cars were examined in terms of hopper cars and other freight cars separately, as it has been assumed that all hopper car movements would be in unit trains. Freight car requirements are expressed in 100-ton car equivalents and have been estimated using assumptions with respect to the number of car trips per year, thus taking into account distance, average speed, and turnaround requirements.

Annual freight car trip assumptions are listed below:

- Interstate coal movements — 40 trips per year.

TABLE 5-82

POTENTIALLY CONSTRAINED RAIL LINKS

Colorado	East from Glenwood Springs to Denver	Moderate	Denver & Rio Grande
South Dakota	North and South from North Dakota border (Aberdeen) to Nebraska border (Jefferson)	Moderate	Chicago, Milwaukee, St. Paul & Pacific
Tennessee	East from Nashville and Knoxville to North Carolina border	Moderate	Southern, L&N

Source: Reference Number 77

- Intrastate coal movements — 50 trips per year.
- Noncoal hopper car movements — 40 trips per year.
- Nonhopper car movements — 10 trips per year.

Estimated freight car requirements are presented in Table 5-83.

These estimates may be compared to the current (1976) freight car fleet of Class I railroads — 360,000 hopper cars and 1,330,000 other types of freight cars [66]. The current hopper car fleet (average car size - 80 tons) is sufficient in number but insufficient in carrying capacity to accommodate the increase in coal and other bulk freight assumed to be required by 1985. However, new cars being built are generally of 100-ton capacity and as old cars are retired the fleet carrying capacity would be increased.

Current manufacturing capacity for all types of freight cars is on the order of 80,000 cars per year [69]. Assuming that freight cars are replaced at an annual rate of four percent, the replacement of the freight car fleet other than hopper cars would require a production rate of 53,200 cars per year. Further, assuming that new jumbo hopper cars average 100-tons capacity per car, and that the balance of manufacturing capacity was devoted to the production of hopper cars, there would be a shortage of about 5,000 hopper cars in 1985 needed to promote the necessary capability. This shortfall is within the margin of error in the estimates developed. However, within the period 1985 to 1990, an additional 106,400 hopper cars would be required and the equivalent of 72,000 100-ton hopper cars would have to be replaced. Existing manufacturing capacity is insufficient to accommodate this requirement by 44,400 jumbo hopper cars; if the needs are to be met, freight car manufacturing capacity would have to expand at a rate of approximately one percent per year through 1990.

To meet increased coal transportation needs, the railroad industry would also have to expand its fleet of locomotives. This fleet has consistently been at a level of 27,000 to 28,000 units during the last decade [66]. Given the above levels of freight car requirements, locomotive requirements have been estimated. Assuming that all interstate hopper car movements would be by unit train operation and would require five locomotives per

unit train for a total of 15,000 horsepower [64] and that all other movements would require comparable locomotive power, locomotive requirements would be approximately 27,800 units in 1985 and 33,700 units in 1990, of which 12,500 and 17,600 units respectively would be attributable to the transportation of coal.

Locomotives are estimated to be manufactured at a maximum of 1,700 units per year [69]. Taking into account that the manufacturing industry also produces 200 to 300 units for export annually, a more conservative estimate of 1,500 units available to the domestic market was used. Based on average annual acquisitions of locomotives by Class I railroads over the past decade, i.e., 1,050 per year [66], current manufacturing capacity would be sufficient to meet locomotive requirements through 1985, but insufficient in the period 1985 to 1990. During this period, 4,800 units would have to be replaced and an additional 5,700 units would be needed due to increased coal transportation. To meet this need, manufacturing capacity would have to increase at an annual growth rate of approximately 15 percent.

Financial Capability. The financial capability of the railroad industry should be viewed in terms of the total investment it might be required to make in order to provide transportation services both for coal and for other freight in terms of rolling stock, trackage, and other railroad facilities.

Over the past decade (1968 to 1977), gross new capital investment by Class I railroads has averaged \$1.8 billion per year. Of this amount, 75 percent has been invested in equipment (allowing for the value of leased equipment) while the balance has been invested in roadway and structures [70]. This may be compared with recent estimates of capital requirements for increased coal transportation through 1985. One study [60] indicates that, between 1977 and 1985, \$5 to \$7 billion would be required to purchase and upgrade hopper cars and locomotives and a further \$4 to \$5 billion would be required to upgrade and build new track. In total, this would represent an annual average of up to \$1.5 billion (87.5 percent of the level of investment in the last decade). Elsewhere, it was stated that between 1978 and 1985, the railroads would have to invest \$6.4 to \$8.8 billion in rolling stock for coal traffic, (\$40 million tons in 1985) of which \$3.7 to \$6.1 billion would be

TABLE 5-83

FREIGHT CAR REQUIREMENTS

EQUIPMENT	<u>1985</u>	<u>1990</u>
	Number in 100-ton Car Equivalents	
Coal hopper cars	249,800	352,200
Noncoal hopper cars	<u>81,500</u>	<u>85,500</u>
Total hopper cars	311,300	437,700
Other freight cars	<u>728,000</u>	<u>766,000</u>
Total freight cars	1,059,300	1,203,700

Source: Reference Number 66

attributable to new traffic [63]. In the same study, it was also stated that even without allowing for the projected surge in coal use, cumulative railroad capital requirements in the period 1976 to 1985 had been estimated by the Interstate Commerce Commission (in Ex Parte No. 271) at more than \$42 billion; of this amount, over \$35 billion represented equipment needs.

Estimates of this magnitude indicate the need for railroad investment in the short-term considerably in excess of the level in recent years. It is unclear to what extent such investment could be attributed to the anticipated increase in coal transportation.

One indication of the magnitude of the investment required to meet this increase is provided by estimating the needs for capital investment in equipment between 1978 and 1990.

Freight car requirements other than for hopper cars are such that investment is required only for normal replacement of equipment. Investment in hopper cars, on the other hand, is required to replace existing rolling stock with larger capacity cars and to increase the size of the fleet due to increased coal transportation. Assuming a unit cost of \$30,000 [61,64], this investment has been estimated at \$7.5 billion through 1990; of this amount, \$2.3 billion would be attributed to increased coal traffic. Similarly, the increase in investment required in locomotives is estimated at \$12.5 billion (based on a unit cost of \$0.5 million [64]) of which \$2.8 billion would be attributed to increase coal traffic. The total investment in equipment through 1990 is estimated, therefore, at \$20 billion, of which \$5.1 billion would be attributed to increased coal traffic.

In addition, an investment would have to be made in upgrading and constructing railroad lines. The size of this investment can only be estimated within a range of values. Currently there are 324,219 miles of railroad track comprising 199,411 roadway miles of line-haul railroads plus yard trackage and sidings. Roadway mileage consists of approximately 100,200 miles of branch lines and 99,200 miles of main lines. Assuming initially that 250 percent of main line roadway represents main line trackage plus yard trackage and sidings, such trackage would total 248,000 miles. However, deducting branch line mileage from total trackage results in a balance of 224,000 miles. It is assumed that the difference, 24,000 track miles, represents

single-track main line. Therefore, an upper bound of potential investment in upgrading single-track main line can be estimated. Assuming that such upgrading requires an addition of 150 percent of track mileage, at a cost of \$1 million per mile (60), the potential investment to upgrade the national rail transportation system would be \$36 billion. A lower bound may be established by assuming that only main lines in the seven western coal-producing states would require such upgrading and that all such lines are currently single-track. The latter assumption is made to allow for the additional investment in constructing new branch lines in states as required. The lower bound is thus established at approximately \$19 billion (based on 12,400 miles of main lines). The investment in new track is, therefore, estimated to be on the order of \$19-\$36 billion.

In addition, upgrading existing trackage would be required. At \$0.5 million per mile for upgrading the balance of railroad trackage, including yard trackage and sidings, the investment required would be on the order of \$5-\$150 billion. The potential total investment in trackage would therefore be from \$24-\$186 billion. The lower bound of this order-of-magnitude estimate is more properly associated with increased coal traffic in the West through 1990. The upper bound represents potential investment in the railroad system that could be made to accommodate future growth in all railroad traffic, including further increases in coal traffic beyond 1990.

However, even the smaller of the above estimated investments, \$24 billion, would increase the investment required of the railroad industry by approximately 80 percent over the level of the last decade and would have even greater impact on the specific railroad companies required to make the investment.

Further, while the financial posture of individual railroads varies considerably, the industry's current financial posture is relatively anemic. Earnings have been inadequate—three percent of operating revenues before payment of fixed charges and an overall deficit after fixed charges—and the rate of return on equity capital has been low (about two percent in this decade [66]). The shortage of internally generated funds has led to the deferment of road maintenance and the delay of road capital improvements by many railroads [63], and an increased reliance on equipment debt

and lease obligations [70]. Therefore, future investments of the magnitude indicated (approximately \$1 billion per year through 1990), would have to be met through externally generated funds. While equipment trust certificates could be the means to acquire investment funds for freight cars and locomotives, the yield required might have to rise [61]. At the same time, the rate of return of railroad companies would have to increase to attract funds for investment in rights-of-way. Other sources of funds to finance rail extensions and engine and hopper car requirements are the coal companies and electric utilities. With increasing frequency, coal companies and utilities are constructing their own local spur lines and providing dedicated unit trains. This practice benefits the rail companies by conserving limited current operating revenues. However, in the longer term, total rail revenues would reduce trackage rights charges for movements over private spur lines and reduce rates for volume coal shipments.

Environmental Impacts. The major impacts resulting from the transportation of coal by rail have been summarized in Table 5-84. These impacts are shown for a base year (1976) and for 1985 and 1990 in terms of the production projections under the no new leasing (base case) and the lease to meet DOE production goals alternatives. The alternative of lease to meet DOE production goals was used for comparative purposes due to the extensive distribution information available for this alternative. The second paragraph of Section 5.3.5 has additional information vis-a-vis the DOE medium production level alternative. It should be noted that increases in future years, under either alternative, over the base year, would be directly proportional to the projected increase in coal traffic, i.e., about 70 percent in 1985 and about 140 percent in 1990. The other program alternatives would have changes in levels of adverse effects which are of the same order of magnitude, as presented in Table 5-84.

For the purpose of this statement, however, the differences in estimated impacts between the above two alternatives considered is of particular interest. In 1985, these differences would be less than one percent and, therefore, negligible. In 1990, the proportionate increase would be higher—on the order of three percent—for all aspects

considered, but it is still considered to be insignificant.

Non-quantifiable impacts of increased coal transportation by rail are perhaps more severe. These impacts relate to the movements of coal trains through rural areas and communities along rail rights-of-way. Historically, major extensions of the rail network preceded the Nation's westward expansion, with many communities aggressively competing for initial rail access and improved rail service. In more recent years, however, there has been growing public concern regarding projected increases in coal movements, particularly in the West.

Impacts of railroads on highway traffic relate to both the length and the number of unit trains. A 100-car unit train averages about 1.6 miles in length. Somewhat smaller volumes of rail traffic are expected from Montana and Wyoming coal fields southerly through the Colorado Front Range to Texas. The volume of train movements, particularly along the east-west lines through Montana and Wyoming, could be 50 trains a day by 1985 and 75 trains a day by 1990. Unit trains normally take about 3.5 minutes to pass a particular point at 20 miles per hour. If the speed slows to five miles per hour, as it often does near inspection, maintenance, and classification yards, the train takes approximately 13 minutes to pass a point. Shorter delays would occur in undeveloped areas where the train's speed can increase. While the passage of a single train may not create significant problems, repeated passages may. Volumes of this magnitude would block non-separated rail/highway crossings (i.e., at grade level) for substantial portions of the day. Queuing of vehicular traffic would increase, thereby appreciably adding to the transit time required to traverse those communities built up along existing rail routes. Grade crossing fatalities could also increase. Blockage of grade crossings would also increasingly hinder the movement of emergency fire, police, and health vehicles.

The extent of the rail/highway crossing impacts would be highly site-specific, depending on the location of the rail line, the volume of rail and vehicular traffic, and the type of rail crossing. Federal Railroad Administration standards for rail crossing protection devices are based in large part on rail and vehicular traffic volumes. In smaller communities, the local traffic volumes would be

TABLE 5-84

Change in Residuals	1.7	5.2	7.8	3.2	1.9	11	14.7

invariably too low to necessitate separated crossings or, in many instances, even flashing warning lights or crossing gates. Additionally, among small communities traditionally developed around rail main lines, the lines often cut the town into segments. Even nominal increases in rail traffic through these communities can create substantial physical barriers to the free flow of commerce and personal traffic. Communities desiring additional safety devices usually would be required to fund these improvements out of local and state tax revenues, via a cooperative cost sharing with or reimbursement by the railway company, or through matching fund programs with the state highway department or agency. Various cost sharing programs are available such as the matching fund provisions for rail/highway grade crossing improvements from the U.S. Department of Transportation (DOT) under the Surface Transportation Assistance Act of 1978 and the Highway Safety Act of 1973.

For new rail extensions, however, there is greater flexibility for advance planning for separated crossings. For example, the Interstate Commerce Commission certificate authorizing the construction of the rail line connecting Gillette and Douglas, Wyoming, required adequate access and ease of movement for local residents. As a result, more separated crossings are being constructed than were contemplated in the initial engineering plan.

Methods of expanding the rail network in the western coal regions also would have the potential to disrupt plans for the orderly development of local coal resources envisioned under the Federal coal management program alternatives. It is possible to construct major new rail lines without prior authorization from the Federal Government [67]. This can be accomplished in a number of ways:

- Aligning new rights-of-way to avoid Federal lands.
- Constructing spur lines rather than branch line extensions, thereby avoiding the certification processes under the Interstate Commerce Act.
- Construction of new lines by coal companies rather than rail carriers (coal companies are not common carriers by rail subject to the Interstate Commerce Act).

Once private rail lines are in place, there is typically greater pressure to lease and develop additional coal reserves in areas possessing adequate rail access as opposed to reserves in areas lacking such access. One coal management program policy suboption (see Section 5.4) would limit new Federal leases to areas with established transportation access. However, this might have limited utility as long as the industry can construct private rail lines to private coal reserve areas. The option would thus tend merely to delay new leasing in limited access areas for the one to two years required to construct major rail extensions.

It should be noted that the construction and operation of additional rail lines can produce beneficial as well as adverse impacts. Rail construction generally requires a 100 foot wide right-of-way. The flora on a right-of-way is eliminated where the trackage is placed and it is altered on either side of the trackage where rail right-of-way maintenance is conducted. Any loss of vegetation results in a concomitant loss of wildlife habitat. Alteration of right-of-way vegetation, however, often results in a linear strip of semi-maintained native vegetation which adds to the ecological diversity of the local area. This vegetative strip can be especially valuable to wildlife in regions such as the Eastern Interior and Western Interior Coal Regions where intensive agricultural practices have seriously reduced available wildlife cover. Other less significant rail-oriented ecological effects include rail kills of wildlife, right-of-way fires, fugitive dust, air emissions, water pollution, and wildlife restrictions due to right-of-way fencing. Rail kills are unusual and do not pose a serious threat to any wildlife population. Right-of-way fires do occur, particularly in regions with arid climates, but they are generally small localized brush fires which only cause temporary alterations to adjoining ecosystems. Fugitive dust, air emissions, and water pollution from train movements and spills cause localized minor ecological impacts. Lastly, fences along right-of-way generally do not restrict smaller mammals and birds. Pronghorn antelope is the only species of wildlife seriously restricted by fencing.

5.3.5.2 Waterways. During the last decade, shipments of coal by water have been on the order of 70 million tons per year while movements involving the use of more than one mode have involved

an additional 35 to 40 million tons [71]. The greater part of these movements has involved the transportation of Appalachian coal via the Ohio and Mississippi River systems. It is anticipated that coal movements by water would increase in 1985 though the market share of shipments by this mode would decrease.

System Capacity. The carriage of coal by water takes place primarily on the inland waterways system developed by the U.S. Army Corps of Engineers. The important segment of this system for coal movement consists of the Ohio and Mississippi Rivers, constituting 9,000 miles of waterways, more than half of which are nine feet or deeper [61].

However, the annual capacity of this system is not a function of mileage or of channel depth; it is determined by the annual throughput of the locks that form part of the waterway. Passage through the locks may involve undue delay, causing bottlenecks in the system. It has been stated that a waterway reaches capacity when the average delay time at a lock exceeds 150 minutes [72]. Certain locks already exceed or are close to exceeding design capacity [72]. These include the following locks:

- Locks 50 to 53 on the Ohio River.
- Locks 26 and 27 on the Upper Mississippi.
- All locks on the Illinois River system.
- Lock No. 3 on the Monongahela River.
- Winfield lock on the Kanawha River.

These are potential congestion points that would impede the flow of waterborne coal generated by increased production. In addition, while a number of other points have been identified as potential problems, they are amenable to nonstructural solutions such as improved scheduling or helper boats [60,62]. The congestion points listed above would require long-term structural solutions through the modification or replacement of the existing locks.

In terms of waterborne equipment for coal transportation, i.e., barges and towboats, requirements for these additional vessels could be met as coal traffic grows through 1985 and beyond [60]. Projected 1985 waterborne coal traffic is about the current level and, therefore, equipment needs would be limited to replacements. Increased requirements through 1990 should pose no problem as sufficient shipbuilding capacity (1,400

barges per year and 40 towboats per year) can produce coal-dedicated equipment with the capacity to handle up to 250 million tons per year during the next decade.

Environmental Impacts. As little movement of coal by water is expected, the environmental impacts are predicted to be negligible. However, some of the likely effects are discussed below in qualitative terms. These impacts would result from any increase in waterborne traffic and are not specifically due to transporting coal.

There would be some increase in noise and in air pollution. Oil discharges from tugs are a potential source of water pollution. Increased traffic might increase turbidity and barge wash thus impacting aquatic and shoreline ecosystems. The dredging of river channels and the disposal of material therefrom may also impact these ecosystems. Finally, increased barge traffic would induce shoreline development to provide barge-related services; such development could result in secondary impacts on air and water quality and on noise levels.

5.3.5.3 Highway Transportation. Coal transportation by highway would be limited to movements within a state and to the movement of coal from mine to rail tipple or barge-loading facility. In either case, coal would move over short distances. Historically, this movement has taken place predominantly in the Appalachian Coal Regions and, to some degree, in the Eastern Interior Coal Region. The impact of such movements, particularly in Appalachia, has been a matter of concern in the past, as coal trucks travel on local and secondary road systems inadequate to withstand repeated usage by heavy duty trucks, even where the gross vehicle weights are within posted limits [61]. A comprehensive study of highway needs related to energy activities, undertaken under Section 153 of the Federal-Aid Highway Act, found that an estimated \$4.1 billion was required for the restoration of highways used for energy resource handling in 1975. In the same study, 18 of the 24 states in which coal resources are located reported a total need for a further \$3.2 billion identified with increased coal production through 1985 [60]. If the preferred program and other program alternatives result in decreased eastern coal production, further impacts on local highway systems, both in terms of roadway deterioration

and traffic volume, would be mitigated. At the same time, it is anticipated that a need for new roadways to move coal and for the transportation of people and goods would emerge in the western coal producing states. The extent of this need cannot be quantified as it is dependent on the location of mines, transportation facilities, and communities developed or impacted.

In terms of equipment, i.e., heavy duty trucks, there would be no perceptible constraint on availability. Manufacturers are currently operating at 70 percent capacity, building just over 60,000 dump trucks annually [60]. Equipment requirements cannot be quantified as the extent of movements involving more than one mode is unknown.

Environmental Impacts. Social, environmental, and safety impacts of highway movements of coal are already being experienced—most severely in Appalachia [60]. Such impacts could become more severe with increased coal production, but are not specifically attributable to any of the program alternatives. Perhaps the most important impact would be the perceived, rather than actual, impact of truck traffic on a local community (i.e., the residents would be aware of more traffic volume, noise and vibrations, coal spillage, and visual impacts). These impacts would be a consideration in determining the need for highway improvements and additions, together with such mitigating measures as restricted routing of coal traffic.

Energy development impacts on transportation systems are currently being assessed by the National Energy Transportation Study Task Force for the Departments of Energy and Transportation. Their study is to analyze energy-related transportation problems and needs on a nationwide basis.

5.3.5.4 Coal Slurry Pipelines. The use of slurry pipelines for the transportation of coal is still in its infancy, although the technology is well developed. Only one such pipeline system, the Black Mesa slurry line with annual through-put of 4.8 million tons, is currently operational. Additional pipeline systems are in the process of being developed to provide transportation capacity of about 140 million tons per year. Due to the time required to plan, construct, and make coal slurry pipelines operational, and to resolve the issues surrounding the development of this industry, no significant

coal pipeline transportation capacity is contemplated through 1990. One study suggests a total capacity of 200 million tons by the year 2000 [73].

The rate at which the coal slurry pipeline industry may develop is a matter of speculation due to the constraints imposed by several issues, primarily water availability and eminent domain. Most of the proposed coal slurry pipelines originate in arid western states where water is already a scarce resource. In these areas, about 90 percent of the existing available water is used for agricultural purposes and the developing energy-related industries have to compete for water with recreation, domestic needs, and industrial activities, as well as farming. The process of coal slurring requires approximately one ton of water for each ton of coal. Based on the assumption that the slurry pipelines currently under developmental study become operational, there would be a need for approximately 100,000 acre-feet of water per year. While this quantity of water would be a small portion of available surface water, and additional water might be available from aquifers such as the one underlying the Madison Formation, the exporting of such a valuable resource has met with a mixture of support and opposition from Westerners. On the other hand, the developers of one of the larger proposed pipelines, Energy Transportation Systems, Inc. (ETSI), have already been assured of the availability of water by legislative action in Wyoming; this suggests that this issue might be resolved in the near future.

The question of eminent domain is equally controversial. To obtain rights-of-way for the proposed pipelines, proposals have been made at both the state and Federal levels to grant pipeline developers the right to exercise the power of eminent domain. While this proposal was recently rejected by the U.S. Congress, a number of western states have legislation that would permit the granting of such rights. Several proposed pipelines companies are seeking rights-of-way without grant or condemnation authority. ETSI appears to have acquired virtually its entire right-of-way in this manner.

Whether the above constraints on the development of coal slurry transportation will be continued or resolved remains a matter of speculation; therefore, the potential impacts of this mode of transportation cannot be assessed at this time. It can, however, be stated that the environmental

impacts of slurry pipelines, with the exception of water requirements, are generally of more concern during the construction of the pipelines rather than during operation. The impacts associated with pipelines, both during construction and operation, have been assessed generally in a recent study [73].

5.3.6 Operating Energy

It takes energy to produce energy. Thus, during all phases of the coal development cycle, energy would be expended. The energy expended in this way, defined as operating energy, is in the form of coal, oil (mainly diesel oil), gas, and electricity. In order to determine how much operating energy would be required, the heat content of these energy forms is equated to the heat content of the coal that would be recovered. To simplify the comparisons, operating energy is expressed in terms of its heat equivalent in British thermal units (Btus). Appendix H presents additional detail on how this conversion is derived. The same amount of energy (in terms of Btus derived from coal) is assumed for all seven alternatives at an equivalent level of production (i.e., high, medium, or low). Therefore, that alternative which requires least operating energy for all of the coal-related activities (all phases of the coal development cycle) at the medium level of production will obviously leave the greatest amount of net energy for other useful purposes, such as heat, light and power. The same will be true at the other levels of production. Conversely, the alternative which uses the most operating energy at a given production level will leave the smallest net energy balance.

The discussion that follows presents background material describing operating energy in terms of phases of the coal development cycle, followed by an analysis of operating energy requirements on a regional basis for the seven program alternatives.

5.3.6.1 Coal Extraction. During coal extraction, energy is consumed by cutting and loading devices, such as drills, mining machines, draglines, crawler-type loaders, and shuttle cars. In underground mining, greater use is being made of continuous mining machines which can cut the coal loose and load it in one operation. Mine cars, conveyors, and shuttle cars are used to bring coal to the surface. Strip mining operations employ equipment such as shovels, dragline and wheel

excavators, scrapers, bulldozers, loaders, and drills. In auger mining, giant coal augers are used to reach coal that cannot be strip mined because there is too much overburden. All mining methods would use various forms of electric and diesel engines to power equipment. The overall operating energy that would be expended in this phase of the coal development cycle is assumed to be four percent of the Btu content of the coal in place [71,74].

5.3.6.2 Beneficiation. Energy would also be consumed in the refining and processing of coal. The major operations involved are crushing, screening, wet and dry washing, and thermal drying. The overall operating energy expended for coal cleaning is assumed to be 0.7 percent for crushing and screening and 4.6 percent for mechanically cleaned and dried coal [71,75].

5.3.6.3 Coal Transport. Energy would be consumed to move coal from the production and beneficiation facilities to other locations. The operating energy expended in the transportation of coal is measured in Btus consumed per ton-mile transported. It is quantified as a function of the mode of transport as follows [76]:

- 670 Btus/ton-mile for rail transport,
- 680 Btus/ton-mile for barge transport in small rivers,
- 2800 Btus/ton-mile for truck transport, and
- 450 Btus/ton-mile for slurry pipeline transport.

5.3.6.4 Coal Conversion and Utilization. Energy would be expended in coal conversion and utilization facilities to operate equipment such as pumps, cooling towers, and pollution control devices. The operating energy required for these purposes is assumed to be as follows [39,45]:

- 3 percent for steam electric power plants,
- 2 percent for gasification plants,
- 0.9 percent for liquefaction plants, and
- 2.7 percent for coke plants.

5.3.6.5 Efficiency of the Coal Development Cycle. Based on the above factors, operating energy can be calculated for each phase of the coal development cycle. For example, for every 100 Btus present in the coal in the ground, four percent or four Btus would be expended in extracting the coal. Thus, a net of 96 Btus would be brought from

the mine. During beneficiation, as much as 4.4 Btus would be expended (4.6 percent of 96 Btus delivered for processing) resulting in a net of 91.6 Btus after this phase. Assuming that transportation would take approximately another one Btu (one percent of 98.6 Btus), of the original 100 Btus, about 90.6 Btus would be available for conversion and utilization. For example, in an electric power plant, 2.7 Btus (or 3 percent of the plant input) would be used to operate the plant and 88 Btus would be the net feed to the plant to be converted to electric power. The flow chart in Figure 5-6 summarizes this discussion.

It is important to note that the Btu loss due to coal conversion into synthetic gas or liquid fuels, or coal utilization to generate electric power, or to make coke is distinct from the operating energies considered in this section. For example, the thermal efficiency of steam/electric power plants is 35 percent on the average; for every 100 Btus in the coal, only about 35 Btus of electricity would be generated. Similarly, the average thermal efficiency of coke plants is 70 percent, of gasification plants 65 percent, and of liquefaction plants 69 percent [1,39].

5.3.6.6 Operating Energy Requirements. Estimates of operating energy expended during the coal development cycle are presented in Table 5-85. The table indicates energy that would be expended at the low, medium, and high production projections for the years 1985 and 1990. These are shown as the differences in operating energies between the 1976 actual values and the expected values for 1985 and for 1990. Table 5-66 shows differences between the no new leasing alternative and the other coal management program alternatives by year and by region. Differences between regions for a given alternative may vary substantially. For example, in 1985 at the medium production projection for the no new leasing alternative, the range between the Northern Appalachian and Denver-Raton Mesa Coal Regions is 415.8 trillion Btus (TBtus). This is equivalent to the combustion of about 19 million more tons of coal in the Northern Appalachian Coal Region. As can be seen below, greater levels of production and consumption in the Northern Appalachian Coal Region would result in higher operating energy expenditures.

	Northern Appalachian Coal Region	Denver- Raton Mesa Coal Region
1985 Production (tons)	211,700,000	5,000,000
1985 Consumption (tons)	182,900,000	20,100,000

In 1985, in the Green River-Hams Fork Coal Region, the lease to meet industry needs alternative would have the greatest increase in operating energy: 38.6 TBtus or about 1.75 million tons of coal equivalent. This would be due in part to a 47 percent increase in coal production in that region over the no new leasing baseline.

For the year 1990, the greatest increases in operating energy are in the Powder River Coal Region (for the preferred alternative medium level), equivalent to about 4.5 million tons of coal. This increase resulted from a 31 percent increase in coal production. Overall, it can be seen from Table 5-86 that at the medium level of production, net changes from the no new leasing alternative (as a base level) would in 1985 be slight for most options. Leasing to meet industry needs would pay an energy premium of about 40 TBtu. The other alternatives would either slightly decrease operating energy requirements or result in only negligible increases. In 1990, at the medium production level, the preferred alternative would increase operating energy requirements by some 30 TBtu. An even larger increase (70 TBtu) would occur under leasing to meet energy needs, whereas leasing to meet DOE production goals would increase operating energy about 7 TBtu and PLRAs by about 20 TBtu. State determination of leasing would show a reduction of more than 10 TBtu from the no new leasing alternative. At the projection of high coal production, the preferred alternative would substantially increase the operating energy requirements in both years over those of the base case.

In summary, wherever coal production, consumption, or transportation increases, operating energy expended will increase. On the average, about 10 percent of the energy in coal is consumed during the coal development cycle as operating energy.

5.4 IMPACTS RESULTING FROM SUBALTERNATIVES AMONG OTHER POLICY ISSUES

5.4.1 Introduction

Sections 5.1 through 5.3 of this statement discuss the preferred Federal coal management program and the major alternative programs. Those sections assume that different leasing strategies would cause different regional levels and distributions of coal production. All alternatives examined were designed to fully satisfy all requirements of existing Federal statutes.

A nationwide Federal coal management program is not, however, something that can be reduced to six or seven alternatives. At each stage in the process of managing Federal coal resources there are a variety of choices to be made—subalternatives concerning a particular issue—which usually are compatible with each of the major program alternatives previously discussed. Analysis of each combination of these various issue subalternatives would require analysis of thousands of alternatives. To make this task manageable and, more importantly, useful to decisionmakers and the public, Sections 5.4.2 to 5.4.10 analyze the subalternatives which, if adopted, could cause significant changes in the degree and distribution of environmental damage from the development of Federal coal. In most instances, the issues and subalternatives discussed here are those which the Department presented to the Secretary and Under Secretary as part of the process to designate the preferred program, and a fuller discussion of these issues is included in the papers presented to the Secretary and Under Secretary and summarized in Tables 3-2 and 3-3. Other subalternatives which have less impacts are discussed in the background papers. (See Section 3.3 which describes these papers and explains how copies can be obtained.)

Previously in this chapter, the Department quantified, where possible, the adverse and beneficial changes to the environment that the adoption of the preferred program and each of the major alternatives would cause, and described the quantitative significance of these changes. This portion of the chapter will consider qualitative effects for the subalternatives. Wherever possible, repetition of material presented elsewhere in this statement is avoided and only information needed to under-

stand the subalternatives and their impacts is presented. Accordingly, the discussion in the following sections should be read in conjunction with the material presented previously in this statement. For each issue and its set of subalternatives, the following factors are discussed, where relevant.

- What environmental elements are most likely to be affected by the subalternatives?
- Does the choice involved affect all regions equally, or is one region more affected than another?

5.4.2 Require Underground Mining

One issue evaluated was the effect of limiting coal extraction on Federal leases to underground mining only. To implement this policy, two subalternatives could be adopted:

- Prohibit use of surface mining techniques on new Federal coal leases.
- Make no rule blanket concerning mining method except as required by the Federal Coal Leasing Amendments Act of 1976 and the Surface Mining Control and Reclamation Act of 1977.

The western coal regions contain vast coal reserves of both underground and surface mineable coal. Despite the large underground reserve base, surface mining produces virtually all coal output in the Fort Union, Powder River and San Juan River Coal Regions. Underground mining produces virtually all of the coal in the Uinta-Southwestern Utah Coal Region. Surface mining accounts for approximately 30 to 60 percent of the production in the remaining regions. In 1976, an estimated 52 western underground coal mines produced 12 million tons and 61 western surface mines produced 97 million tons of coal. Table 5-87 presents projected percentage distributions of surface and underground mining under the preferred program. In general, coal produced by underground mining is more expensive and more capital and labor intensive than that produced by surface mining. Between 1950 and 1978, national coal production has gone from mostly underground to more than half surface mining. Industry efforts to reclaim lands disturbed by surface mining have also increased during this period. The Surface Mining Control and Reclamation Act requires intensive regulation of both surface mining and the surface effects of underground

TABLE 5-87

mining. Under the permanent regulatory program of the Office of Surface Mining Reclamation and Enforcement, no coal mining will be allowed unless, among other things, the surface area disturbed can be reclaimed to pre-mining productivity and approximate original contour.

Several other factors distinguish these two mining methods. Deep mining is more hazardous to the miners than is surface mining, both in terms of fatalities and injuries. Mine safety is comprehensively regulated by the Coal Mine Health and Safety Act, 30 U.S.C. Chapter 22. Surface mining recovers a higher percentage of coal than does underground mining. The degree of recovery differs according to the area and type of mining involved. Typically, the recovery rates are 70 to 90 percent for surface mining versus 29 to 85 percent for underground mining. The Federal Coal Leasing Amendments Act bars the Secretary from approving a mining plan which does not use the method of mining which achieves the greatest recovery of coal. Where both surface and underground mineable coal exist on a given lease, the Secretary must require the lessee to use the method which recovers the greatest amounts of coal. Statutory changes may therefore be needed to carry out a deep-mine only policy, although the Office of the Solicitor has advised the Department that it may authorize "single-seam" leasing which would permit the leasing of only those seams which are recoverable by underground mining methods.

Surface mining usually causes greater surface disturbance, sedimentation, erosion, wildlife loss, and displacement of competing land uses and users than does underground mining. The degree of disturbance caused by surface mining itself varies greatly depending on seam thickness. Table 5-88 shows that acreage disturbed is directly related to seam thickness. Land disturbance from underground mining in the form of subsidence is a potential long-term problem, particularly in shallow underground mining.

Since new leasing would not result in significant production until 1985 at the earliest, adopting this policy would not cause any significant changes to the environment prior to that time. Assuming that a program is adopted which would resume leasing, a limitation to underground mining production from new Federal leases would lower new production for the Fort Union, Powder River, San

Juan River and Green River-Hams Fork Coal Regions (those which have mostly surface mining); increases in production from new leases would be most likely in those regions where Federal coal is already produced by underground mining (Denver-Raton Mesa and Uinta-Southwestern Utah Coal Regions, and in the non-Federal areas in the Midwest and East).

The reason for the effect is almost entirely economic. The surface mineable coal in those areas can be removed for as much as \$8-\$18 a ton cheaper than underground coal. The added costs are sufficient to have consumers seek coal elsewhere. The potential effects on western coal production from a restriction to deep mining could vary from insignificant to critical, depending on whether actual production reaches the low, medium or high 1990 projections. Under the no new leasing mid-level projection, surface mining is expected to increase 50 percent in the six western regions, from 339 million tons in 1985 to 514 million tons in 1990. (Refer to the no new leasing alternative for an analysis of the maximum restraint on new Federal coal leasing—a policy of allowing underground mining only on new leases can be expected to approximate that alternative in those regions where underground mining is not economically competitive with surface mining.) Table 5-89 presents comparable estimates of different effects produced through mining coal by surface and underground methods in one region. The same kinds of transfer of impacts from unleased Federal lands to lands already under Federal leases and non-Federal lands described under the no leasing alternative would occur in the Fort Union, San Juan River and Powder River and Green River-Hams Fork Coal Regions. These changes would not occur in the Uinta-Southwestern Utah Coal Region or in areas of Colorado that are suitable for underground mining. Some interregional effects are also likely to take place with production being ultimately lowered in the surface mining regions and increased elsewhere.

A less likely, but still possible, effect is that a deep-mining only policy would affect neither the amount nor distribution of production to any great extent, but would merely alter the method of mining. Although the cost differences between surface and deep mining of between \$8 and \$18 per ton do not readily suggest this will occur, the possibility cannot be totally ruled out. The produc-

tion cost difference could be reduced by a variety of changes in current conditions, including new technology and lowered Federal royalties and state severance taxes.

If this were to occur, it would be expected that the major effects of the deep-mining only policy would be to exacerbate social costs in rural mining areas, since more employees would be needed to operate an underground mine rather than a surface mine. Per capita miner fatalities and disabling injuries would likely increase, and less coal resource per acre would be recovered. A deep-mine only policy would also require longer lead time and greater investments prior to production, in order to assure that the specialized training needed to develop a work force capable of safe and productive underground mining is accomplished. Experience indicates that safety records may show dramatic improvement where regulatory enforcement, worker participation in decisions about safety requirements, or company economic interests provide incentives for better safety efforts. Notwithstanding the strict requirements of SMCRA, the deep-mine-only policy would also reduce adverse effects to wildlife, preserve existing surface environments, eliminate the risk of creating unreclaimed lands, and reduce total suspended particulates at or near the mine sites in the principal western regions where surface mining is predominant (Powder River, Fort Union, Green River-Hams Fork, and San Juan River Coal Regions). A deep mine only policy might also significantly undercut the policies expressed in Section 714 of SMCRA (see Section 5.4.6) since qualified surface owners have a right to withhold consent only for surface mining not underground mining. Arguments raised in the comment period on the draft version of this statement against adopting the underground mining only alternative include the following:

1. It would retard the mining of high quality, low-cost coal.
2. It fails to give weight to improvement in surface mining reclamation techniques required by SMCRA.
3. Lack of new leasing for surface mining may adversely affect ongoing mines that run out of reserves causing severe social disruptions.
4. The adverse social effects from increased population required to operate an under-

ground mine exceed the harmful environmental effects from surface mining.

These are all valid points which were raised in the original discussion. The decision whether to adopt a policy of this kind calls for a weighing of these problems and benefits. The preferred alternative does not call for adoption of this policy.

The support for adoption of this policy in the past came mostly from those who believe western surface-mined lands cannot be adequately reclaimed. This point should be significantly allayed by the reclamation provisions in SMCRA.

5.4.3 End Use Considerations

Inclusion of limitations in new Federal leases that constrain the end uses of coal produced from those leases was another issue addressed in the coal policy review. Four subalternatives were evaluated:

- End-use considerations should be exercised during the leasing process to satisfy environmental goals and achieve energy policy objectives.
- End-use considerations should be allowed to enter the leasing process through special leasing opportunities afforded other departments and agencies.
- End-use considerations should not be part of a coal management program except as mandated by the Federal Coal Leasing Amendments Act of 1976 for "public bodies".
- End-use considerations should not be implemented, pending an opinion by the Office of the Solicitor on limits of the Secretary's authority.

The principal use of coal is electric power generation. The environmental impacts associated with coal mining and power generation vary greatly, depending on how and where the coal is consumed. The major categories are: mine-mouth power generation (at or near the mine), export (outside the mine area, but inside the United States), and foreign export (coal sent to another country). Consumption of coal at or near the mine site in the West tends to increase certain adverse impacts of coal development. Coal consumption requires large amounts of water, a resource which is already scarce in most of the West, particularly in the Colorado River Basin and in the Powder River Basin. Air quality can also be adversely

affected. Also, the construction of power plants causes large numbers of workers to migrate temporarily to rural areas, which may lead to boom-town economic and social problems. In some instances, coal that is exported from a state may be used to replace mine mouth coal in the destination area causing loss of employment and tax revenue there.

The Department has not historically regulated the way coal from Federal coal leases is consumed (except for coal for railroad purposes under Section 2(c) of the Mineral Leasing Act of 1920, (30 U.S.C. 202), and coal for municipalities under Section 8 of that Act (30 U.S.C. 208)) but Section 2 of the Federal Coal Leasing Amendments Act of 1976, (30 U.S.C. 201(a)), now requires it to do so for "public bodies". The Solicitor is determining whether the Department has legal authority to regulate end-use for purposes other than use by municipalities, public bodies, and railroads.

The Department of the Interior is not the only agency which might have a role in deciding how coal is to be used. The Federal Energy Regulatory Commission and state public service commissions or siting agencies exercise considerable authority over the location of new power plants. The Interstate Commerce Commission's approval is also necessary for rail lines and rates. The Interstate Commerce Commission intends to prepare an environmental impact statement in connection with *Ex Parte* 347, an investigation into western coal rail rates. The environmental impact statement will identify, examine and analyze the environmental consequences resulting from the use of western coal or the substitution of other fuels as well as the impacts associated with use of alternative kinds of transportation. Also, Section 125 of the Clean Air Act establishes a process whereby utilities can be barred from using other than local coal. Proceedings to invoke this clause have begun in Ohio and in Illinois.

Assuming that new leasing takes place, virtually every aspect of the environment could be affected by the first subalternative (application of end-use stipulations in leases).

The subalternative of controlling end-uses through lease terms would not, however, necessarily lead to a single policy objective. The following sometimes mutually exclusive or conflicting controls could either be adopted as a general rule, or be applied in particular instances, possibly at the

request of a state governor. To prevent replacement of eastern and mid-western coal by western coal, a lease stipulation could prohibit a company from shipping the coal more than a specified distance or from selling it to be burned in certain states. If other western coal were not available to substitute for the use-restricted coal, this subalternative would lower western production and reduce environmental impacts in the western regions. Most likely to be affected by this subalternative are the Powder River and Green River-Hams Fork Coal Regions, which are the principal western sources of export coal to eastern and midwestern markets. Lesser effects would occur in the Uinta-Southwestern Utah Coal Region which now supplies some coal to plants in states such as Ohio and Indiana and in the San Juan River Coal Region which supplies coal to Texas. As the high moisture content of the lignite reserves of the Fort Union Coal Region limits that coal's usefulness for export, that region would be relatively unaffected. This subalternative could have impacts in the eastern and midwestern regions if it causes production increases in those regions. Employment and environmental impacts would increase. Finally, it could also cause a shift in how western coal is transported to other markets. The subalternative only involves shipment of the coal. It could cause companies to mine and burn the coal in the West and transmit the power to eastern and midwestern markets. Because of the energy loss in power transmission, more coal production would be needed to produce the same amount of electricity to consumers than would be needed if the coal were shipped by rail. The subalternative might also create new markets for coal gasification and liquefaction.

To minimize use of water, reduce coal-related population increases, and protect air quality in the producing regions, a lease stipulation could prohibit the consumption of the coal from a Federal lease in, for example, the state where it is mined, unless a specified percentage of the power would be used by customers in that state. Again, assuming that this subalternative is effective and that it changes the locus of power production facilities, adoption of this stipulation would retain water for agriculture, grazing, wildlife, and other competing industrial uses to a larger extent than would the absence of any end-use controls. It would also hold down population increases in

areas with small baseline populations, and would relieve concomitant adverse social and economic impacts, including those on housing, law enforcement, schools, sewage treatment, and the like.

If the lease stipulation applies to coal shipped to the West, as well as to the East, it could affect rather severely power production plans in Washington, Oregon, and, to some extent, California, since only western coal is a reasonable, cost-effective source of coal supply for these states.

The subalternative would also shift pollution and water use problems associated with coal conversion closer to areas where electricity would be used, and would require more costly long distance transportation. On the other hand, it would reduce the adverse environmental impacts which result from extensive power transmission lines through sparsely populated areas. It trades savings of social impacts, water use, and loss of power from transmission lines for impacts associated with rail transportation.

It is difficult to forecast with any reasonable precision how significantly the Department could affect utility plans to site power plants on the basis of stipulations in new leases. Depending on a variety of other factors, the actual change in power production patterns could be insignificant. The Department's ability to carry out these policies independently of other agencies varies from region to region. It is the highest in the Uinta-Southwestern Utah Coal Region because of very high Federal ownership of the coal resource and the land over which powerlines must be located (to remedy the lack of an adequate existing rail transportation and power transmission infrastructure). To a similar but lesser degree, the same conditions prevail in the San Juan River Coal Region. The Department has less control through this kind of stipulation in the Fort Union, Powder River, Green River-Hams Fork and Denver-Raton Mesa Coal Regions because the Federal share of both the coal and surface resources is less.

The Department could also decide to combine the previously discussed lease stipulations, and prohibit both long distance rail transportation and mine-mouth power generation for out-of-state consumption. The combined alternative would be the most restrictive approach possible and, if applied to all new Federal leases, would greatly limit new leasing.

Cooperative efforts to optimize power plant siting decisions offer a less direct, but potentially an equally effective way to deal with power plant siting problems. For example, Utah is rich in relatively high Btu, low sulphur underground coal that can often be mined with comparatively small amount of environmental disturbance. It is equally rich in recreational resources, including a variety of national parks and wilderness areas. Utah is receptive to industrial development and employment opportunities, if they can occur without undue adverse environmental changes. How to transport and burn this highly desirable coal resource without destroying the natural features of the State is a highly complex problem. The Department of the Interior and the State of Utah have been closely cooperating to find appropriate sites for plants that will minimize employment, air, and water problems. A decision not to adopt an end-use stipulation is not, therefore, a commitment to unrestricted, deleterious coal development. Formal and informal cooperative efforts can accomplish many of the same results.

To encourage development of new technology, either for DOE projects under Section 908 of the DOE Act, or for privately financed projects, a lease stipulation could require the coal in the lease to be developed by a particular mining method (such as in-situ gasification) to protect lands that offer high potential for a new technology.

Although the Department has not made a detailed investigation of lands potentially suitable for new technologies, there may be lands, because of economic or environmental conditions, that can be mined not only by conventional methods, but also by new mining techniques including in-situ gasification or hydraulic mining of steeply pitched coal seams. Unless a lease stipulation requires a particular form of development, the opportunity to use such techniques could be lost. Opportunities for use of this stipulation are, like many of the technologies it may foster, largely speculative.

Controlling end-use as a consistent policy would cause fundamental changes in how the Department leases coal. The Department does not now "package" its coal leases for any particular buyer or purpose. It offers the coal, and whoever is the high bidder receives the lease. Consider a lease sale for a tract in Wyoming, for example. One bidder may want to mine the coal to sell it for

power generation in the same state. Another bidder may prefer to export the coal to Texas. Other bidders may have buyers in Minnesota and Illinois. As it is often difficult for a mining company to sell coal before it has the right to develop it, still other bidders may not have any customer under contract, but will want to obtain reserves to begin negotiations for customers. As a result of this, under the current policy, the Department's main role is to examine the impacts of coal development at or near the mine site and, for analytical purposes only, to hypothesize where and how the coal might be consumed. This market-oriented system is compatible with the competitive bidding aspects of the Federal Coal Leasing Amendments Act of 1976. A change in this system to accommodate end-use requirements might have significant effects on competition by limiting the numbers of bidders in a sale. This could cause changes in energy costs to consumers.

In the extreme case, under an end-use control policy, the Department would match a particular parcel of land with a particular project. The moving force for coal lease sales would be the company that would use the coal, not the company that would mine it. The Department would attempt to assist the user company to put together all the factors — obtaining a source of water, gaining access rights, acquiring of surface owner consent, ensuring availability of transportation — necessary to bid for and to develop a lease. This would, of course, eliminate much of the uncertainty which exists in a competitive bidding system; it would allow the Department to be confident that the coal it leases would be developed, and that the environmental effects of the entire coal development cycle would be scrutinized. It would also require the Department to acquire planning capability on a scale far in excess of that which it presently possesses. Substitution of Federal authority and decision-making for choices and plans now made by industry and by State and local governments would be a substantial change in traditional Federal responsibility. The consequences of such an increased Federal role would likely be more significant to political and economic relationships in our society, than to the environmental values and standards which are within the scope of this statement.

Some comments raised during the comment period on the draft version of this statement

concurred with the Department's evaluation that adopting this policy would be a departure from past practice. Arguments against adopting an end-use alternative suggested that end-use controls would increase administrative costs and lower competition for coal, and that increased control would not have more desirable results. The administrative cost point is almost certainly correct. The assertions that competition would decline raising the cost of coal to consumers is clear in most, but not all, situations. Some of the end-use alternatives (such as restricting where coal could be burned or how far it could be transported) would be expected to raise fuel costs to some degree, if the restrictions affected distribution to points of consumption that were economic and if the remaining coal available to meet that demand was limited. Some end-use alternatives could have the reverse effect. One comment suggested that the current system raised coal prices to the consumer where (1) a single company was likely to be able to economically use coal from a particular area and (2) there was a lack of competing coal. For example, assume a situation where coal could be supplied to Utility X from area A for 10 dollars a ton but from all other areas for 15 dollars a ton. Under the current leasing system a utility might expect to pay just under 15 dollars for coal from area A. The comment suggested that if the Department leased the coal from area A and specified that Utility X would have a right of first refusal to purchase the coal from the lessee, the price that the utility could obtain might be significantly lower.

In weighing the advantages of this policy, it must be remembered that the same kinds of stresses on social, economic, and government systems that occur in the West, and that might be alleviated by end-use controls, also take place in the East. Prior to adopting a general end-use policy of exercising end-use control in a specific case, the Secretary would have to weigh competing values such as this. Finally, we note that the Department cannot unilaterally decide power plant location. The Congress has given the Department the duty to respond to applications to use particular BLM-administered lands for power plants. If the plants do not meet the standards set by the Congress, or the regulations adopted by the Department, the plant cannot be located on BLM lands. A company is always free to seek to locate its plant

on non-Federal lands. As previously noted in the text above, the Department lacks direct control over this issue. Private landowners, state regulatory agencies, and other groups must continue to make these decisions.

5.4.4. Concentration of Federal Leases

In the past, the Department has made little, if any, effort to examine current production patterns prior to leasing, even though decisions about the distribution of production within a region can influence overall effects almost as much as decisions on quantities of production. Similarly, no state or region has had an effective government planning organization that has long-range plans to optimize location of new mines, although some states have recently passed siting laws for mining activities on private lands. Although coal companies have obtained coal development rights, including Federal leases in a wide variety of areas throughout the West, primarily because of economic considerations (including those related to coal resource quality and transportation availability), western coal development has tended to concentrate in a few areas. Development is now concentrated in the Colstrip and Decker areas in Montana, in the Gillette to Douglas corridor in eastern Wyoming, in south central and southwest Wyoming, in parts of Emery and Carbon Counties in Utah, near Farmington in New Mexico, and near Craig and Delta in Colorado.

In addition, because of the new requirements of Federal laws, the Department must have a reasonably high degree of data collected, rehabilitation considered, and land-use planning done before it can lease. One consequence of the existing development pattern is that the needed information tends to be most complete and accurate in areas where development has taken place in the past. The Department is better prepared to lease in those areas, without requiring new data to be gathered and analyzed.

Another set of subalternatives concerns the limitation of new leasing to areas already producing coal. Specific subalternatives which could achieve such concentration include:

- Adopt a preference prior to planning that (1) new leases be issued only near existing production (concentration), or (2) new leases be issued in areas which would not have such concentration (dispersal)

- Adopt no preference but take these factors into consideration in the tract selection process.

The principal benefits that could occur in terms of the major areas of environmental consideration are associated with the socioeconomic aspects of a particular area, rather than the physical or biological aspects. Concentrated development could allow for centralization of requisite planning efforts within a single county or small number of counties in a region. This could in turn allow for uniformity in regional planning that would not necessarily occur with random dispersion of development. Planning efforts could be directed toward a new community or the expansion of an existing community, which would be the focal point of support for the concentrated development. Housing and community services would be centralized and could potentially benefit from the economies of scale of a single larger community, as opposed to a scattering of smaller communities. Services such as schools, police and fire protection, and waste handling could potentially be provided at a greater level of efficiency and effectiveness through centralization of efforts. Concentration can also reduce costs for agencies which enforce environmental standards on leases, and costs for monitoring compliance with air quality standards. Beyond certain levels, however, the effects of concentration could bring significant disadvantages to a community as discussed in Sections 5.3.4 and 6.3.1 of this statement.

Development in existing areas will be accelerated if new leasing is needed and current nonproducing areas are not available for development. Concentrating leasing could eliminate the need for, and perhaps the economic viability of, new transportation systems. Assuming the policy is coupled with new leasing of any magnitude, it could worsen problems in some areas which have been experiencing recent rapid development. In other areas, concentrated development could take advantage of, and even provide economic reinforcement to, those public and private investments that have been made to accommodate demands caused by initial coal developments.

The effects of development concentration on the physical and biological facets of environmental resources would depend on specific circumstances. The amount of land disturbed within a region as a result of adopting the concentrated development

subalternative would generally be less because transportation and other supporting or ancillary facilities would tend to be fewer. Rail lines, haul roads, power lines, borrow pits, and other facilities could serve multiple mines. Concentrated development, however, could produce levels of impacts which could seriously affect air or water quality or could add significantly to the water demand within a local area. The levels of air pollutants associated with concentrated development could lead to the violation of air quality standards within a region. This has been the case in the Colstrip area of Montana, where concentrated development has produced particulate levels that exceed national primary air quality standards. Similarly, potential water pollutants would more likely be directed toward a single water system with concentrated development, thereby increasing the probability of producing significant adverse impacts on water quality, or requiring significant treatment costs. The increase in water demand associated with such development could potentially exceed the development area's supply, or could preempt development associated with other water uses within the area due to the water requirements of concentrated coal development. The potential for effects on biological resources is basically dependent on habitat disturbance, and the amount or area of such disturbance would be approximately the same with concentrated development as with dispersed development. In areas lacking an established rail transportation network, a scattered development policy may actually preclude development of coal resources for other than mine-mouth conversion. Major rail extensions typically cost in excess of \$1 million a mile to build [63]. Revenues generated from transporting coal from a single, moderately-sized mine may be insufficient to amortize the extensive cost of a major rail extension. Should the extension be financed by a coal company rather than a rail common carrier, the added expense may make the coal uneconomical to a distant electric utility or other consumer.

The advantages and disadvantages of this subalternative are somewhat subjective. While the issue has been extensively discussed outside the Department, its resolution is unclear. The Secretary preferred assessing the social and environmental effects of locating a mine when selecting each tract for a lease sale, without establishing a locational policy which automatically favors con-

centration or dispersal. This assessment would be made in the tract-ranking process in the preferred program.

5.4.5 Due Diligence

Diligent development and continuous operation regulations discourage companies from failing to develop Federal coal leases, minimize inefficiency and wasted effort in planning for coal leasing and production, and help ensure that the government will receive fair market value for leases. In the past, the Department included in leases minimal diligence and continuous operations requirements, but did not exercise stringent enforcement. Due to this policy, economic and other conditions affecting western coal development have resulted in the vast majority of Federal coal leases not producing any coal until very recently.

The Congress, in the Federal Coal Leasing Amendments Act of 1976, strongly affirmed that diligence is to be a major factor in any Federal coal management program by mandating the strict application of diligence standards.

In May 1976, the Department adopted new diligent development and continuous operation regulations which require all existing leases to produce at least 2 1/2 percent of the lease reserves by 1986 (with an extension possible for an additional five years under limited circumstances). New leases are required to produce 1 percent of the deposits within 10 years after lease issuance. By statute, a company that receives a new lease must also submit a mining plan within three years from lease issuance. Since those regulations were enacted, there has been significant movement toward activity on these leases (see Section 2.7, which describes likely production from existing leases).

The Department considered several due diligence subalternatives; however, it no longer has the authority to revise diligent development and continuous operation regulations. The Congress transferred that authority to the Department of Energy in the Department of Energy Organization Act.

The specific due diligence subalternatives considered by the Department include:

- Continue existing standard of producing one percent of reserves by the end of the first 10 years, a minimum of one percent each year thereafter, and total exhaustion

- of all reserves in 40 years after a mine plan is approved.
- Raise or lower initial 10 year production period.
- Raise or lower total 40 year production time.

Major coal mines in the West require at least three years after lease issuance to be in production under the best of circumstances; five to seven years is not unusual. Any effort to reduce diligence below these time frames would create management problems which could frustrate a situation totally unrelated to the purpose of diligence. In addition, coal companies, like other mining companies, have some need to maintain an "inventory" of uncommitted coal reserves. This inventory serves as protection against rising resource costs and gives the companies assurance that they have the resources to enter markets as they develop. To some extent, the long-term coal market, particularly in times of high demand, dictates that a supplier have assured reserves before a customer will commit itself to a binding contract.

The effect of different diligence standards could make a short period for initial development an impediment to effective planning and community capital construction. A significant shortening of the initial diligence period (say to five years) would probably make it very difficult for many operations to commence. Companies may only have time to do initial site preparation before the lease would terminate. This would cause the companies to layoff the initial work force; and preparation for development, such as new roads, housing, school construction, sewage facilities, etc., would be wasted. If the time period were too short, the risk of development might be so great as to discourage otherwise reasonable development.

A significant lengthening of the time for initial production (say to 20 years) would ensure that all planned production would have adequate time to take place in an orderly fashion. If all production tended to be initiated toward the end of this extended period, it could also facilitate community planning by increasing the time from lease issuance to land disturbance. In this longer time period, more capital construction could take place, workers could be trained, and similar pre-mining activity could commence. There is no guarantee, however, that this would actually happen, and, in fact, all production might still occur within 10

years of lease issuance. Expanding the period would also give companies more time to develop complex or new projects. It has been suggested for example, that a 10 year initial production period is insufficient for the development of a lease by a synthetic fuels firm. Any extension of the 10 year period for new leases would require legislation.

A significant increase in the continuous operation rates (i.e., to require total extraction in 25 years) would have two tendencies: either the production rate from each lease would tend to be increased, thereby lowering the total number of producing leases and concentrating the effects of development in a smaller area (i.e., a 100 million ton deposit would be mined at a four million ton per year rate instead of a 2.5 million ton per year rate); or the total number of mines would remain the same, but the period of mining would be shortened by 15 years. The Department can control which alternative results through its tract selection policies. In the preceding example, if the Department wished to see accelerated development on a single lease, it would lease to set up a logical mining unit of 100 million tons; for a lower rate of development, it would lease to set up a logical mining unit of 62.5 million tons. If the 40-year period were reduced to a 25-year period of coal development, this would reduce the number of years for which a commitment to development was made. With this more limited commitment, the Department could reevaluate whether, at an earlier time, it wished to continue the pattern of development. It would give the Department greater ability to respond to changes in demand for Federal coal. The impacts of this earlier reevaluation (25 years rather than 40 years after lease issuance) are entirely speculative at this time. Policies of periodic leasing tend to diminish any benefits. If the subalternatives were carried out to change the yearly development rate, environmental impacts on a particular parcel of land would be concentrated. More acres would be disturbed on the leasehold in any particular year. This might increase problems for effective wildlife management, dust control, rehabilitation, erosion, and sediment loading in streams. On the other hand if few leases were needed, the adverse effects of dispersed leasing might be lessened.

The effects of these possible changes in the diligence policy will be most clearly felt in the coal regions most likely to require more leasing:

Powder River, Green River-Hams Fork, and San Juan River.

5.4.6 Land Ownership Patterns

Land ownership patterns are very complicated in both the West and the East. In the West, vast amounts of land are owned by private, Federal, state and Indian interests. Over six million acres are privately owned, with the mineral estate Federally-owned. Table 2-5 summarizes ownership figures in the KRCRAs.

Because of railroad grants, large amounts of land, including land which is valuable for coal, is held in checkerboard patterns, with alternate sections owned by the United States and private owners. This checkerboard pattern is most prevalent in the Fort Union and Green River-Hams Fork Coal Regions and in the northern portion of the Powder River Coal Region. Small checkerboard areas also exist in the San Juan River Coal Region. It has been estimated that over 300,000 acres of the privately owned portion of the checkerboarded lands have been committed for coal development.

In a very large number of townships in the West, states own sections 16 and 36. The United States transferred this land under the school lands grant programs established in the Statehood Acts.

Both the checkerboard patterns and the school land patterns are in 640-acre units. Coal in these areas, however, can rarely be mined in contiguous areas of less than 2,000 acres. Consequently, areas with these ownership patterns cannot be mined efficiently, if at all, without approval from more than one entity.

The Congress, in Section 714 of the Surface Mining Control and Reclamation Act of 1977, has given farmers and ranchers who own land situated over Federally-owned coal deposits a veto power over leasing for surface mining if they meet certain qualifications and have not previously consented to surface mining (see Sections 1.3 and 3.2.5.1). Split-estate land owned by persons who do not meet the standards in Section 714 may be leased for surface mining; and all split-estate land may be leased for underground mining without the surface owner's consent, if a bond is posted to cover the cost of damages to crops and improvements, among other things, in accordance with the law under which the United States sold the surface estate (see Section 3.2.5.1).

The various owners of tracts in checkerboard areas have not only direct but also indirect, veto power over coal development by their ability to affect access, water rights and other elements needed to develop a coal lease. The control or ownership of adjacent, privately owned properties is also important because it often gives the controlling company some advantage in the competitive coal lease sale. The advantage stems from better resource knowledge, coupled with the certainty of cooperation from the surface owner. This problem is minimized where the mineral owner is willing to share resource information with others, or engage in joint ventures with the development of Federal lands.

Leasing decisions based on surface ownership patterns could produce significant variations in environmental impacts. Specific subalternatives considered in this context include:

- Do not take surface ownership into consideration when leasing, except as required by the Surface Mining Control and Reclamation Act.
- Do not lease unless the Federal Government owns both the coal and the surface estate.
- Do not lease in "checkerboard" areas.

The subalternative of not leasing unless the Federal government owns both the coal and the surface estate (an alternative which was considered during the development of SMCRA) would not be likely to change significantly development patterns in either the Uinta-Southwestern Utah or San Juan River Coal Regions, since approximately 85 percent of all coal in KRCRAs in those regions is overlain by Federal surface. The subalternative has the potential for significant change in the Green River-Hams Fork Coal Region since over 60 percent of the coal there is privately owned. The subalternative would have its greatest effect in the Fort Union Coal Region, where 99.8 percent of all Federally-owned acreage in North Dakota and 87 percent in Montana is overlain by private surface. The Powder River Coal Region would be similarly restricted.

If new coal leasing is needed to meet demand in these regions with significant split estate land patterns, this subalternative could limit the ability of the government to meet this need. The Department specifically studied this question in two areas. (It should be emphasized that these studies

did not measure the impact of providing surface owner consent to that limited number of ranchers and farmers protected under Section 714 of the Surface Mining Control and Reclamation Act, but dealt instead with the much broader question of foregoing leasing under all non-Federal surface.) For southern Campbell County, Wyoming, this subalternative would eliminate from consideration for leasing over 11 billion tons of Federally-owned coal, leaving only 2.6 billion tons available (Figure 5-7). These 2.6 billion tons could be further reduced by the application of unsuitability criteria or other environmental restrictions. Figure 5-7 indicates that the maximum yearly production rate, assuming a 40 year mine life and annual production of five million tons a year, from this reserve would be 51 million tons per year. To the extent this is not sufficient to meet the demand, production above that level would either be transferred to existing Federal leases or to private lands, either within or outside the region. Since the coal in this area has the thickest seams in the United States, and a well-developed transportation network, the net effect of this policy could be to increase the total acres of land disturbed by mining, and to create pressure for construction of new coal transportation networks elsewhere in the West.

The Department also estimated that this subalternative could constrain development in the Decker-Birney Planning Unit in Montana in the northern part of the Powder River Coal Region. Again, as in the Campbell County, Wyoming, area, the Decker-Birney Unit has vast coal reserves, and, in parts, a developed rail system. It is the site of ongoing coal development. As part of the Department's task force on developing land unsuitability criteria, a field test was done in the Decker-Birney Unit to determine how much coal would be available for leasing. Figures 5-8 and 5-9 present estimates of the amount of Federally-owned stripable coal deposits in the Decker-Birney Planning Unit. Lands potentially available for lease were identified after applying the most stringent of the alternative suitability standards (including some which the Department later modified to be less stringent) in two ways: (1) without regard to surface ownership and (2) excluding all coal underlying non-Federal surface. Under the first assumption, eight deposits of 400 million tons or more, two deposits of 150 to 400

million tons, and nine deposits of 20 to 150 million tons were identified as potentially available for leasing. Under the second assumption, only one deposit of 400 million tons, none from 150 to 400 million tons, and eight from 20 to 150 million tons remained. As in the Campbell County, Wyoming, example, the amount of land available for coal leasing would be significantly reduced under this subalternative.

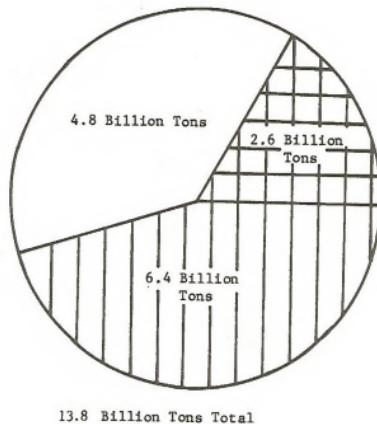

The work done in these two areas appears to be transferable to areas with similar surface ownership characteristics. The studies did not attempt to make any specific findings as to whether the overall impacts of developing the Federal surface versus private surface lands were significantly different in these areas.

The exact effect of shifting leasing to land where both the coal and the surface estate are Federally-owned, compared to land with Federal coal and private surface, or private surface and private coal, is unclear at a general level such as this. Totally private surface and mineral estates, particularly in Wyoming and Montana, tend to concentrate in river and stream valleys and along major highways as compared to estates having whole or partial Federal interests. Similarly private surface estates overlying Federal coal tend to be in these same areas as compared to Federal surface. Except for areas such as southern Campbell County, Wyoming, Federal surface lands and Federal coal would then tend to be in areas further from existing transportation, in rougher topography, less intensively used, not in alluvial valleys or flood plains, and the like. Private lands, including railroad lands, also tend to be closer to towns and roads. Development in all Federal areas would tend to increase the need for new infrastructures. More detailed information on these issues is available in several recent coal studies, including those listed in Table 1-1, and the Northern Great Plains Resource Program.

In the long run, this subalternative would also tend to distribute coal development more extensively in areas where the land and coal are entirely Federally owned. The social and economic consequences of a subalternative that prohibits leasing under non-Federal surface would be substantial. Such a subalternative would not give significant additional protection to those ranchers and farmers whose property rights are already safeguarded under the Surface Mining Control and Reclama-

tion Act, and would eliminate the prospect of cooperation by any non-Federal landowners, including those protected under that Act, and all others who are willing to assist in the development of Federal coal under their lands. In some areas, coal production would not be possible, and those residents who anticipate increased employment opportunities and the other economic changes associated with coal development would not experience such changes.

In other areas, mining on Federal surface could cause social and economic changes that would be experienced by all residents, and the ban on mining of private surface would simply deny some landowners the opportunity to participate in personal economic benefits from Federal coal development in their area.

A less extreme version of this policy -- to allow leasing if the surface were owned by a coal company or a party who did not farm or manage the land for grazing -- would nearly double the southern Campbell County, Wyoming lands available for leasing. This dramatic increase in land availability might not occur in other areas of significant private ownership, since coal companies and investors have long recognized Campbell County as a prime coal area. The Department does not have accurate figures at this time for other areas. Purchases and other ways to control the surface are likely to be more prevalent in Campbell County than in other parts of the West.

The subalternative of not leasing in checkerboard areas presents similar problems. The principal effect of this subalternative would be to forestall development of the coal lands in both the Federal and non-Federal portions of the checkerboard areas where the Federal coal is now unleased. Department estimates indicate that 42 percent of the total coal reserves (Federal and non-Federal) in the Fort Union Coal Region, 16 percent in the Powder River Coal Region, and 27 percent in the Green River-Hams Fork Coal Region would likely be incapable of development without Federal leasing. Other regions have few or no checkerboard areas and would not be changed by this subalternative. The subalternative would eliminate mining in checkerboard areas since relatively little Federal coal has been leased in those areas. Some coal in checkerboard areas may be developed in conjunction with state lands but, in general, mining of coal in the checkerboard

areas would be greatly limited. With the exception of the Fort Union Coal Region and possibly in the Wyoming portion of the Green River-Hams Fork Coal Region, there is probably sufficient coal in non-checkerboard areas to meet foreseeable coal needs from Federal reserves and non-checkerboard private reserves.

The environmental effects of this subalternative are difficult to estimate. The checkerboard areas tend to have better transportation access to rail lines than non-checkerboard areas. The effect of this subalternative may be increased environmental disturbance to build new transportation facilities. Similarly, vegetation distribution and wildlife habitats may vary from checkerboard areas to non-checkerboard areas. The overall environmental impact on these lands as compared to Federal surface or other private surface is not clear. Particularly at low leasing levels, it is likely that equally attractive tracts could be found in both types of land-ownership areas.

The adoption of this subalternative would also have competitive implications. The Justice Department has recommended that the Department of the Interior proceed to ensure that the railroads' control of these lands will not have anticompetitive effects. Further discussion of this aspect of the land ownership subalternative may be found in the May 1978 Annual Report of the Justice Department.

Failure to adopt either of the subalternatives on a program-wide basis would not foreclose the Department from adopting them on either a regional or lease-by-lease basis. Land ownership could, and would in the preferred program, be a factor in tract ranking. Both the land use planning process and the tract delineation and ranking process in the preferred program will give the Department the opportunity to compare the environmental impacts of developing lands with different surface owners.

5.4.7 Maximum Economic Recovery.

Prior to the enactment of the Federal Coal Leasing Amendments Act of 1976, the Department did not have either a statutory mandate or extensive formal guidelines or regulations to assure that coal reserves would not be lost as part of a mining operation, particularly for surface mining operations. The Geological Survey has enforced standard principles of resource conservation as

part of its oversight responsibilities on Federal coal leases. The Congress, in the 1976 Act, added two specific requirements to improve coal resource recovery. First, prior to issuance of a lease, the Secretary is directed to consider and compare which method or methods of mining will result in the "maximum economic recovery of the coal in the proposed lease tract". This determination is not binding upon the Secretary or the lessee. Second, the Secretary is prohibited from approving a mining plan which does not achieve the maximum economic recovery of the coal in the leased tract. Congress' goals in enacting this provision were to prevent waste of coal resources and to minimize environmental damage from mining by assuring that all economically recoverable coal would be mined so that a second mining operation at some later date would not be necessary. Three subalternatives concerning Maximum Economic Recovery (MER) have been considered.

- MER is evaluated seam-by-seam. (The lessee must mine and recover coal from each profitable seam.)
- MER is evaluated on all seams. (The lessee must mine and recover coal from all seams which are collectively profitable excluding seams technically or environmentally unrecoverable.)
- MER is limited to a decision only on what mining method or methods are to be used, and the decision on which seams are to be mined and recovered is one based on sound resource conservation principles.

The subalternative the Department chooses will affect recovery in both surface and underground mines. In surface mining, it could affect the stripping ratio to which a company will have to mine; companies may be required to recover coal under greater depths of overburden. Companies may also have to mine deeper seams than would otherwise be done in surface mines. In underground mines, it may affect the number of seams to be mined, the equipment to be used, the depth of mining, and the amount of coal in each seam that is mined. In all instances, the most likely effect of a decision to apply a strict MER standard is to prolong existing mining operations or increase yearly production rates of those operations, or a combination of the two. This should, to some extent, increase the production from already

opened mines and diminish the need to open other mines.

The first two subalternatives considered for MER, which involve the economics of an operation, impose additional government administrative costs and inject the government more deeply into the mining process than was true in the past. The more stringently the Federal government defines MER, the less value it will receive for leases offered by a competitive bonus system since the increased cost of mining the last, more costly unit of coal lowers the economic rent to the government. Costs to consumers could tend to increase as lower grade (more costly) coal is recovered.

In addition to potential reductions in the lease bonus payments by mining companies, there are several other potential impacts that could result from strict interpretation of the MER authority. These impacts include:

- Shifts from Federal coal to non-Federal coal.
- Increased levels of severance tax revenues.
- Possible reductions in acreage disturbed.

There is the possibility that the rigorous application of the first two MER subalternatives would diminish the competitiveness of Federal coal leases as compared to non-Federal lands. To the extent that is true, it would reduce production from Federal lands, and cause production shifts to state and private lands.

Any shifts from Federal coal lands to non-Federal coal lands would result in decreased bonus payments to the Federal Government. As production commences, however, there will be increased levels of severance tax revenues to the state governments.

Acreage disturbed by mining may be reduced through a strict interpretation of the MER authority. This could occur as a result of surface mining and subsequent deep mining of specific tracts. In this fashion previously foregone coal resources would be extracted and less land would be disturbed per tonnage mined.

The first two MER subalternatives might also prevent certain lands from being developed for gasification or other in-situ processes if these methods were not the method that achieved the maximum economic recovery of the coal resource. This would both reduce the potential supply of natural gas and change the environmental impacts of the mine site, from those associated with a

gasification plant to those associated with other forms of coal development.

Finally, these subalternatives may cause conflicts with other laws. For a particular coal deposit one portion may be amenable to being economically mined both underground mining methods and the other portion by surface mining methods; the application of MER would require the mine plan to show the recovery of both of these economically viable reserves. Over the course of a long-term coal management program, some of these joint mining tracts may present situations where only one type of mining is desirable. This could arise from a variety of situations including failure to obtain surface owner consent, land suitability determinations, hydrologic concerns, and other problems. If no discretion were available to exclude undesirable seams, mining of the entire property might not take place. Although it could be argued that new legislation is needed, the Department believes that MER does not apply to coal which cannot be lawfully mined and, in addition, that the Department retains the authority to do separate seam leasing, i.e., issue a lease which would grant the right to mine only specified coal seams. This latter authority, implicit in section 714 of the Surface Mining Control and Reclamation Act, has been used in several short-term leasing situations since Congress passed the Federal Coal Leasing Amendments Act.

5.4.8 Unsuitability Criteria

Until very recently, the Department issued coal leases for lands without specified standards for excluding lands from leasing. Local BLM managers had little incentive to seek out the best coal lands, or even to avoid the worst lands, and the tendency was to lease lands without careful pre-lease consideration of environmental impacts. In the past 10 to 15 years, and particularly in the last three years, new laws affecting coal development have been enacted including those which prohibit or greatly limit coal leasing or development on some Federal lands.

The Department is now required to take steps to ensure that unsuitable lands are not mined. Section 523 of the Surface Mining Control and Reclamation Act, 30 U.S.C. 1273, requires the Secretary to establish a Federal Lands Program to govern surface and underground coal mining operations on Federal lands. One duty under that

program is to carry out the Federal lands review required by Section 522 of SMCRA. Section 522 of SMCRA requires the Department to conduct a Federal lands review to assess if certain classes of Federal lands are unsuitable for all or certain types of coal mining operations, and to establish a process by which the public may petition to have Federal lands designated unsuitable for all or certain types of coal mining operations. The Department may continue to lease coal even in those lands where no Federal lands review has been done.

In November 1977, a task force composed of representatives from seven agencies and offices in the Department of the Interior (the Bureau of Land Management, the U.S. Geological Survey, the Office of Surface Mining, the Fish and Wildlife Service, the Bureau of Indian Affairs, Office of Economic Analysis, and the Office of the Assistant Secretary - Land and Water Resources) and the Forest Service from the Department of Agriculture began to formulate draft criteria to designate lands unsuitable for coal mining. The task force originally considered 44 criteria, but deleted or combined 21 of them. In late May and early June of 1978, teams drawn from the task force field tested the remaining draft criteria in four areas in the West. The task force's final report of the field tests was filed on September 11, 1978 [11].

The criteria drafted by the task force incorporated the requirements of many laws affecting coal not just those mandated by SMCRA.

The term "unsuitability" has statutory significance only with respect to standards arising under Section 522(a) of the Surface Mining Control and Reclamation Act (SMCRA). The legal basis for the unsuitability criteria which will be described below is not uniform. Three different classes of sources of authority are involved, and each authority has different implications.

Section 522(a) of SMCRA. This section requires mandatory designation of lands as unsuitable for surface mining if reclamation is not technologically and economically feasible and allows discretionary designation of lands as unsuitable for surface mining if operations will:

- Be incompatible with land-use plans;
- Cause significant damage to important historic, cultural, scientific, and esthetic values and natural systems in fragile or historic lands;

- Cause a substantial loss or reduction of long-range productivity of water supply or food or fiber products in renewable resource lands, including aquifers and aquifer recharge areas; or
 - Substantially endanger life and property on natural hazard lands, including areas subject to frequent flooding and areas of unstable geology. Section 522(a) does not apply to:
 - Lands on which surface mining was being conducted on August 3, 1977.
 - Lands for which substantial legal and financial commitments were made prior to January 4, 1977.
- Section 522(e) of SMCRA.* This section prohibits surface coal mining:
- In units in various named Federal land systems such as the National Park System;
 - That will adversely affect any publicly-owned park or places in the National Register of Historic Sites;
 - Within 100 feet of the right-of-way line of a public road; and
 - Within 300 feet of an occupied dwelling or public building, school, church, community, or institutional building, public park, or within 100 feet of a cemetery.

Section 522 (e) does not affect:

- Operations that existed on August 3, 1977; or
- "Valid existing rights".

Statutes other than SMCRA (including the Endangered Species Act, the Federal Land Policy and Management Act, the Wilderness Act, the Bald Eagle Protection Act) also require or authorize certain resource protection. Their application through the unsuitability criteria is discretionary on the part of the Secretary. Each statute must be examined to determine how it applies to existing leases.

Although the Federal Lands Program (including the Federal lands review) is exempt from the requirements of the National Environmental Policy Act (NEPA) for preparation of an environmental impact statement, 30 U.S.C. § 1292(d), the Department has decided to include in this statement an analysis of the environmental impacts of the unsuitability criteria to give the public and the Department a better opportunity to evaluate these criteria before they are finally adopted.

Field tests of the proposed unsuitability criteria were held in late May and early June 1978 in four western coal areas to determine what impact on areas with potential for coal leasing would result from application of the unsuitability criteria. The criteria tested in June 1978 are, in some instances more stringent than the criteria selected for the preferred program (see Table 3-1). The following section describes the four test areas and the specific criteria utilized in the evaluation of areas unsuitable for coal mining.

The four units involved were the Wattis Planning Unit in Utah, the Decker-Birney Planning Unit in Montana, and the Campbell and Converse Planning Units both in Wyoming. The Wattis Planning Unit covers about 439 thousand acres and lies on the eastern flank on the Wahsatch Plateau in Carbon and Emery Counties, Utah. Approximately 250 thousand acres of coal lands were examined in the field test. The Campbell and Converse Planning Units are in northeastern Wyoming, encompassing about 2.3 million acres in Campbell County and 1.4 million acres in that part of Converse County north of the North Platte River. The effects of the unsuitability criteria were examined on about 500 thousand acres of coal lands, estimated to contain 67 billion tons of Federal coal resources. The Decker-Birney Planning Unit lies in Rosebud and Big Horn Counties in southeastern Montana, just north of the Wyoming border. The area covers about 900 thousand acres of which slightly more than 250 thousand acres of coal lands were examined in field testing of the criteria. The Federal coal lands in the area examined are estimated to contain about 13 billion tons of Federal coal resources.

The Decker-Birney and Campbell-Converse Planning Units lie in the Powder River Coal Region. The Wattis area is in the Uinta-Southwestern Utah Coal Region.

The various criteria and, in some instances, alternative criteria which were the subject of the field tests are set forth in Table 5-90. This Table is also found in the September 11, 1978, final report of the Task Force.

Table 5-91 indicates the tonnage of federal coal, acres of Federal coal lands, and percentages of both affected by application of the draft criteria to the field test areas. Based on overlay mapping of the areas affected by the several criteria, their cumulative application in the Decker-Birney Plan-

TABLE 3-90
DRAFT UNSUITABILITY CRITERIA FIELD TESTED IN 1978

CRITERIA AND ALTERNATIVES	EXCEPTIONS	AUTHORITY	DATA NEEDED INFORMATION PROCESS
CRITERION 1-LEASING EXCLUSIONS			
(1) All Federal lands included in or candidates for inclusion in the following Land systems or categories are not available for coal leasing: National System of Trails, National Wilderness Preservation System, Wild and Scenic Rivers System, National Recreation Areas, Custer National Forest (excluding lands within incorporated cities, towns, and villages).	A lease may be issued for underground coal mining within the Custer National Forest with the consent of the Department of Agriculture.	1. SNRA, Sec. 522(e) P.L. 95-87 2. Section 16 of P.L. 94-377	Maps of existing Federal lands within the various land systems. Maps of potential additions to these systems and appropriate agencies. BLM Laster Title Plans.
CRITERION 2-RIGHTS-OF-WAY AND EASEMENTS			
(2) Federal lands that are within rights-of-way or easements for residential, commercial, industrial, public purposes and agricultural crop production shall be excluded from coal leasing. Wherever possible, Federal leases should exclude areas identified in section 522(e) of SNRA (lands within 100' outside of ROW of public highway or within 100' of cemetery, and within 300' of occupied dwelling, school, church, cemetery or institutional building or public park or within 300' of an occupied dwelling unless waived by the owner thereof.)	A lease may include such areas if: (a) it is determined that the level-of-use (e.g., underground mining) will not interfere with the purpose of the right-of-way or easement, or (b) the right-of-way or easement was granted for a valid purpose, or (c) the ROW or easement was issued for a purpose for which it is not being used, or (d) where a particular area involved is not being leased, or (e) if it is impractical to exclude such areas due to location of coal and extent of mining, and such areas can be protected through use of appropriate stipulations.	1. Departmental Policy 2. Section 322(e) of P.L. 95-87 SNRA	This designation would make a case-by-case basis using available plat data, county road maps, etc.
CRITERION 3-ROADLESS AREAS - ALTERNATIVE 1			
(3)(a) Federal lands designated as roadless or under review as candidate roadless areas are unavailable for surface mining and coal leasing until such time as the Congress determines which portions of the roadless lands will be included within the Wilderness System.	No exceptions except valid existing rights will be honored. Where valid title exists for lands included in the wilderness study areas, no leases will be granted until wilderness review is completed. For valid PELAs option of exchange should be considered.	1. P.L. 88-577 (Wilderness Act) 64 USC 1133 2. FPLMA, 43 USC 1702 and 1782 3. Forest Service Rule II in Nov. 19, 1977 F.R.	Maps showing roadless, wilderness study and wilderness areas from BLM, NFS, NPS, and Park Service.
CRITERION 3 - ALTERNATIVE 2			
(V)(b) BLM administered lands designated as roadless and under review as candidate roadless areas will be excluded from coal leasing until such time as the Congress determines which portions of such lands will be included within the Wilderness System.	Forest Service administered lands designated as roadless and under review as candidate roadless areas will be excluded from coal leasing until such time as the Congress determines which portions of such lands will be included within the Wilderness System.		

TABLE 5-90 (Continued)
DRAFT UNUSUITABILITY CRITERIA FIELD TESTED IN 1978

CRITERIA AND ALTERNATIVES	EXCEPTIONS	AUTHORITY	DATA NEEDED OR INFORMATION PROCESS
CRITERION 3 - ALTERNATIVE 3 (3)(c) BLM administered lands designated as roadless are unsuitable for mining and shall be excluded from coal leasing.			
CRITERION 4 - SCENIC AREAS - ALTERNATIVE 1 (4)(e) Scenic Federal lands designated by visual resource management analysis as Class I or II (areas of outstanding scenic quality and/or high visual sensitivity) but not currently on the National Register of Natural Landmarks, shall be excluded from coal leasing.	An exception may be granted if it can be determined that coal mining will not diminish or adversely affect the scenic quality of the designated area.	P.L. 94-579, sections 201 and 202; Departmental Policy	Class I or II according to BLM classification system. This section should also apply to comparable rankings of scenic values by other land managing agencies: e.g., FS.
CRITERION 4 - ALTERNATIVE 2 (4)(b) Scenic Federal lands designated by visual resource management analysis as Class I (areas of outstanding scenic quality) but not currently on the National Register of Natural Landmarks, shall be excluded from coal leasing.	Same as 4a.	Same as 4a.	
CRITERION 5 - LANDS USED FOR SCIENTIFIC STUDIES (5) Federal lands being used for scientific studies involving food and fiber production, natural resources, or technology demonstration and experiments are unsuitable for mining and shall be excluded from coal leasing.	A coal lease may be issued: (1) with the concurrence of the principal scientific user or agency, or (2) where the mining could be done in such a way as to not jeopardize the purpose of the study.	1. Departmental Policy 2. SMCRA 3. PLMPA	Information on each scientific study and the location of study sites are maintained by the surface managing agencies.
CRITERION 6 - STATE UNSUITABLE LANDS - ALTERNATIVE 1 (6)(a) Under the provisions of Section 322 of the SMCRA where State lands designated non-Federal lands to be unsuitable for surface mining and such non-Federal lands are contiguous to or cornering on Federal lands, a buffer zone of Federal lands of (1) mile from the boundary of the lands of non-Federal lands shall be unsuitable for surface coal mining and unavailable for coal leasing. In no case should the ends of the buffer zone exceed the ends of the state lands designated as unsuitable.	1. Any exceptions applicable to the State lands should also be applied to this Federal buffer zone. 2. Federal land management agencies may modify or eliminate buffer zones as necessary to maintain consistency with the purpose of the State designation if the State petition for changes in buffer zones. States must concur with changes in Federal buffer zones. 3. Leasing may be allowed within the buffer zones if the coal would be mined by underground mining methods and would not affect the State designated lands.	1. P.L. 95-87, Sec. 522 SMCRA 2. Departmental Policy	Areas excluding State recreation and preservation areas will be designated unsuitable by the agency to minimize impact water quality, habitat sources and habitat identified by the State as critical to rare designated species.
CRITERION 6 - ALTERNATIVE 2 (6)(b) Eliminate this criteria and direct Departmental land managing agencies to determine buffer zones around State designated unsuitable lands on a case-by-case basis.			
CRITERION 7 - HISTORIC LANDS AND SITES - ALTERNATIVE 1 (7)(e) Sites on Federal lands which are on or eligible for the National Registry of Historic Places (historic, archaeological, architectural, and cultural) and on appropriate buffer zones areas the outside boundary of the property are unsuitable for coal mining and shall be excluded from leasing when such areas or places are of national significance.	Leasing may be allowed where: 1. Areas or sites are of regional or local significance and with the concurrence of the State government.	1. National Historic Preservation Act of 1966 (16 U.S.C. 470 et seq.)	Listing of the National Registry of Historic Places by the National Park Service and listing of properties eligible for the National Register by appropriate State, local and Federal agencies.

TABLE 5-90 (Continued)
DRAFT INELIGIBILITY CRITERIA FIELD TESTED IN 1978

CRITERIA AND ALTERNATIVES	EXCEPTIONS	AUTHORITY	DATA NEEDED OR INFORMATION PROCESS
CRITERION 7 - ALTERNATIVE 2 (7)(b) Same as above except eliminate condition of "national significance" in order to be excluded from consideration for Federal coal leasing	2. The effects of coal mining can be satisfactorily mitigated through the use of mining technology and the action of the Commissioner or the Historic Preservation Officer have consented to mining, if the site or property is on the <u>National Registry</u> . 3. The cultural resources areas can be studied and recovered or they can be items that can be moved or rastered without any loss of significance.	2. Archeological and Historic Preservation Act of 1974 (16 U.S.C. 470(h) et seq.) 3. Historic Sites, Buildings and Monuments Preservation Act of 1935 (16 U.S.C. 461-467) 4. Archeological and Historic Preservation Act of 1974 (16 U.S.C. 469)	
CRITERION 8-NATURAL AREAS (8) Federal lands designated as natural areas or as National Natural Landmarks and Federal lands which will be on or eligible for the <u>National Registry of Natural Areas</u> (ecologic, geologic, scenic, and lands with wild or scenic significance) are unsuitable for surface coal mining and shall be excluded from coal leasing when such areas are of national significance.	Leasing may be allowed in these areas if: 1. Such areas or sites are of regional or local significance and the concurrence of the State government and, where appropriate, the Maritime Conservation and Recreation Service. 2. It can be determined that the effects of mining will be mitigated through the use of appropriate mining technology and with the concurrence of NMFS. 3. The mining of the coal resource will enhance information recovery (e.g., paleontological sites).	1. Departmental Policy 2. Legislation dealing with the establishment of a National Heritage Program has been proposed which will establish a <u>National Register of Natural Areas</u> . 3. S.O. 2017 which establishes the Maritime Conservation and Recreation Service (MCRS).	Listing of any natural areas designated by Federal agencies. NMFS may also have identified some natural areas.
CRITERION 9-ENDANGERED SPECIES (9)(e) Legally designated critical habitat for Federal threatened/endangered (T/E) plant and animal species are unsuitable for coal mining and shall be excluded from coal leasing. (9)(b) Crucial value habitat for Federal T/E species as determined by the FWS and the land management agency where the presence of T/E species has been scientifically documented are areas of environmental concern and are excluded from coal leasing. (9)(c) High value habitats for Federal T/E species, as determined by FWS and the land management agency, shall be considered for leasing only after it is scientifically determined that the area is not a critical or crucial habitat.	Leasing may be allowed if after consultation with FWS it can be determined that the area is not critical habitat and will not be adversely affected by coal development or that complete mitigation is possible.	1. Endangered Species Act of 1973 (16 U.S.C. 1531, et seq.). 2. Departmental Policy 3. Authority for ACER in PLPA, (43 U.S.C. 1702).	Maps of critical habitat for endangered and threatened species from land management agencies and FWS. Maps showing suspected (documented) T/E species presence. Information on high value habitat from wildlife inventories and land management planning documents.

TABLE 5-90 (Continued)
DRAFT INSUITABILITY CRITERIA FIELD TESTED IN 1978

CRITERIA AND ALTERNATIVES	EXCEPTIONS	AUTHORITY	DATA NEEDED OR INFORMATION PROCESS
CRITERION 10-STATE LISTED ENDANGERED SPECIES			
(10) Habitats deemed critical or crucial for State listed endangered or threatened plant and animal species as determined by the State and the agency in consultation with the States and the FWS are unsuitable for mining and shall be excluded from coal leasing.	1. Leasing may be allowed if after consultation with the State, it can be determined that specific habitat will not be adversely affected by the coal development or that complete mitigation is possible.	1. FLPMA (44-579) 2. State Act Sec. 204	Information on State species from appropriate State agency and the FWS.
CRITERION 11-BALD AND GOLDEN EAGLE NESTS			
(11) Bald and Golden Eagle nests that are determined to be active and a buffer zone of land included in a ½ mile radius from the nest are areas which shall be excluded from coal leasing.	A lease may be issued if: 1. Mining can be conducted in such a way and during periods of time that eagles will not be disturbed during breeding season. 2. A permit or special approval is granted by the FWS to allow the eagle nest to be moved. (Permit regulations are currently undergoing review by FWS.)	1. Bald Eagle Protection Act (16 U.S.C. 668). (This includes all eagles). 2. Endangered Species Act of 1973 (16 U.S.C. 1531). (Bald and golden eagles are listed as endangered species in all States where they are listed as threatened.)	Location of active eagle nests. Use definition of active eagle nests on page 39 of March 1 draft criteria. Additional information on inventoried active eagle nests available from the FWS and land management agencies.
CRITERION 12-EAGLE ROOST AND CONCENTRATION AREAS			
(12) Bald and Golden Eagle roosts and concentration areas used during migration and wintering are areas of critical environmental concern and shall be excluded from coal leasing. Where such areas have been designated as critical or crucial habitat for Bald Eagle, coal leasing shall be excluded.	A lease may be issued: 1. If mining can be conducted in such a way and during periods of time that eagles will not be adversely disturbed or 2. For Bald Eagles where such areas are designated as critical or crucial habitat if the exception under endangered species criteria are met.	1. Bald Eagle Protection Act (16 U.S.C. 668). 2. Endangered Species Act of 1973 (16 U.S.C. 1531). 3. Authority for ACRA in FLPMA (44-579 U.S.C. 1702).	Use existing inventory data of roost and concentration areas from BLM FWS, and FS.
CRITERION 13-RAPTOR CLIFF NESTING SITES			
(13) Federal lands containing raptor cliff nesting sites with active nests and a buffer zone of Federal lands ½ mile radius from the next site are areas which shall be excluded from competitive leasing.	A lease may be issued: 1. Where it can be determined that coal mining will not adversely impact the nesting sites during the breeding season. 2. Where nest sites may be moved with concurrence of the FWS.	1. Migratory Bird Treaty Act. 2. Departmental Policy.	Use existing inventory data and any additional inventory data from BLM, FWS, and FS of active nests from page of March 1 draft criteria.
CRITERION 14-MIGRATORY BIRDS			
(14) Federal lands which are habitat for migratory bird species of high Federal interest (as determined by the FWS) that are determined to be critical or high priority habitat by the land management agency in consultation with FWS are areas of critical environmental concern and shall be excluded from coal leasing.	A lease may be issued: 1. Where it is determined by the land management agency in consultation with FWS that coal mining will not adversely impact the migratory bird habitat during periods when such habitat is used by the species. 2. Where the land management agency in consultation with the FWS determines that the impact on the habitat can be minimized through use of appropriate mining and reclamation technology and lease stipulations.	1. Migratory Bird Treaty Act. 2. Fish and Wildlife Act. 3. Departmental Policy.	For definition of criteria and high priority habitat see page 44 of March 1 Draft Bureau draft.

TABLE 5-90 (Continued)
DRAFT UNSUITABILITY CRITERIA FIELD TESTED IN 1978

CRITERIA AND ALTERNATIVES	EXCEPTIONS	AUTHORITY	DATA NEEDED OR INFORMATION PROCESS
CRITERION 15 - CRUCIAL HABITAT FOR HIGH INTEREST FISH AND WILDLIFE SPECIES - ALTERNATIVE 1 (15)(a) Federal lands that have critical or high priority fish and wildlife values for species of high State or Federal interest are areas of critical environmental concern and shall be excluded from leasing.	A lease may be issued where: 1. It can be determined that the coal mining impacts on the habitat will not adversely affect the species during critical periods for breeding, migrating, feeding, or wintering. 2. It can be determined that the impacts of coal mining can be mitigated through use of appropriate mining and reclamation technology.	1. Fish and Wildlife Coordination Act (16 U.S.C. 460-467(a)), (particularly where reclamation could result in diversion or modification of streams or other bodies of water). 2. Wild Free-Roaming Horses and Burros Act (16 U.S.C. 1331-1340). (Where leasing would impact such habitat.) 3. Anadromous Fish Conservation Act (16 U.S.C. 757(d)-757(b)). 4. Departmental Policy.	Various inventories of fish and wildlife habitats from NM, States, FWS, etc., etc. For definitions of "critical and high priority" fish and wildlife values see draft March 1 draft task force criteria.
CRITERION 15 - ALTERNATIVE 2 (15)(b) No specific <i>a priori</i> criteria for this topic; areas containing high fish and wildlife values protected on a case-by-case basis based on resource values and mitigation potential.			
CRITERION 16 - WETLANDS (16) Federal lands containing: (1) inland lakes, impoundments, and associated wetlands, (2) inland shelves predominantly vegetated with wetland, (3) riverine systems, i.e., perennial and upper perennial systems with flow greater than 3 cubic feet per second and riparian zones in a relatively undisturbed state that are larger than one mile long & riverine systems are critical environmental areas and shall be excluded from coal leasing.	A lease may be issued where: 1. The use of appropriate mining or reclamation technology will not significantly effect the wetlands or will provide for complete restoration and mitigation. 2. Where the wetlands contain no significant values for ground-water recharge, fish and wildlife habitat, recreation or scientific study.	1. E.O. 11990, 1977 (National Executive Order.) 2. Fish and Wildlife Coordination Act (16 U.S.C.A. 661). 3. Departmental Policy.	Use wetland inventory data from land management agencies, FWS and SCS.
CRITERION 17 - RARE VEGETATIVE SPECIES AND COMMUNITIES (17) Federal lands that contain rare plant species, species with unusual vegetative form, rare climate and native communities, or relic communities as determined by the land management agencies are areas of critical environmental concern and shall be excluded from coal leasing.	Leasing may occur where: 1. Mining can be conducted in such a way as to not impact the plant species. 2. Coal development will improve the habitat for the plant species. 3. It is demonstrated that complete mitigation is possible by use of reclamation technology.	1. Departmental Policy on natural diversity.	List of rare species by ecoregions- identification of habitat types.
CRITERION 18 - ALLUVIAL VALLEY FLOORS (18) To be provided by OEM Task Force.			

TABLE 5-90 (Concluded)
DRAFT UNSUITABILITY CRITERIA FIELD TESTED IN 1978

CRITERIA AND ALTERNATIVES	EXCEPTIONS	AUTHORITY	DATA NEEDED OR INFORMATION PROCESS
CRITERION 19-FLOODPLAINS - ALTERNATIVE 1 (19)(a) Rivers, coastal, and special floodplains (100-year recurrence interval) are natural hazard lands and shall be excluded from coal leasing.	Leasing may be allowed where (1) leasing a particular tract is the only practical alternative and (2) potential for damage or property and natural and beneficial values of floodplain can be minimized through use of dammed areas and available mining and mitigation measures.	1. Executive Order 11988, May 24, 1977, Floodplain Management. 2. Guidelines for Implementing Executive Order 11988, National Water Resources Council, Feb. 10, 1978.	For description of E.O. and guidelines see paper entitled "Floodplain Management," attached to March 1 Task Force draft.
CRITERION 19-FLOODPLAINS - ALTERNATIVE 2 (19)(b) Same as above except 100-year recurrence interval is replaced by a 500-year interval.			HFD/Corps of Engineers floodplain maps, historical records, USGS modeling.
CRITERION 20-MUNICIPAL WATERSHEDS (20) Federal lands which have been committed to use as municipal watersheds are unsuitable for mining and should be excluded from coal leasing.	Leasing may be allowed: 1. Where it can be determined that mining will not adversely affect the watershed to any significant degree, or 2. Where the municipality or water users concur in the issuance of the lease.	1. Policy from Safe Drinking Water Act. 2. Departmental Policy.	
CRITERION 21-NATIONAL RESOURCE WATERS (21) Federal lands with National Resource Waters, as identified by States in their water quality management plans and a buffer zone of Federal lands 1 mile from the outer edge of the far banks of the water, are unsuitable for mining and shall be excluded from coal leasing.	1. The buffer zone may be eliminated or reduced in size where it can be determined that it is not necessary to protect the National Waters.	1. Water Pollution Control Act. 2. Departmental Policy.	
CRITERION 22-PRIVATE SURFACE-FEDERAL COAL (22) Federally owned coal resources that are overlain by non-Federal surface ownership should be excluded from future coal leasing.	A lease may be issued in such areas where: 1. The surface was owned in fee by a coal company on August 3, 1977 (date of SNRCA). A company which had a lease for the surface or some other arrangement prior to 1977, fee ownership does not qualify as a surface owner. Coal Company is defined as any corporation, partnership, association, or company which has mined or is mining coal resources.	1. Departmental Policy.

*Maximum of a range that varied depending on AVF definition.

ning Unit excluded about 4.1 billion tons of coal or about one-third of the Federal coal resource. The draft criteria excluded 341,000 acres; 72 percent was caused by draft criteria 15. In the Campbell-Converse Planning Unit, slightly less than half of the Federal coal resource (32 billion tons or 256,000 acres) was pre-empted by application of the criteria. In both areas the single criterion which excluded the most coal was criterion 15, fish and wildlife habitat of high state interest.

Insufficient data limited the testing of four criteria (state unsuitable lands, state-listed endangered species, national resource waters, and migratory bird habitat) in both the Wyoming and Montana test areas. Additionally, data were lacking for alluvial valley floors in the Decker-Birney test area and for eagle nest sites and eagle concentration areas in the Campbell-Converse test area. If data were available for these criteria, additional Federal coal lands would likely be excluded from further consideration for coal leasing in both areas.

The field test of the criteria in the Utah area showed little affect on Federal coal availability because the vast majority of the coal in the area is accessible only by underground methods and the criteria are principally oriented to the exclusion of surface mineable coal.

These field tests examined the draft criteria in Table 5-90. As a result of these tests, the Task Force recommended deletion of three draft criteria (private surface Federal coal, alluvial valley floors, and state lands unsuitable), and modifications in virtually all other draft criteria. The Under Secretary made additional alterations in the Task Force's proposals, deleted another criterion, and added five new criteria when, on October 3 and November 2, 1978, he expressed a preference for the 24 unsuitability criteria for the preferred program (see Table 3-3 and the proposed regulations in Appendix A).

As an example of the manner in which changes were made consider the preferred program criteria 15 (State Resident Fish and Wildlife) and 9 (Federally-Listed Endangered Species).

The draft version of criterion 15 first field-tested in the summer of 1978 specified that, "... lands that have critical fish and wildlife values for species of high state and federal interest ..." were to be set aside from coal leasing. In making this determination the field test teams relied on a series

of wildlife habitat atlases prepared for the U.S. Fish and Wildlife Service by the various state game and fish agencies or by contractors working with state data. These field tests showed that criterion 15 was excluding up to 90 percent of potential coal land. In part, this was because some portions of deer and antelope winter ranges cover most of the coal-bearing areas. The unsuitability criteria are meant to narrow down to the most critical areas the land that must be set aside from potential coal mining to preserve the resource values they cover. The earlier form of criterion 15 was not doing this.

As a result of these tests, Criterion 15 was rewritten and retested with a new, narrower wording: "... lands which the land management agency and the State jointly agree are fish and wildlife habitat and which are essential for maintaining these priority wildlife species . . ."

The revised wording signals the local land manager and the States that only the habitat *most critical* to the existence of a viable population of high interest species in an area (e.g., *most critical* deer and antelope winter range) should be found unsuitable.

The draft version of criterion 9 also field tested in the summer of 1978, specified three levels of threatened or endangered species habitat protection: (a) legally designated; (b) crucial (where the presence of threatened or endangered species had been scientifically documented); and (c) high value (where there was a presumption of presence unless proven otherwise). In applying this three-level criterion, the Wattis, Utah team removed an unusually large area of land from consideration because of the assumed relationship between prairie dog towns and black-footed ferrets. As a result of this test, the Department's Unsuitability Task Force, in redrafting criterion 9 for its final recommendations, dropped the third level of endangered species habitat protection from the criterion. When the habitat is not legally designated as critical habitat, the application of the criterion requires *two* determinations. First, the determination that the presence of the species is scientifically documented (e.g. actual sighting or identification of tracks, scat, etc. by a knowledgeable observer in recent years). The second determination, which must be made, is that the habitat is essential to the maintenance of the species.

Thus, while the local land manager would certainly be careful in making determinations in

areas of prairie dog towns and would consult with anyone likely to have documentation of the black-footed ferret's presence, he would not rule prairie dog towns unsuitable *a priori*. He would have to apply the two part test of scientific documentation and essential habitat.

The five criteria added by the Under Secretary to those recommendations by the Task Force were the reclaimability, alluvial valley floors, prime farm lands, state lands unsuitable, and state-proposed criteria. The Secretary deleted the Task Force-proposed rare vegetation criterion.

The 24 criteria selected for the preferred program are presently being applied on an interim basis in certain land use plan areas in accordance with the procedures, and for the purposes, set out in 43 Federal Register 57662-57670 (December 8, 1978).

Any land-use plans which are affected by this round of field tests will be changed to conform to the Department's final criteria.

5.4.9 Role of Industry Nominations

Until the early to middle 1960's, the Department did not coordinate the issuance of coal leases on public lands with any sort of a planning system. Starting in the 1960's, the Bureau of Land Management began to bring its lands under the control of plans that identified land-use capabilities and demands. In 1976, Congress expressly required that land-use planning be done for all BLM-managed lands. Under the Federal Coal Leasing Amendments Act of 1976, planning is specifically required for coal and the Department may not issue a lease unless the mining is compatible with a plan (or the equivalent of a plan for certain lands where the Federal government has only minor interests).

One key question has been to decide the proper role for industry nominations in a land-use planning oriented leasing system. This involves considerations of how nominations affect the amount and location of coal to be offered for lease.

Three major sub-alternatives exist. First, the planning system would evaluate the coal resource and any environmental impacts after individual firms express their need for new coal leases. These expressions could either be by application or nomination. The land-use planners would examine these expressions in light of the plan and would decide whether mining would be "compatible"

with other uses. Lands not identified by industry would not be considered for leasing. This alternative could be used both as part of systems where industry also controls the overall leasing rate and those where it does not. The EMARS II program followed this pattern and both the rate and location of leases was dependent on industry nominations.

The second sub-alternative is to have a formal industry role after the government has identified through land use planning what areas are unsuitable for mining and what areas are acceptable for further considerations for leasing. Prior to the formal role, industry, like other potential users of the public lands, would be encouraged to participate in the planning process. This is the sub-alternative used in the preferred program, coupled with a policy of government control of the overall leasing rate.

The third sub-alternative is to have no formal industry role until the time a lease sale is held. Under this approach government planners would have the responsibility to determine both rates and location of leasing.

The only practical experience with these subalternatives is that gained under the EMARS II program.

Under EMARS II, industry nominated land it wanted the Department to offer for leasing. Persons opposed to leasing nominated tracts where leasing should not take place. Nominators were requested to rank their tracts in order of preference. Nominated lands were to be reviewed for environmental considerations and lands without significant problems would normally be offered for leasing, and leased if the high bid equaled or exceeded fair market value. "Highly ranked" tracts (those nominated by more than one company or tracts highly ranked by a company) were to be offered first. Diligent development and advance royalty provisions were intended to limit speculative holdings of leases.

As part of EMARS II, the Department issued a formal request for nominations on June 1, 1976. The nomination process was boycotted by a large number of western environmental groups. The results of those who did nominate can be summarized as follows:

Nominations in favor of leasing were received from approximately 300 sources, including coal

companies, and from private citizens, many of whom own land over Federal coal deposits.

These nominators identified about 1,000 separate areas covering more than three million acres they would like to see offered in the event of a Federal coal lease sale. Some 75 nominations of 200 tracts covering more than three million acres were registered against leasing. By state, the results of the nominations were:

- Wyoming - 86 nominators favored coal leasing on 300 tracts totaling 578,000 acres, with four nominations registered against leasing on 44 tracts involving several million acres.
- Utah - 37 nominators favored leasing on 110 tracts comprising 292,000 acres; there were no nominations against leasing.
- Colorado - 68 nominators identified 190 tracts totaling 483,000 acres; there were no nominations against leasing.
- New Mexico - 19 nominators favored leasing on 66 tracts totaling 298,000 acres; one nominator listed one tract comprising 3,300 acres on which leasing should not be considered.
- Oklahoma - 15 nominators identified 20 tracts, totaling 44,000 acres; there were no nominations against leasing.
- Montana - 48 nominators favored leasing 187 tracts totaling 989,000 acres; 27 nominators identified 28 tracts comprising 80,000 acres as unsuitable for leasing.
- North Dakota - nine nominators favored leasing on 39 tracts totaling 428,000 acres; 39 nominators identified 39 tracts covering 16,000 acres as unsuitable for leasing.
- Alabama - 11 nominators favored leasing on 24 tracts covering 37,000 acres; one nomination, signed by 150 individuals who opposed coal leasing in the Bankhead National Forest in Northern Alabama, listed 81 tracts comprising 146,000 acres considered unsuitable for leasing.

The Department's analysis of these nominations suggests that the nominations process was less useful than might have been desired. First, significant numbers of people (both industry and other groups) did not participate because of lack of sufficient time. Second, many nominations were unsupported by data or other evidence to show why the tract should be leased. Third, some

companies nominated significantly more coal than they (or perhaps the whole coal industry) could reasonably be expected to produce. For example, in at least thirteen instances a company nominated more lands than it would be allowed to hold under the acreage limitations in the Mineral Leasing Act of 1920. Others nominated lands which clearly do not contain any coal. The following limited conclusions can be drawn from the nominations:

- Competitive interest was highest in Southern Campbell County, Wyoming, where at least 10 companies nominated overlapping tracts.
- Greatest overall interest for coal was shown in Montana (where virtually all known coal areas were nominated) and in Wyoming (where nearly 600,000 acres were nominated).
- In Colorado, New Mexico, and Oklahoma, utility companies rather than coal companies, showed the highest interest.

Criticisms of EMARS II focused on two areas: (1) land-use planning followed industry nominations; and (2) the system minimized the opportunity for control over development-related social and economic problems, since the location and rate of leasing were controlled by industry. With respect to nominations against leasing, many people objected that it was unduly burdensome to force them to express their views for the entire Nation and to do so prior to seeing what lands industry was interested in developing.

The previous sections of this chapter analyze the differences in the amount of lands to be leased that might occur under a lease to meet industry indications of need alternative and other alternatives calling for greater degrees of government planning of when and where leasing will occur. Since the BLM has not completed revising existing land use plans to conform to new statutory requirements such as unsuitability criteria, it is not possible to directly compare the locational effects of these three subalternatives. The discussion which follows analyzes potential differences on a general level.

In comparison to the situation which existed in 1970, (the last year before the moratorium on Federal coal leasing), the Congress has now passed extensive laws governing coal mining and development. All coal development must comply with these laws. The requirements of these laws include:

- Emissions standards for coal burning.
- Water quality standards.
- Revegetation and reclamation standards.
- Rents and royalties for Federal coal.
- Mine health and safety.
- Transportation costs.
- Land-use planning.

Since many major elements of the coal production cycle are regulated and will be constant under any Federal coal management system, the analysis of the relative impacts of these subalternatives must focus on the unregulated aspects of coal development that they might effect. With respect to location of leases, the primary elements are social and economic impacts. Current laws do not impose any obligations on a company to avoid triggering growth in an area in excess of the rate that can be absorbed by the affected communities. There is no obligation to build schools, roads, sewage facilities, or homes. A great many companies have assumed the burden of assisting communities in preparing for the new development, but it is well documented that coal development has created boom-town conditions in several towns in the West. The current pattern of leased tracts developed from a regulatory framework where industry had a free hand. Continued industry control over tract selection is likely to result in similar future effects.

The one important environmental impact of giving greater control over location of future Federal coal leases to industry is a loss of the opportunity to control social and economic costs associated with rapid growth in rural areas. The converse of this is that the impact of more government control may be to increase coal costs if it discourages development in least costly coal areas to avoid adverse social impacts. It is not certain that greater government control in tract selection will necessarily lead to higher costs. Coal companies which have tried to anticipate coal development have sought to gain competitive advantage by purchasing surface estates over Federal coal or by buying private coal adjacent to Federal coal. Their choices of properties could be based as much on a reliable supply of coal as obtaining the least cost coal. They may have also focused on areas that were easy to explore. The government may be able to find equally low-cost coal in areas which offer less opportunity for control by a single company. The degree to which

this trade-off is made is impossible to quantify. It does seem very likely, on the other hand, that greater government control will reduce social impacts. The preferred program will assist in:

- Predicting future development so that planning and capital construction can precede coal development.
- Consulting with state and local officials to determine where in the state coal development can be accommodated with fewest adverse social impacts.
- Using regional tract ranking to ensure that tracts offered for lease offer the combination of least social cost and highest economic efficiency.

Greater government control over the location of coal lease tracts should lessen the environmental effects of coal development by reducing development in areas which are unable to absorb additional impacts and by encouraging properly-paced development in other areas. Table 5-92 summarizes the effects of the three subalternatives.

5.4.10 Land-use Planning Alternatives

One of the key elements of the preferred coal management program is its reliance on the land-use planning systems of the BLM and the Forest Service to identify areas acceptable for further consideration for coal leasing.

During the draft environmental impact statement comment period, major disagreements surfaced over how the Department should conduct comprehensive planning during the transition period to a fully operational, mature coal management program. Should it: (1) use existing land use plans; (2) supplement existing plans as set out in the proposed program; or (3) wait until new land use plans are prepared fully in accordance with whatever final regulations evolve from the proposed planning regulations?

BLM began land use planning in 1969. Such planning was initiated when the pressures from individual resource users began to intensify to a point where serious conflicts arose over the proper uses for specific land areas and the need to balance and coordinate user needs became apparent. Land use planning for multi-resource use (multiple-use planning) was adopted as a device to balance and coordinate use of BLM-managed lands. It was to consider both long-term and short-term resource development and conservation requirements, and

TABLE 5-92

COMPARISON OF SUBALTERNATIVES DISCUSSED IN SECTION 5.4.9

SUBALTERNATIVE 1 (Maximum Industry Role)	SUBALTERNATIVE 2 (Preferred Program Model)	SUBALTERNATIVE 3 (Maximum Government Role)
---	---	---

- A. Who is primarily responsible for key actions?
- | | | | |
|---|----------|------------|------------|
| 1. Determination of Production Goals | Industry | Government | Government |
| 2. Identifies areas for leasing | Industry | Government | Government |
| 3. Identifies tracts for leasing | Industry | Industry | Government |

- B. What are the effects of choosing a subalternative?
- | | |
|--|-----------------------|
| 1. Cost of Planning and Administration | -----INCREASING-----► |
| 2. Chances for Environmental Mistakes | -----DECREASING-----► |
| 3. Chances for Production Shortages | -----INCREASING-----► |
| 4. Consideration of socioeconomic concerns | -----INCREASING-----► |

to incorporate statutory and Departmental policies into the decisions on allotting lands to particular users. As BLM's determination to plan for future uses of public lands increased, it began to formalize its procedures through the adoption of standardized manual provisions that set out what a land use plan should contain and how it should be developed. The resulting plans were called Management Framework Plans (MFPs). During this initial period of BLM development of its land use planning process, the BLM had no direct Congressional sanction or policy direction for such action. When the Congress passed FLPMA, it gave BLM express statutory authority to conduct land use planning and prescribed the basic requirements for a planning process.

The Congress was also sensitive to the need for a transition period until land use plans could be revised in accordance with its express directions; it provided that passage of FLPMA was not to grind the management of public lands to a halt while a new planning process was being established and implemented. The Congress intended, and the Department has consistently interpreted FLPMA to allow, BLM to use plans prepared before FLPMA, or prepared after FLPMA without the benefit of formally-adopted regulations, to make decisions for all activities which ultimately look to a land-use plan for guidance. The House Committee Report on FLPMA says, "The Committee is well acquainted with both the land use planning systems of The Bureau of Land Management and The Forest Service and has found them to be consistent in general principles and practices with the objectives of [FLPMA]" H.R. Rep. No. 94-1163, 94th Cong., 2nd sess. 5(1976). The Department has also, where required and appropriate, revised or supplemented old plans in response to a specific need to analyze a particular resource use. The Department has prepared supplements with respect to timber, grazing, wilderness, and wildlife management, as well as coal. The Department views any of the three subalternative that are set out in this subsection as being legally adequate. (Note: Although the Forest Service began planning much earlier as a result of greater pressure on its lands and with the advantage of the Organic Administration Act of 1897 and the Multiple Use-Sustained Yield Act of 1960, enacted 16 years before the enactment of FLPMA (BLM's Organic Act) the issues remain the same. The National

Forest Management Act, enacted in 1976 (the same year as FLPMA), also provides new planning directions to the Forest Service similar to those provided to the BLM by FLPMA. The National Forest Management Act also contemplated the use of existing Forest Service land use plans for resource decisionmaking until new plans could eventually be developed under new planning regulations. The Forest Service, as the BLM, does in fact continue to make resource decisions on existing land use plans.)

As of 1979, over 80 percent of all BLM-managed lands were covered by a Management Framework Plan. The areas recommended for coal development in these plans, plus some adjacent high value coal lands, are now being reviewed as part of an extensive field test of proposed unsuitability criteria. If new BLM planning regulations are adopted as scheduled (by mid-1979), new land use plans could not be put into effect in accordance with those regulations for some time. It normally takes up to four years to inventory resources and complete the plan preparation and approval process for a large (e.g., one million acre) planning area. Therefore, it is likely to be late 1984 before totally new plans in coal areas are available, and several more years before a sufficient number of such plans are available to be used as a basis for a fully operational coal management program. The rate at which coal areas are covered in new plans will depend on planning priorities and budget capabilities existing during the mid-1980s, which cannot be predicted with any degree of certainty.

Until the new regulations are adopted it is somewhat speculative to say how the new plans will differ from the old ones. New land use plans (called Resource Management Plans) will address specific program issues or problems. Current Management Framework Plans attempt to address all existing resources. The latter plans require a tremendous amount of inventory data. The requirement for inventory data in the Resource Management Plans may not be as great. It is likely, also, that there will have been more effective opportunity for public participation under the new planning regulations. Inadequate data and lack of meaningful public participation have been the principal arguments raised by commenters urging the Department to disavow the use of old plans in coal management decisionmaking. A critical difference in the new planning regulations will be the

importance of full environmental analysis of the proposed alternatives in the planning process and the filing of the environmental impact statement with the plan as the environmental impact statement (see 43 Federal Register 58764-58774 (December 15, 1978)).

Finally, before discussing the effects of the three subalternatives, it should be noted that the conclusions reached in the land use planning process concerning the potential for coal leasing are not a commitment by the Department that leasing will take place and do not end the process of evaluation under any of the coal management program alternatives. At a minimum, a potential lease area will still be evaluated as required by the National Environmental Policy Act and no mining will be allowed except as authorized by the Surface Mining Control and Reclamation Act of 1976. Under the preferred program, even more would be done, through the tract delineation, ranking, selection, and scheduling processes and the regional sale environmental statement. The benefits of each subalternative must be examined in light of its role in an overall management program, not in isolation from proceeding and subsequent activity.

One subalternative is to allow no new coal leasing and to curtail other coal management actions in any area until a land use plan has been prepared for that area in accordance with new final planning regulations. This subalternative would greatly delay the time the Department could, for any reason, first engage in any substantial amounts of leasing. Assuming that the planning regulations are adopted by mid-1979, the planning procedures will not be available until late 1979. They will be tested during 1980 and implemented in 1981. The first totally new plans prepared under these regulations might not be available until late 1984. It is likely that several more years would elapse before a significant number of new plans would be available upon which a mature leasing program could be based. Under this subalternative, delay in being able to resume leasing can be expected to be both lengthy and unpredictable.

This subalternative would have the same effect as the no new leasing management program alternative. If no new leasing is needed until after 1984, at the earliest, this sub-alternative could be adopted without any significant adverse effect.

The sub-alternative would be likely to result in better quality land use plans before leasing would resume. Improvements might include better identification of coal potential and of conflicting resource uses and more detailed evaluation of social and economic goals and issues. It might also result in fuller responsiveness to public demands because of greater opportunity for public participation through the planning process. It is impossible to predict *how much* the activity that finally takes place under this subalternative would be improved, e.g., would the plans more effectively guide subsequent decisions whether to lease coal than would occur under the proposed program resources? It must be expected that at least some overall improvement would occur, although the improvement may be small. This is particularly true in view of the proposed program's emphasis on tract ranking and regional leasing environmental statements. This subalternative is not compatible with any program management alternative, or choice of policy under any alternative, that involves new leasing before the necessary new plans can be prepared. Depending on why the Department would decide to lease before 1984, a variety of adverse effects might occur, including: coal costs could rise; competition could decline; less environmentally sound tracts already leased might be mined; certain coal users might experience shortages; and state and local economies might be depressed by lack of development and mineral revenues. Whether these adverse effects would be compensated for by the benefits from leasing on the basis of new plans depends on how severe the Nation's need for coal becomes and how much the plans improve. Changes in the economy, the oil import situation, conservation effects, and new laws may affect from year to year the merits of this approach.

The preferred subalternative is to issue land use plans to the new standards as quickly as time and personnel permit, but in the interim, to retain the capability to lease in those areas where the coal land portions of an existing land use plan have been supplemented to take into account the major environmental protection standards for coal operations that the Congress has enacted and the Secretary has adopted. These land use plan supplements, since they apply only to areas where coal is found can, generally, be completed in a fairly short time. (There is no need to apply the

new standards to lands outside of Known Recoverable Coal Resource Areas since those lands cannot be leased). In December 1978, the BLM instructed its field personnel to begin applying (and field testing) the unsuitability criteria by supplementing certain land use plans for areas where extensive coal is found and which the BLM State Offices felt might eventually provide tracts for lease sales or exchanges if the Secretary determines a need for leasing. As explained more fully in the Federal Register notice (43 Federal Register 57662-57670) setting out why and how the field test would be conducted, and the criteria applied, the application process serves three purposes: (1) to see if the Department's proposed unsuitability criteria are well drafted, are easy to administer, and effectively identify those lands where additional resource protection is necessary; (2) to begin the Federal lands review required by Section 522 of the Surface Mining Control and Reclamation Act; and (3) to ensure that some plans are improved to provide a better basis for any new coal management program actions which are required in the near term.

One benefit from this subalternative is that, if leasing is needed, the interim supplementing of the plans would address all but the least obvious environmental problems and resource limitations. Environmental assessments in the tract ranking, selection, and scheduling permit approval processes would identify the remaining resource use conflicts and environmental problems. As compared with the subalternative of waiting for new land use plans, this subalternative has much greater flexibility to allow whatever development may be needed. It also has the advantage of beginning the Federal lands review as required by Section 522 of SMCRA in the places where it will do the most good—lands likely to be leased if the Secretary decides to resume leasing. If no new leasing is needed before new plans can be done, this subalternative would divert time and personnel away from the longer-term work.

The third subalternative is to proceed with leasing, if the Secretary decides it is needed, without doing additional planning work in the coal areas shown in existing land use plans either for new unsuitability criteria, or for new planning regulations, and to prepare new plans as time and money permit. Reliance would be put on the safeguards processes built into the activity planning and mine plan approval processes to uncover

all tract problems. The principal benefit from this subalternative would be to save the government the expense of an interim supplement to, or additional planning work on, the plan and the diversion of resources from new plans. Under this subalternative, the review for lands unsuitability criteria would be postponed until after a lease had been issued; no work would have to be done on unleased land, and the cost and time saving might be significant.

The principal problem with this subalternative is that the Department (along with the lessee) may find itself in the position of spending several hundred thousand dollars or more on a tract only to find out two to three years after leasing that a major problem exists that makes its development undesirable. The risk of this happening is much greater than under both of the previous subalternatives. If no new leasing were needed, this subalternative would have no adverse effects as long as the preparation of new plans occurred as rapidly as under the previous two subalternatives.

MITIGATION OF MAJOR ADVERSE IMPACTS OF A FEDERAL COAL MANAGEMENT PROGRAM

6.1 INTRODUCTION

In this environmental impact statement, mitigation means a policy, procedure, or action intended to avoid, minimize, or help compensate for damage that could be caused by decisions made by the Department of the Interior about the management of Federal coal. Mitigation is intended to help protect individuals and communities from adverse social and economic impacts, as well as to protect the physical environment. This chapter recapitulates those aspects of any of the alternatives for a Federal coal management program, and discusses other discretionary measures, which would tend to lessen adverse environmental impacts. The impact analysis in the previous chapter (Chapter 5) includes those mitigating measures required by law or regulation.

The preferred alternative Federal coal management program described in Chapter 3 of this statement requires that, in deciding whether to lease or not to lease, and in deciding where, in what amounts, and under what circumstances leasing might take place, decisions about the management of Federal coal must assure that the environment be protected and that the interests of individuals and communities be considered. These mitigation measures are a direct consequence of decisions by the Secretary, instructions from the President, and requirements included in laws recently enacted by the Congress.

The President, by memorandum of May 24, 1977, instructed the Secretary to "manage the coal leasing program to assure that it can respond to reasonable production goals by leasing only those areas where mining is environmentally acceptable and compatible with other land uses." The President further directed that the Department "scrutinize existing Federal coal leases (and applications for preference right leases) to determine whether they show prospects for timely development in an environmentally acceptable manner, taking steps

as necessary to deal with nonproducing and environmentally unsatisfactory leases and applications."

In response to these directives, the Department has set as one of its primary goals the "use of land use planning and effective enforcement of environmental laws to assure that Federal coal is produced in an environmentally acceptable manner and in a way that is responsive to local communities and private landowners affected by Federal coal development." Of equal importance is the Department's emphasis on consultation and cooperation with state governments, because only through such a cooperative effort could the Department be assured of the effectiveness of mitigation measures designed to protect against adverse social and economic impacts of Federal coal management decisions.

In developing and analyzing the preferred program and alternatives described in this statement, the Department was able to act in response to definitions of environmental acceptability and social and economic responsibility which were not available when the enjoined EMARS II leasing program was developed (see Section 1.2.4). During the development of the previous program, controversy about what constituted acceptable environmental and socioeconomic mitigation created an atmosphere of uncertainty, which prevented all parties interested in Federal coal management from making secure assumptions about the mitigation measures which might accompany Federal coal management decisions.

Enactment of the Federal Coal Leasing Amendments Act of 1976, the Federal Land Policy and Management Act of 1976, and the Surface Mining Control and Reclamation Act of 1977 established, after several years of Congressional debate, specific goals and standards for mitigation, and specific procedures to assure that the goals are achieved and the standards are met. These laws

ended the uncertainty about the legal and policy framework and provided rules for the management of Federally owned coal, the planning and management of the public lands and other Federally managed natural resources, and the regulation of the environmental effects of coal mining. As a result, the uncertainty about the environmental, social, and economic consequences of Federal coal management decisions have been minimized, and the effectiveness of mitigating measures are now more predictable.

In addition to the laws already referred to, many other laws provide standards and procedures requiring avoidance of, or recovery from, damage to the environment and disruption of local communities. Any Federal coal management program that might be adopted by the Secretary would recognize and include the responsibility for compliance with these laws. Statutory standards and procedures would be applied throughout the program; in the land use planning process; in the ranking, selection, and sale of specific tracts; and in stipulations attached to leases and mining plans.

The Department also recognizes its responsibility to use its discretion in the application of additional measures which would further minimize environmental and community disturbance. Certain of these discretionary measures, particularly the additional standards and procedures that will help give direction to the judgement exercised by the Department's resource managers in the field, are integrated into the preferred program and several of the alternatives. Any program implemented by the Secretary would require that other standards and procedures, if warranted, be identified and applied to supplement those described in this statement.

The discretionary measures for environmental impact mitigation are discussed in Section 6.2. The site-specific nature of the data required to apply these mitigating measures and assess their effectiveness significantly diminishes the opportunity to fully address such measures in this broad-based statement. The social and economic impacts of coal development and their mitigation are addressed in Section 6.3.

Throughout the discussion in the following sections, it is assumed that mitigation measures not only provide direct protection of people, communities, and resources, but also produce, as a secondary consequence, a reduction in conflict and an

increase in acceptance of individual resource management decisions. Financial and administrative burdens for the government, prospective lessees, and all interests affected by leasing, will be reduced because the emphasis on early application of protective and mitigative measures will identify, resolve, or avoid conflicts. This, in turn, will provide assurance that the Federal coal development decisions which are made will be subject to less delay and uncertainty. A successful mitigation program, while aimed at minimizing environmental, social, and economic damage to individuals, communities, and natural resources, will also allow coal producers and users to make more timely and secure development plans. The producers' interest in the success of the mitigation efforts is evident and will serve to reinforce the effectiveness of mitigation elements of the Federal coal management program.

6.2 ENVIRONMENTAL MITIGATION STRUCTURE OF THE PREFERRED PROGRAM AND CERTAIN OF THE ALTERNATIVES

The preferred program and several other alternatives contain many structural environmental decision points. The key mitigation elements of the preferred program and the alternatives are described in Chapter 3, but are reviewed briefly in the following paragraphs from the viewpoint of opportunities they provide to protect environmental values.

The most important of the structural environmental features of the preferred program and several of the alternatives is the use of unsuitability criteria to identify and protect resources of major importance. The need to review Federal coal lands and make unsuitability determinations is set out in Section 522 of the Surface Mining Control and Reclamation Act of 1977. The use of criteria to establish a standard list of resource values which must be considered by the land manager is based on the preference expressed by the Secretary. The Secretary recognized the need to ensure both uniformity and consistency in the manner in which the decisions on unsuitability for coal mining are made. The application procedure accompanying the criteria ensures that each potential resource conflict will receive careful, individual consideration before the land manager decides whether to exclude an area from all or certain types of coal

mining, or whether to require mitigation measures that would allow mining. The application of these criteria, based on a comprehensive review and, where needed, on an inventory of an area's resources, would provide a threshold of protection of those resources and interests which could be affected by Federal coal development.

By incorporating unsuitability criteria procedures in the land use planning process, the Department would not abandon its basic multiple-use resource management system. Decisions which determine the best combination of uses for all the resources under the jurisdiction of the Federal resource manager would still be made after application of unsuitability criteria. Coal leasing could be prohibited, or allowed to proceed under special conditions, on lands where the land manager determines that coal mining would seriously conflict with other important resources. In situations where the land manager wants to protect a conflicting resource at or above a desirable level, he could turn to the use of threshold levels. These levels are inherently adaptive to the actual future course of coal impacts (see Section 3.2.2.5). The key decision is the selection of alternative uses best suited to the planning area. The land use planning system, thus, inherently identifies activities which may minimize undesirable impacts and, consequently, reduces the need for additional mitigating measures.

These field level land use planning procedures present a key opportunity for recognizing needed local constraints on coal leasing. The public would have an opportunity to comment on the lands identified as acceptable for consideration for leasing, and participate in the resources trade-off decisions.

In addition to the incorporation of specific criteria as guidance for individual land use planning decisions, the preferred program includes another new and major mitigation element, which assures that mitigation is a priority element in final tract selection decisions. This process requires the ranking of those tracts which could be leased within a region so that the consequences of selecting specific tracts for development can be compared, both within a particular region and among regions.

The process recognizes that, because of the probability that, in many regions, there will be more Federal coal that could be leased than would

be necessary to lease, the Department has a responsibility to select, from among those coal lands which are not excluded from leasing through application of unsuitability criteria or other resource management decisions, those tracts whose development would cause the least environmental, social, and economic damage. This means that mitigation will take place even in those areas where both the application of laws and standards and the exercise of the resource manager's judgement have led to decisions that other resource values must be subordinated to the need for the leasing and mining of Federally owned coal.

The regional tract ranking process also provides the most effective opportunity for consideration of social and economic consequences of Federal coal management. The Department, while recognizing its responsibility in this important area, also recognizes that social and economic values, problems, and mitigation measures can not be categorized, evaluated, and implemented through a process of criteria and standards in a Federal resource management program. Because the ranking process is less a reflection of law and standards, and more a reflection of judgement and discretion, it is better suited to the evaluation of local and regional social and economic considerations. These considerations are to receive priority, along with identification of environmental consequences, in the ranking process included in the preferred Federal coal management program and several other alternatives.

The impacts of developing a specific tract, and the cumulative and interdependent impacts which would result from developing groups of tracts, would be considered in selecting those tracts to be offered for sale. By ranking and comparing all tracts within a region, rather than ranking only those tracts in geographically smaller individual planning areas, and by considering how the timing of tract development could influence the amount or kind of impacts, the Department would be able to select for leasing those tracts which have the least adverse cumulative environmental, social, and economic impacts.

Other significant mitigation measures in the preferred program and several of the alternatives are set out below:

- By providing for extensive public participation and special opportunities for the states to take part in the leasing process from land

use planning through lease sale and beyond, the Department would seek to ensure that the local and regional publics and their representatives—those most knowledgeable about local and regional conditions—will always be well represented in leasing decisions. The careful consideration of the views of the states and the comments of the public before major leasing decisions are made would serve to mitigate adverse local and regional impacts of coal development.

- The procedure for setting regional production goals and leasing targets ensures that the need for coal leasing would be continually reassessed, thus avoiding the leasing of an unnecessarily large number of tracts. Too large a number of leased tracts would diminish the ability of state and local governments to plan with an adequate degree of accuracy to mitigate social and economic impacts of coal development. The leasing of an excess number of tracts also would diminish the effectiveness of the ranking process, require the selection of additional less desirable tracts, and increase local uncertainty about the potential environmental consequences of leasing.
- The manner in which requirements of the National Environmental Policy Act of 1969 would be complied with in the preferred program and several other alternatives would further serve to identify adverse impacts and the opportunities for mitigation. National and interregional impacts of Federal coal management decisions, described in this statement, would be carefully monitored by the Department and considered in supplements to this statement, if required. Environmental impact statements considering the impacts of proposed lease sales for four-year periods within specific coal regions would be prepared. These statements would examine the cumulative environmental impacts of coal development on a region-wide basis, as well as consider the site-specific impacts of each tract to be offered for lease. The public participation opportunities provided during the environmental impact statement process would provide additional extensive opportunity for the public to assist the Department in assuring that decisions at every level of a Federal coal management program would fully consider environmental impacts and mitigation measures.
- The preferred definition of maximum economic recovery (MER) seeks to encourage the aggressive removal of coal from Federal leases. Coal which is considered marginally subeconomic under current practices would, under the preferred program, likely be included in coal production from the lease. To make removal of these deposits possible without unfair economic hardships on the mine operator, the Department would give up some of the bonus bid it might otherwise require for a lease where the MER determination indicates that the trade-off is for the long-term benefit of the public, considering all environmental and social factors bearing on the tract. This approach to MER would in the long run lessen the area disturbed by mining and decrease the possibility of second mine openings over the same area.
- The Secretary has also indicated that the Department should be responsible for determining, with reasonable certainty, that a specific tract can be developed without severe or permanent harm to the environment and for determining the stipulations needed to ensure this protection prior to the lease sale, rather than waiting to make this determination at the mining plan stage. This requires that the Federal coal management program have adequate environmental data available for tract ranking and selection prior to the decision to lease. Site-specific analysis of each tract would be conducted prior to ranking and an examination would be made for each selected tract to develop lease stipulations, if necessary. Where appropriate, additional detailed, site-specific conditions would be imposed in the mining permit issued upon approval of the mining plan.
- The Secretary would require, under the preferred program and several other alternatives, that unsuitability criteria and general land use trade-off decisions be applied not only to new competitive leasing, but also to existing, nonproducing leases, emer-

gency leases, and noncompetitive leases. Appropriate action would be taken where noncompliance is found. This element of the program would help bring consistent mitigation to those lands which could be affected by development of the more than 500 outstanding leases and more than 200 preference right lease applications.

- The Department's Energy Minerals Rehabilitation Inventory and Analysis Program (EMRIA) would provide site-specific reclamation data for use at the several decision points in the preferred program and several other alternatives. EMRIA, begun in 1975, entails inventory and analysis of rehabilitation capability of lands having potential for Federal coal development. Soils, overburden, surface and ground water, as well as revegetation characteristics are analyzed so that prescriptions for reclamation can be developed.

While this discussion has given emphasis to those mitigation measures which prevent or minimize damage by prohibiting, restricting, or directing the relocation of prospective Federal coal leasing, it should be noted that most of the mitigation measures built into the preferred program and several other alternatives are designed to assure that when Federal coal leasing and resultant mining take place, both the damage and the benefits from coal development are considered and are managed in a way that will minimize environmental and social disruption.

The key measures mitigating the physical environmental consequences of coal mining are contained in the Surface Mining Control and Reclamation Act of 1977. In general, the law requires premining permit application and reclamation planning; the application of standards for the conduct of mining which relate to the environmental effects of the mine operation, on and off the mine site, as well as to public health and safety; state or Federal processes for designating lands as unsuitable for mining; and adoption of state laws and regulations for enforcement of regulatory programs which meet minimum Federal standards. The act also applies these standards and processes to the surface effects of underground mining.

These mitigation measures are described in detail in the Final Environmental Statement on the

Proposed Final Regulations of the Office of Surface Mining [1].

6.3 MITIGATION OF SOCIOECONOMIC IMPACTS

Many of the most serious problems associated with coal leasing involve the ancillary social and economic effects of development. In rural areas, coal development has induced wholesale change in the social and economic structures of numerous isolated communities. While the change offers possible long-term benefits for the communities in question, short-term distress has too often been the more visible result. The mitigation of the socioeconomic impacts of coal development presents special problems for the Department, since its statutory authorities and responsibilities are far more limited than the scope of the problems. For the time being, the Department's chief response must be improved coordination and consultation with local and state governments, as provided in the preferred program and several other alternatives.

6.3.1 General Socioeconomic Impact Mitigation

Impact assistance is a policy question of independent national significance. In March 1978, an intergovernmental Energy Impact Assistance Steering Group completed a report to the President which examined the nature of adverse social and economic impacts from energy development, gaps in existing mitigation mechanisms, and a broad range of program energy impact assistance options [2]. The report's treatment of these problems is instructive for this statement and recommended generally as a reference.

According to the report, the fundamental cause of social and economic impacts is rapid economic growth. While the dimensions of growth problems in a given locale vary substantially (see Section 6.3.2), a number of problems seem to recur frequently. The location of most Federal coal is in isolated rural areas of the West. Since the location of the coal resource determines the sites of the economic activity, once a development site has been chosen, there is commonly little choice but to stimulate rapid growth in isolated rural areas, where the new activity is disproportionately large in relation to the existing economic base. There are frequently difficulties with taxation systems which do not target tax resources to impacts, which were

designed to suit an agricultural economy, or which do not coincide with the boundaries of economic activity. Much of the labor force for the Decker mine in Montana, for example, lives in Sheridan, Wyoming, even though the mine produces revenues for Montana. Finally, all of the impact problems are exacerbated by uncertainty, which weakens both individual and institutional accommodations to change.

The report found five leading categories of impacts:

- Public facility and service deficiencies or shortages.
- Commercial facility and professional services deficiencies and shortages.
- Housing shortages and housing price inflation.
- Social disruption.
- Transportation impacts.

The report focused its analysis on five specific categories of gaps in existing mitigation mechanisms:

- Information - timely and accurate information regarding the development is commonly unavailable.
- State/local/tribal participation in the decision-making process—the inability of these institutions to participate early on in decisions regarding timing, location, and scope of development.
- Planning and management – inadequate state, local, and area-wide institutional capacity.
- Coordination of assistance mechanisms – the imprecise targeting of existing Federal programs to impact problems.
- Financing – the difficulty that impacted communities have in securing access to normal financing mechanisms.

The preferred program and several alternatives would attempt to close the first two of these five gaps. The others are not within the Department's direct jurisdiction, but, through cooperation with other Federal agencies and state and local governments, the Department can help make the total effort to mitigate social and economic impacts more effective.

In addition to mitigation of social and economic problems common to all rural areas affected by sudden and large-scale industrial growth, priority is given in the Department's preferred

program and several other alternatives for mitigation to protect those agricultural communities which, in the western states where Federal coal is most abundant, are dependent on sound management of grasslands, watersheds, and other resources which serve as the foundation for extensive livestock grazing and other agricultural enterprises. Mitigation of impacts on agricultural economies is not limited to management measures designed to permit livestock and crop production to continue at existing levels or expand while coal production increases. A principal element of the preferred program and several other alternatives is consideration, throughout the decision process, of measures to assure that those individuals and families who are on ranches and farms, as well as the communities and the resources which support individual agricultural enterprises, are not damaged or disrupted.

It should be emphasized that mitigation also includes measures to assure that the potential benefits of coal development are recognized, and the effect of the distribution of these benefits considered, when decisions are made about management of Federal coal. So, while the preferred program and several other alternatives would operate to protect resources and people from damage, they would also be capable of determining how the distribution of benefits would affect those same people and resources. With information made available from community leaders, tribal officials, state and local governments, and individuals, Federal coal management decisions can reinforce the community development and economic plans of citizens in those areas where Federal coal is located.

Guidance provided to the Department's resource managers and other planners by the report includes identification of nine principal factors that should be considered when evaluating the impacts of proposed decisions:

- Avoidance - the extent to which the occurrence of adverse socioeconomic impacts due to energy development can be minimized, if not averted altogether, in the early stages of the energy development process.
- Closing Policy Gaps - the degree to which the process for formulating energy development policy and making key energy facility siting decisions provides adequate opportu-

- nity for participation by appropriate state, local, and tribal governments; also, the extent to which provisions exist for the preparation and early consideration of impact assessment data.
- Closing Resource Gaps - the degree to which proposed policies or program strategies reduce the inadequacies found to exist among existing Federal, state, local, and industry financial assistance mechanisms available to impacted areas.
 - Barriers to Implementation - special organizational, administrative, or legislative steps which must be taken and the time required to effect proposed actions.
 - Risk Sharing - the manner in which the consequences (e.g., higher costs, potential loss of sunk costs and future revenues from project failure, high interest payments, and other costs) of uncertainty characteristic of energy-related growth are borne by the participants in the energy development process - i.e., Federal, state, local, and tribal governments and industry.
 - Cost Internalization - the extent to which the costs of addressing adverse impacts resulting from energy development are borne by the producing company or passed through in energy product processes to energy consumers.
 - Impact on Federal, State, Local, and Tribal Budgets - the degree to which proposed policies and actions will increase or decrease the amount of Federal, state, local, and/or tribal funds required for impact assistance programs.
 - Enhanced State, Local, and Tribal Capacity - the manner in which authorities, resources, and capabilities of state, local, and tribal governments for addressing the problems faced by energy-impacted communities are increased.
 - Leverage on Industry Participation and Mitigation - the degree to which the role of industry as a participant in avoiding and/or ameliorating the adverse socioeconomic effects resulting from its energy development activities is increased.

The program recommendations of the report led to modifications in Senator Gary Hart's S. 1493, a broad-based inland energy impact assis-

tance bill. This proposal did not pass in the 95th Congress.

Legislation providing a more modest impact authority for the Farmer's Home Administration did pass, as section 601 of the Powerplant and Industrial Fuels Use Act of 1978. This authority for both planning and construction assistance will be implemented by the Secretary of Agriculture, in consultation with the Secretaries of Energy and Labor. Funds, in the form of grants to the states, local governments, and tribal councils, are available under the program to support planning, land acquisition, and development. Coal companies within designated impact areas will be required to report to the Secretary of Energy on request by the state Governor on mine employment and related matters for the coming three years.

The Secretary of the Interior is a member of the interagency committee created by Section 746 of the Act. The function of the committee is to conduct a study of the socioeconomic impacts of expanded coal production and rapid energy development in general, on states, including local communities, and on the public. The committee is required to study the adequacy of housing and public recreational and cultural facilities for coal miners and their families, and the effect of any Federal and state laws or regulations on providing such housing and facilities.

The Secretary of the Interior also participates in another study required by the Act (Section 742 (c)), which is required to evaluate the economic and social impacts on coal-producing counties and states of present and prospective land ownership patterns and levels of income, property, severance, and other taxes paid by coal producers.

6.3.2 Program Socioeconomic Impact Mitigation

One effect of the preferred program and several other alternatives will be to decentralize decisions regarding social and economic impacts. Because of regional and local variations in these impact problems, an aggregate estimate of impacts is inherently misleading, since the mitigation response must take place on a decentralized basis, taking into account the unique aspects of each impact situation. The aggregate perspective is, therefore, not as important as a consideration of the range of potential problems. For this reason, this section addresses eight factors which illustrate the dimensions of impact variation and, hence, the

varying requirements for mitigation which a Federal coal management program must face.

6.3.2.1 Physical Characteristics. The physical characteristics of the impacted areas—topography, quantity and quality of available water, soil, and climate—have an important effect on the cost of both public infrastructure (water and sewer systems, streets) and private infrastructure (residential and commercial construction). For example, site preparation costs in West Virginia typically run much higher than in the West, due to the terrain. The steep slopes and narrow valleys in much of West Virginia also increase the problems of environmental hazards from siltation, slides, and flooding, and so require special mitigation measures that would not be so important in flatter country. Gillette, Wyoming, has different problems resulting from physical characteristics of its area. The sources of available potable surface and groundwater are many miles away from town, and the nearby groundwater requires extensive treatment before it can be used for municipal purposes. Either way, the cost of providing water in Gillette significantly exceeds the national average for per capita expenditures.

6.3.2.2 Economic Structure. Pre-existing economic conditions influence the path of the new economic stimulus provided by energy development. One such condition is the local labor market. If the local economy has a surplus of labor prior to the onset of development, the development will tend to absorb local workers and the change in population will be less than where no surplus exists. Research in the West has shown that the population change attributable to similar energy projects can vary by as much as 50 percent. At the same time, labor market conditions shift rapidly. For example, many of the high unemployment conditions that existed in southern West Virginia no longer prevail, and there are thousands of new jobs to be created in the near future. Finally, since the unemployment rate is no indicator of the availability of specialized labor, a thorough knowledge of an incoming industry's requirements may be necessary to accurately predict local population growth.

A second significant pre-existing condition is the pattern of population and service centers. Isolated communities are more likely to feel the

effects of impacts than communities with services available nearby.

Finally, the nature and extent of local impacts will be affected by conditions in other local base industries. For example, the mid-1970s boom of Rock Springs, Wyoming, was caused by a combination of energy and nonenergy projects increasing their employment at the same time. Oil and gas development and increased uranium mining will cause similar additional boom pressures on several western coal regions in the 1980s.

6.3.2.3 Legal Framework. The legal framework within which local governments operate also affects the role that they can play in solving impact problems. Local governments are the legal entities of the states in which they are located, and the powers given them to raise and spend revenue, as well as to regulate land use and other matters, vary significantly from one state to another. Similarly, the state resources available to solve impact problems differ significantly from one state to another. Most western states now have some form of state funding available for impacts.

6.3.2.4 The Project. Different types of projects produce significantly different sorts of stresses on the impacted community. The labor requirements associated with the construction and extraction phases of individual technologies vary markedly, and are the chief cause of these differences.

The policies of contractors or subcontractors regarding rotations and the provision of housing facilities may also affect impacts. Experience with the Alaska pipeline demonstrated that a 30-day work rotation attracted workers from the lower 48 states; a 10-day work rotation attracted Alaskans from Fairbanks; and a five to seven-day work rotation attracted Alaska Natives to the work force.

6.3.2.5 Community Attitudes. A community's values and goals affect the nature of impacts by setting priorities for the provision of public services. It is not uncommon to find a community insisting on an increase in medical services when other demands are more immediate. The attitudes of the community also affect impacts by influencing the political choices that an impacted community makes. One example is the exercise of the police power; certain kinds of land use control may not be acceptable in a rural community.

6.3.2.6 Pace of Development. The faster the growth rate, the more likely the growth will produce stresses which generate impacts. Clearly, 1,000 new jobs introduced into a small community over five years will have a less damaging effect on that community than would the introduction of the same number of new jobs within a six-month period. The pace of development is similar to uncertainty, in that it tends to aggravate other difficulties.

6.3.2.7 Existing Infrastructure Commitments. Excess capacity in a specific category of public facilities will clearly aid a community in meeting development impacts, and may naturally affect the community's overall perception of the impact problem. This excess or flexible capacity may include administrative services as well as public facilities. Appalachian communities, served by substate planning districts supported for years by the Economic Development Administration and the Appalachian Regional Commission, will be less likely to need certain kinds of rudimentary technical support than western communities. The demand for this technical support has in fact been far greater in the West than in the East or in the coastal zone.

Infrastructure commitments may also have a negative side. For example, water and sewer projects proposed in Raleigh County, West Virginia, provoked unfavorable reactions from pensioners already served by septic tanks. A new water and sewer network might only be financially feasible if it serves all, but user charges impose substantial hardships on established residents with fixed incomes.

6.3.2.8 Overall Population Density. Population density affects the choices available for mitigation measures. Sweetwater County, Wyoming, is substantially larger than New Jersey and, prior to impact, was populated by approximately two persons per square mile; its population has now doubled. This will affect the design of a long-term approach to impact problems.

A sparse population may also affect the share of state and Federal resources directed to a locality, due to formula allocations and lack of political strength.

Providing an appropriate mitigation response to social and economic impacts is a complex institutional problem. Local governments address

impact problems with choices to regulate or to finance improvements and operations, although these choices may be legally or practically limited. State governments affect impact problems through regulatory agencies (land use, facility siting, environmental control, etc.), through state-financed impact relief, and through Federal programs administered by the states. The Federal government offers an additional structure of regulation and financial support, and the private sector may provide its own resources to address certain impact problems.

The Department's role in this complex picture is, of necessity, limited. The most profound limitation is on its capacity to target direct financial assistance for planning, strengthening institutional capacity, operations, or capital improvements. Under Section 35 of the Mineral Leasing Act of 1920, as amended by Section 317(a) of the Federal Land Policy and Management Act of 1976, 50 percent of mineral leasing royalties, rentals, bonuses, and fee sales are returned directly to the states to be distributed according to state law. In spending those funds, the states are directed to give priority to those subdivisions of the state socially or economically impacted by development of minerals under the Mineral Leasing Act. The funds are to be used for planning, construction and maintenance of public facilities, and provision of public service.

A loan program for impacted areas, secured by future royalties, has not been implemented. This program was established under Section 317(c) of the Federal Land Policy and Management Act. All loans would bear an interest rate comparable to the best rates available in the municipal bond market. The loans are limited to 55 percent of the anticipated mineral revenues due a state for the following 10-year period. The Department has circulated proposed regulations for this loan program (43 CFR 1880) setting out procedures under which the loans may be made. Thus far, funds have not been appropriated for this program.

An important social and economic impact mitigation feature of the Department's preferred program and several other alternatives is the emergency leasing program. This program is provided in large part specifically to avoid the hardships of sudden mine closings. Of concern is not only the unemployment caused directly by

such closings, and the consequent disruption of lives, but also the underemployment of still usable community facilities and services that might have to be replaced elsewhere if production were satisfied through development of new mines in previously undeveloped areas.

The Department does not have the authority to directly influence the decisions of the Federal, state, local, or private entities that might provide impact funding. The Department cannot, for example, significantly affect use of the Economic Development Administration's Title IX program. The Department cannot dictate priorities to state agencies such as Montana's Coal Board. Nor can the Department appropriately play a role in persuading a local government to pass a bond issue for needed improvements. Finally, it does not appear to be legally possible for the Department to require private financial assistance through requirements in lease stipulations. The task of providing mitigation rests primarily with the states.

Indeed, the Department is not in a strong position to substantially affect most of the factors discussed in Section 6.3.2—physical characteristics, economic structure, local leadership, legal framework, community attitudes, existing infrastructure commitments, or overall population density. What the Department can do is influence, and in some cases determine, the location, timing, and nature of development. Instead of providing a response after the commitment to development is made, the Department's authority must focus on the decisions that surround the initial commitment to proceed. Mine openings might be spaced out over time to avoid sharp changes in employment levels. Impacts on an area following mine closings must also be considered. The Department, thus, can play an effective role in planning tract sales to minimize or avert impacts at early stages of the development process. The Department is required by Section 522 of the Surface Mining Control and Reclamation Act of 1977 and Section 202 of the Federal Land Policy and Management Act of 1976 to coordinate with and to consider state and local land use and management resource programs in its own general planning processes. Two of the unsuitability criteria, the buffering of state lands unsuitable and state nominations of additional criteria, are directed at fostering this coordination. Additionally, criteria on historic land and sites, natural areas, state listed endangered species,

municipal watersheds, state resident fish and wildlife, and national resource waters provide for direct state or local participation. The Department will also rely on comments from the state and local governments in activity planning (including state participation on the regional coal teams) as a prime source of information in determining where avoidance of an area is warranted because of social or economic impacts. Further, the Department can effectively work to close four of the five gaps in existing mitigation mechanisms which were identified in the report.

- Information – The Department could make all information generated in the coal management program which is not proprietary available to state and local governments as promptly as possible and could use lease stipulations to ensure disclosure of timely and accurate private sector information, and to ensure consultation of the private sector with affected governments.
- State/Local/Tribal Participation in Decisionmaking Process – The Department is ideally situated to consult with and examine development consequences with affected state and local governments prior to making decisions that might unduly burden these governments with undesirable or unmanageable responsibilities for development impacts.
- Planning and Management – Despite the inability of the Department to provide additional direct financial assistance, state, local, and area-wide institutional capacity could be stimulated by timely and consistent Departmental efforts to jointly consider development consequences.
- Coordination of Assistance Mechanisms – While the Department has no direct authority to influence other Federal programs, timely and consistent consultation with other agencies might indirectly affect program priorities.

The preferred program and several other alternatives would provide for and, in fact, emphasize each of the Departmental responses suggested above. Particularly important are the early, frequent, and special access procedures for state government designed into all significant steps of the preferred program and several other alternatives and the special focus given to consultation

MITIGATION OF MAJOR ADVERSE IMPACTS

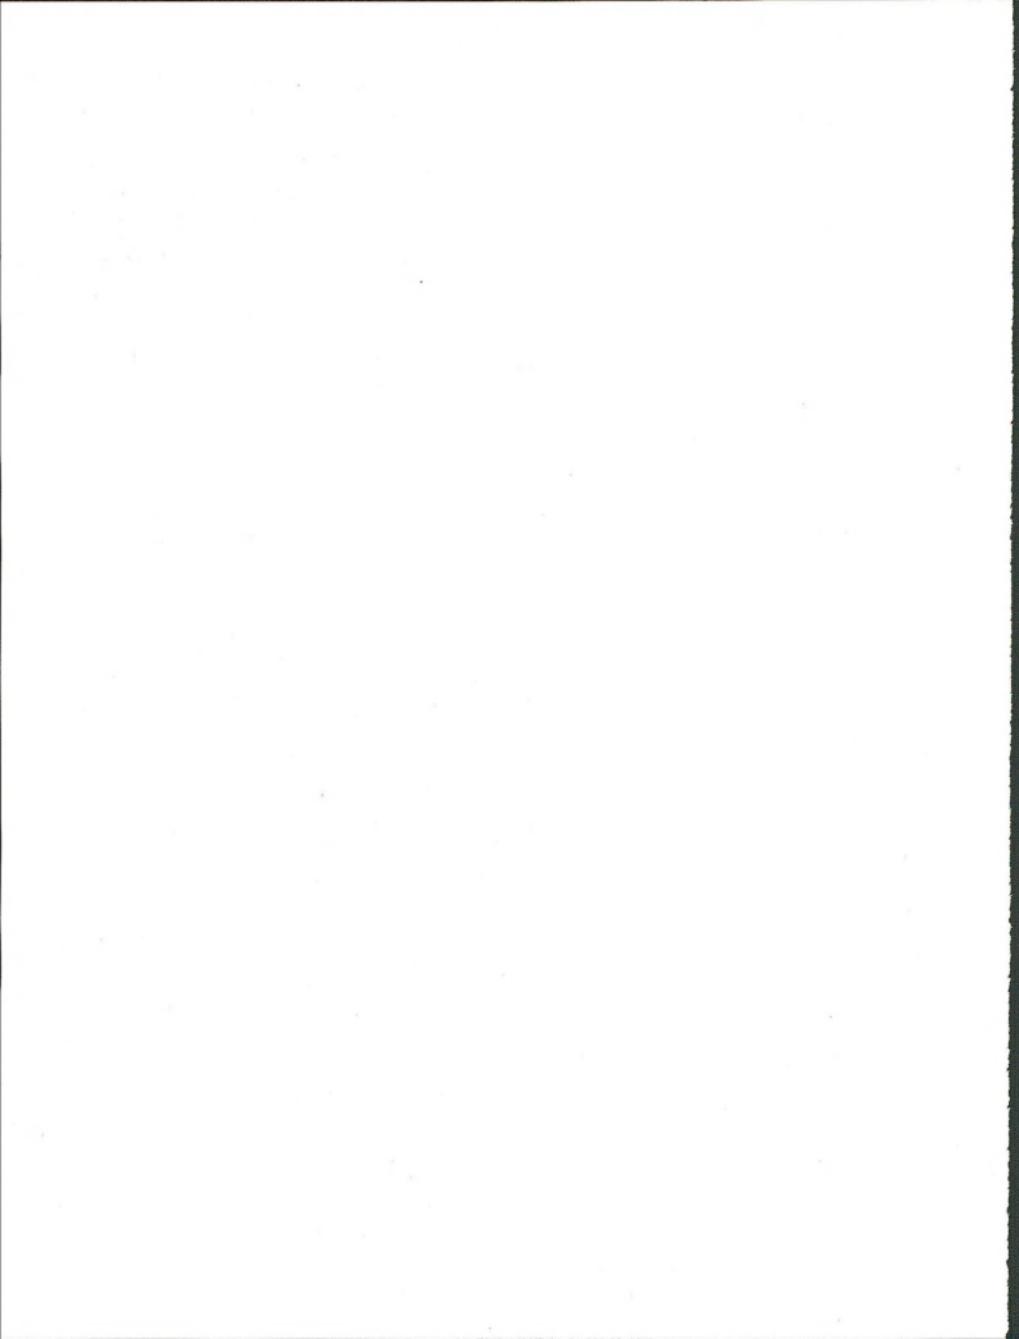

with state governments on the location and timing of lease sales.

In sum, the sensitivity of the land use and activity planning processes assume particular importance for mitigating social and economic impacts. A sensitivity to the social and economic consequences of development presents difficult challenges to the planning system, since the optimum management of Federal resources for strictly Federal purposes may produce intolerable consequences for non-Federal governments. This may ultimately prove the strongest basis for adopting the preferred program and proceeding with renewed coal leasing, since renewed coal leasing offers the opportunity to modify the spatial

pattern of coal development in response to such policy concerns.

LONG-TERM ENVIRONMENTAL CONSEQUENCES OF FEDERAL COAL MANAGEMENT PROGRAM ALTERNATIVES

This chapter presents long-term environmental consequences of the Federal coal management program alternatives. Adverse impacts which cannot be avoided are described in Section 7.1. Section 7.2 discusses irreversible and irretrievable commitments of public resources required to support the alternatives. Section 7.3 addresses losses of long-term productivity versus short-term uses of public lands. Unless otherwise noted, the discussions in these sections are in the context of the preferred Federal coal management program. In deriving the impacts in Chapter 5, all mitigating measures required by law or regulation in a coal management program were considered to be in operation. Thus, the impacts described in that chapter can be considered as those unavoidable under the various program alternatives. This chapter is largely a summary of the material presented there, highlighting the results that need to be considered under long-term environmental consequences. Nearly all the effects discussed here are subject to some form of control, both in the pre-leasing and post-leasing program structures.

7.1 UNAVOIDABLE ADVERSE IMPACTS

During all activities associated with the coal development cycle (exploration, mining, beneficiation, transportation, conversion, and use), programmatic measures would be in operation to mitigate potentially adverse environmental impacts. Nevertheless, it is expected that there would be certain adverse impacts which could not be avoided regardless of the level or types of mitigation employed. This section provides a qualitative discussion of these unavoidable effects. To prevent considerable repetition, the effects are discussed on a general basis with significant regional differences identified where appropriate.

7.1.1 Physical Environment

7.1.1.1 Topography. Topographical features would be unavoidably altered by construction and min-

ing. Construction activities could result in the filling of areas of low relief, the leveling of rolling terrain, and the removal of prominent points of land. In addition, construction of water impoundments would result in the inundation of large areas of land and would completely alter the topography of such areas. Such impoundments are regulated under the Surface Mining Control and Reclamation Act of 1977, but will still result in residual effects on topography. Mining activities, especially surface mining, would result in the disturbance of extensive surface areas. Reclamation would, to a large extent, restore the topography to approximate pre-mining contours in many areas. Subsidence of land would also unavoidably result from some underground mining activities.

7.1.1.2 Soil. Due to the nature of surface mining, and to a lesser extent underground mining, some quantities of native topsoils would be mixed with or buried under mining wastes or lost through erosion. These soils constitute a valuable natural resource which would be irrevocably lost. The Surface Mining Control and Reclamation Act contains several provisions designed to control and minimize the soil loss. With reclamation, new soils would form over time; however, in some areas of the West, particularly the more arid regions, hundreds of years could be required for natural processes to reestablish fertile soils.

7.1.1.3 Archaeological and Historical Resources. Even though coal production activities are accomplished within the framework of existing protective laws and regulations, there would be some loss of archaeological, cultural and historic resources within each coal region. In no case, however, should this loss involve a significant site or a significant assemblage of sites if strict enforcement of statutory requirements and application of unsuitability criteria and other elements of the preferred program and alternatives are maintained. Moreover, surveys required under existing

regulations could add to the cultural resources data base.

7.1.1.4 Paleontological Resources. Coal deposits and overburden material inevitably contain fossil remains. Although significant fossil remains could be lost through mining and mine-related activities, the number and amount of such losses would be minimized by the imposition of recovery stipulations. Criteria and guidelines for protection and recovery of such resources are presently being developed. It is not possible to meaningfully estimate the extent of potential loss of this nonrenewable resource.

7.1.1.5 Water Resources. Water would be required for coal mining in all of the coal regions; additional water would be required for developments of supporting activities and the population associated with coal mining, conversion, and use. In water-short regions, the large volumes of water withdrawn for coal development could be available for agricultural, industrial, commercial, and residential uses. Generally, however, much of this water would re-enter the water regime and be available for such other uses. If coal production were accompanied by development of power plants, gasification plants, or other conversion facilities, consumptive water uses and conflicts with other users would increase. Water exists in sufficient quantities in the three Appalachian Coal Regions and the Eastern Interior Coal Region to support coal development; however, water quality can be of concern. In the Western Interior, Texas, San Juan River, Uinta-Southwestern Utah, Fort Union, Green River-Hams Fork, and Powder River Coal Regions, sufficient water would generally be available on an annual basis, although shortages might occur during the predictable and regular low flow periods or under drought conditions. In the Denver-Raton Mesa Coal Region, water might not be available, even on an annual basis, to support projected coal-related and other developmental activities.

Adverse impacts resulting from some breaching and draining of aquifers during coal mining could not be avoided. The loss of local aquifers can be quite important in the Powder River, Fort Union, and Texas Coal Regions. Here, lowering of water levels may dry up springs and seeps or reduce stream flows. Replacement of aquifers with material of differing water holding capabilities

than those present prior to mining would disrupt groundwater flow patterns and could reduce aquifer storage capacity.

Disruption of existing surface drainage patterns and development of lakes and ponds could result from surface mining, especially where thick coal seams with thin overburden layers are mined. The Surface Mining Control and Reclamation Act specifically seeks to mitigate this effect. Water use in the area could be adversely affected to the extent that stream flow regimes would be changed by channel modifications. In addition, there could be an increased loss of water by evaporation from standing bodies of water.

Increased mining would also create a potential for some unavoidable degradation of local and regional water quality. Construction and mining activities would result in increased erosion, runoff, and sedimentation. Acid mine drainage could occur, primarily in the eastern coal regions. Alkaline mine drainage could occur in some western regions. The operation of coal conversion and utility plants would produce potential water pollutants including dissolved solids, ammonia, non-degradable organic compounds, oxygenated compounds, sulfur compounds, cyanides, phosphates, and trace elements. All of these effects are subject to controls. Even with controls, coal mining would pose some small risk of their occurring and polluting surface or ground water. Consumptive uses could also increase salinity and concentrations of pollutants downstream from the point of diversion where the water had previously been diluting other sources of water pollution. Population associated with coal mines and conversion and mine-mouth plants would introduce increased salts, nutrients, organic materials, bacteria, fertilizers, pesticides, trace elements, heavy metals, etc., into surface waters, especially where they overtax existing sewage treatment facilities.

A general scenic degradation would occur as a result of coal mining, conversion, and use, though the unsuitability criteria on designated wild and scenic rivers and on visual resource areas are aimed at eliminating this possibility. Scenic rivers and other water related recreational activities could be adversely impacted. The waters themselves could be degraded or the land through which the water flows could be affected to such an extent that many of their aesthetic properties would be lost.

The consumptive use of water by secondary or induced energy-related or industrial activities, such as mine-mouth steam electric generating plants, may further degrade water quality in certain streams and rivers by increasing dissolved solid concentrations and by reducing the assimilative capacity for other pollutants as a consequence of reduced water flows.

Since water is a renewable resource, short-term consumption to support coal mining should not greatly affect future availability. The construction of impoundments could result in locally increased reliability of water supplies. On the other hand, the removal of native topsoil could alter drainage patterns and render large surface areas impervious with the result that groundwater levels and pressures would be lowered, thus reducing the future productivity of some aquifers. The use of large amounts of the available water supply during the active life of a mine in water-short regions could result in a significant shift in the local uses of water in other activities; most typically a decrease in irrigated agriculture in relation to urban and industrial water uses. These shifts could outlive local coal mining and affect the long-term regional water use patterns.

Significant long-term changes would result from a decline in water quality resulting from coal development. The long-term quality of the available water supply would probably decline due to the discharge of industrial and municipal wastes, the increased sediment load from construction-related activities, possible return-flow effects, and changing consumptive patterns, including construction of impoundments. Increased salinity in the Colorado River Basin is a major issue of national and international concern. A reduction in water quality could result in restrictions on the productive uses of surface and ground water. Decreased water quality would also have impacts on long-term biological productivity in streams and rivers.

7.1.1.6 Air Quality. Degradation of local air quality would unavoidably occur in all regions as a result of projected levels of 1985 and 1990 coal development under any of the Federal coal management alternatives. Some potential damage to plants, animals, and human health from air pollutants would be unavoidable. Some increases in sulfur oxides, nitrogen oxides, carbon monoxide, carbon

dioxide, hydrocarbons, trace elements, and particulates would occur in all regions even though best available emission control technologies are employed and air quality standards are enforced. A long-term warming trend in the earth's climate might result from the build-up of carbon dioxide in the atmosphere - the greenhouse effect.

7.1.2 Ecological Resources

Coal development would affect ecological systems through the unavoidable disruption of habitats, food chains, predator-prey relationships, behavior patterns, and various activities of species playing key roles in the ecosystem. The coal management program would go to great lengths to avoid these impacts. Several of the unsuitability criteria have as their purpose the avoidance of wildlife impacts. In addition, a very active wildlife program has been proposed, including participation by the U.S. Fish and Wildlife Service (see Appendix B). Terrestrial ecosystems would be affected by land clearing activities, increased presence of human activities in formerly remote areas, changes in air quality, and decreases in soil productivity. Aquatic ecosystems would be affected by changes in water quality, changes in stream hydrology, activities which dry up aquatic habitats, and the construction of reservoirs which would change river ecosystems to lake ecosystems.

Existing vegetation would be destroyed on sites used for mining, solid and liquid waste disposal, community expansion, and the developments of related activities. In addition, increased populations in presently undeveloped areas of the coal regions would intensify recreational activities on lands formerly not subject to intensive activities, resulting in destruction or reduction of wildlife and habitat. At mining sites, reclamation would be required to restore vegetation so that the land would, at the least, be capable of supporting former uses. However, all reclamation efforts would not likely be completely successful in restoring the exact pre-mining conditions, especially on some severely disturbed mine areas which have both low precipitation and infertile soil. Mining will not be allowed on lands that cannot be reclaimed because of physical limitations. In the drier areas of the West or in areas with high evapotranspiration rates, it is possible that many decades could pass before natural vegetation and soil conditions could be restored to disturbed

areas, even with reclamation. Bonding is required to ensure reclamation activity will continue even after the active life of the mine. In the Appalachian Coal Regions, acid drainage could hinder revegetation efforts. Revegetation of an area may result in a plant species composition drastically different from that which existed prior to development if it is for a more beneficial use. Reclamation efforts, on the other hand, may attempt to restore the original use but with an entirely different mix of species. Either way, coal mining could have lasting effects on the ecology of the local area.

Loss of wildlife habitat and reductions in wildlife populations would occur as unavoidable consequences during the mining and use of coal. Some displacement and mortality of animals would occur in all regions.

Mining, transportation, and processing of coal would expose wildlife to various hazards and disturbances. Blasting, construction, and other noises associated with the mining activity would be unavoidable and would frighten away some wildlife species. Reproductive and migratory behavior could be affected.

Destruction of existing aquatic habitat and fauna would occur where streams are altered by mining or by construction of reservoirs. Reduction of water quality as a result of development would also adversely affect aquatic life. For example, increased sedimentation of waters could result in the elimination of those species which require clean gravel for spawning. Changes to or elimination of ponds, streams, and potholes would also adversely affect waterfowl.

In many areas, wildlife would return both during and after reclamation efforts, providing adequate water sources are available. In most cases, however, the diversity, density, and composition of the new populations would be altered from previous conditions.

7.1.3 Community Resources

The influx of a relatively large number of people into a region as a result of coal development could exert a major influence upon the region; primarily, this growth affects existing communities located near the areas of development. The potential impacts to a community would depend on the relative size and the rate of population increases, the existing infrastructure, and the adequacy of any advanced planning for

growth. Other factors affecting community ability to absorb growth include past experience with growth phenomena and mining. There could be instances, however, where large and rapid increases in population would unavoidably create growth rates reaching "hyperurbanization" levels. This is particularly true in more rural western regions where existing base populations of communities are often small compared to the rapid increase in construction and operating work forces related to coal development. Furthermore, the communities in the western coal regions usually have had much less experience with coal mining and growth phenomena than have towns in the eastern coal regions.

Financing and construction of facilities for education, fire and police protection, housing, water and sewer distribution, and health-medical care delivery systems take considerable lead time and often these facilities cannot be developed rapidly enough to accommodate rapid population growth. Local governments may experience severe problems in raising the capital to expand necessary facilities and services, thus creating hardships for long-term residents as well as newcomers.

Shortages of housing and other facilities and services, combined with higher wages of industrial workers, could create inflationary trends most adversely affecting established residents, particularly those on fixed incomes. Hope for higher wages may also lead to an influx of workers seeking employment opportunities in excess of available jobs.

Most rural communities have well-defined and long-established networks of social and political relationships. It is likely that, in such a community, these groups would be fragmented by the intrusion of relatively large numbers of persons who, in effect, would create a new social order. Even were this not to occur, conflicts would inevitably develop between the in-migrating construction and operation workers and the local population over differing personnel, economic, and social values. This could lead to an overall deterioration of the quality of life for everyone in the community.

The extent to which these conditions are unavoidable would be related to the size of the population influx compared to the size and stability of the base population of the given communities. Increases in most of the eastern coal regions such as the Appalachian Coal Regions may

be incrementally small because of the existing high level of coal development there. Conversely, western coal regions could experience large population changes compared to their baseline levels. This is particularly true in the Powder River Coal Region and some of the other more rural areas of the West.

7.2 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF PUBLIC RESOURCES

Once coal is mined, it cannot be replaced. However, this is not the only coal that is lost. Some coal is not recoverable in the process of mining. An average of about 85 percent of the coal resource can be recovered when area surface mining methods are used. Only about half of the coal in underground mining can be recovered, especially when seams are thick. Basically, this is because coal must be left to support the ground above the seam being mined. The preference expressed by the Secretary for the maximum economic recovery policy to be included in the preferred program is meant to mitigate this effect.

Production of coal from Federal lands through 1977 totals about 448 million tons. An additional 15 to 50 percent of this production may have been lost in the mining process. In 1977 alone, coal production from Federal lands was 52 million tons, or nearly 12 percent of the total produced during the past 200 years.

Table 7-1 shows the amounts of projected coal production by regions for the various Federal coal management program alternatives. Under a high coal production projection for the preferred program, for example, approximately 1.2 and 1.9 billion tons of coal would be mined in the years 1985 and 1990, respectively. An additional amount of coal, roughly about 600 and 940 million tons, respectively, would not be recoverable using current mining methods. Less coal would be lost with the Federal program in place than without it because of imposition of the maximum economic recovery requirement and emergency leasing.

As noted in Section 7.1.1.5, those aquifers drastically disturbed during mining or groundwater use may be irreversibly changed. Additionally, if large quantities of groundwater were to be pumped from thick aquifers, irreversible ground subsidence could occur, including compaction of the underlying aquifer. The quality of water in

some aquifers could be irreversibly changed as, for example, when pumping of high quality water permits infiltration by lower quality water. Leachates from solid and liquid wastes of coal facilities could also cause irreversible changes to groundwater quality.

The other principal changes would be:

- Some drainage patterns would be irreversibly changed by mining and construction activities. Changes in drainage could lead to irreversible alterations to surface water hydrology.
- Fuels, electric power, lubricants, explosives, structural materials, capital, and manpower committed for coal development would be irretrievably lost to other uses.
- On those areas reclaimed to premining vegetation, it is doubtful that total reestablishment of the native plant communities to the same level of diversity would be initially possible. The number of exotic species may increase, at least initially and during the early phases of reclamation.
- A considerable portion of land use changes accompanying coal mining would be permanent since areas shifted to industrial and residential uses would likely remain committed to these uses.
- Where crop, grazing, and forest lands could not be restored to former productivity, there would be an irretrievable loss of productive capacity.
- Unidentified historical, archaeological, and paleontological sites would be destroyed by mining and construction activities and irretrievably lost.
- Less tangible values that would be irretrievably lost include areas of natural beauty and those of unique geologic significance as study sites.

7.3 LONG-TERM PRODUCTIVITY LOSSES VERSUS SHORT-TERM USE OF LANDS

7.3.1 Trade-Off Analysis of Multiple Uses of Public Lands

Many changes would be associated with the development of coal resources, and, in particular, surface mining, due primarily to the long-term nature of the land alteration. In many past

instances, the productive capacity of land has been essentially destroyed through the employment of ecologically unsound mining practices. Further, there is insufficient experience in restoring lands to allow any truly accurate estimates to be made of the productivity that would be expected over the long term on reclaimed lands. The Surface Mining Control and Reclamation Act requires that reclamation efforts return the area to at least its former level of use.

Adjustments in the social structure of many communities will be needed as a result of coal development. These include adjusting to new social situations and living with people whose habits and values are different from those previously encountered. There may be frustrations, problems, and reductions in social welfare for both newcomers and long-time residents in the coal development areas. Prediction of the intensity and persistence of this social disruption or its consequences is not possible in a programmatic environmental impact statement.

7.3.2 Time Frame of Coal Leasing

The present Federal coal management program diligence requirements set exhaustion of new logical mining unit reserves within a 40 year period. The average mine is actively in production for about 30 years. Other time dependent elements of the program include:

- Production starts - within 10 years of lease.
- Initial lease term - 20 years.
- Lease renewal term - 10 years.

The management program as presently structured represents a long-term commitment of resources, e.g. 30-40 years. However, not all of the area of a lease is removed from other productive uses. For a surface mine, only a minor part might be actively mined at any one time. Disturbed lands generally enter the reclamation cycle simultaneously with active mining and can be available for other productive uses before shutdown of production. The only exception would be areas committed to long-term use such as building sites, roads, storage facilities, etc. Where areas are reclaimed soon after use, the time for alternative uses foregone and productivity losses experienced typically ranges between five and 15 years. Under the permanent surface mining regulations, mines will find it to their advantage to reclaim disturbed areas quickly.

7.3.3 Productivity

Reclamation efforts and natural revegetation of strip-mined areas would be initiated once the coal resource has been removed. Areas around buildings and other coal development related facilities would likely be revegetated and landscaped once construction of these structures was completed.

In Chapter 5, impacts to natural and agricultural productivities due to land disturbances were presented based on total land requirements between 1976 and 1990. These requirements include both long-term and short-term losses.

Long-term losses of natural productivity would occur on areas committed to hard surface, buildings or other permanent types of structure, and to areas committed to a major change in land use (e.g., land required to support coal related population increases). While there is a potential to return these areas to some stage of natural production, it is unlikely that such a change would occur in the near future.

Short-term losses of natural productivity would occur in areas subject to disturbances that would be alleviated over time (indirect or secondary impacts), and areas that have a potential for being returned to some level of natural production. Such areas include buffer zones around facilities, areas around buildings that would be landscaped, and land required for mining. Estimates of the amounts of land subject to long-term or short-term losses under the preferred leasing alternative medium level production are presented in Table 7-2.

The amount of time required to achieve some return of productivity to short-term land losses will be dependent on actual land use objectives. Reclamation to commercially harvestable forest in the Appalachian and Eastern Interior Coal Regions would take between 25 and 30 years for coniferous species and between 75 and 80 years for hardwoods, based on present silvicultural techniques [1]. Reclaiming the land as cropland could occur within one to two years of soil restoration in some cases.

Estimates of time to reclaim rangeland to pre-mining productivities range from about one year in the Texas Coal Region [2] to 10 years in the Powder River Coal Region and 14 years in the Uinta-Southwestern Utah Coal Region. These are estimates, not precise forecasts, and only more research and experience will develop reliable

TABLE I-2

(a)Committed to "permanent" structures, hard surface areas, or to a major change in land use (e.g. land for coal related population increased).

(b)Areas adjacent to facilities that are undeveloped.

(c)Primarily land required to produce coal.

information about restoration of long-term productivity in the grasslands and other semi-arid and arid areas of the West.

7.3.4 Wildlife

The potential for returning wildlife to reclaimed areas would be directly dependent upon the success of the vegetation reclamation efforts and reclaimed uses of the land. The time to recover stable wildlife populations is highly dependent on individual species characteristics. The long-term reestablishment of wildlife populations must be considered in terms of the short-term, site-specific losses of both species numbers and habitat. This is directly related to the acreage commitments during the average 30-year life of a given mining site. As specific mining tracts are not identifiable in this statement, it is not possible to specifically identify habitats which would be disrupted. Nevertheless, any surface mining operation would result in a temporary loss of habitat for certain species.

Wildlife reestablishment will closely follow the successional stages of vegetation. Areas successfully replanted in seedlings, for example, would be expected to follow a typical pattern for both plant and animal species. Windblown seeds that become established along with planted seedlings would

increase plant diversity and provide additional opportunities for wildlife feeding, cover, and reproduction. The first inhabitants of a reclaimed area would include soil organisms, insects, and other arthropods, and rodents, followed by small mammals, foxes, and ground nesting birds.

Usefulness of range reclamation to wildlife will depend upon the eventual mix of plant species that first establish themselves and the succession that follows. Replanting with vegetation of only one type, as under cultivation, could limit the benefits to wildlife. Control of undesirable plant species and protection of newly established vegetation from grazing animal species may also be required for several years before reclaimed areas can be deemed successful in terms of maximum wildlife benefits.

CHAPTER 8

CONSULTATION AND COORDINATION

Shortly after assuming the post of Secretary of the Interior, Secretary Andrus requested a review of the status of Federal coal leasing, including the lack of new leasing, the 1975 environmental impact statement on the then proposed leasing program (see Section 1.2.4), the new statutory base for leasing (see Section 1.3.1), and the *NRDC v. Hughes* suit which challenged the legal adequacy of the 1975 statement (see Section 1.2.6). The reviewers found that the 1975 program had been outdated by the new statutes and, furthermore, was not compatible with the policy objectives of the new Administration; that the plaintiffs' arguments in the law suit were likely to prevail; and that significant, new Federal leasing probably could not and, moreover, should not begin until a new Federal coal management program which complies with the law and meets Presidential and Departmental policy objectives is prepared and the need for renewed leasing is assessed. The decision to design a new coal management program and prepare a new programmatic environmental impact statement was announced to the public in a July 25, 1977, Departmental press release.

Responding to these findings, the Secretary ordered a full-scale interagency coal policy review which, among other things, would assess the need for leasing and initiate the development of a new Federal coal management program. A review committee, composed of the Solicitor and Assistant Secretaries of the Department was formed. The Office of Coal Leasing, Planning, and Coordination was established at the Departmental level to coordinate the review. Three events in 1977 gave impetus to the review: the April 29, 1977 publication of the National Energy Plan which emphasized coal as the principal domestic fuel to reduce our dependence on imported oil and gas and called for a doubling of coal production by 1985; the President's May 23 Environmental Message to the Congress and May 24 Memorandum to the Secretary which called upon the Secretary to develop an environmentally sound coal manage-

ment program; and the September 27 decision in *NRDC v. Hughes* enjoining the Department from engaging in major leasing activity until certain conditions were met (see Chapter I for a discussion of these events). Although the court order only required the publication of a supplement to the 1975 environmental impact statement, for the reasons discussed above the Secretary maintained his decision to prepare a wholly new draft environmental impact on a newly designed preferred coal management program.

Since these events, the Department has offered numerous opportunities for public participation and has consulted with expert Federal and state agencies, state governors and their representatives, trade associations and individual companies, environmental associations, community groups, and other organizations with expertise on coal development issues on the development of the preferred coal management program and the preparation of this statement.

8.1 PROGRAM DEVELOPMENT COORDINATION

The process of selecting the preferred new Federal coal management program began in October 1977 and continued through March 1979. The first step in the process was the convening of task forces assigned to specific issue areas. These task forces were staffed with coal, land use planning, and other specialists drawn mostly from the Bureau of Land Management, the Geological Survey, the Fish and Wildlife Service, and the Office of Policy Analysis. Each task force developed and submitted to the Office of Coal Management, Bureau of Land Management, a background issue paper which was made public and continues to be available from the Bureau of Land Management upon request. The Office of Coal Leasing, Planning, and Coordination reviewed these papers and from them prepared concise issue option papers which were submitted to the Secretary or Under Secretary. (These issue option papers, listed

in Table 3-1, were also made public and continue to be available from the Bureau of Land Management upon request.) The Secretary or Under Secretary circulated the issue option papers to the Assistant Secretaries and the Solicitor for comments and recommendations on which issue options should be selected. After all comments and recommendations were also circulated among the Assistant Secretaries and the Solicitor, they or their representatives met and discussed the comments and recommendations with the Secretary or Under Secretary. The Secretary or Under Secretary subsequently selected the option he preferred under each issue presented to him in the issue option paper or papers then under consideration. These preferred options formed the bases of the preferred program in this statement. Program development was coordinated with the states, industry, environmental groups, citizens organizations, and Indian tribes in the West by the Denver based Assistant to the Director of the Office of Coal Leasing, Planning, and Coordination.

In addition to the program development coordination described above, the Bureau of Land Management conducted interagency consultations concerning jurisdictional authorities and responsibilities. Major coordination activities have taken place between: (1) BLM and the Fish and Wildlife Service (FWS) concerning coal related wildlife management responsibilities, (2) BLM, U.S. Geological Survey (USGS), and the Office of Surface Mining Reclamation and Enforcement (OSM) concerning pre- and post-lease coal management responsibilities, (3) the Advisory Council on Historic Preservation, BLM, USGS, and the OSM concerning the protection of cultural resources on Federal lands, (4) between BLM and the Forest Service (FS), Department of Agriculture, concerning application of unsuitability criteria national forest system lands, and (5) between BLM and the Small Business Administration on small business coal lease set aside sales. A Memorandum of Understanding (MOU) was completed between BLM and FWS on September 26, 1978 (Appendix B). Additional MOU's are currently being negotiated.

The Department has met on a quarterly bases with the Department of Energy through the Leasing House Committee (see Section 1.3.2.2) and has worked closely with the DOE Office of Leasing Policy Development in developing the preferred

program. The Department negotiated a Memorandum of Understanding with the Department on Energy concerning the setting of energy minerals production goals (see Appendix B). The Department's Office of Coal Leasing, Planning and Coordination and the Assistant Secretary, Land and Water Resources, have held several briefing and information-gathering meetings in the West, beginning in January 1978 with representatives of the western states Governors' Offices and state resource agencies to obtain state and local government viewpoints on and participation in the development of, the program. The Office and the Assistant Secretary also met with various industry groups and environmental organizations for similar purposes.

8.2 ENVIRONMENTAL IMPACT STATEMENT PUBLICATION

This section deals with consultations and coordination efforts since the original Final Coal Leasing Programmatic Environmental Impact Statement was published on September 19, 1975 [1].

Consultation efforts for this document commenced with a departmental news release on November 17, 1977, which requested the public to comment on the 1975 final environmental impact statement. A total of 265 comments were received from various governmental, industrial, and private sources. These comments were considered prior to the preparation of the draft version of this statement.

Thereafter, BLM negotiated a contract with the MITRE Corporation to assist in the preparation of the new statement. This contractual assistance commenced on April 14, 1978. Subsequently, the contractor and the Department of the Interior consulted with the organizations listed in Table 8-1 to obtain advice and information for the preparation of the draft statement.

8.2.1 Preparation of Draft Environmental Statement (DES)

Three types of consultation occurred during the preparation of the draft version of this statement (DES). Specifically, they included circulation of the DES outline, coordination with the Department of Energy to determine coal production level scenarios, and the circulation of copies of the preliminary draft environmental statement.

The Format Outline for The Coal Programmatic DES was made available via a Federal Register notice on July 31, 1978[2]. Copies for the general public were available upon request. The alternative coal production levels which serve as the basis for impact analysis in Chapter 5 were derived from production projections provided by the Department of Energy. Lastly, the preliminary draft environmental statement, PDES, which represented a "first cut" effort on the draft statement, was distributed to selected agencies for comment. In addition to Interior agencies, DOE, FS, the Environmental Protection Agency (EPA), and western state Governors' Offices received copies of the PDES and were asked to comment. See Table 8-2.

Representatives of western state Governors' Offices participated jointly with Departmental representatives in the review of the PDES. The assistance of these representatives was of substantial value in the assessment and analysis of key program issues, policy implications, and effects on state and local government policies, plans and programs. All PDES comments which were submitted in a timely manner were considered prior to the printing of the DES. Where appropriate, the statement reflected those comments.

8.2.2 Publication and Distribution of the Draft Environmental Statement

The DES was published on December 13, 1978, and a notice of availability was published in the December 15, 1978, issue of the Federal Register.

After publication of the notice of availability, 2,000 copies of the DES were initially distributed to a wide range of individuals, including Federal and state agencies and nongovernmental organizations such as conservation and environmental groups, industrial organizations, mining companies, libraries, and others. During the extended 60-day review period (45 days is mandatory), an additional 3,000 copies were distributed to other nongovernmental organizations and individuals for review and comment.

8.3 PUBLIC COMMENTS AND RESPONSES

The extended 60-day public comment period was scheduled to provide the public with the opportunity to review and offer comment on the

effects of the Federal coal management program, including the preferred program and alternatives, described in the DES.

During this period, the Department placed a high priority in obtaining wide media coverage in order to allow divergent groups and individual citizens an opportunity to participate in the review process, either by public appearance at scheduled meetings and hearings or through written responses.

On December 15, 1978, Secretary Andrus released the DES at a Washington press conference during which time he stressed the need for maximum public participation. Assistant Secretary, Guy Martin delivered a similar speech in Denver, Colorado, on December 14, 1978, emphasizing the need for total public participation in the environmental statement review process. He stated, "Publication of the Draft Environmental Statement represents the first opportunity for all parties who are interested to examine and comment on the unified proposed program and its alternatives."

This theme was carried out further in a nationwide press release issued by the Secretary on December 15, 1978. Similar news releases were issued by BLM State offices during the subsequent public meetings and hearings that were held in 16 cities located in the major coal resource regions.

Individual news releases were disseminated to the following media:

Radio stations	105
TV stations	84
Newspapers	231
Newsletters	11
Magazines	9
News services (wire)	2

8.3.1 Public Meetings

In its concern with ensuring wide public involvement in the preparation of the DES, the Department took the innovative step of scheduling special, pre-hearing informational meetings for the public. The purpose of these meetings, which were held in 12 cities during early January 1979, was to fully advise the public of the contents and availability of the DES and the upcoming formal DES hearings and to provide an opportunity to interested parties to informally question those in the Department who are responsible for coal management policy decision making and preparation of the DES.

CONSULTATION AND COORDINATION

A total of 380 persons attended the 12 pre-hearing meetings held in the following locations:

January 3, 1979 —	Albuquerque, NM
January 3, 1979 —	Denver, CO
January 4, 1979 —	Salt Lake City, UT
January 4, 1979 —	Cheyenne, WY
January 5, 1979 —	Grand Junction, CO
January 5, 1979 —	Sheridan, WY
January 8, 1979 —	Price, UT
January 8, 1979 —	Billings, MT
January 9, 1979 —	Craig, CO
January 9, 1979 —	Miles City, MT
January 10, 1979 —	Rock Springs, WY
January 10, 1979 —	Bismarck, ND

Total attendees at all 10 hearings	360
Total witnesses at all 10 hearings	74
Total number of attendees at 12 public meetings	380
Total number of written comments (including witnesses testimony)	287
Total number of written comments (after extended 60-day period)	84
Total individual questions	1392
Total individual questions (after 60-day extended period)	385

The number of individual letters received both during and after the review period were separated into six major categories for the purpose of classifying each comment. A breakdown of these major categories and the number of comments in each category is as follows: policy comments, 891; compliance comments, 25; technical comments, 403; regulatory comments, 25; general-non specific comments, 20; and vote (expressions for or against the preferred alternative), 28.

The comments were provided by four major groups: governmental agencies, industry, environmental organizations, and private citizens. No single group dominated. The bulk of the comments were directed at the program as opposed to the DES. Industry's major concerns were that the program involved excessive governmental control. Environmental organizations were concerned that the program was driven by a desire to implement the program by 1980; that the model used during DES preparation was inaccurate; that the need for new leasing was not identified in the DES, and that the reclamation estimates were inaccurate. Governmental agencies mostly provided comments on the technical details of the DES. Lastly, private citizens expressed their concerns with the way in which they would be affected by the program.

8.3.4 Review Procedures for Handling Public Comments

During the review process, 287 documented comments were received as a result of solicitation by Federal Register notices, news releases, public meetings, and formal public hearings.

The February 15, 1978, issue of the Federal Register stated, "Written comments on the draft statement will be accepted on or before February 13, 1979, submitted to the Office of Coal Management (140), Bureau of Land Management, Department of the Interior, 18th and C Streets, N.W., Washington, D.C. 20240."

8.3.2 Public Hearings

The Department of the Interior conducted (10) formal public hearings to receive comments and suggestions relative to the DES. Administrative Law Judges (ALJ) presided over the hearings which were recorded verbatim by professional court reporters.

A panel of officials representing the Secretary's Office, Department of the Interior, the Office of Coal Leasing, Planning, and Coordination, the Bureau of Land Management, and the Solicitor's office received the testimony.

At the conclusion of each witness' testimony, members of the hearing panel answered some questions within their expertise and clarified issues presented in the testimony.

Oral testimony at the ten hearings was given by a total of 74 persons and amounted to 334 individual comments and/or questions. Approximately 60 percent of these comments were directed at the functional aspects of the program. Testimony was received from a diverse group of individuals representing environmental organizations, industry, governmental agencies, and private citizens. Comments ranged from support of the statement to requests for a complete rewrite of various sections of the program.

The public hearings were conducted at 10 different locations. Sessions were scheduled beginning at 1:30 p.m. and 7 p.m. at the locations cited on Table 8-3.

8.3.3 Public Comments

At the end of the extended review period, BLM analyzed and compiled the following statistics representing the total of all public comments:

The congressionally mandated 45-day review period was extended by the Department to 60 days in order to allow those commentors preparing their statements the maximum amount of time to respond to the DES.

All letters and testimony were reviewed by the environmental staff in the preparation of the final environmental statement. Letters received by the BLM were first reviewed relative to either draft corrections or issues raised. All substantive comments—those which presented new data, questioned analyses, or raised questions bearing directly upon the environmental effects of the proposed action and its alternatives—were responded to separately.

Every person who testified at the hearings and every letter postmarked no later than February 11, 1979, or received no later than February 13, 1979, were assigned an index number. (Section 8.3.7 lists all substantive comments and Departmental responses.)

The comment was presented verbatim whenever possible; each independent comment was identified by an index number. Comments which duplicated others were responded to by referencing the first response (index number). Once a comment or issue was responded to fully, the initial response was not repeated; the reader is referred to the initial response in answering all similar comments.

Such substantive comments were then analyzed for subsequent change or insertion into the text of this final environmental statement.

Letters which were general, vague, or did not contain substantive comments were reviewed, but no specific response was prepared. Comments of an editorial nature, if not substantive, were also not responded to, although appropriate text changes were made. The reader who wishes to identify comments and testimony by topic may refer to Section 8.3.7, and then to the appropriate list of hearings witness (Section 8.3.6) or comment authors (Section 8.3.5) to specifically identify appropriate comment/responses. All respondents who provided written comments and all of the persons appearing as hearing witnesses are listed in Section 8.3.8, for general reference.

8.3.5 Letters Received with Substantive Comments

Over 131 letters were received during the 60-day review period from environmental groups, interested citizens, industry, and Federal and state

agencies. All letters were reviewed and considered. Below is a list of only those respondents who submitted substantive comments. Letters that were repetitive or did not address the adequacy of the DES were assigned an index number but are not listed below. (Refer to Section 8.3.8 for a listing of all commenters.)

8.3.7 Substantive Comments and Departmental Responses

During the extended public comment period, a total of 287 written comments (including witnesses testimony) were received and recorded.

Each letter received and each person who testified at the hearing was assigned an index number. In the following part of this chapter, substantive comments received are grouped by separate categories (e.g., Background, Reserves Estimates, etc.). The comment was typed verbatim in most cases; these comments are followed by the index number of the agency, organization or person who made the comment. Similar comments received from more than one source have several index numbers identifying the source. An appropriate Departmental response either identifies that the text of the ES was changed or provides rationale for why the comment did not require a text change. Those comments solely editorial in nature were incorporated within the text of the final ES but were not repeated or responded to in this chapter.

Comments and Responses

BACKGROUND

1. Comment. "In many cases, the DOI may not even be aware a coal resource exists. According to Section 1.3.1 of the Draft Statement, almost half of the federal coal leases issued in the past have required no competitive bidding; indicating that almost half the areas of interest to private industry were not known by the government to have significant coal resources prior to leasing. Under the preferred program, such lands would not be leased. A pragmatic program must receive the input of industry to determine which lands should be open for leasing and to encourage evaluation of potential coal properties."

Commenters 066, 083, and 192

Response. As stated in Chapter 2, prior to 1976, the Department could grant coal prospecting permits for lands that needed additional exploration and if the company that had the permit found an economically attractive deposit, and showed the Department, it could receive a lease. Congress repealed this authority in 1976 as unnecessary and contrary to its view that coal should be disposed of only for fair-market value. About half of all leases were granted under this now repealed procedure. This does not mean that the government did not know about these deposits before the prospecting permit or lease was issued. The discovery and delineation of commercial coal deposits has been a cooperative effort by industry and government. Partially as a result of the legal structure that existed until 1976, the Department often made the initial identification of potential coal deposits, what are now commonly referred to as coal resources, through mapping programs, surveying, and other governmental functions. Intentionally, however, the role of the government stopped there,

and industry had the role to do the additional work to further identify which resources were capable of being mined; that is, to identify reserves. Congress has now subtly changed this relationship by giving the Interior Department greater responsibility to identify coal reserves. This does not mean that industry's role is no longer needed or wanted. The reverse is true. Even under the revised statutory provisions, industry must participate heavily in a coal program if it is to be a success. This is true both with respect to working with the resource managers in the land-use planning process and to continuing drilling and exploration efforts. The Congress specifically authorized the Department to grant exploration licenses to give companies the right to explore for coal. These exploration licenses do not give a company any right to a lease, but they do provide the opportunity to the company to obtain the information it needs to decide whether or not to bid to acquire a new lease.

2. Comment. "The second background issue concerns the analysis of the federal laws now in effect which are designed to minimize environmental damage resulting from various aspects of federal coal development. These laws are summarized at section 1.3.1 of the DEIS. A further analysis of the impact of these laws on coal development would be valuable in evaluating the impact of the preferred program and alternatives for federal coal development."

"Historically, severe abuse of natural resources has occurred in surface mining of coal. These are still visible, particularly in the Appalachian region. However, these abuses can no longer occur in large part because of the passage of the Surface Mining Control and Reclamation Act of 1977. An in depth analysis of federal laws governing coal development will impart to the reader of the FEIS an understanding that the limitations on development which appear in the preferred program, or whatever alternative is chosen, are not the only regulations in existence. The program must be viewed not as the last barrier to mindless coal development, but rather as one part of a multi-faceted federal system which will permit rational utilization of federal coal assets."

Commenters 019, 069, 090, and 135.

Response. The Department hopes that its presentation of material in this statement shows that the Federal coal leasing program is only one

of many elements that affect coal development and that, independently of any actions taken here, other programs and laws ensure a high degree of resource protection. Particularly with the contemporaneous in-depth analysis of SMCRA now underway, we do not think additional in-depth analysis of all applicable laws is needed here; presenting the principle that many ways exist to protect the environment is more important to forming a national coal management program than would a recital of the details of these laws.

3. Comment. "Section 1.1.2 also describes the various alternatives briefly and reveals vividly in its summation of the preferred alternative that offering tracts for leasing would be the last alternative after all other land use options have been exhausted. It is felt that this was not the intent of either the Congress or the Administration in placing emphasis on rapidly increased development of coal in the Nation which the Statement acknowledges must, to some significant degree, be based on new federal leasing. If it is the opinion of the Department that some legislation demands the assignment of the lowest priority to coal leasing then it would be necessary in explaining the preferred alternative to provide a detailed discussion of that legislation. Furthermore, it would be most enlightening to have a discussion of what, if any, legislative authority there is for putting such uses as the establishment of recreational areas above that of coal leasing."

Commenters 066 and 071

Response. The summary description of the proposed program and the fuller description of the program in Chapter 3 and the example regulations do not, in our opinion, make coal a last alternative. The program does make a strong attempt to identify lands which statutes or executive orders have put off-limits to coal development as early as possible in the process. It also strives to set up a system that minimizes loss of existing surface resources. If expensive recreational facilities have been built at a site, it makes little sense to develop coal there if nearby lands that have similar or better coal can be found. Otherwise, the coal company would have to bear the needless expense of other rebuilding or relocating the recreational site. Common sense is the only authority needed for actions of this type. Coal development will invariably have to displace other uses - grazing,

wildlife, recreation, timber or the like; it is not a last alternative. The Department does believe, that it can afford to attempt to plan the uses of its land to encourage coal development to take place so as to minimize costs to other users of public lands. Statutory citations for the emphasis on land use planning are provided in the statement. In response to this and other comments, a more complete discussion of the role of and procedures for land use planning is given in Chapter 3 of this final statement.

The comment on NEP goals will be responded to in the comments on Chapter 3.

4. Comment. "Section 1.1.4 suggest that, although the Department will complete ongoing regional environmental impact statements, it contemplates the preparation of at least an environmental analysis for each and every coal lease and mining plan which would probably result in the initiation of a full environmental impact statement for most such leases and plans as well as new regional impact statements and revision and updating of the programmatic impact statement. Such a procedure again requires unnecessary delays. As is evident from Figure 1-2, most of the major areas where coal mining is planned or can be expected to occur in the West are currently covered by a regional environmental impact statement that has either been completed or is in some stage of preparation. Even with significant new leasing in any particular region, much of the information that has already been presented or has been collected for ongoing regional impact statements can be used for any new additional leasing in the area. This information includes general topics such as climatic conditions, reclamation characteristics and certain socio-economic considerations. It is urged that the Department make it clear in the final programmatic statement that wherever possible, such information will be incorporated by reference and that ongoing regional impact statements will be only supplemented or updated where new leasing is provided, in order to minimize delay."

Commenters 066 and 071

Response. The Department's proposed program uses larger "regions" than did the environmental statements started by the Department in 1976. The principal reason for the change is to give the Department a better opportunity to analyze

regional impacts and to mitigate possible adverse social or economic effects. The Department has not finally decided the exact format of the regional statements, but certainly the alternative of incorporating material by reference from the existing statements is under consideration as is doing entirely new statements. In either event, the Department will use, wherever possible, the information it has previously developed in the existing regional statements.

5. Comment. "In the second paragraph of Section 1.3.1.3, reference is made to the fact that SMCRA gives the Office of Surface Mining little discretion in enforcing the provisions of that Act. Such a statement would certainly come as a surprise to the drafters of final regulations for that Office and the critics of those regulations which are being hotly debated at this time. It would seem that the Office of Surface Mining has somehow developed the attitude that the Act gives them a lot more discretion in formulating regulations and implementing the various provisions of the Act than the drafters of this Statement and other agencies of the Department of the Interior recognize. It might very well avoid a lot of extensive litigation if the Department would, from the higher levels of the Department, work directly with the Office of Surface Mining to assure that the regulations which it develops are indeed within the tight authorization granted to the Office by SMCRA."

Commenter 066

Response. The word "overall" has been added before "design" to clarify that the SMCRA does not give OSM the authority to drop whole standards or objectives. In individual areas, OSM does have considerable authority to interpret Congress's intent. The introductory background description of statutory authority here, as elsewhere in Chapter 1, cannot be construed in any way to be substantive comment or the mandate of the law. Certainly, for SMCRA, the more authoritative document is the final environmental impact statement on the permanent regulations prepared by the office established under SMCRA to administer the Act - the Office of Surface Mining Reclamation and Enforcement.

6. Comment. "P. 1-4, Figure 1-1. A large scale map, or several maps, would help the public to

properly evaluate the location of the coal supply region."

Commenter 025

Response. The map has been altered but it is not practical to print it at a larger size. For more detail on the specific counties involved within a given region refer to Appendix H, Table H-6 and Appendix J. Section 3420. 3-1 of the proposed regulations sets out a method for changing regional boundaries should the need for such a change become evident.

7. Comment. "P. 1-11, Table 1-4. The mining method shown for the Delta, Colorado lease is incorrect. It should read "underground."

Commenter 025

Response. The FES contains this correction.

8. Comment. "Figures 1-2. The Northwest Colorado study boundary is not adjacent to the West-Central Colorado ES boundary as shown."

Commenter 025

Response. The boundaries of Figure 1-2 have been corrected for the FES.

9. Comment. "Figure 1-2. The boundary of the Star Lake-Bisti region is incorrect."

Commenter 019

Response. The boundaries of Figure 1-2 have revised, where appropriate, for the FES.

10. Comment. "Table 1-1 (page 1-6) lists only one site-specific mining and reclamation plan. Two DEIS's already have been issued (Nerco and Peabody) for the Powder Regional EIS."

Commenter 071

Response. The FES contains the suggested modification.

11. Comment. "The functions shown for the Forest Service in Table 1-7 should be broadened and rearranged, as follows, to more nearly reflect a balance of programs:

- land and resource management planning necessary for the administration of National Forest System lands and the management of renewable natural resources;

- the development of lease stipulations and the exercise of consent authority in lease issuances and mining and reclamation plan approvals;

- the issuance of easements and permits for ancillary facilities off the lease area;

—the administration of an abandoned mined land reclamation program.”

Commenter 282

Response. The FES contains the suggested modification.

12. **Comment.** “The purpose and major relevance columns of Table 1-5 should be reworded to reflect the primary impact of the National Forest Management Act of 1976, as related to coal mining:

Purpose: Provides for a comprehensive system of land and resource management planning for National Forest System lands.

Major Relevance: Key factor in the Secretary of the Interior's determination of where coal leasing will occur.”

Commenter 282

Response. The FES contains the suggested modification.

13. **Comment.** “The major relevance column of Table 1-5 should be reworded for the Multiple Use-Sustained Yield Act of 1960 to align it with FLPMA:

Major Relevance: Mandates land management principles similar to those required of the Department of the Interior under FLPMA.”

Commenter 282

Response. The FES contains the suggested modification.

14. **Comment.** “(Page 1-11) In Table 1-4 (Leases Issued Between 1974 and 1978), with respect to 1978 CO-Delta, the type of mining should be underground (not surface).”

Commenter 091

Response. Agreed. The FES contains the corrected information.

15. **Comment.** “(Page 1-14) A production rate of 96 million tons for 1977 is given for mines on or related to Federal leases. The basis for this production rate should be given so that appropriate comparisons with proposed production increases can be made (e.g., comparison with Table 2-2).”

Commenter 091

Response. The basis for the 96 million ton figure is the production records of the Department. Table 2-2 is the demonstrated coal reserve basis for the United States. There is very little to compare between the table and the production figure.

16. **Comment.** “The rationale used for redefining the 12 coal Regions to cause the preparation of new coal ES's is not clear (pages 1-4, 1-5 DES).”

Commenter 282

Response. This is more thoroughly discussed in chapter 2 and the response to comments in that chapter.

17. **Comment.** “p. 1-21 P.L. 94-429 should be included in the list of pp. 1-17 to 1-21. Sec. 9 of this law requires a determination whether any *natural landmark* is threatened or being destroyed by any surface mining activity. The major relevance is recognition and protection of nationally significant natural areas as they relate to surface mining.”

Commenter 233

Response. The table has been modified to include a citation to this law (Act of September 28, 1976, Public Law 94-429, 90 Stat 1342, 16 U.S.C. 1908).

18. **Comment.** “We know the leasing strategies preferred by the Department will all rely on the surface management agencies' planning systems to identify areas suitable for coal leasing; this can be done by June 1, 1979.

We would like to use the period of September 1978 through March 1979 to review and revise *the areas planned for coal only* in selected recently completed MFPs on high potential coal deposits, to insure that these plans are consistent with current Departmental policy and ready for use in developing the mid-1980 coal lease offer options. Doing this will involve the following steps, to be completed by March 1979.

Instruction Memorandum No. 78-381, July 19, 1978 (emphasis in original).

The process described in Instruction Memorandum 78-381 constitutes implementation of the “preferred alternative,” and it is not a part of a general and comprehensive land use planning process. It is solely and specifically designed to prepare for a mid-1980 coal lease sale. IM 78-381 does not order consideration of coal resources in the context of resource management activities. It explicitly cautions the State Directors “to review and revise the areas planned for coal only”

Commenter 089

Response. The process described in I.M. 78-381 does not implement any leasing program, and is part and parcel of the planning system. As a subsequent instruction memorandum makes total-

ly clear, the review referred to here is to carry out land-use planning duties, to further test unsuitability criteria and to begin the Federal Lands review, 43 Federal Register 57662-64: I.M.-79-76.

19. Comment.

"II. NRDC vs. HUGHES"

"Under the U.S. Constitution and the Separation of Powers Doctrine, it is improper and inappropriate, if not unconstitutional, for the Executive Branch (Department of the Interior) to permit the Judicial Branch (Judge Pratt) to require the Executive Branch to address the question of the 'need for leasing'.

- (a) The Executive Branch, by a number of Acts of the Legislative Branch, has been granted both the authority and the responsibility to manage the lands and mineral resources owned by the United States of America.
- (b) Leasing of federal coal is the statutory responsibility of Interior. The determination of the need to lease is both a statutory and proper responsibility of Interior as the agency designated to manage coal owned by the United States.
- (c) The determination of the need to lease, when, and in what quantities, are determinations that cannot constitutionally be delegated to the Judicial Branch. Nor can the Executive Branch *properly* submit even to inquiry by the Judicial Branch as to the determination of "need", let alone feel it necessary to justify such determination to a Federal judge as a prerequisite to preparing a leasing program.
- (d) Judge Pratt acted improperly, if not unconstitutionally, in requiring Interior to demonstrate to him the "need for further leasing". Interior acted improperly, if not unconstitutionally, in recognizing any authority on the part of the Judicial Branch (Judge Pratt) to require a showing of "need".

If an administrative agency, in carrying out its statutory responsibilities, acts "arbitrarily and capriciously" that is one thing. When that is alleged, the burden rests on the plaintiff to show by convincing evidence that such is the case. That was not the issue in *NRDC vs. Hughes*.

In short, it is no business of the Judicial Branch to inquire into, let alone sit in judgment on, the "need for leasing". The authority, the responsibility, and the duty to determine the "need for leasing" reposes upon the Executive Branch *alone*. So long as the Executive Branch, in making its determinations, does not act arbitrarily and capriciously it is simply no business of the Judicial Branch.

How the Executive Branch exercises its management authority and discharges its management responsibilities is, of course, another matter."

Commenter 053

Response. This comment does not involve the substance of either the environmental statement or the program. It has been sent to the solicitor's office for appropriate action.

- 20. Comment.** "Memoranda written by the Director of the Bureau of Land Management (BLM) and the Directors of the Western Coal State Offices of the BLM reveal a strenuous and systematic program to prepare for a mid-1980 lease sale. The program, directed specifically toward the identification of forty lease tracts in time for the 1980 sale, requires updating of MFPS prepared for coal management under EMARS II and the Application of the draft Lands Unsuitability Criteria. The 700,000 acres of land to be reviewed as part of this program have not been selected pursuant to comprehensive resource planning. There has been no intraregional evaluation of competing values. The criterion by which the selection was made was simple. "Focus on planning areas where completed MFPS delineate areas potentially suitable for coal leasing to meet short-term (1980) leasing goals."

Commenter: 089

Response. Secretary Andrus has personally stated that no decision as to whether to adopt a leasing program and whether to resume leasing will be made until after this statement is completed. We regard the steps that have been taken so far to be in rigid compliance with both the spirit and letter of the *Hughes* order. The ongoing activity is needed to ensure that any program, if adopted, will be one that is based on sound data and standards.

- 21. Comment.** "The issue in *NRDC v. Hughes* was the adequacy of the final Environmental Impact Statement prepared on the Energy Minerals Activities Recommendation System (EMARS

II). The Court concluded that the EIS was inadequate. It found both the explanation of EMARS II and the consideration of alternatives to be insufficient. The court specifically referred to the necessity that the Department consider the need for any leasing at all, and ordered the Department to prepare a new draft impact statement and the Secretary of the Interior to personally reevaluate federal coal leasing policy, based on information contained in the new final EIS, and to make a new decision as to whether a new leasing program shall be instituted and, if so, what kind of program it should be.

"Natural Resources Defense Council v. Hughes, *supra*, 437 F.Supp. at 994 (emphasis added).

Until that task is complete, the Department is enjoined from taking "any steps whatsoever, directly or indirectly, to implement the new coal leasing program" 437 F.Supp. at 993.

"The Department has apparently concluded that the provision of the Court's order, as modified, which permits the 'preparation of comprehensive land use plans,' 454 F.Supp. at 152, forbids only implementation of EMARS II and the identification or leasing of tracts. 43 Fed. Reg. 57663 (December 8, 1978); Memorandum for the Deputy Solicitor to the Director of the Bureau of Land Management 'Planning and Data Collection Efforts Under NRDC v. Hughes,' at 1-2. Such a conclusion is incredible in the context of the decision of the court. The order of the court explicitly bars implementation of 'the new' (emphasis supplied) coal leasing program; the point of the order is to compel the Department to properly complete the EIS process before it adopts, let alone implements, a new program.

The language which permits land use planning to go forward is addressed to comprehensive planning which incidentally involves consideration of coal. Yet the Department has instituted planning activities directed only to the leasing of coal.

We regard the Department's violation of the court's order as so complete as to render the Programmatic Impact Statement functionally irrelevant. The Department's memoranda and actions suggest that the decision to lease and to lease soon was made before the basic tasks imposed by the court were even addressed. The Impact Statement will inevitably turn into an effort to justify that

decision rather than a means to inform the decisionmaker."

Commenter 089

Response. The original order in *NRDC v. Hughes* contained only very general language on what activities could occur until a new environmental statement was filed and the Secretary decided whether to adopt a new program. It only said: that federal defendants, their agents and employees, and all those in concert or participation with them are enjoined from taking any steps whatsoever, directly or indirectly, to implement the new coal leasing program.

The Department was concerned that the order might be construed overbroadly. On February 25, 1978, the plaintiffs and Federal defendants in *NRDC v. Hughes* agreed that "Federal defendant's activities respecting federal coal are of such a complex and diverse nature that the scope of the general language of the court's order is subject to honest dispute." In an attempt to clarify and modify the original order, the following language was added to the original order:

Federal defendants are not enjoined from engaging in any general studies or from preparing any general analyses or environmental impact statements with regard to federal coal leasing on either a national or regional basis. Federal defendants may prepare comprehensive land use plans as long as they do not recommend the leasing of any tracts of coal; however, the plans can consider present and potential uses of public lands.

The Department's view of the import of the modified court order was clearly stated in a memorandum signed by the Deputy Solicitor on May 24, 1978, three weeks before the court approved the proposed stipulation. The memorandum says:

Although land use planning was an integral part of EMARS, and a "comprehensive land use plan" is required by section 3 of the Federal Coal Leasing Amendments Act of 1975, 30 U.S.C. §201(a)(3)(A)(i), before a lease sale is held, land use planning is also mandated wholly outside the context of the coal program by section 202 of the Federal Land Policy and Management Act, 43 U.S.C. §1712. The potential application of Judge Pratt's Order to land use planning was one of the subjects that led us to stipulate with plaintiffs in Hughes "that the scope of the general language of the Court's Order is subject to honest dispute."

Even though the revised court order has not yet been approved by the District Court, this language can be used to guide data collection and land use planning efforts.

In our view, the gathering of raw data is in no way circumscribed, whether in the form of Unit Resource Analyses, contract studies, or Geological Survey mapping of federal coal resources, including drilling and core sampling. Further, the collation and analysis of such data is in no way circumscribed.

The only proscription deals with the recommendations, or proposals for action contained in a land use plan as they relate to coal and actions in furtherance of the recommendations or proposals. BLM, with the help of GS and OSM, as appropriate, is free to evaluate coal resources and other resource values to determine if lands are *suitable* for coal development or not, and it is free to designate lands as unsuitable for surface coal mining under section 522 of the Surface Mining Control and Reclamation Act, 30 U.S.C. §1272. BLM may make recommendations or "decisions" *not* to lease or to mine coal in its land use plans.

BLM is prohibited only from recommending or proposing to lease a tract otherwise found suitable for coal development, or from taking action that directly implements such a recommendation or proposal.

Similarly, on June 28, 1978, the Deputy Solicitor advised the Director, Geological Survey, that "work designed to determine the suitability or unsuitability of public land for coal development is in no way circumscribed. The unsuitability tests now being done are being done (1) as part of a land-use planning process and (2) focusing on potential coal development areas rather than tracts. It is clearly within the scope at the F1 Hughes order."

RESERVES ESTIMATES

1. Comment. "Table 2-29 was made using data from BLM District Offices which has in many cases changed drastically."

Commenter 019

Response. Table 2-29 was based on a survey by the Geological Survey and data from DOE, not the BLM. The figure of 8.5 million tons was the best estimate by the Geological Survey mining supervisor as of March 1978.

2. Comment. "The DOI may also underestimate likely production. A persistent self-fulfilling prophecy that deep reserves will not be developed in the West eliminates from consideration PRLA's and the use of deep reserves in the private sector."

Commenters 097, 156, and 174

Response. Western prospects for deep mining are poor, except in certain areas, because of the large reserves of surface mineable coal and its relatively much lower mining cost. Environmental considerations could favor underground mining in particular circumstances.

3. Comment. "Adding only production from deep PRLA reserves to 1990 likely and probable production allows us to meet all western-wide production projections except the 1990 high projection."

Commenters 097 and 156

Response. If these leases were granted quickly and if production occurred in proportion to reverse size, the comment would be correct. Because of high production costs, PRLA underground reserves are unlikely to be in production by 1990 except in the Uinta-Southwestern Utah Coal Region and in some special circumstances. The largest amount of PRLA underground reserves are in the Powder River Coal Region where very little or no underground mining is expected. It is possible that reserves of this type will not meet the commercial quantities test and no lease will be issued.

4. Comment. "Table 2-4. Total surface-mineable reserves in the San Juan Basin are approximately 6 billion tons, according to the New Mexico Bureau of Mines. Yet this table states that 4 billion tons alone are on Indian lands. This figure is very questionable."

Commenter 019

Response. The estimate for Indian lands was provided by the Bureau of Indian Affairs. It reflects a less restrictive standard for inclusion of reserves than employed by the Bureau of Mines and, thus, probably counts some reserves that the Bureau of Mines would consider too speculative to include, until further delineation. See new discussion in Section 2.7.2.

5. Comment. "Table 2-23. How were these PRLA reserves estimated?"

Commenters 019 and 097

Response. A BLM task force report on PRLAs, entitled "An evaluation of Coal Preference Right Lease Applications," explains this methodology and can be obtained on request.

6. **Comment.** "No coal is recoverable today until it is known that the coal is legally available to mine and legally mineable and that cannot be known until all required permits are in hand."

Commenter 053

Response. The currently accepted definition of recoverable reserves does not require that all permits be in hand before counting such reserves.

7. **Comment.** "In Table 2-19, why are recoverable reserves of existing federal leases for Montana confidential?"

Commenter 071

Response. Current policy is to hold reserve information on individual leases confidential and not to disclose reserve information for groups of less than 32 lessees. Where two or more leases have the same owner, or where one lease has an unusually large share of the coal, the Department may also hold data confidential for groups of more than three leases. The Fort Union region in Montana has only 3 leases and its data is held confidential. Montana lease reserves in the Powder River Basin are in fact shown in table 2-19, but because of an insufficiency of underground lease reserves, the breakout between surface and underground reserves is held confidential.

8. **Comment.** "The statement that 45% of the nation's reserves on a BTU basis is found in the West is in direct contradiction to the findings of the National Coal Policy Project which reports that '70 percent of the remaining coal in the United States - in terms of energy value - lies east of the Mississippi River."

Commenter 118

Response. The 45 percent figure is based on the distribution of coal by weight and a Bureau of Mines estimate of average eastern BTU content of 12,500 BTU's per pound and western Btu content of 9,000 BTUs. Given the distribution of reserves by weight, if western coal is assumed to average 9,000 Btu's per pound, eastern coal would have to average more than 20,000 Btu's per pound to constitute 70 percent of coal energy. This Btu content far exceeds actual eastern Btu content. Hence, the figure of 70 percent given by the

national Coal Project appears to be a large overestimate of eastern coal's share by energy value.

MINE SIZE & PRODUCTION

1. **Comment.** "Mr. Freudenthal stated that the 2,560 acres listed in Table 2-27 and paragraph 2.7.3 is used as the minimum acreage of nonfederal coal in a continuous block that could be developed. Yet the smallest mine plan in the San Juan Basin is 6,095 acres."

Commenter 019

Response. Any acreage selected for a standard mine size would be somewhat arbitrary. The figure of 2,560 acres was selected to be most representative of western coal mine sizes. With a 10 foot seam, 2,560 acres would support a 1 million ton per year mine for 30 years. This acreage provides a conservative estimate of the inhibitions that would be placed on development of nonfederal coal by a lack of leasing. The standard acreage adopted depends on the mine size assumed, which can vary considerably within regions as well as among regions. If the higher figure were adopted, the relative importance of federal coal in mixed mineral ownership areas would increase.

2. **Comment.** "Likely production from existing leases without mine plans in the Powder River Basin in 1985 is stated to be 7M tons. Our investigations indicated 27.2M is a lot closer."

Commenters 097 and 118

Response. The Department does not want to generate a debate with individual companies concerning predictions on the production likelihoods of their individual leases. The estimates for likely production from leases without mine plans were made by GS mining supervisors, taking into account lease size, environmental, transportation, coal type and other factors. It is likely that the actual production will fit into a reasonable range above or below the estimate depending on changes in markets.

3. **Comment.** "One of the more serious difficulties in the chapter 2 concerns the estimates of time required to bring a lease into full production (2.8.1, page 2-43)."

Commenter 069

Response. Full production may require more than 7 years in some cases but, if the demand exists, 7 years should normally be adequate.

Several companies have suggested to us in the context of this statement and in public information on proposed openings of new mines that seven years is too lengthy a projection and that it could and should be halved.

4. Comment. "In section 2.8.2 of the DEIS reference is made to the fact that a decision not to lease federal coal could result in a shortfall of coal in the overall national energy picture."

Commenter 090

Response. It is difficult to predict the precise impacts of a shortfall in national coal production due to no Federal leasing although the no new leasing alternative tries to do so. Depending on the total demand for energy, the major impact would be expanded imports of foreign oil, however added gas production and increased nuclear production could also result in higher energy costs, but little change in the overall fuel mix.

5. Comment. "Will the final EIS reconsider the aggregate coal production targets in terms of recent developments which mitigate the probable demand for coal—i.e., Mexican gas, Canadian gas availability, loosened Canadian crude restrictions, Alaskan gas, etc.?"

Commenters 090 and 121

Response. The developments noted that would tend to reduce coal production requirements are to some extent offset by even more recent increases in the instability of Middle Eastern oil supplies. If Middle Eastern oil production were significantly reduced or international oil prices were to rise substantially, the pressures for greater coal development would be heightened. All these recent developments — both increasing and decreasing potential coal needs — illustrate the great uncertainty of long range coal projections. The final EIS does not contain revised projections because the low-medium-high range of production levels still encompasses any likely future production levels. A long-term decision on whether to establish a Federal coal management program cannot be based on almost month to month shifts in coal prospects. The decision whether to lease once a program is adopted can take these concerns into account.

6. Comment. "Without back-up data, the assigned likely production figures for existing leases without mine plans raise some interesting ques-

tions. Nearly 95% of the reserves under lease in the Powder River Basin are assessed not to be developed. Does GS have different views on the potential demand for PRBR coal than DOE."

Commenters 097, 108, and 118

Response. Assessing the true development prospects of a lease for which there is no mine plan requires an inherently subjective estimate. There is no substitute for good judgment, and no elaborate formulas or mechanical procedures would be likely to improve on good judgment. GS mining supervisors are closely involved with Federal leases and mining circumstances generally in their areas and are in a position to make such judgments. Sixty-six percent of the existing Federal lease reserves in the Powder River are expected to be in production by 1986. However, the great majority of these reserves are already in approved or pending mine plans. Reserves not expected to be producing are of lower quality and located in some cases off the prime Wyodak seam which has the highest development prospects.

7. Comment. "States should have a role in evaluating the inherent reasonableness of the targets based on available market information and forecasts."

Commenter 121

Response. States will be given the opportunity to comment on and participate in the regional production goal and leasing target setting process indirectly through consultation but, more importantly (if the preferred program is established), directly through their representation on the regional coal teams which have formal advisory authority to the secretary in the goal and target setting process.

8. Comment. "In Chapter 2 DOI apparently calculated its planned production estimates in the Powder River for 1985 in terms of what it believes will actually be produced. This results in a smaller production capacity for existing and newly approved mines."

Commenters 097, 108, 118, and 121

Response. Planned production estimates were based largely on the stated plans of individual coal companies. It is possible that actual production might be larger but this would be hard to predict.

9. Comment. "The Draft ES tackles non-Federal, non-Indian coal by estimating 1985 production at

35.7 million tons. Doubts over these figures increase when it becomes obvious from checking through the multitude of charts, that this represents a significant *decrease* in non-Federal, non-Indian coal production."

Commenters 097 and 108

Response. The comment is mistaken in assuming that 35.7 million tons represent all non-Federal coal production in 1985. The bulk of non-Federal, non-Indian coal production will occur in mines that include both Federal and non-Federal coal. This production was summarized in Section 2.7.1.1. The planned production described in the comment includes only mines that have no Federal coal at all and, thus, no Federal mine plan is involved. The stated drop in non-Federal production thus results from a mistaken comparison of all non-Federal production in 1977 (including mixed Federal-non-Federal mines) with 1985 production from the much more limited number of mines that have only non-Federal coal.

10. **Comment.** "(Page 2-1) Column 2, paragraph 3 states that the Federal Government owns essentially no coal within the Northern and Central Appalachian, Eastern Interior and Texas Coal regions. The State of Kentucky is an exception to this statement that should be taken into account. There are considerable Forest Service acquired lands in Kentucky."

Commenter 091

Response. This has been changed to indicate some Forest Service reserves in the East.

11. **Comment.** "(Page 2-29) Table 2-18 gives consumption patterns for Western coal. The DES should provide a detailed discussion of the basis for this table."

Commenter 091

Response. A detailed table supplementing Table 2-18 has been added to the text.

12. **Comment.** "(Page 2-32) For later comparison purposes, what is the breakdown by coal region for 1977 production from mines located on Federal leases?"

Commenter 091

Response. A column to that effect has been added to Table 2-20.

13. **Comment.** "(Page 2-30) With regard to the application of diligent development requirements to leases existing prior to 1976, the DES states that

"the Department at present expects that the great majority, if not all, of such existing leases would be cancelled if they are not producing by 1986." Because application of diligent development requirements has a significant bearing on the need for additional leasing to meet projected 1990 coal production needs, the text of the DES should specifically address under what conditions such requirement might not be applied (i.e., a discussion in the text as opposed to purely a statement in the Example Regulations in the Appendices)."

Commenter 091

Response. This discussion has been added in Chapter 3 and Appendix I.

DOE MODEL

1. **Comment.** "The DES probably is not accurate in estimating the impact of the preferred program due to uncertainties in both demand and supply estimates on the part of the government."

Commenters 042, 071, 087, 089, 156, 168, 178, and 193

Response. The Department prepared its estimates of the future coal demand and supply for the FES in such a way as to bracket all probable levels of these functions for 1985 and 1990. There is, indeed, much uncertainty about the future levels of these figures, but we believe by choosing the broad range of figures that we have in the ES, e.g., 1990 level production ranging from 1,091 to 1,921 million tons, we have provided for prudent lowering of all levels of impacts.

2. **Comment.** "The DOE projections assume that electricity demand will grow from 1977 to 1985 at the rates of 4.4% per year in the low case, 4.8% per year in the medium case and 5.8% per year in the high case. The level of population growth, estimates of future cost of electricity, and amount of conservation, are not specified, making it difficult to perform a detailed analysis of the projections."

Commenters 019, 038, 042, 061, 062, 067, 071, 079, 087, 089, 097, 099, 130, and 187

Response. From 1969 to 1973, production of electric power grew at the average annual rate of 7.1 percent. Following the OPEC shock, it grew negligibly in 1974 at 0.2 percent, a little higher at 2.6 percent in 1975, went back up to 6.3 percent in 1976 and then declined to 4.6 percent in 1977 and 3.7 percent in 1978. Thus, electric power demand has behaved erratically in recent years and will be

difficult to predict for the future. The average growth rate for the past three years has been 4.9 percent, slightly above the medium assumption to 1985 of 4.8 percent. Future demand will depend on uncertain questions such as whether abundant conservation opportunities remain or whether the easier and cheaper conservation opportunities have already been exhausted. There is also an important question of whether rising oil and gas prices might not cause a shift to greater use of electricity as a substitute energy source for industrial and residential use. The underlying electricity growth rate assumptions generally reflect the assumptions employed in the PIES model by DOE.

3. Comment. "The Department of Interior's claim that it is not basing its assessment of the need for new coal leasing on the DOE production projections is not credible."

Commenters 089, 156, 079, 066, and 281

Response. DOE production projections play an important role in assessing the need for leasing. However, there are a number of other possible reasons for leasing that do not involve the DOE production projections. These include improving coal development patterns and creating greater coal industry competition. Long lead times require that coal be leased a number of years in advance of the date production is expected to begin. See the proposed regulations and Chapters 2 and 3 for further discussion of these reasons.

4. Comment. "The draft statement does not consider the impact of the preferred program upon demand for coal."

Commenters 089 and 019

Response. An increase in coal supplies driving down coal prices can be seen as a successful establishment of a competitive coal market. Coal companies will not produce below costs for long. The interaction between federal leasing and other energy prices would require a complete general equilibrium model of national energy markets. Such an effort is well beyond the requirements of this EIS. An analysis has been made of the impact of the preferred program on coal prices and a brief summary has been added to Section 2.8.1.

5. Comment. "The low crude oil price estimate should be increased and the 5.8 per cent NERC electric growth rate projection is practically useless.

Commenters 156, 038, 097, 099 and 104

Response. Future oil prices are almost impossible to predict with any certainty. A wide range of assumptions are thus needed. New gas price assumptions will be incorporated in succeeding model runs. It is on those succeeding model runs that the need for leasing would be continually reassessed under the preferred program and several other alternatives. The high electricity growth rate assumption is in line with long run historical experience, not unreasonable for a high assumption. From 1972, the average annual electricity growth rate was 7.2 percent. As recently as 1976, it was 6.3 percent. The electric utility industry is currently projecting 5.0 percent growth in 1985 as most likely.

6. Comment. "We are confused as to how (DOE) and DOI will resolve their projection differences and to whom the states will appeal if we are dissatisfied."

Commenters 155, 130, 170, 172, 187, 019, 079, 071, 089, 061, 062, 067, 097 and 066.

Response. The process for setting regional production goals is fully set out in the example regulations (see Appendix A, Section 3420.2). States will participate directly in this process and are assured access to the Secretary of the Interior before he makes his decisions on regional goals and targets. Comments on the regional goals (projections) will be taken at least twice before the Secretary makes his final decisions.

7. Comment. "The design and assumptions for the national coal model or NCM overestimate the need for western coal. NCM uses a least cost linear model which, among other things, assumes the resumption of leasing to make available least cost coal."

Commenters 156, 130, 170, 172, 019, 079, 087, 071, 089, 061, 062, 067, 042, 187, 097, 193 and 121

Response. The modeling assumption that all coal — Federal and nonfederal—is available provides a projection indicating how much production would occur without environmental, federal leasing or other constraints. Model runs are also made which specify that no Federal leasing will take place. It can then be assessed whether leasing of federal coal is necessary to achieve such a level of production. Any shortfalls that would occur without new leasing provide an estimate of the need for new leasing. This is a standard with and

without technique also used widely in traditional benefit-cost analysis. The decision might still be made not to lease for environmental or other reasons, or special environmental constraints could be introduced into the model. The purpose of the national coal model is not to maximize production, but to determine the least cost way of providing for national electricity and coal requirements. Estimates of underground mining versus surface mining reflect the higher costs of underground mining.

8. Comment. "The linear NCM model does not have a feedback mechanism to account for such certain constraints, or those due to environmental or socio-economic considerations."

Commenters 156, 170, 172, 079, 071, 061, 062, 067, 121, and 089

Response. This consideration is given to adding feedback constraints due to shortages or bottlenecks into future model versions. However, for projections 5 and 10 years in the future, there is still considerable time to make adjustments to avoid such bottleneck constraints, and these will be considered in the subsequent environmental analysis and in the two year regional production goal and leasing target setting procedures.

9. Comment. "Since the NCM production projections are linear programming model, the program alternative which depends on these projections similarly emphasizes production from the Powder River Coal Region. A policy of no new leasing would restrict available productions both by preventing expansion of the Federal coal lease reserve base and by affecting the economic viability of the Federal coal lease reserve base and by affecting the economic viability of private coal dependent upon adjacent Federal reserves for their development."

Commenters 121, 156, 147, 130, 170, 172, 187, 019, 079, 087, 071, 089, 061, 062, 067, 042, 097, 193 and 121

Response. Electric power and coal requirements are specified by consuming region, not by producing region. Thus, Montana, Idaho and Wyoming form one consuming region in the model with specific electric power and coal requirements. The model then solves for the least cost way from a national perspective of supplying overall electric power and coal requirements. The regional distribution of coal production results from the solution

to this cost-minimizing problem. There are no initial assumptions as to the role in coal production from any region (except that production must be at least as great as already committed regional production). The high production projections in the Powder River Basin result from the fact that total national costs for electric power production and coal transportation and mining are reduced by placing major reliance on the large and inexpensive surface minable reserves in this region.

10. Comment. "Any econometric model is basically inadequate. The DES acknowledges the existence of more advanced end-use forecasting methodologies, but dismisses using them as too time consuming and costly."

Commenters 156, 147, 130, 170, 172, 187, 019, 079, 087, 071, 089, 061, 062, 067, 042, 097, 193 and 121

Response. The DOE model is a linear programming, not an econometric model. It can be adjusted to reflect greater conservation expectations and reduced energy demands by changing the electric power and coal use growth rates. There are benefits to end-use analyses in that the specific circumstances of users are taken into greater account. On the other hand, these techniques are costly to apply on a national basis. It is also less easy to take account of factors such as the impacts of basic economic growth trends on electricity demands. Greater use of survey and other demand estimation techniques may be made in setting electricity and coal use assumptions for future production target setting. The entire production goal setting process will be reviewed and updated biennially.

11. Comment. "Table 2-29 on Page 2-45, 'Summary of Planned and Projected Production,' indicates that Fort Union would produce 21.8 million tons in 1985. Department of Interior's data on coal production should be correlated with the data from the Regional EIS."

Commenters 184 and 066

Response. The production projection for the Fort Union Coal Region of 21.8 million tons shown in Table 2-29 was developed by DOE. As shown in Table 5-2, for the purposes of environmental analysis, DOI modified the DOE projection to 31.9 million tons for the Fort Union Coal Region, partly because of the higher Fort Union regional EIS figures mentioned in the comment.

12. Comment. "Another factor which will result in the likelihood of demand levels lower than projected by DOE is the recent authorization granted to the EPA to require the use of local coal."

Commenters 089, 019, 079, 071, 061, 062, 066, 067, and

Response. Since EPA orders to use regional coal are issued on a discretionary basis, and seem to be somewhat controversial, there is almost no way in which this factor can be modeled. Predictions on how much coal production might shift from west to east would be highly speculative.

13. Comment. "How do exports fit into regional demand estimates?"

Commenters 019 and 089

Response. Export requirements are incorporated into regional coal demands in the specification of coal consumption assumptions for the DOE projections.

14. Comment. "DOI's estimates of total planned and likely production with which the DOE need projections are compared include planned and likely production from mines on existing Federal leases, planned production from Indian Lands and planned production from wholly non-Federal mines. Not included, however, is the production potential from outstanding Preference Right Lease Applications."

Commenters 089, 079, 042, 130 and 097

Response. It should be noted that issuance of preference right leases would constitute new leasing. PRLA production potential is not included in Table 2-29 because production projections for 1985 can already be met without resort to PRLA potential except in the Green River-Hams Fork Region. In this region, there is very little PRLA production potential. In Table 2-30, which examines 1990 leasing needs, PRLA production potential is in fact included, but as a separate column. This allows PRLA potential to be distinguished from the more stringent definitions for "planned" and "likely" production. Much of the total PRLA production potential is suitable only for underground mining, which has poor prospects in most areas. Of the 250.8 million ton annual PRLA potential, 143.6 million tons per year consist of potential underground mining in the Powder River Basin where it is generally recognized that little if any underground mining will occur for many years. Only 90 million tons per year represent

PRLA surface mining potential that may actually have a high likelihood. This potential is shown in Table 2-30.

15. Comment. "*Regional Production Targets.* Both the manner of intended application of regional production targets and the timing of their use presents serious difficulties."

Commenter 098

Response. DOE and DOI will be undertaking further efforts to develop production projections that are as accurate as possible. Further studies will be made to determine the best ways of translating regional production targets into federal leasing objectives.

16. Comment. "We question the assumption that exports will increase by nearly 50% between 1977 and 1985 as is indicated in the DOE projections."

Commenters 089 and 019

Response. The increase is much less than 50 percent. Projected coal exports in 1985 are 73.7 million tons. In 1970, U.S. coal exports were 70.9 million tons and in 1975 they were 65.7 million tons. Thus, although there have been ups and downs, little increase in export production is projected compared with recent higher years for U.S. exports.

17. Comment. "Since the preferred leasing system will superimpose production levels from above (DOE national projections), it would seem important to have some idea of what the ratio of outstanding leases granted/actual production levels should be. At this point in time the ratio of coal tonnage potentially available annually (based on a 30-year mining life) to existing Federal production is something on the order of 15:1. Recognizing the numerous constraints to development, has the Department given thought to what kind of ratio would be appropriate assuming that most leased areas would be developed?"

Commenter 281

Response. The Department recognizes that there will be a need to maintain some level of on-the-shelf, non-producing coal leases. This level will be addressed as part of the Secretary's decision on the levels of regional leasing needed during the coming decade. The Secretary's decision paper on need for leasing will discuss the topics set out in this comment. Finally, the 15:1 potential production to actual production ratio cited in your letter

is not the ratio that would be chosen by the Department as a matter of policy, and, judging from the amount of activity in mining plans being processed, the actual ratio will soon be greatly lower. Determination of the proper ratio requires consideration of future changes in production goals, the necessary lead time allowances, and the percentage of leases that might never reach active mine production.

18. **Comment.** "Because of the uncertainty involved in establishing 1990 production figures for western coal, we strongly urge the Secretary to hold off any decision on the need to lease until after EPA has reached a final decision on the NSPS and DOE has an opportunity to analyze the coal demand impacts of that decision."

Commenters 097 and 066

Response. EPA computer projections indicated only minor changes in western coal production according to the proposed new source performance standard (see Section 2.4).

19. **Comment.** "The ICF model overestimates Western coal demand."

Commenter 097

Response. The Interior Department believes that the range from low to medium to high projections covers likely future western coal production levels. The model will be reassessed and updated regularly to introduce any needed technical refinements or new assumptions.

20. **Comment.** "The inherent flaws in the DOE model give rise to serious doubts concerning its fitness as a tool for decision-making. These problems are compounded by the choice of assumptions and inputs on crude oil price, natural gas price, electricity growth rates, etc., employed in the DOE model adopted in the Draft ES."

Commenters 097, 156, 089, and 066

Response. Any likely coal production levels are covered in the low-medium-high range developed in Chapter 5 for analyses of the preferred program and the no leasing alternative. Coal projections will always be subject to modification as new information becomes available. In making a basic long-term decision such as whether to adopt a coal management program, fluctuating changes in coal production expectations should not be major factors. The assumptions employed by DOE in its modeling are generally reasonable, although cer-

tain changes, may be required. See other comments on specific assumptions.

21. **Comment.** "Input factors which DOI considered in its production target 'adjustment' process are listed in Appendix H, however, demand for the coal does not appear to be included."

Commenter 121

Response. The "predetermined" western coal production levels referred to are the DOE coal production projections adjusted for the effects on regional production of the different federal coal management alternatives. Coal demand is closely reflected in the DOE production projections and the adjusted figures derived by DOI.

22. **Comment.** "The DOE estimates of coal required for synfuel production and exports are overstated. For example, the low projection for 1985 was based on the assumption that seven (presumably liquefaction) plants with a capacity of 10,000 barrels per day each will be in operation by 1985; the medium and high projections assume thirteen and twenty-seven plants respectively. In view of the extensive Federal funding which will be required to make such facilities available on a commercial scale in the near future, we question the realism of these estimates."

Commenters 089 and 066

Response. Production of 10,000 barrels per day (oil equivalent) would be suitable for no more than a small demonstration plant. A single full scale commercial synfuel operation would produce in the range of 50,000 to 100,000 barrels per day. Production projected from the American Natural Gas plant in North Dakota, for which permits are now being sought, was recently scaled down from 100,000 to 50,000 barrels per day. Hence, the low 1985 assumption for synthetic coal use of 70,000 barrels per day is basically only one full scale commercial facility. Similarly, the medium and high assumptions would not require 13 and 27 full scale facilities, respectively. However, there may be a need to reduce somewhat the expected medium and high levels of synthetics production for 1985 at least.

23. **Comment.** "How does the BLM anticipate improving its data base to a level capable of making tract specific leasing decisions?"

Commenter 121

Response. In recent years BLM has made considerable expenditures for new inventories and other data gatherings. Further efforts would be continued as part of any coal management program. Where broad-area data are not available, BLM may have to rely on data specifically gathered for proposed leasing tracts.

24. Comment. "Industrial coal demand is overstated in the DOE projections."

Commenter 089

Response. Industrial demand is difficult to project. The National Energy Plan projected large increases in industrial coal use, but these were widely criticized. The rapid rises in oil prices, however, have spurred renewed expectations of possible major increases in industrial coal use. The assumptions for industrial use will be reexamined in the next projection update.

SUPPLY AND DEMAND

1. Comment. "The DES seems to imply that the largest reason coal needs to be mined in the West is that it is required there. This might be an appropriate and meaningful statement if one were not to question the definition of 'West'."

Commenters 118 and 097

Response. The largest reason for mining in the West is the need to meet national energy requirements. A substantial part of these requirements are in the West and can be met by western coal.

2. Comment. "The assumptions which underlie the ES's discussion of need for additional leasing greatly inflate the expected levels of supply and demand for coal, leaving us with an analysis which badly distorts the true situation and could be used to justify a need for leasing where none exists."

Commenters 060, 097, 118, and 281

Response. The low to high range of coal projection assumptions is very wide. High assumptions tend to promote western production, while low assumptions inhibit it. The range should be wide enough that most reviewers can find their own views as to the most likely energy and coal production within this range.

3. Comment. "Most non-Federal coal reserves in Montana have been eliminated from consideration in the DES because they occur outside the regions covered. Potential production from non-Federal

reserves could be important in Montana without additional federal leasing."

Commenter 071

Response. The areas in Montana with major nonfederal ownership outside the Fort Union and Powder River Coal Regions are projected by DOE to have little current development prospects.

4. Comment. "We believe that environmental protection and recent law enacted for that purpose both require a resource management policy in which coal management decisions must take place. However, the DES confuses the questions after failing, we believe, to definitively address demand and supply."

Commenters 097, 118, and 060

Response. The issues of supply and demand are addressed in Chapter 2. The elements of the preferred coal program which provide environmental protection are explained in Chapter 3.

5. Comment. "The major flaw in the PIES model is that it consistently overstates energy demand."

Commenter 097

Response. Predicting future energy production is an inherently very uncertain activity. Regularly revised forecasts of coal production will be prepared to try to keep as current as possible.

6. Comment. "The draft environmental statement does not give adequate consideration to alternatives for meeting the nation's energy demand."

Commenters 089 and 134

Response. The Interior Department did not originate the conclusion that coal should be a main avenue for reducing dependence on foreign oil. Heavy reliance on coal has been central to the National Energy Plan and almost all other analyses of national energy policies. It is unrealistic to expect that the Interior Department should perform a comprehensive analysis of alternative energy sources and the future relative national reliance on these sources as a part of this EIS. This responsibility belongs to DOE and also involves other parts of the executive and legislative branches in a continuing process. Similarly, any major analysis of national energy conservation potential would go far beyond a proper scope for this EIS. We note that a great many documents have been prepared by the Federal government on this topic including the recently completed CEQ

Report entitled 'The Good News about Energy". We think that these previous documents present the issue in great detail and the summary type materials in the statement are better suited to assist the decision-maker and the public in evaluating the proposed action.

7. Comment. "Although the assessment of likely coal production on pages 2-30 through 2-38 assumes current mining plan estimates of annual levels of production over a 30-year period, recent experience has shown that existing mines are capable of significantly increasing their production if the demand is there. We can find no legal or other obstacle under current legislation that would limit yearly increases in production. It appears that the economics of this approach are attractive, requiring minimal additional capital investment."

"Increases of production beyond mining plan levels do appear to pose considerable uncertainty to those planners who will try to estimate future leasing needs. Has the Department tried to make an assessment of what the upper limit of annual coal production is likely to be over time in terms of a minimum number of years of production from a lease? Are there any other practical constraints that would lessen this tendency to maximize production from industry's existing leases?"

Commenter 281

Response. The Department has not estimated what the upper limit of coal production from existing leases might be for all-out production. The Department views short term bursts in production lasting from a few months to a few years as not terribly relevant to the long term (5- to 10-year frame) decisions on need for coal leasing that must be made in this program. Maximum mine production is costly to sustain over the long term. New mines will be supplying coal that is less costly because it is being removed at a more orderly rate. These mines would be expected to be able to bid away any short term advantages an existing mine might gain from an increase in production due to a sudden increase in coal demand. Such increases in coal demand were seen in 1978 due to the shutdown of certain major coal fields during a strike. Men and equipment can be pushed at maximum effort for just so long before productivity falls and costs rise. Rising costs at the mine caused by too rapid an extraction rate will quickly be seen in rising consumer energy bills. The

Department is aware of the importance of its assumptions regarding typical mine life and will revise them if the industry norm changes. The Department will also consider readjusting the typical mine life if the Department of Energy exercises its authority in the area of diligence to force tracts to be mined out at a faster rate than the presently specified 40 year maximum time.

REGIONAL BOUNDARIES

1. Comment. "There is no rationale developed for the selection of the 12 coal supply regions." Commenter 025

Response. Regional boundaries were selected to represent common coal types, transportation routes, market areas, socioeconomic concerns and other common features. Future consideration will be given to changing regional boundaries if there appear to be problems with the current ones.

2. Comment. "The Colorado region, west-central Colorado should be in the Green River-Hams Fork production region."

Commenter 196

Response. A recheck of the west-central Colorado region does not establish that it should be moved to the Green River-Hams Fork region. However, regional boundaries are not unchangeable and the issue can be considered again in the future.

ALTERNATE ENERGY SOURCES

1. Comment. "Statement on p. 2-17 indicates that national installed hydroelectric capacity decreased from 1975 to 1977. This seems doubtful. Perhaps megawatt-hours produced decreased."

Commenter 121

Response. The statement should refer to actual production, not capacity. Production declined because of low water conditions due to drought.

2. Comment. "The discussion of solar energy is totally without substance."

Commenter 097

Response. Solar potential is a subject of wide controversy. The Department believes the estimates given are reasonable to the purpose of this program evaluation and that the full potential of solar can be considered in subsequent production goal estimates, widely available studies can be consulted if more detail is needed.

3. Comment. "One other task that the Department could undertake would be to expand on its brief discussion of Nontraditional Energy Sources."

Commenter 097

Response. The ES is focused on coal. Extensive discussions of other energy sources, traditional and nontraditional, can be found in referenced materials. Most readers would not be served by locating such discussions in Chapter 2 itself.

4. Comment. "Section 2.5, and particularly section 2.5.1 should be expanded to more fully consider the volatility of the international petroleum market."

Commenters 090 and 121

Response. A discussion has been added in Section 2.5.1 of the increased instability in the Middle East due to the Iranian change in government. Section 2.5 addresses noncoal energy sources. Coal is then discussed in Section 2.6.

5. Comment. "The trend of increasing production of oil and gas from the 'overthrust belt' is not discussed. Supplies becoming available from this new source should markedly affect growth of coal demand in the West, where it is stated that the majority of Federal leasing would take place."

Commenter 233

Response. This point has been added to Section 2.5.

EAST VS WEST COAL PRODUCTION

1. Comment. "Section 2.2 (page 2-3) makes reference to the fact that although the vast majority of low-sulfur coal reserves are in the western coal states, there are substantial low-sulfur reserves of coal in the East. This fact has been misconstrued by many critics of renewed Federal coal leasing to indicate that such low-sulfur coal in the East is a readily available and viable alternative to expanded Federal coal leasing."

Commenter 066

Response. As noted in the DES, much of eastern low sulfur coal is metallurgical. Because of the price premium metallurgical coal gets, expense would certainly be a major factor in any proposed plans to rely on eastern low sulfur coal for steam generation.

2. Comment. "Section 2.4 (page 2-10) discussed the effect of recent changes in Federal air pollution

standards for coal-fired power plants with the incredulous conclusion that: 'Overall demands for western coal will not be greatly affected by the new air quality standards, because most new demand for western coal will be from power plants and industries in the West.'

Commenter 066

Response. EPA studies indicate that new proposed sulfur standards will reduce western production by at most 10 percent. See additional discussion in Section 2.4.

3. Comment. "The DES justifies the large shift in coal production westward in part due to more rapidly increasing demand in the West. This is misleading."

Commenters 156 and 061

Response. Where coal is converted in the West and then the final energy product is consumed in the East, the use of western coal for western consumption purposes is in fact overstated. However, the great majority of western coal used for eastern purposes would be exported to eastern regions. The most important reason for the more rapid rate of growth in coal use in the West is the low base from which it starts. In the East, there has been extensive use of coal for power generation while such use is only now becoming common in the West.

4. Comment. "Nowhere in the DEIS was there a full analysis of the impact on the DOE forecasts of a limitation on Federal coal availability."

Commenter 090

Response. In Table 5-18 estimates are developed of the impacts on western and eastern coal production of alternative Federal coal management programs, including no leasing.

5. Comment. "Regardless of any alternative, there appears to be a need for separate coal management programs for the eastern and western U.S. due to the vast differences in regional environment."

Commenter 052

Response. The Department must manage eastern as well as western coal according to FLPMA, SMCRA, FCLAA, and other laws. Recognizing the requirement in these acts, the Department cannot find any benefit to developing two programs which would, by law, have to be substantially the same. The program does allow

the comprehensive land use planning step to be modified if the Federal resource in question is relatively insignificant and it can be managed in accordance with a state or local government land use plan.

EXISTING LEASES

1. Comment. "USGS mining supervisors estimated that 57.3 million ton production will result from existing leases which do not currently have mine plans. These estimates are entirely undocumented."

Commenter 156

Response. Whether or not a particular lease will get into production by 1986 is a judgmental estimate. It would be difficult to formulate any rules for making such judgments. Factors taken into account included lease size, mining cost, environmental problems, coal type and transportation. The estimates were made by GS mining supervisors who have first-hand knowledge of the circumstances of individual leases. The estimates were made in fuller form in task force reports and use data now incorporated into the Department's automated data system.

2. Comment. "In Section 2.8.2, the assumption is made that actual production of coal is not likely to occur until five (5) to ten (10) years after issuance of a lease."

Commenter 168

Response. It is likely to require at least one year to prepare a mine plan, one year to write and approve the plan, and two years to open the mine. Four years appears to be the bare minimum — assuming everything goes as fast as possible.

3. Comment. "In the document there is an absence of any resolution of the unnecessary existing leases in the environmentally unacceptable regions of the country, especially the West."

Commenters 130 and 105

Response. A new section in chapter 3 and a new appendix have been added to address all the elements of the program that affect existing leases.

4. Comment. "By starting with the KRCRAs as the areas in which coal leasing must occur, the Department has already and without any detailed industry input, excluded at least three-quarters of Federal coal lands from leasing."

Commenter 066

Response. The existing and planned KRCRAs include the areas with Federal coal that are believed to have any significant current development prospects. As industry or Interior exploration points out new areas, the Department will examine these areas and create new KRCRAs as appropriate. Congress has prohibited the Department from leasing lands which have not been classified for competitive leasing.

5. Comment. "Table 2-30, column 4 gives a figure of 11.3 million tons. This figure was calculated using small PRLA's which the BLM's Albuquerque District acknowledges can't be developed individually, or mined at all without the development of adjacent coal."

Commenters 019 and 097

Response. PRLA production potential was not surveyed by size of the PRLA. It is possible that some of the PRLAs would be too small to be developed. On the other hand, some of them could be incorporated into larger mines that included nonfederal coal and/or existing federal leases.

6. Comment. "Santa Fe emphatically rejects the "subalternative" of "not leasing in checkerboard areas" (4-136). The DES presents no practical justification for such a policy."

Commenter 096

Response. A policy of no checkerboard leasing was not one of the alternative coal management programs analyzed in the EIS. It is brought up more as a possibility that might in some circumstances be discussed. As it is discussed in Chapter 5 and in the Department of Justice's Report on Competition in the Coal Industry reasons for not leasing coal in those areas include the difficulty of having truly competitive leasing where one entity controls half of the resources.

7. Comment. "The potential of Indian leases is underestimated."

Commenter 097

Response. We believe the estimates are reasonably accurate and in the absence of new information to the contrary, have not changed them. Production of Indian coal has been well below expectations of a few years ago. Indian tribes are divided and uncertain as to the extent that coal development should be promoted. Legal disputes have tended to hold up Indian coal development.

Since no new evidence was submitted with the comment, no change was made.

8. Comment. "The lack of clarity continues in the review of the 172 outstanding PRLA's. The Draft ES accurately notes the significant reserves associated with PRLAs and then does its best to discount the potential."

Commenter 097

Response. The production potential of PRLA's reserves is substantial where they are surface mineable as discussed in Section 2.7.1.3. Underground PRLA reserves have limited potential except in the Uinta-Southwestern Utah Coal Region.

9. Comment. "Section 2.8.3 of the DEIS reflects the Interior Department position that it 'has little choice legally but to process' preference right lease applications (PRLAs). This attitude is offensive to Western Fuels and to others who have invested substantial money and effort."

Commenter 090

Response. The statement was not meant to imply any attitude about processing PRLAs but simply to state the fact that the Department's legal position, thus far sustained in the Courts, is that it must issue a lease within a reasonable time after an applicant has complied with the Department's regulations and to distinguish this from the competitive leasing situation where the Department has the discretion not to lease.

10. Comment. "The Department's argument that new leasing is required for legal and administrative purposes rests mainly on the legal requirement to process outstanding PRLAs. This, however, does not require the resumption of competitive leasing."

Commenter 097

Response. The Department's proposal to resume issuance of PRLAs is discussed in Sections 2.8.3, 3.1.1.6, 3.1.3, 3.1.4, 3.1.5, 3.1.6, and 3.1.7. In addition a new section is added to Chapter 3 and Appendix I which bring together and summarize all of the Department's proposed actions for PRLAs. It is true that the Department does not have the same legal obligation to proceed with competitive leasing as it does with PRLAs.

11. Comment. "Section 2.8.2 of the DES indicates that a decision by the Federal government not to lease Federal coal could result simply in a shift to the development of non-Federal coal sources."

Commenters 090 and 281

Response. These points are made in Section 2.8.2. A full examination of the impacts of development of non-Federal coal would require study of alternative Federal and non-Federal mining sites in each region. Such a study can better be done on a regional basis. Chapter 5 presents an analysis of interregional shifts in production due to no leasing.

12. Comment. "Table 2-5, the Hospah KRCRA is left out."

Commenter 019

Response. The Hospah KRCRA was not established until July, 1978. The study on which Table 2-5 was based included only KRCRAs established before March, 1978.

13. Comment. "Do we really want to chase production off unleased Federal coal lands and onto fee areas and existing lease tracts?"

Commenter 197

Response. The Department's only explicit policy in this regard is to favor development of coal lands underlying federally owned surface to development of those that do not, all other factors being equal. The relative benefits of development of private and federal lands are discussed in Section 5.4.

14. Comment. "As a first step, the Department needs to present a detailed discussion of the status of the present Federal leases and PRLAs. We are aware from the earlier programmatic EIS, that the Department has made some evaluation of the environmental merits of existing leases and PRLAs. Yet this most critical discussion has not ever been presented for evaluation in a public document. We believe this should be presented in the final EIS. A necessary first step would be to identify the size and location via regional maps of these leases (with and without mining plans) and PRLAs in the final EIS. EPA is also aware that the Department has begun an evaluation of high-priority Management Framework Plans in coal areas using the proposed unsuitability criteria. We have some reservations regarding the criteria as presently listed (discussed below). However, we think that an essential first step in implementing the transitional phase of the Federal coal program would be through unsuitability evaluation of existing Federal leases and PRLAs. Only when it is

possible to determine the number and amounts of existing leases that are environmentally and economically unsuitable can an intelligent appraisal of needed new leasing be made."

Commenter 281

Response. Because of the concern with existing lease and PRLA management, the Department is including with the final Environmental Statement a "Discussion paper on Departmental management of existing coal leases and preference right lease applications" as Appendix I of the final ES. The principal points in the discussion paper have also been incorporated in chapter 3, the description of the preferred program and its alternatives. The Department does not believe that a presentation of the status of all existing leases and PRLAs would materially benefit the ES. This material would immensely increase the size of the ES with a level of detail that may be of some interest, but is of little use to decision-making. This material is available from the files of the Bureau of Land Management. The U.S. Geological Survey did include environmental viability as a factor in their assessment of the production potential of existing leases. The Department would be concerned about making public these necessarily undetailed, professional judgments regarding future environmental conflicts that might face specific leases and PRLAs. The Department does not want to be bound to these preliminary estimates of whether operation on an existing lease or PRLA will or will not create problems or be permissible under SMCRA. Unsuitability assessments and the weighing of other environmental conflicts are an essential part of the process of adjudication of the preference right to a lease. It is beyond the scope of this ES to adjudicate the 172 pending PRLAs on their merits. In addition, the Department regards it as fruitless to conduct special assessments of existing leases for acceptability for development if no development is contemplated by the lease. The lack of production from such leases can be safely assumed in setting leasing targets without any further environmental assessment at all.

15. Comment. "Although we can sympathize with the U.S. Government's desire to promote greater competition in the western coal industry, we wonder whether additional leasing will have any practical benefits in this regard. It would appear that willing producers not now owning leases could

do so simply by buying them (through the assignment process). Will additional leasing change this situation in any discernable way? Other reviewers have indicated that there seems to be a tendency to concentrate the leases that have been sold. Recent sales of leases have been to large corporations. We wonder whether a situation of greater competition among lease holders might result from new leases rather than among coal producers. We do recognize that diligent development requirements may alleviate this situation. We wonder whether a provision to eliminate re-sale of leases might further prevent concentration and speculation. Although there may be benefit in having re-sale of present leases, we can see no good reason why re-sale of future leases would have practical advantages to government or commerce. A lease could simply be returned and re-leased if necessary. Would a statutory change be necessary to implement such a provision, and if so, has the Department considered doing so? How will the Department police assignments that are made?"

Commenter 281

Response. The Department records indicate that most coal leases have passed into the hands of companies with the capital and the technical expertise to develop them. Previously there was an element in the coal lease market that was principally interested in the leases for their possible resale value. As the Secretary will first judge the need for leasing and then decide on targets for leases for coal production, the coal program should reduce the earlier high levels of speculation that were evident among Federal coal leases. The Department is making an effort to put coal leases in the hands of new groups of producers through the public body and small business special opportunity lease sales. These new entrants should enhance competition in the coal industry. The Solicitor's Office is now examining the question of legal limits on the Department's ability to manage assignments; the policy question you raise in your comments will be considered if it is determined that such actions are within the authority of the Secretary. An advantage of assignments is that they do allow the Department greater certainty that the leasing targets will be met. That is, they increase the probability that the coal in any Federal area will be mined by some company, if not the original company winning the lease. If leases were to be returned for reletting, the

Department's ability to conduct leasing to satisfy a target would be lessened. The Solicitor's paper on assignment of leases will be available when it is completed.

16. Comment. "Para 2.8.3 This paragraph should acknowledge that it is presently illegal for the Secretary to make exchanges of existing leases and that Congressional legislation is necessary to give him this authority. This authority, by the way, is sorely needed, and should be addressed as a means of reaching the goals of the Preferred Alternative."

Commenters 019 and 135

Response. The Secretary does have limited exchange authority. In addition lease modifications and bidding rights may be usable for exchange with holders of undesirable leases. The Department is on record as favoring a general exchange authority, but is not recommending that the Congress re-open examination of this question until it can do so in the context of an operational coal management program. The Secretary's authority in this regard is fully set out in a new appendix in the final ES.

NEED FOR NEW LEASING

1. Comment. "Para 2.8.4 states that increased leasing may increase competition in the coal industry, but it does not state how stifling to competition have been the laws issued since 1970."

Commenters 019 and 043

Response. The Department does not believe that on the whole the laws passed since 1970 have stifled competition. The reverse appears to be true since new laws require: competitive bidding with bonus bids deferred at least half of the time, impose more strict acreage limitations, ease entry into federal coal for public bodies and involve Justice Department pre-lease issuance anti-trust review. The Justice Department noted in its report to Congress that all markets are workably competitive, but leasing should resume to prevent future problems.

2. Comment. "The DES seems to assume that cancellation of leases in 1986 will create an abrupt discontinuity in production potential that can only be avoided by new leasing prior to that time. The fallacy in this position is that production estimates are based on current intentions, leading naturally to a shortfall in the longer term."

Commenters 042, 060, 062, 043, and 097

Response. The Interior Department intends to cancel existing leases not producing by 1986. Leases lacking production plans now will have a difficult time in achieving 1986 production. If there is to be a supply of new Federal leases available to begin production from 1987 on, these leases must be awarded well before the year production is expected to begin. From four to seven years after lease issuance is likely to be required to get a mine into production. Hence, if production is expected from new leases in 1987, these leases should be issued soon.

3. Comment. "Don't just encourage 'new entry in coal mining' to encourage competition."

Commenter 160

Response. It is not clear from the comment what is suggested. The Justice Department is primarily concerned with controlling outright collusion. The Interior Department's greater Federal leasing will aid in dealing with this problem.

4. Comment. "The analysis of national need for leasing is based on a questionable and illogical assumption that national need can be determined on a regional level at a later date."

Commenter 058, 043, and 038

Response. It is difficult if not impossible to assess the national need for leasing without looking at regions. The national leasing need is the cumulative need that results from the separate circumstances of the regions where Federal coal is found.

5. Comment. "There is a puzzling sentence in the ES which reads 'The principal consequences of leasing less Federal coal than is needed to meet national energy objectives would likely be to alter patterns of coal development, both at the national and regional levels'."

Commenters 103, 168, 062, 187, 097, 096, and 087

Response. According to computer projections of coal production under a no leasing scenario, the greatest impact of an absence of Federal leasing would be to shift coal production from Federal to nonFederal coal. In some cases such shifts would occur within the same coal region. In regions without much nonFederal coal, an absence of Federal leasing would cause production to shift to other regions with greater nonFederal production potential. The effect of these shifts would be to

alter coal development patterns, and the decline in overall national coal production under a no leasing policy probably would not be very great. The greatest cost to the Nation of no leasing thus would probably be in the less environmentally satisfactory and less economically efficient development patterns that would result.

6. Comment. "In the final analysis, the Department bases its justification for adopting a new coal leasing program on the perceived future need for vast amounts of Federal coal."

Commenters 097, 042, and 103

Response. At the risk of oversimplification, it would base this decision on its evaluation that (1) Congress has given it the authority to manage Federal lands (2) Federal lands contain vast amounts of coal (3) under some conditions it is clear that this coal can make an important contribution to national energy needs and (4) the Department must be ready to respond to any needs that do occur with a program that will work quickly, efficiently and result in environmentally sound development. The Department is not basing its proposal to adopt a program directly on any specified level of need for leasing whether it is characterized as vast or minuscule.

7. Comment. "The Department proposes that new leasing is necessary to promote desirable patterns of coal development. This argument assumes that private coal development patterns will be undesirable."

Commenters 097 and 103

Response. The environmental statement discusses the pro's and con's of developing private versus public lands for coal in Chapter 5. The analysis shows that on a general review there are comparative advantages and disadvantages to develop each. These include factors such as proximity to transportation, effect on wildlife, grazing, agriculture and availability of land for new housing. Because each region has different characteristics, however, it is very difficult on a national level to "prove" that Federal development is better than private development or vice-versa. This is one of the factors that could be studied in any regional coal leasing statement.

8. Comment. "A sound Federal management program is an essential element of a national coal

resource management strategy that can serve to mitigate the impacts of a no-lease policy."

Commenter 122

Response. The Department agrees completely with this statement. One of the three major factors the Secretary will be asked to consider in making his decision on the need for leasing is the environmental benefits that will result from relying on a soundly planned Federal coal management program. Starting up the program not only benefits the environment from the greater degree of planning for new mines, but also, and possibly more important for the short run, benefits such other elements of the coal management program as lease exchanges, existing lease management, and preference right lease application management.

9. Comment. "In its zeal to escape the problems created by errors rampant in earlier leasing efforts, the Department has established a program primarily aimed at new leases."

Commenters 103, 042, and 058

Response. The Department has proceeded with equal emphasis on the management of existing leases and on the need to study and prepare for a new leasing program. Additional material has been inserted in Chapter 3 that explains these efforts.

10. Comment. "Two questions of great interest to us with regard to the proposed Federal coal management program are, one, how it was decided how much coal needs to be mined and, two, how is it decided which new land should be leased for coal mining. I will just briefly outline our concerns on these two issues tonight and also submit further comments before the deadline."

Commenter 134

Response. In answering these questions the Federal coal management program will consider the following major factors:

1. The DOE National Energy Plan target figure for coal;
2. The advice of the individual states;
3. Information available on industry plans for future mine openings and expansion;
4. Utility industry future plans;
5. Industry expressions of interest in Federal coal leasing;
6. Development potential of Federal coal deposits;

7. Recommendations from the public, state and local governments, and other Federal agencies;
8. Environmental and social capacity of various areas to withstand coal mining.

Many of these factors are set out in the ES, but the ES does not draw a conclusion. This conclusion will be reached by the Secretary after he has considered the ES and comments received on the preferred coal management program.

11. **Comment.** "The preferred alternative seems the most sound of the seven presented. However, throughout the report and particularly in Chapter 2, it is emphasized that new coal leasing will be necessary to satisfy future demand since nearly all existing non-producing leases will be cancelled in 1986. The incongruity of this situation (canceling leases and issuing new ones at the same time) should be examined further. Once the coal management program policies and criteria are applied to existing non-producing leases as outlined in section 3.1.1.5, it might develop that enough acceptable leases of commercial quality exist to obviate or reduce the need for a new leasing program. Although some means might be found to get the good idle leases into production, the possibility is never discussed in the DES."

Commenter 233

Response. The Department prefers that good idle leases come into production and that these leases reduce the need for new leasing. The Department is certainly not pursuing a policy of aggressively cancelling existing leases during the period before diligence requirements come into play. Quite the opposite, the Department is seeking to encourage the development of these leases within the next seven years if they are environmentally acceptable. Congress, through its provisions to ensure the diligent development of coal leases, established standards that would require the cancellation of leases that are not in production by 1986. There is also provision in the existing regulations to consider the particular circumstances of each lease and possibly offer some form of relief to existing lease holders. The entire policy area of diligent development, while administered by the Department of the Interior, falls within the policy setting powers transferred to the Department of Energy by the Department of Energy Organic Act.

DILIGENT DEVELOPMENT

1. **Comment.** "Our concern is with the criteria for due diligence which are now inadequate to their intended purpose of keeping Federal resource management in the hands of Federal land managers."

Commenter 042

Response. The Department of Energy is responsible for issuing new diligent development regulations. DOE is examining possible means to tighten diligent development standards in the course of preparing regulations. We note that the Congress considered but rejected tougher standards prior to the time it passed the Federal Coal Leasing Amendment Act. The Interior Department is also exploring ways to ensure the enforcement of the current standards.

2. **Comment.** "The Department argues that if demand is not strong enough to stimulate development of existing leases by 1986, the enforcement of diligence requirements will result in the cancellation of these leases, necessitating new leases in order to meet demand by 1990. The argument does not make sense, however, in view of the fact that the Secretary of the Interior has discretion to extend that period for five years."

Commenters 089, 163, and 062

Response. The five year extension has only limited applicability. In addition, the Interior Department cannot plan its future leasing on the assumption that diligent development standards for existing leases will be relaxed. Many of these leases would be environmentally and economically inferior to potential new leases. Demand may be insufficient by 1986 to stimulate production in that year, but increased demand in subsequent years may require new leasing to accommodate production starting up in those years. If no leasing took place, this might affect the Department's decision whether to extend the period, rather than vice-versa.

3. **Comment.** "In the meantime, we cannot understand from the ES why existing leases, if diligently developed, will not meet coal needs."

Commenters 163, 089, and 042

Response. Existing leases for meeting coal needs will generally only be available until 1986, when they are expected to be cancelled if not yet producing. New development of Federal coal after that will require new leasing well before the

production is expected to begin, if demand equals or exceeds the medium projection levels.

BONUS BIDS

1. Comment. "It is difficult to support the conclusion that an excess of leases offered would result in so much less compensation being paid to the government in lower bonus bids than the resulting loss would not be more than offset by the total gain realized when even a few such leases are developed."

Commenter 066

Response. Excessive leasing would create strong pressures for reduced bonus bids and production distortions. While certain measures could be taken to counteract these pressures, these measures would have costs and there would be no guarantees of success.

STRIP MINING RULES

1. Comment. "Does the decision to suspend the effective date of the strip mining rules affect the coal leasing ES?"

Commenter 121

Response. The coal programmatic ES involves long term issues not significantly affected by the effective date of the strip mining rules. This date could, however, affect decisions made under a new coal management program, if one is adopted.

PREFERRED PROGRAM

1. Comment. "We feel the statement should indicate the level at which various decisions in the proposed leasing process would be made. References are made throughout the statement to decisions to be made by the 'department.' To those not familiar with the Department of the Interior, its many bureaus and agencies, regional, state and district offices, the entire leasing process could become a confusing maze. We respectfully suggest that the final document indicate what offices or officers would be involved in the various steps depicted on the schematic flow charts on pages 15, 16 and 17 of chapter 3 (which are figures 3-2, 3-3 and 3-4)."

Commenter 159

Response. Chapter 3 of the FES contains more detailed information on the elements of the preferred program. The proposed regulations also clarify these relationships.

2. Comment. "A second major concern relates to implementation of the preferred program. Our questions relate to whether Interior will have the budget, expertise, and necessary legislation to see the preferred option through."

Commenters 155, 170, 098, 120, 147, and 083.

Response. The Department recognizes that this proposed program, as well as the new land use planning program mandated by FLPMA, will require more comprehensive resource inventories and socio-economic planning and impact assessment capabilities. The Department is requesting funds to meet these needs. In addition, it expects to depend to a greater degree on local and state government planning, particularly in the socio-economic area, in developing its own plans and the environmental assessments required by NEPA.

3. Comment. "Number 8, funding. As with other government programs funding and personnel are key elements of a successful endeavor. I am not concerned that Montana may be burdened—I am concerned that Montana may be burdened by this financial crunch. I have not seen an adequate assessment of the coal program budget and the State's role in that budget."

"The Environmental Statement clearly admits that it lacks a significant data base to implement the entire program in all of its regions.

"Base-line scientific studies are extremely vulnerable to budgetary cuts, which, conceivably, could jeopardize the proposed program. The legitimate demands of the nation and equally legitimate constitutional rights of present and future generations of Montana must be balanced."

Commenter 170

Response. The Department is fully aware of the budget and man-power requirements of conducting the program as proposed. It is recognized that obtaining the necessary support will be a continuing problem.

4. Comment. "CWI is concerned, however, that in seeking to achieve the maximum degree of environmental and community protection, on a national scale, the Department has created a system which is excessively complex, prone to extensive delays, and extremely unpredictable."

Commenters 120, 088, and 098

Response. The preferred program is not considered excessively complex, prone to delay, or unpredictable. Since many of its elements are

required by new law, it is unfamiliar. The Department believes that all involved will find the program is workable, not unduly lengthy, and understandable and that it strives to serve the public in an environmentally sound manner.

5. Comment. "Obviously, if you are going to have any coal mining at all you will have to have some people mining the coal. In other words, you are going to have to have industry or one person working on his own coal mine, and if this is so, you are going to have to have people producing the coal, and in this statement you hardly refer to industry at all, as I understand it, so I have just got one page here which I thought was rather significant. This is on Page 3-1 in your preferred program for Federal coal management. It's right at the bottom of the page. In this preferred program the four primary goals list things that are strictly your own business, you might say, that are pertaining to the Federal Government and not really what industry would be involved in. It seems to me like one of your four primary goals would be a harmonious relationship with the coal mining industry and I don't think you really indicate that at all in your Draft Environmental Statement, so my comments have been rather broad here."

Commenter 150

Response. The Department recognizes that coal is produced by private enterprise and the importance of having a program that will meet their needs. For this reason, the Department will look for industry advice and counsel during every major stage of the program.

6. Comment. "Individual coal operators should be compelled to internalize the cost of their operations on the impacted local communities by contribution of front end money for community development."

Commenter 160

Response. The Department agrees that the burden of meeting these financial needs should be placed on the coal production and conversion activities. The methods for accomplishing this should be determined by state and local governments.

7. Comment. "As the title of the Draft ES acknowledges, the 'Preferred Alternative' is much more than a Federal coal leasing program. The title calls it a Federal Coal Management Program. Given

the massive mineable coal deposits owned by the U.S. which 'overhang' the coal industry and the markets for the coal industry; given the mine shutdowns occurring in the east as the OSM regulations are applied and the costs of complying with OSM, EPA, OSHA and other agency regulations become apparent; and given the necessity for significantly increasing coal production to stand any chance for our Nation to avoid economic disaster resulting from physical shortages of energy or from the Nation's inability to afford higher volumes of higher priced oil from overseas; knowledgeable people will recognize the Proposed Program is more than a Coal Management Program. It is a coal control program. By reason of the foregoing, it is a *National Coal Control Program*.

In essence; the government will determine what coal is needed; what to make available; where and when to make it available; what must be mined; how it will be mined; at what production rate; at what return on investment and possibly how, where, and by whom the coal will be consumed.

Query: If Congress set out to nationalize the nation's coal industry what further 'controls' would be necessary to achieve that result beyond what the 'Preferred Alternative' provides?"

Commenter 053

Response. The Department acknowledges that the Federal government will estimate national demand for coal, estimate how much of that amount will come from each of the proposed production regions and of that amount, how much should come from Federal lands. The Department will be responsible for leasing enough Federal coal on each of those areas to meet that estimated demand. (These goals may not be met if they are incompatible with the previously developed land use plans.) In addition to the above Congressional directives, the Department must insure the maximum economic recovery of the coal resource and a fair market value return for Federal resources. Limits are also placed on production by the diligence requirements. The Department is not proposing any rules that would prescribe end use; however, there are other Federal standards, particularly air pollution controls, that will influence the end use of coal. The Department does not believe it is appropriate for it to recommend what steps are needed to nationalize the nation's coal industry. It should be noted, however, that most of the coal

being produced today is not coming from Federal lands and, therefore, would not be controlled by this program.

8. Comment. "Members of the association have attended the informational meetings in Billings and Miles City. It is our opinion the Draft Environmental Statement would propose the Federal Government restrict the marketing of coal from Federal lands by determining where a company that has a sale for coal is located. The Federal Government personnel would decide whether or not a customer for coal should be permitted to purchase coal from Montana or from Illinois or some other state. We believe this is contrary to the free enterprise system and opposes the process of the supply and demand marketing system that makes the United States economy function. We strongly oppose the Federal Government using the leasing of Federal coal in this manner to manipulate the the market place for coal, as defined in Sections 2.8.2. and 2.8.4."

Commenter 179

Response. The Department will not dictate any marketing terms for a particular company. The Department will determine the demand for Federal coal in a production region and lease that amount of coal to the highest bidders, assuming the amounts of coal demanded can be met within the constraints of established land use plans.

9. Comment. "Finally, we urge the preparation of a Regulatory Analysis in accordance with the provisions of Executive Order 12044, signed by the President on March 23, 1978. The proposed coal management program appears to meet the criteria of section 3 of EO 12044." In "We also urge that the Regulatory Analysis examine the impact of the proposed coal management program upon the coal industry itself, as well as coal consumers. Such an analysis should be beneficial to the decision-making process, and, of course, should accompany the proposed regulations, when published."

Commenter 089

Response. Your comment in regard to regulatory analysis has been considered by the Secretary. He has decided to conduct enhanced economic analyses of maximum economic recovery and of unsuitability criteria.

10. Comment. "Interior's program must comply with a number of laws enacted by the Legislative

Branch. Interior's program for leasing falls within the purview of NEPA and requires a 'legally adequate' ES. The Program and the required ES do not depend upon justifying the 'need to lease'. Furthermore, leasing itself is no longer, if it ever was, a 'major federal action significantly affecting the human environment'."

Commenter 053

Response. The Department must examine the no-action alternative which, when compared to any alternative that includes the leasing option, results in an analysis to determine a need for leasing. The Department, therefore, chose to address this issue directly rather than indirectly.

11. Comment. "We find, as another shortcoming of the proposed program and the draft EIS, far too much emphasis placed on strip mining as opposed to underground mining. This is inconsistent with DOI's Coal Extraction Task Force recommendations that emphasis be placed on underground mining in order to minimize environmental and social impacts. The reasons cited by this group were: to avoid the serious environmental impacts of a large increase in strip mining; to concentrate on the vast majority of the available coal resources which are farther underground; to lower required production level due to the higher energy content of deeper coal; and to provide the smoother growth and sustained production associated with underground mining, as opposed to the boom-bust cycle associated with strip mining. The EIS should address the recommendations of this task force."

Commenter 085

Response. The conclusions drawn here are largely in error.

1. Underground mining has different but equally troublesome environmental impacts. The two greatest problems are the much greater number of people required to extract an equal amount of coal. This leads to greater socio-economic impacts, as well as environmental impacts from increased urbanization and general land use demands. In addition, human safety hazards associated with underground mining are much worse than those associated with surface mining.

2. Surface mines are no more prone to boom and bust than are underground mines.

12. Comment. "On page 3-18, Col. 1, the DES describes proposed planning rules and regulations by both the Forest Service and the BLM. However,

there is no discussion of how the two agencies will coordinate activities, or which agency will prevail in the event of conflict. There should be specific discussion of the Department of Interior's plans to avoid stalemates in areas of multiple agency control."

Commenter 094

Response. "A memorandum of understanding" is being negotiated between the Bureau of Land Management and the U.S. Forest Service for managing coal leases from Forest Service land. Relationships between the two agencies are clearly spelled out in the law (e.g., Section 3 of the Federal Coal Leasing Amendments Act of 1976); good relationships exist between the two agencies, and the Department does not expect that any managerial impasses will develop. When completed the memorandum of understanding will be available to anyone interested in the specific details of this relationship upon request to the Department.

13. **Comment.** "I am concerned about many of the economics-oriented policy questions, on such topics as bidding systems, allocated by statute to the Department of Energy, but for which coordinated working relationship of the two agencies must be strong in practice. The vague memorandum of understanding found in Appendix B of the Environmental Statement is no guarantee of performance. Interior established a rigorous schedule for itself and has held to it. It seems that Energy should do the same."

Commenter 147

Response. The Departments of Energy and the Interior will diligently work together, where necessary, to implement any decisions to which they must mutually agree.

14. **Comment.** "Our questions are:

-What effect will the proposed program have on development or production of these coal resources?

-To what extent have these coal resources been considered within the framework of a Federal Management Program?"

Commenter 031

Response. The effects of the proposed program are presented in Chapter 5. For more detail on coal resource consideration in existing MFP's, refer to Chapter 3.2.11.

15. **Comment.** "Para. 3.1.1. I recommend 2 points to be added to this Preferred Program:

- a. Add an exchange authority to allow the Secretary to retain coal lands which may have other greater values.
- b. Allow selective noncompetitive leasing to assure cheap coal supplies for local markets."

Commenters 019 and 135

Response. Lands with greater value for other resource features than coal recovery will be eliminated from leasing by unsuitability designations and resource trade-off planning decisions made during the initial land use planning stage of the preferred program. The Department is limited in how it may reobtain the mining rights to undesirable existing leases. It may do so only by offering compensation in the form of:

- a. lease exchanges and fee land exchanges if the existing leases are in alluvial valley floors,
- b. bidding rights,
- c. lease modification, and
- d. exchange for lease on another Federal leasable mineral.

The Department unsuccessfully sought generic exchange authority for undesirable coal leases during the last Congress. It presently lacks such exchange authority. Small amounts of non-competitive coal are available for local markets through the coal mining license feature described in the regulations (see Section 3440); the Federal Coal Leasing Amendments Act of 1976 otherwise removed the authority to sell Federal coal through noncompetitive leases.

16. **Comment.** "The preferred program should include provisions for denying federal leases to companies or individuals that are in violation of performance standards established under the Surface Mine Control and Reclamation Act of 1977."

Commenter 061

Response. Final SMCRA regulations which are implemented by the Office of Surface Mining, provide the appropriate enforcement.

17. **Comment.** "Wyoming has created many organs of State and Local Government which deal with various aspects of coal development. Where Wyoming has addressed these questions, I naturally oppose Federal actions which would pre-empt

or tend to abrogate functioning state and local authorities. By and large, the preferred alternative has successfully avoided these sorts of conflict. A number of examples illustrate the problem and the point.

"(1) The Land Quality Division of the Department of Environmental Quality has primary authority for mined land reclamation in Wyoming. It is possible for stipulations in BLM leases to infringe upon the determinations that are properly left to our state regulatory authority. The preferred alternative has consciously avoided this conflict.

"(2) Our Industrial Siting Council protects the health and welfare of Wyoming by operating permit procedures which thoroughly examine new energy facilities in Wyoming. Interior has proposed an investigation of its authority to regulate the end uses of coal, which might affect the powers of our state authority. The proposal is presently tabled for further study, and I hope that it will remain tabled indefinitely."

Commenter 147

Response. The Department will not propose actions contrary to the State's interest as expressed above.

18. **Comment.** "General. We consider the sections of the DES treating evaluations and assessments of regional environmental impacts to be comprehensive and of such quality and scope as to properly address all levels of potential leasing activity. We have serious concerns, however, about the Preferred Coal Management Program described in Chapter Three. In our judgment, this proposed program has several fundamental problems:

1. We are concerned that some of the laws upon which the program is based do not properly recognize the balance required by our nation's environmental, energy, and economic goal.
2. The land use planning system, as proposed, goes far beyond the President's intent regarding environmental protection, and seriously jeopardizes attainment of coal production goals.
3. The inherent uncertainties associated with utilizing long term projections of coal supply and demand to determine the need for leasing could result in underestimating the levels of leasing necessary to meet our nation's future coal requirements.

4. The potential consequences of a more centralized form of Federal coal management, the exclusion of industry input to the land use planning process, and the prospects of underleasing of needed coal resources on our nation's energy and economic goals have not been adequately addressed."

Commenter 084

Response. This comment is answered as follows:

1. Congress is responsible for the laws upon which the program is based. The Department acts on the assumption that these laws are the nation's goals.
2. The land use planning system is aimed at meeting the multiple-use goals of the nation, one of which is energy production. The Department anticipates meeting those goals within the framework of existing laws and the proposed land use planning and coal management program regulations.
3. All predictions of future demand are subject to reasonable question. The Department recognizes the need to maintain adequate supplies of coal available for development. The management system proposed would make coal available for leasing seven to 10 years ahead of anticipated production dates. Coal demand would be updated every two years. If additional needs were evident, new leasing would be initiated. In addition to these demand projections, the Department will be concerned with artificially high prices for coal and may lease coal to improve competition if the administration determines it is in the national interest. The Department will not act to constrain the national level of coal development. It may constrain development in local areas where it serves the local, state or national interest.
4. All interested parties, including industry, will be able to participate in the land use planning process. (See proposed BLM planning regulations, Federal Register, December 15, 1978.) Areas that are desirable for development can be identified by industry. However, no tracts will

be identified until the activity planning step. Text has been added in Chapter 3 to discuss industry's role in land use planning—a role which the Department hopes will be very active.

19. Comment. "With respect to the amount of federal coal which will ultimately be available under the preferred alternative for the Federal coal leasing program, it must be observed with deep regret but not with a great deal of surprise that the Department's present position is apparently that, if all the various government agencies to be directly involved in leasing cannot, among themselves, or by virtue of public comment think of *any* reason for excluding a tract of federal coal land from leasing, the tract in question might possibly then be considered for a lease sale. Some specific parts or characteristics of the preferred alternative which would seem to unnecessarily restrict the amount of federal coal available for leasing are:

1. Designation, by means not fully discussed and probably not quantifiable, of only those reserves of "medium and high potential" as available for leasing;
2. Apparent reliance on existing Known Recoverable Coal Resource Areas (KRCRAs) as defining the areas in which future federal coal leasing will be considered, even though the present KRCRAs include a very small portion of all of the Federal lands that are known to contain the coal resources; and
3. Implementation of no less than 24 separate unsuitability criteria for elimination of otherwise qualified Federal lands from any future consideration for leasing by what will apparently be a much more uncompromising application of such criteria than is mandated by law and which has been experienced in the past."

Commenter 066

Response. Congress has eliminated exploration for coal by private companies through the use of preference right lease applications. The proposed regulations do provide for private exploration of Federal coal (see subpart 3410). The Department has an active program which will, in time, define the nature of all Federal coal resources. Available manpower and budgets limit the amount of land use planning the Department can do in any given

period; therefore, some limits must be in place on how much of the Federal lands will be reviewed for potential coal mining. The Department believes it is reasonable to limit its efforts to those areas where there are known coal resources of medium to high potential for development. These areas are described by procedures set out by the U.S. Geological Survey and are available upon request. Text has been added in Chapter 3 and provisions have been added in the proposed regulations to ensure those areas not already classified as having medium or high development potential can be considered if existing data or new data presented by industry or others indicate a reasonable probability of developable coal being present.

The unsuitability criteria are based on numerous statutes and clear environmental policies stated by Congress. The authority for these criteria are shown in a new table added to chapter 3.

20. Comment. "The DES states that under the preferred alternative, 'The principal coal resource decision in the land use plan would be the determination of which areas are acceptable for further consideration for coal leasing.'

"In fact, however, the process described as the preferred program consists of screening all federal lands through a series of successive reviews, the sole purpose of each of which is to preclude, on various grounds, any further consideration of the lands involved for federal coal development.

"The process itself, and the sequence of the decisions in the program, systematically gives precedence to all other articulated environmental social and natural resource development policies. Land management decisions would be required to be made in the absence of adequate information concerning the nature or desirability of federal coal resources. Indeed, the recognition of the relative importance of such resources in comparison with other competing environmental or social values is specifically precluded throughout this stage of the planning process."

"However, both industry and the Department might have a specific need for the coal involved in any given area: industry might require a lease to complete or obtain access to an otherwise undevelopable logical mining unit of federal or non-federal coal, while the Department might determine that coal from a given area is required to fulfill one of its 'production targets' (see discussion,

below). In either case, throughout this process of elimination, there would be no opportunity to identify such specific need."

Commenter 098

Response. The preferred program consists of a series of screens which eliminate lands from further consideration for coal leasing. The first screen would eliminate all those lands which have no known coal resources or coal resources of low potential economic value. The second screen would be the application of unsuitability criteria. This screen would eliminate areas from consideration for the leasing that are protected by environmental statutes or policy. The third screen would be a multiple-use trade-off screen in which areas which may not be protected by the unsuitability criteria but have unique or strong local support for protection would be eliminated from consideration for leasing. We would expect that relatively small amounts of land would be permanently precluded from this step, but instead, the timing and amount of development that would occur would be controlled. The fourth screen would be applied as a result of the surface owner consultation. Recognition of the relative importance of coal resources with other competing environmental and social values would be specifically included in the multiple-use planning step. The leasing targets would be applied during the activity planning stage. It is assumed that sufficient areas will be available in the early years to meet these leasing targets. Should it be impossible to meet a leasing target in any specific region, the possibility and advisability of shifting that demand to another region would be studied. As the social and environmental values changed, however, additional coal resources may become available in the planning areas in question.

21. Comment. "Western recommends that the Department include a timetable for the planning tract identification/leasing/environmental assessment process, to include a guarantee for meeting this timetable. The proposed process appears awfully complicated and unwieldy, and the coal and utility industries would like some guarantee that this ambitious program will be carried out in a timely fashion."

Commenters 019 and 135

Response. The following timetable shows expected typical times to conduct the activities referred to in the ES:

Comprehensive land use planning	two-three years, with most of the activity occurring during the last year
Activity planning	18 - 24 months
Target setting	six-nine months
Tract sales	beginning one to two months after the Secretary's decision on the lease schedule and continuing over four years

It should be kept in mind, however, that these activities will be conducted in parallel, and it would be expected that if a need for coal leasing is determined in a region, there will be tracts coming up for sale within that region continuously.

22. Comment. "With respect to the various planning stages leading to a lease sale, (Fig. 3-1), there should be timetables projected for each identifiable step so that the total timetable could be incorporated into a development schedule for potential lease applicants, particularly for relatively new entrants such as Santa Fe. These timetables should then be further broken down to apply to the detailed process steps defined in Figs. 3-2, 3-3 and 3-4."

Commenter 096

Response. A general table indicating typical times needed to accomplish the major steps of the preferred program has been provided in response to another commenter. The details of the processes encompassed within these major steps was not developed sufficiently to be ready for publication with the final ES. These times are available from the final task force reports that will be completed for the Secretary's decision. Departmental representatives in State and District BLM Offices are always available to discuss with anyone interested the details of the coal management activities of the Department.

23. Comment. "Section 3.1.1 describes the general characteristics of the preferred alternative for the proposed federal coal leasing program. In general, this discussion should satisfy the requirements resulting from the decision *NRDC v. Hughes* that

any proposed federal coal leasing program be described in sufficient detail.

"There are, however, several points concerning this program which are disturbing to industry. First is the apparently inflexible requirement that all necessary land use planning involving the identification of coal lands, the application of the numerous unsuitability criteria and the nebulous resource trade-offs be completed before the activity planning stage can proceed which involves regional environmental impact statements. Considering the tens of millions of acres of land involved even if new coal leasing is restricted to existing KRCRAS, it is difficult to believe that the Department can maintain the schedule for resuming actual lease sales within eighteen months after the adoption of a coal leasing program. In fact, related land use planning efforts by the primary public land administrative agencies, the Bureau of Land Management and the Forest Service, concerning wilderness designation would seem to make it absolutely impossible to keep such a schedule. It is imperative in the preferred alternative be expanded to include specific assurances, with supporting illustrations that such a schedule can be accommodated."

Commenter 066

Response. The Department is directed to manage lands according to a comprehensive land use plan (FLPMA and FCLAA). The Federal Land Policy and Management Act validated all existing Federal land use plans. About 85 percent of the BLM administered land has such valid plans. The Department has proposed these plans be updated by applying the unsuitability criteria. Once this step is completed, activity planning can begin. The Department must strike a reasonable balance between developing all new land use plans under new planning regulations, which will take 10-15 years to complete, and issuing new leases under existing plans without any review. Section 3.2.8 describes the process the Department proposes to pursue. The Department is well aware of the demands that will be placed on the BLM. It should be noted that the Department cannot compromise the values protected by statute in order to expedite coal development, there is nothing magic about a goal to begin leasing in 18 months, and no such goal has been set. The Secretary must first reach a decision that there is a need for renewed leasing. If he does, contingency

planning by the BLM has suggested that competitive leasing could resume within 12 to 18 months of the Secretary's decision.

24. Comment. "It should be expressly provided in the new program that those areas previously nominated under EMARS II, and those areas with respect to which specific indications of interest have been or may be received by the Department, shall automatically and on a priority basis be advanced through the land use planning process and subjected to review under the activity planning process."

"Moreover, we suggest that on a continuing basis the orderly development of the nation's coal resources would be best served by providing in all instances that the coal industry and all interested persons be afforded an opportunity to focus the attention of the Department upon particular land areas for consideration for division into tracts and offering for lease."

Commenter 098

Response. The Department has developed a planning process which will identify those areas that are suitable for consideration for leasing. At the beginning of the tract identification and evaluation phase of the process, coal industry and all other interested parties will be afforded an opportunity to focus the attention of the Department on particular land areas for consideration for division into tracts. At that time, areas previously nominated under EMARS II that are located in those areas determined to be suitable for consideration for leasing can be renominated by industry. No consideration will be given to the EMARS tracts prior to this step of the process.

25. Comment. "Lastly, we hope that the Department will evaluate ways in which to streamline and better integrate the coal permitting processes and incorporate such ideas into the final EIS. As you know, the current environmental review and regulatory processes at all levels of government are cumbersome, duplicative, wasteful, and overly time-consuming. Rather than improving our environmental understanding of a project, the existing fragmented approach has impaired our environmental awareness."

Commenter 155

Response. Lease stipulations, a central feature of the coal permit, logically follow from the coal leasing management program described in this

Environmental Statement. Paragraphs 3.2.4.2 and 3.3.9 described stipulations of a preliminary nature to assure the proposed lease would be economically and environmentally acceptable. As explained, the subsequent mine plan required of a lessee would involve more detailed and perhaps different stipulations. In large part, the coal permitting process is subsequent to the described management program, but early and continuing opportunities for public and industry participation provide for smooth integration of the management and permitting processes. In addition, the Department and representatives of the western coal states have investigated opportunities for greater administrative efficiency among the Federal and the various state coal management programs.

26. Comment. "Section 3.3.9 concerns the relative detail of stipulations for environmental protection which would be attached to a particular lease prior to sale and then to any mining plan submitted upon lands covered by that lease. The only comment on this procedure is that it would be a great disservice to the objectives of the coal leasing program if the stipulations attached to the mining plan were significantly different or more restrictive than those attached to the lease. A bidder for the lease has, in all fairness, a right to know that the mining plan stipulations will not be so different from the lease stipulations or from typical mining plan stipulations that a significant quantity of the coal he had expected to mine is rendered unmineable."

Commenter 066

Response. The Department agrees.

27. Comment. "The first area of concern that we have is the initiation of an exchange and the timing of such a proposal. Specifically, who should initiate the fee coal exchange? Will the Department of the Interior, through the Bureau of Land Management's land use planning efforts, approach the fee coal owner and/or lessee concerning an exchange? Or will the fee coal owner and/or lessee have the burden of initiating the exchange?

"Our position is that both the fee coal owner and the fee coal lessee, as well as the BLM, should have the right to initiate coal exchange procedures. The fact that a fee coal owner or lessee initiates the procedures should not mean that they must automatically bear the cost of the exchange procedure.

"In conjunction with the above, the Department of the Interior has not made it clear in the draft EIS as to how the coal exchange program fits into the overall context of the 'preferred alternative' for the Federal Coal Management Program. For example, will the Federal coal available for exchange purposes be included in reaching final regional production targets under the Federal Coal Management Program? Will a BLM land use study be required prior to exchanging Federal coal under the Federal Coal Management Program? Will the Federal exchange coal be subject to regional tract ranking selection and scheduling similar to that for leased Federal coal? What role will the public have in any coal exchange program? Will the unsuitability criteria be applied to all lands proposed for exchange prior to such an exchange taking place? Would there be a maximum acreage limitation on the Federal exchange coal? Will there be any provision made for emergency exchange of fee coal within an alluvial valley floor when such an exchange is needed to meet the fee owner or lessee/operator's contractual commitments? What role will the local and State governments play in the exchange program?

"Will the Department of Interior consult with other agencies such as the EPA, Department of Agriculture, etc. to determine if those agencies have any objections to the particular Federal coal tract to be exchanged for fee coal? These questions must be addressed in the final EIS in order to provide the Secretary of the Interior a complete picture of the impact of the proposed management program.

"Peter Kiewit Sons' position is that exchange coal should not be included in reaching final production targets for Federal coal deposits or for tract ranking of Federal coal. The rationale is that the Federal exchange coal is replacing fee coal that would not be subject to production targets and ranking for Federal coal. On the other hand, any land containing Federal exchange coal should undergo the unsuitability review in order to ensure that the exchange coal will be mineable. Furthermore, the Department must adopt procedures for emergency exchanges of AVF coal when such an exchange is necessary to meet the fee owner or lessee/operator's contractual or other financial commitments."

Commenter 100

Response. The administration of fee coal exchanges is now being studied by a Department task force with results expected by May, 1979. Your comments and suggestions will be passed along to this task force. You should also review the proposed regulations presented in Appendix A for answers to many of your questions. We agree that the exchange program should not affect regional coal target setting in so far as production potentials are the same: the tracts to be exchanged may well come from the tract ranking and selection process used for preparing new tracts for lease sale.

28. Comment. "There also appears to be an opportunity to create Regional Coal Advisory Panels for each of the 12 coal supply regions. These advisory panels would be similar to the Geothermal and Oil Shale Advisory Panels, and could provide a means for input into the program in each coal region by the public, industry, special interest groups, and state and local representatives. This would reaffirm the Departments' position that the preferred coal program be *continually* responsive to the interests of organizations and individuals."

Commenter 01 and 13

Response. Extensive participation has been structured into the Federal coal leasing process. While advisory panels have been useful in the case of oil shale development, we believe they would be of only marginal use in the case of coal management since coal management already includes very extensive participation and communication opportunities. The preferred program will include Federal-state regional teams with defined roles. These regional teams will guide the entire coal activity planning process.

29. Comment. "Since Friends of the Earth will present more detailed comments at other such hearings, my statement will address a narrow apparent inadequacy in the Federal Coal Leasing (sic) Draft Environmental Statement, this being the complete failure of the Statement and due process. Without question the resumption of federal coal leasing will stimulate industry activity, thereby placing an even greater strain on an already overwrought state enforcement process. Alternative methods for implementation of federal oversight and watchdog responsibilities under all relevant statutes must be described. It is rather obvious at my level of involvement that the present

system is in some difficulty. Cady v. Morton, F.O.E. is now in the seventh year of our effort to ensure due process for the East Fork Sarpy Basin. Yet we may lose on a simple inability to post an enormous bond that a court might require before looking at the coming impasse that has been obvious for all those seven years and has often been brought to your attention. Such an eventuality would be a travesty of justice and proof that the general public can expect no chance at due process in the enforcement of coal mining statutes and regulations.

"There must be no resumption of federal coal leasing until the citizens are assured that the law will not continue to be taken as lightly as at present by some major parties to this process. The present Environmental Statement offers not the slightest hint that your office is aware there is a problem."

Commenter 181

Response. Enforcement and public participation concerns regarding mining and reclamation activities are more appropriately addressed to the Office of Surface Mining's permanent regulatory program. Due process and enforcement are detailed in OSM's regulations which are designed to handle vigorous coal development to meet the nation's future energy needs. The relationship of such activities and programs to the level of leasing determined to some degree by the alternative chosen in the coal management environmental statement is not sufficiently direct to merit the extensive coverage requested. It is anticipated that the program developed by OSM will fully protect the public interest, allow extensive participation and effective enforcement. Included in OSM's activity is full review of state enforcement offices, authorities and resources. A separate, full environmental impact statement on the OSM permanent regulations has been prepared.

30. Comment. "Our fifth concern is that management program goals will not be achieved because of inadequate enforcement. The heart of the new management approach is mitigation of social, economic, and environmental impacts in one way or another. As we read current laws, if impacts cannot be mitigated adequately, then mining shall not occur. Land managers will attempt to screen tracts prior to offering leases for bid, but ultimate responsibility for mitigation must lie with the

purchaser. To enforce this responsibility we feel two new requirements are needed: the mine development plan submitted by the lease holder should include proposed measures to mitigate all anticipated social, economic, and environmental impacts (to include arranging for front money where necessary) with documentary evidence sufficient to support the reasonable conclusion that the proposed measures would be successful, and the prior record of a bidder or lease holder should be admissible for consideration by the land manager in deciding such matters as whether to accept or reject a bid, whether to approve a development plan, or whether to require the posting of a bond."

Commenter 042

Response. The GS and OSM or the state regulatory authority are responsible for enforcing the terms of the lease agreement. The Department is responsible for developing the lease stipulations. Such stipulations will require the mitigation prescribed by the FLPMA, SMCRA and other applicable Federal and state laws. Complete mitigation of all impacts is clearly not possible. There is no legal basis for requiring a company to provide "front money" for public services, and the Department will not recommend such action. Prior records of would-be bidders will not, generally speaking, be considered for qualifying bidders. All lessees are required to post performance and reclamation bonds.

31. **Comment.** "A programmatic impact statement represents a task unique in Federal policymaking. It imposes a nondiscretionary duty upon Federal officials to think in a certain way about discretionary acts. The programmatic impact statement is a vehicle for introducing human environmental values into the decisional process. It is designed to affect and inform that process from its earliest stages, yet is required to be made public, subjected to public scrutiny and comment, and to be responsive to public views. The programmatic impact statement requires an agency to consider values outside its mission at the very moment it develops the basic policies for carrying out its mission. It requires comprehensive analysis which ranges far outside the normal ambit of an agency's responsibility. For this reason the programmatic impact statement is unique and essential. It is

virtually the only process for effectively addressing such broadscale human concerns."

Commenter 089

Response. Yes, we agree. The Department has responded to NRDC's concerns in its formal response to their letter to the Secretary (of February 15th, 1979) alleging possible violations of the *NRDC v Hughes* agreement. Unsuitability comments have been filed for consideration when the results of field tests are on hand - April or May, 1979.

32. **Comment.** "Far more comprehensively than its predecessor, the DES addresses critical issues. But the analyses begun are often left incomplete. Discrete topics are described but remain isolated, unconnected by analysis. The treatment of the need for leasing is critically deficient. The description of the environmental and other impacts which will result from the development of Federal coal is inadequate. Important issues, including the rehabilitation of mined lands, are treated only cursorily. The alternatives considered are not genuine alternatives, but rather fragments of alternatives."

Commenter 089

Response. We do not agree with most of this comment. Chapter 5 has been expanded to provide a more detailed discussion of the reclamation and rehabilitation issue.

33. **Comment.** "It is apparent that this draft impact statement, like the previous draft and final programmatic impact statements, fails to contain a 'detailed' explanation of the proposed preferred management program. While the number of pages devoted to explaining this program undoubtedly exceeds the number of such pages contained in either of its predecessors, it does not present a comprehensible and comprehensive picture of the manner in which coal leasing decisions will be made. Thus it effectively prevents readers from making an informed judgment regarding the degree to which this program will achieve the Department's expressed goals."

Commenter 089

Response. The comment is rather unbelievable in view of the great detail in Chapter 3 (both in the draft and in the expanded final). The example regulations presented as an appendix to the statement in the draft (now proposed regulations), and the widespread availability of background papers clearly explain the Department's goals.

Significantly the comment lacks any concrete examples of where problems do exist that interfere with an understandable program. Equally significant is that virtually all commentators were able to understand the program. We will continue to improve the clarity of the program as the Secretary decides what part or parts of the proposal he will adopt.

34. Comment. "As a consequence of our position that there are many substantive deficiencies in the proposed coal management program, and because the EIS recognizes that some existing leases and PRLAs are not acceptable for development, EPA believes that the Department's first priority should be toward fully developing the analyses of existing leases and PRLAs that are unsuitable for mining. We urge the Department to concentrate on using both the land use planning process and the activity planning phase to identify unsuitable existing leases and PRLAs. Any leasing in the near term should be oriented toward replacing those existing leases that are unsuitable for mining. The Department should then re-evaluate the need for additional leasing given such an exchange program."

Commenter 281

Response. The final ES incorporates extensive discussions of the management of existing leases and preference right lease applications in Chapter 3 and Appendix I. The Department looks to existing leases and to non-competitive leases issued as a result of preference right lease applications as sources for coal to meet regional production goals before it considers new leasing. The Department, under the preferred program, would use the land use process and the activity planning process to identify unsuitable existing leases and PRLAs, though, because of existing rights, the Department will have to consider these leases and applications on a case-by-case basis. Analysis of the regional levels of leasing would include consideration of the impact of unsuitability findings on existing leases and preference right lease applications. Finally, a consideration in the formulation of regional leasing targets is the need to identify mining units to support the exchange features of the coal management program. The Agency comment reflects a lack of understanding of the statutory limitations under which the Department must manage existing leases and PRLAs. There is no

statutory authority for carrying out general coal lease exchanges on the public lands.

35. Comment. "Section 3.1.1: The Preferred Program. The seventh element of the preferred program, 'a strategy to integrate the environmental analysis requirements of the National Environmental Policy Act of 1969 in the new program', is extremely important. It is impossible for national and regional leasing programs to adequately analyze site-specific impacts or recommend appropriate mitigation measures. There must be a mechanism for identifying and solving site-specific problems on a site-specific basis."

Commenter 266

Response. The program provides several opportunities for conducting site specific analyses. Each step in the process is at an increasing level of specificity. The program, thus, clearly provides for adequate analysis of site specific impacts. Site specific analysis will first occur during the preliminary tract analysis step immediately following tract delineation. There is an additional opportunity for site specific analysis together with regional cumulative analysis during the selection of the regional sales schedule; in this process, some tracts might be scheduled late in the four-year sale period covered by the schedule to allow additional data to be gathered on them or might be entered in the schedule on a contingency basis subject to additional pre-sale analysis results. Finally, site specific analysis will be carried out under the Surface Mining Reclamation and Enforcement regulations as part of the mining permit process.

36. Comment. "Chapter 3 creates a significant misapprehension that the Forest Service has the statutory authority and responsibility to plan for the disposal of coal. We believe any such connotation should be removed from the text in publishing the Final Environmental Impact Statement, and that such authority and responsibility be recognized as a function of the BLM."

"The problem starts to surface in *Section 3.1.1 Planning Systems* with the statement that the Department of the Interior would rely on the land management agencies' planning systems in both the land use and activity planning stages to provide the initiative and the forums for decision making regarding the Federal coal program.

"In the discussion under *Section 3.2.2 Activity Planning*, it states that, on completion of the land

use plan, preliminary tracts would be identified within the areas designated acceptable for coal mining. In delineating the tracts, the *land management agencies* would consider such items as:

- (a) technical coal data, including reserve tonnage, sulphur content, etc.;
- (b) coal conservation, including maximum economic recovery, etc.;
- (c) expression of coal mining interests on adjoining lands, etc.;
- (d) surface ownerships, including terms of private surface owner consent, etc.

In essence, BLM's activity plans are analogous to Forest Service functional plans. However, we know of no Forest Service authority, under either the old or new planning concepts, which would allow planning for disposal of a specific mineral resource other than common varieties, such as sand and gravel.

"The Federal Coal Leasing Amendments Act of 1976 contains a mandate that the Secretary of Agriculture take into consideration any proposed coal development in 'comprehensive land use plans.' It further states that the Secretary of Agriculture shall include an assessment of the amount of coal, identifying the amount which is recoverable by deep mining, and the amount recoverable by surface mining operations.

"We perceive these requirements will be met in the process of developing the multi-functional Forest plan. Forest planning will also be the forum in which lands suitable for coal mining are identified, as well as giving broad consideration to the impacts from such activity."

Commenter 282

Response. Should reorganization occur, this comment could become moot; however, the necessary changes have been made in the final environmental impact statement. The roles of the Forest Service and the Bureau of Land Management in managing coal under the National Forest System lands will be set out in a memorandum of understanding between these agencies now under negotiation.

37. Comment. "(Page 3-6) The FES should address the question of how mining plan reviews fit into the processing of preference right lease application associated with existing leases."

Commenter 091

Response. The coal management program has not set a policy on this subject. The question should be raised again in connection with the MOU to be negotiated among BLM, GS, and OSM on coal management.

38. Comment. "(Page 3-5) Mine Plan Approval." Material in section 3.1.1.4 implies State could approve a mining plan without Departmental approval. To correct this we suggest deleting the words "... the State agency or" from the third sentence so that it would read, "To obtain the permit, the lessee would be required to have a mining plan approved by the Department if a plan has not been previously approved or requires change, the new plan must be included in the permit application."

Commenter 091

Response. The implication that a state could approve a mining plan on Federal lands without Departmental approval is not correct. This is a shared responsibility (see section 741.4 of the OSM, Permanent Regulatory Program, 44 Federal Register 15311-15463).

39. Comment. "(Page 3-5) With regard to production target, the DES states that 'the Department would review and, if necessary, adjust the portion of the national targets which applies to the eight regions containing Federal coal.' The FES should provide an expanded discussion of what is actually involved in the review and adjustment function".

Commenter: 091

Response. Chapter 3 in the final statement contains a more detailed discussion of how the regional production goals and leasing targets are set.

40. Comment. "(Page 3-2) What criteria will be used in the inter-regional analysis to determine regional production targets?"

Commenter: 091

Response. The criteria considered in determining targets from DOE's production goals are:

1. Industry need
2. Environmental impacts
3. State and local gov't policy
4. Public comment

41. Comment. "(Page 3-25) In Section 3.2.4.2, the DES states that the Department would conduct an environmental analysis for each proposed lease to develop lease terms and stipulations so that the

Department could be reasonably certain that the lease would be environmentally acceptable. What would be the extent of this environmental analysis? Does it appear that a site-specific mining plan environmental statement would later be required?"

Commenter :091

Response. The Department intends that the environmental analyses will be to a depth at which the Department can be reasonably certain of no unexpected environmental impacts after leasing. We intend as much as possible to consolidate the environmental analysis of the Federal LMU with that of the mining permit and reclamation permit process in our analyses prior to leasing and to seek all means of making these processes compatible. Even so, however, it would be expected that ESSs will be needed for a few mining permit approvals because of the limits of our resources available for preleasing analysis and because of changing circumstances.

42. Comment. "(Page 3-36) Would all pending mining and reclamation plan approval actions be included in the regional leasing environmental statements?"

Commenter :091

Response. Our intention would be to include these plans in the regional ES wherever possible.

43. Comment. "*Preleasing.* A principal theme of the preferred alternative is the determination *prior to leasing*, that a specific tract can, with reasonable certainty, be developed in an environmentally acceptable manner. If such a determination is to take place prior to leasing, detailed baseline data must be used together with "red-flag" criteria (or levels) for possible non-achievement of the performance standards of SMCRA (e.g., restoration to equal or better land use, restoration of approximate original contour, and protection of the hydrologic balance). The red-flag levels might be developed, for example, with respect to the sensitivity of surface and ground water to degradation; topsoil availability; vegetative cover and species; and wildlife habitat."

Commenter :091

Response. OSM will be asked to be one of the "expert" agencies participating in the ranking and selection processes, including review of the tract profile analysis for flagging special OSM concerns.

ALTERNATIVES

1. Comment. "I think another thing—and this is sort of the alternative that I would opt for—is that we need to be looking at a combination of the alternatives that you have there, that instead of just saying we want the preferred alternative or we want short-term criteria or no leasing, that instead you ought to be looking at different ways you might try to pull this all together."

Commenters 148, 130, 058, 135, 019, 195, 060, 145, 107, 108, 123, and 089

Response. The Department, after analyzing the various issues associated with Federal coal management, has proposed a full range of options that cover all reasonable alternatives available. As shown from the summary in Chapter 3, the preferred program is composed of numerous elements, each of which may or may not be part of the final program.

2. Comment. "Section 3.1.1.8 describes how an emergency leasing system to maintain existing mines or to permit the mining of otherwise bypassed federal coal would be coordinated with the broader Federal coal leasing program proposed. The purpose of this emergency leasing program is to respond quickly enough to situations in which a broader long range leasing program would result in the loss of coal or employment unfairly. However, it is apparent from reading this section that since the emergency program could not proceed until the complete land use planning stage is finished, that such "emergency" leasing would, for at least the next few years, offer no relief to coal operators who would otherwise be in a position to benefit, and to benefit the government, by mining coal that might otherwise be lost. The need for such comprehensive land use planning before such emergency leasing, which is certainly going to be on a very limited basis either in terms of the acreage in any particular lease or the cumulative effect in any region, would seem to be unjustified. It should be enough that if the emergency lease is not clearly in conflict with the likely land use scheme for the area that the lease could proceed without such crippling delay."

"The insistence that an environmental assessment be made for each such emergency lease, presumably with public hearing requirement and resulting delays, is likewise unjustified. It would seem from the discussion of emergency leasing

under the preferred alternative that such a system would completely replace any emergency leasing which is not now permitted under the settlement agreement in *NRDC v. Hughes*. Serious consideration ought to be given to preserving that portion of the settlement agreement which now permits such emergency leasing rather than redoing essentially the same program in the form of a component of the long-term coal leasing program."

Commenters 066, 059, 073, and 184

Response. Emergency leasing would conform with existing land use plans as updated by the application of unsuitability criteria. The emergency leases will not require redoing land use plans under the new proposed planning regulations (see Section 3425.2 of the proposed regulations); analysis will be conducted on a site-specific basis. Using this method, the BLM will be able to respond quickly to emergency needs. The proposed regulations on emergency leases have expanded on the existing *Hughes* standards for short-term leasing.

3. **Comment.** "In section 3.1.1 and 3.1.1.6 of the DEIS a discussion is had of the interrelationship of the preferred program for federal coal leasing with the processing of PRLAs and lease issuance. A much fuller discussion of PRLA treatment must be included in the FEIS which would consider, *inter alia*, the application of environmental and planning standards to PRLAs, the procedure to be followed if preference right lease issuance for a specific lease is opposed by the Department and the legal basis for any non-issuance of a preference right lease. Part 3430 of the example regulations, Appendix A to the DEIS, are of some assistance, but they do not fully delineate the impact of this treatment of PRLAs.

It is Western Fuels' understanding that these regulations are not yet proposed. When and if they are proposed, Western Fuels will comment fully upon them."

Commenters 090, 083, 013, 108, 112, 066, 098, 145, and 095

Response. The description of the management of preference right lease applications has been revised and expanded with a new section in Chapter 3 and a new appendix (Appendix I) to make the Department's intentions with regard to this large class of possible coal leases clearer. Environmental and planning standards will be

applied to the PRLAs during general land use planning or planning amendments; if a preference right lease holder successfully makes final showing of commercial quantity and the Department still opposes the issuance of the lease because of general planning considerations, the Department may enter into negotiations for exchanging the non-competitive lease for another lease if possible and where permitted by law or for other consideration.

4. **Comment.** "Mobil particularly objects to DOI's attempt in the preferred program to subject existing leases and preference right lease applications (PRLAs) to the same standards as new Federal leases. The preferred program would accomplish an unauthorized change in the meaning of "commercial quantities" in connection with existing PRLAs and would also retroactively affect existing lease rights. Existing lease and PRLA rights cannot be changed by the rules developed for new leases without raising serious legal problems."

Commenter 083

Response. The Department recognizes that preference right lease applications and existing leases have a special standing in the law (see Appendix I). The comment raises only general objections to the aspect of the preferred program; it does not give any specific examples, or any supporting rationale for its views. It is somewhat difficult, therefore, to respond to the comment. We will respond to more detailed comments submitted on the proposed rules and offer the following general response at this time.

Existing Leases. The most important point is that the "unsuitability criteria" do not all have the same statutory source; they come from a variety of laws, executive orders and general rulemaking power. Some are derived from statutes passed 10 or more years ago. Other are derived from section 522(e) of SMCRA and impose restrictions which the Department must enforce. The second most important point is that the Department's authority to apply some criteria may depend on the particular lease involved. Most lessees have agreed to be bound by subsequently enacted regulations; some have not. Particularly in the case of discretionary standards, the lease terms may decide whether the Department has the authority to apply the proposed conditions. The third important point

is that *none* of these past standards would apply to producing leases and that leases for which there have been substantial legal and financial commitments are substantially exempt from the standards. Suggestions on how to better clarify these points in the final rules are encouraged.

Noncompetitive (Preference Right) Lease Applications. The application of the unsuitability criteria is not a change in the "commercial quantities" standard. Section 30 of the Mineral Leasing Act requires the Department to set lease terms to protect the public interest. The Department has a long-standing practice and case law of exercising its authority to set different lease terms for a noncompetitive (preference right) lease than it might have used at the time the prospecting permit was issued. The unsuitability criteria are nothing more than a lease term that the Department, in accordance with Section 30 of the Mineral Leasing Act, is imposing to protect the public interest. The filing of a preference right lease application does not prevent the Department from exercising its authority to impose lease terms that protect the public interest. This principle applies not only to unsuitability standards but also to conditions affecting rent, royalties and diligent development.

LAND USE PLANNING

1. Comment. "The document often confuses the need for resource management with the need for leasing. It ignores or shortchanges several management issues not directly related to new leasing. Coal policy seems to be outrunning resource policy and the implementation of adequate land use tools."

Commenters 156, 069, 019, 135, 130, 098, 159, 200, 068, 194, 101, 148, 178, 060, 083, and 137

Response. The ES clearly sets out, and differentiates between multiple resource management (land use planning) and coal resource management (activity planning). The discussion of land use planning in the final ES has been re-edited for clarity. Coal management and the Department's other resource responsibilities, e.g., land use planning program, wilderness reserves, grazing ESs, surface mining protection, and endangered species protection, are being coordinated. The coal management program review has included participation from all Bureaus and offices with the Department having potential to play important

roles in the final program. Both FLPMA and the Forest Services' Organic Act, specifically, allow the use of existing land use plans in the interim until new plans prepared under the Acts' standards are available. In this way the Congress expressed clearly the need to avoid paralyzing this Nation's resource management program while the new planning systems were being put in place. This issue is discussed fully in section 5.4 of the impact statement, which reviews the alternatives of using existing plans as is; using the existing plans with modifications (the preferred alternative); and delaying all cost activities of the Department until new plans were available.

2. Comment. "The principal weakness of the discussion on land-use planning is the absence of definition concerning the screening process for coal leasing. There is no serious misunderstanding about lands not containing coal reserves with 'high to moderate development potential' or lands declared unsuitable for leasing under the provisions of SMCRA, though we have serious reservations about the latter. However, the statement that areas which 'are considered to be of higher value for other uses as determined by multiple-use, resource management trade-off decisions' would be eliminated from further consideration for leasing does not provide an understanding of either the criteria or the mechanism by which comparative land-use values are to be judged. Clearly, economic considerations are not prominent in the trade-off, since much of the Federal land containing coal has no other potential use rivaling coal development on economic grounds. Hence, the 'higher value' must refer to environmental, social, or aesthetic considerations which are not spelled out in the DES."

Commenter 069

Response. Resource management decisions are necessarily subjective, because all public land values cannot be reduced by one common denominator such as economic return. The proposed rulemaking for BLM planning regulations published in the Federal Register on December 15, 1978 reveals the methodology that will be used in making resource use decisions. Section 1601.0-8 explains the principles of planning to be followed. In part 5 Response Management Planning Process, the various actions taken in a planning effort are described. The Department has received many

recommendations that it prescribe specific values for various resources beyond those defined by law. This is generally viewed as a method to gain control over the resource without judging its value relative to other associated resources on a site by site basis. If we assume seven resource uses—minerals, timber, watershed, recreation, wildlife, grazing and lands—we can construct 5,040 possible rankings. The Department does not believe that the selection of one of these 5,040 possibilities would result in good land use for all federal lands.

3. Comment. "The Secretary's preferred coal leasing program ignores the possibility that Federal coal may occupy a minority (perhaps insignificant) position in some attractive coal mining areas.

"Hopefully, isolated tracts of federal coal can be included in an LMU and be mined in the public interest."

Commenter 074

Response. The tract identification process will consider state and privately-owned coal where that coal is available for mining in forming LMUs. The industry indications of leasing interest and the close cooperation of the states in the tract delineation, ranking, and selection process should facilitate our ability to offer coal to complete LMUs and to time lease sales with private and state coal lands actions.

4. Comment. "Chapter 3 discusses alternatives briefly and the proposed program in detail. Several problems are inherent in the preferred alternative:

"1) The federal land use planning process is indefinite at this time, since proposed BLM planning rules are in a draft state. The planning process is a very important step in Federal coal leasing. It is therefore imperative that well defined and formally adopted regulations be provided and discussed in the DES. It is irresponsible to state that 'the land management agencies' planning efforts...are to provide the initiative and forums for making of the principal decisions in the Federal coal management program' when the mechanics of these planning efforts are in limbo.

"All areas to be considered for possible coal leasing should be subject to the new planning process rather than based on results of the old process. The DES states that proposed differences in the planning process (BLM) are designed to substantially improve the quality of land use plans.

This implies that existing plans are not nearly as good as new plans could be. A land resource decision as significant as coal leasing should not be based on the lower quality existing land use plans. Decisions should be postponed until new plans are available."

Commenters 038, 061, 071, 147, 148, 156, 158 and 173

Response. Proposed regulations have been published for the new BLM and Forest Service planning systems. Because of this and because of our day-to-day working relationship with the managers of the BLM planning system and their involvement in the coal management review, we can see no difficulty in continuing to further define these two processes in parallel. We do not believe that it is good public policy to delay the possible year for coal leasing by four years at a minimum while waiting for new plans to be prepared. Existing plans would be supplemented to meet the requirements of the coal program should the Secretary decide to proceed with the leasing of coal from any particular region. The decisions on which plans will be reissued first are not based on which plans have coal leasing, but on a balance of the many other resource management concerns pending before the Bureau of Land Management at this time. Both FLPMA and the National Forest Management Act permit the use of existing plans until new plans are available in order to avoid management paralysis. This is a clear indication that the Congress did not intend to freeze all resource decisions, including those on coal, until they could be made in the context of a "new" plan. This issue is fully discussed in Section 5.4 of the final ES.

5. Comment. "The lands unsuitability criteria are a joke since exceptions are listed for virtually every criterion. It is not in the interest of sound land use planning to make exceptions for everything. Definite plans for evaluating unsuitable lands should be included in the planning process. It is stated that "a responsible official would make his recommendations on the best available data that can be obtained given the time and resources available to prepare the land use plan". This is utterly ridiculous. The land use planning process should be designed to include methodologies to provide for a sound evaluation of unsuitable lands in a timely manner. Too many Federal decisions in

the past have been based on "best available data ... given the time" with less than desirable results."

Commenters 038, 061, 071, 147, 148, 156, 158, and 173

Response. The Department believes that the use of exceptions with unsuitability criteria will ensure a better program and one that is more adaptable to individual situations. We have structured the use of exceptions so as to discourage anyone that would abuse them. Similarly, the local land managers have been instructed to continue lands in the system about which they may be unsure only if they provide for the collection of data and its analysis in order to remove this doubt. Until the BLM office is reasonably sure of its unsuitability findings for that area the area will not be leased. The tract ranking system is also set up to screen out areas with poor data coverage.

6. **Comment.** "Of the many questions raised during review of this DES, the emergency leasing system (page 3-27) is of particular concern. It is very poorly defined. How and when is it determined that emergency leasing conditions exist? How will the method of tract identification differ from normal and how would the scope and breadth of planning and environmental assessment differ from normal? When the applicant (company) shows coal is needed to sustain or increase production levels, will production be correlated to the need for coal? ... or to the need for profit? In view of the limited information provided on emergency leasing, it would appear that this is a 'quick and dirty' technique, so to speak, for companies to either get around the normal leasing process, or to avoid proper planning, or to make up for lack of foresight."

Commenter 038, 061, 071, 147, 148, 156, 158, and 173

Response. Emergency leasing would be conducted after petition for relief by a mine operator. In numerous places in the DES the Department has stated its policy that emergency leasing would not be used to circumvent the normal leasing process. Planning and environmental assessment would be conducted on a site specific basis with reference back to the unit plan for the area in which the emergency lease is proposed. Emergency leases would not usually be judged against the regional coal target because of their size and because their effect would be to continue rather

than to add to production. The general aggregate level of emergency leasing would, however, be considered in forming the regional leasing target.

7. **Comment.** "The statement is made that, 'The Department would rank all available tracts within a production region'. Again, no criteria are provided for ranking tracts. The preceding paragraph on that page indicates that preliminary tracts, once identified, would be analyzed for 'the potential environmental impacts related to each tract.' But no indication is given as to whether environmental criteria are to be solely determinant in the ranking process, or whether factors such as quality, quantity, and accessibility of the coal will also be used in comparing and ranking potential lease tracts. We believe that the description of the proposed process should be amplified to include details about the methods by which potential lease tracts will be ranked and selected."

Commenters 159, 069, 148, 098, and 097

Response. The Department is in the process of further defining the tract ranking process. One element that will be considered is quality, quantity and accessibility of coal. This process is more fully explained in the final ES and the proposed coal management regulations (Appendix A).

8. **Comment.** "Although the DES is somewhat confusing in describing the proposed system, it seems to provide for the comparative analyses of tracts on the basis of the amount bid per ton of coal with some weight given for differences in coal quality. However, it does not account for differences in environmental circumstances or differences in the cost of extraction, processing, transportation recovery of the coal and reclamation, since detailed engineering will not have occurred until after lease issuance. As a result, no true comparison between tracts is possible prior to leasing. Moreover, the system does not take into account the requirements of leasing to form logical mining units where certain elements of a prospective unit are already subject to lease."

Commenters 087, 069, and 096

Response. The Department recognizes that the intertract system cannot be run on a simple dollar-per-ton basis. At the same time it believes that an intertract system can be a good means for ensuring the government competition in coal sales. The Department will, however, continue to proceed with caution in the use of this untried approach to

mineral lease sales. All intertract sales will be of leases within logical mining units. The last logical mining unit sale will be that which meets or exceeds the total volume goal for that sale, assuming all offers are at or above.

The tract ranking and selection process would take into account differences in environmental circumstances, both among individual tracts and cumulatively for different groupings of tracts. The principal attention at this stage in the process will be on impacts on regional air and water quality. The relative economics of the proposed tracts and their socioeconomic impacts are the other major ranking factors. The Department feels that it will know enough about the proposed tracts at this stage to make valid ranking judgments. It is not necessary to wait for the mine plan to be submitted by the lesser before conducting analyses that would allow tracts to be sorted as acceptable, not acceptable, or borderline for sales.

9. Comment. "Section 3.2.2.1-Tract Identification and Industry Expression of Interest, discusses the designation of coal tracts for lease based on factors including technical coal data. In the absence of prospecting permits, there would be a lack of complete reserve data. Section 3.2.2.2-Regional Tract Ranking, Selection, and Scheduling, also discusses the possibility of this technical data insufficiency, but does not propose positive action to remedy the problem.

"The lack of sufficient technical data could be remedied by a means of awarding prospecting permits to industry operators, thereby permitting more meaningful tract recommendations to be submitted."

Commenter 094

Response. The prospecting permit program was ended when the Congress in 1976 prohibited non-competitive leasing. Private developers may still enter on Federal coal lands for obtaining technical data on coal resources by using coal exploration licenses, see subpart 3410 of the proposed regulations (Appendix A). The Department expects that coal companies will, therefore, still be able to obtain the information they desire on coal deposits in advance of leasing through the exploration program and in many areas through exploration on adjoining private coal deposits. The U.S. Geological Survey is another source for the coal data required by the preferred program.

10. Comment. "The statement is made that 'site-specific analysis of each tract would be conducted *prior to ranking* and an examination would be made for each selected tract to develop lease stipulations if necessary' (emphasis added) (page 6-3, column two, second paragraph). Given the level of protection afforded by SMCRA in setting mine permit requirements, and the fact that many of the 'ranked' tracts may not be finally offered for lease, detailed analysis, prior to ranking, may be a waste of federal resources. At that stage, much of the work will be of no consequence and will unnecessarily contribute to a monumental workload problem for the agencies involved."

Commenter 069

Response. The OSM regulations are primarily concerned with protecting site specific values and insuring complete reclamation. The tract ranking process is concerned with determining the relative values of several tracts and the potential impacts the development of those tracts might have on adjacent areas. The Department would not attempt to answer all the questions that must be answered before permit approval at the ranking step. Where answers were efficiently, and easily attained, however, they would be sought. Of prime concern are the cumulative impacts of developing several tracts in the same planning unit or production region.

11. Comment. "While Section 3.2.2.2 does indicate that comments will be sought on the relative merits of individual tracts under consideration for leasing, there is little indication of the weight to be given to various tract characteristics (i.e., low sulfur content vs. wildlife habitat)."

Commenter 069

Response. Under the preferred program the weights used to combine factors for judging the relative worth of different tracts, and the factors themselves, will be chosen by the regional coal teams. These weights can be adapted to regional value structures and to changes in the relative importance of the values over time. The factors will be chosen from a list of possible factors prepared by the Department. The ranking system will be used to broadly classify the acceptability of the tracts for further development.

12. Comment. "The process of ranking potential tracts on a nationwide basis 'and not separately within each land use planning area,'

assumes that all land-use planning areas within the region have completed plans, with all the required NEPA statements, etc. Ranking and comparing tracts in a region is relatively meaningless if significant numbers of tracts (not otherwise declared unsuitable) are unavailable because the planning is incomplete or inadequate. An early indication of market interest could be used to help schedule planning activities on the public lands. The preferred alternative precludes such indications until well after planning is presumed complete."

Commenter 069

Response. The Department does not anticipate delays as a result of incomplete planning. Approximately 85 percent of BLM lands have approved plans. Under the start-up considerations proposed by the Department, these plans would be updated by applying the unsuitability criteria. After completion of this process, tract identification and ranking could begin. Ranking of tracts from various planning areas in coal, even if not from all planning areas because of planning constraints, would still provide a better method of selecting tracts with less adverse impacts, particularly socioeconomic impacts, than simply selecting tracts from individual planning areas with no comparison between areas at all.

13. **Comment.** "The preferred program contains no procedure under which a potential lessee can obtain consideration of specific tracts of federal land that may be essential to its operations on adjacent lands.

"The necessary federal land may never even be available because it conflicts with other land uses for which there are many acceptable alternative sites, because it is considered unsuitable for mining under a number of questionable criteria, because it is arbitrarily set aside for leasing by public bodies or small business or because DOI's leasing goals have already been satisfied in the applicable region. Even the proposed emergency leasing system will provide little relief if the potential lessee cannot conclusively show that its need for the land resulted from circumstances beyond its control or which it could not reasonable foresee."

Commenters 083 and 069

Response. We disagree. There are numerous procedures in the preferred program to permit potential lessees to obtain tracts of particular

interest. Potential lessees are expected to participate actively in land use planning—showing why areas have medium or high coal potential, providing data to show exceptions to unsuitability criteria, and arguing for coal leasing over alternative uses. In activity planning, a company can and is expected to specifically submit its desired tracts. The unsuitability criteria are based on statute and national policy and are not considered questionable. Federal coal will not be leased contrary to the unsuitability criteria, comprehensive land use plans or in areas where projections indicate no demand.

The Department does not foresee the potential for conflict between public bodies, small business and other coal developers. These set asides are required or authorized by law. The system is designed to meet all reasonable demands. Although the clearly dominant interest of Federal land management is to protect the public interest, which ranges from wilderness designation to coal mining, activities of private interests on the public lands are considered and encouraged where they are compatible with this primary goal.

14. **Comment.** "Regional Tract Ranking. Section 3.2.2.2 of the DES contains the criteria to be used by land-use planners in the regional tract ranking and selection process. We submit that, in addition to the elements stated, such factors as the end-use of the coal, the existence of a firm commitment for a project, and the time-frame for use of the resource should be considered in the ranking and selection process. In addition, we feel that no discrimination should be made between Federal and non-Federal surface ownership, if the private surface owner has given his written consent to surface mining of the Federal coal underlying his tract.

"Finally, we understand that the three-man team which will rate the tracts and recommend to the Secretary the tracts proposed for sale will include a representative that will be selected if the region covers more than one State."

Commenter 96

Response. The relative commercial viability of Federal coal deposits would be a factor in the ranking and selection of Federal coal tracts. Also, industry indications of interest, which would include the desired coal location and quality descriptions, would be very important in the

selection of which tracts to lease. The Department would not commit coal deposits to any particular private development project in advance of sale except for coal lease modifications, since we must offer all coal competitively. The Secretary has decided that it is to the government's advantage to offer coal under Federal surface before offering coal underlying private surface—other things being equal. In making this decision, the Secretary had in mind avoiding disruption of private enterprises and ensuring the competitiveness of lease offerings. The regional decision teams would have one representative from each State Governor and one from each state BLM office in the region, plus an additional member appointed by the Director, BLM, who would serve as chairman.

15. Comment. "Regional Tract Ranking, Selection and Scheduling (DES; 3.2.22). The proposal to rank federal coal lands acceptable for further leasing consideration for mining would appear to insure the maximum production and most efficient leasing of 'priority' coal lands. Priority would be determined as either low, medium or high in rank. Although not specified in the DES, it implies that all economic factors including transportation, coal quality, and market needs would be analyzed along with environmental and multiple use trade-off considerations in the ranking process.

"Two serious faults in the DES ranking process exist. First, the process is not clearly outlined. No indication is given as to how the criteria, other than surface owner consent, would be applied and to what degree each would count towards the final decision. Economics should be a key factor. Maximum economic recovery and fair market value of the lands result from considerations of mineability and profitability. Profitability of a tract is determined on the basis of detailed mine planning and market availability. Without significant geologic knowledge of the coal deposits and mine planning, the maximum recovery potential of a tract in terms of profit can not be accurately determined.

"Second, a tract considered to be low ranking in terms of quality, its thermal value, transportation or economic recovery could quite easily become high ranking due to sudden changes in utility or other industry plant siting capabilities and market needs. Currently, the preferred leasing

program would be unable to react to these market changes without significant time losses from re-evaluation of tract rankings and potentially lengthy legal delays in preparation and acceptance of an environmental impact statement. These delays in time would all contribute to increased costs of plant construction and mine development and would mean the difference as far as the attractiveness of the tracts' resources versus other more costly fuel sources.

"Northern recommends the system of free enterprise and competition be allowed to determine tract value and ranking. Also, that economic recovery must be based on sound economic principles of evaluation and mine design without imposing probable undue economic constraints upon unleased tracts and mining companies which are ultimately revealed in the form of higher costs of production and use."

Commenter 073

Response. As the Department proceeds through the planning process, the economic values of the coal assume greater importance. These economic values would become very important factors in the tract ranking step. The Department expects industry to play a key role in this step of the planning process. This entire process is explained in greater detail in the proposed regulations (see Appendix A). The Department would review the activity plans every two years and plan sales in any given area every four years. Regulations allow emergency leasing at anytime. These provisions should make it possible for the Department to respond to changing market conditions. An industry-nominations system such as EMARS would not have the capability to respond to radical market changes more quickly than the preferred alternatives since new nominations and analysis would have to be done prior to leasing. Contrary to the comment, tract ranking and selection should not be based solely on economics. The degree of environmental and socioeconomic impacts must also be considered. Free enterprise and competition alone would not provide this critically important aspect of lease sale decisionmaking.

16. Comment. "Earlier in Chapter 3, page 4, it is stated that *boundaries* or preliminary tracts would be established on the basis of coal data. However, there is no indication that any of these criteria, especially surface ownership patterns, would play a

role in actually ranking tracts, once their boundaries are determined. We believe the EIS is seriously deficient because of this omission."

Commenter 159

Response. The Department is in the process of further defining the tract ranking process. Coal geology will be the major basis for preliminary tract delineation. Surface ownership patterns will however, have a significant impact on how tracts are delineated and ranked since ownership affects the competitiveness of proposed tracts and the Department desires to define preliminary logical mining units that are as competitive as possible. The Department's intention is to avoid as much as possible situations in which the LMU ownership pattern discourages bidders from participating in a lease sale. As noted in the final EIS, the Department prefers to avoid leasing in areas of split ownership.

17. **Comment.** "A related point is the threshold analysis concept mentioned in the statement. This concept is exciting to us, but we are confused as to how, when and where it will be employed as an analytical tool. For example, if adverse community conditions can be forecast under one level of coal development, is there a lower level which is acceptable? The same analytical approach could be applied to meeting air or water quality standards. We believe the concept needs further discussion."

Commenters 155, 066, 060, 145, 148, 160, 037, 030, 061, 057, 097, 118, 105, 108, 124, 076 and 281.

Response. The Department has begun a special effort aimed at further analyzing the threshold concept. Provisions based on this analysis will be included in the BLM planning regulations scheduled to be published in final form in June, 1979.

18. **Comment.** "The Programmatic in Section 3.2.1.4 offers the remedy that many decisions may be oriented more toward impacts dependent on levels or rates of development. Threshold development levels may be used to limit the amount of Federal coal leasing to levels which a community or area is able to support." This is certainly a fine idea, but nowhere is there any requirement that it be adopted. I urge that threshold development levels be a mandatory part of the planning process. The BLM should determine acceptable levels of coal development for each region and area within

the region and refuse to permit development that would be socially and economically excessively disruptive. Without this requirement, we have no assurance of protection for our families against skyrocketing crime rates, overcrowded schools, unprepared roads and polluted air and water."

Commenter 164

Response. The Assistant Secretary, Land and Water Resources, has asked the Director, BLM, by memorandum, to further study the threshold concept and include a requirement in the final BLM planning regulations that consideration of its use be a required aspect of land use planning. The threshold concept is not expected to be used in every area; however, when the information gathered indicates the appropriateness and necessity of a threshold level, the land use planners would establish the policy and leasing would be conducted accordingly.

19. **Comment.** "Threshold levels must be specified in every plan. They should not be discretionary."

Commenter 156

Response. The threshold levels would not be used in every instance, but planners would be required to consider whether they should be used. The threshold level could be established in the land use plan or later, depending on when its necessity becomes apparent. The Assistant Secretary-Land and Water Resources-has asked the BLM to study the threshold concept as part of its development of the final BLM planning regulations. At this time we believe that it is impossible to specify a single set of specific threshold levels that would be reasonably applicable to all of the planning units administered by BLM. In addition we do not believe the BLM should determine by itself what socio-economic changes are acceptable. This should be determined in concert with state and local governments with full review by the public. This requires active participation and concrete suggestions by state and local governments if socioeconomic thresholds are to be considered.

20. **Comment.** "In the Draft ES for the Western Coal Leasing Programmatic is a paragraph on page 3-21 which addresses Thresholds - ecological and socio-economic. How can a person or a governmental entity go about requesting a socio-economic threshold study for the North Fork? If resources

other than coal are to be preserved, such a study appears to be imperative."

Commenter 032

Response. The BLM has conducted studies in the North Fork and developed a land use plan. That plan places limits on the amount of Federal leasing primarily for socio-economic reasons. Before that plan could be modified, an updated plan or most likely new planning effort would have to be undertaken. This plan would be coordinated with the state and local plans and in all likelihood, conform to socio-economic thresholds recommended in these plans. If no local or state plans or goals exist, the BLM, through its planning process as defined in the regulations would develop such goals. This process is, of course, open to the public and requires their input.

21. Comment. "We further request that the concept of threshold development levels, found on page 3-21, be clarified and that the final document state that this concept can be applied to existing MFP's."

Commenter 157

Response. The Department is working on refining the threshold concept. The results of this work may be reflected in the final BLM planning regulations scheduled for release in June, 1979, if appropriate. This concept will generally not be applied to existing MFP's, however. Before any new leasing, the Department would (1) apply unsuitability criteria and conduct surface owner consultation and publish supplements to existing MFP's; (2) delineate and rank tracts from all the planning units within a production region and (3) write an ES documenting the tract, delineation and ranking process. Socio-economic and environmental thresholds could be proposed during steps 2 and 3 above.

22. Comment. "Criteria should be developed to determine threshold development levels, and these should be used to identify areas as unsuitable for mining as early as possible in the planning process."

Commenters 202 203, and 281

Response. The threshold development concept and the unsuitability criteria are supplementary insofar as they tend to avoid or minimize impacts of coal development; however, the threshold concept is inappropriate as a criterion. The unsuitability criteria are used to eliminate areas

initially from mining while the threshold concept involves a balancing judgment by the land manager useful throughout the planning and leasing process. The threshold pertains not to areas unsuitable but to levels or rates of development that are so great as to cause excessive stress to other resource values or to result in impacts not expected at lower levels or rates.

The unsuitability criteria are a test that determines the need to eliminate a specific area from leasing because of the innate value of that area. The threshold concept considers the need to limit the number of leases in a given area because of the effects that leasing would have on values associated with the surrounding lands. The need for establishing thresholds may become evident early in the planning process, however it may not become evident until the regional level tract ranking process is conducted. The Department is presently examining options for including threshold analyses in the BLM planning regulations. These regulations will be published in final form in June, 1979.

23. Comment. "Number 6, threshold development level. The threshold concept is particularly appropriate and applicable to Montana's balanced growth program when considering socio-economic impacts. The threshold concept would orient decisions more toward impacts dependent on levels or rates of development rather than on a site specific basis alone. Threshold levels could be developed for wildlife species populations.

"For example, a ten percent decrease in total population of wildlife might be an acceptable trade-off. It might be appropriate to establish threshold development levels in association with the unsuitability criteria.

"In terms of social and economic infrastructures, the rate and amount of coal development might be critical. A recommended threshold leasing or development level and rate would be appropriate and compatible with the balance growth policy.

"The draft indicates that this could be a part of any of the alternatives but does not definitely include it.

"It would appear to benefit Montana if threshold leasing or development levels could be specified in the land-use plan prior to tract

selection and identification, assuming that such information is available at the time.

"I would like to see an expanded use of the threshold concept in future land-use plans, unsuitability criteria and tracts ranking and selection procedures."

Commenter 170

Response. While some threshold development levels conceivably could be determined during application of unsuitability criteria, these decisions as to optimum levels of development would be established, where appropriate during the planning process as information is gathered and digested. Thresholds could also be determined in later steps of the leasing process, but if the planning process indicates the necessity it could and should be made during this earliest phase. The environmental statement describes the significant use of the threshold concept that would be made whatever the adopted management approach. As pointed out this concept would be least useful in the lease to meet industry needs alternative.

The threshold concept is now the subject of a special Department of the Interior study being conducted by the Bureau of Land Management. It is expected that the threshold concept will be expanded and become a part of the BLM land use planning regulations.

24. Comment. "The Colorado Mountain Club requests that a threshold analysis be done on the North Fork Valley. Threshold analysis is referred to under section 3.2.1.4, pg. 3-21 of the DES Federal Coal Management Program. The threshold analysis should cover socio-economic concerns such as transportation for both coal and workers, housing, schools and support populations. The purpose of the study should be to determine what level of mining the valley can absorb and still retain its attractive rural character."

Commenter 026

Response. At the present time, the Department does not foresee the immediate need for any additional Federal coal leasing in the North Fork Valley. If subsequent demand projections indicate a need to lease, one of two courses of action would be pursued. One, the existing MFP would be updated as described in chapter 3 of the FES or, two, a new planning effort as described in the BLM-proposed rulemaking for planning the use of public lands as described in the December 15,

1978, Federal Register would be accomplished. In both efforts, the issues raised above would be thoroughly considered.

25. Comment. "The Department should move toward more of a problem-solving approach in the next round of regional EIS's to identify and resolve regional environmental-social problems. Threshold environmental criteria should be established in the EIS process. We request that EPA be named as a formal participant in the "scoping" process for these EIS's."

Commenter 281

Response. The Department will, if the preferred program is adopted, move toward a problem-solving approach in the development of regional lease sales environmental impact statements. Regional analyses would include consideration of threshold levels of environmental degradation, though the Department prefers to conduct its analyses in terms of minimization of environmental damage rather than risk setting a standard for damage. EPA would be asked to participate in the regional analyses in the areas of its expertise, including participation in the scoping meeting for the impact statements.

26. Comment. "Section 3.2.1.4 on page 3-21: Threshold Development Levels We endorse the concept of threshold development levels for a given area based on land use planning rather than going solely by industry's expression of need. We also suggest that units of habitat may be a better criterion than actual numbers of animals or percent of population. Some wildlife populations fluctuate drastically from year-to-year within a given area of habitat."

Commenter 266

Response. The Bureau of Land Management is conducting a study to determine the feasibility of employing the threshold concept throughout their planning system. It is expected that the threshold for most wildlife purposes will be set on the basis of habitat disturbed.

UNSUITABILITY CRITERIA

1. Comment. "A number of commenters expressed technical concerns with the unsuitability criteria and others suggested new criteria."

Commenters 148, 144, 098, 057, 034, 037, 157, 017, 134, 178, 163, 067, 093, 066, 060, 108, 076, 095,

200, 109, 167, 165, 164, 042, 029, 092, 068, 101, 197, 202, 266, 281 and 287

Response. Because of the on-going field tests of the present version of the unsuitability criteria, the Department has selected to postpone technical response to the unsuitability criteria. All comments will be considered while preparing the final version of the unsuitability criteria after the results of the field tests are compiled in early May.

2. Comment. "The lands unsuitability criteria must be based on competent scientific opinion without arbitrary and capricious exceptions. They must place the burden for determining reclaimability on the BLM and must take into account off-site, cumulative and socio-economic impacts. The planning process must mandatorily apply consistent threshold criteria to levels of development."

Commenters 156, 168, 108, 121, 085, 092, 076, 060, 188, 197, 097, 099, 193, 105, 123, 154, 144, 148, 164, 157, 042, 203, and 165

Response. The BLM under the preferred program will determine the unsuitability of lands for mining based on sound resource data. The criteria will be applied as a part of all planning efforts. The Assistant Secretary for Land and Water Resources has directed that the BLM further define the threshold concept for incorporation in the BLM planning regulations. It must be recognized that the best planning regulations insure consistent application of law and policy while providing the planner with enough discretion to take advantage of site or area specific environmental differences.

Although there is a criterion that eliminates those lands which are clearly known to be unreclaimable during the land use planning process, the final determination on reclaimability of all coal land proposed to be mined will be made after review of the mining and reclamation plan except for extreme cases. Only at this stage will there be available the site specific data needed to make this more definitive determination.

3. Comment. "The results of this land use planning are proposed to be continued under the 'start-up considerations phase'. The plans will be overlain with the thin veneer of the lands unsuitability criteria. Lands unsuitability criteria is a much needed management tool which we fully support. As proposed, the criteria are weak and ignore important kinds of impacts, but these can

be corrected with rewriting. However, their effectiveness depends on the quality of the land use planning system, which forms the foundation. Use of the criteria cannot redress the deficiencies of the planning system, just as one can't patch a crumpled foundation. Yet these criteria are being used now, before public comment and rewriting, before a coal management system has been chosen, before compliance with the National Environmental Policy Act, and before new land use plans have been written using the multiple use-sustained yield mandate of FLPMA (Federal Land Policy and Management Act)."

Commenters 154, 168, 144, 097, 125, 165, 060, and 123

Response. Application of the unsuitability criteria to existing plans is dependent upon the data needed to apply the unsuitability criteria. These data should be contained in the existing resource inventories. Where these data are found inadequate, they will be supplemented or that area dropped from immediate consideration. Those criteria that are changed as a result of the review comments on the Draft EIS will be re-applied to the selected planning areas. Changes to the exceptions are more likely. Such changes would be easy to incorporate in to the on-going analysis after the Secretary's coal program decisions. Note that the process for applying unsuitability criteria as set out in the Federal Register notices of December 8, 1978, discourages the local land manager from using the exception provision of the criteria.

The unsuitability criteria are only one step in the start-up phase of the program. Tract identification and ranking on a production region basis will also be carried out after a substantial opportunity to discover and avoid environmental conflicts. This phase of the program will be documented in an EIS, with opportunity for additional public comment. Finally both FLPMA and the National Forest Management Act permit the use of existing plans until plans prepared under these acts are available (see Section 5.4).

4. Comment. "B. Premature Application of unsuitability criteria. The application of unsuitability criteria should be halted because of the following reasons:

(1) The criteria are part of the preferred program and should not be applied until

- the criteria are in final form and a coal program in effect.
- (2) The criteria are being applied prior to public comment.
 - (3) The final criteria could be different than the proposed criteria.
 - (4) The Department is locking itself into the preferred alternative, and will be unable to seriously consider other alternatives.
 - (5) The BLM does not have an adequate data base.
 - (6) The criteria are being applied to ten (10) priority leasing areas.
 - (7) The criteria are being applied to existing approved MFPs, some of which should not have been approved.
 - (8) Instructions state that application of the criteria "... should in effect, confirm prior planning decisions." (F.M. No. 79-4, Oct. 13, 1978).
 - (9) The criteria are being applied to (approximately 900,000 acres) acreage sufficient to result in at least forty (40) potential lease tracts in Colorado, Wyoming, Montana, and Utah (F.M. 78-85, Sept. 21-78).
 - (10) The November, 1978 to May 1, 1979 schedule violates NEPA and the District Court's Order in *NRDC v. Hughes* (Attachment 2, Terris letter of Nov. 24, 1978).
- Commenter 168
Response.
- (1) The on-going application of the criteria will enable the Department and the public, to gain experience with this new coal management feature before it is finally accepted. The Department believes this is good management practice.
 - (2) The application of the criteria allows for public comment and allows the public to become better informed on the strengths and weaknesses of the process and the unsuitability criteria before the Secretary's final decision.
 - (3) Any changes in the draft criteria used in preparing the supplements will be re-analyzed and entered into the supplements before their final publication.
 - (4) "In no way do I feel bound to the preferences I expressed last summer,"
- (5) Cecil D. Andrus, letter to Natural Resources Defense Council, March 23, 1979. The BLM is under instructions to provide for data collection on unsuitability later in the process if presently available data are inadequate to make a reasonably certain decision.
 - (6) The criteria are being applied to 9 western planning units and in the north central Alabama Land Use Analysis.
 - (7) BLM procedures provide for amending existing approved land use plans.
 - (8) The instructions do not specify that land use managers confirm prior decisions *uncritically*. This is an incorrect inference.
 - (9) The criteria are being applied to 540,000 acres in Colorado, Wyoming, Montana, and Utah. If the Secretary decides there is an immediate need for lease sales in these states, these acres might, after unsuitability and surface owner consultation screening, be areas from which it would be expected that from 10 to 40 logical mining units could be formed.
 - (10) The Department believes its actions in this regard are wholly legal.

5. Comment. "Re: Draft EIS Coal Management Program. Feel that program overall is well conceived. Have doubts about status of PRLA's in program. Since legal situation is not yet clear, legislation for reimbursement or exchange does not exist. Feel that a separate EIS should be done on PRLA. Strongly support notion that Unsuitability Criteria should be applied to PRLA's and rejection or exchange made as necessary. Also not clear as to whether Unsuitability Criteria apply equally to deep mining especially as regards socio-economic impacts, water quantity and quality, and subsidence in alluvial valleys needs to be clarified."

Commenter 086

Response. The Department believes the proposed program and this EIS adequately address management of PRLA's. A new section has been added to Chapter 3 and a new appendix (Appendix I) has been included, both of which address the management of PRLAs. Some new authority may be required for exchanges. Unsuitability criteria will be applied to PRLA's. Unsuitability criteria will consider the on-site impacts of underground mining. All unsuitability criteria are under review.

Modifications will be published in proposed rulemaking. Socio-economic and water quality and quantity questions are addressed mainly in the regional environmental analysis. Subsidence and alluvial valley questions are addressed during unsuitability screening and again at the mine plan review.

6. Comment. "We believe that the DES does not adequately address the effect of making unsuitability determinations at the time of the first step in the preferred program, which is the land use planning stage. Neither does it adequately address the effect of the unsuitability criteria, which are excessively restrictive. Nor do the unsuitability criteria nor the priorities expressed in the DES, with respect to multiple use resource management tradeoffs, appear to be in conformance with the policy of the Mining and Minerals Policy Act of 1970.

"In order for the land use planning process to work properly, there must be industry input in the land use planning stage to narrow the area to be examined in detail for potential mineral production. Section 522 of the SMCRA indicates that unsuitability determinations must be made on the basis of competent scientific data. At the land use planning stage, there is not enough data in the hands of the government to do this over the large areas encompassed in the land use planning units. Therefore, it is important to have early input from the extractive industries as to areas of interest in order to focus the study efforts.

"There must also be industry input before any unsuitability designation becomes final or before adoption of any multiple-use resource management tradeoff which would exclude mining from any area. This is essential in order to obtain the benefit of various opinions as to the possible reclaimability of the land or the applicability of other unsuitability criteria or as to the value of the area for coal production as compared to other uses. In this regard, mineral production has been historically considered to be a land use superior to other potential uses due to the fact that minable concentrations of minerals are rare and that *they must be mined where they are found*. In reading the DES, one obtains the definite impression that the Interior Department has swung 180° and now considers coal production the land use of last resort. For example, with respect to the resource

tradeoffs to be made in the multiple use determinations, there is a bias against mineral production evidenced in the DES, as witnessed by statements to the effect that recreation sites or campgrounds would be considered values clearly superior to coal production.

"Moreover, a number of the 24 criteria which can determine that lands are unsuitable for mining are strictly within the discretion of the DOI, are not mandated by statute, are unreasonable and arbitrary and are not supported by the experience of industry."

Commenter 087

Response. The Department does not agree with these allegations regarding its intentions. Specific responses have been made elsewhere to similar comments.

7. Comment. "Finally, according to the Memorandum of Understanding between BLM, the Office of Surface Mining, and the United States Geological Survey (published in the *Federal Register* 12/8/78), OSM must concur with the criteria employed in BLM's federal lands review. To our knowledge, this concurrence has not yet taken place, thereby invalidating any BLM efforts to implement that review."

Commenter 144

Response. While a letter setting out primary responsibilities of these three agencies has been published, the formal Memorandum of Understanding will be developed after the Secretary's decision on the coal management program. The standards eventually approved will be those approved by the Secretary and both BLM's and OSM's views will be taken into account.

8. Comment. "The criteria should be consistent with the laws under which they are promulgated. This is of particular concern with respect to the criteria which cover endangered species, bald and golden eagles, falcons, and reclaimability."

Commenter 060

Response. The Department believes these criteria are consistent with law. A change was made in the bald and golden eagle criterion to ensure such consistency.

9. Comment. "The impression one gets from reading all the criteria to be used to determine 'suitability' is that when no other 'values' can be identified for coal lands, such lands will be considered for leasing. At least some effort should

be made to quantify how much 'Roadless Areas', 'Scenic Areas', 'Natural Areas', 'Endangered Species Areas', 'Migratory Birds Areas' etc. the nation can afford. Some effort should also be made to determine 'cost/benefit' ratios for such 'areas' vs. coal development. "For example, Table 5-73 on page 5-154 indicates that the 'Lands Unsuitable Field Test Summary' shows *Montana* to be 100% Historic Lands, 98.2% High Interest Habitat, 89.9% Private Surface/Federal coal. So much for Montana.

"I also thought the *authority* for setting forth criteria used to determine 'suitability' or 'unsuitability' rested on *statutes*. In a number of instances, Table 5-72 indicates the '*authority*' rests on '*Departmental Policy*', not Acts of Congress. In the case of 'Criterion 8-Natural Areas', the '*authority*' rests on '*Departmental Policy*' and a '*proposed*' piece of *legislation*. Query, suppose Congress decides not to enact the proposed legislation establishing a 'National Register of Natural Areas'. What happens then to '*Department Policy*'?"

Commenter 053

Response. All of the unsuitability criteria are required by statute or are designed to meet goals or purposes of statutes through discretionary authority granted to the Secretary by statute. In reference to National Areas, the Department will protect most of these areas of Critical Environmental Concern as defined in FLPMA. It should be noted that the exclusions made under this criterion were 0% in Wyoming, 0.8% in Montana and 0.75% in Utah. The reference to the Montana statistics do not reflect the amount of land that would be set aside under these criteria because no exceptions were applied and the data were incomplete. If the Congress specifically repudiates the "natural area" concept, the criterion will be dropped. Further testing will help the Department better understand the effects of these standards before they are finally adopted.

10. **Comment.** "Recommendation - The process of defining and applying exceptions to otherwise applicable criteria should be clarified, so that the resulting product will allow all areas which are or could be determined to be subject to exceptions remain available for further consideration in the planning process."

Commenter 098

Response. The purpose of the unsuitability criteria is to protect identified resource values associated with the land in question. In areas where mining can occur without damaging these values, exceptions can be applied unless statutes specifically prohibit mining in the area, i.e. National Parks.

11. **Comment.** "We recommend that the procedural aspects of the unsuitability criteria application mechanism be substantially clarified. It should be clearly delineated from management activity which would determine multiple resource use trade-offs, and specific departmental responsibilities assigned."

Commenter 098

Response. The procedure for applying the unsuitability criteria are explained in the December 8, 1978, Federal Register (Vol. 43, pp. 57662-57670). The BLM land management planning steps are defined in the December 15, 1978, Federal Register. (Vol. 43, pp. 58764-58774).

A further description for determining threshold levels will be included in the final rulemaking on the BLM Land Use Planning procedures.

12. **Comment.** "Section 3.3.3, concerning management of existing leases, indicates that in the case of non-producing leases, the Department's preference is to apply the unsuitability criteria to the area of the leasehold at the time the lessee submits a mining plan. Utah Power would strongly object to this procedure in that substantial investments are often required in the preparation of a mining plan and the lessee should have some indication prior to risking such substantial investment that much of the property will not be determined to be unsuitable for mining. It believes, in most cases, that adequate information would be available to the various agencies involved to make a preliminary determination as to unsuitability. We suggest a procedure whereby an application for a preliminary determination could be made and an early response received as to whether there is any reasonable chance that any of the lands involved in the mining plan would subsequently be declared unsuitable for mining. The same section indicates that outstanding P.R.L.A.s would be examined for acceptability for mining, using the same unsuitability criteria, but this process would not depend upon applicant initiative. This would appear to indicate that there should be some

process by which existing leases could be examined, preliminarily at least, without the cost, expense and time in preparing a mining plan from the first instance.

"Utah Power is, in fact, extremely concerned about the procedure which may be followed in eliminating the so-called 'lands unsuitable for mining'. While we recognize that the Department's choices are limited by statutes and other constraints, the opportunities for abuse are so extensive as to be staggering. In reviewing the numerous bases for classifying lands as unsuitable for mining, it becomes obvious that more coal lands in the West could be classified as unsuitable (if the rules were to be stringently followed) than would be available for mining. While this is an area which might better be discussed in another forum, Utah Power strongly urges that great restraints be followed in applying the lands unsuitable for mining criteria. Otherwise a situation could arise not only where extensive tracts would be unavailable for mining, but where those tracts left after elimination would be of a nature that economical mining there would not be possible. Moreover, it is imperative that an adequate system be devised to compensate lessee for the financial losses which would naturally occur to them if lands upon which they have made substantial legal investments are subsequently declared unsuitable for mining and the lessees are precluded from utilizing them for that purpose."

Commenter 078

Response The recommendation for a preliminary finding is being considered by the Department.

The application of the unsuitability criteria will be a public process; as such, all interested parties will have the opportunity to provide information and recommendations to the land use planners involved. The purpose of twice field testing the criteria is to better ensure that the Department has full understanding of the likely effects of applying each criterion before the Secretary decides upon the criteria.

13. **Comment.** "There also is no basis to try and determine certain things like buffer zones. I mean is a quarter mile or is a half mile better? I don't really see any kind of supporting data on that."

Commenter 148

Response. Wildlife management practice provides ample guidance for the concept of buffer zones. Local conditions must be considered when establishing buffer zones to protect important wildlife and their habitat. Consideration of adequate habitat for feeding, breeding, and resting are necessary. The suggested buffers in the criteria are designed to assure that planners consider buffers before going below the specific sizes indicated. It is intended that buffer zones would be set on a case-by-case basis.

14. **Comment.** "We want the extraction of the coal to be of the least total disturbance to the land, to the present landowners and to the existing communities. To be fully consistent with this goal, the same criteria should be followed for existing nonproducing leases, preference right least applications and presently unleased coal lands."

Commenter 145

Response. The unsuitability criteria will be applied to all federal coal lands of medium and high development potential. These criteria will generally be applied during land use planning and review of mining and reclamation plans. The unsuitability criteria will be applied to PRLAs and existing non-producing leases before mine plans are approved if not during land use planning.

15. **Comment.** "The land use planning process will be used to identify lands that are unsuitable and suitable for coal mining, through the Lands Unsuitability Criteria. The EIS states that the application of the unsuitability criteria is the key activity of the land use planning process in the preferred program. However, we have found the unsuitability criteria to be one of the weakest components of the proposed program, for the following reasons:

(1) The unsuitability criteria do not account for cumulative and offsite impacts, but only impacts that will result on an individual lease tract. Such a narrow approach will cause serious consequences to such resources as wildlife habitat.

(2) The criteria and the numerous exceptions to them encourage subjective judgments concerning the significance of impacts from mining to other resources such as scenic, scientific, historic, and wildlife resources, wetlands, municipal watersheds, and National Resource Waters.

(3) The unsuitability criteria demand subjective judgements concerning the significance of a

resource itself. For example, historic resources must be of national significance if they are to be protected. Historic features of local or regional significance are given no protection.

(4) The unsuitability criteria offer no protection to roadless areas during the inventory processes, before Wilderness Study Areas are designated."

Commenter 200

Response. The unsuitability criteria are designed to eliminate areas from consideration for leasing because of the innate high value of that land. There are many other points in the planning processes where cumulative and off-site impacts are assessed such as the multiple use trade-off process early on in the land use planning process and in the tract identification and ranking process and the socio-economic and governmental analysis associated with these steps. At all of these steps cumulative and off site resources will be considered. The commenter makes the mistake of ignoring the rest of the management process and demanding all critical decisions be made in only one step in that process — the criteria application step.

Any comparison of the relative values of wildlife resources, wetlands, coal development, municipal watersheds etc., is necessarily a subjective process. The only certainty in this process are in those areas where definable resources are given statutory protection. Recognizing the subjective nature of many of these decisions the Department has developed a program that fully discloses these values, resolves to the maximum extent resource use conflicts, and makes the necessary trade-offs in a public forum with full opportunity for local government participation in the decision process.

In regard to the importance of historic resources of regional significance they could not be considered for leasing without the concurrence of the State. These resources could be permanently protected by a state proposed criterion that was adopted by the Secretary under criterion (w). In regard to BLM lands possessing wilderness characteristics but not yet designated as study areas, these areas specifically require review before leasing by the wilderness study area criterion to determine if they possess wilderness characteristics. If they do, they will be found unsuitable.

16. Comment. "The second major deficiency of these criteria is that they give BLM the authority to make determinations in areas where it has little or no expertise. Several of the criteria require BLM to 'consult' with other agencies, such as the United States Fish and Wildlife Service. Consultations are not binding, thereby leaving BLM to make final decisions which may or may not be consistent with the information derived from the consultation."

Commenter 144

Response. The BLM is the agency ultimately responsible for land use management decisions relative to national resource lands. Congress has required the BLM to seek advice from state and local governments, public and private organizations, individuals and other federal agencies. Some consultations are mandatory, but at no time has Congress recommended another party be responsible for determining the use of national resource lands.

The Department does not believe one agency should make specific land use decisions and a second agency carry out those decisions.

17. Comment. "Section 3.2.1 (p. 3-18) makes reference to guidelines of the Federal Land Policy and Management Act which include the giving of priority to designation and protection of areas of critical environmental concern. Such areas have been highly favored recently by some of the environmentalist groups as representing a compromise between industry and environmentalists in the battle over designation of lands for wilderness preservation. It is of course uncertain at this time how much land otherwise available for new federal coal leasing would be segregated as a result of the designation as areas of critical environmental concern. However, it is initially puzzling that this type of land use designation is not specifically listed or discussed in any of the unsuitability criteria. Hopefully, this can be construed to confirm that areas of critical environmental concern will be treated as wilderness areas are in the Statement, namely, as areas which automatically prohibit new federal coal leasing. There is nothing in FLPMA which would suggest that such areas should be treated like wilderness areas. It would be very helpful if the Department made clear in the impact statement that areas of critical environmental concern will not be automatically excluded from consideration for new federal coal leasing."

"Also on Page 3-18 the land use planning process for excluding lands as unacceptable for consideration for coal leasing is again described but this time it is stated that land would not be excluded in favor of another use unless that other use was clearly superior to new federal coal leasing. This statement is easily lost among the many statements which would indicate to the contrary that new federal coal leasing has been given a very low, if not the lowest, priority among all other land uses. The final environmental impact statement should correct this confusion by consistently stating that federal coal leasing will not be eliminated as a possible land use in favor of any other land use unless that alternate use is clearly superior to coal leasing.

"At the end of Page 3-18 the final paragraph refers to the fact that the land use plans would be updated only every five to seven years. This would appear to be inconsistent with the long term four-year cycle of new coal leasing. Presumably each new lease sale would require at least a review and possible update or supplement to the land use plans to reflect changed conditions particularly as regards criteria which previously applied to exclude lands from mining."

Commenter 066

Response. Many areas of critical environmental concern, will likely be eliminated from consideration by application of the unsuitability criteria. Where unsuitability criteria would not apply to areas of critical environmental concern, the management plan for each area would determine whether all or certain types of mining would be permitted. It would also be possible, although less likely that although a type of mining would still be permitted after application of a criterion, the management plan for the area would preclude such mining. The Department will not publish regulations for determining areas of critical environmental concern but instead will issue guidelines and manual instructions to the field. The impact of these directions will be wholly dependent on site specific conditions and might permit mining in rare cases. Unsuitability criteria are aimed at determining those situations where resources exist that would be protected regardless of the value of the coal.

The Department expects that the land use plans that are developed in accordance with the new regulations would not have to be redone for

several years. The tentative target is 15 years. In the activity planning step of this process, many potential lease tracts would be identified and ranked. At the completion of this ranking, a number of tracts sufficient to meet the anticipated demand would be offered in a competitive lease sale. Lease sales would be scheduled for every fourth year, however, two years after the initial sale, the demand would be reassessed. If it were determined that the demand had been underestimated on the previous sale, another sale would be scheduled. The tracts to be offered would be selected from the tracts previously ranked and from tracts that had been identified in plans completed in the intervening two years. Older plans would not be supplemented.

18. Comment. "Section 3.1.1.1 deals in detail with the various planning systems of the preferred alternative. Under the Land Use Planning portion of this Section the first criteria for screening out areas unacceptable for new federal coal leasing would be areas that do not contain coal reserves of high to moderate development potential. It is not clear what authority or justification the Department is relying on in applying this criteria which is presented as distinct from the general unsuitability criteria and every other factor suggested by law or regulation which should affect the potential development of coal reserves. Apparently, the Department is attempting to substitute its engineering and marketing judgement for that of the industry and this is not warranted. The economic potential for the development of reserves aside from clear legal restrictions, is constantly changing and the federal government cannot hope to have as much information concerning current market conditions or have sufficient expertise to predict future market trends as will potential lease bidders throughout the industry. Since this screening criteria is so nebulous, it would be appropriate to include in the final impact statement, at the very least, some detailed justification for this screening criteria along with an example of how the criteria might be applied over and above all other restrictions and limitations on new federal coal leases to exclude property which would otherwise qualify for a lease sale.

"In the same section on Land Use Planning, a very disturbing implication is left that the Department will indirectly engage in population control,

presumably only at the instance of a state government request, by deliberately limiting coal production from a region regardless of other factors and of the market demand in order to accomplish an artificial maximum limit on population in that area. It is unknown what, if any, authority the Department could claim for such action but it would certainly be necessary for the Department to elaborate on this suggestion in the final impact statement and particularly to discuss what, if any, public input would influence a decision to so control a region's population even without the request of any state government."

Commenter 066

Response. The method of determining medium and high potential coal development areas is described in USGS publication 1450B. If industry representatives believe there are areas in the low potential area that should be considered in the planning process they can submit supporting information to the BLM for their consideration.

The FLPMA directs the Department to coordinate their land use plans with local plans. Those plans may support the need to control population growth rates. If this is an objective of the local or state government the Department would constrain development on federal lands to insure the success of those plans unless it was clearly contrary to the national interest.

19. **Comment.** "While there is some merit in reviewing potential lease areas for 'unsuitability' before the lease is executed, it should be noted that relatively little technical information is available until a mine plan is actually developed. Hence, until the latter stage, there is little or no available information which could or would form the base for mitigation of harmful effects of mining — mitigation which would render an area entirely suitable for such activity, even though pre-lease information might lead to the opposite conclusion.

"More importantly, by placing the unsuitability test in sequence prior to an expression of area interest on the part of industry, and, for that matter, even prior to any preliminary tract selection by the Department, the workload is grossly and unnecessarily compounded, especially with the detailed tests which would be required by the use of the proposed criteria. Moreover, the unsuitability test may well be reapplied during the mine plan review phase after the lease is issued. Hence,

the earlier unsuitability review could be duplicative."

Commenter 069

Response. The Department's proposed program is essentially a series of screens that eliminate areas that are unsuitable for consideration for leasing as soon as they are identified. Application of the unsuitability criteria is one of those screens. The data needed to apply the majority of the unsuitability criteria are available. The Department believes it would be wasteful to consider any areas for leasing which could easily be tested early in the planning process. It is true that some criteria such as alluvial valley floors cannot be adequately assessed in all areas. The procedure for application of the criteria clearly calls for continuing the land in the planning process for further consideration for leasing if not enough data are available. It is very likely that some alluvial valley floor lands may be carried all the way through the process to the development of the mine plan stage before they are rejected.

20. **Comment.** "Indeed, if tables in Chapter Five Unsuitability, (page 5-154) are any indication, the criteria would prohibit coal leasing on an almost wholesale basis."

Commenter 069

Response. Present data indicate the criteria will not prohibit coal leasing on an almost wholesale basis. If this turns out not to be true, and the problem lies in overbroad actions by the Department it can take steps to reuse the standards to achieve the correct balance between resource protection and coal development. If the fault lies in statutes, or executive orders, changes will be sought in these areas. The data cited were data from the field-testing of draft criteria. If the commenter had more carefully read the statement, he would have learned that the few criteria which excluded significant percentages of land were more tightly drawn when selected by the Under Secretary for the preferred program. The Department is again field-testing the selected criteria. Should any of these criteria also exclude too high a percentage of coal land they too would be altered.

21. **Comment.** "Table 3-1 describes in general terms the twenty-four separate unsuitability criteria all of which would be applied to each and every tract of federal coal lands considered for new leasing under the proposed program. In reviewing

this criteria it must be again stated that it would appear that the Department's new coal policy is that: 'When in the slightest doubt, don't lease.' That is, if the collective imaginations of all the government officials and public interest groups which will be influencing the application of this unsuitability criteria cannot exclude coal leasing on the basis of using the land for anything else then that land will have an opportunity to be further considered for possible eventual leasing. It would seem that assigning what amounts to the lowest possible priority to federal coal leasing on any tract of unleased federal coal lands is completely contrary to numerous expressions of Congressional and Administration intent to greatly increase coal production for federal lands.

"Certain of the more potentially significant unsuitability criteria deserve specific attention because in some respects all or almost all of them are felt to be overly broad or poorly conceived. The first criterion deals with Federal Land Systems and indicates that all federal lands which are recommended for inclusion in preservation systems such as the wilderness Preservation System would be automatically excluded from further consideration as unsuitable for coal mining. Taken literally, this would mean that *all* lands in National Forests presently under review in RARE II process would automatically be given no consideration for coal leasing as well as all lands under the administration of the Bureau of Land Management which are presently being inventoried for review as potential wilderness areas. The Bureau of Land Management review will not necessarily be concluded until the year 1990. Clearly, such an automatic exclusion without opportunity for appraisal by individual land unit or particular lease tract to determine if indeed there is any potential for further review and designation is unwarranted and could eliminate vast tracts of federal coal lands unjustifiably.

"The criterion concerning Rights-of-Way and, Easements would, with certain exceptions, exclude portions of 'federal lands' as unsuitable for coal mining which are within any rights-of-way and easements or within surface leases for just about any use. Since the term 'federal lands' is used in the text to describe lands in which the United States owns the coal but private interests own the surface, the application of this criteria would require initially the horrendous task of reviewing

title to all private surface over federal coal to identify such rights-of-way, easements and leases. Apparently, the existence of a surface agricultural lease even by one who would not otherwise be granted surface owner protection would be enough to completely exclude an area from future coal mining and particularly from strip mining. There is no legal justification for this situation and this criterion must be strictly limited to landowners otherwise protected by SMCRA so that it is not readily abused by groups which could obtain such rights-of-way or easements for nominal prices in the hopes of delaying or completely blocking federal coal production from the land in question.

"The criterion related to Wilderness Study Areas has the same problems as those discussed for the criterion related to Federal Land Systems above.

"The dual criterion related to State Lands Unsuitable for mining and State Proposed Criteria would seem to have the potential effect of requiring the Secretary of the Interior to abdicate his authority and discretion in the leasing of federal coal lands to the State in which the federal coal lands are located. Again, there appears to be no legal justification for this extreme result and it is contrary to the clear intention of Congress that the Secretary retain primary authority and discretion for leasing such lands with considerable state participation but not control.

"The criteria concerning both federal and state designated endangered species would not seem to allow for the flexibility which has characterized the resolution of problems related to most applications of the Endangered Species Act since its enactment. Environmental groups and the Administration fought the amendment of the Endangered Species Act in the last Congress on the basis of statistics which indicated that of the thousands of instances in which the Act created a conflict with development of any kind, including numerous coal mining operations, the government, public interest groups and the private companies involved were able to work out compromises which did not result in the serious modification or prohibition of the development. However, when one considers that the application of criteria only somewhat more strict than the criteria presented in the Statement resulted in the exclusion of one-third to one-half of coal lands in sections of Montana and Wyoming as unsuitable for coal mining based largely on

identification of endangered species and critical wildlife habitat, it would appear that these two criteria are going to be applied in the proposed alternative for the long range federal coal leasing program with an inflexibility that would not permit similar compromises but would completely prevent the development of coal operations on the lands in question. If these implications are indeed an accurate reflection of what the Department is proposing in this Statement, then that should be made clear and a justification should be presented in detail for departing from what has been a rather successful and reasonable past practice.

"The last criterion which deserves particular mention is the one related to reclaimability. In the text the discussion of reclamation assumes unusually long time periods (ten to fifteen years) for reclaiming to legally required conditions. Apparently this time period really assumes that the initial vegetation will not be completely compatible with surrounding vegetation in undisturbed lands and that reclaimability means the slow natural progression of grasses from neighboring undisturbed lands to establish dominance over and eliminate other native grasses which are required by law to be planted in the disturbed areas. Obviously, putting the burden, as it is apparently placed, on the operator or potential lease bidder to prove such reclaimability would require long term tests that could greatly frustrate any renewed federal coal leasing in the next decade. Certainly, the Department could not have intended such a result. It is hoped in the final impact statement that this area of concern will be clarified by making it definite that compliance with existing federal reclamation requirements will be all that is necessary to prove reclaimability and that the land will not be completely withheld but that flexibility will be applied to conduct test mining operations to give a potential operator or bidder ample opportunity to prove reclaimability of the tract involved when such proof is necessary."

Commenter 066

Response. The unsuitability criteria are designed to protect public land values that are described in numerous pieces of Federal legislation. They are formulated for the purpose of protecting values not preventing coal mining. By definition, mining would be an incompatible use of Wilderness areas, therefore, the Department does not believe lands should be leased in areas that

may be recommended for wilderness designation. Congress has also prohibited leasing within the wilderness system itself and it has also severely limited issuance of new leases in the National Forest System. The Secretary will retain primary authority on leasing of federal lands. Any criteria proposed by the State must be approved by the Secretary.

Application of Criteria on endangered species and important wildlife habitat will be similar to the approach the Department has used in determining Critical Habitat in the past. Again, if the commenter had read the draft statement more carefully, he would have discovered that the endangered species and critical habitat criteria were changed to reduce their effect (see new discussion in Section 5.4 which explains the changes to the reader).

Reclaiming western strip mined land is known to take long periods of time. The purpose of the criterion is to remove those lands that are clearly known to be unreclaimable from consideration for leasing. A much more critical analysis of reclaimability will be made at the time the mining and reclamation plan is reviewed.

22. Comment. "The unsuitability criteria do not address cumulative impacts, socio-economic impacts, off-site impacts or adequately address deep-mining impacts, and there is really no public participation in their creation. We believe that the Department of the Interior is also trying to avoid NEPA review of these criteria, and we support NEPA review at all levels of this coal program from individual specific mining plans to development proposals such as the railroad into the Kaiparowitz Plateau from Cedar City as well as regional analysis. These should all be reviewed by NEPA."

Commenter 130

Response. The unsuitability criteria are not intended to cover cumulative impacts, socio-economic impacts or off-site impacts; they are intended to cover specific physical problems associated with coal mining that are the subject of various statutes, executive orders and regulations. These other areas are addressed in other ways under the program, through the land-use plans, tract selection and ranking and region wide environmental statements. The commenter has attempted to require all critical environmental decisions be made in this one step in the coal

management process, while ignoring the other steps which are more suited to the environmental decisions which are assigned them. Public participation in the process started informally late last spring after the Department's draft criteria were made available to hundreds of people, upon request. The formal involvement began on December 8, 1977 when the Department formally advised the public of the availability of draft criteria, notified the public of upcoming extensive field testing of the criteria with further public participation, and asked for comments on the criteria over three months before the Department expected to formally propose the rules. Again, the draft environmental statement on the coal management program set out the criteria in full, presented the results of early field tests and again requested comments. The present fieldtesting of the criteria has formal public participation steps as part of the process. Rather than seeking to avoid NEPA compliance in this process, the Department sought it out. Adoption of unsuitability criteria is a requirement of the Federal Lands Program under section 523 of SMCRA. The entire Federal lands program enjoys a specific NEPA exemption under section 702 of SMCRA. Thus the unsuitability criteria are specifically exempted from NEPA's environmental impact statement requirement. The inclusion of the criteria in this environmental statement is not in response to a legal duty, but in response to the Department's policy of making every element of the proposed federal coal management program open to public scrutiny.

23. Comment. "The initial step of the 'preferred program; described in the DES, consists of land use planning utilizing the planning systems already in existence in the Federal land management agencies. In this process, there would be a determination of the lands unsuitable for mining and a determination of lands considered more valuable for other uses. We believe it is imperative that the coal industry and private mineral interest owners be consulted during this planning process, in addition to the State Governments, because of the substantial effect the selection process will have on adjacent or contiguous private and State owned reserves. If Federal reserves are withdrawn from development without sufficient consideration of adjacent reserves or effects on those reserves, the remaining parcels may be fragmented or too

small to be economically developed. For example, Burlington Northern has substantial ownership checkerboarded with Federal lands in Montana and North Dakota. Those reserves cannot be considered in many instances to be logical mining units without the adjacent Federal coal and the same would be equally true for the Federal reserves if our coal is not developed. Thus unilateral Federal decision that the Federal coal is unsuitable for mining could make the mining of our coal uneconomic. To deny the opportunity to share in this decision-making process would be tantamount to confiscation of our property without compensation."

Commenter 067

Response. Industry participation is welcomed during general land use planning, and this has been emphasized in the final EIS. Industry would be expected to be a strong, forceful advocate of leasing certain lands. The unsuitability criteria are designed to protect naturally occurring features or values designated directly or indirectly by Congress as worthy of protection. Industry data bearing on the criteria or their exceptions may be submitted to the local BLM office.

24. Comment. "Criterion (w), state proposed criteria, should be rewritten so that it can be applied to existing MFP's. The wording now indicates that such criteria can only be proposed before a draft land use plan is issued. There is no indication in the planning process that draft land use plans will be written where there are existing MFP's. This is undoubtedly an oversight and should be corrected in the final."

Commenter 157

Response. We have modified the criterion to allow application of state proposed criteria to BLM supplements.

25. Comment. "Another concept warranting serious consideration, whether in a criterion or applied in some other way, is whether the leasing or approval of a mining plan in an undeveloped area requires a new major transportation system, which in turn would require many more mines to be approved in order to support the system financially, in other words, what the effects of approving the mining plan in the undeveloped area are beyond that of the effects of the mine itself."

Commenter 134

Response. These aspects must be considered in the regional lease sale EIS.

26. Comment. "The 'unsuitability criteria,' it seems to me, are likely to prevent the development of federal coal rather than to provide appropriate safeguards for its orderly development at a rate consistent with National energy needs. Individuals or groups who wish to block all future new mines could claim that one or another of the unsuitability criteria as written could be applied to virtually every tract of federal coal land no matter where located."

Commenter 017

Response. The Department does not believe that "unsuitability" will seriously constrain regional coal development. The Department has field tested an earlier set of criteria and after reviewing the results of the field tests, altered the criteria to those proposed in the draft EIS. The Department believes that the criteria as now drafted would not seriously constrain regional coal development. However, to be certain of this, the proposed criteria are now undergoing a second, more extensive field test. These draft criteria will be modified to accommodate objective comments received as a result of the EIS review; however, we do not expect major changes in the amounts of land that would be designated unsuitable by the application of these criteria. It should be noted that these criteria are based on several statutes generally related to environmental values.

We do not expect individuals or groups, who may be interested in blocking coal development, to be able to use these criteria as a tactical weapon. There is a petition process; however, a *prima facie* showing of unsuitability by the petitioner is required before the petition receives processing.

27. Comment. "there is presently no provision for appeal from lands initially classified as unsuitable for mining within the proposed program. One should be provided and it should be drawn in a manner that encourages response and is designed for prompt resolution. Such a plan might be as follows:

- (1) Identification of tracts which may be considered unsuitable by BLM
- (2) Reasoning-briefly on basis for unsuitability

- (3) Publishing of said list to all interested parties and in newspapers of record within area (state and local government, other Fed agencies affected, mailing list of those desiring such information)
- (4) Submission of data to support or refute preliminary classification suggested by BLM.
- (5) Public hearing on data and conflicts as necessary within 90 days after submission of data
- (6) Resolution of status by BLM at local level
- (7) Appeal period - 30 days
- (8) Inclusion of parcels removed from unsuitability category in remainder of BLM environmental analysis and tract ranking."

Commenter 152

Response. Petitions can be submitted under the SMCRA regulations to have land designated as unsuitable or to have unsuitability designations removed. In addition the proposed planning regulations 1601.6-1(c) provide an appeal process for any decisions made during the formulation of new plans.

28. Comment. "First, Wesco has a great concern that many of the decisions that will be made during the application of the unsuitability criteria will be made without a right for an appeal or legal challenge to the final decision. Further, it seems plausible that other bureaucratic decisions will be made during the various steps that will not allow the decision to be challenged. For instance, final guidelines will be applied in the determination of alluvial valley floors and be given the force of law. Guidelines should not be treated or given the effect of law. (See 3-13) The same concern exists for the determination of prime farmlands or for decision as to ability to reclaim.

"Second, Wesco has a major concern with the uniformity with which the established criteria will be applied across the various coal regions of the nation. Because of the forecasted cooperation among state officials, political considerations could prevent wise resource management decisions. Appeals should not be foreclosed when one set of criteria is used to determine leasing one state while a different application of the same criteria could be used to make the same decision in another state."

Commenter 034

Response. Coal developers have expressed a belief that the Department is trying to lock up federal lands with the unsuitability criteria. Other private interests have claimed the criteria are so nebulous that values that are supposed to be protected by these criteria will not be. The Department is reviewing and modifying the criteria in an effort to develop an objective screening process that can be uniformly applied and that protects the values of concern without unnecessarily removing coal from consideration for leasing. The application of these criteria will be a public process as described in the Federal Register, December 8, 1978, pp. 57662-57670, and Federal Register, December 15, 1978, pp. 58764-58774. All parties will have ample opportunity to challenge the decisions during and at the completion of the review process.

29. **Comment.** *"Application to existing Rights -* We do not believe the Department to have the authority assumed in the Program to apply its new 'suitability' criteria to existing but non-producing leases and to the preference right lease applications (PRLAs) now pending before the Department. To the degree that the Program would cancel or nullify an existing lease or PRLA, the taking of a valid existing right may be involved. This issue is currently in litigation, and adoption of this Program element should await judicial resolution of the nature of the rights involved. To the extent that the Program proposes the exchange or substitution of other rights for any so taken, it would appear to exceed existing statutory authority. At a minimum, specific legislative proposals should be addressed and the alternative thereto considered in the final statement."

Commenter 098

Response. The Department has the authority to apply the unsuitability criteria to all federal lands. A new section in chapter 3 and a new appendix (Appendix I) discussing the management of existing leases and PRLAs, and, in particular the application of the criteria to them, have been added to this statement.

30. **Comment.** "While the Department plans to apply land use planning criteria to existing leases, this should be done at the same time as all the other lands are being reviewed. Further, no lease should have a mine and reclamation plan ap-

proved by the Secretary until the facility demonstrates compliance with the in-place regional land use plan."

Commenter 118

Response. The Department prefers to apply the unsuitability criteria at the time of general planning. Setting this as firm policy would, however, be extremely unfair to the holders of non-producing existing leases if land use planning is not promptly scheduled in their area, since all existing leases are under a ten year diligence requirement and since they were sold without restriction on how soon they could be put into production. Consequently if planning is not scheduled and a mining plan is submitted, the criteria would be promptly applied during the mining plan review. Existing leases face thorough environmental reviews under the many environmental protection features of the Surface Mining Control and Reclamation Act.

31. **Comment.** "Another area that I noticed was inadequately developed in the Impact Statement was the ranking of unsuitability criteria. While Table 3-1 did indeed list several areas of unsuitability for possible ranking, there was no discussion given to the ways in which those different criteria are going to be intermeshed, which ones take precedence over others, how are they ranked in the over-all system. I think that the idea of ranking sites within a series of industries is a very valuable one, but the ranking system is not as well developed in the draft impact statement as it would need to be really implemented."

Commenter 137

Response. The concept of tract ranking was not, as you observe, described in the programmatic EIS draft fully enough to permit its implementation. It was developed in enough detail to describe the program for the purposes of the Programmatic. In the period between the draft EIS and the final EIS, over twenty task forces have been at work developing the procedural details of the federal coal management program, including the tract ranking process. The results of their work are available from the Department. Some of these additional details are presented in the final EIS. Incidentally, unsuitability criteria are not a ranking factor. If an area is found to be unsuitable under the criteria, it is dropped from further consideration for coal leasing.

32. "Comment The preferred program needs to strengthen the unsuitability criteria generally and improve the existing land-use plans (MFP's). This should include a better definition of management tradeoffs of resources vis-a-vis coal development and a commitment to develop land-use and activity planning processes. Better public and agency access is needed to review MFP's before the leasing process is started."

Commenter 281

Response. The unsuitability criteria list to be issued with the final regulations for the coal management program will be improved over the current version as a result of what the Department learns from on-going field tests, as well as language improvements to the criteria to clarify their application and responses to specific public suggestions for improvements to the criteria. Existing MFP's will be improved prior to any coal management decisions through application of criteria and surface owner consultation. The land-use planning carried out by the Bureau of Land Management is undergoing a major change at present as a result of the statement of policy regarding planning on public lands set out in the Federal Lands Policy and Management Act of 1976 by the Congress. This includes clarification of public and outside agency participation in the preparation of plans. The input of the coal management program to the development of policy for the land use planning program of the Bureau of Land Management is limited to setting out the steps needed to identify lands acceptable for further consideration for leasing. The Department is studying further development of the threshold concept in the planning process context, but adoption of formal threshold criteria is not anticipated.

33. "Comment Lands Unsuitable for Surface Coal Mining At several places in chapter 3 it is indicated that on existing leases, the unsuitability criteria would not be applied until after a mining plan had been submitted. We believe that lessees should be given the opportunity to avoid mining plan development costs until after the unsuitability criteria have been applied. This could be accomplished in several ways. Rather simply, the lessee could advise the Department of his interest in mining the tract, with a request that the determination of unsuitability be completed and made public. Some controls could be built in to avoid

requests that were not associated with a genuine desire to proceed with mining at an early date."

Commenter 091

Response This proposal was considered and rejected during construction of the preferred program.

PRODUCTION TARGETS

1. **Comment.** "It should be noted that the preferred program is now described as a coal management program rather than a coal leasing program. It would appear that one of the most salient features about the preferred program is the centralization of decision-making in the federal government with the resultant control of large elements of the economy of the western United States. The unprecedented degree of management proposed to be employed by the government will, of course, result in a corresponding reduction in the freedom of action on the part of the private sector. The level of new leasing is to be determined by the government's estimate of coal demand on a region-by-region basis. New leasing levels will be established according to such governmentally derived estimates of demand. Furthermore, it is stated on page 3-41 that consideration is being given to imposing upon new leases conditions which specify how, where, or by whom coal would be consumed. It appears that the government is completely ignoring the operation of market forces in the development of federal coal resources."

Commenters 087, 066, 069, 083, 098, and 093

Response. Any good businessman will try to make forecasts about future demands; the Department is trying to do so with the regional target setting process. We wish to offer the amount of lease rights that we can sell. The Congress has declared that we must provide for other activities in conducting our business such as comprehensive planning, the receipt of fair market value, the determination of maximum economic recovery, surface owner protection, and the setting of national production goals and leasing targets. Many of these requirements are of recent origin. Since there has not been an active coal program in the Nation since 1971, none of us is familiar with these provisions in operation. But, just as clearly, these provisions are not created at the whim of the Department but reflect the unambiguous intent of the Congress. In summary, then, we must both enforce the laws of the nation and we must closely

follow the laws of the market for coal if we are to properly conduct our business, the selling of coal extraction rights. In coal, the Department's managing a resource will have a major role in the future economy and environment of the West, but the Department cannot abrogate its responsibilities just because they are important, rather we must redouble our efforts to fulfill them with heightened sensitivity to all who will be affected by the future development of coal.

The term "management" was used because any Federal coal program includes many more activities than just leasing, i.e., administration of lease assignments, readjustments, relinquishments, cancellations, terminations, and transfers, application of planning and unsuitability requirements to existing leases; and the exchange of Federal coal and other mineral leases for environmentally unacceptable Federal coal leases and of Federal coal for alluvial valley floor coal.

2. Comment. "*3.1.1.2 - Regional Production Targets*" -Perhaps the most troublesome aspect of the statement, and the preferred program itself, is the reliance on regional production targets as the driving mechanism for the program. The establishment of targets in the so-called major production regions' implies that the coal market is cordoned into neat, autonomous market areas. In reality, there are many instances when coal from the West must compete with Midwestern and Appalachian coal, and even coal from Australia and South Africa. To discern in advance, as the preferred alternative proposes, that certain levels of production are desirable in each region simply flies in the face of reality. It will be disruptive in the coal market, impose additional, artificial costs in an already marginal industry, and it would seem to raise serious questions about the federal role in determining the level of economic activity in the various states. None of these issues is raised in the statement.

"Moreover, even presuming the efficacy of setting regional production targets, it is not clear that such targets would in fact serve as the driving mechanism for federal coal leasing. Not only does the statement indicate that the targets set by the Department of Energy would be subject to adjustment by Interior (3.1.1.2), but that such targets could be adjusted according to the available tracts deemed to be suitable for leasing. Section 3.2.3 states that 'the regional ranking and

selection process should consistently indicate the optimum tracts for the desired level of development..."

"Previously offered, but unleased, tracts are an obvious indication of market miscalculation and the need to adjust production targets. But the statement implies that, in many cases, the *targets* will be adjusted to meet the number of available, suitable leases. If that is the case, then the production targets serve only as a planning guide, not as the piston for coal lease sales. In any case, the role of the regional production targets would seem to require further description in the final impact statement."

Commenter 069

Response. The Department will rely heavily on the DOE projections, however, the regional targets may be increased or decreased in response to other projections or expressions of interest in specific regions. These composite projections will indicate the demand for coal in a particular area. The land use plans will determine the amount of coal available for development-The supply. In the next several years, the Department believes that with few exceptions, there will be more than enough tracts to meet demand.

3. Comment. "Section 3.2.3, (page 3-23) of the Draft Environmental Statement describes a system whereby regional coal production targets would be developed by the Department of Energy. We suggest that the program provide for adequate availability of federal coal leasing so that enough coal is available even if the production targets turn out to be grossly underestimated compared to actual demand. Although the preferred program does provide for industry comment after the regional production targets are initially set by the Department of Energy, we believe that industry, including both the coal producers and the coal users, should be more closely involved in the initial target setting."

Commenters 151, 098, 118, and 066

Response. Before the Department of the Interior adopts any regional production goals or leasing targets there will be full consideration given to industry estimates of demand as well as other non-governmental forecasts. There are limits to the Department's authority to involve industry prior to the proposal of the production goals since the

Department of Energy Organization Act (P.L. 95-91) granted DOE authority to propose those goals.

COMPETITIVE BIDDING

1. Comment.: Competition is for the most part not realistic as it is almost non-existent especially in L.M.U.

Commenters 110, 019, and 135

Response. The level of competition for any particular tract is often a problem for the Department. We have proposed many measures throughout the preferred program to encourage competition on tracts where it is within our power to do so. Fair market value represents another means for assuring the Department a fair return from its lease sales.

2. Comment. "IV. The Single Tract Sales System and Cash Bonus Bidding Method Should be Used

"The public interest is best served through the use of the single tract sales system, which results in lower end use costs, administrative efficiency in the planning process and a more equitable comparison of competitive bids. The intertract sale system inequitably forces comparison of bids on different tracts, because adequate consideration cannot be given to tracts, because adequate consideration cannot be given to differences in coal mining, processing, transportation and reclamation expenses.

"The cash bonus bidding method, of the five methods of bidding considered in the preferred program, is best suited to the government's coal management goals. Cash bonus bidding maintains strong incentive for development on the part of the successful bidder. It also reinforces the incentive for diligent development otherwise required by the federal government. Royalty and deferred payment bidding methods, on the other hand, encourage lease speculation."

Commenter 092

Response. The Department recognizes there are certainly operational difficulties with intertract bidding, and we will proceed with caution with implementation. An interagency task force is presently studying the intertract bidding concept. The report of the task force will be made public when completed. Because of ownership patterns in the west, there will be many lease sales in which all who would be lessees would not be on an equal

footing in the bidding. This becomes particularly true where a valid pre-existing surface owner consent that is not transferable is involved: Intertract sales, in which several leases are offered in one simultaneous sale, is a means to re-introduce competition into such sales. The promulgation of regulations to govern bidding methods is the responsibility of the Department of Energy. The Department plans to continue to offer tracts by deferred bonus bidding unless the Department of Energy invalidates this method.

3. Comment. "Provision for intertract competitive bidding should be deleted from the Program."

Commenter 098

Response. The Department believes intertract bidding is the only way it could conduct a competitive lease sale which included tracts where the surface owner gave consent to mine to one company and that consent is not transferable. Elimination of intertract bidding would eliminate those tracts from consideration for leasing unless a new transferable consent is negotiated. The Department intends to support the DOE in maintaining the option of using intertract bidding in selected areas.

4. Comment. "It will also be desirable to make sufficient tracts available in order that goals stated in the Draft Environmental Statement such as doubling the 1977 coal production by 1985 (page 1-7) and improving competition in the coal industry through new leasing (page 2-43 and 2-49) can be achieved. The more that coal is made available through federal leasing, the more competitive the coal market will be."

Commenters 151 and 137

Response. The proposed program is designed to insure that sufficient Federal coal resources are available to maintain a competitive coal market and meet national demands.

5. Comment. "Similarly, the argument falters that leasing is necessary to increase competition. It is not ever clearly established that lack of competition is a major problem in the coal industry. But if this were a concern of the government, here again, it has numerous means at its disposal by which to resolve the problem. It could, for instance, pursue vertical or horizontal divestiture, prohibit mergers of a certain sort, use the powers established in Section 501 of FLPMA to deny rights-of-way

which would give applicants unfair competitive advantages, make the Justice Department's antitrust review of lease renewals and readjustments mean something rather than the proforma treatment they're given now (See Section 15 of the Federal Coal Leasing Amendments Act of 1976), enforce the provision of the Mineral Leasing Act which bars common carrier railroads from obtaining federal leases, and conduct an aggressive antitrust review when lease assignments arise. Measures such as these would appear to be much more effective means of promoting competition than leasing. As described in the ES, the Interior approach to antitrust if applied, for example, to the steel industry, would not be to break up the giants which are the cause of the problem. Rather it would be to make additional lucrative contracts available to them."

Commenter 060

Response. The Department views competition as a major potential problem. One of the many concerns of the Department in this regard is for the pool of potential bidders for lease sales. Questions of divestiture are beyond the Department's authority, but the Congress in the Federal Coal Leasing Amendments Act clearly had in mind that the Department promote industry competition in carrying out its other leasing duties. The Department is examining the question of rights-of-way control. The Justice Department's review of lease sales has been considerably simplified in the preliminary rulemaking. The railroad holding limits are enforced by the Department, and the Department is examining the question of more tightly controlling the assignment market. The Department would follow all avenues open to it to promote competition.

6. **Comment.** "Section 3.2.4.4 lists several alternatives being considered for sale and bidding procedures for new federal leases. The sliding scale royalty bidding would increase the percentage royalty with the value of the coal. With coal prices expected to continue to rise, this method would probably insure that marginal deposits or small areas of logical mining units would be increasingly by-passed by companies. The profit sharing method would probably be the worst of all worlds for both the government and the operators since the government would effectively have nationalized the portion of the coal mining industry engaged in

mining new federal leases requiring an horrendous new bureaucracy.

"The fixed rental method would probably not reflect a return of fair market value to the government over the long term period."

Commenter 066

Response. The Department expects that deferred bonus bidding will be the most common method used for coal lease sales over the next few years: As noted in earlier responses, the Department of Energy now has the authority to promulgate regulations for sale and bidding procedures.

INDUSTRY INPUT

1. **Comment.** "The preferred program for coal development is described in the DEIS generally in Chapter 3. Western Fuels' primary concern with the preferred program involves industry participation in the leasing process. First, the preferred program permits industry involvement which is both too little and too late. As is clear from sections 3.2.1 and 3.2.2, the initial opportunity for input by industry occurs after the basic land selection decisions have been made. In undertaking the initial selection of tracts to be considered, the federal agencies take on a heavy responsibility of determining needs and balancing those needs against the numerous other factors impacting decisions to mine coal. In the final analysis, it is industry which develops federal coal resources. Industry's input is both necessary and appropriate at the earliest stages of the planning process. This input must occur prior to initial selection of lands.

"Further, the level of industry input is too small. In the preferred program, only industry 'expressions of interests' are permitted. Western Fuels submits that industry should be permitted to submit nominations, rather than merely expressions of interest."

Commenters 090, 104, 098, 087, 066, 068, 084, 069 and 083

Response. The Department agrees that "industry's input is both necessary and appropriate at the earliest stages of the planning process." This was our position at the time of preparing the draft EIS but was not well explained. This final EIS has been revised to correct for this poor communication. Basically, in land use planning the Department is interested in the general level of activity the private coal developers expect in the area and any special resource information they may have

available that would be important to general planning decisions. We are particularly interested in information that indicates the need to widen our screen for medium and high development potential coal, data to demonstrate appropriate exceptions to the application of unsuitability criteria, and arguments in favor of coal development over other potential uses of the land. The difference between participation in the planning process and in the expression of interest is that between general interest in seeing further coal development in an area and being ready to identify specific potential tracts in contemplation of purchasing a lease and opening a mine. The expressions of interest are expected to have the same level of detail as nominations have had previously. The role of expressions of interest has been more fully described in this final EIS.

2. Comment. *Industry Input*

"As now drafted, no timely or meaningful input would be sought from industry to identify those areas of federal coal lands which are most desirable for immediate development. The coal industry will continue to be the developer of whatever land areas are leased (DEIS 3.1.8, at 3-14). Such input in the land use planning process would serve to focus DOI's attention on those areas which should receive priority review for lease potential. This would be especially important in the early rounds of resumed lease offerings, but would involve no derogation of the Department's other or subsequent planning responsibilities."

Commenters 098, 069, 087, and 066

Response. The Department will be seeking industry input throughout the entire process of land use planning, target setting, tract identification, ranking, and lease sales.

3. Comment. "The expressions of interest described in the DEIS at section 3.2.5 are not idle musings of the industry. The expressions of interest apparently must include maps, geologic data, mining methods, proposed transportation system, etc. This data, which can be developed only by expending great amounts of time, energy and dollars, can in many instances be proprietary in nature. Some alteration of the leasing system must be made either to keep the submitted data confidential or to give the entity which develops the data some preference in the leasing of that land. A plan which calls for the submission of

substantial data which can be used by one's competitors and does not place one in a preferential leasing status will not evoke substantive industry input."

Commenter 090

Response. The Department believes that the information submitted with an expression of interest should not be held confidential. Competitive sales will not take place where the government knowingly countenances one potential lessee holding information on the federal coal deposit not available to other lessees. The Department will not select a favored bidder for any sale. Private companies must balance the strength of their interest in seeking leasing of a coal deposit against their desire to keep their competitive edge over the federal coal because of the information that they hold. A similar policy will be followed by the government regarding information submitted during general land use planning.

4. Comment. "We believe the Final Environmental Statement should not only permit, but specifically provide for, input and use of industry information in the land use planning process. A possible means to this end might be a process similar to the BLM proposed Regional Technical Working Groups in various outer continental shelf areas which will address the entire planning process for OCS leasing. We suggest similar advisory groups could be established for various coal leasing regions, specifically providing for industry representation on each of the groups."

Commenter 084

Response. The recommendation for advisory groups will be considered prior to publishing final planning regulations. It should be noted that the role of industry in land use planning is regarded as very important to the Department and the discussion of land use planning in Chapter 3 of this final statement has been expanded to make our intentions clearer.

PUBLIC PARTICIPATION

1. Comment. "Opportunities for Public Input are Inadequate as Proposed. It is appropriate for the federal government to examine reliable, timely forecasting data made available to it by a variety of sources, thus enabling the government to prepare its projection and set its production targets on the basis of the best evidence available. The

importance of such production targets cannot be over emphasized, as forecasting errors would likely result in an imbalance of supply and demand, which could be difficult if not impossible to correct in light of the long lead time now necessary to obtain permits and approvals to open a coal mine. Such information can be obtained by providing the opportunity for the public as well as the federal government to initiate lease sales. In the land-use planning process, too, opportunity for participation of all interested parties is essential to evidence the public's priorities in assessing land use and to improve the quality of decision making.

We therefore urge that the preferred federal coal management program be revised, in line with Executive Order 12044, to facilitate public participation and also to provide for public initiated leasing.

Commenters 092, 074, 064, 019, 135, 131, 058, 170, 166, 097, 076 069, 093, 203, and 138

Response. Public input will be sought twice during the setting of regional leasing targets. The Department will accept expressions of leasing interest for areas acceptable for further consideration for leasing and will respond positively whenever possible. Thus, the public could, under the preferred program, initiate many of the lease sales. Chapter 3 of the EIS is being rewritten to emphasize the Department's commitments to having all parties interested in coal leasing participate in land use planning and activity planning. The final comprehensive planning regulations, which will be issued in June 1979, will make the process for participating in land use planning much clearer.

2. Comment. "The land manager is awarded arbitrary powers in the very early stages of the land-use planning process, in the event that new unit resource analysis, socio-economic profiles and planning area analysis, which are all considered to be a part of the MFP's are to be done for an area. There is no provision for public input at this stage."

Commenters 203, 066, 092, and 166

Response. As indicated at 3.2.5.2 of the Draft Statement, a public hearing is provided in order to consider recommendations on the land use plan before the final decisions are made. Opportunities for public participation continue throughout the coal management process. The public does not

have to wait for formal opportunities to present their views and knowledge to the local BLM land manager. Inputs from the public are welcomed at any time.

3. Comment. "CERT is concerned about a few elements of the preferred alternative. First, there is no provision for tribal participation in the program except as a part of the general public. The Department has made a commendable and appropriate effort to include states and localities in decisions concerning federal coal leasing and development. States, however, do not speak for Indian tribes. In fact, they often have interests that are in direct conflict with tribal interests. Many CERT tribes, especially those in the Powder River, San Juan River, and Fort Union coal producing regions are very near and in some cases, virtually surrounded by, land bearing federal coal. Developments of that coal would have a profound impact on the natural, social and economic environments of these reservations. Tribal governments are responsible for managing the impacts of energy development on our reservations. We want and need to coordinate our efforts with the federal program, but to do this we must be directly involved in your planning process.

"Federal agencies, when developing programs, often do not include provisions for the participation of Indian tribes—usually not out of ill-will but merely as an oversight. When that happens, tribes are often ignored and have tremendous difficulty participating in federal agency decisions.

"CERT therefore urges you to make explicit provisions for tribal participation in the program. Tribes should be given the opportunity to participate in the ranking and selection of tracts, setting regional production targets, land-use planning, and assessing impacts. Attached to this letter is a list of our suggested modifications to the sample regulations to allow for active tribal participation.

"Indian tribes should have been given the opportunity to participate in the development of the DES and the preferred alternative. Perhaps the lack of tribal participation accounts for the inadequate treatment in the DES of the significant impacts of the program on those tribes located near federal coal regions. We feel that greater attention should be paid to those impacts in the section on regional impacts."

Commenters 055, 172, 180, 079, 118, 108, 019, 135, 138, 160, 175, 137, 148, and 057

Response. There is specific provision for tribal participation in the BLM land use planning process. The method for accomplishing this participation is in section 1601.4-1 and 1601.4-2. This section describes the methods used to contact Indian tribes and the intent to coordinate BLM plans with land use policies, plans, processes and management programs of Indian Tribes. It should be noted the BLM is only one party and for this process to be productive, Indian Tribes must play an active and aggressive role. The Interior recognizes its trust responsibilities to assist Indian Nations in their land use planning and resource management activities and is prepared to assist any Indian Nation that expresses an interest and commitment to coordinated land use planning.

Strong efforts were made to give Indian tribes the opportunity to participate in the development of the DES on the preferred program. The Denver-based Deputy to the Director of the Office of Coal, Leasing, Planning and Coordination (OCLPC) contacted those tribes with major coal deposits adjacent to large Federal coal fields. Those tribes that expressed an interest in the program were personally visited by a representative of the OCLPC and were briefed on the development of the program. All departmental issue papers were sent to these tribes as they were developed. The Department offered to continue to work with the tribes individually or collectively. No Tribal Government made any request for follow-up coordination meetings.

The OCLPC is presently examining with the commenter and other concerned parties what additional methods there might be to ensure tribal participation in leasing.

Changes have been made in Chapter 5 of this final EIS to recognize the impacts of the various management program activities on the Indian tribes.

Your comments on the regulations have been addressed separately.

SPECIAL LEASING CONSIDERATIONS

1. Comment. "Public Body Leasing"

"The program for public body leasing should be carried out under the supervision of the joint state-federal coal selection and ranking team in each production region. The governor of each state

should be allowed to review and approve any lease sale of coal under the public body provisions to a public body from another state."

Commenter 093

Response. The Department intends to provide State governors with an opportunity to consult with the Secretary of the Interior on all lease sales, including public body sales. Additionally, the federal/state regional coal teams will be closely involved in preparing tracts for special opportunity sales.

2. Comment. "In section 3.2.6 of the DEIS, the special leasing opportunities for public bodies and small business are discussed. Western Fuels supports this concept but urges expansion of the discussion in the FEIS to include a consideration of the amount of coal land which would be available for special leasing opportunities and the precise procedures which would be utilized."

Commenter 090

Response. The Department plans to make sufficient coal available to satisfy the needs of those firms qualifying for special opportunity sales. The Department believes that this will not represent a major amount of the Federal coal leased in the program. The amount of coal supplied to special opportunity sales but not sold will be offered in later normal lease sales.

3. Comment. "Special Leasing Opportunities Provisions are mandated by Section 2 of the Federal Coal Leasing Amendments Act. The present Draft Environmental Statement is inadequate in that it fails to specifically identify such a program. The final Environmental Impact Statement must address this issue or it too will be inadequate."

Commenter 151

Response. The final EISs do adequately recognize the special leasing opportunities provision of the Federal Coal Leasing Amendments Act of 1976. We refer you especially to Section 3.2.7 of the EIS and to subpart 3420.1-4 of the preliminary regulations.

4. Comment. "The Draft Environmental Statement (section 3.2.6, page 3-27) and the Example Regulations (sections 3420.1-4(a) (2), page A-11 and 3472.2-2(e), page A-36) provide for a 'special leasing opportunity' in the form of a small business set-aside. The authority for this

special class of bidder apparently is derived from the Declaration of Policy of the Small Business Act, 15 U.S.C. 631(a). There is no small business set-aside provision in the Federal Coal Leasing Amendments Act of 1976 or in other mineral leasing authorities.

"The American Mining Congress fully endorses the policy of the Small Business Act to assist small businesses as a means to encourage free competition in the private enterprise system.

"Without intending to diminish our support for small business, it is appropriate to point out that the authority relied upon in the Small Business Act is open to serious question. In this regard, 15 U.S.C. 631(a) would appear to be directed to the 'sale' of government property, which contemplates the passing of title, as distinguished from a leasehold interest which falls short of complete ownership. Moreover, the Coal Leasing Amendments Act of 1976 indicates the intent of Congress to only create set-asides for certain public bodies.

"One concern can be expressed in the context of the large areas of land that may eliminate from mining during the land use planning stage. An additional exclusion of tracts of the remaining lands acceptable for mining at least has the potential of rendering adjoining tracts uneconomical for mining by larger companies and may seriously complicate the problem of creating logical mining units.

"Assuming that such set-asides are legal, the DES characterizes the amount of land to be set-aside as a 'reasonable number of tracts. It is our understanding that the SBA will determine the number of small mining businesses in a particular area and on that general basis arrive at a figure for the amount of reserves to be set-aside. Although it is not clear how this determination will work procedurally, it is recommended that public and industry input be allowed at the earliest possible stage. Only through such early and continued open discussion of this process can Interior make the necessary selection decisions.

"It is also recommended that the set-aside process be accomplished early in the activity planning stage. While we note that there will be no special determinations of fair market value, maximum economic recovery, diligent development, or other possible financial incentives, DOI has not indicated how the set-aside concept will impact the regional production targets. If these targets will

serve to rank and select tracts, early set-aside information is absolutely necessary.

"We would also note that the application of terms such as 'fair market value' and 'maximum economic recovery' may take on different interpretations in the small business context. A fuller discussion of these issues is absolutely necessary.

"Our recommendations generally have equal applicability to the special leasing opportunity offered to public bodies under the authority of section 2 of the Federal Coal Leasing Amendments Act of 1976. This is particularly true with regard to the early and continued opportunity for input from the public, industry, and other interest groups.

Commenters 087, 098, and 034

Response. The Department believes that its statutory, and policy, bases for the small business special opportunity sales are sufficient. We see nothing in the language of the Coal Leasing Amendments Act of 1976 that would foreclose the sale of leases in the small business program.

The Department does not expect that the size of the special opportunity set-aside program will be large enough to have a material effect on the normal leasing process. The Department would run these programs largely on the basis of their public purpose rather than on the basis of satisfying a regional coal target. The probable size of the special opportunity sale for any upcoming schedule will be known at the time that tract ranking, selection, and scheduling begins. Any participants in activity planning and the associated regional sales EIS will be able to comment on the proposed special opportunity schedule. In addition, the Small Business Administration requested comments on its definition of small business for coal leasing purposes in Federal Register, March 14, 1979, p. 15514

Fair market value and maximum economic recovery would not take on a separate meaning when used in connection with the special opportunity sales except that in computing these parameters the Department would recognize the unique tax structures that sometimes face such firms, i.e., it would not negate the tax preferences shown these firms.

START-UP CONSIDERATIONS

1. **Comment.** "We need a new MFP to consider such socio-economic disasters, and the Land Unsuitability Criteria need to be changed to

protect our farmland and water. But the impression I get is that we will receive very little protection from the preferred alternative because of the start-up program as described in 3.1.1.8. You plan to lease in our area because it has existing MPF and ES. This is contrary to NRDC v. Hughes, which has already been quoted. It also violates the requirements of NEPA Act, 3.1.1.7, where you state that an environmental statement is needed for Management Framework Plans."

Commenters 165, 144, 176, 203, 145, 148, 167, 168, 156, 038, 085, 172, 097, 063, 155, 160, 157, 164, 124, 108, 107, 105, 038, 089, 130, 111, 061, 076, 088, and 148

Response. The Department has not made any decision to lease coal in any area except under the short term emergency procedures allowed by the *NRDC v Hughes* amended order. Before any new competitive leasing is proposed in any planning area, that area will at a minimum be tested by the unsuitability criteria as updated by the response to comments received on the draft EIS, this EIS, and the proposed regulations and by surface owner consultation. [In addition, the tract identification and ranking process would consider again, the socio-economic impacts of leasing additional coal that would be considered for the ranking process.

NEPA requirements would be fully met by a new regional lease sale EIS which would be written to support this tract delineation, ranking, and election process.]

On March 23, 1979, Secretary Andrus responded to a letter from NRDC which raised many of the same issues concerning start-up considerations as are set forth in this section. See the Secretary's letter. (page 8 77)

2. Comment. "C. 1980 Lease Sale Date.

"These start-up considerations would not be necessary if the 1980 coal lease sale date was not so rigid. Both the public and the Department would benefit if this leasing date were abandoned so that DOI could take the time to 'do it right' and develop a satisfactory coal policy without frantically trying to meet political deadlines.

"Unfortunately, we are doubtful that DOI will halt its application of the unsuitability criteria and abandon the other start-up considerations. A draft instruction memo from the Director to the State Directors concerning planning for the preferred

alternative makes it perfectly clear how important is the mid 1980 lease sale schedule".

Commenters 168 and 281

Response. Start-up procedures are established to allow the best management possible should leasing in the near future be necessary.

The Department has not scheduled a 1980 lease sale. The Department has set the goal of having a coal management program in place by 1980. This program would make it possible to have a lease sale in 1980 if it were determined (1) that the component of the program that determines the need for leasing indicated a lease sale was in order and (2) all the necessary data acquisition and environmental analysis required by the program could be completed. Any lease sale held in the next few years would include all the major coal management program elements of the preferred program. They include application of unsuitability criteria and the tract delineation and ranking and selection process, and a production regional lease sale EIS. During all of these steps there are repeated opportunities for public participation.

SURFACE OWNER CONSENT

1. **Comment.** "Where a consent has been issued, the Department should infer only interest in the tract, and encourage development by offering such area for a lease."

Commenter 098

Response. Tract delineation, ranking, and selection will consider all lands available for mining on the relative socio-economic and environmental merits of developing that lease not on the basis of who owns the private surface rights unless that surface owner is a bona fide 714 (e) surface owner and he has withheld consent or filed a statement of refusal to consent. (A preferred program policy change in this final EIS).

2. **Comment.** Page 3-18; "By designating land, the surface of which is owned by people who oppose surface mining, as suitable for coal development consideration, the local land manager would create a situation where tremendous pressures to consent to the mining would be brought on the surface owners."

Commenter 057

Response. The Department will not identify or rank tracts which include lands owned by bona fide 714 (e) surface owners when those owners

United States Department of the Interior

OFFICE OF THE SECRETARY
WASHINGTON, D.C. 20240

MAR 23 1979

Mr. Jonathan Lash
Senior Project Attorney
Natural Resources Defense
Council, Inc.
917 15th Street, N.W.
Washington, D.C. 20005

Dear Mr. Lash:

I have read your letter of February 15, 1979, on the Department of the Interior's proposed Federal coal management program. I cannot concur in the judgments expressed there.

In the letter you state that:

Despite the court's explicit command to the contrary, the Department has chosen and begun to implement a coal leasing program long in advance of completion of the required Programmatic Impact Statement.

This statement is simply not correct. First, this Department is not even proposing a leasing program. It is, instead, designing a comprehensive coal management program. Certainly leasing would be a component of that program, but it would encompass a whole range of coal actions, including the application of planning and land unsuitability requirements to existing leases; the processing of lease readjustments, relinquishments, cancellations, terminations, and transfers; the consideration of preference right lease applications; and the exchange of Federal coal and other mineral leases for environmentally unacceptable Federal coal leases and of Federal coal for alluvial valley floor coal. Second, and most importantly, not only has the Department not yet chosen a management program, but it will not do so until the final programmatic environmental statement, the comments thereon, and the comments on the proposed coal management regulations have been thoroughly reviewed. Finally, my approval of a coal management program is entirely

separate from any decision on a need for new competitive leasing. The competitive leasing component of that program would most emphatically not be initiated unless and until I decide that there is a need for renewed competitive leasing.

I am particularly dismayed by your statement quoted above because of the special efforts made by this Department to not simply comply with the order in NRDC v. Hughes, but to go way beyond its minimum requirements. All that the order required was a supplement to the 1975 final programmatic environmental statement. Preparing a completely new draft environmental statement was my idea. I chose to do so in order to avoid building on a proposed program which did not reflect the policies enunciated in the President's Environmental Message, the directions I have set for resource management in this Department, and the goals and provisions of the Federal Coal Leasing Amendments Act of 1976 and the Surface Mining Control and Reclamation Act of 1977.

I made this decision knowing that development of a wholly new preferred alternative coal management program and the preparation of another full programmatic statement would be a time consuming activity. This was not an easy decision given the recent uncertainties in energy supply and the emphasis on coal in the President's Energy Plan. However, I felt no amount of tinkering with the 1975 proposal could ensure the full incorporation of the new statutory and policy directions I noted above.

Having briefly commented on your letter, I will proceed to discuss more fully the basic issues which, as I see it, divide us.

First, I detect in your letter a suggestion that the coal program development efforts are being conducted without my full knowledge and concurrence. Your references to "the Department" and "the BLM" and your request for a meeting directly with me give rise to this inference. If this suggestion was

intentionally made, I wish to promptly dispel it. I take full responsibility for the Federal coal management program. As this responsibility was given to me by the President upon his appointment of me and was explicitly assigned to me by him in his May 24, 1977, memorandum directing me to undertake certain activities in fulfillment of his Environmental Message, I view it most seriously. Either I or the Under Secretary have considered fully every significant policy option put forward in the development of the alternatives and subalternatives analyzed in the draft programmatic statement. I directly monitor on a biweekly basis detailed milestones for the establishment of the coal management program and will continue to make all decisions necessary for the successful completion of a lawful and open coal policy review. To accomplish day-to-day Secretarial level management oversight, I have even taken the unusual step of establishing a special office under the Assistant Secretary, Land and Water Resources, to plan for and coordinate the coal policy review and the work in establishing the program.

It is a difficult and not very constructive task to respond to inferential arguments such as those made in your letter. For the record, however, I will repeat again that I have made no open or secret commitment to resume competitive coal leasing by mid-1980 or any other date. The competitive coal leasing component of a coal management program cannot be implemented until, first, I personally choose a program after reviewing the final programmatic statement and the public comments on both it and the proposed regulations, and, second, if and until I make a separate determination that leasing should resume. In any Department of this size, misconceptions can arise from reading brief excerpts from the great number of intra-Departmental and intra-agency communications. Despite whatever inferences may be drawn from those communications, none of the decisions I discuss above will be made until June 1 at the earliest. I am confident the Department is fully complying

with the letter and spirit of the amended court order. The Department is, in short, properly completing the "EIS process before (your emphasis) it adopts, let alone implements, a new program be it EMARS II or any other".

The issue which is discussed in greatest detail in your letter is the relationship between the Hughes order and the ongoing field tests of the unsuitability criteria in selected planning units. Concerning that issue, I bargained for and the Court approved the right of the Department to do any coal-related planning which does not delineate, select, or otherwise focus on particular tracts. The order allows the Department to continue land use planning efforts, revise or alter existing land use plans, and conduct studies of new planning standards. I am, therefore, satisfied that the Department has rigidly adhered to the order in its field test application of unsuitability criteria.

In part, the opinions you express in your letter would seem to be based on a misunderstanding of the purpose of identifying a preferred program alternative. The preferred program in the draft programmatic statement represents the program I would have selected last summer based on the information then available and without the benefit of the environmental impact analysis in the statement. As you will recall, one of the principal criticisms of the 1975 programmatic statement made by the plaintiffs in NRDC v. Hughes--a criticism with which the court concurred--was that EMARS II, the proposed program, was not sufficiently detailed to provide an understanding of how it would function if it were adopted. To remedy that defect, I asked that a fully detailed preferred program alternative be developed and presented in the new draft programmatic statement. Now, largely as a result of providing a high level of detail to all interested parties, we are the subject of criticism that the Department has overcommitted itself to a program. I have already said this is not true. In no way do I feel bound to the preferences I expressed last summer.

I have already agreed, and the Under Secretary has officially concurred on my behalf, to several changes in the preferred program alternative which will appear in the final programmatic

statement. These changes resulted from review of some of the comments on the draft statement. I am confident that additional, major changes will be made after review of the comments on the final statement and on the proposed regulations. As your letter particularly addresses the unsuitability criteria, let me assure you that, when I make my decisions on the coal management program, I will not be bound by the existing preferred program proposal. I will, instead, fully consider the appropriateness of the concept of requiring the initial application of unsuitability criteria in the land use planning process, the proposal to place the criteria in regulations, and the language of each criterion. I will not commit this Department to a multi-million dollar, multi-year principal feature of the preferred program without careful consideration. I certainly will not do so simply because the Department will expend limited amounts of funds this fiscal year to improve land use planning so that the coal leasing component of a Federal coal management program can be implemented promptly if I determine on or after June 1 that competitive leasing is needed. If changes need to be made in the unsuitability criteria or the manner in which they are established or used, they certainly will be made.

On the other hand, I will also not commit this Department to this decidedly innovative feature, whether as proposed now or changed, unless I am confident of its value and am assured as to the manner in which it will work. The only way to obtain the necessary level of confidence is to field test the unsuitability criteria as we are doing. As you know, these criteria are highly controversial. Many who have commented on them have expressed concern that they are not sufficiently stringent, but at least an equal number have stated that they are far too stringent. I, certainly, will not make a decision on the proposed criteria and on how and when they should be applied until I have a good idea of which, if either, position is correct. The application of those criteria now in certain land use planning efforts will provide me with sufficient information to make the necessary informed judgment.

It is not at all surprising to me that the agency officials who have responsibilities for running the Department's land and resource management programs as effectively and efficiently as possible have used as an assumption for their future budget and work planning

that the preferred alternative would become the Federal coal management program (nor that they may have occasionally slipped from the use of the future perfect subjunctive tense that the lawyers would have preferred they use). I would be deeply disturbed if such planning were not taking place. If it were not, we could find ourselves either lacking the funds and the personnel to implement whatever program I choose or seriously endangering other programs by drawing off the necessary funds and personnel to assure that implementation. The basing of management planning on the preferred alternative is obviously an appropriate decision for the agency officials to make as the proposed action or preferred alternative is, normally, the most likely outcome of the environmental impact statement process. Such contingency planning work, however, should not and will not commit me to choosing the preferred alternative coal management program.

I will continue to aggressively seek to develop an environmentally sound coal management program which meets the goals of both the President's Environmental Message and his Energy Plan and to do so in full compliance--in fact, more than full compliance -- with the NRDC v. Hughes opinion and order. I believe the chances are extremely good that this task will be a success. I certainly hope that, when success is achieved, you and all citizens who support environmentally responsible domestic energy production efforts will join me in welcoming and celebrating it.

I am grateful for this opportunity to exchange views on the critical issues concerning the management of federally-owned coal. Should you wish to meet with me to discuss further the development of the Federal coal management program, I would be happy to do so. I suggest any such meeting include representatives of those groups who, with you, co-signed the subsequent letter dated February 16, 1979.

Sincerely,

Cecil D. Andrus
Secretary

have filed statements of refusals of consent. The Department will not propose to lease any tracts for surface mining which include bona fide 714 (e) surface owners' land unless their consent to mine has been obtained. The refusal to consent procedure and the removal of the exception which permitted the holding of a lease sale even where consent had not been given are preferred program policy changes made in this final EIS as a result of these comments.

3. Comment. "Implementation Schedule Preempts Proper Planning"

"While the principle is sound, the execution of that principle, as proposed, misses the mark and misses so badly that the principle is lost. The problem with the preferred alternative is the rapid implementation schedule, which calls for lease sales in 1980, timed to occur before the November elections. This creates massive problems in all program areas. For example, this does not allow enough time for the District BLM offices to put into effect the new land use planning system.

"Instead, adoption of the real, preferred alternative is put off and the 'start-up considerations' (p. 3-28) phase is substituted for up to 15 years, according to the proposed planning regulations (1601.6-3(c)). This substitute is nothing less than the activities done under the old system, EMARS (Energy Minerals Activity Recommendation System), dusted off and injected with life again."

Commenters 154, 058, 061, 130, 173, 165, 203, 202, and 179

Response. The Department has not decided to conduct lease sales in mid-1980, but it is maintaining that option. It is unrealistic to assume that federal land use decisions should be held in abeyance until new land use plans could be generated. Congress recognized this when both the Federal Land Policy and Management Act and the National Forest Management Act were enacted by validating existing land use plans. The methods used to identify potential lease tracts in both the start-up phase and the mature program are totally unrelated to previous decisions based on the Energy Minerals Activity Recommendation System.

4. Comment. "The mid-1980 lease sale target date effectively implements much of the EMARS

planning process by necessitating reliance on existing land use plans and industry nominations."

Commenters 061, 130, 154, 058, 173, and 165

Response. First, the Department is not committed to a 1980 lease sale, it is committed to having a process in place that could accomplish leasing in 1980 if it was determined to be needed. Second, the Department is not proposing to lease previously identified tracts. The Department is proposing to update some BLM plans developed in accordance with its multiple use planning regulations by applying the unsuitability criteria described in the draft statement. This update would identify areas suitable for consideration for coal mining. From this point, the activity planning process would be initiated. The first step of this process would be tract identification. It should be noted that this tract identification will occur after environmental, social-economic, and surface-owner consultation steps have been completed. These tracts may or may not be similar to tracts previously identified by industry. It will be very likely that many will have been previously identified since as much as 85% of Federal coal lands with high development potential have been previously nominated. To claim that the Department is implementing the EMARS program because it may propose to lease lands that were proposed for leasing during that program is irresponsible.

5. Comment. "Since there is no provision for override of the surface owner's decision on the final lease, it should be presumed that no opportunity for override in the planning process is allowed either."

"A consistent interpretation and application of the Surface Mining Control and Reclamation Act is called for."

Commenters 057, 189, 146, 171, 013

Response. The Department is requesting comment on the following policy. The consultation and consent processes should be kept separate. However, during the consultation process, the Department would remove any land from further consideration for leasing if the surface owner of that land is a Section 714 surface owner and if he indicates on the consultation form that he has not previously consented to surface mining and that he firmly intends not to consent during the life of the plan. After the surface owner consultation screen has been applied and the local land manager (i)

has determined each general area in which a significant number of surface owners have expressed a preference against leasing (preference areas) and (ii) has made a determination concerning the removal of those preference areas from the areas which the land use plan will identify as acceptable for further consideration for coal leasing, the disclosure of firm intent not to consent (firm intent disclosure) would be considered.

Those specific lands covered by firm intent disclosures which are within the preference areas removed from further consideration for leasing would be noted in the plan. Those specific lands covered by firm intent disclosures which are not situated in the preference areas removed from further consideration would also be removed from any further consideration for coal leasing in the land use plan.

As a consequence of these procedures any land covered by firm intent disclosure on the consultation form (within or outside of preference areas removed from further consideration for coal leasing) would not be considered for coal leasing again for the life of the land use plan unless the ownership of the land changed, either the new owner is not a Section 714 surface owner or he is and is willing to file a written consent to surface mining, and the BLM decides to proceed with a plan amendment.

6. Comment. "All consents which have been given prior to the activation of the program, and which are non-transferable, must be respected as such. Second, after the initiation of the program, consent should not be required to be transferable."

Commenter 118

Response. The preferred program explicitly recognizes pre-existing consents. Transferability is required of new consents to ensure competitive lease sales in accordance with the Federal Coal Leasing Amendments Act of 1976. Consents are legal contracts and should be enforceable no matter who is party to them. The preferred program does specify that consents are to be individually negotiated between surface-owners and the coal company without government involvement.

7. Comment. "The DES does not adequately address the validity of surface owner consents obtained by coal companies after the date of the Surface Mining Control and Reclamation Act and

before final publication and implementation of the Coal Management Program.

" We believe that the transfer of any surface owner consent from the company holding such consent to the successful bidder at a lease sale should be based on the cost of acquisition of the consent plus recovery of overheads normally allocated to capital acquisitions.

" If a tract is offered for lease under the exception which permits the Secretary to continue a tract in a lease sale without the prior filing of a surface owner consent, the successful bidder should be allowed a sustained period of time in order to obtain such consent."

Commenters 096 and 189

Response. It is not the Department's intention to penalize companies who have obtained a consent after the date of SMCRA and before final publication of coal management regulations, at the same time the Department wishes to avoid any potential bidder's gaining a competitive advantage. Thus, such consents must be transferable unless the company can demonstrate to the satisfaction of the Department that their consent will not be used to discourage other potential lessees from participating in a sale. A statement that the consent will be assigned without extra cost to whomever would be the successful bidder would be sufficient.

The Department is considering recognizing the carrying costs of a consent in providing for the compensation of the party originally obtaining the consent. Further comments on this policy are solicited. The Department considered requiring reimbursement of the administrative costs of acquiring consent as well as the direct costs of the consent. The idea was discarded because we could not visualize a fair means for establishing what the administrative costs of consent acquisition actually were. Thus, the Department decided that opening the reimbursement process to recover administrative costs had just as much potential for reducing competition as the scenario referred to in this comment. The Department has included other safeguards in the delineation and surface owner consent processes to counter the tendency to only sell tracts in which few bidders could be expected to be interested. The delineation process will design tracts that maximize competition by taking into account what is known about ownership and consent process required complete disclosure of the content of surface owner consents and of any

knowledge of surface owner consent that might affect the sale.

The Department would not continue a tract past sale notice without evidence of written consent. This represents a change in policy as a result of comments on the draft EIS. This exception is certainly valid under the letter of the law (Sec. 714 prohibits leasing, *not* holding lease sales, unless consent is obtained) and is excellent public policy from a land use and resource planning perspective. However, numerous comments have been received by parties most concerned with the surface owner consent provision of SMCRA all of which suggest that the exception violates the *purpose and spirit* of that provision. Once the lease sale is held, according to the commenters, it will at least appear that the industry and BLM have jointly decided the coal should be mined and have "joined forces" to obtain consent. The commenters maintain that, even if this impression is not given, this exception would still have the inevitable impact of placing heavy pressure on the surface owner to consent to surface mining—pressure of the type the proponents of Section 714 had hoped was foreclosed by that provision's enactment.

8. Comment. "An unnecessary restriction is the provision for allowing the surface owner to have final or irrevocable veto power over the leasing of federal coal. The checkerboard pattern of coal land ownership so common in many parts of the west further complicates the problem."

Commenters 017 and 019

Response. The surface owner protection feature to which you are referring is spelled out clearly in the law, Section 714, Surface Mining Control and Reclamation Act. The Department has in no way expanded on the protection granted by the Congress to a certain class of surface owners whose lands overlay Federal coal.

The complex pattern of land and coal ownership does complicate the management of the Federal coal management program. The Secretary's authority for handling land ownership is limited.

9. Comment. "I understand now that the government is in the process of proposing to increase its royalty in the coal realms even though it underlay surface owned by others to two dollars and a half a ton, so whatever the government might have to recover in these mining ventures—it

is protected. The surface owner has no royalty at the present time to come to him to assure him anything to replace what can and what will happen in operations of the kind I have just mentioned."

Commenter 128

Response. The royalty payment is payment to the public for the right to extract the coal resource on public lands. At present, Congress has directed that 50% of this royalty be returned to the state in which it originated with priority for the use given to the local governments socially or economically impacted by the coal mining. The overlying surface owner is also directly protected from damages done by coal mining under the law. In the case of surface mining, for the special class of surface owners defined in Section 714(e) of the Surface Mining Control and Reclamation Act of 1977, most farmers and ranchers, the Secretary must have written evidence that the owner of the overlying surface has consented to mining. In the case of underground mining, on the other hand, the overlying surface owner may negotiate directly with the coal company for compensation or the company may be required to post a bond against damages to the surface owner's property.

10. Comment. "The manner in which such consultation is actually being carried out at the present time differs in some respects from the preferred program, and to the extent that our interests may be affected."

Commenter 096

Response. BLM State Offices have used different forms to conduct surface owner consultation. The results of these experiences have been compiled and a report prepared recommending the consultation procedures the Department should adopt. The Department has decided that the consultation process and the consent process should be clearly separated because of their differing objectives. Consultation aims at making a recommendation for or against surface mining in the area; consent aims at discovering whether individual surface owners will agree to surface mining on their property. The Department will attempt to conduct consultation and then gather consent statements. The final consultation may be expanded to include questions regarding whether consent has been previously granted and requests that, when appropriate, respondents identify themselves as qualifying under Section 714 of SMCRA.

11. Comment. "The surface owner that does not qualify pursuant to Section 714 of the Surface Mining Control and Reclamation Act of 1977 for the considerations therein mandated by Congress ('nonqualified surface owner') should not be allowed to distort the competitive bidding situation."

Commenter 092

Response. "Non-qualified surface owners," including coal companies owning surface, are protected under the Mineral Lands Leasing Act of 1920. Such surface owners are protected against damages, but do not have the right to block entry to the mineral estate as do surface owners who qualify under Section 714 of SMCRA. Such a surface owner cannot block entry.

We interpret Section 714 to mean that consultation must take place during land use planning. Its purpose is to identify areas where a significant number of surface owners prefer to have no surface mining on their lands. Consultation after ranking would not meet the intent of the Congress.

12. Comment. "We would like to see a mandatory surface-owner consent screen during the land-use planning process to be included in the area's management framework plan."

Commenters 171, 057, 128, and 198

Response. In response to these comments, a procedure has been added to the preferred program to permit a Section 714 surface owner to file at any time during activity planning a letter with the BLM district office stating that he will *not* give consent to surface mine his land. If such a letter is filed that land will not be considered available for leasing until the ownership changes or a new land use plan is prepared.

Consent *to* mine involves a contractual agreement between the landowner and coal developer or broker. The Department does not believe it is appropriate for a governmental agency to enter into negotiations that set a price for surface rights that would be purchased by a private party. Therefore, the Department will not seek the consent to mine from land owners during surface owner consultations or at any other time.

13. Comment. "What will happen in the event the surface owner should refuse to give his consent."

Commenters 128, 037, and 146

Response. A Section 714 surface owner has the absolute right to refuse entry to surface mine beneath his land for coal. No Interior authority can abridge that right.

14. Comment. "The National Wildlife Federation is concerned about the current proposal for surface owner consent in the preferred alternative. The major deficiency is that the BLM may proceed with the selection, delineation, and ranking of tracts, and may even proceed to the point of lease sale prior to industry's soliciting the consent of the surface owner."

Commenter 160

Response. A Section 714 surface owner could file a statement during activity planning with the BLM district office stating he will not grant consent to mine on his land. The BLM would then exclude this land from consideration for leasing for surface mining until ownership changes or a new land use plan is prepared. This refusal to consent policy is a change made as a result of public comment.

15. Comment. "Surface owner consultation is a wonderful concept, but, unfortunately, has been rendered totally meaningless by the statement."

Commenters 203, 057, 128, 092, and 198

Response. A Section 714 surface owner has the absolute right to withhold consent to surface mine on his land. No local manager or any other Interior official has the authority to abridge that right. No lease sale will be held where Section 714 surface owner land is involved prior to a filing of surface owner consent. The statement referred to concerns for surface owner consultation, a statutorily required activity very different from surface owner consent acquisition. As a result of this and many other similar comments text has been added to Chapter 3 of this final statement to explain more clearly the distinct statutory differences between surface owner consultation and surface owner consent and to spell out more precisely the procedures for each.

16. Comment. "A negative response from a surface owner as to whether or not he/she wants to lease his land has the effect of a non-binding response."

Commenter 099

Response. A change in the final EIS, based on comments received, makes a negative statement

on consent to the BLM from a Section 714 surface owner binding.

17. Comment. "There are no provisions in the preferred program or the sample regulations which protect the surface owner from harrassment or from incomplete, inaccurate or misleading information by 'the industry' representative who solicits the written consent. A surface owner is ultimately assured greater protection, or at least a greater opportunity of redress, in cases of abuse and harrassment when the responsibility rests with the government not 'the industry.' The preferred program creates an atmosphere which encourages harrassment of the surface owner. Even under those circumstances where 'the industry' is presenting the surface owner with complete and accurate information which is not misleading, the surface owner under the preferred program is defenseless against persistent requests by 'the industry' to sell leases despite repeated negative responses."

Commenters 099 and 061

Response. The arguments you raise in favor of having the government negotiate for surface owner consent were considered when we made our decision that industry should negotiate directly with surface owners. The Department felt that it was unwise to become directly involved in a process that is basically a transaction between two private parties. We have removed the provision that would have allowed the BLM State Director to continue a tract lease sale without consent and made several other changes aimed at avoiding "harrassment" of surface owners.

18. Comment. "How would the Department proceed to convince the surface owner that it is in his best interest to allow the Federal coal to be developed?"

Commenter 198

Response. The Department would make all the information on hand affecting the surface owner decision available so that the surface owner could make his decision based on full knowledge of likely future outcomes. The Department has decided that industry ought to negotiate with surface owners for consent. The Department does not seek to "convince" any one of the parties to a consent as to what may be in his best interest.

19. Comment. "Section 3.3.4 suggests that in dealing with split estate leasing the Secretary

would attempt to regulate the amount of compensation paid for surface owner consent through some vague notion of fair market value while publicizing all consents."

Commenter 066

Response. It is assumed that if a surface owner asked for compensation above market value, he would be less likely to find a buyer. Also, the Department does not foresee the availability of coal to be so limited that the cost of surface consents in general could be escalated to unreasonable levels. In any event, the Department will continue to follow the Congressional requirement that it obtain fair market value for the coal it leases.

20. Comment. "We recommend that the Department delete from the Preferred Program the provision on pages 3-25 that provides that tracts not be offered for sale unless included in an intertract sale if a pre-existing consent is determined to be non-transferable."

Commenter 068

Response. The Congress has directed the Department to make coal available through competitive lease sales. The emphasis is on competition. The Department does not believe this directive could be met by conducting the sale as recommended above.

21. Comment. "The Secretary's preferred coal leasing program fails to recognize the equality of the surface and mineral estates."

Commenter 074

Response. Surface and mineral rights are not always equal. The Department lacks the authority to lease land for surface mining where surface owners as defined by Section 714 of SMCRA have not provided consent to the development of Federal coal resources under the surface. The Federal government can lease coal under a non-Section 714 surface owner without his consent after compensation or promise of compensation is provided.

22. Comment. "We were told that the surface leases taken years ago were still considered consents, no matter what the circumstances, and that our land would be included in any planning done for leasing. They said any other considerations on the leases would have to be settled in court. By the time the surface owners in my area

discovered that the things they had been told when they leased were not true, the time delay and the time to go through the court process made it very doubtful that anything could be done."

Commenter 188

Response. The consent to mine privately held surface is a contract between that surface owner and the coal developer. The Department does not have the authority to nullify a contract between two private parties.

The Department will recognize consents given prior to the passage of the Surface Mining Control and Reclamation Act as required in that Act. If these consents are not transferable, the Department would only consider putting those up for bid in an intertract lease sale.

23. Comment. "Some suggestions for an improved Federal coal management planning process include removing the broad discretionary powers of the Bureau of Land Management in determining areas unsuitable for leasing by setting strict rules and guidelines. In the proposed lands unsuitability criteria, the exceptions to the criteria and the broad powers of discretion in application of these exceptions render them meaningless. The Department should have a clear, strict set of rules for soliciting and subsequently utilizing local public participation from the beginning to the end of the planning process. This participation should begin with the Department, not industry, being responsible for acquiring surface owner consent. Surface owner consultation on Page 3-21 should be conducted by the Department prior to rather than during the planning process, and it should not be just another screen for identifying lands that should not be leased. Surface owner consent should be the foremost provision of the lands unsuitability criteria. If the Department fails to obtain the consent of a surface owner to lease at the outset of planning, then that land should be removed from further consideration."

Commenter 105

Response. The Department believes it is necessary to maintain flexibility in the application of the unsuitability criteria. This flexibility is needed because of the unique difference between the various environments in which coal might be mined. Criteria are designed in a way to protect the values considered in the criteria but not unnecessarily eliminate coal from consideration

for mining. If mining could be conducted in a way that would not damage the values covered by the criteria, the land could be considered for leasing. The public would participate in this process as set out in planning regulations and procedures.

We can see no benefit from conducting consultation prior to general planning. The Department of the Interior's proposed coal management program can be divided into two major planning steps. The first is the general land-use planning for all of the resources, including grazing, timber, recreation, wildlife, mineral, etc. The second step is the activity planning stage which relates specifically to one resource, coal. During the first level of planning, the Department of the Interior will conduct surface owner consultation and will ask surface owners to state their preferences for or against leasing. The Department is considering a policy whereby if the surface owner states a preference against surface mining of his land and he is a surface owner as described in Section 714 of the Surface Mining Control and Reclamation Act, that land would be excluded from the activity planning steps. For those areas where the land owner has stated a preference in favor of surface mining or has not stated a preference, those lands may enter into the tract identification and ranking process depending on the outcome of the other screens applied during general planning. We do not understand the comment "just another screen" since these are the most important steps for identifying lands acceptable for further consideration for leasing during the general planning process. The Department has carefully examined the options for obtaining surface owner consent and has determined that this consent should be negotiated by the two parties that must reach an agreement on the terms of that consent, industry and the surface owner.

24. Comment. "The Secretary's preferred coal leasing program has taken a timid approach to coal leasing when an aggressive approach is in the public interest."

Commenter 074

Response. The Department disagrees with the conclusion stated above. The Department is moving aggressively to end the moratorium on Federal coal leasing and put into effect a program that will lease the amount of coal needed to meet national demand. It must be recognized that the

application of unsuitability criteria and the land use planning regulations is not an indication of timidity, it is an application of the law of the land. Coal development is an integral part of the national goals, however, it must be consistent with national environmental and socio-economic goals.

The coal program has not been developed anticipating wide-spread opposition to mining by surface owners. The surface owner consultation and surface owner consent steps are required by law. They are accomplished at times in the planning process consistent with the guidance given in the SMCRA.

POST-PROGRAMMATIC ES STRATEGY

1. Comment. "EIS Strategy. In response to a question by Peabody at the 3 January 1979 public meeting in Denver on the DES, Assistant Secretary Guy Martin and other Department officials indicated their 'hope' that EISs would not be necessary at the mine plan stage. It was explained that the Department intends to prepare a 'good enough' regional sale EIS to anticipate the site-specific impacts on each lease. We do not believe that is possible. As several industry representatives pointed out at the same meeting, it is impossible to propose a mining plan, reclamation, or even ancillary facilities until it is possible to obtain more definitive coal resource information necessary to do engineering and reclamation planning but which is unavailable prior to actual leasing. There is considerable NEPA case law which indicates that significant technical changes in proposed actions between regional or programmatic EISs and site-specific are legally sufficient to trigger site-specific EISs. Such impacts as hydrological impacts, air quality, water quality, subsidence, and other equally fundamental impacts all depend on site-specific mine and reclamation plans. The different natures of the Federal actions and alternatives involved at each level also strongly indicate the need for separate EISs. For example, at the regional sale EIS stage, the Department is evaluating how many and which tracts to lease on a regional basis; the alternatives analyzed at this point include different tract rankings and lease conditions. At the mine plan stage, however, the decision is the approval (for Federal lands only) of mining and reclamation plans; the alternatives evaluated at that point include approval or disapproval, approval with conditions, and various

technological environmental mitigation measures which are clearly beyond the scope of any regional sale EIS."

Commenter 097, 281, and 099

Response. The need for environmental impact statements on mine plans would be considered on a case-by-case basis. Environmental assessments will be prepared for every mine plan submitted. We believe that the effects of a mine can and should be indicated at the time the regional lease sales EIS is prepared in sufficient detail to permit a thorough and meaningful examination of the impacts of the actions before a lease decision is made; whether the detail is sufficient to make a full EIS necessary upon mine plan review can only be determined in each instance when the mine plan is submitted. The Department will not make a firm commitment one way or the other until we have operational experience with the coal management and mining plan approval systems.

2. Comment. "Another area of concern could be classified as the regional impact statement and its relationship to this programmatic. Other speakers have mentioned the Star Lake-Bisti Region. I have trouble following the rationale which would allow a regional impact statement to be part of a national program if the national program is not implemented as yet. There seems to be a problem with the timing more than a problem with the framework in which BLM is trying to make their decision making. With the Star Lake-Bisti you have an impact statement which is addressing two right-of-way applications where there are on the order of 15 mining claims being considered, thus the regional coal impact statement is not specifically addressing the regional coal development. I think that were the Star Lake-Bisti statement, the final one on the Star Lake-Bisti, it should be delayed until the Federal coal management program was implemented. I think that many of the inadequencies of the Star Lake-Bisti document could be cleared up."

Commenter 137

Response. Should the Secretary determine that new leasing is appropriate in any of the regions described in the Programmatic EIS, new regional lease sale EISs will be prepared analyzing these new proposed actions and their site specific and cumulative impacts. Data developed in con-

nction with the presently on-going regional impact statements, such as Star Lake-Bisti, will be used in the new regionals as appropriate. This and similar statements will not be used to fulfill NEPA requirements for new competitive leasing. They are being completed on a schedule apart from the programmatic because of the need to do NEPA analysis proposals to mine existing leases and take other non-leasing actions.

3. Comment. "In Section 3.4 there is a brief discussion of numerous on-going studies which are described as clarifying procedural details and which will apparently not be the subject of any further impact statements. Although the Department is not encouraged to increase the number of impact statements for any reason, it is felt that these studies are so important to industry and other public interests that failure to at least provide an adequate public comment period for them could seriously jeopardize the legal defensibility of the entire Federal coal leasing program as well as result in an inequitable situation in which parties most knowledgeable in the areas specifically being studied would not be given the proper opportunity to influence the decisions of the Department."

Commenter 066

Response. These studies, for the most part, are to simply detail procedures in any coal management program selected by the Secretary. Few, if any, of the studies' results would likely produce significant environmental impacts separate from the policies and procedures which the detailed procedures would implement and which are fully analyzed in this final statement. Moreover, most of the task forces' work is already reflected in the proposed regulations in Appendix A and changes in the text of this statement. Any additional task force results which are considered significant will be made available for public comment.

4. Comment. "Page 3-6, Section 3.1.1.7, paragraph 3 of the Statement indicates that EISs will be prepared for each MFP completed by BLM (coal and non-coal related). Is this statement correct or does it refer to the regional lease sale environmental impact statements? The issue of preparing EISs on land use plans was previously discussed during public hearings on BLM's Wilderness Inventory Procedures, and it was determined at that time that this requirement would be

excessive (especially since the public is involved in the planning process)."

Commenter 013

Response. The statement is correct. BLM has stated in their proposed rulemaking for planning "approval of a resource management plan is considered a major Federal action significantly affecting the quality of the human environment. The environmental assessment of alternatives and the proposed plan shall be accomplished as part of the resource management planning process and shall be documented and filed as an environmental impact statement." (43 Federal Register 58769, December 15, 1978). We have described the coal management process as it relates to other processes that will be in effect at the time the program might come into being rather than processes we believe are fairly certain to be outdated. Text has been included in Chapter 3 of this final EIS comparing the resource management plan (RMP) and MFP processes.

5. Comment. "The Draft Statement does not provide any mechanism for coordinating the studies required under the preferred program with studies that will later be required by OSM or USGS as the lessee attempts to develop a mine. The potential for wasteful and expensive duplication of effort is high. The preferred program alone contemplates the preparation of four different environmental impact statements prior to leasing."

Commenter 083

Response. The program as described involves the BLM, USGS and OSM. It is an integrated program. The Department is actively seeking means to streamline the coal management function. Among other things, the Department has established an interagency task force to study means of making more efficient, less costly, and more effective the data gathering tasks at each step of the coal management program.

6. Comment. "Page 3-41: The discussion of compliance with the provisions of the National Environmental Policy Act is troubling for the same reasons that I have set out above. While the plan is to provide a two-level system of Environmental Impact Statements, one national and interregional and one site-specific and intra-regional, both applying the provisions of the Federal coal management program, compliance with the Act is threatened by the preparation of the Star Lake-

Bisti Statement and the commitment of resources which will be the inevitable result of approval of that statement. Unless the final statement on this area is delayed and modified to comply with the final Federal coal Management Program serious questions about the Management Program and its compliance with NEPA are raised."

Commenter 057

Response. No new competitive leases will be made unless a new regional lease sale EIS is written and the leases are in compliance with the proposed regulations in Appendix A.

7. **Comment.** "The Program should expressly include and provide a Departmental undertaking that EISs under NEPA will not normally be performed upon a lease offering."

Commenter 098

Response. NEPA requires an EIS on major Federal actions, and the Department must do one for lease sales that meet the statutory standards.

MAXIMUM ECONOMIC RECOVERY AND FAIR MARKET VALUE

1. **Comment.** "The proposal to define maximum economic recovery as 'collective profitability' would increase the cost of coal to the consumer by requiring the recovery of coal that the prudent operator would not otherwise mine. It would be preferable to continue the U.S. Geological Survey's current vigorous enforcement of the Congress' mandate to ensure maximum economic recovery, as the Office of Surface Mining has chosen to do in its proposed surface mining regulations, rather than to increase the consumer's costs by adopting the present proposal."

"Furthermore, maximum economic recovery as proposed could require production of coal that the consumer cannot readily use because it fails to meet quality specifications for boiler design, or to otherwise fulfill contract requirements for the market's coal needs. Finally, the impact of the definition as proposed would be counter-productive to achieving the domestic priorities set forth in the President's recent State-of-the-Union message, and contrary to his pertinent reflection, expressed in that message, on the advantages of letting the competitive market, rather than government, control industry performance."

Commenters 092, 083, 078, 106, and 087

Response. The definition tentatively selected by the Secretary is to calculate maximum economic recovery on the basis of all seams in land with consideration for social and environmental costs. The purpose of MER is to maximize the coal recovery from mines and thus to minimize overall surface disruption. A task force developed an operational process for this definition that basically computes the profit maximizing level of output for each seam. Thus, company profits would not be threatened nor the cost of coal to the consumer raised. Instead the Government would, on a case-by-case base, accept a lower recovery of its coal on more costly seams to avoid external environmental and social costs. Because the economic evaluation would be carried out seam by seam, where coal in a seam is unmarketable MER will not force the company to extract it. A task force is presently studying methods of determining MER in accordance with the Secretary's preference plus at least two other alternatives. At the request of the Council on Economic Advisers, the task force will also do an economic analysis of the alternatives. The report of the task force will be considered by the Secretary when he makes his final decision on the coal management program.

2. **Comment.** "Requirements for provision in the lease for a determination of specific levels of 'maximum economic recovery' should be deleted from the Program."

Commenter 098

Response. The law directs the Department to require maximum economic recovery.

3. **Comment.** "The intent of the definition of maximum economic recovery contained in 3.3.6 is a good one. Minimization of surface disturbance is a sensible objective in both surface and underground mining. By limiting the area of surface disturbance, conflicts with other values and land uses, especially those associated with wildlife, can be minimized. But the desire to achieve maximum economic recovery cannot be the absolute, overriding, dominant concern. The definition of maximum economic recovery needs to be tempered with a common sense qualifier: The seams that are recovered within the scope of this collective profitability test must be marketable. The seams that are recovered within the same deposit are not necessarily homogeneous. The diversity in quality of the coal can be such that one or more of the

seams may not be marketable end-use due to the poor or aberrant quality of the coal. An additional qualifier is that maximum economic recovery should be based upon coal recoverable from current, existing technology."

Commenter 093

Response. The maximum economic recovery process has been studied by a special Departmental task force, and a report on this task force's efforts is expected to be available by March, 1979. This study is likely to recommend that the maximum economic recovery determination should consider new technology that is likely to be employed in coal mining within the life of the lease. Since changing technology may affect the profitability of the deposit, the tract delineation would be adjusted to recognize this possibility. Analyzing tracts in the light of changing technology will improve conservation of the coal resource, and may also avoid processing later by-pass leases and the administrative costs associated with them. The MER study is also likely to contain an alternative for the Secretary to consider the determination of MER based on individual seam profitability.

4. **Comment.** "I am concerned that the conceptual implementation of statutory fair market value requirements may be too complicated to be workable. The transformation of techniques that inform market decisions into techniques that comprise regulatory mandates often yields unforeseen or undesirable consequences, not the least of which are ever more applications of technical concepts. One example is the limitation on surface owner compensation, which is tied to fair market value determinations. I would prefer to see Federal analysis based on simpler conceptions of protection for the Federal taxpayer, which I believe was the Congressional purpose for the fair market value requirement."

Commenters 147 and 78

Response. The Department recognizes the complicated nature of fair market value determinations and its implications for surface owner compensation. It now has a task force actively working on these complicated issues and expects, with the help of the states, to be able to resolve them in the next two to three months.

5. **Comment.** "Section 3.2.4.3 concerns fair market value and states that it would be establish-

ed by a discounted cash flow analysis. We feel that the actual methods used to define fair market value should be presented in more detail to allow a basis for evaluation of the methodology to be employed as well as the likely results of its application. Inclusion of an example or test case could allow a better understanding of this concept by the public and industry."

Commenters 106, 098, 096, and 101

Response. The preferred method of establishing fair market value is the use of comparable sales. The discounted cash flow model is described somewhat in a report of the special task force on that subject which is available on request from the Department. It has been the position of the Department that the detailed description of the discounted cash flow model used by the Department is for government use only since it relates quite closely to the evaluation of bids on coal leases.

6. **Comment.** "The State of Utah clearly and unequivocally rejects the notion that the Federal Coal Leasing Amendments Act direct the federal bureaucracy to maximize its monetary return from each individual lease, or to use the coy euphemism employed by the advocates of this institutionalized avarice, 'capture all the economic rent'. It is a contradiction of the spirit of FCLAA, the creation of maximum competition, for the Department of the Interior to pursue the maximization of profits like some nineteenth century Robber Baron. The intent of Congress was to insure that the federal government receive a fair and reasonable return from private use of public resources. The best measure of 'fair market value' is comparable transactions from state and privately-owned coal. Such an estimate based upon available data, will more accurately reflect market conditions — hence 'fair market value' — than federal behavior suitable only to the most brazen attempts at a monopoly market.

"An approach that seeks reasonable returns through a suitable combination of front-end bonus bids and royalty payments will maximize total revenues to the federal government over the long run. Efforts to extract everything the market bears from each individual lease can actually be counter-productive to production. At some level of production royalty or front-end bonus bid would be bidders will shift their capital to non-federal coal if

these are available or even other types of energy resources. The intent of FCLAA was clearly to get development of federal coal resources going – not at any cost, but at fair and reasonable return to the owners of the public lands. An effort to extract maximum return off each lease can be motivated by a bureaucracy defensively misreading Congressional intent, or greedily misreading Congressional intent, or by distorting that intent to frustrate development of federal coal. Whatever the motivation, an insistence that ‘fair market return’ is a license to pursue monopoly profits will hold down development of federal coal and aggregate returns to the treasury from that development. Those charges for front-end royalty bids will inevitably be passed back to the public in their roles as consumers of power, so it is fiction to pretend that the people experience a net gain from heavy front-end bonus bids or royalties.”

Commenter 093

Response. The Department has taken a close and detailed look at the subject of fair market value. Comparable sales data have been and continue to be one of the bases of established fair market value. When the comparable sales cannot be determined, a coal resource economic valuation (CREV) is conducted in an attempt to predict the worth of the coal. The Department does not wish to extort high prices for its coal or to cause consumers high energy prices because of the policy it pursues with regard to acceptable bids on coal leases. At the same time, the Department feels that it must attempt to recover the same amount of compensation for leasing Federal coal as an informed private owner of coal would for his coal. Congress clearly did not intend the Federal government to subsidize the class of consumers that rely on Federal coal. Since more than half the royalty recovered from Federal leases is returned to the states from which it originated, we also feel that good management in acceptance of bids on coal leasing is in the interest of the coal state residents as well.

END-USE CONSIDERATIONS

1. **Comment.** “The DES indicates that the Department is considering an inclusion in the preferred program of a procedure for issuing leases containing stipulations regulating the sale of the coal produced from those leases. We are extremely concerned by such a suggestion as it would reduce

the coal lessee to little more than a mining contractor for the federal government and would indicate an intention by the government not only to control the amounts and locations of production, as is implicit in the provisions of the preferred program, but would also imply that the government will undertake to tell consumers from whom they must purchase their fuel. Not only is such a thought violative of the Mining and Minerals Policy Act, which relates to the encouragement of mineral production by the private sector, but its implications go far beyond the confines of a federal coal leasing program and extend into the area of government control of all industries which use coal either as a fuel or in some manufacturing process. Clearly, the authority for and the effects of such a concept have not been discussed in the DES.”

Commenter 087

Response. The Department disagrees that the statement fails to discuss the effects of adopting an end-use program. Most importantly, the statement notes that “Controlling end-use would cause very fundamental changes in how the Department leases coal.” and that “the consequences of such an increased Federal role would likely be more significant to political and economic relationships in our society than to the environmental values and standards which are within the scope of the statement.” Some additional text has been added to clarify the extent of this change, but no fundamental changes have been made in the text. As the comment notes, the Solicitor has not yet determined whether and to what extent authority for this program would exist.

2. **Comment.** “DOI’s contemplation of placing end use restrictions on coal mined from federal leases is without authority or justification and has no place in a federal coal management program.”

Commenters 083, 092, 078, and 104

Response. The comment does not provide any support for its assertion that an end-use control program is without authority or justification; no specific response is needed in this situation. As a general matter, the discussion of this issue shows that these would appear to be benefits to all concerned if a coal lease was conditioned on certain end-use restrictions. Whether there is justification for a full-scale program is much more arguable. There are

significant costs and risks from involving a government agency in a program of that type. As to the legal authority for the program, the Solicitor's Office has not completed its opinion on the topic. Comments on the Department's legal authority should be sent directly to Solicitor, U.S. Department of the Interior, Washington, DC 20240.

ENVIRONMENTAL DESCRIPTION

1. **Comment.** "Since there is little federal land in Illinois underlain with coal and the leasing of this specific coal will not have a significant impact on the overall development of Illinois' coal resources, The Federal Coal Management Program will not have the importance in the Eastern Interior Region as it does in the West. Nevertheless, the Draft EIS regional projections target Illinois (as part of the Eastern Interior Region) as one of the key areas for future coal production. In light of such a conclusion, we find it disturbing that the federal government's assessment of environmental conditions and impacts is so inadequate, specifically the conclusions the Statement draws concerning reclamation. We also find it disturbing that the Statement is concerned about the region's ability to recover from mining to uses such as forest and pasture lands, when the majority of the state's land is prime agricultural land. (See page 4-9.)"

Commenter 111

Response. The reclaimability text of Section 4.2.1 is based on adequate land management practices and the fact that natural succession is a common ecological phenomenon of the eastern deciduous forest. If, however, the land is not properly managed and erosion or some other long term adverse condition prevails, reclaimability may be seriously jeopardized. Forest and pasture lands reclamation is pertinent to the discussion as much of the southern portion of this region is used for these purposes. Prime farm land mining and reclamation would be conducted within the constraint of SMCRA and the unsuitability criteria.

2. **Comment.** "Page 4-17 discusses various Federal lands in Texas. Camp Swift is not mentioned even though a mine is being considered on this property."

Commenter 091

Response. Camp Swift has been added to the FES' list of Federal lands in Texas.

3. **Comment.** "I think the first major point that I would like to say is that you look at the definition of the Powder River Coal Region. It's said to include seven Montana counties and six Wyoming counties. I couldn't even count that many in Wyoming that I could figure out that were the Powder River Basin, as we plunged through it.

"The area then this programmatic speaks to when it always talks about the Powder River Coal Region encompasses somewhere around thirty-one thousand square miles. While this may be the fact in proper technical definition of Powder River Basin, it does not speak to where the majority of coal is centralized and thus to where this impact is centralized."

Commenter 146

Response. The counties involved in each coal region have been tabularized in Appendix H of the FES. The site-specific impact locations are not known at this time, as they would be a function of future tract delineation.

4. **Comment.** "There are several errors in the description of the Powder River Coal Region Environment. On page 4-19 the Powder River rather than the Tongue River should be named as a stream with a heavy sediment load. On page 4-20, prairie chickens are included as birds occurring in this area. However, it is very doubtful that any of this species occurs in the Powder River Coal Region. A reference is made on page 4-21 to a fish species called the shovelnose sturgeon chub. Actually, there is no such species. The authors are probably referring to a shovelnose sturgeon or a sturgeon chub."

Commenter 121

Response. The FES text contains the suggested modifications.

5. **Comment.** "In Chapter 4, Description of Regional Environments, Page 4-20, in Paragraph 4, it is noted that Madison Limestone water reserves exceed 13-million acre-feet. We feel that this figure is extremely conservative and should be revised to more accurately describe the potential of this aquifer. In a statement by Floyd A. Bishop, former Wyoming State Engineer, on the Coal Slurry Pipeline Act of 1975, H.R. 1863, et al, before the committee on Interior and Insular Affairs, House

of Representatives, Nov. 14, 1975, it is noted that there is almost universal agreement that the Madison Formation in this area constitutes a tremendous aquifer, with estimates of total water in storage running from 500-million acre-feet to more than one billion acre-feet."

Commenter 006

Response. Section 4.5.1 has been changed to reflect that the groundwater reserves in the Madison aquifer are uncertain and that estimates range to over one billion acre-feet.

6. **Comment.** "I am pleased to find that Chapter 4, "Description of Regional Environmental Environments" contains several sketchy historical sections entitled "The Environment and Man." Since this is an overall management plan, the omission of numerous historical events, personages, and sites from this section is understandable if unfortunate. Yet, it does not appear that adequate identification and/or evaluation of properties eligible for or enrolled in the National Register of Historic Places was performed for the Powder River Coal Region. The section mentions no sites enrolled in the National Register and Sheridan and Johnson Counties alone contain more that 65 historic sites eligible for or enrolled in the National Register. Section 4.6 'Green River-Hams Fork Coal Region' provides an adequate listing of 50 sites listed on the National Register. However, Danger Cave mentioned on page 4.6.2 is located within Tooele County, Idaho and not in Wyoming."

Commenter 122

Response. The FES contains the suggested modifications. It should be noted that no survey or evaluation of properties eligible for or enrolled in the National Register of Historic Places was performed for this FES because the specific sites involved for any given region are not known at this time.

7. **Comment.**

4-25, and 2nd Column, 1st full paragraph, 2nd sentence:

"Fonelle" should be Fontenelle.

4-26. 2nd column, 1st full paragraph, 2nd sentence:

Should be "Kendall warm springs dace", (not darem). In same sentence the Utah prairie dog occurs in the Uinta-Southwestern Utah Region. It

is doubtful if it occurs in the Green River - Hams Fork Region.

4-26, 1st Column:
