What is now the actual result? A net income of £300 per annum (after payment of rent and other details) is guaranteed to every practitioner entering into arrangement with the Board. His income is not limited to that amount. Herein lies economic emancipation.

Tenure and income are both secured. Starting from this basis, I willingly proceed to meet your correspondent's desire for information regarding Dr. Mackenzie's cardinal objection.

No. (2). The scheme is to be opposed or postponed because the time given for consideration is too short, and many medical men are serving with the forces. The main outlines of the scheme have been before the profession and the public since the recommendations of the Dewar Committee were published in January, 1913. Medical associations, as well as individuals, have had abundant time in the interval to place their views before the Board. The interests of men absent with the forces will in the meantime be in nowise prejudiced, and it is difficult to divine any objection to Governmental subsidies for their substitutes while the principals are honourably employed in the service of their country.

3. As far as I can discern, remuneration will be assessed upon work actually performed; ability and attention to duties will naturally be rewarded, and "mediocrity and inefficiency" will be guarded against by the much-opposed system of inspection.

4. Clerical work is simply not made of greater importance than medical service. It is a cheap and absurd assertion to hold the contrary.

5. There is no Lowland area in the Highlands. It is a self-evident contradiction in terms. Discrimination would lead to very curious conundrums. Geographically, how discriminate? Ethnologically, how discriminate? Are we to have Celt and Saxon differently classified for medical service? Pict, Scandinavian, Celt of the blonde type, Celt of the melanotic type? Or is it to be a tribal distinction in which the various clans will advance their claims in time-honoured fashion? Or is it to be a religious preference in which the "Wee Frises" will fight their battles over again against a host of worldly sects? Or, finally, is language to be the test and the Sassenach be despoiled? Will your Edinburgh correspondent be inclined to come in and lend a hand in deciding?

6. There will be no "interference with the liberties and rights of individual medical men." They are entitled to guard their own freedom, and the so-called "scrutiny" is only such as income-tax officials are privileged to exercise for purposes of business accounting.

To me, Sir, it appears—and I am speaking entirely on my own responsibility—to be no validity in the objections set forth.

The Board are charged with a legal duty under the Act. The members are persons of irreproachable character and standing. They have acquainted themselves with the "complicated and delicate problems" to which reference has been made, and they are required by their office to allocate the funds at their disposal without any further delay. The war, in fact, renders their performance more urgent than in peace time. Suspension would probably lead to a great boon being diverted into other channels, and for my part I would warn my brethren against that risk. To your Edinburgh correspondent I would respectfully offer these observations with a motto which, doubtless, he will understand:

'A sheanshain co theireadh é!

—I am, etc.,

Fort William, Sept. 11th.

A. C. MILLER, M.D., F.R.S.E.

INFANT FEEDING.

SIR,—Dr. Charles Cameron's address, published in your issue of August 21st, with reference to the position of the proprietary foods in the feeding of infants, cannot but call forth approval from all those interested in infant welfare. There was, however, one remark of his that I would beg

leave to criticize. The remark in question is as follows: "It does not matter whether we use the cow's milk undiluted with the addition of a little sodium citrate, and we shall then obtain both the good effects and the bad effects of a diet of cow's milk in the purest and most pronounced form, or whether we dilute the milk by the admixture of water or barley water and add very small amounts of sugar. . . . In every case the result which we shall attain will be very much the same."

To my mind the results are absolutely different. I contend that the use of diluted milk during the first nine months of life is one of the chief causes of constitutional ill health of infants, and Dr. Cameron's picture of the baby with the flabby muscles, pale face, distended abdomen, offensive motions, excessive sweating, and profuse micturition is typically that of the "diluted milk plus sugar" baby.

I have never yet—and I am inclined to think many will agree with me—seen a child who has been fed from birth with a good quality whole citrated milk appear at the end of nine months as Dr. Cameron suggests it might. While realizing that the mere negation of his statement is of no value in proving my point, yet the experience of many goes to show that in whole citrated milk we have a method of feeding that has satisfied in the fullest sense the hopes of those of us who have looked for a feeding process which shall as nearly as possible approach the ideal.

The whole question of milk dilution needs revision. The profession originally advised dilution in order to overcome the caseinogen difficulty, and with it they advised the addition of cream and sugar. From that has been evolved the now almost universal method of adding water or barley water, with no subsequent addition of cream but frequently with the addition of a large amount of cheap sugar. Such a method ends, in nine cases out of ten, in constitutional disaster. Seeing that in sodium citrate we have a substance which makes whole milk feeding a possibility, the necessity for diluting passes away, and one can confidently assert, in appealing for the more extended use of whole milk, that the results fall very little short of those attained when the natural food has been available.—I am, etc.,

Leeds, Aug. 27th.

C. W. VINING, M.D.

SHOCK DURING OPERATIONS UNDER CHLOROFORM.

Sir,—Sir Lauder Brunton's suggestion that shock plays an important part in deaths under chloroform recalls to me some experiences I had in a Tokyo hospital in the Seventies. Many eyes had to be enucleated through previous neglect by the old school of Japanese doctors. We never had a death from chloroform, but when the optic nerve was being cut it was quite usual to see sudden pallor come into the face of the unconscious patient. I began to give chloroform more freely just before severing the nerve, and found the effect was very satisfactory, no signs of shock being perceptible.—I am, etc.,

Hanley, Staffordshire,
Sept. 1st.

HENRY FAULDS, L.R.F.P. and S.

A-NOCI-ASSOCIATION.

Sir,—It was careless of me, as Dr. Allen remarks, not to have carried my criticism forward to the no less defective third syllable of this clumsy name. Well, I did not think the term worth much critical attention. It is neither etymological, nor elegant, nor descriptive; it is ill begotten and deformed—for example, the false caesura "u-ass." Let us discard it, and produce something neater and better.—I am, etc.,

September 13th.

INNOCEUS.

Sir,—Your correspondents desire, with good reason, to change the word "anoci-association," and suggest "innoci-association" or "innoc-association" as less objectionable. But as what Dr. Crile has succeeded in doing is not in associating the brain cells with innocent or innocuous impulses, but in dissociating them from noxious impulses, would not "noci-dissociation" or "noccu-dissociation" be more expressive?

But I can suggest a better term still. Dr. Crile in his book on the emotions says that anoci-association differs from anaesthesia in that it signifies a process which

protects the brain cells not from some noxious impulses but from all. I suggest, therefore, that the word "pan-anaesthesia" would be at once expressive, euphonic, and etymologically unobjectionable.—I am, etc.,

Edinburgh, Sept. 13th.

W. B. DRUMMOND.

THE TOURNIQUET IN WAR.

Sir,—In the JOURNAL of July 24th Captain Ward has a very useful letter on the use of tourniquets in war. When on duty in Japan in 1907, I talked to the military surgeons there on this very subject. They fully appreciated the uses as well as the dangers of tourniquets. To each tourniquet was attached a piece of very cheap thin red cotton cloth about 3 ft. by 1 ft. This blew about in the wind, or was, anyhow, very easily seen, so that tourniquet cases were under constant observation, and were examined very frequently. I have referred to this in my report, "Sanitation in Japan" (Mysore Government Press).—I am, etc.,

JOHN SMYTH, M.D., Colonel, I.M.S.

MEDICAL STUDENTS AND COMBATANT COMMISSIONS.

Sir,—We must all sympathize very much with junior or intending medical students who are in doubt as to whether their duty lies in remaining at their work or in offering themselves for combatant service.

It would no doubt lessen their difficulty if the War Office could say definitely that it is in the national interest that no medical student should relinquish his studies. The War Office is unwilling to do this, and one can easily imagine that there are many medical students well fitted by temperament and physique to make good combatant officers who should in the national interest not be discouraged from accepting commissions.

But this fact throws upon those of us who are responsible for medical education, and can foresee the serious dearth of doctors with which the country will be faced after the war, the duty of encouraging the entry into our medical schools of as many young men as possible who, while fit for service as medical practitioners, are not specially qualified for military duty.

It may become necessary, if the war is greatly prolonged and the ranks of the profession are still further depleted, to devise some means of opening wider the somewhat narrow door into medicine. The proposal set forth in your columns by my colleague, Dr. King Brown, might be helpful to those students who have already started their medical course. In any case the members of our profession throughout the country will be doing a national service by pointing out to well-educated young men who for any reason are unable to enter the army, that the country has great need of additional doctors, and that the medical session commences in October.—I am, etc.,

London, W., Sept. 11th.

LACRISTON E. SHAW.

Obituary.

DR. LEVI FARNDON, late of Maidenhead and London, died at his residence in Ardlin Road, West Norwood, on August 27th. Dr. Farndon was born in June, 1846. He took the diplomas of L.S.A. Lond. in 1879, and L.R.C.P. Lond. in 1892. In the earlier part of his medical career he practised in London, but in consequence of ill health removed to Maidenhead, where he carried on a general practice for seventeen years. His kindness and generosity will scarcely be forgotten by the poor and needy with whom he came into contact.

DEPUTY SURGEON-GENERAL ARDEN HELME BEAMAN, Madras Medical Service (retired), one of the rapidly diminishing number of Mutiny veterans, died at The Pines, Barnstable, on August 24th, aged 86. He was born on December 10th, 1828, and entered the Indian Medical Service as assistant surgeon on June 10th, 1854, becoming surgeon on June 10th, 1866, surgeon-major on July 1st, 1873, brigade-surgeon, on the institution of that rank, on November 27th, 1879, and retired on August 1st, 1882.

Except for a brief spell in his early years as civil surgeon of Rajamundri, his whole service was spent in military employ. He was medical officer successively of the 28th, 27th, 39th, 4th, and 37th Madras Native Infantry. He served in the Mopla insurrection of 1855, and was present in the action against the insurgents at Marur, and as medical officer of the 28th Madras Native Infantry throughout the Mutiny, in the United and Central Provinces. Although his regiment did not take part in any of the principal actions or campaigns of the Mutiny, they shared in several minor affairs; among others he was at Hishingabad in the Central Provinces when the European refugees from the States of Gwalior and Indore came into that station.

BRIGADE SURGEON HENRY BLACK PURVES, Bengal Medical Service (retired), died suddenly at Malvern on August 14th, aged 72. He was born on July 2nd, 1843, educated at Edinburgh University, and took the L.R.C.S. and L.R.C.P.Edin. in 1864, also subsequently the F.R.C.S.Edin. in 1884. Entering the Indian Medical Service as assistant surgeon on October 1st, 1865, he became surgeon on July 1st, 1873, surgeon-major on October 1st, 1877, and brigade surgeon on June 16th, 1889, retiring on December 4th, 1895, with one of the extra compensation pensions for that year. The *Army List* assigns him no war service. Most of his service was spent in civil employ in Bengal, where he filled many important appointments, being civil surgeon successively of Darjiling, Bardwan, Dakka, Patna, and Howrah, as well as superintendent of the vernacular medical schools at Dakka and Patna.

COLONEL FERDINAND CAMPION BACHELOR, of the New Zealand Expeditionary Force, died at Dunedin, New Zealand, on September 4th. He was educated at Guy's Hospital, and took the diplomas of M.R.C.S., L.S.A., and L.R.C.P.Ed. in 1871. He graduated M.D.Durham in 1885. He went to New Zealand and settled at Dunedin, where he was honorary surgeon and gynaecologist to the Dunedin Hospital and lecturer on midwifery and gynaecology in the Otago School at Medicine. He filled the post of president at the Intercolonial Medical Congress of 1896, and was the author of many papers on surgery and gynaecology.

COLONEL JOHN MATHEW JONES, Army Medical Staff (retired), died at Bryn Tyron, Church Walks, Llandudno, on August 30th. He was born on January 2nd, 1853, educated at University College, London, at Liverpool, and at Edinburgh University, and took the diploma of L.R.C.P.Ed. in 1876, and that of L.R.C.S.Ed. in 1878. Entering the army as surgeon on March 6th, 1880, he became surgeon-major on March 6th, 1892, lieutenant-colonel on March 6th, 1900, and attained the rank of full colonel on September 18th, 1907, retiring on January 2nd, 1910. Before entering the army he served as a civil surgeon in South Africa, in the Zulu campaign of 1879, receiving the medal and clasp, but he appears to have seen no war service during his thirty years in the army. When the war broke out he rejoined for duty, and was employed as A.D.M.S. at Plymouth till invalided on account of ill health.

LIEUTENANT-COLONEL JOHN JOSEPH LAMPREY, R.A.M.C. (ret.), died at Putney on September 6th, aged 65. He took the diplomas L.R.C.P.I. and L.R.C.S.Edin. in 1874, and that of L.S.A. in 1876. He entered the army as surgeon on August 4th, 1877, retiring as surgeon-lieutenant-colonel on February 24th, 1897. Most of his service was spent in West Africa, where he served with the Ashanti expedition to the Gold Coast in 1881, was senior medical officer in the West African Settlements in 1883-4, and as a member of the Anglo-French Boundary Commission for delimiting the frontiers of Sierra Leone, in 1891-2. He was a Fellow of the Royal Geographical Society, and had written many articles and papers on West Africa.

A REVISED copy of the notice on incendiary bombs, as to which an illustrated article was published in the *JOURNAL* of May 29th, may be obtained in the form of a placard from the British Fire Prevention Committee, 8, Waterloo Place, London, S.W.

The Services.

THE EXAMINATION OF RECRUITS.

IN the *Royal Pay Warrant* (1914), paragraph 364, the fee for examining recruits of the regular forces is stated to be 2s. 6d. On June 26th, 1915, the Command Paymaster of the Southern Command issued a notification to the A.D.M.S., who transmitted it to recruiting medical officers. Similar notifications have, it is understood, been issued in other commands. The notification stated as follows:

In view of the fact that very few claims for fees for examination of recruits are received in this office in order, will you kindly note as follows:

1. The claims should be rendered at the end of the recognized quarters in all cases where the doctor's employment is continuous.
2. Recruits of the Territorial Force should not be included in Army Form 0.1661, the fees for the Territorial Force being payable by the County Associations.
3. The dates of examinations should be entered in rotation on Army Form 0.1661.
4. The scale of payment is as follows:
Before and up to September 16th, 1914, 2s. 6d. per man (Art. 364 Pay Warrant).
From September 16th, 1914, to March 12th, 1915, 2s. 6d. per man, but not exceeding 24s. per diem (C.R.S.C. 2 10580).
From March 13th, 1915:

Men.	2s. each.
1 - 4	10s.
5 - 9	20s.
10 - 19	30s.
20 - 29	40s.
30 - 40	Maximum 40s.

(S.C.C.O. 507 1915.)

It will be distinctly to the advantage of all concerned if the above points are attended to, as useless correspondence which takes up the doctors', the recruiting officers', your own, and my time, will be obviated, and the doctors will receive their fees earlier.

Fees for the medical examination of recruits for the Territorial Force are payable by the County Association under para. 747 Territorial Force Regulations. If in any case expenditure for the Regular Army cannot be separated from that for the Territorial Force, the whole will be charged against the Association funds.

TERRITORIAL FORCE.

EXCHANGE DESIRED.

CAPTAIN, R.A.M.C.(T.), at present with Field Ambulance (T.) in France, wishes to exchange to Territorial General or Casualty Clearing Hospital, either at home or in France. Captain's pay and allowances.—B. W., c.o. Editor, *BRITISH MEDICAL JOURNAL*.

Medical News.

DR. W. H. WILCOX, physician to St. Mary's Hospital, and senior scientific analyst to the Home Office, has been appointed consulting physician and toxicologist to the Mediterranean Expeditionary Force, with the rank of lieutenant-colonel. Dr. Wilcox began his duties some weeks ago.

A MEMORIAL to the late Dr. Hugh Dewar was unveiled in the Abercorn Public Gardens, Portobello, Edinburgh, on September 5th. It bears the following inscription: "This fountain has been erected in remembrance of Dr. Hugh Dewar, Portobello, by his grateful patients and numerous friends, who deplore the loss in the prime of manhood of a kind friend and skilful and beloved physician. His quiet charity was known to the needy. 1866-1914."

A BED was dedicated recently at the Worcester Infirmary bearing over it the following inscription: "In memory of George Edwin Hyde, M.R.C.S., L.R.C.P., Hon. Surgeon to this infirmary 1876-1898, and Hon. Consulting Surgeon 1898-1914. This bed was endowed by his sons and daughters, April, 1915." The ceremony was performed by the Chairman, after Mr. T. Bates, consulting surgeon to the hospital, had paid a warm tribute to Mr. Hyde's qualities as a surgeon and a man.

ACCORDING to the *Deutsche medizinische Wochenschrift* the war is responsible for the disappearance of two medical papers. The first is the *Allgemeine Wiener medizinische Zeitung*, established sixty years ago, and the second is the *Prager medizinische Wochenschrift*, established forty years ago. Both papers were in financial

difficulties before the war, and the fall in the number of subscribers and of advertisements due to the war left these papers no alternative but extinction. The second paper was the official journal of the Germano-Bohemian Medical Society in Prague.

THE attack on the French military medical arrangements for dealing with the wounded, so far as it was a political manoeuvre, was stopped by a very eloquent speech by the Premier, in the course of which he said that all the facts had been fully placed before and fully discussed by the proper Committee of the Chamber, and effective measures taken to repair the defects revealed. So far as the attack was a real expression of public apprehension, anxiety was quieted by the statement of M. Charles Bernard, who, with others, had been sent by the Committee on Hygiene to make detailed inquiries. He said that the service was found to be in good working order and in possession of well-appointed hospitals.

THE French Foreign Minister has formally intimated to the Académie des Sciences that considerable deposits of carnotite, a mineral yielding radium, have been discovered in Colorado, and that the experts who have examined the ore consider that the yield will be so large that the price of radium will fall to less than a quarter. The radium market has been rather a puzzle for some years; as is well known, the chief deposits worked in early days were in Austria and the price was more or less settled by the Austrian Government and financiers in that country. Later the American yield has steadily increased, and the price has tended to decline, but the market before the war was understood to be more or less controlled by an international syndicate.

SIR PETER EADE, who died on August 12th, aged 89, left unsettled property of the gross value of £22,132, including personality of the net value of £17,092. He bequeathed £1,000 to the Norfolk and Norwich Hospital, and the same amount to the Children's Convalescent Home, Great Yarmouth, and directed that the residue of his property, after the deduction of certain legacies, was to be divided equally between these two institutions. Among the other legacies were included £100 to the Norwich Jenny Lind Infirmary for Sick Children, also £200 to the Great Hospital, St. Helens, Norwich, with a request to the trustees, without any trust being imposed upon them for such purpose, to consider whether such a sum could not be best applied for the medical department of that hospital; £100 were bequeathed for the providing of a Lord Mayor's Chair for Norwich; £500 to the vicar and churchwardens of St. Giles, Norwich, towards the cost of erecting the parish hall, etc., and £200 to the Church House. Sir Peter Eade left to the Norwich Castle Museum an Egyptian mummy case, a bronze figure of Osiris, and an oil painting by Ladbroke.

M. AND MME. VICTOR HENRI have studied the variations in micro-organisms, chiefly in the *Bacillus anthracis*, brought about by ultra-violet radiation. They exposed an aqueous suspension of sporing anthrax to ultra-violet rays for varying periods (some minutes), and afterwards to subculture. The majority of the organisms were killed, but those which survived developed certain modifications in form. They state (*Archives d'électricité médicale*, June, 1915) that they have obtained two new forms of the anthrax bacillus, one a coccoid form taking the Gram stain, and the other a thin filamentous form not taking the Gram stain. Both the normal anthrax organism and the new coccoid form failed to develop in media containing either ammoniacal salts or acid amines; they developed in media containing peptone. The filamentous form, on the other hand, developed also in the presence of ammonium lactate or acid amines. The normal anthrax organism developed less strongly in media containing sugar than in the same media without carbohydrates; the coccoid form showed no appreciable difference, and the filamentous form developed much better with carbohydrates. From these and other experiments the authors venture upon a theory to explain the more or less profound biochemical and biological modifications brought about by ultra-violet rays. They had previously discovered that if such an organism as the *B. coli* were irradiated for a short time (3 to 5 seconds) a modification was produced, persisting at least for two hours, and on repeating the brief irradiation every two hours the organism was at length killed; the total duration of the isolated irradiations was equal to that of a single long irradiation which was immediately bactericidal. They suppose that, under the influence of a brief irradiation, the microbe of anthrax loses its power of secreting proteolytic ferments while retaining its power of producing amolytic ferments.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Aitoulay, Westroad, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (ADVERTISEMENTS, etc.), *Arundell, Westroad, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisera, Westroad, London*; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

DR. J. NUMA RAT (Stonchaven, St. Kitts, B.W.I.) asks for advice in the treatment of persistent hiccough with which a middle-aged professional man has been afflicted for three years; he suffers from dyspepsia and dilated stomach.

DR. T. LUSON (Wilton Lodge, Norbiton) is anxious to hear of a farm on gravel or sandy soil, with bracing air, where a young man who is a draughtsman, but would like to work on the farm, would be received as a paying guest at about £1 a week.

DIPHTHERIA CARRIERS.

DEVONENSIS, M.D., M.O.H., asks for a reliable method of curing diphtheria carriers. Everything possible in the way of local antiseptics has been given and tried, and also additional injections of antitoxin, but without avail. Reference to any literature on the subject would be welcomed.

THE NOMENCLATURE OF DISEASE.

S. M. O. (Narford Hall Camp, Swadlow, Norfolk) writes: The regulations of the R.A.M.C. require that all illnesses shall be classified according to the *Nomenclature of Diseases* of the Royal College of Physicians. Attempts to buy this only bring the reply that the publication is now out of print, and has been replaced by the *International List of the Causes of Death*, a work that is of no use to me. I shall be very much obliged if any of your readers can let me have a copy of the *Nomenclature* for which they have no use.

*. The *Nomenclature* is now under revision.

"THE CIGARETTE HABIT."

"MONK" asks for suggestions as to the treatment of a severe case of "cigarette habit." The patient is aged 39 years, and smokes from twenty-five to thirty cigarettes daily. He realizes that the habit is doing him great harm, and has attempted at various times to give himself. The effect of abstinence is, however, great mental depression—so much so that the physical effects have seemed the lesser evil, and he has always resumed his habit after a shorter or longer interval. The substitution of a pipe for the cigarettes only aggravates his symptoms, as he is a "wet" smoker, and inhales whenever and whatever he smokes.

INCOME TAX.

M.R.C.S., L.D.S. writes: Having taken a partner, I sent to the surveyor of taxes a return of the net profits of the practice for the first year, deducting the expenses from the fees actually received. He refuses the return, demanding one based upon the total bookings less the expenses incurred. Is there any redress? The latter mode of assessment would adversely affect both partners.

*. The legal position is that the new firm has "succeeded" to the practice or practices carried on by the former proprietors, and the assessment for 1915-16 should be calculated by reference to the average profits of the three previous years. The basis of "cash takings" is theoretically incorrect, but is accepted where the practice has been in existence some years, so that the year's cash receipts approximate to the value of the year's total bookings. Our correspondent's statement as to the effect of taking the cash receipts as the basis of assessment *ipso facto* shows that it is inadmissible; but if, as we understand, there has been a "succession" to an existing practice, it might be possible to take the previous three years' cash receipts and expenses of that practice.

J. P. C. has in the past three years derived an increasing income entirely from public appointments, and has paid tax on the yearly income. He inquires whether he can obtain any repayment in view of the fact that the amounts of "yearly income" have exceeded the average of previous years.

*. Salaries received from public authorities are assessable on the amounts accruing for the year of assessment, and our correspondent accordingly does not appear to be entitled to any repayment of income tax. Where the amount of the income cannot be stated beforehand—for example, as in the case of vaccination fees—the authorities would probably admit a claim to assessment on the average under Schedule E, Rule 4, and as a matter of practice they appear to acquiesce in a

request for the inclusion of public fees or salaries in the general return of a local practitioner, but J. P. C.'s case seems to stand outside both these classes.

ANSWERS.

M.B.—From £60 to £80 a year would be a fair salary for a Poor Law district such as described by our correspondent, if he is allowed extra fees, and the details of work submitted fairly represent the whole of the duties of the medical officer.

QUANTITATIVE DETERMINATION OF PEPsin.

D.—In their *Lehrbuch der Physiologie des Menschen*, 1913, Zuntz and Loewy recommend Gutzner's method for the quantitative determination of pepsin. Fibrin is made to swell up by immersion in 0.1 per cent. HCl. This is stained red with carmine; it is readily dissolved by pepsin, when the carmine is set free into the solution. The depth of colour of the solution after a given time affords a means of estimating the amount of fibrin digested, whereby the amount of pepsin at work may be calculated. This method, as modified by Roaf, and other valuable methods of estimating pepsin, are fully described in Professor Halliburton's *Essentials of Chemical Physiology*, eighth edition (London, 1914, Longmans, Green, and Co.), which our correspondent would do well to procure.

COLLAGEN.

J. S.—Collargol, consisting of black-coloured suspensions of colloid silver containing from 1 to 15 per cent. of the metal, has been very extensively employed as an antiseptic on the Continent since its use was first suggested by Créde in 1897. The most surprising cures were attributed to it ten, or even five, years ago. Cases of septicaemia, erysipelas, acute endocarditis, acute arthritis, pneumonia, enteric fever, and puerperal infections of all sorts were said to have recovered after intravenous injections, inunctions, or even enemata containing collargol had been administered. The claims made for it during the last few years have been more temperate. It is extensively employed for the treatment of gonococcal infections of the eye and the urinary tract by direct application. It continues to give good results in certain cases of septicaemia and even pyaemia, 10, to 25, to 100 c.c.m. of the 2 per cent. solution being given by intravenous injection. Patients with gonococcal arthritis have improved after deep injections of collargol near the affected joints. Used superficially it has the dissuative quality of staining the skin. In the form of ointment (1 to 5 per cent.) it has been used for treating burns, wounds, ascites, and gonococcal arthritis.

LETTERS, NOTES, ETC.

RESEARCH IN ANTISEPTICS.

MR. F. W. GAMBLE (Member of the Scientific Advisory Committee of the Pharmaceutical Society) writes: You only go to Dr. Hale White's inquiry does rather less than full justice to the *British Pharmaceutical Codex*. The French *Codex Medicamentarius* describes liqneur de Labarraque as containing 6.34 grams of available chlorine per litre (that is, 0.634 per cent.). Solution of chlorinated soda of the *British Pharmacopoeia* contains not less than 2.5 per cent. by weight of available chlorine. The *British Pharmaceutical Codex* therefore correctly describes Labarraque's solution as "about one-fourth the strength of the B.P. preparation," and your reply errs in stating that liqneur de Labarraque is between four and five times as strong as the B.P. preparation. Eau de Javelle is prepared in the same manner as liqneur de Labarraque, using carbonate of potash instead of crystallized carbonate of soda. See *Officine du Répertoire Général de Pharmacie Pratique*, Dorvault, p. 363; also Redwood's *Supplement to the Pharmacopoeia*, p. 805.

The formulas for the solution officinale d'hypochlorite de soude (liqneur de Labarraque) in the *Codex Medicamentarius* and for the solution of chlorinated soda in the *British Pharmacopoeia* are compared in the following table; the proportions of chlorine given in the *Codex* and the B.P. respectively are those quoted by Mr. Gamble:

	<i>Codex</i> .	B.P.
Chlorinated lime ...	100 grams	100 grams
Sodium carbonate ...	200 "	150 "
Distilled water ...	4,500 "	1,000 millilitres

With regard to eau de Javelle, the matter seems to be mainly of archaeological interest. According to Thorpe's *Dictionary of Applied Chemistry*, vol. ii (1912), p. 26, "the first to suggest the industrial application of chlorine to bleaching was Berthollet, in 1785, and in 1789 was produced the liquor called 'Eau de Javel,' manufactured by passing chlorine into a solution of potash." At p. 31 we read: "Hypochlorite of potash (chloride of potash or Eau de Javel). This liquor was first made in 1789 at the Javel Works, near Paris, and was the first bleaching compound known. It was then made by passing chlorine into a solution of potashes (crude potassium carbonate) in eight parts of water. This liquor is rarely

made at the present time, as it has been replaced by the cheaper soda compound, which has now mostly usurped its name." The next paragraph is headed "Hypochlorite of soda (Eau de Labarraque, usually called Eau de Javel)."

EXAMINATION OF RECRUITS.

DR. H. DE CARLE WOODCOCK (Leeds) writes to express the hope that as the need for men in the forces is becoming more urgent, greater discrimination is being exercised as to causes of rejection. "I have," he writes, "in mind one O.T.C. candidate who failed to obtain a commission on account of heart disease, which he had not got, and another who was refused because of a cervical rib; the number is great of those who have been rejected because of unimportant varicose veins, or even varicocele." He concludes his letter by suggesting that really serious conditions—for example, pulmonary disease—are sometimes overlooked.

MEASLES.

DR. R. GIRDWOOD (Wigan) writes: After careful observation in a number of epidemics I have come to the conclusion that measles is a toxæmia, and the "pneumonia" so often present a "septic" one. The "pneumonia" cases with the most virulent type in being most often present at the most acute stage of the disease, in my opinion, probably an "insufflation pneumonia" set up by the insufflation of septic bacteria, from the condition of oral sepsis so frequently present. The treatment I follow is to keep the mouth as aseptic as possible and give lib. ammon. acid. and ir. ferri persulf. in mixture; I find that if one gets the case early enough pneumonia does not complicate the case so often.

POLLITICES AND VENESECTIONS IN GAS POISONING.

DR. WILLIAM BRAMWELL (Liverpool) writes: Perhaps one of the most noteworthy instances I have yet read of in connexion with German gas poisoning is that set forth in the following statement by Dr. Walter Broadbent (Theobald), however, which did not draw away the most good was a big linned poultice placed over the whole back. The men constantly asked for the poultice to be repeated." Dr. Broadbent, however, gives no physiological reason for the evident benefit of this procedure. I know a man, a sufferer from chronic tubercular turgescence, who can never attend a chemical laboratory the atmosphere of which is more or less impregnated with gas, without having his malady pass instantly from the chronic to the acute state, with most distressing nasal congestion. This, I think, is a mild pathological picture of what actually happens in the lungs in gas poisoning. The result of the experiments of Sir Edward Schafer appear to be sufficiently conclusive that: "The only visible change is in the lungs, which even after the shortest exposure to a fatal dose are intensely red and congested, either all over or in innumerable patches. . . . The liver and abdominal organs have a normal appearance; they are not especially congested; indeed, the intestines are usually bloodless, although the veins at the back of the abdomen are full of blood." And this, in my opinion, is the explanation of the benefit derived from the linned poultice, which relieves the congestion by drawing a considerable quantity of blood from the lungs to the tissues lying immediately outside. India-rubber hot-water bottles, therefore, to the feet and other surfaces of the body, and particularly to the abdomen, it seems reasonable to supplement and add to, for everything that would be cleaner, more convenient, and keep hot longer than the poultice, and with no danger of the injuries and distressing clamminess which always takes place when a poultice is going cold, the simple heat in these cases appearing to be all that is required. The ancient physicians who died empirically and blindly for everything beneficial effect, except in those cases which had already been bled from a wound. And it would be well if army surgeons would carefully observe whether the anæmic are as great sufferers from gas poisoning as the plethoric, for gas poisoning may, after all, bear the same relative fatality to the alcoholic plethoric as does pneumonia. It is probable, too, that many lives would be saved in this latter disease were the inebriate bled as a routine system of treatment. Such physiological and pathological reasoning, therefore, would perhaps justify the surgeon in adopting this method of cure for sufferers in some cases in his endeavours to alleviate the sufferings wrought by this cruel system of warfare.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE
BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 8 0
A whole column	10 0 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, W.C.2, at least one week before the date of publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restant* letters addressed either in initials or numbers.

SURGERY ON THE GALLIPOLI PENINSULA.

By JOHN MORLEY, CH.M., F.R.C.S.,
CAPTAIN R.A.M.C.(T.F.); MEDITERRANEAN EXPEDITIONARY
FORCE;

HONORARY SURGEON, ANCOATS HOSPITAL, MANCHESTER, AND
MANCHESTER CHILDREN'S HOSPITAL; LECTURER IN
CLINICAL ANATOMY, MANCHESTER UNIVERSITY.

It would be hard to find a more striking contrast than that between the administrative problems involved in the treatment and evacuation of wounded from our front in Flanders on the one hand, and from the Gallipoli Peninsula on the other. In Flanders good roads and abundant motor transport to the railhead have permitted evacuation to be on the whole so rapid that all cases requiring operative treatment can be removed, if not to a base hospital, at least to some stationary hospital or casualty clearing station out of the zone of artillery fire, without any such delay as would be prejudicial to their prospects. On the southern end of the Gallipoli Peninsula, during the three and a half months that the present writer has been stationed here, and up to the date of writing (August 21st), the situation has been as follows:

The front line of our trenches extends across the peninsula in an approximately straight line. The field ambulances working with the British forces at the southern end of the peninsula collect their wounded from the regimental aid posts, and evacuate them, first by hand and for the latter part of the journey by horse or motor ambulance, to the casualty clearing stations. The more important of the clearing stations, and the one with which our field ambulance has had to deal, is situated near Lancashire Landing. A very serious drawback from the surgical point of view lies in the fact that the dust inevitable in a great base camp during these long months of dry weather is blown up in great clouds by the prevailing breeze, and often makes operative work during the daytime almost impossible.

From the clearing station the wounded are embarked on lighters at a landing stage that is perforce used also for the unloading of ammunition and supplies for the army. These lighters are towed by steam pinnacles to the hospital ship that lies a mile or two off the shore, and, without changing stretchers, are slung on to the ship by cranes. Except during and shortly after an action, the wounded are sent off to the hospital ship twice in the twenty-four hours. The hospital ships fill up in "peace times," as the weeks of siege warfare by artillery and sniping in the intervals between assault are called, in a week or ten days (after an action much more rapidly), and then leave for Egypt or Malta, taking three or four days respectively to reach the base. Minor cases are not taken to the hospital ships at all, but are either detained in the field ambulances or sent in small boats to be treated in stationary hospitals.

This brief account of the general position is given to show how circumstances have forced a good deal of surgical work on to the field ambulance, to which the writer is attached. The army medical authorities as a rule discourage surgical enterprise in field ambulances. The importance of speedy evacuation of wounded is ever most prominently before their minds, and they prefer that the field ambulance should devote its energies primarily to evacuation and only secondarily to treatment, and that all but the most urgent operative measures should be deferred until the casualty clearing station, or even the base hospital, is reached. The advantage of this system, by which the most experienced surgeons and best surgical equipment can be concentrated at the clearing station or further back, is obvious. But the advantage is dependent on two conditions: That circumstances should be favourable as regards absence of shell fire and dust, and that the wounded should be brought down from the firing line so quickly as not to prejudice the results of operations. The second condition involves no difficulty here, for wounded reach the clearing station within two or three hours from the trenches, but, as we have seen, there is no escape from shell and dust, and these disturbing elements are so serious at the clearing station as often to reduce operative work to a minimum. The hospital ships, no matter how well staffed and equipped, cannot entirely solve the problem,

because there must usually be some delay at the clearing station, and it is often twelve hours or more from the infliction of their wounds before patients can be got on board. Though this would formerly have been considered early enough, the experience of this war has taught us that for badly soiled wounds twelve hours is far too long to wait.

When the field ambulance came ashore at the beginning of May, within a fortnight of the historic landing of our army, we were fortunate in securing a site on the Aegean shore, less than a mile from the Lancashire Landing. Here a series of little gulleys, dry during the summer, fall steeply away from the plateau to end on the cliff below, which drops sheer some 60 ft. to the sea. The deepest of these gulleys, by dint of much excavating and levelling with picks and shovels, was so altered in two days that it could house 40 stretcher cases. A deep little bay off the main gully, with walls worn smooth by the torrential rains of winter, formed an operating theatre readily screened from the patients (see photograph), and the whole place, when roofed over with tenting and wagon covers, gave us an improvised field hospital, invisible to the Turks, that enabled our A Section tent subdivision to get to work.

The road along which our field ambulance evacuated wounded from the regimental aid posts through the advanced dressing stations to the casualty clearing station does not pass by this cliff hospital, but runs a quarter of a mile inland. From the dressing station only those wounded who need operation or rest and observation for a day or so are diverted to the cliff. The main stream of cases passes straight down to the clearing station. In the comparatively quiet weeks of trench warfare our tent subdivision can deal with all the cases passing through our field ambulance that require early operation. Such cases are sent on via the clearing station in one, two, or three days' time, as seems advisable. When a considerable action takes place we can, to the extent of our capacity (40 cases), relieve the clearing station of some of the urgent cases, which are apt to be crowded down on them in such numbers as to make some delay in giving them appropriate treatment almost inevitable.

So much has been written on the treatment of wounds from the western theatre of war, that one can hardly pretend to say anything fresh on the problems that confront us. In a general sense, however, it may be of value to describe the principles on which various classes of wounds have been dealt with in our "dug-out" hospital.

LACERATED WOUNDS.

The considerable experience of soiled and lacerated wounds that one gets in an industrial town such as Manchester has long convinced me that for such cases no antiseptic lotion can possibly, by its mere application to the soiled tissues, ensure healing without suppuration. In a contused and lacerated wound, such as we get from bombs, high explosive shells, and often from shrapnel, nothing short of complete excision of the soiled and devitalized tissues can be relied on to secure the healing by first intention that should always be regarded as our ideal. This local excision of soiled tissues is of no avail when once enough time has elapsed to permit the multiplication of organisms in the wound, and then invasion of the lymphatics; to put it in another way, the prospect of securing primary healing of these wounds varies inversely with the time that elapses between the infliction of the wound and operation. Another factor of no less importance is the completeness with which excision of the wound is possible. If no vital part is involved the operation can be complete; and, given early operation (say within two to four hours) and sound technique, results will be uniformly satisfactory. But if the presence of some important vessel, nerve, or other organ in the wound prevents complete excision, results become less satisfactory at once.

The conditions to be dealt with vary so widely with the locality and nature of the wounds that one can hardly describe a uniform technique. Local infiltration with eucaine and adrenalin is preferred to a general anaesthetic whenever possible. The surrounding skin is cleaned and dried with spirit and painted with tincture of iodine. Iodine is swabbed into the wound and a clean excision made of the contused tissues, every care being taken to avoid contact of the new clean surface of the wound with

the parts excised. The wound is then swabbed out thoroughly with a solution of hydrogen peroxide, closed as far as the local conditions permit, and drained. In a case where our ideals have been achieved (as regards early operation and thoroughness), there will be no fear of suppuration, and, of course, none of gas gangrene or tetanus. The drainage tube or tubes can be removed in forty-eight hours, and the wound will heal by first intention. But since we can only hope for an approximation to the ideal in most cases antitetanus serum is always given, and where a complete excision has not been possible the wound is not closed, but lightly packed with gauze soaked in hydrogen peroxide, which is changed once or twice in the twenty-four hours.

By these means not only are such tragedies as gas gangrene and tetanus avoided, but in cases where no limb is lost or permanently put out of action, the shortening of convalescence by avoidance of suppuration is of the greatest value from the point of view of the army. By dissecting out superficial lacerated shell and shrapnel wounds and converting them into linear sutured incisions, I have frequently sent back to duty in ten days, with their wounds soundly healed, men who would otherwise have been condemned to a convalescence of at least four or six weeks, while the slow process of suppuration and granulation went on. I am convinced that the importance of very early operation as a time-saving factor in these cases is not sufficiently realized. A recent official pamphlet, entitled *Hints on War Surgery*, issued to medical officers, contains the statement: "Shell wounds are septic, and should be treated by free irrigation and drainage." Our experience in this field ambulance shows definitely that such teaching as this, though undoubtedly true of many and perhaps most shell wounds, loses sight of an often attainable ideal, and is only true of all cases when operation is unfortunately delayed.

AMPUTATIONS.

The same principles guide us in cases of shattered limbs, where the need for amputation is not in doubt. Amputation is performed as early as possible, and, as a rule, through healthy uninjured tissues. A great deal depends on securing primary union, and that it is an attainable ideal in most cases our experience here shows. It is my custom to keep all amputations (and as far as possible most other major cases) under observation for two or three days after operation, so that before losing sight of them we can see the course the wound is taking, and it is usually found to be healing by primary union at the end of this period.

In cases of very severe injuries to the limb, as where a shell has blown off one leg, and perhaps lacerated the other, shock is profound, and it is often a difficult matter to judge whether the patient will stand operation or not. It is my custom, with a badly shocked patient, to give morphine on arrival, if not already administered, and copious saline infusions into the axillae. About an hour after the saline infusion is usually the most favourable time for amputation, and by this means one avoids waiting an indefinite time for reaction from shock. But in spite of all precautions many patients with these terrible injuries succumb to shock, often without operation being feasible.

HEAD INJURIES.

The extent of injury to the skull by a penetrating bullet varies remarkably. In some cases the bullet drills a clean hole of entrance and exit. More often there is considerable splintering and fissuring of the skull. But these bullets at short range appear to have a disintegrating effect on the semifluid brain matter that is altogether out of proportion to the injury to the bone, if one may judge by the large quantity of brain matter that frequently escapes.

In clean penetrating rifle bullet wounds involving the brain, unless there is some urgent indication, such as signs of compression, I do not as a rule trephine, but merely shave the scalp locally and sterilize the wounds of exit and entrance with iodine. The majority of these cases die within the first forty-eight hours, and those with a large escape of disintegrated brain matter are the most rapidly fatal. But occasionally one is surprised by a rapid revival in some case that one had regarded as almost moribund.

The head is almost the only part of the body where shell and shrapnel often offer a better prognosis than rifle

or machine gun wounds, by reason of their lesser tendency to penetrate the skull. Shrapnel bullets from a shell that bursts rather high have no great velocity, and will often cause a local depressed fracture without penetrating the brain, and fragments of high explosive shell, if they have travelled some distance from the burst, are often partially resisted by the scalp and skull. It is in these compound depressed fractures, without laceration of the dura, that I have obtained the most satisfactory results. The essential points are early operation, complete excision of the contused edges of the scalp wound, removal of all depressed and soiled fragments of bone by trephining where necessary, and the rounding off of the gap in the skull with gouge forceps. The wound is drained as a precautionary measure, but suppuration is rare if operation has been early, and one can easily remove the tube in forty-eight hours. Concerning the late results of these cases, one has, of course, no opportunity of forming a judgement here.

PENETRATING ABDOMINAL WOUNDS.

These wounds fall into two fairly distinct categories:

1. Rifle or machine gun wounds, with an equally small wound of entrance and exit.
2. Penetrating shrapnel or shell wounds, or rifle bullet wounds with wound of entrance only, or with a large wound of exit.

1. It can generally be assumed, where the wound of exit, like that of entrance, is the typical small puncture of the modern rifle bullet, that the bullet will have drilled through the intervening viscera, causing holes no greater than those in the skin, and that the redundant mucosa of the stomach or intestines will plug up the holes, and prevent the escape of their contents until plastic adhesions have completed the healing process. If the stomach is distended at the time, or if the patient drinks freely, or is roughly handled, there may be enough escape of stomach or intestinal contents to set up general peritonitis. But given morphine and rest, with nothing by mouth for the first twenty-four hours, the great majority of these cases make an uninterrupted recovery. The chief exceptions are cases of death from internal haemorrhage, where the bullet has caught a large blood vessel. The question has been a good deal discussed whether these cases of "clean" rifle wounds of the abdomen should be kept at rest under morphine in some advanced dressing station close to the trenches or brought down to the main dressing station where the operative work of the field ambulance is performed. My own feeling is decidedly in favour of the latter course. The chief difficulties in carrying the patients will be encountered in the twists and turns round the traverses of the narrow trenches through which they must in any case be brought before they reach the advanced dressing station; and I do not think that (after a dose of morphine) an extra hour's journey on a carefully carried stretcher down an open road will add perceptibly to the risk, though I hold it of importance that these patients should be hand-carried all the way, and not put into a jolting ambulance van on uneven and shell-pitted roads. The advantage of bringing them at once to the main dressing station, or field hospital, where the best trained nursing orderlies are concentrated, and where, should indications arise, operation can be performed without delay, is sufficiently obvious. The routine treatment that we adopt for these cases consists in morphine, the Fowler position, nothing by mouth for twenty-four hours, and saline when necessary. The saline is usually given by subcutaneous infusion into the axillae, as rectal salines might involve danger of leaking from a perforation in the colon. The patient is allowed to rinse his mouth out frequently with water, and is warned of the danger of drinking any. One injection of saline at the end of twelve hours will generally tide him over without great thirst to the end of the first twenty-four hours, when fluids are first given by the mouth. Given these precautions general peritonitis will rarely supervene, and for this class of case rapid recovery without any need for operative interference may be expected as a rule.

2. Penetrating shell and shrapnel wounds of the abdomen, on the other hand, involve an infinitely graver prognosis. The jagged sharp fragments of metal thrown off by a high explosive shell have often great penetrating power, and cut terrible rents in the hollow viscera which no plastic adhesions could possibly heal. Indeed, I have

A DUG-OUT OPERATING THEATRE, GALLIOLI.

(Official photograph circulated for the Press Bureau by the Central News.)

seen several cases where the gut has been practically divided by a small fragment of shell.

The following was a striking instance of the penetrating power of these shell fragments:

Lieutenant D. was one of seven men wounded by a "Jack Johnson" shell that also killed two other men outright. He was admitted less than half an hour after the explosion with an apparently insignificant wound on each buttock, neither of which would admit more than a finger tip. There were signs, however, of general "peritonism" with haematuria. The abdomen was opened without delay, and it was found that one of the fragments had passed up through the pelvis, making a tear 2 in. wide in the peritoneal surface of the bladder, had lacerated the small intestine in over a dozen places, traversed the stomach, and lodged somewhere in the liver. Resection of 2 in. of small intestine had to be performed, with end-to-end anastomosis. The bladder and stomach were sutured, and the bladder sutured and drained supra pubes. The patient rallied well from the operation, but died after forty-eight hours of general peritonitis.

Only less grave are the injuries inflicted in the abdomen by shrapnel bullets. There is a good deal of variation in the size of the bullets from Turkish shrapnel. The heaviest shells carry round leaden bullets almost as large as walnuts; the 75 mm. field guns throw bullets the size of small marbles. But even the smallest of these cause wounds in the intestines and stomach that are vastly more severe than those left by the conical rifle bullet. It may be regarded as a rule to which there are few exceptions that if a shrapnel bullet penetrates the gut, general peritonitis will supervene unless it is prevented by timely operative interference.

Operation consists in opening the abdomen by an appropriate incision, suturing all perforations, or resecting gut where it is too badly damaged for mere suture, ligaturing bleeding vessels, and swabbing the peritoneum dry. In ordinary cases, where operation is performed within six hours or so, I usually close the peritoneum completely, and

content myself with draining the abdominal wall, as it is there, if anywhere, that suppuration may occur.

I do not propose at present to deal statistically with the prognosis in these cases, but it may be said with general accuracy (assuming early operation) that the prognosis is bad in proportion to the number of perforations rather than the amount of extravasation of intestinal contents, and that perforations of the colon are the most fatal of all. Where there are many perforations the operation is necessarily long and tedious, and this is an additional handicap when one has often to operate at night in our "dug-out" theatre, with a cool breeze blowing down on to the exposed viscera. But early operation gives them their only chance, and though I have had many disappointing cases, I have never regretted operating. Some few have recovered that would otherwise have had no chance, and in nearly all the fatal cases the injuries disclosed at operation have been so grave that the prognosis, apart from surgical help, must have been quite hopeless.

I have placed in the same category with shell and shrapnel wounds those in which a rifle bullet at long range has penetrated the abdomen, but has not emerged. Without the evidence of a wound of exit one has no means of telling whether the bullet has turned over in its course and cut through the viscera broadside on. The right course in such cases is to keep them under observation for a short time, and, if there are definite signs of peritoneal irritation, explore. An early operation does not in any case prejudice their chances, and in some cases will save life. Similarly where a rifle bullet has caused a large wound of exit one must be guided by the degree of tenderness and rigidity in deciding whether operation is necessary. Needless to say, the primitive conditions under which these operations in the field must be conducted render it all the more important that they should not be undertaken by officers who are not thoroughly familiar with the technique of modern abdominal surgery.

THREE CASES OF GUNSHOT WOUNDS OF LARGE ARTERIES, WITH TRAUMATIC ANEURYSM.

By JOHN A. C. MACEWEN, M.B., C.M., B.Sc.,
F.R.F.P.S.,

CAPTAIN, NO. 4 SCOTTISH GENERAL HOSPITAL, STOBHILL, GLASGOW;
SURGEON, ELDERHOLM TAYLOR GOVANS' ASSISTANT SURGEON,
GLASGOW ROYAL INFIRMARY; SENIOR ASSISTANT
TO REGIUS PROFESSOR OF SURGERY,
GLASGOW UNIVERSITY, ETC.

The chief interest in the first of the cases here reported lies in the fact that it is possible for a perforating wound of the aorta, albeit small, to be inflicted without death resulting. This man, who had his aorta shot through, lived for three weeks after the wound, and died from concurrent injury to the lung.

CASE I.—Perforation of the Aorta, about an inch above the Aortic Valve, by a Shrapnel Bullet: Traumatic Aneurysm.

Sergeant B., aged 33, was wounded on October 27th, 1914, by shrapnel, and was admitted to No. 4 Scottish General Hospital, under my care, on November 4th.

On admission he was pale and anxious-looking, obviously very ill, and rather short of breath. There were several small wounds over the left shoulder and chest, the most conspicuous being situated below the clavicle. The whole left chest was much swollen, the tissues being infiltrated with blood, and the skin discoloured by ecchymosis. Owing to the great infiltration of the chest wall repeated physical examination was entirely negative. Skiagrapha revealed no foreign body, but there was always a marked want of definition, involving even the ribs. Captain Kiddie, who personally superintended the taking of the plates, suggested pleurisy with effusion as a possible cause of the want of definition.

The external wounds improved rapidly, the effusion of blood in the chest wall slowly diminished, the temperature was generally about 99° F., and the pulse little above normal; the patient took his food fairly well.

On one or two occasions breathlessness became rather pronounced, and slight cyanosis would then develop, but on the whole the patient progressed favourably until November 17th, when, impelled probably by breathlessness, he crawled to the bottom of his bed, was given a dressing-gown by another patient, and tried to crawl on a chair close at hand. The nurses' attention was immediately attracted, but the patient collapsed before they could reach him, became deeply cyanosed, and had to be lifted back to his bed. Restoratives were applied, and tracheotomy was considered by the orderly officer, who, finding no evidence of tracheal obstruction, did not perform it. The pulse remained good, but the struggle for breath and cyanosis remained pronounced, and the patient died shortly afterwards.

Necropsy.

On post-mortem examination the left pleural cavity was found filled with blood, much of which was liquid. At the apex there was a small detached portion of lung adherent to the pleura, and at the base a larger detached portion adherent to the pleura and diaphragm, but the rest of the lung was torn away from these portions, much damaged, and compressed by the blood. Death would appear to have been due to a fresh haemorrhage, caused by further tearing of the lung from the portion attached to the base.

Attention was next turned to the heart, which was slightly enlarged and fatty, but otherwise normal, and then to the aorta. Distinct from the mouths of several small vessels which were conspicuous on the inner surface of the aorta when it was opened up for inspection, there was an obvious small perforation of the aorta on either side. On the inner surface of the vessel the little holes were quite distinct, patent, and irregular in outline, while on the outer surface the track of the punctures could not be traced. On the outer surface, however, opposite one of the points of puncture, there was a cherry stone, filled with minute laminated clot. Careful search did not reveal any fragments of shell.

So far as one could see, the man might have lived indefinitely in spite of the aortal wound. The point is one to be noted by the medical jurist, who is prone to assert dogmatically that certain injuries cannot have been inflicted because the victim is still alive. While little or no attempt at healing appeared to have been made by the inner coats, the outer seemed to be quite capable of preventing escape of blood into the surrounding tissues.

The little aneurysm was situated in the coats of the aorta, which formed its walls, and to that extent might be regarded as being of the dissecting type. There was, however, no evidence of lateral extension.

It is not easy to explain the extensive damage to the lung. Had the chest been penetrated by several large pieces of shell the lung would doubtless have been torn by them, but, as a matter of fact, no metal was found, either

in the x-ray photographs or in the subsequent careful post-mortem examination. While small fragments of metal might easily have been overlooked, notwithstanding such examination, large pieces could not be. Probably, therefore, the condition of the lung was one of rupture and consequent haemorrhage and collapse. Such rupture might be caused by the patient receiving a violent blow on the chest from a large piece of shrapnel after the shell had exploded, and this theory would also explain the great bruising and infiltration of the chest wall with blood. Had the lung collapsed entirely at the time of the injury the patient would probably have died immediately, but the presence of clot of varying age and of liquid blood in the pleural cavity make it tolerably certain that there were repeated haemorrhages, accompanied by increasing compression of the lung.

One other point illustrated by this case and the next is the remarkable penetrative power possessed by small fragments of shell. It is difficult to realize that such fragments may possess sufficient momentum to penetrate the chest wall and bury themselves deeply in the tissues.

CASE II.—Traumatic Arterio-Venous Aneurysm of Common Carotid Artery and Internal Jugular Vein.

Sergeant R., aged 32, was wounded on May 3rd, 1915, at Ypres, by a small splinter of shrapnel which struck him on the right side of the neck about the level of the cricoid cartilage. Immediately a thin jet of blood spurted out, which drenched his clothes. A comrade at once caught the puncture between his finger and thumb and pinched it, thereby arresting the bleeding, and then applied a field dressing. The neck, however, began to swell, and this swelling increased as the patient was conveyed to a field dressing station, and thence to a field hospital, until finally it had extended up over the right side of the face, the eye becoming closed. The patient was transferred to hospital at Boulogne, and remained there for eleven days. While there skiagraphs were taken of the neck, but no metal was detected. By this time the swelling had begun to decrease; the face and neck were markedly discoloured. As the general swelling subsided, a tumour became apparent in the neck, and pulsation was observed. The patient was transferred to Stobhill on May 15th, when he came under my care. On admission he had a pulsating swelling over the line of the carotid which was most prominent above the level of the cricoid. There was no evident scar, but the skin over the most prominent portion was slightly stretched.

In addition to the marked pulsation a distinct thrill could be detected, particularly to the outer and posterior aspect of the swelling. The patient stated that he had been suffering from headache due to the transmission of the beating to his head, but that this headache was now much less intense, and that he was sure the swelling was steadily decreasing in size. He was therefore kept under observation for three weeks, but, while his general health improved, the swelling not only did not decrease, but became larger and more pointed, the skin over the most prominent portion being now glazed. A diagnosis of rapidly enlarging arterio-venous traumatic aneurysm was made, and operation was decided upon.

Operation.

On June 5th an incision was made below the swelling in the line of the carotid artery, and ligatures were placed on the carotid artery and internal jugular vein. A second, oblique, incision was then made above, just below the tip of the mastoid process, and the origin of the sterno-mastoid muscle cut through. The internal jugular vein was then ligatured close to its point of emergence from the skull, and the branches of the carotid artery and ligatures. The upper and lower incisions were then united by an elliptical incision surrounding the portion of glazed skin, and the involved area was exposed. The artery and vein were now found to be much damaged, and adherent to one another and communicating with the skin over a large aneurysmal sac partly in the substance of the sterno-mastoid muscle. All the structures were much matted together. The sterno-mastoid muscle was next divided for the second time, but low down in the neck, and the separated portion of muscle, containing part of the aneurysm, was removed with the mass. It was hoped that removal of the skin over the mass would be sufficient to stop the flow of blood, but such was not the case. The vagus nerve had also been damaged, and was firmly adherent to the mass. While separating it, the sac was opened into, and very free haemorrhage occurred. The opening had therefore to be closed by digital pressure, and the mass separated rapidly from other less close adhesions; the smaller distended branch vessels were caught and divided, and then, finally, all sources of blood having been cut off, the vagus was carefully detached and the mass removed.

After-History.

The patient made a slow but steady recovery; he exhibited no cerebral symptoms, nor did he suffer appreciably from shock. He now (August) feels very well, and is beginning to go about.

(I wish to express my thanks to Major Pringle for his kind advice and assistance in this case.)

Description of Specimen.

The specimen removed shows a large sac—even now, after shrinkage in preservative, fully 1 in. in diameter—which projects into and distends the sterno-mastoid muscle on the one hand, and on the other comes to within a quarter of an inch from the skin surface. The portion of the aneurysm in the muscle presents a distinct sac wall, composed of the dilated coats of the vessels, while that which projects toward the skin surface has no true wall, and is occupied by a dark red thrombus.

In this case, as in the last, while there is a perfectly distinct history of wounding, no metal was found, either by x-ray examination or at the operation. The presumption is, therefore, that the penetrating fragment was a very small one, and so was overlooked. It is possible, however, that it penetrated quite beyond the area examined. The complex nature of the aneurysm will be noted, that part which projected into the sterno-mastoid muscle having a true sac wall derived from the coats of the damaged and distended vessels, while the portion which projected toward the skin was of the purely traumatic type, there being no true sac wall.

It is remarkable that this man should have suffered such grave injury to his carotid artery, internal jugular vein, and vagus nerve, and yet have complained only of headache due to the throbbing of the aneurysm. So far as he is aware, he never lost consciousness.

It is significant of the changes in methods of warfare that while the two cases reported above were caused by shrapnel, the patient in Case III was wounded by a rifle bullet.

CASE III.—Traumatic Femoral Aneurysm.

T. B., a Boer, was shot on February 8th, 1900, the bullet, presumably a Lee Metford, entering the thigh at the junction of the middle and lower thirds of the femur, in the line of the femoral artery, and coming out about 6 in. higher up, on the outside of the thigh. The wounds of entrance and exit were alike in appearance. The patient was brought to the Military Station Hospital, Orange River, where I was stationed as a civil surgeon, on April 8th, 1900, and placed under my care. The history given was that he had been supposed to be suffering from fracture of the femur, with great throwing out of callus, and that he had been treated by massage without effect.

On examination the whole limb was found to be oedematous, while a large swelling existed on the front and inside of the thigh, extending from above the wound of entrance to about the apex of Scarpa's triangle in front, and to 3 in. below the groin on the inside, where the swelling was most prominent. The swelling was very tense and hard in front, but it presented slight fluctuation on the inside. Pulsation of the femoral artery could be faintly but distinctly made out below Poupart's ligament, and a slight thrill was also occasionally detected over the swelling. Pulsation of the popliteal or tibial arteries could not be detected, but the oedema was quite sufficient to account for this, even had pulsation been present. The patient complained of pain and discomfort over the whole limb.

Operation.

The operation was performed on April 12th. An incision, 4 in. long, was made over the most prominent part of the swelling. Immediately the skin had been incised dark blood clot presented, while dark-colored blood flowed from the upper end of the incision. The clot was removed in large masses, both fresh and old, some portions having become organized. About four pints of clot were removed. As the tourniquet did not entirely control the bleeding and it was impossible to determine the bleeding point within the sac, the superficial femoral was ligatured through a fresh incision, and then the remainder of the clot was turned out and the cavity packed with iodoform gauze.

After-History.

The patient was collapsed after the operation, but quickly responded to restoratives. The oedema had very markedly decreased by next day, and on the day following had almost disappeared. The patient made an uninterrupted recovery, the temperature never rising much above normal.

The aneurysm in this case was of the regular traumatic type, in which, the vessel having been wounded—and extensively wounded—the blood is poured into the surrounding tissues, which are stretched and compressed thereby. There was, therefore, no true sac wall, the blood being confined by the compressed surrounding tissues and by blood clot. The diagnosis of fracture, with great effusion of callus, made in another hospital, should not be lightly set aside as ridiculous, since the hard nature of the swelling, its slow increase in size, and the entire absence of pulsation might easily mislead.

The Governor reports that in the two weeks ending September 9th, 7 cases of plague occurred in Mauritius, with 2 deaths.

THE TREATMENT OF WOUNDS IN WAR.

BY E. G. KENNEDY, M.B., B.CH., CAPTAIN I.M.S.,

SURGICAL SPECIALIST, LAHORE INDIAN GENERAL HOSPITAL, FRANCE.

A YEAR after the beginning of the present European war all surgeons who have had experience of recent military surgery agree that our preconceived notions on the subject require considerable modification. Since the war began I have worked in an Indian General Hospital, seeing and treating every variety of injury produced in modern warfare. The purpose of this paper is to call attention to the importance of certain methods of treatment and to describe some modifications of practice which, in my hands, have given very gratifying results after unusually short convalescence.

With the exception of some perforating wounds of soft parts, practically all wounds met with are septic, the majority suppurating freely. The kind of wound to which I particularly wish to draw attention is the large lacerated wound of soft parts with considerable loss of skin, often accompanied by compound comminuted fracture of the long bones—for example, the so-called explosive exit type. This is the type of injury which causes the most permanent disability, the subsequent usefulness of the limb depending very largely on the nature of the treatment adopted.

All surgeons are agreed on the desirability of procuring free drainage at the earliest possible opportunity. To attain this end the entrance wound is enlarged if necessary, and a rubber drainage tube passed along the track of the wound. Free drainage is then taken for granted, although the object of the tube is only too often defeated by placing a thick pad of dressing, such as gauze or cotton-wool, over the wound. What happens is that at first the discharge flows freely into the dressing, but the discharge is of a viscid character, and capillary attraction soon fails to make the fluid permeate into the dressing as fast as it is exuded from the wound. In a short time, varying according to the amount of the discharge, drainage comes to a standstill. Pus accumulates in the wound behind the tube, dammed back by a sodden, practically impermeable, mass of dressing, and the surgeon, on removing the latter, is greeted with a flood of pus, a most disappointing and disconcerting end to an honest effort to secure free drainage.

If further proof be required, take a dressing partially soaked in pus and run a gentle stream of water over it. It will be seen that where the dressing is covered with pus the water runs over it as over the back of a duck, and with an equal amount of penetration in either case. If water behaves like this, what of viscid pus? Of course, in time a certain amount of pressure will arise behind the pus, but let us hope, for the sake of the patient, that this seldom amounts to anything appreciable. To get over this difficulty, I have for some time treated these cases without anything in the way of dressings in contact with the wound; the method adopted is as follows:

A piece of perforated zinc sheeting is bent, so as to form an arch of suitable size over the wound. Some wool is arranged to absorb any discharge after it has left the wound. The zinc sheeting arch is fixed in position by a bandage at its extremities only, and covered with two thicknesses of gauze. The wound is now inside a little chamber, open freely to the air; there is nothing to hinder the exit of discharge, and it is protected from flies or dust by the gauze, which acts as an efficient filter. The free access of oxygen seems to be of distinct benefit, and of greater value than the occasional application of hydrogen peroxide, though there is no reason why this should not be used as well. In the case of a limb it is at times of great help to sling the limb by flannel strips to a Balkan splint, the discharge dripping into a mass of cotton-wool placed on a mackintosh sheet on the bed beneath.

As to the results obtained, at the end of forty-eight hours the discharge diminishes to an extraordinary extent. At the end of a week or ten days there is only a scanty, thin, sero-purulent discharge, which continues until the wound heals completely. From the commencement the wound should be irrigated from time to time with saline—either normal or hypertonic, or some weak antiseptic lotion. In severe cases continuous irrigation may be called for.

The position of the drainage tube is, of course, very important. The tube and patient must be so arranged that the utermost recesses of the wound are reached, and that full advantage of gravity is taken to assist the flow of discharge towards the mouth of the wound. Sometimes this ideal state cannot be reached, but much can be done by care and experiment. A mistake frequently made is to drain a wound with a tube, and although the tube is not carrying off all discharge by the action of gravity alone, to imagine that free drainage has been attained by the insertion of such a tube. If the drainage is not perfect it is soon manifest; if a wound so treated continues to discharge freely after three or four days, then there is only one cause for it—namely, a foreign body; for example, a large slough, dead bone, pieces of shell or portions of clothing, etc. The wound should be explored and the cause removed.

As to the lotion employed, Sir A. Wright's arguments seem convincing; it really makes no material difference whether a sterile or a weak antiseptic solution be employed; the irrigation depends for its good effects entirely on the mechanical action of lavage of the surfaces, and its antiseptic action only affects those micro-organisms present in the pus, leaving those in the walls of the wound unaffected.

Secondary Suture of Septic Wounds.

Until recently it was thought that nothing could be more fatal than to sew up a wound in the slightest degree septic. Practical experience has shown that this is far from being so. Once a wound has been brought by the

FIG. 1.—Wound of thigh. Leg slung to Balkan splint. Wound, without dressing, allowed to drain into dressing in bed. treatment above described to a suitable condition, secondary suture will give almost the same union as that of an aseptic incision.

For secondary suture of septic wounds, the following conditions are necessary:

1. Absence of any foreign body. If there be a compound fracture, the discharge must be almost purely serous, which will not obtain as long as any dead bone is present.
2. The wound should be of such a nature that healing by granulation would be a lengthy process.

These conditions are generally present, in a wound treated in the method above described, in from five to ten days, according to the nature of the wound. The operation is performed under an anaesthetic. The lacerated muscle is united by deep sutures of strong catgut inserted mattress fashion. If the loss of skin is great, free under-cutting must be resorted to, and the edges brought together by coarse silk-worm gut mattress sutures. It is important to use mattress sutures of coarse gut, as they often have to be left in for ten days or more. Fine gut inserted in the ordinary way will cut out at the end of eight or nine days. Before the sutures are applied, the wound must be thoroughly cleansed by gentle swabbing out with ether, followed by rectified spirit. Any tendon or fascia seen lying loose in the wound should be clipped away, as it is a most frequent source of long-continued suppuration. The skin sutures are removed as soon as union is certain,

namely, about the tenth to the fifteenth day. No drainage is employed. The deep sutures are absorbed.

Skin-Grafting.

When the skin edges cannot be brought together by undercutting, without undue tension, skin-grafting should conclude the operation. By the following method a wound, however large, can be completely covered in and healed after eight days. The subsequent scar is soft and flexible, leaves scarcely any deformity, and is freely movable on the subjacent tissues. Healing by granulation, on the other hand, often means (1) very slow healing—perhaps two to four months; (2) a deep, puckered, unsightly scar; (3) adhesions of the cicatrix to the underlying muscles and tendons, causing deformity and disability of the limb. The technique is as follows: The surface from which the grafts are to be taken is prepared the previous day. The front of the thigh is a suitable spot. It is first washed with soap and water and shaved. It is then thoroughly rubbed over with ether followed by rectified spirit. A sterile dressing is then put on.

The operation is commenced by thoroughly cleansing the wound by sponging with ether followed by rectified spirit, special attention being paid to the edges of the skin, all sodden epithelium being removed. The surrounding skin is painted with tincture of iodine, care being taken that this does not reach the wound. The graft site is then exposed and once more cleaned with ether and alcohol. The grafts are then cut from the dry skin with an ordinary sharp razor, the size varying somewhat with the extent of the surface to be covered, an average graft

FIG. 2.—Wound of forearm. Perforated zinc shield in position for skin-grafting. Z, Shield alone showing shape adapted to arm; U, ulcer; G, one layer of gauze; B, bandage, fixing ends of perforated zinc.

being about 1 sq. in. The graft should be about the thickness of stout brown paper. The surface from which the graft has been removed should appear dead white with numerous freely bleeding points all over it. The graft is immediately placed on the raw surface of the wound and spread out with a couple of probes. This is repeated until the whole area has been covered. Finally, gentle pressure is exerted with a dry swab to get rid of any air bubbles or blood between the grafts and the wound and to ensure accurate contact in all places. No dressing is placed on the grafts, but the site is protected, as is also that from which the grafts have been taken, by a piece of perforated zinc sheeting, just as above described for the treatment of septic wounds. There is no need to scrape the granulations or to cause bleeding by rough handling. Provided that there is no active inflammation, slight suppuration is no contraindication, the pus escaping between the grafts.

On the second day the grafts are unchanged in appearance, except that a little pus or serum may appear between them and they are a little swollen. To the touch they can be felt quite firmly in position and adherent to the underlying granulations. By the eighth day the wound is completely healed up, all the grafts having invariably "taken," and each graft being united to its neighbours and to contiguous margins of the wound.

As to the source from which the grafts were taken, a scab forms under which the epithelium is regenerated. This scab falls off about the twentieth to the twenty-fifth

day. A general anaesthetic is usually required to graft any area larger than a five-shilling piece, but for smaller areas I have used local anaesthesia with success.

Summary.

To sum up, I am of opinion that the above described treatment for septic cases has the following advantages:

1. Simplicity.
2. A saving of expense by cutting down dressings to a minimum.
3. Better results than those obtained by other methods.
4. Ununited fractures tend to unite rapidly when once the superficial wound is healed.
5. A very much shorter convalescence for the patient.

In conclusion I may say that the substance of this paper is based on the treatment of many cases which have remained from start to finish under my own personal care.

ON THE RECRUDESCENCE OF LOCAL SEPSIS IN COMPLETELY HEALED WOUNDS

AS THE RESULT OF SOME SURGICAL INTERFERENCE
OR PASSIVE MOVEMENT.

By C. J. BOND, F.R.C.S.,

HON. COLONEL R.A.M.C.(T.); HON. CONSULTING SURGEON TO
MILITARY HOSPITALS IN THE NORTHERN COMMAND;
HON. CONSULTING SURGEON AND VICE-PRESIDENT,
LEICESTER ROYAL INFIRMARY;
MEMBER OF THE NATIONAL MEDICAL RESEARCH COMMITTEE.

THERE are reasons for thinking that cases are occurring in the military hospitals in the country in which some slight surgical interference—for instance, an incision for the removal of a piece of shrapnel under strict antiseptic conditions—has relighted a violent local reaction in the neighbourhood of a recently healed wound. Further, I have records of several cases under different surgeons in which, after all incisions and sinuses round a compound fracture involving the elbow or hip or other joint had completely healed, even such a simple procedure as passive movement of the joint under an anaesthetic has lighted up quite a violent reaction, the reappearance of the old sepsis, and the formation of local abscesses, although no incision was made nor any solution of skin surface produced.

Struck by the frequent absence in many cases of guiding signs, either local in the condition of the tissues, or general in the condition of the patient, which can be relied on as accurate indications that the original septic process has quite died down, and that all pathogenic organisms in the neighbourhood of the fracture and along the track of the wound have been completely killed off in any given case, we have lately tested this point in some cases by dropping the piece of shrapnel or the fragment of bone removed at the time of operation directly into a culture tube, and I hope to record these results on a subsequent occasion. I wish now, however, to express the opinion that if observations on these lines were carried out by surgeons on an extended scale as a routine procedure, valuable information would probably be obtained on some points in the life-histories of pathogenic organisms in their relation to the body tissues which are now obscure. For instance, we want to know more about the conditions under which pyogenic organisms can dig themselves into the tissues and remain quiescent in sheltered situations without causing any local or general symptoms and without losing their virulence, just as the malaria organism is supposed to bury itself in the bone marrow or the tubercle bacillus to become encapsuled in a lymph gland.

To what extent is the capacity of such organisms to remain alive and virulent the result of the formation of the barrier of fibrous or granulation tissue which surrounds them, or is it aided by the concomitant presence of a foreign body or some devitalized piece of tissue—for example, a fragment of bone—within the uneven surfaces of which the cocci can more readily defend themselves against phagocytic attack?

Is the time interval of essential importance, and, if so, how long after the complete healing of a wound under ordinary conditions may we suppose that the cocci or

bacteria which caused the original sepsis can retain their virulence and their capacity for renewed activity?

How does the surgical interference, the incision, or the passive movement under an anaesthetic bring about the renewed activity of the organisms and the reappearance of the local sepsis? For it is quite clear that this result is due to the lighting up of the activity of organisms already present in the tissues, and not to the introduction of a fresh infection. The fact that passive movement without skin incision can bring about the result is conclusive evidence on this point.

Does the fresh mechanical injury operate by breaking through encapsulating barriers of tissue cells or by lacerating capillaries or lymphatics plugged with the cocci or their spores? Such suggestions seem only partially adequate to explain what happens. For, although the injury may set free the organisms, it also causes a refushing of the local area with blood serum, and this might be expected to inhibit the growth of any organisms liberated amongst tissues which have themselves recently experienced and recently recovered from infection, and which should therefore have acquired some degree of immunity against subsequent attack.

The routine examination of the cultural characters of the reactivated organisms and a comparison between these and the characters of the original infection would probably throw light on this problem.

Meanwhile, some highly practical questions also arise. It would, for instance, seem desirable to allow a longer interval of time to elapse after the sound healing of a wound before undertaking any renewed surgical interference in some cases than in others, and at present we do not know how to distinguish the cases in which the longer interval is necessary. Some guidance can be derived from a previous bacteriological examination of the serous fluid withdrawn by a needle from a joint or cavity in the neighbourhood of which the foreign body lies embedded. Thus, in the case of a piece of shrapnel embedded in the cartilage of the outer condyle of the femur and removed from the knee-joint of a soldier at the Leicester Royal Infirmary two months after the healing of the wound, a few cubic centimetres of the serous effusion aspirated from the joint some days before operation proved to be sterile. In this case the piece of metal removed from the cavity in the bone and dropped direct into a cultural tube failed to give any growth of organisms.

In this case also previous attempts to use the joint had brought on considerable effusions on repeated occasions, but these were evidently due to the mechanical effect of the foreign body, which projected slightly into the joint cavity, and not to infection.

Some indication that danger of renewed sepsis does exist may also, I think, be gained at the time of operation from a close scrutiny of the condition of the tissues immediately surrounding the foreign body. If, on cutting down, the piece of metal is found in a distinct cavity, which also perhaps contains some grumous fluid, then it is probably wise to take steps to sterilize the cavity and to drain, instead of completely closing the possibly reinfecting wound.

In conclusion, I should like to add that the renewed septic process which I am here describing is no more slight reaction, or swelling or effusion which subsides with rest and time. It represents a violent reaction on the part of the tissues against a renewed virulent infection. It ends in local suppuration, and in some cases has been sufficiently serious to threaten the limb or even the life of the patient.

FROM statistics published by our Italian contemporary, the *Avvenire Sanitario*, it appears that in the whole of France there were before the war some twenty thousand practitioners. Paris alone had more than three thousand; next came Lyons, Nice, Dijon, Marseilles, and Montpellier. Of the Parisian doctors, five or six earned from £8,000 to £12,000 a year; ten or fifteen from £4,000 to £8,000, while eight hundred earned £400 to £600, and twelve hundred about £320. The rest averaged £160. Of the practitioners in the rest of France, only seven thousand earned professional incomes of more than £280. The others eked out a living by other means, including politics. As French parliamentarians are paid £600 a year, it is not surprising that so many doctors in France take to politics. The present Chamber of Deputies has about eighty medical members.

TRENCH NEPHRITIS: A RECORD OF FIVE CASES.

By NATHAN RAW, M.D., M.R.C.P.LOND.,
LIEUTENANT-COLONEL, R.A.M.C.;
WITH THE BRITISH EXPEDITIONARY FORCE.

IN THE BRITISH MEDICAL JOURNAL of July 17th, 1915, there appeared a short description of what was called a new disease occurring amongst soldiers who had been for a considerable time in the trenches.

Certainly from my own clinical hospital experience I had not met with such a symptom-complex, and as the etiology of this condition has up to the present remained uncertain, a careful record of cases is desirable.

CASE I.

A soldier, aged 33, was sent down from the front suffering from acute nephritis. He had been in the trenches for seven weeks, and had often been up to his waist in water. He stated that the onset was sudden, and that he first noticed a feeling of chilliness and swelling of face and feet. The urinary changes were characteristic; there was suppression of urine for the first twenty-four hours, and, afterwards, very small quantities (not measured) accompanied by great pain in the back and constant vomiting.

On admission to hospital he presented a typical clinical picture of acute nephritis. Analysis of the urine gave the following results: Specific gravity 1025, smoky, albumin present in large quantity. Microscopically, blood corpuscles, hyaline, and blood casts were seen. No specific micro-organisms could be isolated. Under careful treatment the albumin rapidly disappeared, the symptoms passed off, and he made a complete recovery, the attack only lasting twelve days. He had not previously had any kidney trouble.

CASE II.

A soldier, aged 33, was a much more severe case. He had been in the trenches for several weeks, and had been exposed to very bad weather. On admission he had almost complete suppression of urine, and it was with great difficulty that urinary secretion could be induced. Only after hot pack and hot mustard and linseed poultices had been applied to his loins was there any secretion of urine. It was loaded with albumin, with numerous hyaline casts, but no blood. No distinctive organisms could be isolated.

He remained in a state of eclampsia for three days, with strong convulsions, but these subsided, and he made an excellent recovery. His blood pressure on admission was systolic 230, diastolic 190, soon considerably reduced.

CASE III.

A soldier, aged 27, admitted in a serious condition; continuous vomiting and semi-unconsciousness; urine very deficient, specific gravity 1028, granular casts, albumin, no blood. Headache severe, with general anæmia.

Hot packs and injections of pilocarpine had an excellent effect, the urine increased in quantity, and the albumin was reduced to 1.1 grains per ounce. In sixteen days the albumin had disappeared, and he was well enough to be sent home.

CASE IV.

A soldier, aged 24; had been in the trenches for some weeks, and had been frequently very wet. His condition was much the same as Case III. The urine secreted was only 18 oz. in twenty-four hours, and it was loaded with albumin and granular casts.

The attack, although very acute, passed off rapidly, and the albumin quite disappeared.

CASE V.

A soldier, aged 42. No previous renal trouble. Had been in trenches for several weeks.

On admission he was only passing 10 oz. of urine in twenty-four hours, highly concentrated, and containing a large quantity of albumin and casts; no blood and no special organisms.

Treatment with hot packs and diuretics had the desired effect, and he soon made a quick recovery.

CONCLUSIONS.

1. There seems to be some association between life and conditions in the trenches and the disease.

2. None of these patients had any previous kidney trouble, and they all made a good recovery from what seemed to be a serious lesion of the kidney structure.

3. Bacteriological examinations were negative, and one is inclined to think that some infective process—giving rise to a toxin with a selective action on the renal epithelium—is the cause of this unusual symptom-complex.

ARTIFICIAL PNEUMOTHORAX:

MANOMETRIC ABERRATIONS.

By FREDERIC C. COLEY, M.D.,
PHYSICIAN, NORTHERN COUNTIES HOSPITAL FOR DISEASES OF
THE CHEST.

HAPPY is the operator who, on first entering the needle in a primary case, sees the manometer registering -14 to -16 c. in inspiration and -6 or -8 in expiration, and then going on with steady and ample oscillations in time with the patient's regular breathing, the pressure rising very gradually as nitrogen enters the pleural cavity. But things do not always go on in this encouraging way, and the operator who has well impressed upon his mind a wholesome fear of gas embolism will often find the aberrations of the manometer providing him with anxious problems.

A slight *minus* pressure inspiration, becoming less in expiration, may be produced by the point of the needle not actually entering the pleural cavity at all, but pushing the parietal pleura before it. It would obviously be dangerous to force in gas in such circumstances. But anything between the normal ample oscillations and the abortive manometric readings last described may be produced when the point of the needle is in a very small "pocket" in the pleura surrounded by adhesions. A pocket of very moderate size may give fairly normal manometric readings at the outset, but the pressure rises very rapidly with the entrance of gas in comparatively small quantity. We may hope for adhesions to give way, yielding either suddenly or gradually to gas pressure, but the smaller the space into which gas enters the less chance there will be of this taking place. For a given pressure to the square inch the pull upon the surrounding adhesions must be small when the space containing gas is small, increasing as the pressure is exerted over a larger area. It follows that when the "pocket" is very small the prospect of benefit is small; and the risks are increased. The indication is to abandon the attempt to induce a pneumothorax at that point; puncture somewhere else may be more successful.

In a primary operation, where the pleura is fairly free from adhesions, 500 c.cm. of nitrogen will not produce a *plus* pressure, even in expiration. And it is not, as a general rule, advisable to exceed this quantity at first. The exception is in hæmorrhage from a cavity. It is then imperative to induce a complete pneumothorax at once, if possible, because to do so is the most effectual means of restraining hæmorrhages. The risk from hæmorrhage is greater than that from rapidly filling the pleura with gas.

On first inserting the needle in a primary case a *plus* pressure in expiration is proof that the needle has gone through into the lung.

The reading found at the commencement of a secondary operation (or "refill") will be the pressure left at the conclusion of the previous operation, modified by what has since taken place. Usually the pressure will have fallen, owing to absorption of gas. But the occurrence of pleural effusion (which takes place in a considerable proportion of these cases) may actually raise the intrapleural pressure. The rule, therefore, that a *plus* pressure in expiration implies that the needle has gone through into the lung, only applies to a primary operation before any gas has been injected, but it is then a rule absolutely without exception.

There will be no movement of the manometer at all if the opening of the needle is in consolidated lung. But what may be called the typical pulmonary oscillations will be likely to occur when it is in a bronchial tube, or a cavity either tuberculous or bronchiectatic, or the space formed by the fusion of emphysematous vesicles. In the circumstances, the oscillations will approximate to an atmospheric mean—that is, the *minus* pressure in inspiration will be equal to the *plus* pressure in expiration, or nearly so. The amplitude of the oscillations will depend partly upon the nature of the space entered by the needle and partly upon the character of the respirations, whether tranquil or laboured. But when the patient speaks the expiratory effort with a closed glottis produces, while it continues, a greatly increased pressure. And this is greater still in coughing. I may remark in passing that the same thing happens also when the needle is in the pleural cavity after gas has been injected. So that it is

wise always to keep a watch for the approach of a cough, and to pinch the tube leading to the manometer when that is observed. Otherwise it is quite possible for some at least of the water in the manometer to be violently forced out. Which is a somewhat annoying accident, because the lumen of the manometer is sufficiently narrow to make the recharging it with liquid and getting rid of air-bubbles a somewhat troublesome business. Of course, the nitrogen should also be cut off immediately when a cough is imminent, because the act of coughing is very apt to displace the needle. When the patient has done coughing for the present, communication with the manometer should be reopened; but, until its readings are found to be satisfactory, no more gas should be admitted.

In doing a "refill" it is, of course, quite possible to meet with an atmospheric mean pressure in the pleural cavity if the final pressure at the previous operation was higher. But an atmospheric pressure should always be regarded with some suspicion, and special care must be taken to be sure that the point of the needle is in the right place. For this purpose, keeping a record of the depth reached by the needle, for use at subsequent operations, may be useful; but it is not wholly free from possible fallacies.

When it is found that the admission of a large quantity of gas does not raise the pressure, it is evident that this can only be because the gas is escaping as fast as it enters. This, of course, indicates that the opening of the needle is not in the pleural cavity, but in the lung. It has been suggested to scent the gas with peppermint or the like, in the expectation that the patient would recognize the odour in his own breath if the gas should be escaping in that way. In my experience this suggestion has not proved to be of any practical value.

On first inserting the needle, whether in a primary operation or a refill, we may find no movement of the manometer. This may be due simply to our having underestimated the thickness of the chest wall. In that case a little further insertion of the needle might produce normal oscillations. But it is far more often due to the opposite—namely, to going right through into lung. This is certain to happen if the puncture chances to be made at the site of an adhesion. And it may very easily happen anywhere near an adhesion, unless the needle is entered very slowly and cautiously, with the eye on the manometer all the time. On this account (as well as for other reasons) I am opposed to the practice of dispensing with local anaesthesia in refills, and entering the needle with a sudden stab. It by no means follows that the point which was free from adhesions at the first operation will be necessarily clear on the next occasion. This remark applies with especial emphasis when the puncture is made posteriorly, for there the lung may come into contact with the parietal pleura in spite of the presence of a very considerable quantity of gas, especially when the patient is lying on his back. The slight traumatism of the first operation would be very favourable to the production of an adhesion in such conditions. It is often difficult, if not impossible, to recognize the existence of such adhesions by auscultation.

It sometimes happens, when the needle is being entered for the first time, that the manometer leaps up to a normal minus pressure of 14 or 16, and there remains stationary. This is so far satisfactory, that it is a clear indication of the absence of adhesion at the point of puncture. The opening of the needle has been, at least momentarily, between two free pleural surfaces, in what may be called the potential pleural cavity. But it would be extremely unsafe to send in gas while the manometer is motionless. For though the minus pressure shows that the open end of the needle has been where we wish it to be, through the costal pleura, and pushing the visceral pleura before it, the absence of oscillations suggests that it may not be there still. It may be that some movement of the patient has caused the needle to be slightly withdrawn, so that its opening is now in the chest wall. It is more likely that it has gone through into the lung. It is therefore safer first to withdraw it until we are quite sure that its point is in the intercostal space. Then it may be very cautiously and slowly advanced again, the eye being fixed on the manometer. If still no oscillations occur it is probable that the lumen of the needle is blocked with blood. It is, of course, quite possible that this obstruction might be cleared away by injecting nitrogen. But the attempt would be very risky. In the absence of oscillations there

can be no proof that the open end of the needle is between the parietal and visceral pleura; and while this is uncertain, to inject nitrogen is to risk the possibility of gas embolism. In such circumstances it is recommended to clear the needle by passing in the stylet. But to do this with the ordinary Saugman needle is by no means free from danger. For with that instrument it is impossible to make way for the passage of the stylet without opening communication with the external air, which is, for more reasons than one, more dangerous than admitting nitrogen. To obviate this I have devised a needle with a stylet working through an airtight stuffing-box, as in Potain's aspirator. Only in Potain's instrument the stuffing-box simply plugs into the mount of the needle, which rarely produces an airtight joint. And besides, it is somewhat apt to tumble out at inopportune moments. In my instrument, therefore, the stuffing-box screws into the mount of the needle, with a leather washer to make a perfect joint. As supplied by the manufacturer, the stuffing-boxes in such instruments are provided with a packing made of leather or india-rubber. Leather is damaged by boiling, and india-rubber deteriorates by time, so that neither is reliable. I prefer a packing made of cotton-wool soaked in sterilized vaseline. This is perfectly airtight, and can easily be renewed whenever necessary. The leather washer for the joint should not be boiled. It may be soaked in B.P. glycerine of carbolic acid, not carbolic oil, which sterilizes nothing, not even itself. This special needle is made by Messrs. Allen and Hanbury of London, and by Messrs. Brady and Martin of Newcastle.

In using this needle, it is convenient to insert it without having the stuffing-box attached, because it is only occasionally that the stylet is required. It can easily be attached, with the needle *in situ*, if the occasion to use it arises.

In the absence of such a special needle, rather than use a stylet without a stuffing-box, it is far safer, in the circumstances just described, to withdraw the needle and reinsert it after clearing it thoroughly; or, better still, use a fresh needle. The slight additional traumatism of a second insertion is far less objectionable than the risks involved in making an open communication with the external air.

An abnormality which is at first somewhat puzzling is this: In the course of induction of a pneumothorax the pressure rises on the admission of a very small quantity of gas. But on shutting off the nitrogen and watching the manometer, we find that in the course of a minute or two it falls again. On repeating the process several times, we see that the pressure falls less after each admission of gas, so that eventually there is a permanent rise of pressure. I have seen this in three or four cases. In one the fall of pressure only took place when the patient took very deep breaths. No doubt this is due to gas being admitted into a small "pocket" surrounded and limited by adhesions, except for a narrow communication leading to a large intrapleural space. At the next operation it will be wise to attempt to enter this larger space directly. If auscultation and percussion do not help us to locate this larger space with sufficient clearness x rays may be found very useful. Some little care may be needed to distinguish between the phenomena just described and the manometric signs presented when the needle is in the lung. But in the lung there can never be a minus pressure during expiration; and the admission of gas will never produce a permanent rise of pressure.

A CASE OF ROTATORY NYSTAGMUS WITH RECOVERY UNDER OPTICAL TREATMENT.

BY

T. STEWART BARRIE, M.B., F.R.F.P.S.G.,

EXTRA DISPENSARY SURGEON, OPHTHALMIC INSTITUTION, GLASGOW.

In June, 1914, a girl, aged 7 years, was brought to me on account of defective vision. There was a slight convergent strabismus of the left eye, but the most striking objective sign was the presence of concomitant rotatory nystagmus, involving both eyes equally, and alleged to have existed from birth. The child was very fair and somewhat deaf, the latter being a sequel to otitis media acuta two years before. The visual acuity of each eye was $\frac{5}{20}$.

After the use of a mydriatic for eight days, retinoscopy gave the following results:

Glasses were prescribed for constant use, namely:

Right eye + I. 50 D.C. ax. 80.
Left eye + O. 75 D.S. + I. 50 D.C. ax. 90.

On August 17th, 1915, the child was brought again, when it was found that the rotatory nystagmus had apparently completely disappeared. Confirmatory evidence was sought in an ophthalmoscopic examination by the direct method; this showed complete absence of oscillation in the right eye, with slight lateral movements in the left. The visual acuity of the right eye had risen with the correction to $\frac{5}{6}$ and partly $\frac{3}{4}$, while in the left eye it remained as before. The fundus of each eye showed, as might be expected, well-marked choroidal vessels.

The interest of this case is the disappearance of the nystagmus under optical treatment. It is true that Sym (*Diseases and Injuries of the Eye*) foreshadows such an improvement by the correction of any errors of refraction; according to May and Worth, however, "infantile cases (of nystagmus) are not amenable to treatment, though the condition sometimes becomes less marked with advancing years; the correction of high errors of refraction seldom improves vision."

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CALCIUM HYPOCHLORITE SOLUTION AS A WOUND DRESSING.

I HAVE read with interest the article in the *JOURNAL* of July 24th on the antiseptic action of hypochlorous acid, by Professor J. Lorrain Smith, M.D., F.R.C.S., and others, and think it may interest some of your readers to know that for several years I have used a preparation of bleaching powder for dressing dirty wounds. As far as I can recollect, it is some fifteen or sixteen years since I read in the *BRITISH MEDICAL JOURNAL* an article contributed, I believe, by a Welsh doctor, saying that he found a 1 per cent. solution of calcium hypochlorite of the greatest value in the treatment of varicose ulcers of the leg. Having some difficulty in obtaining this, I prepared a solution of the salt from 3 drachms of bleaching powder, as sold in penny packets for domestic use, to which 20 oz. of water were added, making a solution of about 2 per cent. This is thoroughly dissolved, and after allowing the bleach to settle the clear supernatant fluid is poured off and is ready for use.

I have found it invaluable in the treatment of offensive sores, especially of tertiary syphilitic ulcers. For these, small pieces of lint soaked in the lotion are cut exactly the size of the sore, which is filled up level with the surrounding skin. A thin layer of cotton-wool is then applied to equalize pressure under a thin firm bandage. While the wound is dirty, the dressing must be changed three or four times daily, or oftener if required, but when the wound is clean it is sufficient if it be kept constantly moist, but on no account must an impermeable covering be applied. In the cases in which Dr. Louise McIlroy and I have had opportunity of trying it we have found it entirely satisfactory.

L. STEWART SANDEMAN.

CEREBRO-SPINAL CONTACTS.

THE urgency of adopting some simple method in the treatment of contacts and others liable to infection by the germ of cerebro-spinal meningitis impels me to write suggesting an easy and, I hope, efficacious method of dealing with the problem—namely, inversion douching of the nose and naso-pharynx, as used by rhinologists, in lieu of spraying. The method is as follows:

The patient is placed in the supine position, the shoulders parallel with the end of the stretcher or couch (or rolled up knapsack), the head hanging vertically down, the neck muscles being relaxed to allow of this, so that the plane of the anterior nares is parallel with the ground, somewhat in the position in which some surgeons operate for post-nasal growths. The patient is now told to open the mouth, and to continue breathing through the mouth for the rest of the operation.

The solution to be used (say, for example, sanitas one part to five parts of warm normal saline solution, or potassium permanganate 1 in 1,000 in warm normal saline solution) is now poured into each nostril from some vessel with a lip, or from a douche-can with a rubber tube connexion, till the nose and naso-pharynx are filled with the solution, which will then overflow. Breathing comfortably through the mouth, the solution can now be retained from five to twenty minutes with practice.

The patient, when finished with, is told to turn quickly on his side, and the solution flowing out from the nose, is received into a vessel containing antiseptic solution.

Only two points need to be remembered: (1) Keep the head hanging as vertically as possible, else the solutions will flow down on to the base of the tongue and epiglottis and cause coughing; (2) the same result will happen if there be any attempt at nasal inspiration.

There is an obvious superiority in this method over that of spraying. As a spray falls on a vertical surface, those drops falling on the highest portion begin to roll down at once under the influence of gravity, their contact with that part being only momentary; also, a spray cannot penetrate and cover every part of the nose cavity and naso-pharynx, whereas by filling up the nose the whole interior is in contact with the solution almost at once, and as long as the head is kept in the correct position. Again, the necessity for the use of a spray, which is liable soon to get out of order, is done away with.

Adelaide, South Australia.

COMPLETE AVULSION OF TESTIS.

ON August 26th, 1915, whilst acting as locum tenens for Dr. John Kirkwood, Kensal Rise, N.W., I was called to see a boy, C. C., aged 10 years, who had met with an accident, through falling from the branch of a tree on to an iron railing. I found an elliptical wound in the right scrotum, extending from the level of the spine of the pubes to nearly the base of the scrotum, and also some laceration of the inner side of the right thigh. After thorough cleansing of the scrotal wound, examination showed that the right testis was absent, and there was no trace of the spermatic cord on that side; the wound was thoroughly cleaned, the edges trimmed and brought together, and dressings applied. The following day the mother produced the missing testicle, which she had found in the boy's trousers (removed before I saw him). Attached to it was two inches of spermatic cord and some cotton lining from the inside of his trousers.

The scrotal wound is gradually healing, and so far the boy does not seem much the worse for his involuntary castration. There was a small amount of hæmorrhage only, and very little shock.

PUTTING THE TONGUE BEHIND THE SOFT PALATE.

SOME weeks ago a patient came to see me complaining of a muco-purulent discharge from his nose, which he said he thought was due to nasal polypi. I examined his nose and throat, and could find nothing more than a post-nasal catarrh; however, he was not satisfied, and said he was certain that he had polypi because he could feel them. On my asking how he could do so, he at once put his tongue right up behind his soft palate into the naso-pharynx; he said he could then feel a ridge in the middle and a soft mass on each side (no doubt the posterior ends of the turbinates), which he thought were polypi. The appearance on looking into his mouth during this manoeuvre was most peculiar; the soft palate was bulged forwards, and the tongue pushed up so far behind it that the uvula was in

contact with the frænum lingue. I showed the case to four of my colleagues here, and as none of them had ever seen or heard of anyone who could perform this feat, I thought it might be of interest to put it on record.

MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

BRISTOL ROYAL INFIRMARY.

A CASE OF TETANUS: RECOVERY.

(By A. COLBY TINGEY, Lieut. R.A.M.C., M.R.C.S., etc.,
late House-Surgeon.)

On January 5th, 1915, the patient, a carrier aged 39, had his right foot crushed by a heavy log falling on it.

On admission to the infirmary he was found to have a deep wound on the dorsum of the foot, beginning at the cleft between the big and second toes, and extending upwards about 4 in. There was a comminuted fracture of the first metatarsal and proximal phalanx of the big toe, the bones being broken into small fragments. The second metatarsal was also fractured in one place. A general anaesthetic was administered. All loose pieces of bone were removed and the wound swabbed with 1 in 20 carbolic. The skin wound was closed in part and a rubber tube put in for drainage.

On January 9th the wound was very septic, and the foot was kept for several hours in a lysol bath daily until January 19th. On January 12th the big and second toes were found to be becoming gangrenous, and were amputated under a general anaesthetic.

At 6.30 a.m. on January 19th the patient found that his jaw was stiff, and he was unable to eat any breakfast. On examination marked trismus was found; the teeth could only be separated half an inch; risus sardonicus was present. No pain was complained of. At 10.30 a.m. 3,000 units of antitetanic serum were given intravenously. The serum was not repeated. Subsequently the patient was given 15 minims of a 3 per cent. solution of carbolic acid every four hours. He was nourished on fluids only. On January 23rd the trismus was worse, and the patient could only separate his teeth a quarter of an inch. Marked rigidity of the muscles of the back and abdomen was present. The patient became very depressed about his condition. On January 24th the carbolic injections were increased to 20 minims every four hours.

On January 27th the nurse reported that the patient had a severe spasm at 8.40 a.m.; it lasted about five minutes, and in the course of it he became very cyanosed. He had another marked spasm in the evening of the same day, but it only lasted a few seconds. The carbolic injections were increased to 30 minims every four hours. At night 40 grains of chloroform in 4 oz. of olive oil were given per rectum. The patient passed a comfortable night. The same dose of chloroform was repeated on January 28th and 29th. The patient had no more severe spasms. On January 31st the jaw muscles began to relax and he was able to feed himself. On February 3rd he was able to protrude his tongue and was generally better. On February 5th the carbolic injections were stopped. The treatment did not at any time cause carboloria or other signs of poisoning. The temperature remained subnormal throughout. On February 16th the patient was discharged. The wound on the foot was then in a healing condition.

Although it would certainly be rash to attribute recovery in a case of tetanus to the method of treatment adopted, yet one may perhaps be allowed to infer that the injections of carbolic acid cut short the duration of the disease, seeing that the patient was free from all discomfort fourteen days after the onset. The chloroform was very useful as a sedative when the symptoms were most severe.

The case illustrates the uselessness, where tetanus organisms are concerned, of employing 1 in 20 carbolic for the purpose of cleansing wounds.

I am much indebted to Mr. Rendle Short for permission to publish the details of this case.

Reviews.

INJURIES TO JOINTS.

THE publication of a series of Oxford War Primers has been commenced by the issue of five volumes—three on surgery, one on medicine, and one on the training of stretcher-bearers. The general object of the series has been well expressed by Major ROBERT JONES with particular application to his own subject in the preface to his book on *Injuries to Joints*. "The object of this little book," he says, "is to attempt to give some help in the diagnosis and treatment of injuries of joints in a form which will be useful to the hundreds of practitioners who have left the quiet paths of private practice for the more eventful career of military surgery."

Major Robert Jones's volume is one of the most valuable contributions to surgery so far produced by the war. It will be of the highest value to the military surgeon but of almost equal value to the civil practitioner, for, as a practical surgeon of long experience has observed to us, if the volume were to be thoroughly studied by every house-surgeon, not a little disability, temporary and permanent, would be prevented among the industrial population.

The book falls into two parts—the first five chapters in which general principles are discussed, and the remaining six in which they are applied to particular joints and particular varieties of injury. It is to the first five that we would particularly direct attention, because if their significance is fully grasped the rest becomes easy to any man trained in the practice of modern surgery. No doubt a great many readers will search the book for practical "tips," and they will find them in plenty. But if they adopt them without understanding the why and the wherefore they will, we are sure, disappoint the author, who is always careful to explain the aim and object of everything he recommends to be done. Moreover, no two cases are quite alike, and unless the reason is understood the application may fail. The author is always asking the young surgeon to use his knowledge of anatomy, physiology, and pathology, and his common sense. The science without common sense is no good, neither is common sense without science. Their combination make up the whole art and mystery of the management of joint injuries, from a common sprain or tennis elbow to a severe gunshot wound.

In the first chapter, which contains an outline of general principles, it is said that the practitioner's two chief difficulties are to decide what is the most appropriate immediate treatment, and when and how to commence moving the injured joint, especially after the more serious injuries. The solution of the first, we are told, is found in accurate diagnosis of the injury, and in forming a clear idea of the mechanical and physiological factors which enter into the processes of repair. As an illustration, an ordinary sprain of the ankle, caused by jumping on to the edge of a cleft of earth and violently twisting the foot inwards, is taken. The surgeon finds that, though the ankle is very painful, it will bear gentle but firm handling. The history points to an injury about the external malleolus, and the inference is that there is a rupture of one of the three slips of the external lateral ligament of the ankle, or perhaps an avulsion of a scale of bone from the tip of the malleolus, which, though technically a fracture, is for all practical purposes a sprain. Pressure with the finger over each division of the ligament in turn will find a point of extreme tenderness, and so the exact nature of the injury is located. The treatment carried out should be with the definite object of getting the torn ends of the ruptured ligament to unite by first intention—that is to say, by immediate rather than by delayed union. By appropriate simple treatment it must be made impossible for the patient to put tension on the torn ligament when walking, but the foot must not be kept fixed, for "the physiological exercise of the foot will prove a better stimulus to the normal processes of circulation and repair than even the best massage."

Movement, he says, is always bad for an actively inflamed tissue, using the term "inflamed" to mean tissue actively hyperæmic as the result of a lesion, such active

¹ *Injuries to Joints*. By Robert Jones, Ch.M., F.R.C.S.E. and L.D., Director of Military Orthopaedic Hospital, Liverpool, etc., Major R.A.M.C.(T.). Oxford War Primers. London: H. Frowde, and Hodder and Stoughton, 1915. (Fcap. 8vo, pp. 187; 29 figures, 3s. 6d. net.)

hyperaemia being part of the process of healthy repair. Speaking on the starting pains of injured bones and joints, he says that when a patient is awake and the injured part is not completely fixed, he unconsciously keeps it at rest by means of his muscles—a nerve-muscle effort which is in itself exhausting. When the patient falls asleep his nerve muscle system sleeps also; the injured part deprived of the muscular guard moves, a spasm of pain ensues, then a reflex contraction of the muscles, which again causes pain, and the patient is awake. Such starting pains, therefore, are proof to the surgeon that he has failed to attain efficient fixation.

With regard to permitting voluntary movement, Major Jones lays down the general principle that pain is the index. Pain is Nature's method of controlling voluntary movement which may be harmful, so that early active movement which causes no pain can seldom be harmful, and is often beneficial. Therefore, fix a joint so that the one particular laudible movement cannot be performed. The harmless movements will make for good nutrition and rapid repair. Passive movement performed by a second person, regardless of warnings by pain, should never be resorted to unless the surgeon knows exactly what he wants to do and why. It should be limited to forcing a free path for movements obstructed by adhesions. When these are broken down under an anæsthetic the process should be thorough and carried out by one firm movement; afterwards the joint should be put through its full range of movement once a day, and once only, until the patient can perform the movement voluntarily. "I would again emphasize the fact that repeated to-and-fro movements are liable to cause unnecessary damage, increased reaction and effusion, and an increase of pain."

The author then goes on to consider pain and stiffness in relation to diagnosis and treatment, and lays down two general rules, which are: "(1) Pain on movement in every direction suggests a lesion in the joint or in parts intimately connected with it; (2) Freedom of movement in one or more directions, but not in all, suggests a lesion of some groups of structures outside the joint proper." Again and again he insists on the necessity of gentle handling both in diagnosis and treatment. He points out the dangers of too early or too rough passive movement in connexion with fibrous cicatrices in soft parts, and says that the same doctrine applies even more strongly where the process of repair includes ossification. In a case of fracture into a joint or of a bullet having traversed the joint and ploughed up the osseous cartilages, the line of treatment must be directed towards obtaining healing of the breach of surface on each bone separately and allowing the union from one to the other to be as slight as possible. When sufficient time has elapsed for repair to have commenced slight movement should be allowed. "Part of the treatment of ununited fracture of a long bone is to manipulate the seat of fracture roughly, so as to produce fresh exudation and vascular activity and to excite osteogenic processes. It is therefore obvious that violent movements of a joint, instead of securing non-union between opposing surfaces, may have the opposite effect."

The last chapter of this part of the book deals with contraction of scar tissue and compound injuries about joints; and here again the author insists that the surgeon must take a long view and not be satisfied in securing an early healing of the wound if that is attended by the serious disadvantage of leaving the limb in an awkward position. In the remainder of the book injuries of the joints of the upper limb, of the spinal column, of the joints of the lower limb, and of the ankle-joint and foot, are separately discussed, and the treatment of various conditions fully explained.

The book, as has been said, is full of tips. One is the use of a pad in certain conditions, as, for instance, in dislocation of the outer end of the clavicle upwards, consisting of many folds of sticking plaster, sticky side out. Such a pad adheres to the skin, does not shift, and acts as a local splint. Another tip is the "contrast bath," depending on the same principle as the alternate hot and cold douche so useful in many chronic conditions of muscles and joints. All that is required are two buckets, one with the hottest water the patient can bear, and the other with the coldest that can be procured. The foot or wrist is plunged first into the one and then into the other as fast as the patient can change them, for five or ten minutes. "The

effect is to cause the small vessels to dilate and contract rapidly. The treatment thus acts as a species of gymnastics for the muscles in the vascular walls. Besides relieving the pain the result is an improvement in the physiological efficiency of the tissues at fault. This is not achieved to anything like the same extent by hot air and the various electric treatments."

But the book is also full of aphorisms, though the author is too modest to set them out in that form. Such a one is, speaking of treatment after adhesions have been broken down, "The passive movements should be carefully regulated, the active should be unlimited." Others are: "So long as callus is tender on pressure or manipulation, it is safe to say it is not too hard to be twisted or forced by manipulation so as to adjust an erroneous or imperfect reduction." "Fully matured fibrous tissue has no more tendency to contract than any other tissue, and as a scar takes a long time to become composed of fully matured tissue, extension of the scar must be prolonged." "The bandage in the hands of the surgeon is an important part of the apparatus for retaining the joint in the required position. The bandage is not a mere means of keeping a dressing in position, but should be regarded as a modified splint."

The volume is well printed on a small octavo page with rounded corners and bound in a serviceable khaki limp cloth. The only quarrel we have with the publishers is that they have used heavy glazed paper fatiguing to the eyes, and so thick that the volume is twice as bulky as it need have been. The answer will probably be that the thick, glazed paper has been used for the sake of the illustrations—reproductions of photographs which are quite well done. But a thin paper would have been much more fitted to meet service conditions, and this ought to have been the primary consideration. Its use would have necessitated drawings instead of photographs, and good drawings are, of course, more expensive than photographs, but it is a pity to spoil the ship for the sake of a ha'porth of tar. A senior officer of the Army Medical Service recently asked us why publishers used heavy, glossy paper, and quoted uncomplimentary remarks of railway men who had to handle his baggage. The reason is, we have no doubt, that given above, but why should not the Oxford Press set an example by using Oxford India paper, more especially in an enterprise which must have appealed to the patriotism of the distinguished authors who have written these primers for it?

NOTES ON BOOKS.

DURING the last 200 years Russia has learned much from Germany, and suffered much. Peter the Great's ambitious schemes for the regeneration of Russia and the reorganization of her government, at the beginning of the eighteenth century, came before the Russian people were ready for them. Accordingly, when he needed men of education and ability to carry out his will unhampered by any connexion with the order of things he wished to destroy, Peter fell back on the German barons of the recently conquered provinces of Estonia and Livonia. In this way the German ruling class got a footing in Russia, and their power and activity have spread there ever since. How far this has been to the detriment of Russia is made plain in DE WESSELETSKY'S pamphlet on *Russia and Democracy*, a little book that should be read by all who are interested in the past and future development of our great ally. German princes and German States are here shown to have used Russia indifferently as stalling horse, whipping boy, and milch cow for more than two centuries, constantly retarding her progress and retelling by advocating a reactionary policy. The author gives good historical reasons for believing that the complete de-Germanization of Russia is the only safeguard for her future independence and progress.

The seventh edition* of HUTCHISON and COLLIER'S well known *Index of Treatment* has recently appeared, and within eight years of the issue of its first edition; no

* *Russia and Democracy: The German Chamber in Russia.* By G. de Wesseltsky. With a preface by H. Cnst. London: Published for the Central Committee for National Patriotic Organization by W. Heinemann, 1915. Demy 8vo, pp. 104. 1s. net.
Index of Treatment. By Various Writers. Edited by R. Hutchison, M.D., F.R.C.P., and J. Sherrin, F.R.C.S. Seventh edition, revised and enlarged. Bristol: J. Wright and Sons, Limited; London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited, 1915. Demy 8vo, pp. 1129; 78 figures. 25s. net.]

further witness to the merits of the book need be required. The new improved and enlarged edition appears without the name of Mr. Collier on its title-page; Mr. Collier's place as editor has now been taken by Mr. SHERREN. All the articles have been thoughtfully revised, and in many cases they have been rewritten; several new articles have been added, including an account of radium-therapy by Dr. Hayward Pluch, and an essay on the treatment of the psycho-neuroses by Dr. Crichton Miller. Except in the headlines, a new font of type has been used throughout the volume, which gains considerably in clearness and ease of reference as a result. Comparison with the sixth edition, published four years ago, shows that a considerable amount of judicious pruning has been carried on throughout the book, which has none the less increased by a hundred pages. We cannot do more than recommend it in terms of high laudation; it is a volume that should be in the hands of every practitioner of medicine.

The title, *Medical Annual Synoptical Index to Remedies and Diseases*, 1905 to 1914,* explains both itself and the want that it supplies. A list of drugs has been added, giving the doses in imperial and metric measure, in accordance with the *British Pharmacopoeia*, 1914, and indicating the alterations which have been made. There is also an article comparing the measures of the *British Pharmacopoeia* and the Apothecaries' Scale. The editor defends the older method, and is not afraid of declaring that the metric system is ill-adapted for dispensing the small quantities of which the medicinal doses consist. The metric system is universally used on the Continent for scientific calculations, but the editor maintains that it should not be argued that medical prescriptions should follow the same lines. That argument is based on the false hypothesis that a medical prescription involves calculation. We are further reminded that the Americans, both a scientific and a practical people, use the decimal system for commercial purposes, while, on the other hand, apothecaries' weight is employed for prescribing because it is more simple and admits of greater accuracy.

CIVIL PRACTICE TO-DAY IN FRANCE.

EXPERIENCES OF AN ANGLO-FRENCH PRACTITIONER

The declaration of war found our season in full swing, but from one day to the next two out of three of my fellow practitioners under 42 had disappeared without any leaving-taking formalities. Of the remainder, five out of eight were elderly, not to say aged, men, not addicted to general practice. Of the outlying villages within a radius of fifteen miles many were, and still are, wholly deprived of medical assistance except such as is obtained from this centre. When it is borne in mind that many of these villages lie high up on the flanks of the mountains at an altitude which may be as much as 2,000 ft., the difficulty of providing any sort of medical aid in emergencies can be imagined, especially as telephonic communication between private persons was forthwith prohibited outside urban areas. This difficulty, however, was overcome in some measure by turning to account the privilege accorded to mayors of communes of communicating with each other. Within the last month or two this restriction has in great measure been removed, subscribers being allowed to telephone within the department. On the other hand, the proclamation of the state of siege rendered it incumbent on every one to obtain a police permit to wander outside the district by road or rail; but this restriction was soon found to be impracticable, and a number of permanent permits were conceded, especially to officials and medical men.

So much for civil medical practice, but a further hindrance presented itself in that the services of every valid, though elderly, medical man were enlisted to provide staffs for the numerous "formations sanitaires," or auxiliary hospitals for the wounded, who began to arrive early in September. There was a great shortage of skilled surgical assistance at first, and had it not been for the abnegation of an English surgeon, who happened to be in the town and consented to remain, the situation would have been unenviable both for the wounded and for the medical men, few of whom had much experience of practical surgery. The work entailed by these hospitals

was heavy, and left the few remaining practitioners little leisure to attend to ordinary practice.

These auxiliary hospitals were installed in schools, hospitals, asylums, and in such of the hotels as were available for the purpose. These hospitals comprised from 25 to 100 beds, and the cost was met in part by a Government allocation of 2s. a head a day, and in part from private donations and funds belonging to various Red Cross societies. Of this allocation, four-fifths went for the maintenance charges, and the remaining fifth was reserved for pharmaceutical requirements, dressings, and so on, including x rays. The allowance was sufficient in respect of hospitals established by Red Cross societies, since any shortcomings could be met from their funds, but it was a tight fit when no other financial assistance was forthcoming, especially when winter brought extra expense in the matter of heating. The operating theatres had to be organized as best might be, the medical officers having to provide all instruments and fittings; this they were able to do, thanks only to the generosity of their wealthy patients. In certain centres military hospitals were organized by the authorities in addition to the "formations bénévoles," or voluntary institutions. Where it was found impossible to provide a civil medical staff, doctors from other towns who had been mobilized—that is to say, who had been called to the colours—were requisitioned for the purpose; but all hospitals, civil or military, were placed under the surveillance of a military medical officer appointed for the district, whose duty it was to ensure that the patients were properly attended to, and to see that records of cases were properly kept and the returns duly made.

Considerable hardship was caused by the requisitioning of the municipal hospitals, since this meant the exclusion of civil cases, both surgical and medical, and considerable pressure had to be brought to bear to secure accommodation for urgent cases.

The mayor of this town, a medical practitioner, was one of the first to go to the front, and he gladly availed himself of my offer, though a foreigner, to act as his locumtenent. This was no small undertaking, for, in addition to a large general practice, he is public vaccinator for all the surrounding districts, inspector of epidemics (roughly speaking, a sort of medical officer of health with very limited powers), inspector of nurseries, and insurance referee. His practice extended ten or twelve miles round in a very mountainous district, where roads are few and bad. Early in the war all valid horses were requisitioned, and soon afterwards all private and public motor cars, which, for that matter, would not have been of much assistance, seeing that all the chauffeurs had been sent to the front. One's only resource, therefore, was the cycle or motor cycle; and incidentally I should like to bear witness to the inestimable services rendered me by my 4-h.p. motor cycle with side-car. It climbs anything in reason, costs little to keep up, is very robust, and almost as stable as a motor car.

To one whose professional experience has been limited to what I may call seasonal practice—weak chest, rheumatism, gout, and the like—general practice of the class with which I was now called upon to deal is apt to be rather trying. One gets an urgent call to some isolated, picturesquely situated, but inaccessible spot, as likely as not late in the evening or early in the morning, with scant information as to what is wrong, so that one has to be prepared for everything. It may be a labour that has baffled the resources of the local midwife, or a dislocated hip or a perforated gastric ulcer or meningitis. Even when the patient has been visited it takes hours to fetch the medicine or appliances, and the only assistance is such as can be rendered by willing but unskilled, and possibly weeping, relatives. One difficulty for a foreigner like myself is that outside the towns the peasants mostly speak patois, and many are quite unable to express themselves in classic French. If, however, they persist in talking patois, I reply in English, so we get along somehow.

Not the least of my troubles is prescribing. Under ordinary conditions there are several English chemists, that is to say, pharmacies provided with British assistants who are familiar with British pharmacy, but when the Anglo-American visitors fed the country the British

* The *Medical Annual Synoptical Index to Remedies and Diseases* for the ten years 1905 to 1914. Bristol: John Wright and Sons, Ltd., London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd., 1915. (Demy 8vo, pp. 467. 8s. 6d. net.)

* By Ministerial order no mobilized medical man is allowed to be appointed to a post in his own district, but the order is one which has been evaded on a large scale.

assistants followed suit, so that it was no longer possible to prescribe British fashion or to order British pharmacopoeial preparations. Since French preparations do not correspond to ours, and as the French *Codex* contains no titrated solutions of alkaloïds nor any dilute acids or compound products, inasmuch, moreover, as liquids are dispensed by weight and not by volume as with us, prescribing becomes a delicate and complicated process. If we want to order a compound syrup of the glycerophosphates we must order it in detail, and how many of us are equal to the task? If we order an infusion we must specify the strength, and the same with tinctures. The difficulty is enhanced by the fact that drugs are described under their French and not their Latin names, so that *senega* becomes *polygale*, *lucina bucco*, *cinchona quinquina*, and so on. Last but not least, drachms and scruples have to be abandoned in favour of grams and centigrams, and however theoretically perfect the metric system may be, it is rather tricky in inexperienced hands.

To give a concrete idea of what my work is like, let me describe it. It happens to be the epoch for compulsory vaccination and revaccination (paid at the rate of 1 franc a head—or, rather, per arm—irrespective of distance). On receiving an intimation that I propose vaccinating on a given date, the mayors of the various communes issue printed notices to that effect. The vaccinations are done at the school buildings or Mairie, usually in the same block of buildings, and the schoolmaster (who is usually the mayor's secretary) takes down the names. The vaccine is furnished to the order of the prefecture by a central institute. Careful antiseptic precautions are taken to avoid infection, and I may note *en passant* that even the peasants are alive to their importance, and would promptly criticize any carelessness in this respect. In about a dozen districts I did between eight and nine hundred vaccinations. There does not appear to be any prejudice against vaccination in France; on the contrary, there seems to be an impression that the process is protective in the widest sense of the term.

Advantage is taken of the presence of the doctor in these outlying districts to obtain advice, by all and sundry, for an average fee of half a crown, or five shillings if a visit be necessary. One woman, living in an isolated farm half an hour's walk from the main road, had been in bed two days, having "ricked" her side when digging potatoes. The abdomen was greatly distended and hard and did not move on respiration; she had high fever, and was plainly very ill. The tenderness made exploration of the viscera impossible, and she gave no history pointing to the nature of the mischief. I had her brought down to the municipal hospital, where an exploratory operation was done, and she was found to have a huge perforated gastric ulcer. She was so deeply poisoned that she died on the table. As it happened, I, who was to have administered the anaesthetic, arrived rather behind time, so the patient was already under ether. When the mask was removed for me to apply my Junker's inhaler (chloroform), I saw that she was dying. Now, French surgeons have a dread of chloroform, and had I got there in time to administer it, the death would assuredly have been attributed to the chloroform.* The next day I was asked to see a woman who had been bitten by a dog. The teeth had penetrated the back of the hand and had torn out the tendon of the extensor indicis in its entirety, together with a fragment of the muscle. On my way back I was summoned to an old woman who had been knocked down by a reckless cyclist, fracturing the surgical neck of the humerus—a diagnosis which I verified next day by the x-rays in town. The next day I was called 17 kilometres into the mountains to a youth, 17 years of age, presenting symptoms of meningitis. As I had been warned what to expect, I was provided with the means of practising lumbar puncture, and the cerebro-spinal fluid proved to contain the *M. intracerebralis*. The father was dispatched to the county town, 25 kilometres distant, for some serum, which was duly injected on several occasions, but the patient succumbed ten days later in spite of temporary improvement. I reported the circumstances to the prefecture, expecting that special inquiries would be set on foot as to the source of the infection, but disinfection of the premises was all

that was thought necessary, no doubt because war conditions rendered it impracticable to do more.

Once a month there is an inspection of nurslings in the various hamlets. No woman is allowed to take a nursing unless she can produce a medical certificate of health and a certificate of moral character from the mayor. She is then provided with a book with counterfoils on which are noted details of the infant's progress when seen by the medical inspector, and details of any illness and its treatment. The annexed certificate is torn out, filled in by the medical inspector and forwarded to the prefecture. The women assemble in the Mairie (having been duly notified of the date and hour), where the babies are undressed and weighed and the increase of weight inscribed on a chart. They are invited to ask for medical advice if required, and any mother inscribed on the list of the Assistance Publique is entitled to a consultation *gratis*. A sheet of tissue paper is provided for each baby in order to avoid contact with the scales and possible contagion.

Indigent patients apply at the Mairie for a ticket entitling them to one visit or consultation by a local practitioner, and the chemist supplies the medicines at the cost of the commune—much the same process as applying to the relieving officer at home. The visits within the town limits are paid—Fr. 1.50 (1s. 3d.)—with an allowance per kilometre outside the borough of 4d. on the level and 7½d. in the mountains. In the latter case the patient has to provide the carriage. Country visits to the peasantry are paid at the rate of about 1s. 3d. per kilometre, carriage fare in addition.

The privilege accorded by law to wine growers to distil a certain (but apparently uncontrolled) quantity of alcohol without payment of duty (known as "eau de vie de marc," from the fact that it is made from the "marc" (residues) of the grape), independently of the fact that it deprives the State of millions a year of revenue, is the cause of much chronic inebriety, consequently one meets with many enlarged or cirrhotic livers. Pulmonary tuberculosis is also very common, and occupies a large space in the mortality returns. At this altitude (nearly 1,000 ft.) the grape does not ripen, and the wine is therefore horribly tart. This, however, does not affect the taste for it, and among the working classes the average consumption per (male) head must be between two and three quarts a day—quite enough in the long run to determine symptoms of chronic alcoholism, since the wine contains from 6 to 7 per cent. spirit. Drunkenness is uncommon, but inebriety, even among the women, is rife.

The peasants are an intelligent, robustly independent set of men, many, probably most, of them owning their farms. They work very hard and their women folk share in their labour. One consequence of this addiction to outdoor work is that they have neither time nor energy to keep their houses in order. The latter are simply filthy—unwashed floors, blackened walls, and dust everywhere. As they have a superstitious horror of fresh air, the windows are few and small, and are kept rigorously closed. Manure heaps fester at the very door, so that flies are a terrible nuisance. This is forbidden by law, but as it lies with them to apply the law to each other it is a dead letter.

THE DESTRUCTION OF FLY LARVAE IN HORSE MANURE.

IN THE JOURNAL of May 1st last (p. 768) an account was given of a series of valuable scientific investigations undertaken by the United States Department of Agriculture with the object of ascertaining the most suitable means for destroying fly larvae in horse manure without injury to its fertilizing properties. They had been reported in an official bulletin of the department (No. 118), and we are now indebted to Dr. F. C. Cook, who has charge of this work, for a further bulletin (No. 245), which deals with a continuation of these experiments during last year. The results of the first series showed that the only chemical which fulfilled the necessary requirements of being efficient, non-poisonous, economical, non-injurious to vegetable life, universally procurable, and easy of application, was ordinary commercial borax. Whilst the Commission was fully convinced of the efficacy of this chemical, if properly used, it is admitted that the recommendation to limit the dosage of borax to 0.62 lb. per

* One can understand the feelings of French surgeons in respect of chloroform, seeing that anaesthetics in French hospitals are given by the sisters or by any first year's student who happens to be there. Obviously in such hands ether is vastly preferable to chloroform.

10 cubic feet of manure, and to apply such treated manure to the land at the rate of 15 tons to the acre, in order to make certain of no injurious effect on vegetation, might not be universally carried out through carelessness. It was therefore thought advisable to try and discover some material which would not have this disadvantage. The bacteriological, chemical, and entomological investigations were carried out as before, except that, in addition, some concrete pits were utilized, and cages for collecting flies were provided for some of the open pile experiments. The substances tested were both inorganic and organic, the latter including volatile and non-volatile agents as well as some plant materials. Under the first heading arsenical dip, chloride of lime, lime sulphur and sulphuric acid were used, but the only effective substance coming within the requirements was arsenical dip, and this was condemned on account of its poisonous properties. The objections to chloride of lime are stated to be the large quantity required, its action in drawing off ammonia, its probable toxic effect on bacteria, the irritating action of liberated chlorine, and its high cost. The investigators, therefore, turned their serious attention to organic substances, their hopes of success being apparently founded on the very reasonable argument that, as inorganic applications are likely to prove toxic to plants when excess is established in the soil, organic substances, on the other hand, if volatile, will disappear, or, if non-volatile, will decompose and probably assist in forming useful instead of harmful compounds. Aniline, in dilutions extending to 1 to 500, nitrobenzene, particularly when emulsified with fish oil soap, in the ratio of $\frac{1}{2}$ lb. to 1 lb., and added to 10 gallons of water, and pyridine, 1 to 500, are shown to be effective larvicides and apparently harmless to manure, but their toxic nature makes them difficult to handle and the cost is said to be prohibitive. Beta-naphthol, cresylic acid, para-dichlorobenzene, formaldehyde and oxalic acid proved very unsatisfactory as larvicides. The researches with plant material were found to be the most satisfactory. Corn cockle (*Agrostemma githago*), which is abundant in wheat swards, and agave (*Agave lecheguilla*), which is very plentiful in Texas and Florida, were tried on account of their saponin content, and met with moderate success, as was also the case with larkspur (*Delphinium*) and stramonium. "Blackleaf 40," a strong extract of tobacco, ox-eye daisy, and pyrethrum were ineffectual. The Commission, however, appears to think that the desired success was attained as a result of the experiments made with hellebore. The varieties used were the white (*Veratrum album*) and the green (*V. viride*), the former being an importation from the neighbourhood of the Pyrenees, and the latter being indigenous to swampy lands in America. Both are used as insecticides against root pests. An average of twelve experiments showed a larvicidal action of 95.5 per cent.; no ill effects were produced on plants or on chickens scratching and picking amongst manure so treated, and the substance was found to be completely decomposed within thirty days. It must be powdered, mixed with water ($\frac{1}{2}$ lb. to 10 gallons), thoroughly stirred, and then allowed to stand for several hours before applying it with a watering-can to the manure on removal from the stable. This proportion is sufficient for 8 bushels, a liberal estimate of the manure yielded daily by a horse being 2 bushels. It is stated that the comparative cost works out at 5 or 6 cents per lb. for borax, and at 11 cents per lb. for hellebore (powdered roots). Such a favourable comparison, however, could scarcely be expected to obtain in this country, the white variety of root being listed at 11d. a lb. for 28 lb. lots, to which must be added the cost of grinding, whilst there is practically no difference in the cost of borax. There would probably also be considerable difficulty as regards supply, so that hellebore does not seem likely to come into use over here. It is recommended that borax should be universally used for "the treatment of outhouses, public dumps, refuse piles of all kinds, cracks and crevices, floors of stables, and any accumulation of organic material which offers a favourable place for the deposition of eggs," but that, in view of careless handling, it "seems best" to use hellebore for treating manure. The report contains two excellent photographs, showing the economy of larvicidal treatment in reference to bulk, an untreated pile being absolutely collapsed and disintegrated, through maggot infestation, and a treated one being quite unaffected in this respect.

The Commission is to be congratulated on the excellent work so far accomplished; the results attained clearly show the value of true scientific research into the means available for solving the problem of how to deal successfully with the fly pest. Whatever the ultimate agent may prove to be, larvicidal treatment has now been shown to be both sound and practical.

MEDICAL DEFENCE UNION.

The annual general meeting of the Medical Defence Union was held at the County Hospital, Bedford, by the kind permission of the Board of Management, on September 16th, at 4.15 p.m.

The chair was taken by Sir JOHN TWEEDY, LL.D., F.R.C.S., the President, and he was supported by members of the Council and members drawn from the town and county. The attendance was fair, considering the numerous professional engagements with which medical practitioners are overburdened in consequence of the war and the absence of so many on active military service. The minutes of the last annual meeting were read, approved, and signed. The usual statutory resolutions were passed *nemine contradicente*, and Sir John Tweedy, Dr. Rigden, and Dr. Gunton Alderton, who retired under Article 23, but who offered themselves for re-election, were re-elected, no other nominations being made.

The report of the Council was approved, and a vote of thanks to the President and Council was passed unanimously. The value of the work of the Council is again fully proved by the report just issued, and it is satisfactory to find that due and important progress has been made. The war has increased the duties devolving upon the Council, as numerous matters arising out of it have required to be dealt with. The adjustment of partnership disputes has again been a feature in the work of the Union, and several arbitrations have been conducted. The Union does not litigate in actions between medical practitioners apart from exceptional circumstances, the work of medical defence being sufficiently onerous in respect of protection from the public.

The report of the Solicitor is interesting and should be read by every registered practitioner, who will then realize the perils and dangers of medical practice which should be guarded against. The total number of cases placed by the Union in the hands of Mr. Hempson during 1914 was 110, and of these 36 were directed to the support of members in actions for libel and slander, either defended or instituted on their behalf under circumstances affecting their professional honour and reputation. Twenty-two concerned actions in which questions of malpractice were raised; 5 related to the prosecution of unqualified practitioners and the suppression of unqualified practice, and 47 referred to matters falling within the heading of personal and miscellaneous. Of these 47 cases, 21 referred to matters arising out of the National Insurance Acts, in which legal intervention was necessitated; 9 to the support given to members in connexion with appointments which they held and where their interests were imperilled; 12 to the adjustment of partnership dispute, and 5 were cases arising out of inquests, etc. Mr. Hempson gives excellent tabular statements in his report showing the number of cases placed in his hands since his appointment and the actual legal costs involved. It is interesting to note that the legal expenditure for fifteen years, during which he has held an official position as solicitor, amounted to nearly £16,000, the average cost per case being £174.

We congratulate Sir John Tweedy, the President, and the Council of the Medical Defence Union upon the valuable work which they have accomplished and for the excellence of the results obtained. Without the assistance of societies such as the Union many members of the profession would have been very hardly hit in the past; and it behoves every registered practitioner to reap the advantages of a skilled and efficient organization which will protect him in matters affecting his professional life. The fact that Sir John Tweedy is the President is a testimony in itself to the high status and reputation of the Medical Defence Union, and the support which a man of his position in the profession affords it is a proof of its worth and excellence.

British Medical Journal.

SATURDAY, SEPTEMBER 25TH, 1915.

THE REPORT OF THE DRUG TARIFF COMMITTEE.

AN outline of the long-expected report of the Departmental Committee on the Drug Tariff is published in the SUPPLEMENT for this week; its recommendations were published in full in the SUPPLEMENT for last week, p. 131. The Committee consisted of Sir Rowland Bailey, Chairman; Dr. John Adams, Member of the Council, and Dr. Alfred Cox, Medical Secretary, British Medical Association; Mr. James P. Gilmour, Member, and Mr. W. J. Uglow Woolcock, Secretary, Pharmaceutical Society of Great Britain; Dr. J. F. Tocher, Aberdeen; Mr. R. V. Vernon of the Treasury; and Mr. S. P. Vivian, Assistant Secretary of the Insurance Commission, England. Broadly speaking, its report is a complete justification of the attitude which the British Medical Association has taken up on behalf of the profession in respect of the drug tariff. After reading the memorandum of evidence put in by the witnesses for the British Medical Association and the conclusions of the Committee, one is bound to infer that the evidence of the Association has had a very marked effect on the mind of the Committee. The Association pointed out that the present tariff was so complex and so full of anomalies and inconsistencies, that it seemed quite impossible to deduce any definite principles on which it might be supposed to have been based. Even the ostensible guiding principles set forth in the preface to the tariff were so freely departed from on every page that they proved unworthy of the name of basic principles. This charge against the tariff is fully borne out by the Committee, which admits that "the effect of the system may almost be said to show a different rate of charge on every particular quantity of every particular drug. It has rendered the tariff incapable of proper adaptation to meet the needs of changing circumstances. Assuming that the ultimate yield of the tariff, when originally constructed, was fair, the fact remains that the yield, being the net resultant on balance of a large number of varying circumstances, could only continue to be fair so long as the circumstances were unchanged. The original balance, being based not upon any constant law but solely upon the circumstances of prescribing by practitioners at some particular time, would be destroyed as soon as those circumstances altered. This, we believe, has, in fact, happened; and we are satisfied that the habits of practitioners in prescribing have been modified and are likely still to be modified to such an extent as to render inaccurate any calculations based upon the nature of those habits at any given time." The Association also pointed out that the system was so chaotic that on a single prescription it was possible that the chemist might gain a profit at seven points: (1) The discount he got from the wholesale chemist. (2) The percentage profit on the primary price in the tariff. (3) The additional percentage profit on smaller quantities than the ounce. (4) The profit obtained by levelling up fractions to the next halfpenny. (5) Profit derived from the fact that one halfpenny was the minimum charge per ingredient. (6) Dispensing fee. (7) Emulsifying fee.

The Association's plea was not so much that the profit gained by the chemist was exorbitant as that the system was too complex and illogical for the real state of affairs to be revealed except by an elaborate actuarial calculation. It was pointed out that the medical profession was asked to economize so as to keep the drug bills down to a reasonable level, but that owing to the anomalies of the tariff a practitioner who was an economical prescriber in his own surgery might appear to be very extravagant with his insurance patients on the same prescriptions; that economy depended not only on the items ordered but on a detailed knowledge of a whole series of complicated and arbitrary details of the official tariff. The Association's plea for a sharp and clear demarcation between the cost price of drugs to the chemist and his reasonable and adequate trade profit and professional dispensing fee has been conceded in its entirety. The Committee proposes to sweep away the whole of these complexities and inconsistencies and to reduce the pricing of a prescription to two items:

(a) The bare cost of the drugs calculated to two places of decimals of a penny. The Association had asked for the substitution of the nearest single place of decimals instead of a gradation to the nearest halfpenny.

(b) The dispensing fee, which is calculated on the time and skill required in dispensing the various types of prescriptions, plus a fixed allowance per prescription of 0.8d. for establishment charges.

The establishment charges must cover the rent, rates, taxes, non-professional assistance (professional assistance is paid for in the dispensing fee proper), lighting, heating, corks, labels, wastage, packing expenses, etc., as far as they are properly chargeable to the insurance dispensing part of the business. The Association witnesses took the line that they could not judge what percentage of trade profit the chemist might reasonably expect to make, not having the necessary data in their possession. The Committee, basing itself on the results of an investigation made by a firm of chartered accountants, has determined what it considers a proper establishment charge on the basis of the profits obtained for this class of work before the commencement of medical benefit. This investigation led to the figure of 0.8d. per prescription, which figure allows a very slight increase on the trade profit formerly obtained without taking into consideration the increased turnover. It is interesting to note that the three members of the Committee with pharmaceutical interests dissent from the amount allowed for the establishment charges, without, however, giving any indication as to what the figure should be. It is to be regretted that the members of the Committee should not have been united on this matter as on nearly all others, seeing that the point in question is one which could only be settled by an investigation such as that promoted by the Committee and carried out by Messrs. Peat, a firm of standing in business circles. In Appendix VII of the report is a table of calculations made by Messrs. Peat, showing how the chemists' remuneration would have been affected had the tariff charges now recommended by the Committee been in force since the inception of medical benefit. Examination shows that the total drug bills may be expected to be reduced by 78 per cent. if the habits of doctors as regards prescribing remain as they were in 1913-14.

The Committee's scale of dispensing fees seems to be more rational than the present scale. Those processes which take up a great deal of time are paid for generously, while others are reduced in price. The most important point of all is that every act of

dispensing is paid for, whereas on the present system pills, capsules, confections, lozenges, ointments, blisters, tablets, suppositories, etc., included in the list carry no dispensing fee. All drugs of any sort will, at any rate, carry a dispensing fee of 1d. exclusive of the establishment charge, while stock mixtures or other liquids stocked in bulk will carry 1d. Extemporaneously prepared mixtures and other liquid preparations will take a dispensing fee of 2d. independent of quantity. The extra dispensing fee for large bottles is thus abolished. On the whole it may be said that the chemist will exchange a somewhat high account which must be always delayed in payment and may never be paid in full, for a moderate bill which can be paid directly and which he is absolutely certain of receiving in full. He will also save an immense amount of difficult clerical labour in the pricing of his prescriptions, since this is to be done by the expert staff of the Insurance Committee. One further advantage gained by the chemist will be that he will no longer be financially interested in the method of prescribing, and therefore will no longer have the odium and trouble of initiating proceedings against practitioners under the obnoxious Regulation 40.

The whole report reflects great credit on the members of the Committee, who have successfully attacked a financial and administrative problem of great complexity, and have extracted order out of chaos, with an obvious desire to bring forth a settlement which shall be just and equitable to all parties concerned.

TREATMENT OF CEREBRO-SPINAL SYPHILIS BY MERCURIALIZED SERUM.

THE resistance of tabes, tabo-paralysis, and general paralysis to antisypilitic treatment has long been the despair of the syphilologist and the neurologist. It is true that in cases which are not too far advanced some improvement occasionally occurs after intense mercurial treatment, but the great majority of cases are not amenable to antisypilitic drugs when administered by any of the ordinary routes; indeed, some authorities have stated that these conditions are made worse by such treatment. Tabes, tabo-paralysis, and general paralysis were therefore regarded as parasypilitic affections, and, although syphilitic in origin, beyond the scope of antisypilitic treatment.

The discovery, by Noguchi and others, of the *Spirochaeta pallida*, in its typical form, in the brain of general paralytics and in the spinal cord of tabetics threw a new light on the pathology of these affections and gave cause for hope for further success in treatment. It appears that they must now be regarded as cases of true cerebro-spinal syphilis and not parasypylis. Mott introduced the term "parenchymatous syphilis" to distinguish them from cerebro-spinal syphilis of vascular origin. To explain the failure of mercury and arsenic to influence parenchymatous syphilis, when introduced by the usual routes, it has been suggested that the cells covering the choroid plexus exercise a selective action and do not allow these drugs to pass from the general circulation to the cerebro-spinal fluid. The method of direct intraspinal treatment introduced by Marinisco was founded on this hypothesis. Both a dilute solution of neo-salvarsan and serum taken from a patient after intravenous injection of salvarsan or neo-salvarsan have been used. The latter method is assumed to depend on the presence of antibodies in the serum, produced by the preliminary intravenous

injection of salvarsan, since the amount of original or altered salvarsan present in the quantity used for intraspinal injection must be infinitesimal. Owing to the irritation caused by direct injection of the arsenical preparations treatment by "salvarsanized serum" has obtained most support. Swift and Ellis of New York, in 1912, tried this method in cases of tabes, and in the following year Robertson of Edinburgh used it in general paralysis. Since then intracranial injections have been tried in general paralysis.

The results of treatment by salvarsanized serum in parenchymatous syphilis are doubtful, although temporary improvement has been reported by several observers. The question naturally arises whether better results could not be obtained from the use of intraspinal injections of mercurialized serum or some preparation of mercury. This question has recently been studied by C. M. Byrnes, of the Johns Hopkins University, who, after a year's unsatisfactory experience with salvarsanized serum, has devised a method of treatment by what he terms "mercurialized serum." In the preparation of his serum Byrnes employs aluminate of mercury, for the reason that this is the form in which mercury is supposed to exist in the blood after ordinary mercurial treatment. When an inorganic salt of mercury comes into contact with albumin coagulation occurs with the formation of albuminate of mercury. This is soluble in excess of albumin, so that the addition of more serum forms a clear solution. It was found that approximately 0.02 gram of mercuric chloride solution added to 2 c.cm. of serum caused complete precipitation, and that 4 c.cm. of serum was required to dissolve the precipitate. Thus 6 c.cm. of serum will hold 0.02 ($\frac{1}{50}$ grain) of mercuric chloride converted to albuminate in solution, a larger quantity than is required for therapeutic purposes. After experimenting with very small doses, Byrnes found that 0.0013 gram ($\frac{1}{50}$ grain) or even 0.0026 gram ($\frac{1}{25}$ grain) could be given safely. The technique is as follows: (1) Sufficient blood is withdrawn to yield from 12 to 30 c.cm. of serum; this is centrifuged and the serum removed; (2) 1 c.cm. of a solution of mercuric chloride in distilled water, made to contain 0.0013 gram to 1 c.cm., is added to 12 c.cm. of serum; (3) to the serum thus prepared is added salt solution up to 30 c.cm., if diluted serum is to be used; if a concentrated solution is required this is omitted; (4) the mercurialized serum is heated to 56° C. for half an hour; (5) lumbar puncture is performed with the patient in bed; pressure readings are taken and the spinal fluid withdrawn till the pressure falls to 30 mm. The serum is then administered by gravity at body temperature, and the foot of the bed raised.

Byrnes has used this method in 32 cases, comprising 13 of tabes, 14 of general paralysis, 2 of tabo-paralysis, and 3 of cerebro-spinal syphilitic meningitis. In tabes there was improvement in the gait and also in the gastric and bladder symptoms. Some cases of general paralysis were also improved, and in one case of tabo-paralysis the grandiose ideas are said to have disappeared, and the mental state of the patient to have become apparently normal. Favourable results were obtained in the cases of meningitis. The diminution in cell elements of the cerebro-spinal fluid was more rapid than after treatment by salvarsanized serum.

It will be noted that Byrnes's method by "mercurialized serum" differs from that by "salvarsanized serum" in that it consists of direct treatment by means of a preparation of mercury dissolved in serum, instead of indirect treatment by serum containing

hypothetical antibodies. In this respect it would appear to be the more rational form of treatment, for the quantity of mercury present in serum withdrawn from a patient after intense mercurial treatment has been found to be quite insignificant, and the amount of antibodies present in such serum must be problematical. It also has the advantage of being a simpler procedure, since it avoids the preliminary intravenous injection required for salvarsanized serum.

The introduction of mercury into the subdural space had been previously tried by Ravaut, who used the perchloride and the cyanide in two cases, but the results were disappointing. This led Byrnes to seek for a non-irritating preparation similar to that in which mercury circulates in the blood (albuminate). In the usual doses this form of mercury was found to be quite as powerful as the inorganic preparations, and it has since been used for intravenous injection in ordinary cases of syphilis by L. Thompson, who regards it as a useful method when rapid results are required. The initial dose given in his cases corresponded to $\frac{1}{15}$ grain of mercuric chloride, and this was increased to $\frac{1}{3}$ grain. Further results of this form of mercurial treatment will be awaited with interest.

THE MEDICAL WAR EMERGENCY ABROAD AND AT HOME.

The account which a correspondent gives at p. 473 of the work of a civil practitioner in France to-day will be read with interest, and may give rise to some salutary reflections. The area to which it refers is far removed from the actual fighting line, but we get a vivid impression of the working of universal military service as it affects the medical profession. Upon the man who stays at home—the elder man—fall heavy duties: He must help in the treatment of the wounded in an auxiliary hospital; he must attend to another medical man's widely scattered practice, and must undertake official obligations as to vaccination, and so on, throughout a big district. All this work has somehow to be crowded into the week, and the substitute has to cover long distances on a motor cycle over roads with bad surfaces and difficult gradients. The cheerful spirit of the writer is admirable, and that he has rather understated his tribulations we know from several private letters received during last winter and spring, when the hard work, and the broken weather, and the consequent exceeding badness of the mountain roads, occasionally drew from him a complaint of his hard lot. With such an example before us it would not seem that too much is being asked of the medical profession in this country. Though many practitioners may have been hardly worked, there has not been any evidence of a really serious shortage in the attendance on the civilian population. In view of the disconcert from the medical point of view which civilians in France appear to be putting up with, it can hardly be too much to ask the British public to endure cheerfully the slighter inconveniences they are likely to suffer, so that medical practitioners in this country who are of military age may hold themselves prepared to take service if called upon to do so. The reflections which a study of the facts with regard to France may arouse will be strengthened in their application to this country by a perusal of the stirring address given by Colonel Littlewood of Leeds at a meeting held recently at Wakefield, and reported in the SUPPLEMENT for this week. Colonel Littlewood will be known to most of our readers as the distinguished civil surgeon who, a couple of years ago, retired from the staff of the Leeds General Infirmary. He remained *à la suite* of the 2nd Northern General Hospital, and, owing to the illness of Colonel Dobson, he is now administrator of that hospital. Colonel Littlewood does not mince his words. He sets out in most uncompromising terms the nature of this great

emergency, and what he conceives to be the duty of the medical profession. We doubt not that his winged words will have great influence in the North of England, where he is so well known. Their influence will be reinforced by the results of the meeting at Leeds on September 16th, which was addressed by Sir Clifford Allbutt, a member of the War Emergency Committee which meets at the house of the British Medical Association in London. He told the meeting that the district should furnish twenty-six more men for the army, and though no definite decision was made there and then, and was not, indeed, to be expected, the meeting unanimously resolved that a list should be drawn up of men retired or partly retired, or senior partners, who would be prepared to take charge of practices, or help in conducting practices during the absence of men on service. Sir Clifford Allbutt deprecated anything like a disposition on the part of senior men to stand on their dignity as to what kind of practice they would undertake. Thereafter a committee was formed consisting of representatives from each several district of the Division to advise with doctors offering themselves for service, and to arrange for a written guarantee that their practices would be carried on for them, and restored to them intact at the end of the war. This also was carried unanimously. A discussion followed on the question of the keeping of records under the Insurance Act, and on a division it appeared that the opinion of the majority of the meeting was that, though the keeping of these records was tiresome, it was not in fact a serious difficulty. The scheme of enrolment and the form of agreement between the practitioner going on service and his local colleagues (SUPPLEMENT, September 18th, p. 130) proposed by the War Emergency Committee seem to have met with general acceptance among the medical profession, and every fit man of suitable age should sign the form issued by that Committee.

THE PRACTICES OF MEN WHO DIE ON SERVICE.

At a meeting of the Executive Subcommittee of the War Emergency Committee, held at the offices of the British Medical Association on September 20th, it received information as to a plan evolved in Nottingham for safeguarding the interests of the families of local practitioners who may lose their lives while serving the country as military medical officers. In the Nottingham area, counting those who have already gone and the quota which that area has just been asked to furnish, there will soon be a considerable number of medical men on active service; and the secretary of the Nottingham Committee, Mr. A. M. Webber, F.R.C.S., who has himself applied for a commission, urged on his Committee the desirability of some special arrangement being made in the event of a medical man dying on service. Mr. Webber expressed the opinion, which was shared by the Committee, that all the men who had gone would be more easy in their minds if they knew that some definite plan was in force for looking after the interests of their families in the event of their decease. The plan which commended itself to the Nottingham Committee was that the local War Emergency Committee should appoint a small subcommittee, consisting of a few men of high standing in the local profession, who should undertake to act as professional advisers to and collaborators with the legal executor of any man who died on service. In such an event their duty would be either to sell the practice on the best terms available to the men who were already doing the work, or to see that the practice was carried on until some period after the war when practices again become easily saleable. The responsibility would undoubtedly be very great, but the Nottingham medical men felt that anything that could be done to relieve the minds of those of their number who had gone, or were going, on active service should be done, and small committees were accordingly appointed for both the city and the county. The plan was strongly approved

by the Executive Subcommittee in London, and is one which seems well worthy of consideration by every local War Emergency Committee, with a view to its extension to every area in the country.

TREATMENT OF TYPHUS WITH TYPHOID VACCINE.

In the *Wiener medizinische Wochenschrift* for June 5th Dr. W. Mollow, senior physician to the Alexander Hospital in Sofia, has given an account of his experience of typhus and typhoid fever, and of the results of vaccination with Besredka's sensitized typhoid vaccine in both diseases. Early in 1915, many Bulgarian Macedonians, who had served in the Serbian army, and had been taken prisoners by the Austrians, were sent back to Bulgaria. Among these 140 cases of typhus occurred, but it did not, however, break out as a rule before the patients had reached Bulgaria. The first batch of patients admitted to hospital were chiefly suffering from typhoid fever, some were also suffering from relapsing fever, and only a few from typhus. But towards the end of January there were no new cases of typhoid fever, whereas there was an increase in the incidence of typhus. Several cases at first diagnosed and treated as typhoid fever ultimately turned out to be typhus. In the meantime these cases had been treated with Besredka's sensitized typhoid vaccine, with strikingly beneficial results. This observation led to the prescription of typhoid vaccine in cases of typhus, recognized as such from the outset, and again the results were very good. Dr. Mollow gives details of several cases illustrated by temperature charts, which show how intravenous injections of the vaccine caused a fall of temperature by crisis or lysis. The improvement in the general condition following these injections was also striking, but it was not clear why a typhoid vaccine should be so potent in cases of typhus in which the agglutination test for typhoid fever was negative. Though there may at present be no rational explanation for this phenomenon, Dr. Mollow points out that it is not unique, and that diphtheria antitoxin has been found to have a beneficial effect on erysipelas, and a sensitized *coli* vaccine has strikingly benefited cases of typhoid fever and sepsis.

AN ANCIENT AUSTRALIAN.

WHEN the British Association met in Australia last year Professor J. T. Wilson, of the University of Sydney, was in a position to show to the members of the Anthropological Section a fossilized human skull found in the bed of a creek, Darling Downs, Queensland. The condition of fossilization was exactly the same as that of the remains of certain extinct marsupial animals found in the same locality—remains which belong to a deposit which geologists regard as having been laid down during the Pleistocene period. There seems to be no ground for doubting the genuine antiquity of the human skull thus brought to the notice of anthropologists; it is the skull of a youth who lived in Queensland when Enrope was passing through a period of glaciation. For the first time definite evidence of the existence of man in Australia during the Pleistocene period has been obtained. The manner in which the discovery was made is both interesting and instructive. It was found fully thirty years ago by a stockman; it ultimately found its way to Sydney, where it was discovered a very short time before the visit of the British Association. The anatomists and geologists of Australia, stimulated by the success which had attended the efforts of their colleagues in Europe, North America, South America, and South Africa, began a systematic search for human remains, with any claim to antiquity, in the private collections throughout the country, with the result that public sympathy was enlisted and a document of first-rate importance—the "Talgai skull" it has been named—has been rescued from oblivion. We learn from *Nature* (September 9th, 1915) that the Talgai skull has been

purchased by the Hon. Joynton Smith and presented by him to the museum of the University of Sydney. When shown to the members of the British Association, the skull was encased in a mass of matrix, which hid its chief features; only the palate and teeth could be clearly seen. The dentition was incomplete; the stage of eruption was that which we expect in a youth of 14 or 15 years of age. The palate and teeth, however, exceeded all modern dimensions. The canine teeth, although large, had none of the simian features which characterize the dentition attached to the skull found at Piltdown by Mr. Dawson; the teeth and palate appeared to represent such a form as we may expect to find in the more primitive type of Australian native. Professor Wilson being unable, on account of military duties, to undertake a systematic examination of the skull, handed it over to Dr. Arthur Smith (brother of Professor Elliot Smith), who at present is filling Professor Wilson's chair. Dr. Smith has succeeded in removing the matrix from the skull, and we may expect his full report at no distant date. In the meantime he claims for the Talgai skull an importance equal to that which anthropologists attach to the human remains found at Piltdown and Heidelberg. At the present time every one is necessarily more interested in problems connected with the present and future of our race than in those which pertain to our history in the distant past. Nevertheless, the discovery of the Talgai skull is worthy of note even at the present time, for it is more likely than any discovery yet made to throw light on the time and manner in which modern races of men became differentiated into their present forms and varieties.

SLEEPING SICKNESS AND WILD GAME.

An interesting experiment as regards the prevention of sleeping sickness is about to be carried out in Nyasaland. It is proposed to throw open a large area of territory for free shooting, and a thorough endeavour is to be made to clear this of tsetse flies by driving out or killing off the game. Natives are to be encouraged to hunt in every way. Several years ago a smaller area in the Ngara subdistrict was thrown open, but after a considerable period of time was closed again because the natives were not disposed to avail themselves of the privileges offered except in a very irregular way. The present area, however, is much larger, and the fact that the shooting is free is to be widely advertised. Time alone will show to what extent the game will be reduced by such measures. The result will be influenced considerably by the nature of the country and the number of people who take advantage of the privilege. It is to be hoped, however, that the experiment will succeed, and if it does the knowledge acquired will be of the greatest value for other places.

"A PUFF IN A PENCIL."

In reply to a paragraph under this heading which appeared in the *BRITISH MEDICAL JOURNAL* of August 28th (p. 335), we have received a letter from the firm on whose way of calling the attention of the medical profession to the virtues of a special brand of tea which they sell we felt it our duty to comment. The writer, after saying that it is not his purpose to enter a defence of the general publicity methods of his firm, goes on to state that "the instance under discussion has been, in effect, endorsed as acceptable by more than 33 per cent. of those to whom the offer of the pencil has been made, for in this proportion they have availed themselves of it to the extent of many thousands, and as there has followed a daily stream of acknowledgements, often very kindly expressed, I assume the recipients consider that, in this instance at any rate, they have not been 'led astray.'" We can almost fancy we hear the voice of Aetolycus declaring Trust to be "a very simple gentleman." We had no idea there was such widespread ignorance of the ways of the world among the

members of a profession which is in closer contact with the facts of life and human character than any other. The writer insists that "the essence of commerce is *service*," and this end he believes his firm attains through the pencil, which is merely a reminder "never . . . accompanied by any hint of obligation expressed or implied." It is obvious that the pencil or any other gift is a "reminder," and in that very fact lies the objection, from the professional point of view, to this form of advertising. The tradesman has his own code of commercial ethics, and as long as he does not use dishonest methods or make false statements he has a perfect right to proclaim his belief in the superior value of his wares. What we find fault with is the attempt by such concrete "reminders" to induce unsuspecting doctors to help the sale of those wares.

EXHIBITION OF FRACTURE APPARATUS.

The exhibition of various forms of apparatus that have been found useful in the treatment of fractures met with in the war will be opened at the Royal Society of Medicine, 1, Wimpole Street, by Sir Alfred Keogh, K.C.B., Director-General Army Medical Services, at 3 p.m. on Friday, October 8th. The principal exhibits will be brought from Boulogne by officers of the R.A.M.C. Surgeons in the various commands are invited to send exhibits, and those desiring to contribute should communicate with the consulting surgeon for their command. The exhibition will remain open until the evening of Monday, October 11th. On Sunday visitors will be admitted on presentation of their visiting cards. On other days the exhibition will be open from 10.30 a.m. to 5.30 p.m. On Friday, Saturday, and Monday, Colonel Sir Almoth Wright will give demonstrations of his most recent researches into the drainage of wounds.

THE CASUALTY RETURNS FOR THE FIRST YEAR.

The statistics of the total casualties, for the first year of the war, of the British forces engaged, given by Mr. Tennant in the House of Commons on September 14th, and those for the Dardanelles, which he gave on September 16th, enable a rough calculation to be made as to the proportion of those killed or who died of wounds to the wounded. The general proportion appears to be about 1 to 3½, but when the two areas of operations are considered separately, it would appear that the ratio was a little higher in the Dardanelles than for the force in France. The German losses in the war with France in 1870 showed a ratio of killed to wounded of 1 to 3.1; in the British forces in the Boer war the ratio was 1 to 3.9, and in the Russo-Japanese war it was 1 to 3.6 for the Japanese, and 1 to 5.5 for the Russians. There seems to be an impression that the ratio of officers to men killed in the Dardanelles is unusually high. The figures do not appear to bear this out. The ratio on the total figures is about 1 to 14, and on those for the Dardanelles about 1 to 15.

Medical Notes in Parliament.

The Budget.

The chief interest of the session so far has centred in the Budget introduced on September 21st, the third since the outbreak of war. Mr. McKenna said that in 1913-14, the last year of peace, the revenue and expenditure nearly balanced at about £198,000,000. On the existing basis of taxation the revenue might be put at £272,000,000, and the expenditure at £1,590,000,000; it was obvious that the deficit could not be met by taxation alone. The country had responded magnificently to the call to subscribe to the recent war loan, and on some future occasion it would be necessary to borrow again. The dead weight of the national debt at the close of the year might be estimated at £2,200,000,000; four and a half months ago, in his speech on the Budget he then introduced, Mr. Lloyd George had said that the triple task this country had

assumed in the war was—to keep the command of the sea, to maintain an army, and to assist our Allies by furnishing them with supplies and aiding them in financing their purchases in countries other than our own. The expenditure on all these heads had since then increased, and the country had now to contemplate a navy costing £190,000,000, an army costing £715,000,000, and external advances to the amount of £425,000,000. Taking the whole period until March 31st (1916) the best estimate which could be formed of the total daily rate of expenditure on all services from now onwards was upwards of £4,500,000, and in the later weeks of the financial year it might rise to more than £5,000,000.

After referring to the greater burden every new tax imposed upon the Board of Inland Revenue and on the Office of Customs and Excise, he said that the new taxes to be proposed were of such a nature that the departments would be able to give effect to them promptly and efficiently. The principal head of the new taxation was under income tax; he proposed to add 40 per cent. to the existing rates, but to give special relief to an income which had fallen more than 10 per cent. As the 40 per cent. rate of increase would be for a full year, in the remaining six months of the current year only 20 per cent. increase would become due. It was proposed to reduce the exemption limit from £160 to £130, and to reduce the abatement from £160 to £120. While the exemption limit would become £130, the abatement would be £120 where it was previously £160, and £100 where it was previously £150 or £120. Hitherto income tax for the full year had been payable in January, but in future, in the case of persons liable to direct assessment in respect of trade, profession, or husbandry, it would be payable in half-yearly instalments on January 1st and July 1st. This would be a postponement of payment, and not a device for getting tax paid at an earlier date. For employees of all descriptions both assessment and collection would be quarterly, but this change would not take full effect until next year. Relief was proposed from the additional income tax in the case of any individual proving that his actual income from all sources for the year was less by one-fifth than the income on which he had paid the tax. This was an endeavour to redress the hardship upon the individual who, this year, having a very small income, was nevertheless assessed on the average of the three preceding years, when he had a large income, and found that he was called upon to pay 3s. 6d. in the £ income tax in respect of income which he once enjoyed, but now no longer possessed. Where the income was less by one-fifth it was proposed that he should be relieved of the whole of the 40 per cent. increase, and where the deficiency did not amount to one-fifth, but was more than 10 per cent., repayment of a proportionate part of the additional duty would be allowed. The total effect of these changes in 1915-16 would be to increase the revenue by £11,274,000, and in a full effective year by £44,400,000. It was proposed also to revise the super-tax scale applicable to incomes in excess of £8,000. At present any excess over that amount was chargeable at the rate of 2s. 8d.; henceforth the charge would be 2s. 10d. between £8,000 and £9,000, 3s. 2d. between £9,000 and £10,000, and 3s. 6d. on the surplus of all incomes above £10,000. This would yield £2,150,000 this year, and £2,685,000 in a full effective year. Mr. McKenna then quoted some examples of the effect of the proposed changes. A man with no children earning £2 15s. a week would be directly assessed, and would pay 12s. 1d. quarterly; a man with no children earning £3 a week would pay 18s. 11d. quarterly; a man with no children earning £4 a week would pay £2 6s. 2d. quarterly. Any such man showing that he did not earn such a sum as to make him chargeable under that tax in a whole year would be entitled to repayment. At the other end of the scale a man with £5,000 a year would pay £1,029, which, combining super-tax and income tax, was a virtual rate of 4s. 1½d. A man with £10,000 a year would pay with income tax and super-tax £2,529, a virtual rate of 5s. 1d. in the £. A man with an income of over £10,000 would pay £2,529 on the first £10,000, and 7s. in the £ on all excess over £10,000. Thus a man with £20,000 a year would pay £5,029 in tax, a virtual rate of 6s. in the £, and a man with £100,000 a year would pay £34,029, a virtual rate of 6s. 10d. in the £.

The next source of additional revenue was the taxing of excess profits; the tax would be 50 per cent. without

deduction of income tax and just over 60 per cent. with such deduction.

The duty on sugar would be increased from 1s. 10d. a hundredweight to 9s. 4d., but contemporaneously the Royal Commission on Sugar Supply, which now supplies the whole of the sugar to the consumers of the country, would reduce its price to the refiners and dealers by amounts ranging from 2s. 6d. to 3s. a hundredweight. The effect of the double action would be to raise the cost of sugar about 5s. a hundredweight, or 1d. in the pound, in the case of granulated sugar. The price of lump sugar would rise a great deal, not on account of the tax, but on account of the shortage of supply. The duties on tea, tobacco, cocoa, coffee, chicory, and dried fruits would be increased by 50 per cent., and there would be an increase on motor spirits of 3d. a gallon, raising the existing rates of 3d. and 1½d. to 6d. and 4½d. Mr. McKenna said that he proposed to double the patent medicine duty, at present 1½d. in the shilling; he expected an addition to the revenue from this source in a full year of £250,000.

In view of the need to maintain our foreign exchanges and cut down expenditure on imported luxuries, he proposed to impose an *ad valorem* duty of 33½ per cent. on motor cars, motor cycles, and parts thereof, kineama films, clocks, watches, musical instruments, plate glass, and hats. The estimated total additional revenue for this year from these various sources was £11,500,000, and in a full year £25,070,000. Adding the estimated yield of the new inland revenue taxes, £77,085,000, the estimated total yield from new taxation was £102,155,000. In addition, changes in postal, telegraph, and telephone rates were estimated to yield an increase of revenue of £4,975,000. The postal changes had been recommended by the Retrenchment Committee, and all its recommendations had been adopted with the exception of that advising an addition of ½d. to the penny postal rate for inland letters. The halfpenny postage, including post cards, would be entirely abolished. The inland letter rate of 1d. would in future carry a letter not exceeding 1 oz.; under 2 oz. the stamp must be 2d., and 1½d. for every additional 2 oz. Sixpenny telegrams would be abolished; the new charge would be 9d. for twelve words, and 1½d. for each additional word. For inland parcels an addition of 1d. a parcel would be made. In respect to telephones, flat rates would be increased from £17 to £20 a year in London and from £10 to £12 in the provinces. The subscribers' penny call would not be changed, but the trunk service charges and those made in call offices would be increased. In addition, the rates for press telegrams would be largely increased.

A brief discussion ensued, during which certain free traders expressed disapproval of the import duties; the resolutions imposing the new duties and for altering the rates of income tax and increasing the postal and telegraph rates were agreed to before the House adjourned.

The following, extracted from the official statement issued on the evening of September 22nd, shows the rates on incomes of the amounts specified wholly earned, under the old tax 1915-16, the new tax 1915-16, and the proposed tax, 1916-17:

Incomes Wholly Earned,

	£200	£500	£1,000	£1,500	£2,000
Old 1915-16 ...	3 0 0	26 5 0	75 0 0	131 5 0	200 0 0
New 1915-16 ...	7 4 0	35 0 0	90 0 0	157 10 0	240 0 0
Proposed 1916-17	8 8 0	42 0 0	105 0 0	183 15 0	280 0 0

These figures do not take into account allowances in respect of life insurance premiums and children, which in many cases will substantially reduce the tax payable and the virtual rate.

Military Mental and Nervous Cases.—In reply to Mr. Anderson and other members the Under Secretary of State for War stated, on September 16th, that uncerifiable soldiers sent to buildings attached to county asylums were not in any way dealt with under the Lunacy Acts, but remained under the control of the Secretary of State for War. Each case was the subject of special consideration

by general physicians and neurologists, and was placed under the care of the most appropriate specialist in the appropriate institution. The continuation of the system in the future must depend upon the accommodation and the number of specialists available. In reply to Sir Henry Craik, he said that the medical profession was most anxious that none of the practices of inspection which otherwise applied to asylums should apply to these cases.

Naval and Military War Pensions Bill.—The discussion of this bill, adjourned in the House of Lords on July 23rd, was resumed on September 16th, when the bill was read a second time, the Government undertaking to introduce amendments providing for the reinstatement of representatives of the Soldiers' and Sailors' Families Association, for the inclusion on local committees of persons who have been engaged on similar work, and the appointment by the Statutory Committee of a special subcommittee comprising representatives of employers and labour to provide for the care of disabled officers and men.

Nursing of Insane Male Patients.—In reply to Mr. Peto, on September 16th, Mr. Bruce, Under Secretary for the Home Office, said that for many years women had been employed in some asylums in nursing male patients who were not dangerous or otherwise unfitted for female care, and, provided precautions were taken, the practice was approved by the Board of Control, which had found its results satisfactory. Since the outbreak of war, in consequence of the difficulty of obtaining suitable male substitutes to replace attendants who had joined the forces, there had been some extension of the practice, but in every case within proper limits and without any harmful results. Careful consideration had been given to the representations of the National Asylum Workers' Union, but the Secretary of State regretted that he was unable to comply with the request that he should ask asylum authorities to discontinue the practice.

Swine Fever.—Mr. Acland stated, on September 16th, in replying to Sir John Sparc and Sir Walter Essex, that the recommendations contained in the final report of the Departmental Committee on Swine Fever had in the main been adopted and brought into operation in respect to the revocation of certain restrictions on the movement locally of swine. The procedure to be adopted as to serum treatment in swine fever outbreaks would be published almost immediately, and would be operative from September 26th. Any further action must be based upon experience acquired.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE WEEK'S SUBSCRIPTIONS.

The subscriptions to the Belgian Doctors' and Pharmacists' Relief Fund received during the week have been as follows:

S. Essex Division, B.M.A. (per Dr. J.E. Maxwell, Joint Hon. Sec.)—	£ s. d.	Dr. Lloyd	£ s. d.
Dr. Perkins	0 10 6	Dr. Stovinj	0 10 6
Dr. Floyd	1 1 0	Dr. Killard-Leavey ...	0 10 6
Dr. Walker	0 10 6	Mr. E. D. H. Carpenter	(sixth donation, total
Dr. Hinks	0 10 6	£6)	1 0 0
Dr. Watson and	...	South Australian Belgian	Doctors' Relief Fund
Wacher	0 10 0	(fourth donation, total	...
Dr. Prentis	0 5 0	£37)	27 0 0
Dr. Adams	0 5 0	Mr. Alfred Freer ...	0 5 0
Dr. Bruce Poole ...	0 10 6	Mr. E. Nash	1 1 0
Dr. Forreth and Dr.	...	Mr. G. H. Morgan ...	1 1 0
Noruan	1 1 0	Messrs. Francis and Co.	1 1 0
Dr. Waag	0 10 6	Mr. J. Fawcett	0 12 6

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

Surgical instruments should be sent to the Master of the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C.

THE WAR.

OPERATIONS IN THE DARDANELLES.

THE DIFFICULTIES OF THE MEDICAL SERVICE.

Sir Ian Hamilton's New Dispatch.

EVERY ONE will have read the new dispatch of Sir Ian Hamilton describing the operations in the Dardanelles, but there are a few points to which it seems well to call attention here. His first dispatch left off at the point where, on May 5th, our troops had forced their way forward for some 5,000 yards from the landing places at the point of the peninsula. There followed three days of severe fighting, which resulted in a gain of 600 yards on the right of the British line, and 400 yards on the left and centre. The gain, though small, was important, and for the next two days the enemy made obstinate counter-attacks which were all repulsed, while in the northern zone the Australian and New Zealand Army Corps strengthened their grip. On May 11th, for the first time for eighteen days and nights, it was found possible to withdraw the 29th Division from the actual firing line and to replace it by the 29th Indian Infantry Brigade and by the 42nd Division, which had completed its disembarkation two days previously. "The withdrawal gave no respite from shells, but at least the men were, most nights, enabled to sleep." What this condition of affairs must have meant for the medical service can easily be imagined. The nature of the fighting inevitably involved heavy casualties, and as the total advance brought the front line less than 6,000 yards from the landing places at the point of the peninsula, there can have been few, if any, places where casualty clearing stations, to say nothing of field ambulances, could have been established in situations secure from long-range artillery.

On May 20th, at 5 p.m., the appearance of white flags and red crescents from the enemy's line was followed by an interview, half way between the trenches, between a Turkish staff officer, two medical officers, and a company commander of the enemy and Major-General H. B. Walker, commanding the Australian Division. The staff officer proposed a suspension of arms for the removal of dead and wounded. As the officer had no written credentials he was informed that neither he nor the General Officer Commanding Australian Division had power to arrange a suspension of arms, but that at 8 p.m. an opportunity would be given of exchanging letters on the subject; meanwhile hostilities would recommence after ten minutes' grace. At this time some stretcher parties on both sides were collecting wounded, and in front of other sections men with white flags came out to collect wounded. It was observed that the Turkish trenches opposite ours were packed with men standing shoulder to shoulder two deep, and that columns were on the march in the valley up which the Turks were accustomed to bring their reinforcements. Towards evening the enemy's concentration continued, and everything pointed to their intention of making use of the last of the daylight to get their troops into position without being shelled by our artillery.

"A message was therefore sent across to say that no clearing of dead or wounded could be allowed during the night, and that any negotiations for such a purpose should be opened through the proper channel and initiated before noon on the following day. Stretcher and other parties fell back, and immediately fire broke out. In front of our right section masses of men advanced behind lines of unarmed men holding up their hands. Firing became general all along the line, accompanied by a heavy bombardment of the whole position, so that evidently this attack must have been prearranged. Musketry and machine-gun fire continued without interruption till after dark, and from then up to about 4 a.m. next day."

At about 4.30 a.m. on May 21st musketry fire had died down to normal dimensions, and as the Turks seemed anxious to bury their dead, and human sentiment and medical science were both of one accord in favour of such a course, a suspension of arms was arranged from 7.30 a.m. to 4.30 p.m. on May 24th, and the procedure laid down was correctly observed on both sides. After that the fighting continued from day to day. On June 4th the gallant

Manchester Brigade of the 42nd Division suffered very heavily, and in the evening that division had to be extricated with loss from the second line of Turkish trenches.

"From the date of this battle," says Sir Ian Hamilton, "to the end of the month of June, the incessant attacks and counter-attacks, which have so grievously swelled our lists of casualties have been caused by the determination of the Turks to regain ground they had lost, a determination clashing against our firm resolve to continue to increase our holding." On June 28th the Border Regiment rushed a small redoubt known as the Boomerang, and the 87th Brigade captured three lines of Turkish trenches. The 4th and 7th Royal Scots captured the two Turkish trenches allotted to them, but further to the east, near the pivotal point, the remainder of the 156th Brigade was unable to get on. Later the 86th Brigade, dashing over the trenches captured by the 87th, pushed on with great steadiness and took two lines of trenches, while the Indian Brigade managed to secure, and place into a state of defence, a spur running from the west of the farthest captured Turkish trench to the sea. "Our casualties," the dispatch says, "were small—1,750 in all."

In a general summing up Sir Ian Hamilton says:

"During the whole period under review the efforts and expedients whereby a great army has had its wants supplied upon a wilderness have, I believe, been breaking world records.

"The country is broken, mountainous, arid, and void of supplies; the water found in the areas occupied by our forces is quite inadequate for their needs; the only practicable beaches are small, cramped breaks in impracticable lines of cliffs; with the wind in certain quarters no sort of landing is possible; the wastage, by bombardment and wreckage, of fighters and small craft, has led to crisis after crisis in our carrying capacity, whilst over every single beach plays fitfully throughout each day a devastating shell fire at medium ranges.

"Upon such a situation appeared quite suddenly the enemy submarines. On May 22nd all transports had to be dispatched to Mudros for safety. Thenceforth men, stores, guns, horses, etc., had to be brought from Mudros—a distance of forty miles—in fleet sweepers and other small and shallow craft less vulnerable to submarine attack. Every danger and every difficulty was doubled."

Sir Ian Hamilton records his "admiration for the cool courage and unflinching efficiency with which the Royal Navy, the beach personnel, the engineers, and the administrative services have carried out these arduous duties." The casualties, he says, among the Royal Engineers engaged in the working of the telegraphs, telephones, and repair of lines, have been unusually high, and as an instance he mentions that the central telegraph office at Cape Helles (a dug-out) was recently struck by a high explosive shell; the officer on duty and twelve other ranks were killed or wounded and the office entirely demolished. The best photograph we have seen of a dug-out, showing what can be done with it, is that produced this week to illustrate a paper by Captain John Morley of Manchester, which shows such a place in use as an operating theatre.

It is quite evident that during the time covered by Sir Ian Hamilton's dispatch the Army Medical Service had to carry out its duties under very serious disadvantages; not only was the number of wounded large in relation to the confined area, but it must have always been very difficult, and sometimes practically impossible, to find any place where the wounded could be safely treated on shore. On these difficulties Sir Ian Hamilton makes the following comment:

"The Royal Army Medical Service have had to face unusual and very trying conditions. There are no roads, and the wounded who are unable to walk must be carried from the firing line to the shore. They and their attendants may be shelled on their way to the beaches, at the beaches, on the jetties, and again, though I believe by inadvertence, on their way out in lighters to the hospital ships. Under shell fire it is not as easy as some of the critically disposed seem to imagine to keep all arrangements in apple-pie order. Here I can only express my own opinion that efficiency, method, and even a certain quiet heroism have characterized the evacuations of the many thousands of our wounded."

His praise will be read with keen satisfaction by the profession at home, more especially as it knows that

many of the medical officers employed on these dangerous duties a year ago or less engaged in civil practice.

That the difficulties encountered by the medical service at previous landings recurred during the landing at Suvla Bay is clear from the correspondence from Mr. E. Ashmead-Bartlett, published fully in the *Daily Telegraph* of September 20th. He mentions the difficulty of water, of which the medical service, it may be observed, requires more than others, not only for the wounded to drink, but also for the proper treatment of wounds. Immediately after the troops had landed, the infantry ammunition and water had to be taken ashore, but the enemy's shrapnel was bursting on all sides; he frequently sent an 8 in. high-explosive shell close to the beaches, scattering rocks and earth and fragments of steel in all directions. "Streams of wounded arrive from the firing line, those who are able to walk hobbling down to the beaches, and others being carried on stretchers." The day was as hot as a furnace, but in the cool of the evening thousands were searching for a drop of water, thousands of wounded were wending their weary, suffering way to the beaches, waiting their turn to be conveyed to the hospital ships outside the bay. The picket boats, he says, at every beach in Gallipoli, and at all the islands, form the ultimate means of communication between the sea and the shore. "The lot of their crews is not to be envied, for they work under continuous shell fire. At Anzac, Helles, and Suvla Bay the enemy constantly shells the landing-stages, and day and night these picket boats are exposed to shrapnel and common shell. But the work never stops. There is a still more arduous time coming for the destroyers, trawlers, and picket boats this autumn and winter, when the gales come rolling up from the south-west, but I fancy that these hardy sailors from the North Sea and our seamen in the destroyers will take a ship through any sea, provided they can lay her up alongside of something in order to discharge her cargo."

The following table, constructed from the replies given by Mr. Tennant in the House of Commons at various dates, shows the total number of casualties, and from it can be calculated the rate of increase in the number of wounded to be treated:

Casualties in the Dardanelles.

	Up to May 31.		Up to June 30.		Up to July 18.		Up to Aug. 21.	
	Off'rs	Men.	Off'rs	Men.	Off'rs	Men.	Off'rs	Men.
Killed ...	496	6,927	541	7,543	562	7,537	1,130	16,478
Wounded ...	1,134	23,542	1,257	25,557	1,375	28,508	2,371	59,257
Missing ...	92	6,445	135	7,901	154	8,486	373	8,021
	1,722	36,914	1,933	40,501	2,091	44,531	3,874	83,756
	38,536		42,434		46,622		87,530	

It will be seen that the number of wounded down to May 31st was 24,676, that it was increased by 2,138 during the month of June, by 3,069 during the first eighteen days of July, and by 31,745 between that date and August 21st.

The position in respect to the difficulty in establishing casualty clearing stations does not appear to have changed materially since we published a note on the subject on August 14th. The wounded are got on board the hospital ships as quickly as possible by means of tugs and picket boats, supplemented, no doubt, by this time by the barges and motor boats provided by Mr. John Masfield through the British Red Cross. These hospital ships may be described as additional casualty clearing stations, and also as first line hospitals for the force ashore, the base hospitals being at Mudros on the Island of Lemnos, at Alexandria, at Malta, where the number of beds now available is very large, or even at home. The Joint Committee of the British Red Cross and the Order of St. John, in addition to its work on the peninsula and at Lemnos, is providing comforts of various kinds for the hospitals in Malta and also to hospital ships. Among other such enterprises it is arranging to set up a plant for making soda-water in connexion with one of the hospitals at Malta for the supply of all the institutions there.

THE PROPORTION OF RECOVERIES AMONG THE WOUNDED.

[From an Occasional Correspondent in France.]

It is not easy at the present time to obtain figures showing the proportion of the wounded in the French armies as a whole who recover sufficiently to return to the front, such as those published recently in the *BRITISH MEDICAL JOURNAL* (September 11th, p. 414) for the German and British armies, but it may not be without interest to place on record the statistics of a particular region kindly communicated to me by Dr. Baradat, chief medical officer to the Privas area. Privas is the chief town of the Department of the Ardèche, which borders the Rhone below Lyons on the western side. The graphic tables devised by Dr. Baradat to show the incidence of varying proportions of invalids are extremely ingenious and clear. In the early stages of the war, when the wounded began to crowd into the distant hospital centres, the general feeling was that the gallant fellows had discharged their duty to their country and were entitled to be nursed and then coddled, with the result that their sojourn in hospital was apt to be unduly prolonged. At that time, too, the proportion of soldiers accorded protracted terms of convalescence was extremely high. This soon attracted the attention of the military authorities, who recognized the necessity of instituting some form of control over individual hospital centres. When Dr. Baradat appeared on the scene at Privas he began by compiling tables showing the average period of hospital treatment in each "formation" in his district, and, having done so, he could see at a glance which formations called for inspection. It was in December that this tendency to stagnation in hospital reached its height, and at that time the average proportion of the wounded returned to their depôts as fit for further service was only 22.4 per cent. (94 out of 419). Under the influence of frequent inspection during the January-February period the proportion of men returned as "fit" rose to 64 per cent., and in the February-April period to 85 per cent. (852 out of 993), with a corresponding reduction in the proportion of convalescents and of men discharged from the army as unfit.

Speaking from my own experience in various voluntary hospitals, I am enabled to state that the instructions were in no way harsh, but merely tended to prevent stagnation in the hospital services. In almost every instance in which I thought it proper to append a note recommending that the man should be sent home for prolonged convalescence or discharged, the suggestion was accepted, and it is hardly necessary to add that we civil surgeons always erred, if at all, on the side of indulgence. It follows that the men returned by us as "fit" were really in a good state of health, possibly not in all cases such as to warrant their return to the fighting line, but at any rate enabling them to be of service in the auxiliary services.

GERMAN EXPERIENCE OF MEDICAL COMPLI-CATIONS IN MODERN WARFARE.

Die Deutsche medizinische Wochenschrift published on April 8th a series of brief notes on the most common medical casualties of the present war, and on the methods of treatment advocated as most suitable by well-known authorities in Germany. According to Dr. Moritz of Cologne, the most common pulmonary diseases among soldiers were pneumonia, pleurisy, and tuberculosis. For pneumonia he recommended optochin (ethylhydrocuprein hydrochloride) in doses of 0.2 gram, given six to eight times a day. This treatment sometimes caused auditory disturbances and amaurosis. For pleurisy artificial pneumothorax sometimes afforded relief, and for tuberculosis open-air treatment was to be recommended. According to Dr. FINDER of Berlin, relapsing catarrh of the nose and throat were very common owing to the insanitary conditions to which the soldiers were exposed. Diseases of the accessory

¹ A derivative of cupreine, an alkaloid which occurs in cuprea bark along with quinine, to which it is allied. Sir Almonro Wright has shown that the compound acts powerfully on pneumococci *in vitro*, cured mice infected with the disease, and rendered human blood bactericidal. In man the results were negative, probably because in man pneumonia is attended by coagulation of lymph in the air spaces, whereas in mice the infection takes the form of a septicaemia (see Martinale and Westcott's *Extra Pharmacopœia*, where references are given).

sinuses played an important part, and were most frequently due to influenza and coryza.

According to Dr. A. Schmidt of Halle, great mental strain was often responsible for severe gastro-intestinal disturbances, the most common of which were atony, subacidity, motor insufficiency, and acute intestinal catarrh. Vegetables rich in cellulose, whole potatoes and coarse bread should be avoided; and papaverin, atropin, and charcoal should be prescribed. According to Dr. Richter of Berlin, wounds and excitement were apt to provoke or increase diabetes; and early in the war it was noticed that progress of the disease occurred in almost every case of diabetes. In the case of nervous glycosuria, antineurasthenic treatment, not a rigoros diabetic diet, was indicated. True traumatic diabetes was seldom observed, but traumatic gout was exceedingly common. Chills, nervous excitement and exhaustion, and tiring marches frequently provoked acute attacks of gout, the subjects of which were no longer fit for service. Exophthalmic goitre was also found to develop as a sequel to great mental strain. Chills and infections were largely responsible for acute nephritis, which was also often a sequel to sore throats. In this connexion the amount of albumin in the urine was of no certain value as a guide to the progress of the case.

Dr. Weintraud of Wiesbaden considered that acute articular rheumatism and the allied diseases of the joints were not common, and that septic infections and sore throats ran an exceptionally mild course. According to Dr. Brugsch of Berlin, the demands of modern warfare constituted an unexpectedly severe strain on the vascular and nervous systems, and provoked mental instability and insufficiency of the whole vasomotor system, with a fall of blood pressure and dilatation of the heart. Recovery was exceedingly slow.

TYPHOID INOCULATION IN THE GERMAN ARMY.

In the *Deutsche medizinische Wochenschrift* for July 8th a correspondent has given the following account of inoculation against typhoid fever and cholera in Flanders. Only in a few cases did any severe local or general reaction follow typhoid inoculation, and then only as a sequel to the second injection. The reactions culminated on the day of the injection, and had disappeared three days later, except for slight tenderness at the site of injection. Among more than 40,000 persons thus treated only a few were incapacitated from work. In about 25 cases the inoculation was followed by diarrhoea, which did not last long. Persons subject to bronchitis and pulmonary tuberculosis suffered more than others from the reaction, which was accompanied by increased expectoration. Since the introduction of typhoid inoculation in Flanders the disease had disappeared, but the epidemic had already begun to die out before wholesale inoculation was introduced. The exact value of this measure could not, therefore, be gauged. It was found that the inoculated had no reason to dread the "negative phase," and in spite of the insanitary conditions and abundant opportunities of infection, there were no extensive outbreaks of typhoid among the inoculated. There were, however, several cases of diarrhoea, fever, and enlargement of the spleen among the inoculated. The symptoms were clinically indistinguishable from those of typical typhoid fever, but in most of these cases bacteriological examination revealed the paratyphoid B bacillus. The reaction to inoculation for cholera was, as a rule, less severe, but in many cases the local and general reaction was accompanied by diarrhoea. The correspondent concludes by asserting that in other respects the health of the German troops in Flanders was as good as ever.

Dr. B. Johan, of the Pathological Institute of Budapest, reported in the same issue of the same journal that, in conjunction with Dr. M. K. John, he had prepared and tested a typhoid vaccine which, he claimed, caused a less severe reaction than the Pfeiffer-Kolle vaccine. Though this was the vaccine most commonly used it often provoked a most severe reaction—rigors, a temperature of more than 104° F., vomiting, diarrhoea, and headache, all developed within a few hours of the injection. As these symptoms appeared so early, Dr. Johan attributed them to soluble poisons in the vaccine and not to poisons still contained in the dead bacteria. He assumed that the

soluble poisons must either have been thrown off by the bacteria during their growth (exotoxins), or had been set free from the bacteria during the preparation of the vaccine (endotoxins). He argued that, as recent investigations had shown, immunity is not an antitoxic but a bacteriolytic process; a satisfactory vaccine could be made out of bacteria without their toxins. Accordingly, Dr. Johan prepared a vaccine without soluble poisons in the following manner: Bacteria killed by heat were washed by centrifugalization, repeated three times. In addition to the dead bacteria, the vaccine contained only physiological saline solution and 0.25 per cent. carbolic acid. This vaccine, which contained 1,500 million bacilli to the cubic centimetre, was tested on more than 2,000 persons, including children, and was found invariably to provoke a slighter reaction than Kolle's vaccine. As this contained the same number of bacilli, and was made from the same original growth of typhoid bacilli, the comparative reactions of the two vaccines were all the more instructive.

In a supplementary note on the vaccine prepared by Dr. B. Johan, Dr. M. K. John emphasized the difference in the reactions provoked by this and the Pfeiffer-Kolle vaccine. The general disturbances caused by the former were very slight indeed, and whichever vaccine was used the agglutination test was found to be invariably positive within twelve to fifteen days of the second injection. In most cases the agglutination was a little more complete in the case of the Pfeiffer-Kolle vaccine, and on this account it was considered advisable to give three injections of Johan's vaccine. Dr. John insisted that there was no relation between the violence of a reaction and the degree of immunity conferred; and that the weakness or absence of reaction was not, therefore, to be interpreted as a fault, but rather as a virtue, of a vaccine.

GERMAN EXPERIENCES OF WAR SURGERY.

INJURIES TO THE SPINAL CORD.

At a meeting of the Verein für wissenschaftliche Heilkunde of Königsberg, Dr. Michaelis reported the case of a patient wounded by a bullet, which inflicted a small wound of entry in the back of the neck, somewhat to the left of the middle line, and at the level of the fourth cervical vertebra. There was no wound of exit, though the lower jaw on the left side was badly shattered. A day after the infliction of the wound both arms and legs were paralysed, but there was no paralysis of the bladder. The paralysis of the right arm and leg soon began to disappear, leaving only slight weakness of the right arm. A skiagram showed slight injury to the fourth cervical vertebra at the junction of its body with its arch. Viewed from in front, the bullet could be seen lying behind the much shattered horizontal ramus of the left lower jaw. No active treatment was attempted during the first fortnight, as it was hoped that the paralysis of the left arm and leg would disappear spontaneously. Treatment of the fractured vertebra by Glisson's extension apparatus was impracticable owing to the fracture of the jaw. The fragments were united by bronze wires, and the bullet was removed. As there was no improvement in the paralysis of the left side after a month, laminectomy was performed, on the assumption that the paralysis was due to pressure on the cord by a fragment of bone, or to peripharyngitis, with local oedema of the cord. The arches of the third, fourth, and fifth cervical vertebrae were removed, but no loose fragment of bone could be found. There were, however, signs of peripharyngitis. To the left of the middle line the dura was adherent to the fourth cervical vertebra over a small area. This adhesion was severed. After the dura had been opened, and a considerable quantity of cerebro-spinal fluid had escaped, a narrow groove was seen passing across the cord from behind and to the left, forwards and outwards. This wound of the cord, which had been gouged by the bullet, was closed by catgut ligatures, passing upwards and downwards, so as to unite the upper and lower margins of the groove. The wound in the dura was then closed and the operation completed. Three days later the movements of the left big toe were regained, and during the following days the paralysis of the left leg

¹ *Deut. med. Woch.*, July 8th.

gradually receded upwards. Eleven days after the operation there were active movements about the ankle, and three days later the patient could also move his legs slightly about the knee. Movements of the left arm did not begin to return till about four weeks after the operation, when first the thumb, then the fingers, and finally the rest of the arm began to regain the power of movement, the paralysis gradually receding upwards. Though the use of the left leg was almost completely restored, that of the arm remained much impaired. Dr. Michaelis, while insisting that the operation was very successful, admitted that the reason for this success was not perfectly clear. It might have been due to relief of pressure on the cord, which, in its turn, might be traced to the drainage of cerebro-spinal fluid. The improvement might also have been largely due to the closing of the groove in the cord.

At a meeting of the military surgeons in Strassburg, Dr. Levin² said that he had often seen paralysis of the bladder and intestine, as well as sensory disturbances, disappear spontaneously, and marked improvement in other symptoms occur, even in cases in which there was evidence of complete transverse section of the cord (*vollständige Querschnittläsion*). It was, therefore, unwise early in the case to diagnose total division of the cord, and to give an unfavourable prognosis. Brown-Séquard's unilateral lesion did not run such a favourable course as the total transverse lesion (*Querläsion*). In some cases of injury to the cord there were only a few isolated symptoms. Thus, in one case, in which certain nuclei of the medulla were involved, the symptoms were paralysis of the recurrent nerve, and unilateral atrophy of the tongue. In another case the symptoms consisted of difficulty in swallowing, loss of the patellar reflexes, and static-atactic manifestations. In a third case, weakness of the legs, diminution of the tendon reflexes, and diffuse sensory disturbances were observed.

Dr. Guleke said that he had come to the conclusion that it was often extremely difficult to learn the extent to which the cord had been injured, and that he was therefore in favour of early operation as a rule, for though this principle led to superfluous operations, it also saved the lives of many who would otherwise have died. He had performed 20 laminectomies, and in none had any harm been done. He did not advise this operation in cases complicated by severe pneumonia, meningitis, open and much infected wounds or "urosepsis." Haemothorax, on the other hand, was no contraindication, but when it was present the operation should be performed under local anaesthesia. In ten of his cases the cord was completely crushed, and they all terminated fatally. In five other cases death was due to sepsis. There were, therefore, only five recoveries among his 20 cases; but he was certain that three of the patients who recovered would have died had not the operation been performed. In these 3 cases splinters of bone or bullets were found in the cord, which they had much injured.

DIAGNOSIS OF GAS PLEGMON BY X RAYS.

Early in 1915³ Dr. Payr called attention to the importance of distinguishing between superficial and deep gas phlegmon. When it was subcutaneous, multiple superficial incisions were often sufficient, whereas when the gas phlegmon was deep-seated, extensive incisions were usually inadequate, and had, as a rule, to be followed by amputation. This view has recently⁴ been endorsed by Professor M. Martens, who added that the relatively benign, superficial gas phlegmon was far less common than the malignant, deep-seated type. As far less radical treatment was necessary for the one than for the other, it was of the greatest importance to distinguish between the two: to amputate for superficial gas phlegmon on the supposition that the disease was deep-seated was bad practice. In most cases the differential diagnosis could be made clinically or during an operation, but in doubtful cases the x rays were of the greatest value in detecting and localizing gas. Though this method of diagnosing gas phlegmon had but recently been employed, Professor Krause of Bonn had several years ago shown that subcutaneous emphysema was demonstrable by the x rays. The first patient to be examined in this connexion by Professor Martens was a dentist, who had been wounded

below the knee by a fragment of shell. The x rays showed an extensive layer of gas under the skin, covering the tibia, and bubbles of gas were also demonstrable between the various layers of muscles. The boundaries of the gaseous infection could be clearly seen. In spite of high fever and great swelling of the limb, the patient refused amputation, and insisted on the operation being limited to deep incisions. The further progress of the gas phlegmon was arrested, and the temperature fell; but, as so often happens, Professor Martens says, in such cases, gangrene set in, and the leg had to be amputated at the knee. Professor Martens had found the x rays useful in revealing the extent and depth to which gaseous infection had spread, and in indicating the best site for incisions and the most suitable level for amputations. In addition to their prognostic, diagnostic, and therapeutic advantages in gas phlegmon the x rays had, he said, a medico-legal value. A wounded soldier, who had been sent home, brought charges against the medical authorities for having amputated his right arm against his wishes and for insufficient reasons. He stated that he had been only slightly wounded, that he had been given a general anaesthetic, and that he had awakened without his arm. He had been operated on by a foreigner, against whom he brought a charge of malpractice, as well as against the senior surgeon in charge of the hospital in which the amputation had been performed. A skiagram which had been taken of the wounded limb clearly showed a fragment of shell and a fracture of the lower end of the humerus, separating the epiphysis from the diaphysis, which was displaced forward. The fracture involved the joint and was probably compound. In front of the fracture a dark shadow was cast by infiltration of the tissues with blood. The skiagram was also showed lighter points, which were attributed by Professor Martens and several other x-ray experts to the presence of gas phlegmon. Consequently it was agreed by medical experts that amputation of the limb was the only means of saving the patient's life, more especially as it was proved that gangrene of the skin had already set in.

THE TREATMENT OF THE WOUNDED IN THE FIELD.

Professor Körte of Berlin, who has been attached as consulting surgeon to the army in the West and later to the army in the East, has lately published in pamphlet form a lecture on the care of the wounded, which he gave on April 11th. Owing to the host of publications by military surgeons at the various fronts now appearing, he advises his colleagues always to state the locality where, and the conditions under which, their experiences were gained. Without such particulars, generalizations were apt to be misleading. He had found the organization of the medical service satisfactory, and he warmly recommended the policy of not attempting to make use of every medical officer in the field as a surgeon. In the treatment of wounds, including those inflicted under the dirty conditions of trench warfare, swabbing the skin around the wound with alcohol or tincture of iodine was found to effect satisfactory disinfection. In the case of bullet wounds, infection was usually so slight that immobilization and the early application of dressings were sufficient to ensure the patient's uneventful recovery. On the other hand, wounds inflicted by artillery were always to be regarded as infected. In his opinion, phlegmon, gas phlegmon, and tetanus were due to primary wound infection; secondary wound infections were rare under proper treatment. The modern infantry bullet, provided it did not strike sideways or inflict a wound at point-blank range, was more humane than the old infantry bullet. Like many other surgeons, he had not once seen a definite dum-dum wound.

RESECTION OF THE INTESTINE FOR METASTATIC ABSCESS OF THE MESHENTRY.

At a meeting of military surgeons in Berlin⁵ Dr. Ulrichs recorded the case of a soldier, aged 22, who was wounded on September 24th by a French infantry bullet, which entered his right shoulder. After his discharge, which occurred before the wound of exit, just below the right scapula, had completely healed, he developed osteomyelitis of the left fibula. Accordingly, on December 24th, osteotomy was performed, and on January 6th a gluteal abscess on the right side was opened. Towards the end of

² *Deut. med. Woch.*, July 8th.

³ *Muench. med. Woch.*

⁴ *Bert. Klin. Woch.* for July 1914.

⁵ *Deut. med. Woch.*, April 8th.

January occasional attacks of severe abdominal pain were accompanied by acceleration of the pulse and slight fever. There was no vomiting, and aperients were followed by normal evacuations. On February 4th the abdominal wall was rigid, and next day there was marked resistance in the right, lower abdomen. Laparotomy was therefore performed, though a definite diagnosis had not been made. A much inflamed coil of small intestine was found, with a thickened, phlegmonous mesentery. Thirty-eight cm. of the small intestine, which was neither twisted nor kinked, were resected. While the corresponding portion of mesentery was also being resected as near its attachment to the posterior abdominal wall as possible, an abscess in its substance was opened. The abscess was closed, the ends of the intestine were reunited, and the wound in the abdominal wall was sutured. Dr. Ulrichs suggested that in this case, in which recovery ultimately took place, the bullet wound of the shoulder must have been infected, and have been responsible for the metastatic, septic thrombo-phlebitis, the osteomyelitis, and the abscesses of the gluteal region and of the mesentery.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed.

CAPTAIN HUGH COCHRANE STORRIE, R.A.M.C., killed in France on September 12th. He was the second son of Mr. Storrie of Paisley, where he was born twenty-eight years ago. He entered Glasgow University in 1903, and after a brilliant career as a student, graduated M.B., Ch.B. in 1908. Soon after graduation he became house-surgeon to Sir George Thomas Beatson at the Western Infirmary, Glasgow. In the following year he was house-surgeon with Mr. Peter Paterson, house-physician with Dr. John Cowan, and later resident assistant in the Special Diseases Section at the Royal Infirmary, Glasgow. Later he held indoor and outdoor appointments at the Royal Glasgow Maternity Hospital. Soon afterwards he entered the fever service of the Metropolitan Asylums Board, and during his period of work in London studied at University College, and in 1913 graduated M.D. at Glasgow. He joined the Special Reserve R.A.M.C. on September 16th, 1914, and went to France with the 2nd Queen's (Royal West Surrey). A. H. G. writes: It is hard to think that Storrie is gone; the medical profession has lost a worthy man. He devoted himself to his work with great ardour and enthusiasm; unswerving in his devotion to a lofty ideal of duty, he forsook the comforts of life at home to help suffering humanity on the field of battle. He was most painstaking and conscientious in the discharge of all his professional work. In the Royal Infirmary, amongst the residents, he was often the consultant. If Storrie said, "Better take the case in," it came in. Now that our friendship has been broken by death, new duties remain, in the remembrance of his self-sacrifice, his fearlessness, and his influence for good. Storrie was a staunch friend and a wise physician; we can ill afford to lose such men. Of him it may truly be said, "Nunquam non paratus."

Died of Wounds.

Lieutenant John Clarke, R.A.M.C.(T.F.), reported as having died of wounds in the Dardanelles on September 9th, was the third son of Mr. W. Clarke, of Ballymena, county Antrim. He was educated at Belfast and at Edinburgh University, and took the Scottish triple qualification in 1906, after which he went into practice at Abergeorge, near Cardiff. He joined the 3rd Battalion of the Monmouthshire Regiment as Lieutenant and medical officer on October 24th, 1914, and when wounded was serving with the 1st Welsh Field Ambulance.

Died on Service.

Lieutenant Stephen Barry Walsh, R.A.M.C., whose death in France is reported, was educated at the Catholic University, Dublin, and took the B.A. at the Royal University, Ireland, in 1903, the M.B., B.Ch., and B.A.O. in 1905, the M.D. in 1909, and the D.P.H. Camb. in 1913. After acting as resident physician of the Mater Misericordiae Hospital, Dublin, as clinical assistant at the Royal London Ophthalmic Hospital and at the Throat Hospital, Golden Square, he became medical inspector of schools

and assistant medical officer of health at Merthyr Tydfil; later he was appointed school medical officer at Gillingham, Kent. He took a commission as temporary Lieutenant in the R.A.M.C. on November 1st, 1914.

Captain Arthur Verge, of the Australian Army Medical Corps, died at Alexandria, on September 4th, of dysentery contracted at the Dardanelles. He was the second son of Austral Verge, of Macleay River, New South Wales, and was educated at Sydney University, where he took the M.B. and Ch.M. in 1905. He was afterwards house-surgeon and house-physician of the Sydney Hospital. Later on he became house-physician in the Skin Department of the Edinburgh Royal Infirmary, and took the F.R.C.S. Edin. in 1908. On his return to Australia he became assistant dermatologist to the Royal Prince Alfred Hospital, Sydney. He accompanied the Australian contingent to Europe as medical officer of the 6th Regiment, Australian Light Horse.

Major John O'Leary, I.M.S., reported to have died in Egypt, was born on May 16th, 1878, educated at Queen's College, Cork, and took the M.B., B.Ch., and B.A.O. of the Royal University, Ireland, in 1901. He entered the I.M.S. as Lieutenant on September 1st, 1902, became Captain on September 1st, 1905, and Major on September 1st, 1914. He served in the Tibet war of 1903-04, receiving the medal. Since November 18th, 1907, he had been medical officer of the 8th Bengal Cavalry, but was serving in Egypt as Commandant of No. 124 Indian Field Ambulance.

Lieutenant Joseph McGowan, R.A.M.C., is reported to have died of dysentery at Malta. He was a native of Kierkintilloch, and was educated at Glasgow, where he took the M.B. and Ch.M. in 1895, and the M.D. in 1905. He settled in practice about seventeen years ago at Grangemouth, where he was medical officer of the North District, Grangemouth Parish Council, and also to the Shipping Federation. He took a great interest in public affairs, was for many years a member of the School Board, of which he was thrice Chairman, and was also Chairman of the local Liberal Association. He was a member and elder of the West United Free Church. He joined the R.A.M.C. with a commission as temporary Lieutenant on April 14th, 1915. He leaves a widow and three children.

Wounded.

Captain C. T. Edmunds, R.A.M.C., Dardanelles.
 Captain G. S. Pirie, R.A.M.C. (Special Reserve), Dardanelles.
 Captain J. R. R. Trist, R.A.M.C. (Special Reserve), Flanders.
 Captain A. G. W. Compton, R.A.M.C. (Special Reserve), Flanders.
 Lieutenant T. A. Flynn, R.A.M.C.(T.F.), Dardanelles.
 Lieutenant F. S. Bedale, R.A.M.C.(T.F.), Dardanelles.
 The name of Captain Edmunds, R.A.M.C., has appeared in the casualty lists at least twice before. He was reported as missing, in the retreat from Mons, in the list published on September 5th, 1914, and as wounded in that of September 30th.

MEDICAL STUDENT.

Cameron, Donald R. C., Lieutenant 11th Battalion Highland Light Infantry, son of Mr. Donald R. Cameron, L.D.S., of Langside Road, Glasgow, killed in France, aged 29. He was educated at Stanley House School, Glasgow Academy, the Glasgow Dental College, and Glasgow University, where he was in the O.T.C., and was in his final year as a student of medicine, when he took a commission as Second Lieutenant in the I.L.L.I. on September 24th, 1914.

DEATHS AMONG SONS OF MEDICAL MEN.

Garrard, Stanley Charles, Second Lieutenant 14th Battalion Rifle Brigade, youngest son of the late William Garrard, F.R.C.S., of Melbourne, killed in France, August 28th. He got his commission on March 19th, 1915.

Hudson, A. F., Corporal Gordon Highlanders, son of Mr. A. B. Hudson, M.R.C.S., of Victoria, British Columbia.
 Moreton, Archibald Herbert, 8th Light Horse, Australian Imperial Force, second son of Frederick Moreton, M.R.C.S., of Geelong, Victoria, killed in Gallipoli peninsula in August, aged 24.

O'Carroll, Frank Brendon, Second Lieutenant 6th Battalion Royal Dublin Fusiliers, youngest surviving son of Dr. O'Carroll, of Merrion Square, Dublin, killed in Gallipoli peninsula, August 10th. He was born on July 18th, 1895, educated at St. Mary's College, Rathmines, and at Shrewsbury, where he was in the O.T.C., and entered University College, Dublin, in 1913. His commission was dated September 24th, 1914.

Scriven, John Barclay, Lieutenant-Colonel commanding 21st (Empress of India) Lancers, was a son of the late Surgeon-Major John Barclay Scriven, I.M.S., killed in action on the Indian frontier. Colonel Scriven was born on April 3rd, 1869, entered the army as Second Lieutenant in the 5th Lancers on October 3rd, 1888, became Lieutenant on March 26th, 1890, Captain on May 4th, 1899, and Brevet Major on August 22nd, 1902. He was appointed Major in the 21st Lancers on October 17th, 1906, and succeeded to the command as Lieutenant-Colonel on September 7th, 1914. He served in the South African war, in Natal, the Orange River Colony, and the Transvaal, took part in the actions of Elandsplaagte, Lombard's Kop, and Rietfontein, and in the defence of Ladysmith, when he was wounded; was mentioned in dispatches, and received the Queen's medal with four clasps, the King's medal with two clasps, and a Brevet-Majority. After the war he served in the South African Constabulary from March 22nd, 1901, to March 21st, 1906.

NOTES.

HONOURS.

In addition to the officers mentioned last week upon whom awards for distinguished service had been conferred, the Distinguished Conduct Medal was conferred upon 138 non-commissioned officers and men, including six belonging to the medical services:

Corporal G. Gallagher, R.A.M.C., and Sergeant J. H. Heap, R.A.M.C., of the 16th Field Ambulance; Private W. Hughes, R.A.M.C.(T.F.), 11st East Lancs F.A.; Private A. P. Inglis, R.A.M.C.(T.F.), 13rd Lowland F.A.; Private H. Meakins, R.A.M.C., attached 2nd York and Lancaster Regiment; Private H. Price, R.A.M.C.(T.F.), 12nd East Lancs F.A.

MEDICAL OFFICERS WANTED.

21st North Midland Field Ambulance.

Two or three medical men are wanted to take commissions in this unit, now under canvas at Watford. For foreign service only. Apply, Lieutenant-Colonel Dawson, Officer Commanding, Watford.

Home Service Field Ambulance (T.F.).

Medical officers under 55 years of age are wanted for this ambulance. Full outfit allowance provided. Applications to No. 4865, BRITISH MEDICAL JOURNAL OFFICES, 429, Strand, W.C.

22nd East Anglian Field Ambulance.

There are vacancies for four medical officers in this unit to replace officers proceeding overseas. Pay and allowances as in the regular army, with promotion to the rank of captain after six months' service. Apply to Lieutenant-Colonel G. Blake-Masson, O.C. 22nd East Anglian Field Ambulance, 44, Crown Street, Bury St. Edmunds.

England and Wales.

A WORKMEN'S HOSPITAL AT BLAINA.

The Blaina and District Cottage Hospital at Nautyglô, Monmouthshire, was built in 1910 at a cost of about £5,600, provided by the colliery workmen through voluntary deductions from their wages. It soon became evident that more accommodation was required, and three years ago the representatives of the workmen on the committee determined on an extension at a cost of £6,500. The colliery men have been joined by those of the urban council and gasworks, the Co-operative Society, and members of the N.U.F., and it has been decided to allow outsiders to participate in the privileges on payment of £1 a year. The extensions and the rearrangements of the original buildings have raised the number of beds from 11 to 25, and in addition a new operating theatre, with sterilizing, anaesthetic, and x-ray rooms, has been provided. The operating theatre has a northern light, the floor is of white terrazzo. The two new wards have bath, lavatory, and kitchen accommodation, and an outpatient department has been provided, as also additional accommodation for the staff. Detached from the general building is an engine-house, battery-room, and mortuary. The building is lighted electrically throughout, and is heated with low-pressure hot water, with the exception of the operating theatre, which has special steam radiators. The consulting staff consists of Major W. J. Greer, R.A.M.C.(T), Mr. J. A. Lee, F.R.C.S. (laryngologist), and Dr. Coulter (ophthalmologist), of Newport. Dr. W. T. Ewan, of Blaina, attends daily, and all the local medical men give their assistance. The nursing staff consists of the matron, two nurses, and

three probationers. On an average, about 100 operations are performed annually.

At the opening ceremony of the enlarged building, Mr. John Wyke, chairman of the Hospital Committee, who presided, said that of the £6,500 required £3,200 had already been paid, owing to the workmen having agreed to a double poundage for a year. He asked them to realize that the upkeep of the establishment would need a larger revenue than formerly.

Major W. J. Greer, in declaring the hospital open, praised its construction, and said that, in particular, the x-ray installation was one of the most complete that could be got in any hospital. Mr. E. W. G. Richards, the architect, presented Major Greer with a gold key with which to open the door leading into the new portion of the hospital. Mr. Manning then presented a silver inkstand and pen on behalf of the Hospital Committee, bearing the following inscription: "Presented to W. Jones Greer, Esq., F.R.C.S.L., L.R.C.P., by the Blaina and District Hospital Committee, as a token of respect and esteem, and to commemorate the occasion of the opening of two new wards and theatre, September 15th, 1915." Major Greer returned thanks, and the company then inspected the new wards and other rooms.

HEALTH OF LIVERPOOL.

Owing to the war the annual report for 1914, by Dr. Hope, the Medical Officer of Health and President of the Liverpool Medical Institution, was later in appearing than usual. It affords, however, interesting reading, and sets forth steady progress in all that concerns the hygienic condition of the city. The birth-rate, which it is to be hoped will show a steady increase in the future, was 30 per 1,000 of the population, against 30.4, the average of the past five years. The death-rate was 19.5 per 1,000, which is lower than the average 21.8 for the past ten years.

It is interesting to note that in July a whole family was infected with plague, and there were three deaths. The source of infection could only be surmised. The number of rats destroyed was 24,938. There were only two cases of small-pox, and both patients recovered.

Enteric fever claimed 177 individuals, of whom 44 died, and 79 per cent. were treated in the city hospitals. Shellfish were considered to be the source of infection in some of the cases. The ravages of alcohol are striking. Coroners' juries returned a verdict of excessive drinking in 125 cases, and 52 were females; and the statement that alcohol is responsible, directly and indirectly, for more deaths than any other poison or microbic cause cannot be gainsaid.

Diarrhoea was the cause of death in more than one-half of those infants that died under 12 months old. Among those who died within three months of life the mortality of children artificially fed was fifteen times as great as that of children breast-fed. Every medical practitioner should impress upon the mother the importance of suckling her offspring, and point out forcibly to her the risk to the life of her child if she shirks her responsibility in this respect. Liverpool for some years has had sterilized milk dépôts, and by this valuable agency, there is no doubt, much infant life has been preserved. But it should never be forgotten that human milk is "living" milk, and no artificial substitute, no matter with what care it may be elaborated, can take its place without risk to the infant's health and power of resistance to infantile disorders. Infantile mortality was 139 per 1,000 in 1914 and 132 per 1,000 in 1913. Measles accounted for 517 deaths, and whenever possible hospital accommodation was provided, although it would appear that the mothers frequently refused it when offered. The female sanitary service supplies a most important link between the school medical inspection and the homes of the children, and much benefit has accrued to the health and well-being of the rising generation.

The question of the removal of the central abattoir—a perennial subject which has agitated medical men in Liverpool for many years—to a more suitable position is still in abeyance. But no one who has given the subject even the slightest consideration can approve of the continuance in its present situation of a slaughter establishment inseparably associated, as all such establishments must be, with offensive trades that may easily endanger the health of the community.

Ireland.

MEDICAL APPOINTMENTS TO THE VICEREGAL HOUSEHOLD.
His Excellency the Lord Lieutenant of Ireland has made the following medical appointments to the Viceregal household:

Physicians in Ordinary: E. MacDowd Cosgrave, M.D. Univ. Dubl., President Royal College of Physicians of Ireland; James Craig, M.D. Univ. Dubl., F.R.C.P.I., King's Professor of Practice of Medicine, School of Physic, Trinity College, Dublin.

Surgeons in Ordinary: F. Conway Dwyer, M.D. Univ. Dubl., President Royal College of Surgeons in Ireland; Edward H. Taylor, M.D. Univ. Dubl., F.R.C.S.I., University Professor of Surgery, School of Physic, Trinity College, Dublin.

Surgeon to the Household: W. L. de C. Wheeler, M.D. Univ. Dubl., F.R.C.S.I.

Surgeon Consultant in Ordinary: H. C. Mooney, M.B., B.Ch., R.U.I., F.R.C.S.I.

Surgeon Dentist in Ordinary: G. J. Goldie, L.D.S., L.R.C.P. and S.Ed.

SOUTH DUBLIN UNION AND CHILD MORTALITY.

At the last meeting of the South Dublin Union a lady guardian called attention to the system which, she said, was growing up among the women who had children at nurse. The children were neglected, and when they were dying they were brought into the workhouse so that they might be buried at the expense of the guardians. She thought the relieving officers or the lady inspectors ought to visit these women and see that the children were not neglected. She had seen at the crèche a crowd of children actually dying. The chairman said he was glad the matter had been mentioned. The guardians had frequently been condemned for the high death-rate among children. Her statement showed that it was not the fault of the guardians, but of the parents who sent the children out to die. A lady guardian suggested that those women who neglected the children should not be allowed to take any more children. In the master's journal it was stated that since last report fifteen children were admitted to the workhouse for medical treatment.

Correspondence.

SURGEON PROBATIONERS, ROYAL NAVY.

Sr.—Many inquiries have reached me concerning the position of senior medical students, now serving in the navy as surgeon probationers, who desire to complete their professional course with a view to speedy qualification. By the kindness of the Medical Director-General, I am enabled to state that the following instructions have been issued from the Admiralty:

(a) Surgeon probationers are to be granted reasonable leave of absence to attend their final examinations (Order of January 1st, 1915).

(b) If the period of leave granted (which has been fixed at three weeks) is not sufficient, the request of a probationer to be demobilized for any period he likes is never refused.

In the present emergency it is desirable that the fifth-year students now on duty with the fleet should without delay become qualified for commissioned service. Their places might be taken by less advanced students who have passed the second professional examination, and have received special instruction in "dressing" and in other "first-aid" methods of dealing with the wounded. Many of these men are eager to leave their studies and do service in the war. Some might find their opportunity by offering to take six months' duty as surgeon probationers in the navy. They would thus liberate senior men who have already served for that period or more; and they might expect to be liberated in turn by their juniors, in time for the summer session.

I am assured that the Admiralty desires to co-operate with the medical authorities in minimizing the difficulties attaching to the "probationer" service. One of these difficulties—the undue interruption of the studies of men whose early qualification is a pressing need—would become less serious under the system of short service and frequent rotation which I here suggest.—I am, etc.,

DONALD MACALISTER,

President of the General Medical Council.

University of Glasgow, Sept. 21st.

MEDICAL STUDENTS AS MILITARY SURGICAL ASSISTANTS.

Sr.—Surely the proper and most effective method of making use of medical students of eighteen months' standing or upwards (excepting perhaps fifth-year students) is to utilize them as military surgical assistants. Let them have a short course of surgery (say three months) with special reference to military requirements, and then give those that are fit commissions in the R.A.M.C. as temporary second lieutenants with at least the pay and allowances of those of this rank in the combatant branches. They would form a grade very similar to that of the military assistant surgeons in the army in India.

Students of under eighteen months should at once concentrate on anatomy and military surgery (the preliminary sciences and physiology can well wait until the star of peace returns), and as soon as possible be given commissions also.

I believe that such men would in practice be far more useful than many of the older men who are now being appointed to commissions in the R.A.M.C. By adopting this method a large addition would be made to the commissioned ranks of the R.A.M.C. at an early date.

I totally disagree with Dr. King Brown's suggestion that medical students should become privates in a special corps under the R.A.M.C. This would be simply wasting good material; and why should they be privates when their education and attainments fit them for commissioned rank?—I am, etc.,

J. E. ROBINSON, M.B., B.S. Lond., D.P.H.

Weymouth, Sept. 11th.

MEDICAL EDUCATION OF WOMEN.

Sr.—As the number of women studying medicine is increasing every year, and is likely to increase rapidly now, it is right that women who are thinking of beginning should know, before they decide to study in Edinburgh, that it is only the "Edinburgh degree" that is given to women, not the "Edinburgh training."

In a paragraph in the JOURNAL of September 4th, p. 377, it is said, "The Edinburgh School of Medicine for Women provides all the classes required for a complete curriculum." That is true enough, but it is very disappointing for a woman after she has begun the course and it has become almost impossible to change, to find that there are many classes held in the University, and many clinics given in the Royal Infirmary, to which she has no access, and for which she has no equivalent. Then again, it is only through obliging male students that she can find out what the professors who are to be her examiners are teaching. Last, and not least, she has no choice of clinic in the Royal Infirmary. She may, it is true, take out her classes at any of the other Scottish universities, or, indeed, "in any University of the United Kingdom, or in any Indian, Colonial, or Foreign university recognized for the purpose by the University Court, or in such Medical Schools or under such teachers as may be recognized for the purpose by the University Court."¹ If she chooses not to study in Edinburgh, she may get a more thorough training and better opportunities of seeing and doing, but then it is still not the "Edinburgh training."

A medical missionary said to me that women who were thinking of going to the mission field should study at one or other of the new English universities, because there they got the best opportunities of doing surgical work. I understand that women have very good opportunities in Glasgow, Aberdeen, and St. Andrews (with Dundee).—I am, etc.,

R. MARY BARCLAY, M.A., M.B. Edin.,

Cambridge Teachers' Diploma.

Edinburgh,
September 5th.

GAS POISONING.

Sr.—Is chlorine gas poisonous? Although it may be classed among the irritant poisonous gases, still it is not so poisonous as people think. Over forty years ago Tyneside was a great centre for the manufacture of soda ash and bleaching powder, and perhaps there was more bleaching powder made on Tyneside than any other part in England. It is still made, but to a much smaller extent. In the manufacture of bleaching powder, although it was customary to regulate the amount of chlorine gas so as

¹ Edinburgh University Calendar, 1914-15.

to waste as little as possible when the chamber doors were taken down to pack the bleaching powder, still occasionally something went wrong, and the maker found that he was going to get a weak powder under market strength, and crammed the gas into the chamber until it was full and overflowing. At the present time bleaching powder is made principally by large works, and I should think that they will take all due precaution to pass as little chlorine into the air as possible. In the smaller works a bleaching powder chamber may be about 30 ft. long by about 20 ft. broad, and about 6 ft. high, but in the larger works the usual size is about 60 ft. by 30 ft. by 5 ft. Does it do harm to the people? No; nothing of the kind. It soon mixes with the air, and the direction of the wind always comes to the rescue, and an effort is made to keep it off the dwellings as much as possible. Both sulphurous acid and chlorine gas do harm to vegetable life, especially if much gas gets into the atmosphere. They do not appear to do any harm to human life if in moderation.

How many men has Tyneside killed with chlorine gas? I only know of one death. It arose out of a drunken freak. A man boasted with his companions, when he and they were drinking, that he could stand more gas than any other man. He was taken to a chamber full of gas and the door was taken down, and consequently he was immersed in chlorine; perhaps they were too drunk to pull him out of the gas.

There is no doubt that persons not accustomed to chlorine may have a choking and a spasm of the glottis if exposed to a double dose. I have seen it often, but in ten or fifteen minutes or more they were all right. Give them air. Give them a stimulant. My brother, Dr. J. Aitchison, Newcastle-on-Tyne, when a young medical student, was called in haste to attend a man who was unconscious, and dying from suffocation. This man was convalescent from typhoid fever; he was getting his supper at the time, with a shovelful or more of bleaching powder under the table brought to disinfect the house. My brother, using his own expression, found him black in the face, and unconscious. He thrust his penknife into his windpipe, and in a few seconds the man rallied. He then sent for my father to bring a tracheotomy tube. This man got better, or was well the next day—laughing and joking; he wished the tube to be taken out. To use a coroner's expression, he died a natural death many years afterwards.

In *A Treatise on Poisons*, by the late Sir Robert Christison, Professor of Materia Medica in the University of Edinburgh, the following passage occurs:

Although this gas is very irritating to an unaccustomed person, yet by the force of habit one may breathe with impunity an atmosphere much loaded with it. I have been told by a chemical manufacturer at Belfast that his men can work in an atmosphere of chlorine, where he himself could not remain above a few minutes. It is not probable, however, that the above is an unhealthy one; for several of this gentleman's workmen have lived to an advanced age; one man, who died not long ago at the age of 80 years, had been forty years in the manufactory, and I have seen in Mr. Tennant's manufactory at Glasgow a healthy-looking man who had been also about forty years a workman there. It is an interesting fact, that during the epidemic fever which raged over Ireland from 1816 to 1819, the people at the manufactory at Belfast were exempt from it.

My father often advised men who were threatened with phthisis to work at bleaching powder chambers, and as far as I am aware they all got well. Among the most poisonous gases in chemical works are nitrous fumes (nitric peroxide, N_2O_4), used in the manufacture of sulphuric acid. Christison says that nitrous acid vapour is a very violent and dangerous poison when inhaled. He mentions that a chemical manufacturer in endeavouring to remove from his store-room a hamper in which some bottles of nitrous acid gas had burst, breathed the fumes some time, and was seized in four hours with inflammation of the throat and stomach. At night the urine was suppressed, the skin then became blue; at last he was seized with hiccough, acute pain in the diaphragm, convulsions and delirium, and he died twenty-seven hours after the accident. Another case he mentions proved fatal in two days, and the symptoms were those of violent pneumonia.

My father had an experience of a batch of men dying in agony in a few days and at different times. They were sent in to clean the bottom of a sulphuric acid chamber

which required repairing. After running off the acid and clearing the gas out of the chamber for some days, they went into the chamber to remove the lead sulphate which is always lying at the bottom of a sulphuric chamber, and this stirred up nitrous fumes. Every man died gasping for breath.—I am, etc.,

THOMAS AITCHISON, M.B. Edin.

Willington Quay-on-Tyne, Aug. 18th.

INFANT FEEDING.

Sir,—I think that Dr. Vining and I regard the subject of the artificial feeding of infants from very different points of view. Dr. Vining is one of those who looks for, and even hopes that he has found, an artificial diet which is universally and invariably successful. By refraining from adding a proportion of water to the milk and by omitting the usual addition of sugar, he claims to have passed at a bound from disaster to success. I wish I could share in this faith, but to me everyday experience proves it false. Cow's milk without excessive addition of sugar should certainly be the diet of choice for all normal and healthy children—a diet which I should like to call the standard diet, and which should never be abandoned except on the advice of a medical man. Moreover, the use of whole citrated cow's milk has a powerful action in controlling the increased fermentation in the intestine which is set up by a diet too rich in starch or sugar. Nevertheless, it seems to me beyond question that whole milk is often ill digested by young infants suffering from infective disorders of all sorts, and that in a considerable minority of children its habitual use is accompanied, not indeed by excessive fermentation, but by increased intestinal putrefaction, the symptoms of which I endeavoured to describe.

In all cases I would urge the importance of the close study by medical men of the nature and origin of digestive disturbances in infancy, in the hope that we may learn more and more effectively to control them by the therapeutic modification of the diet in the direction indicated by the symptoms. To adopt the position that any one form of diet always "suits" and never gives rise to ill symptoms is to deny the necessity for the existence of any study of the digestive disturbances of infants at all. If the routine use of whole citrated milk is always successful, the doctor may well leave the whole business to any intelligent nurse or mother who can be trusted to measure accurately and to enforce scrupulous cleanliness.—I am, etc.,

London, W., Sept. 19th.

H. CHARLES CAMERON.

DIAGNOSIS OF GOUT.

Sir,—In the BRITISH MEDICAL JOURNAL of August 14th, p. 278, Dr. Bramwell criticizes my letter which appeared the previous week. As an earnest advocate of the revival of counter-irritation in its more powerful forms, I should like to know on what evidence he bases his sweeping assertion that it is futile and harmful in diseases in which micro-organisms play a prominent part. My experience, extending over more than sixteen years, is quite the contrary. I do not even except pulmonary tuberculosis. Skillfully used in suitable cases, continuous counter-irritation is of great value and perfectly safe.

I make thousands of minute punctures in the skin with needles and paint over them a mixture of croton oil, cantharides, and almond oil. A crop of pustules appears within from twenty-four to forty-eight hours. I have benefited patients when vaccines have failed.

In my opinion this treatment heightens the power of the system to form antibodies. Moreover, it is now well known that the leucocytes have the power to carry poisons of all kinds from all over the system to hyperæmic areas produced by heat or irritants, and also to pustules and abscess cavities. The principle of the treatment is practically identical with that of the seton, the blister followed by savin ointment and the fixation abscess. An instructive article on the latter appeared in the *Medical Press and Circular* of May 5th.

Dr. P. W. Latham and I have published several articles on continuous counter-irritation (*Lancet*, April, 1901; *Fractitioner*, January, 1912, etc.).—I am, etc.,

Bournemouth, Aug. 15th.

W. J. MIDELTON.

Obituary.

JOHN HENRY DAUBER, M.B.Oxon., F.R.C.S.I.,

SUBROON, HOSPITAL FOR WOMEN, SOHO, LONDON; LIEUTENANT-COLONEL, R.A.M.C.(T.).

LIEUTENANT-COLONEL JOHN HENRY DAUBER, M.B., F.R.C.S.I., R.A.M.C., East Anglian Casualty Clearing Station, to whose death on the transport *Royal Edward* we have already made brief reference, was the eldest son of the late Mr. John Stockdale Dauber, of King's Lynn, Norfolk. For some twelve years he had been attached to the Sussex Yeomanry, and when war broke out was mobilized. It was then found that the Sussex Yeomanry had two surgeons, whereas the War Office only permitted of one. Dauber and his colleague tossed a coin as to who should remain, and Dauber lost. He had nothing permanently to do for some time, but after an interval became attached to the Eastern Command. Early this year, as second in command under Colonel Gibb, he formed the East Anglian Clearing Hospital. Owing to the somewhat sudden death of his colonel from pneumonia, Dauber took command.

Dr. Dauber received his medical education at the Middlesex Hospital and at the King's and University Colleges. He took the diplomas of L.R.C.P. and M.R.C.S. in 1890, graduated M.A.Oxon. in 1892, and M.B., B.Ch. in 1894. He became a Fellow of the Royal College of Surgeons of Ireland in 1899. He was associated with the Soho Hospital for Women for many years. He had a long period in the out-patient department, but some ten days before he left England on his ill-fated voyage to Gallipoli he was appointed surgeon to in-patients. He worked harmoniously with his senior, Mr. Mansell Moullin, who of late years allowed him many beds in the hospital. He took an active interest in the rebuilding of the hospital seven years ago, and was also a member of the committee of the hospital concerning the new by-laws and regulations, under which the appointment of gynaecological surgeons, with modern surgical equipment, was created to supersede the old position of obstetric physicians. He gave much time to the general work of the hospital, which was to him a labour of love, and did not hesitate to visit a severe case several times a day. His loss will be keenly felt in the hospital. He was also President of the Chelsea Clinical Society. Whatever Dauber undertook to do he did with all the energy and enthusiasm of his nature. He was one of the original members of the Executive Committee of the Westminster Division of the British Medical Association when the Association was reconstituted in 1902, and by his outspoken criticisms, especially during the period when the Insurance Bill was under discussion, held the attention of the meetings. His year of office as Chairman of the Division was successful, and on more than one occasion he acted as the Representative of the Division in Representative Meetings.

Colonel Dauber was a pleasant and agreeable companion, alike amusing and entertaining, with a high code of honour. He married, in 1895, Margaret, third daughter of the late Colonel Addison Potter, C.B., of Heaton Hall, Newcastle-on-Tyne, and leaves one son, aged 14. He was a devoted husband and father, and in his passing away on the *Royal Edward* those who knew him have lost a faithful friend.

Dr. Dauber held strong views as to the need for this country to put all its energies into the war. In a letter published in the *Times* not many months ago he wrote: "A grim struggle is before this country. All who know Germany are well aware of it. There is but one thought, one aim, one hope for every one of us—ultimate victory. Nothing else on earth counts for us. Let it not elude us through our thoughtless dissipation of strength." He showed the faith that was in him by offering himself at an age (56) when he might well have been held excused.

W. JOSEPH SMITH, J.P., M.R.C.S., L.M., L.S.A.,

D.P.H.CAMB.

MR. JOSEPH SMITH, a vigorous advocate of the rights of the members of the Royal College of Surgeons of England, died, aged 77, on Saturday, September 18th, at his residence, 13, Wellesley Road, Gunnersbury, after a long illness. He became a Member of the College of Surgeons

in 1861, and he joined the ranks of the Licentiates of Midwifery of the College, now slowly disappearing, as the Board of Examiners for that diploma was abolished in 1888. Mr. Joseph Smith became an L.M. in the year after he passed the Membership examination, so that he held the diploma for no less than fifty-three years. According to the Calendar for 1915 of the College of Surgeons, 250 Licentiates are still living.

Joseph Smith was a link with a past generation of family doctors. He was best known among his professional brethren for his efforts to obtain reform at the Royal College of Surgeons. Both with the Association of Members and its successor, the Society of Members, he was a leading spirit; his interest in the movement was the outcome of his intense and honest desire to secure for all Members what he claimed to be their ancient rights and privileges. When, in furtherance of the cause for which Joseph Smith was so zealous, the Society of Members was founded in 1894, he was elected President, and retained that office until the burden of years and ill health compelled him, in October, 1915, to resign. The original "Association of Members" of the Royal College of Surgeons was founded in 1884, when a meeting of members was held on April 30th at 3, New Inn. Its purpose was to obtain for the Members certain rights and privileges, in reference to the management of the College, which they did not possess. At a subsequent meeting, three months later, Dr. Robert Collum was elected chairman of the committee of the association and Mr. Joseph Smith vice-chairman, and in January, 1885, they headed a deputation to lay before the Council of the College the views of their association with respect to the alteration or proposed change in the new charter about to be applied for. The deputation was received by the President, Mr. Cooper Foster, and the Vice-Presidents of the College. Mr. Joseph Smith on this occasion spoke with much force and eloquence. He argued that the official head of the College was really President of the Council only, and that his post could be made far more distinguished in future should he become the representative of the sixteen hundred members. The annual meeting of Fellows and Members became an institution, although attempts were made, especially by Sir Spencer Wells at the end of 1888, to abolish it. The agitation reached its height in February, 1887, when a meeting of Fellows and Members having been convened without the authority of the President and Council, the gates of the College were closed so as to exclude the deputation, and the case of Steele v. Savory followed, in which the verdict was given for the defendants. The legal expenses proved ruinous, and the association had afterwards to be reconstituted, reappearing in 1894 as the Society of Members, of which, as already stated, Joseph Smith was elected the first president.

Joseph Smith retired to Gunnersbury after years of general practice, many of which were spent at Guildford, where he was M.O.H.; he was J.P. for the County of Middlesex, and at one time honorary surgeon to the Royal Surrey Hospital, Guildford.

Mr. Smith was married twice, and leaves a widow and two sons, who are not members of the profession, but who appeared in uniform as members of the R.A.M.C. and the Royal Naval Air Service, respectively, at the funeral on September 21st, when their father was laid to rest in Chiswick Churchyard. A nephew in the Civil Service Rifles, Commander Stewart of the Royal Naval Air Service, and Dr. Brindley-James, President, and Dr. Sidney C. Lawrence, Honorary Secretary of the Society of Members, were also in attendance.

SIR CHARLES EUGENE BOUCHER DE BOUCHERVILLE, K.C.M.G., the oldest Canadian Senator, recently died at Ottawa, at the age of 93. He was a member of a French-Canadian family whose ancestor, General Pierre Boucher, was Grand Seneschal of Nouvelle France, in the seventeenth century. He was a native of Montreal, and studied medicine in Paris, where he took the M.D. degree in 1843. Like other distinguished Canadians, he turned his attention to politics, and soon became a conspicuous figure among the statesmen of the Dominion. He was Speaker of the Legislative Council of Quebec from 1867 to 1873, and was Premier of the Province from 1874 to 1876, and again from 1891 to 1892. He was called to the Senate in 1879.

M. JULES SOURY, director of studies in the Paris Ecole Pratique des Hautes Etudes, was not a member of the medical profession, but the importance of his work in neurology was acknowledged by all physiologists and biologists. In his lectures on the functions of the brain he synthesized all the researches made on cerebral localizations, and in his great work, *Le système nerveux central, structure et fonctions*, he gave a critical review of theories and doctrines on the nervous system, remarkable alike for erudition and clearness of exposition. M. Soury was the author of numerous other works on philosophy, religious psychology, and literary criticism. He was 74 years of age.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are: Dr. Giuseppe Cattaneo, surgeon to the S. Matteo Hospital, Pavia, and founder of an out-patient department for tuberculous cases, and of other charitable institutions, aged 83; Dr. Gorenx, a well-known Paris laryngologist; Dr. P. Brynberg Porter, recording secretary of the Medical Association of the Greater City of New York, for some time editor of the *Transactions of the American Therapeutical Society*, and a prominent member of the staff of the *New York Medical Journal*, aged 70; Dr. David Strett, dean of the Baltimore College of Physicians and Surgeons, and professor of the principles and practice of medicine at the University of Maryland Medical School, and president of the Baltimore Medical and Surgical Society, aged 61; and Dr. St. Clair Spruill, clinical professor of surgery in the University of Maryland Medical School, and surgeon to the Maryland General Hospital, Baltimore, aged 49.

Universities and Colleges.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

Election of Professor.

At a special meeting of the President, Vice-President, and Council, held on September 16th, Mr. F. Conway Dwyer, President, in the chair, Mr. William Caldwell, M.A., R.U.I., F.R.C.S., etc., was elected Professor and Professor of Physics in the Schools of Surgery. The election of a Professor of Pathology was postponed. Professor Caldwell had a very distinguished career as an undergraduate. He was educated at Campbell College, Belfast, and subsequently pursued his studies at Queen's College, Belfast; Trinity College, Dublin; and in Würzburg University, Bavaria. He obtained the Andrew Scholarship in Chemistry and Physics, and subsequently the 1851 Exhibition Research Scholarship in Organic Chemistry. After his appointment to Trinity College, Dublin, he graduated as Senior Moderator in the University of Dublin. In Trinity College, Dublin, he has been teaching for the last ten years the subjects of physiological chemistry to the medical students, and inorganic, organic, and physical chemistry to the students in the Indian Civil Service School, as well as lecturing in other institutions, and has found opportunity to carry out and publish researches in many chemical subjects.

The Services.

EXCHANGES DESIRED.

ROYAL ARMY MEDICAL CORPS.

LIEUTENANT R.A.M.C. (TEMPORARY), at present x-ray specialist at general hospital in France, wishes to exchange with x-ray specialist anywhere in Eastern Command. Address No. 4,799, BRITISH MEDICAL JOURNAL, 429, Strand, W.C.

TEMPORARY LIEUTENANT, attached to military hospital in Mediterranean, wishes exchange with officer serving at home—Newcastle and neighbourhood preferred. Address No. 4,800, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

TERRITORIAL FORCE.

MAJOR R.A.M.C. (T.F.), at present serving with a field ambulance T.F. in France, desires to exchange with an officer of similar rank at home. O. L., c/o Editor, BRITISH MEDICAL JOURNAL.

SEVERAL arrests made recently in Paris show that, in spite of the increased activity of the police during the last three or four years, the illicit traffic in cocaine at certain night cafés and beerhouses continues. It is carried on by male and female hawkers, who buy the drug from complaisant chemists, one of whom is among the persons arrested.

Medical News.

THE winter session at the Middlesex Hospital will commence on October 1st. There will be no address, but the prizes are to be distributed by Sir James Kingston Fowler, K.C.V.O.

THE next election to Beit Memorial Fellowships for Medical Research will take place on January 1st, 1916. Applications must be received by the honorary secretary of the fund by October 15th. Further particulars will be found in our advertisement columns.

THE list of past and present students of King's College, London, on active service is being revised, and the Secretary would be glad to receive, either from the men themselves or from their friends, the latest details of rank and regiment of all former students on service.

A COURSE of four lectures on typhus fever and cerebro-spinal meningitis will be given on October 5th, 6th, 7th, and 8th, by the Gresham Professor of Physic, Dr. F. M. Sandwith. The lectures, which will be delivered at 6 p.m. each day at Gresham College, Basinghall Street, E.C., are free to the public.

THE Local Government Board in England has revised the list of sanatoriums and other residential institutions approved under the Insurance Act, 1911, for the treatment of persons suffering from tuberculosis, and resident in England (excluding Monmouthshire). The list has been revised to September 11th, and copies, price 1d., can be obtained through any bookseller.

MISS FANNY CRESSWELL PARR, of Yarmouth, Isle of Wight, who recently celebrated her 101st birthday, is a daughter of Dr. John Aynon Paris, a former President of the Royal College of Physicians, and one of the physicians to George III. He was the author of a learned treatise, entitled *Pharmacologia*, the introduction to which is full of historical matter that gives it enduring vitality.

A COURSE of lectures for teachers, voluntary health workers, and mothers has been arranged by the National Association for the Prevention of Infant Mortality and the Welfare of Infancy. It will be held on Thursdays, at 6 p.m., at the London Day Training College, Southampton Row, W.C. The first lecture, which was on ante-natal hygiene, was delivered by Dr. Amand Routh on September 16th. The course will conclude on November 25th.

MESSRS. ELAND BROS., of Exeter, have published, under the title *Voluntary Aid in Devon*, an account, edited by Mr. W. Fothergill Robinson, M.A., of the organization of voluntary aid work in the county. We gave a description of the hospitals in Exeter in our issue of August 28th. The pamphlet, which is published at the price of 1s. net, post free 1s. 3d., for the benefit of the V.A.D. Devonshire, is well illustrated, and contains information as to the hospitals, not only in Exeter, but in other parts of the county, down to the beginning of May.

AN interesting pamphlet on *The Louse and its Relation to Disease* has just been published by the British Museum (Natural History). Its author is Mr. Bruce Cummings, assistant in the Department of Entomology. The life-history and habits of lice are dealt with, and the measures which can be adopted for their extermination are discussed. It is now known that typhus and relapsing fevers are spread by lice, and there are grounds for suspicion in tubercle, leprosy, and probably other diseases. As the little pamphlet is published at 1d., it should be within the reach of all, and its general distribution will do much to show how the troubles caused by these annoying and dirty parasites may be alleviated.

FROM the annual education number of the *Journal of the American Medical Association*, published on August 21st, we learn that during the year which ended June 30th, 1915, there were 14,891 persons studying medicine in the United States. These were distributed as follows: 13,914 in the non-sectarian colleges, 736 in the homoeopathic, and 241 in the eclectic colleges. There are 7 fewer colleges than in 1914, the total now being 95, consisting of 83 non-sectarian, 8 homoeopathic, and 4 eclectic colleges. Since 1904 52 medical schools have been closed, 52 of which were merged into other medical schools, and 40 became extinct. During the same time 25 new colleges were organized, making a net reduction of 67 colleges. Women students constituted 4 per cent. of all students, and of all graduates 3.7 per cent. were women. Of the 95 existing colleges 83, or over 87 per cent., now require one or more years of work in a college of liberal arts for admission. There is now 1 doctor to from 600 to 650 people in the States as compared with 1 to from 1,500 to 2,500 in the leading nations of Europe.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Attilage, Westrand, London*; telephone, 2651, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Attilage, Westrand, London*; telephone, 2650, Gerrard. (3) MEDICAL SECRETARY, *Medicera, Westrand, London*; telephone, 2654, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

G. A. D. asks for advice in the following case: A patient, aged 65, wishes to have an operation for the removal of piles. Some years ago, however, when under an anaesthetic (A.C.E.) for their removal he had a most severe and prolonged spasm of the throat, and tracheotomy was performed. He will not consent to this form of anaesthesia again. Would a local anaesthetic be possible or effective? The patient himself wishes to have spinal anaesthesia. What are the dangers, if any, to (a) life, (b) paralysis of sphincter, etc.?

INCOME TAX.

H. A. N. asks whether the surveyor of taxes has the right to demand that policies of life insurance should be forwarded to him. If so, under what section or sections of the Acts?

* If the claim is for repayment of tax the authorities to be satisfied are the Commissioners for Special Purposes, and otherwise apparently the Commissioners by whom the assessment is made (Section 54 Income Tax Act, 1853). The surveyor of taxes, as such, seems to have no right to require any evidence, even the premium receipt. On the other hand, the Commissioners concerned would no doubt refuse the allowance if the taxpayer had withheld evidence necessary for the proper establishing of the claim. The surveyor's request may have reference to Section 17 of the Finance Act, 1915, which limits the allowance to 7 per cent. of the actual sum assured. The policy forms the best evidence on this point, and on the maxim that the best evidence available is the only proper evidence, the surveyor's request may be held justified in reason, even though it may not be immediately enforceable by him.

ANSWERS.

HICCUGH.

DR. P. DE HAVILLAND HALL (London) writes: Has Dr. J. Numa Rat tried chloretone? If not, I would advise his doing so. I have found this drug in 5-grain capsules every four hours most useful in persistent hiccough.

WESSEX suggests that the hypodermic injection of hyocyanine sulphate, combined with massage of the stomach, will relieve the hiccough if not due to an organic cause.

DR. WILLIAM BRAMWELL (Liverpool) writes: In a case of persistent hiccough—a woman of about 35 years, who it appeared had suffered almost incessantly for nearly twelve months—I accidentally discovered that on pressure over the ensiform cartilage with the stethoscope the hiccough instantly ceased, but commenced again the moment the pressure was removed. Judging that the beneficial effect of the pressure was due to relaxation of some undue tension in the central tendon of the diaphragm, I made a pad of lint and bound it tightly on so as to exert firm pressure on the cartilage. The hiccough completely ceased so long as the pad remained in position, but returned whenever it was displaced. The patient wore the pad for two or three months with great benefit, but the hiccough finally returned so that not even pressure over the cartilage would relieve it, and I lost sight of the case. I have had no opportunity of testing the efficacy of this method in other cases, but it is perhaps worth a trial in Dr. Raf's case if no osseous or other impediment exists in the cartilage.

HUMBLE BEES.

In reply to the question of "Humble Bees" in the JOURNAL of August 7th last, Mr. William Cole, the well-known Secretary of the Essex Field Club, sends to Dr. Armstrong-Jones, of Claybury, a reply of which the following is a summary: The phenomenon of dead humble bees under lime trees with the contents of the thorax eviscerated has been described in the third volume of *Proceedings of the Essex Field Club and in the Naturalist*, 1910, p. 425. Mr. W. Cole, Agent, Professor Meldola, F.R.S., Mr. J. W. Carter (Bradford), and Mr. E. Saunders, F.L.S., give several theories. First, that the abundant honey of the lime blossoms attracted *Bombus terrestris* after sunset, and the cold nights numbed and killed them; but against this view is the fact that the nectar of the lime is an excellent honey-making material, yet it is known that the honey of certain flowers—dahlia, crown imperial, oleander, and passion flower—acts on bees as a "narcotic." Secondly, that the humble bees were killed by birds, possibly the butcher-bird,

the honey of the lime rendering them an easy prey and attracting them in large numbers. Other birds are said to kill the bees, and the spotted fly-catcher, woodpecker, wagtails, the great tit, and even the nightingale have been observed to do this. Thirdly, that the wasp has actually been discovered in the act of attacking humble bees, and after mutilating them clearing out the contents of the thorax (E. Saunders, *Wasps and Ants*, 1917; Sinden, *The Humble Bee*, p. 81). Mr. Wood, gardener to Mr. Firth, of Salfaire; Mr. J. S. Wood, of Nyborg, Denmark; Mr. W. D. Roebuck, of Leeds; Mr. R. M. Christy, Mr. F. W. Pim, Monkton, co. Dublin; and the *Natural History Journal* conducted by societies in Friends' schools, vol. iv, York, 1880, have all commented upon this phenomenon which Mr. W. Cole and Mr. H. Whitehead have so kindly re-investigated and replied to.

LETTERS, NOTES, ETC.

THE writer of the obituary notice of Lieutenant T. A. Peel, R.A.M.C., published in the JOURNAL of September 11th (p. 415), regrets that there was an error in the transcription of the lines quoted from Francis Thompson. The word printed "cracked" should have been "cracked."

We have received *The Investor's Simplified Account Book* (Mortimer, Harley and Co., Ltd., 2a, 6d.). It is a convenient and portable indexed account book containing pages for the entering of "particulars of securities held," "dividends," "revaluations," "securities sold," "particulars of bonds and debentures," and "particulars of certificates." It enables the investor to keep an eye on his dividends, and to see how far his investments have proved judicious.

PREVENTION OF TYPHUS.

A LETTER has been received from Dr. Howard G. Barrie, who when it was written was serving in Serbia, in which he makes the following observations: (1) Nose breathing, as infection, body-lice are undoubtedly the specific carriers. The bed-bug and flea are to be looked upon as probably innocent. The disease appears to be due to a species of direct inoculation. We have observed no clinical evidence which suggests that the route is via the nasal passages, but, on the other hand, it would appear that an occasional infection takes place through the mouth and tonsils. Nose breathing we have found to be a valuable precaution in itself. (2) In ordinary kerosene, such as is employed for lighting, we possess an efficient prophylactic against the disease, for it unquestionably kills the vermin which harbours about the body. Working under difficult conditions, such as existed in Serbia, it has proved an efficient and economical insecticide. It may be used "neat," the entire body being anointed with it once daily. Where the oil irritates the skin unduly, it is useful to dilute it with ordinary vaseline. Equal parts of kerosene and vaseline form an admirable mixture for delicate skins. The hair of the scalp, beard, axillae, and pubes should be shaved as a preliminary. The oil is then applied by immersing the hands in it and smearing it over the body from crown to soles of feet. Friction is to be avoided, as it tends to irritate. In the grim conditions associated with typhus it would be trifling to suggest that the disagreeable odour or the greasy nature of the remedy are serious arguments against its use. The question of bathing and subjecting the undergarments to dry or moist heat are obvious additional measures.

HYPOCHLORITE SOLUTIONS.

DR. RAWDON WOOD (Hove), in a note on this subject, writes: The old practitioner always chortles when one of his old drug friends comes to the fore and wins. For over twenty years I have loudly proclaimed that liquor sodae chlorinatae (*B.P.*) suitably diluted was the best, cheapest, and most satisfactory of all antiseptics. I never use it stronger than 1 in 4 and never weaker than 1 in 40. 1 in 10 is the usual strength. Why use 1 in 4 when 1 in 10 is strong enough for any ordinary case, and much less annoying to the nasal organ? The neutral solution advocated by Dr. Dakin (*BRITISH MEDICAL JOURNAL*, August 28th, p. 319) is, however, a great improvement. It is just as efficient as my old friend, very nearly as cheap, absolutely unirritating, and not nearly so pungent.

DR. T. FREDK. J. BLAKER (Brighton) writes: I see some firms are charging 3s. for half a gallon of hypochlorite solution (Dakin's formula). I found no difficulty whatever in making the same quantity for 2s.6d. according to the formula in the JOURNAL of August 28th, page 313.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
4 weeks	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 71, Strand, London, not later than the first post on Wednesday preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restant* letters addressed either in initials or numbers.

INJURIES OF THE SUPERIOR LONGITUDINAL SINUS.

[WITH SPECIAL PLATE.]

BY

GORDON HOLMES, M.D., F.R.C.P.,

ASSISTANT PHYSICIAN, CHAIRING CROSS HOSPITAL AND NATIONAL HOSPITAL, QUEEN SQUARE; TEMPORARY LIEUT.-COL. R.A.M.C.,

AND

PERCY SARGENT, M.B., F.R.C.S.,

ASSISTANT SURGEON, ST. THOMAS'S HOSPITAL, AND SURGEON, NATIONAL HOSPITAL, QUEEN SQUARE; TEMPORARY LIEUT.-COL. R.A.M.C.

SYMPTOMS OF INJURY OF THE LONGITUDINAL SINUS.

EXPERIENCES in the present war have made us acquainted with many conditions which are rarely seen in civil practice, and have especially presented to us groups of uncommon neurological symptoms or clinical pictures; these are also often less complicated and more sharply defined than those due to the ordinary pathological lesions with which we were previously familiar.

The vascular lesions of the brain met with in civil life, for instance, are most commonly due to arterial disease, to thrombosis, hæmorrhage or embolism, while primary affections of the cerebral veins are uncommon; on the other hand, in gunshot injuries of the head, especially when tangential or superficial, disturbance of the cerebral venous circulation by depression of fragments of the skull is frequent, owing to the superficial course of the cerebral veins and the fact that their thinner walls and the lower pressure of the blood that flows through them make them more liable to be blocked by pressure than the arteries.

The most striking clinical effects are, however, produced when the cranial sinuses into which these cerebral veins flow are affected, and in our experience much the most common of these to be involved is the superior longitudinal sinus. This receives on either side the veins which drain the mesial aspect, as well as those which carry blood from the superior half of the lateral surface of each hemisphere, while the veins from the lower part of each lateral surface pass through the Sylvian system which opens directly, or through the sinus sphenoparietalis, into the cavernous sinus. There is often, however, a fairly free anastomosis between these two sets of lateral cerebral veins, and, consequently, complete occlusion of the one set may not necessarily produce permanent blocking of the venous outflow from the area naturally drained by it. A sudden blockage may, however, lead to circulatory disturbance sufficient to abolish, temporarily at least, the functions of a part of the area normally drained by the venous system affected.

The manner in which the superior cerebral veins open into the longitudinal sinus is important in relation to the symptoms produced by lesions in its neighbourhood. This arrangement has been fully described by one of us (P. S.). Although there is no strict constancy, the superior lateral veins usually unite into four principal trunks—a frontal,

a precentral, a post-central, and an occipital; of these, the post-central is usually the largest, and, as it drains the central gyri, the most important. As a rule these veins do not open directly into the sinus, but into thin-walled lacunae that project from it over the lateral as well as over the mesial surface of the hemisphere. A small frontal lacuna receives the frontal vein, a large parietal lacuna the pre- and post-central veins, and an occipital lacuna the occipital vein. Sometimes these lacunae are more or less continuous. The larger veins either open directly into the floor of the lacuna, from which the blood finds its way into the sinus by several small openings (Fig. 1), or they may pass beneath the lacuna and open directly into the longitudinal sinus (Fig. 2). The parietal lacunae are often more extensive than is generally supposed, and may spread at least 2½ cm. on to the convexity of the hemisphere; consequently any depressed bone or direct injury in their neighbourhood within this distance of the middle sagittal line may block the venous circulation of the upper parts of the central gyri, and, owing to the thinness of their walls, this is more easily produced by pressure on the

lacunae than on the rigid sinus.

Different groups of symptoms are produced by lesions of the different lacunae, but we intend to limit our description to those due to disturbance of the circulation through the parietal lacunae, when they are predominantly those of disturbance of motion and sensation.

We have up to the present seen over 70 cases in which the longitudinal sinus was injured or the circulation in its venous tributaries disturbed in its immediate neighbourhood, that is, in the lateral lacunae, or where the veins enter it.

In many of these cases there was no direct damage to the brain, either by the projectile or by depressed fragments of bone, but in others the disturbance of the venous circulation was associated with gross cerebral lesions.

The symptoms in these cases have naturally varied very much according to the severity of the injury and the region in which the sinus was damaged, but the chief features of the condition can be best conveyed by describing a typical case; other types and other symptoms which occur will be considered later.

CASE I.

Private J. H. was wounded by a bullet on December 12th, 1914. He became unconscious at once, and was unable, on admission to the base hospital two days later, to give any accurate information about himself. He was dull and apathetic, but answered questions quite readily.

There were two separate penetrating wounds, 4 cm. apart, and equidistant from the mid-line, and about 17 cm. behind the nasion—that is, slightly behind the mid-point. The entrance was on the left and the exit on the right, slightly larger and slightly anterior to it; the skull between them was comminuted.

His speech and the functions of all his cranial nerves were unaffected, but the retinal veins were swollen and the inner margins of the optic discs were blurred and indistinct.

His arms lay adducted to his side, flexed and pronated at the elbows, and were very rigid at the shoulders and elbows, but only slightly so at the wrist and in the fingers. He was unable to perform any voluntary

Fig. 1.—a, Superior longitudinal sinus laid open by cutting away its roof. b, A lateral lacuna, laid open in a similar manner, showing a Pacchionian tuft projecting into its floor, and at c the valve-like opening of a large cortical vein. d, Dura mater turned back to show the cerebral convolutions. e, Glass rods showing the channels by which blood reaches the sinus from the lacuna. (From a drawing by D. C. Bluet.)

movement with the right, but could flex and extend the left fingers feebly. The abdominal muscles were rigidly contracted and respiration was mainly thoracic.

Both lower limbs were very rigid and fully extended at hips, knees, and ankles, and rotated inward and adducted at the hips, so that the patellae came in contact with one another; owing to their position and their extreme rigidity they resembled strongly the lower limbs of a severe case of Little's disease. This extensor rigidity was not constant, as occasionally the limbs were found rigid in flexion, but as a rule it was so great that the limbs could not be passively flexed or separated from one another by any reasonable force. The knee and ankle jerks were much exaggerated and the hamstring-jerks were present and brisk; the flexor-jerks in the arms were also exaggerated, but the triceps-jerks were feeble; both plantar responses were extensor and the abdominal reflexes were absent. When admitted his mental state was too dull to permit a proper examination of sensation.

Three days later he had a prolonged left-sided Jacksonian fit which commenced in the face. Ten days after receiving the wound he showed definite signs of improvement; his lower limbs were still completely paralysed and extremely rigid, fully extended, adducted and rotated inwards, but he was now able to move his fingers freely, and perform feeble movements at the elbows; the shoulders were, however, still rigid and their movements paralysed.

Twelve days later all movements of the upper limbs were possible, but the proximal muscles, especially of the right, were very feeble and all efforts he made were very ataxic; both arms were still rigid at the shoulders, and the right at the elbow, and constantly lay closely adducted to the sides and flexed.

The legs, too, remained extremely rigid, extended, adducted, and rotated inwards, but he occasionally had strong flexor spasms in them, especially when turned on his side. No definite voluntary movement of either was possible, and any effort only resulted in a general contraction of all their muscles, and a slow vigorous extension if any segment of the limbs were flexed. Stimulation of either sole produced a vigorous withdrawal movement of the limb without any contralateral effect.

All the tendon jerks were greatly exaggerated, the plantar responses were of the Babinski type, and the abdominal reflexes were abolished.

The examination of sensation revealed, especially on the right side, the disturbances found in pre-cortical lesions when the stage of shock or diasthesis has passed; the lightest touches could be appreciated normally, but a certain percentage of purely tactile contacts failed to evoke a response, and this failure bore no definite relation to the intensity of the stimulus. Localization of touch stimuli was, however, not seriously disturbed. There was no diminution to painful stimuli, and no definite subjective difference in pin-pricks between normal and possibly affected parts. The appreciation of position and of passive movement was almost completely lost in both lower limbs and in the right arm, but was little affected in the left arm; and corresponding thereto the discrimination of Weber's compass points was much disturbed in the legs and in the right arm; the two points could be distinguished 1 cm. apart on the left palm, while on the right they could not be recognized at double this distance, or on the soles when separated to 10 cm.

During the time he remained in the base hospital he had slight difficulty in passing urine, and occasionally incontinence; this he explained as due to the fact that he could "only hold his water for five minutes or so," and that if it then passed involuntarily if he did not receive a urinal.

He was evacuated to England five weeks after receiving the wound, and had gradually improved during this time. His subsequent history is not at present known.

In other cases we have been able to keep the patients longer under observation and in some instances learn of their subsequent course. From our own observation we are of opinion that when the brain itself has not been at the same time damaged by the missile the symptoms due to obstruction of the venous circulation diminish gradually, and will eventually disappear, almost or entirely; and this impression is borne out by the later histories we have received of patients transferred to England. The degree and rate of improvement may depend as much on the inconstant anatomical arrangement of the veins and the amount of anastomosis between the two lateral venous systems as on the severity of the lesion.

Such relatively rapid improvement in a severe case may be illustrated by

CASE II.

Lance-Corporal S. was wounded by a bullet at short range on December 21st, 1914. He was unconscious for a short time and was afterwards unable to move either leg or his right arm. Speech was, however, unaffected, and he had only slight headache.

There was a sagittal gutter wound of the scalp 5 cm. long, its anterior end slightly to the left of the mid-line and vertically above the tip of the mastoid, and its posterior end on the mid-line, with fracture of the outer table and probably depression of the inner table.

When he entered the base hospital, two days after receiving the wound, his face and tongue were unaffected, but the right arm was completely paralysed. The power of his left arm was unaffected, but there was considerable sensory ataxia in its movements. The lower limbs were also powerless and the right especially was rigid.

All the deep reflexes were exaggerated, stimulation of the soles gave extensor responses, and the abdominal reflexes were absent.

The sense of position and the discrimination of compass points were lost in the right arm and in both lower limbs, but tactile and painful stimuli were normally appreciated everywhere.

He was occasionally incontinent, which he attributed to the fact that often he did not feel when he should pass urine.

Five days after the wound there was some return of power in the right fingers, wrist and elbow, but the movements he could execute were weak. His legs were still rigid and motionless. A week later all movements of the right arm were possible and those of the distal segments almost quite strong, but the limb was very ataxic owing to severe disturbance of sensation in it. His legs were less rigid and he was now able to flex and extend both hips, but no movement of the knees, ankles, or toes was possible. The sense of position, the appreciation of passive movement, the discrimination of compass points, and the localization of tactile stimuli were seriously disturbed in his right arm and in both lower limbs, but light touches, painful stimuli and vibration were normally appreciated. The recognition of form (stereognosis) was also defective, but not quite lost, in the right hand.

Five weeks after being wounded his right arm was slightly weak only at the shoulder, but was still ataxic, and he could now execute all movements at the hips and knees, but they were weaker than normal; the ankle and toe movements were still completely paralysed. The deep reflexes were still much exaggerated, and ankle clonus was present on both sides, as well as the Babinski sign.

The rapid improvement of his symptoms continued till he was evacuated to England two months after being wounded. His right arm was then quite strong and all movements of both lower limbs were possible, though the distal segments were still slightly weaker than normal. His legs could now bear his weight, but he needed assistance in walking, owing to the marked ataxia of these limbs due to the sensory disturbances, which, though less pronounced, were still considerable.

We have learned from Dr. H. Head, under whose care he came in England, that five and a half months after the infliction of the wound he could perform all movements of both lower limbs, but he could not yet walk alone owing to the pronounced sensory ataxia of his legs.

PATHOLOGICAL CHANGES TO WHICH SYMPTOMS ARE DUE.

Before we discuss the symptoms in this large group of cases it will be advisable to consider the pathological changes to which they are due. We have been able to study these pathological lesions in a certain number of cases by *post-mortem* examination and have obtained microscopical preparations of the affected areas in a few, but the opportunity for a complete histological examination has not yet occurred.

We have already stated that in many of the cases in which the chief symptoms were due to injury of the longitudinal sinus or its tributary veins, associated lesions of the brain existed, and in describing the essential pathological changes it will be obviously necessary to separate such cases from those in which the venous system only has been directly damaged.

The most common type of injury is a gutter or tangential wound at the middle line of the head, which may be either

sagittal, coronal, or oblique. In many cases the skull, though exposed, showed no evidence of fracture of the outer table, either to inspection or on a ray examination, but the latter generally revealed a depression of the inner table at or near the middle line. In other patients both outer and inner tables were depressed, and if the damaged bone was removed it was seen to present a spoon-shaped depression in the skull, the inner table being more depressed than would be expected from a superficial examination. Such depressions as a rule merely compressed the sinus or its lacunae and rarely injured their walls. Frequently, however, the injury was a perforating wound or an in-and-out wound of the skull, the entrance and exit being on opposite sides of the middle line and close to it, with considerable comminution of the bone between them; here the sinus was generally lacerated, and in certain instances it was completely cut through by the missile, but it was occasionally only compressed by indurated fragments of bone.

On removing the skull-cap *post mortem*, or on operation, a thrombus was usually found in the longitudinal sinus, its character depending on the duration of the case, but as the sinus is divided up by irregular transverse trabeculae and held open by its rigid walls and the support it receives from the dura mater, it is probable that in many cases the thrombus did not occupy its whole lumen. When the injury lies to one side of the middle line the thrombosis may be limited to the lateral lacuna beneath it.

When the dura mater was removed the most striking feature was the condition of those superficial cortical veins which enter the sinus at the position of the wound; these were swollen, firm to touch, and could not be emptied by pressure, and there frequently seemed to be congestion of the neighbouring veins which were not actually thrombosed.

Figs. 3 and 4 in special plate). The superior parts of the hemispheres which are drained by these veins were usually swollen and their convolutions flattened by pressure against the inner surface of the skull, and generally firm to touch. On section there was obviously much oedema of the cortex and subcortical white matter, and minute haemorrhages, which were grouped more closely in the neighbourhood of the wound, were found (Fig. 5 in special plate). In a few instances there was an actual softening near the mesial fissure, the disintegrated brain matter being blood-stained, and punctiform haemorrhages were found in the cerebral tissue around it.

In a few of the cases which came to *post-mortem* examination, and in others in which the condition could be observed during operation, there were widespread subdural haemorrhages, which usually formed a thin layer of blood over the convexity, and sometimes extended to the base of the same hemisphere; in other cases cerebrospinal fluid removed by lumbar puncture was either blood-stained or straw-coloured. These superficial haemorrhages undoubtedly produced some rise of intracranial pressure and contributed to the severe headache with which many of these patients suffered, but they seemed to play a subordinate part in the production of the other symptoms. Thin layers of haemorrhage into the soft membranes and even subpial haemorrhages are common.

Under the microscope the most striking change is the oedema of the affected areas, which is more prominent in the white than in the grey matter. Many of the superficial veins may be thrombosed and the rest are much congested. Minute haemorrhages occur in both the grey and white matter, but chiefly in the proximity of the wound; many are mere perivascular extravasations. Occasionally slight perivascular round cell infiltrations are met with, especially in the neighbourhood of softenings. The walls of the latter consist of disintegrated tissue and large numbers of granule cells.

The nerve cells in the affected areas show pronounced changes; they are generally swollen and in advanced chromatolysis, the Nissl bodies having disappeared, or being represented merely by irregular clumps at the periphery of the cell. Many cells, however, appear almost homogeneous and hyaline, and, in relation to the age of the patient, often contain an excess of pigment when death did not occur soon after the infliction of the wound.

DISTRIBUTION OF MOTOR SYMPTOMS.

When we look at the clinical symptoms we are at first most struck by the unusual distribution and the type of the motor paralysis.

The extent of the palsy naturally varies according to the site, severity, and extent of the lesion; we at present have notes of 20 cases in which all limbs were affected; in 31 both legs and one arm were weak; in 16 only the lower limbs were affected; in 6 the symptoms were mainly hemiplegic, and in 5 one leg alone presented any palsy.

The distribution of the paralysis and its relative severity in different segments of the limbs is, however, peculiar, and differs from that of the cerebral palsies most commonly seen in civil practice. As in Case 1, when the upper limbs are affected, the finger movements either escape, or are weak for only a short time after the injury, and rapidly recover and regain their normal power. The hand movements have never remained long weak except when the sinus condition has been complicated by an

independent injury of the brain. The wrist movements, and especially those of the elbows, are affected more severely and recover less rapidly, while those of the shoulder often suffer when the more distal segments of the limbs escape, and recover much less quickly when the whole limb has been involved.

It is consequently the more proximal segments of the upper limbs which are most seriously paralysed, and the weakness diminishes distalwards. In this respect the paralysis contrasts strongly with that seen in the ordinary hemiplegia due to vascular lesions, in which the distal segments of the upper limbs are almost invariably more severely affected than the proximal, and recover less rapidly. Further, a definite paresis of the face or tongue is extremely uncommon, and is at the most transient, while speech is never affected in the pure sinus injuries. The trunk muscles may be, however, affected, especially those of the back; the patient is then unable to sit up and often cannot roll over in bed.

The distribution of the palsy in the legs is the converse of that of the arms; here it is always the distal movements that suffer more severely, and in slight cases and during the recovery of more severe ones we have

Fig. 2.—a, Sinus laid open as in Fig. 1. b, An elongated lateral lacuna similarly opened. c, Glass rod inserted into the mouth of a large cortical vein, e, which is seen running beneath the lacunar floor. d, Glass rods showing openings from the lacuna into the sinus. (From a specimen in St. Thomas's Hospital Museum.)

repeatedly seen complete paralysis of the toes and ankle only, with the knee movements only relatively weak and those of the hips strong.

This distribution of the paralysis and its relative severity in the different segments of the limbs obviously depends upon the arrangement of the cortical motor centres and on that of the cortical veins. The motor centres for the lower limbs are arranged from above downwards on the apex and lateral surface of the hemisphere in the following order: movements of the toes, ankle, knee, hip; then the small motor centres for the trunk movements intervene, and below them come in succession the motor centres for the shoulder, elbow, wrist, and fingers. On the other hand, the superior cerebral veins which open into the longitudinal sinus drain the central gyri, as a rule, to just below the inferior genu of the fissure of Rolando, which corresponds approximately to the centre for the wrist movements, and if the area they drain be put out of function a complete paralysis of the voluntary movements of the opposite lower limb, shoulder and elbow, with weakness of the wrist movements, and little disturbance of those of the fingers, might be expected.

The distribution of the lateral cerebral veins and the amount and the freedom of the anastomosis between the superior and the inferior systems apparently vary greatly, and this will naturally influence the extent of the paralysis, even though there be complete occlusion of the superior system; but if the lesion is slight and the occlusion is incomplete, the circulation through the smaller and more slender veins that drain the apex of the hemisphere and its mesial aspect would be more liable to become blocked than that of the larger and more thick-walled vessels; in this case only the motor centres for the more distal segments of the lower limb may suffer.

Further, while a mesial lesion is liable to produce bilateral symptoms, a one-sided paralysis of the same type may result from an injury to the one side of the middle line, which blocks the circulation through a lateral lacuna or in the veins as they enter the sinus.

When these symptoms which we attribute to venous lesions, and especially weakness of both the lower limbs, result from an injury of the vertex of the skull in the neighbourhood of the upper ends of the fissures of Rolando, they might be attributed to direct damage or to compression of the motor centres which lie under the wound. But, in the first place, the type of the paralysis, and especially the rigidity associated with it, is unlike that which occurs when other parts of the motor cortex are injured or compressed, and in the second, as in Case 1, the paralysis is often too extensive in relation to the severity of the wound to permit the assumption of a direct injury. Thirdly, as the lateral parietal lacunae overlie the more mesially situated motor centres they must obviously be involved by any injury that would directly damage or compress the cortex.

RIGIDITY.

Even more striking than the unusual distribution of the paralysis is the rigidity which is almost always associated with it. It is generally coextensive with the paralysis, and closely related to it in its degree. Thus it is always most pronounced in the lower limbs, and, when the upper are also involved, it is greater at the shoulder than at the elbow, and is rarely present and never pronounced in the wrist or fingers.

The early onset of this rigidity is another striking point; we have seen it well marked within twenty-four hours of the infliction of the wound, and in some instances at least it has been noticed by the patient almost at once. It has

shown no tendency to increase after the patients have reached the base hospitals, that is usually within forty-eight hours, but on the other hand it gradually diminishes *pari passu* with any return of power that may occur. The rigid limbs generally assume very characteristic attitudes; when the arms are affected they lie closely adducted to the sides and rotated inwards, with the elbows flexed and pronated, and in severe cases the wrists and fingers in moderate flexion. Even the trunk muscles may be involved, and then the abdominal wall is unnaturally rigid and respiration is mainly thoracic; in a few cases, indeed, there has been slight difficulty in coughing, and phonation has been monotonous and toneless owing to the poor inspiratory intake.

As a rule the lower extremities lie fully extended at all joints, firmly adducted and rotated inwards, with the feet occasionally crossed; in fact, the attitude is practically identical with that which is so characteristic of a severe cerebral diplegia. In certain cases, however, the knees are partially flexed, but they are always adducted and rotated inwards.

The rigidity is often so great that the resistance to passive movement is extreme; it may, for instance, be quite impossible for a man of moderate strength to separate the knees. If passive movement is possible, it is found that the rigidity involves all groups of muscles and is more or less equal whether the limb is passively flexed or extended. It is also continuous throughout the whole range of any passive movement that is made, and it has never shown any tendency to the "clasp-knife type."

We have also observed that peripheral stimulation, as pricking the sole or palm, increases the rigidity, and the legs may become more rigid when the patient coughs or attempts any strong voluntary movement with his arms.

It is interesting and important that, despite the great rigidity, there seems to be very little tendency for contractures—that is, organic shortening of the muscles—to develop; in one severe case, of which, through the kindness of Dr. Head, we have heard six months after the

infliction of the wound, no contractures have occurred, although there was for a considerable time great rigidity of the legs.

Reflex spasms of the lower limbs have been associated with the rigidity in a certain number of cases; they have been of the flexor type, and in one case at least occurred from the day of the infliction of the wound. They may be so severe as to cause considerable discomfort to the patient, but gradually diminish in frequency and severity as improvement sets in. Reflex withdrawal of the legs can be easily evolved by peripheral stimulation, especially of the soles, but in only one case have we a definite record of an associated contralateral extension of the opposite limb.

In the rigid cases the tendon-jerks have been much exaggerated from the earliest moment at which they have come under observation, a striking feature, as in ordinary hemiplegia and in cerebral palsies directly due to gunshot injuries of the head these reflexes are frequently absent for some time; but when the limbs are in rigid extension the extensor reflexes—that is, the knee and ankle jerks—are much brisker than the hamstring-jerks, while if in flexion the latter jerk has been the more exaggerated. Similarly, in a case in which the elbows were rigid in flexion, the flexor reflex—that is, the biceps-jerk—was much increased, but the extensor reflex—the triceps-jerk—could not be obtained.

The great toes are usually permanently extended, and a typical extensor response is usually obtained on stimula-

DESCRIPTION OF SPECIAL PLATE.

Fig. 3.—Photograph of the left side of a brain, with the dura mater thrown back over to the right to show its inferior surface and the lateral surface of the left hemisphere. The frontal and parietal lacunae are surrounded by broken lines; the entry of the larger cerebral veins into their under surfaces is clearly seen. Those entering the frontal lacunae, as well as the smaller vein which passes from the precentral sulcus into the parietal lacunae, are thrombosed, but the main post-central veins escape. The dura mater was not torn, but the sinus was compressed between the points a and b by a depressed fracture of the vault. For the sake of clearness the smaller veins which entered the sinus or lacunae have not been preserved in this dissection, or in that from which Fig. 4 is taken.

Fig. 4.—Photograph taken as in Fig. 3. In this case the frontal and parietal lacunae were not definitely separated, and are both enclosed by a broken line. The condition is similar, and the lacunae were compressed by a depressed fracture between a and b, and the veins which enter it at this region are completely thrombosed. The swollen oedematous condition of the brain in the region of the thrombosed veins is obvious.

Fig. 5.—A sagittal section of a brain to show the multiple small haemorrhages into the affected region, a subarachnoid haemorrhage on its surface, and the oedema of the grey and white matter extending backwards behind the fissure of Rolando.

GORDON HOLMES AND PERCY SARGENT: INJURIES OF THE SUPERIOR
LONGITUDINAL SINUS.

FIG 3.

FIG 4.

FIG 5.

tion of the soles, but in a few cases there has been a definite flexor response, although there was unquestionably motor paralysis of the distal segments of the lower limbs. Naturally this is also obtained in another type, to which we shall later refer, in which the inability to move the limbs is due to sensory disturbance only.

Perhaps the most interesting physiological problem presented by a study of these cases is this extreme muscular hypertonus which appears very early after the injury and is closely related to the paralysis of voluntary movement. It is obviously impossible to enter here into the complex problem of the pathogenesis of rigidity, but it is now generally assumed that, as Hughlings Jackson originally taught, the increase of tone is due to removal of the inhibition which higher centres, and in this case the cerebral cortex, normally exert on the lower nervous mechanisms which maintain tone in the muscles. In an ordinary hemiplegia due to a cortical or internal capsular lesion the affected limbs are, apart from some transient early rigidity, flaccid for ten days at least, and lose their tendon reflexes for a shorter period, and we have found the same condition in severe traumatic cerebral lesions. There must be consequently some essential difference in either the site or the nature of the pathological condition which produces paralysis in these cases, which we may group together under the title of the "Longitudinal sinus syndrome." It appears improbable that the level of the injury—that is, the portion of the upper motor neurone that is involved—is the essential factor, as it is only the cell bodies and the upper portions of their axis cylinders which suffer with thrombosis of one of the cortical arteries, and we assume that it is only the cell itself that is temporarily put out of function by a prolonged local epileptic attack, in both of which conditions the palsy is flaccid. This temporary flaccidity, which is later followed by an exaggeration of muscle tone, is attributed to the effect of shock, which depresses for a time the activity of the lower centres that reflexly maintain tone.

If we look for any possible peculiarity in the nature of the cerebral lesion in these sinus cases we are at once struck by the remarkable absence of evidence of such shock. This is especially seen on investigating the disturbances of sensation which they present; while in the early stage of an ordinary case of cortical hemiplegia the sensory loss is partly due to functional disturbance produced by shock in the subcortical sensory mechanisms, in the cases we are considering here the sensory loss, even in the earliest stage, is almost invariably such as can be attributed wholly to a pure cortical lesion. It must be remembered, too, that the damage to the cortical cells associated with this sinus thrombosis is not complete or irrevocable; the nature of the histological changes, and the fact that a remarkable degree of recovery of function may occur is evidence of this, but it is improbable that the type of cell change produced by the oedema and ischaemia of the brain can be the explanation of this early persistent rigidity. On the other hand, we are probably correct in assuming that the venous thrombosis produces a pure cortical paralysis unaccompanied by any shock effect on the subcortical centres which subserve muscle tone.

Disturbances of Sensation.

The sensory disturbances in these cases are especially interesting, as they are almost always those of a pure cortical lesion unaccompanied by any shock effect. The appreciation of pain and temperature is unaffected, and there is no definite diminution of tactile sensibility, but a certain number of light contacts are not recognized; there is, however, no threshold alteration, and the proportion of those missed is not directly related to the intensity of the stimulus. On the other hand, the localization of tactile stimuli, the recognition of the position and of passive movements of the limbs, and of form, shape, and size, as well as the discrimination of the compass points, may be seriously disturbed. The slightness of the affection of cutaneous sensibility has been frequently astonishing, as many patients have complained spontaneously of numbness or of having "no feeling" in their legs.

When the wound has been some distance behind the upper ends of the fissures of Rolando, sensory symptoms have been the most prominent feature. One man, in whom there was a superficial coronal wound of the skull

6 cm. behind the mid-point, had no demonstrable weakness of his legs or change in their reflexes, but he complained that both legs were numb, and on examination profound loss of the sense of position and in the discrimination of compass points was found. Owing to this sensory loss he was unable to walk, and on trying to do so only staggered and fell about the room; Romberg's sign was also well marked.

It is, of course, known that when the sense of position and the appreciation of movement are suddenly and completely abolished in a limb, aimless involuntary movements of it may occur spontaneously. This was well illustrated by one case in which an oblique tangential wound crossed the mid-line 7 cm. behind the mid-point. It is possible that the brain was directly damaged by undriven fragments of bone, but more probable that the symptoms were due to venous thrombosis. There was no weakness or rigidity of his legs, though both were very ataxic, and the reflexes were normal, but in both there was pronounced sensory loss of the cortical type. When his legs were uncovered both were jerked about at irregular intervals in a curious aimless and irregular manner. Sometimes the one was raised from the bed and either thrown across or separated from the other; at other times it was quickly drawn up and extended again, or the foot was dorsiflexed or the toes moved about. The patient became conscious of the movements only when one leg touched the other or when it fell to the bed. In their impulsive, aimless, and inco-ordinate character these movements were very similar to those of chorea.

DISCUSSION OF OTHER SYMPTOMS.

In a certain number of cases the functions of the bladder were affected. In the majority of these there was at first some difficulty in passing urine, or even retention necessitating the use of a catheter in one case for as long as five days, but this symptom always disappeared rapidly. Less frequently incontinence occurred, owing to deficient cerebral control, and in a few patients persisted for a considerable time; the bladder apparently emptied itself reflexly when it had filled to a certain point, and some patients, as Case 1, explained that they were able to hold their water for a few moments only after the desire to micturate had come.

As a rule the functions of the cranial nerves were unaffected, but in several patients the ocular movements were disturbed. In one group there was either temporary weakness or paralysis of the associated conjugate movements of the eyes without ptosis or affection of the pupils; one patient, in whom all four limbs were affected, was unable to move his eyes to order in any direction except slightly downwards, but he could follow, though not fully, a finger which was moved to either side or upwards. The visual axes always remained parallel. Within a fortnight, however, all movements had returned, and only upward deviation was at all defective. There was a similar inability to perform all conjugate ocular movements in another patient in whom all four limbs, excepting the fingers, were paralysed, and this persisted till his death on the fifth day after the infliction of the wound. More commonly, however, there was only weakness of the lateral conjugate movements of the eyes to one or both sides, or much effort was needed on the part of the patient to perform them.

We have not yet been able to make the histological examinations necessary to determine the cause of this palsy of the conjugate movements, but it seems probable that it is due to a temporary paralysis of the centres for ocular movements in the posterior part of the second frontal convolutions. We have occasionally observed a similar defect in local lesions of this region.

In other cases—8 in all—we found an isolated palsy of one or other oculo-motor nerves, generally of the third, or of the third and fourth cranial nerves. This proportion is very striking when we consider the comparative rarity of ocular palsies in other types of gunshot wounds of the head; it seems probable, therefore, it is related to the lesion we are considering. On the other hand, it might be due to a fracture of the base of the skull, to basal meningitis or haemorrhage, or to the effect of the considerable rise of intracranial pressure which is so often present in these cases. In some cases, however, in which a *post-mortem* examination was made, we could exclude

basal lesions, and in only 2 of the 8 cases was the sixth nerve affected, although it is, of course, known that this nerve is much the most liable to suffer from a pathological increase of intracranial pressure.

Fits were observed in ten of the patients; in two both sides of the body were involved, but they were limited to one side in the others. From the descriptions we received, as well as from our personal observations, the unilateral seizures apparently commenced in the face or hand when there was extensive palsy of the convulsed side, or in the lower limb when the paralysis was limited to its distal segments; that is, the excitation started either in motor centres which were only partially damaged, or in their immediate proximity.

Other complications are relatively rare. Meningitis occurred in some in which the dura mater had been lacerated and the brain damaged directly; and in one a general pyaemia, from which, however, the patient recovered, developed secondarily to a septic wound of the sinus. It is surprising that we have encountered only this one case of general infection considering how commonly pyaemia occurs in connexion with septic bone related to the lateral sinus. A secondary hemiplegia occurred in two cases; in one after an operation in which the longitudinal sinus bled freely and had been plugged with gauze, and in a second thirteen days after the infliction of the wound and ten days after an area of depressed bone compressing the sinus had been removed.

The general symptoms of intracranial pressure have been as a rule pronounced. Most of the patients have suffered considerably from headache, and in some it has been particularly severe. In five cases there was also definite optic neuritis with considerable swelling of the discs, and not merely such congestion and blurring of their edges as is seen in a large proportion of all gunshot wounds of the head. In four of these cases at least we could exclude meningitis and secondary cerebral abscesses, and must consequently attribute the ophthalmoscopic changes to the oedema and swelling of the brain.

TREATMENT.

The treatment of injuries of the longitudinal sinus presents considerable difficulties. When there is a defect in the skull to one side of the middle line, and the brain is lacerated by indriven fragments of bone, the wound should be dealt with as if it lay in other regions of the head, but special care is necessary to avoid and control the serious haemorrhage that is apt to occur from the sinus or its lacunae.

If the symptoms are due, however, only to compression of the sinus or its lacunae the immediate removal of the compressing bone would at first sight appear to be the rational treatment; but experience has shown that the results of surgical interference have been extremely unsatisfactory. Among 39 cases we observed which were operated upon either by ourselves or others, 15 deaths occurred in the base hospitals, while only one among the 37 unoperated upon cases died before transfusion to England. These figures have not, of course, an absolute value, as it was naturally the most serious cases which were on the whole selected for operation, and in 7 of the fatal ones there was, in addition, some direct injury of the brain. They are, however, sufficient to emphasize the danger of operation.

On the other hand, it must be remembered that the uncomplicated cases show a remarkable tendency to improve, probably owing to the free venous anastomosis permitting a re-establishment of the circulation.

If operation is necessary, it is advisable to remove bone all round the depressed portion, and only then elevate this; for if haemorrhage occurs the surgeon is then in a more favourable position to control it. As a rule, some bleeding from either the sinus or its lacunae occurs when the fragments of bone are removed, but it can generally be arrested by placing a piece of pericranial tissue or muscle on the laceration, keeping it in position for a short time by moderate pressure, and then carefully replacing the scalp flap over it. The method is certainly preferable to arresting the haemorrhage by a gauze plug, as it is not so liable to produce further thrombosis. When the sinus is completely divided or much lacerated a plug may be, however, necessary.

When there are serious symptoms of intracranial pressure a subtemporal decompression may be necessary;

it was performed in a few of our patients. It is, of course, a safer operation than a large opening in the neighbourhood of the wound, as the latter exposes the patient to the risk of intracranial infection from the septic scalp.

We have, however, found lumbar puncture, repeated frequently if necessary, sufficient to relieve the pressure symptoms in several cases.

It might naturally be expected that an injury which damages the sinus, or the lacunae and their tributary veins, might be complicated by the occurrence of a subdural haemorrhage, especially as the somewhat similar injuries in the newly born which produce cerebral diplegia have been shown by Harvey Cushing¹ to be frequently associated with such haemorrhage; and one would on these grounds be tempted to perform a subtemporal decompression in cases which show evidence of a high degree of intracranial pressure, especially when prolonged or increasing. Both operative experience and *post-mortem* examinations, however, have made it clear that such haemorrhage is rare. When it does occur it takes the form of a thin film of blood spreading over the cortex down to the base of the brain—a condition in which surgical interference is unnecessary and undesirable. In only one case in our series was there a haemorrhage of such magnitude as to need operative relief, and in this case the progress of the symptoms gave definite information before the operation was undertaken.

THE TREATMENT OF GUNSHOT WOUNDS OF THE HEAD, WITH SPECIAL REFERENCE TO APPARENTLY MINOR INJURIES.

BY

J. E. H. ROBERTS, M.B., B.S., F.R.C.S.,
TEMPORARY CAPTAIN, R.A.M.C., SURGICAL SPECIALIST.

The number of patients who arrive at the base hospitals with gunshot wounds of the scalp is large. As their injuries are apparently superficial and their symptoms few or none, they frequently come down as "sitting" cases, and on arrival there is a tendency to overlook the fact that among them there is a fairly high percentage of cases with definite injury to the skull or to the skull and brain.

The following analysis of the lesions found at operation in 140 cases demonstrates that any scalp wound should be viewed with grave suspicion and the necessary measures to determine the presence or absence of a fracture of the skull taken.

Scalp wounds only	82
Fracture of outer table only	19
Fracture of inner table only	1
Fracture of both tables, dura uninjured	18
Fracture of both tables, dura lacerated	1
Fracture with laceration of dura and brain	19
	140

Excluding scalp wounds only, the percentage of head injuries = 41.5; excluding scalp wounds and fractures of outer table only, 27.8.

A careful examination of the patient should be made, and any disturbance of cerebral function or lesion of cranial nerves observed. The optic discs should be examined. The anamnesis is important. If unconsciousness is caused at the time of injury by the force transmitted by the bullet or piece of shell which is concentrated on a very small area of the skull, the chances are considerable that at least fracture, and possibly injury of the brain, has been caused. The latter is more probable if the unconsciousness has been deep or prolonged. Transient local paralysis, or the occurrence of local spasm or epilepsy does not necessarily indicate gross trauma of the brain, but in such cases at least depressed fracture or localized haemorrhage may have occurred. Persistent headache should be viewed with suspicion.

Owing to the difference in velocity of the missile, and therefore to the difference in the momentum imparted to the tissues displaced when the skull is struck, an injury to the skull or brain is usually far less severe when caused by a non-penetrating shrapnel bullet or piece of shell than when caused by a non-penetrating rifle bullet which strikes the skull tangentially. The injury is the same in kind in both cases.

1. There may be propulsion of fragments of bone into the brain substance.

2. Though no fragments of bone are forced into the brain, yet the dura may be lacerated by the displaced bone, which may spring back again, and the momentum imparted to the superficial pulped area of brain substance may force that inwards, or the commotion above may be transmitted onwards, so that a track indistinguishable from that caused by the passage of a foreign body is formed. The pieces of bone removed at the operation should therefore be carefully examined to see that none are missing; and if this examination is impossible or unsatisfactory, the track should be explored by the finger.

3. Even though the dura is not lacerated, this pulpung of the brain may be quite marked. The disintegrated brain substance is of no use; it acts as a foreign body, causing further destructive changes in the brain substance around and should be allowed to escape through a small crucial incision in the dura. On the other hand, cerebral symptoms may be due to concussion or other cerebral injury which cannot be relieved by operation. At the same time a severe lesion may be present in the absence of severe symptoms, as the following cases show.

CASE I.

Sergeant-Major B. Admitted four days after injury with a small circular wound $\frac{1}{2}$ in. in diameter above inner end of left eyebrow. The wound was covered with a dry scab. The patient complained of a slight frontal headache, otherwise nothing abnormal was discovered. A skiagram showed a shrapnel ball just inside the skull. At operation the wound was excised and a flap turned down. The ball was lying between the skull and dura and a piece of bone, consisting of outer table the size of the ball with a larger piece of inner table, was removed from a depth of 2 in. in the frontal lobe. The brain was drained for a few days through the original wound and three months later the patient returned to the front.

CASE II.

Private G. R. Admitted five days after injury with a similar wound in the same situation. A piece of shell had been removed at a clearing station. There were no symptoms, not even headache. On picking off the scab, the serous fluid in the wound pulsated. At operation several pieces of bone were found in the frontal lobe at a depth of $\frac{1}{2}$ in.

CASE III.

Private W. C. Admitted to a general hospital with a small wound of forehead. Slight headache for the first two days. Remained in hospital for eight days and then discharged to base, where he stayed a week. At the end of the week a swelling appeared under the wound which up to then had been painless and covered with a small dry scab.

On admission to No. 5 General Hospital, a small circular wound, $\frac{1}{2}$ in. in diameter and $\frac{1}{2}$ in. above the outer end of right eyebrow, was discovered. The tissues around were swollen and oedematous, the swelling extending down the right cheek. The scab was removed, and an ounce or so of pus evacuated. Under treatment with hypertonic salt solution, the swelling and oedema rapidly disappeared. A skiagram showed several small fragments of bone in the brain, but no obvious hiatus or fracture.

Operation.—The wound was excised and enlarged. A small hole in the bone was discovered. After trephining, a lacerated track in the brain was found filled with deliquescent brain matter and pus. Several fragments of bone were removed from a depth of 2 in. A tube was inserted into the brain and the inner part of the wound sutured.

A culture from the brain abscess yielded *Staphylococcus aureus*.

He was sent to England with a clean granulating area at the outer end of the wound. The sutured portion united by first intention. Throughout his stay in hospital he had no headache or other cerebral symptoms.

EXAMINATION.

A skiagram should be taken, preferably at right angles to the wound. Too much reliance should not be placed on the results, as in several instances a depressed fracture has been found, which was not shown in the plate, and in two cases, where the plates apparently showed depressed fractures of the inner table, no such lesion was found. At the same time much valuable information is usually gained, especially as to the presence and situation of metallic foreign bodies.

The wound should on no account be probed, as in this way superficial infection is carried into the depths of the wound. If the wound is very septic and the scalp around is oedematous, it is preferable, if there is no urgent indication for operation, to apply hypertonic saline treatment for

a day or two before operating. Urotropine, 20 grains, three times a day, should be given to all head cases from the time of admission. The scalp should be completely shaved and painted with iodine.

OPERATION.

The first step of the operation should be excision of the scalp wound. Unless the edges are undermined, a narrow margin suffices. The scalp is steadied with the fingers and two incisions surrounding the wound are made passing down to and including the pericranium, the island of tissue so isolated is then picked up with forceps, stripped off the bone from one end to the other and removed. The instruments used are then rejected. By this procedure in most cases the whole of the infected tissues are removed and an uninfected wound remains to be dealt with.

This incision should always be the first step and should not be postponed to a later stage in the operation. The wound should never be enlarged by incision through its septic edges without preliminary excision, as by this procedure primary union is rendered very improbable. The bone is now examined by the eye and finger, the pericranium being further stripped up if necessary and if no bony injury is found, the wound is sutured without drainage. If a fracture is discovered, it is necessary to obtain more room, and, as pointed out by Colonel H. M. W. Gray, this in the majority of cases is best done by enlarging the wound and not by turning down a scalp flap, unless when the lesion is extensive or multiple. In ordinary head operations the value of a flap is evident, but in these cases a wound is already present directly over the lesion in the brain, and its extension does not add to the disabilities already present. In actual practice it is found that sufficient room is readily obtained.

If there is bony injury it is dealt with on the same lines, a $\frac{1}{2}$ in. trephine crown being raised and the possibly infected bone cut away with craniectomy forceps, all loose fragments of bone being removed.

If the dura is uninjured the wound is then closed without drainage and mastic wound varnish and gauze applied. For twenty-four hours a firm compress of gauze is banded on.

When a laceration of the brain is found, the track is very gently explored by the index finger and any fragments of bone or metal removed if readily accessible, a drain is placed into the brain, and the wound sutured as before.

Results.

Of the 118 cases in which primary suture without drainage was practised, 114 healed by primary union. Of the remaining 4, 3 which came early in the series showed slight superficial sepsis for a few days, and 1, where a too early attempt to suture a wound caused by opening an abscess in the scalp was made, broke down altogether. In a number of these cases two or more wounds were excised, so that the percentage of primary union is really higher than is shown by the figures. The size of the wound sometimes renders suture difficult, but by freeing the scalp for some distance around the wound by lifting the cranial aponeurosis with an elevator approximation of the edges was obtained in all but the two following cases. These results should correct the opinion which has sprung up in some quarters that it is difficult and undesirable to obtain primary union in excised scalp wounds.

CASE IV.

Corporal D. was admitted in an irritable condition. No paralysis, no changes in optic discs. A very foul lacerated wound, 6 in. by 3 in., was present in the occipito-parietal region. After three days' treatment with hypertonic saline the wound was excised and a fissured fracture 4 in. long with no depression was found. On trephining comminution of the inner table for an inch on either side of the fissure was discovered, the fragments lying loose in blood clot. The fragments were removed and the wound sutured, deep tension sutures passing through rubber tube being used. For an inch in the centre of the wound the edges were $\frac{1}{2}$ in. apart. The wound healed by first intention, and at the end of a week the edges of the central part were freshened and the wound completely closed.

CASE V.

Sergeant H. Large septic lacerated wound left temporal region. Wound excised and enlarged. Depressed gutter fracture. Trephined, bone removed with craniectomy forceps. Dura bruised, but tension and pulse normal. Wound sutured

after making another incision parallel to the first, and 3 in. away. This wound was left open. Both wounds remained aseptic, and the second was closed seventeen days later without difficulty.

Although it is inadvisable to open the dura in the presence of a septic wound, yet where the septic tissues have been excised by a surgeon who can rely on his technique the results of allowing exit to the pulped brain tissue are excellent. In over 30 cases treated in the Rouen area the dura has been opened with no deaths, while in 3 cases where this has not been done cerebral abscess followed by death has occurred. The following case illustrates this point.

CASE VI.

Private R. E. B. Admitted nine days after injury, having been transferred from another hospital. A small circular wound in left parietal region with pus exuding; complete paralysis of intrinsic and extrinsic muscles of right hand. Movements of wrist, elbow, and shoulder unimpaired. The paralysis followed immediately on the wound, which rendered the patient unconscious for a few minutes. The septic wound was excised with a $\frac{1}{2}$ in. margin, and the septic tissues with a shrapnel ball embedded removed. A flap was formed and a small orifice in the bone discovered. Trephined, and depressed fragments of inner table removed. The dura was intact, but a small area of softening could be felt. The dura was opened by a $\frac{1}{2}$ in. crucial incision, and about a teaspoonful of liquid brain was extruded. A drain was inserted through one end of the original wound and the rest sutured. After a fortnight power was completely regained in the extrinsic muscles, and at the end of three weeks some return of power was noticed in the interossei and in the opponens pollicis. A month later the patient reported still further improvement.

Advantages of Removing Depressed Fragments.

Since we know that depressed fragments of bone, even though the dura be uninjured, may give rise to symptoms after an interval of time which may be longer or shorter, and that though the spicules of bone which are driven into the brain may be aseptic at first and yet give rise to cerebral abscess through infection tracking down from the surface, it seems reasonable to perform an operation which has little risk, and to perform it early in the expectation of avoiding these serious sequelae.

The following cases illustrate the benefit of removing depressed fragments.

CASE VII.

Bandsman C. W. Admitted with a small healing wound covered by a dry scab in the posterior parietal region. No symptoms. At the end of ten days generalized fits. A skiagram showed a depressed fracture. Operation showed a depression of the inner table 2 in. in diameter. Dura uninjured; primary union; no further fits.

CASE VIII.

Sergeant A. W. W. Admitted with two small nearly healed wounds, left temporal fossa. No symptoms. Was very energetic in helping with work of the ward for four days when he had a general epileptic fit, followed during the night by others. Wounds excised and sutured. A large flap was then turned down. An area of bone $1\frac{1}{2}$ in. by $1\frac{1}{2}$ in. was then found to be depressed. The temporal muscle was still attached to the depressed area, so that examination through the original wounds by finger or probe would not have revealed the depression. Trephined, depressed area removed. Much splintering of inner table; spicules of bone had penetrated the dura mater, and clear cerebro-spinal fluid was flowing from a $\frac{1}{2}$ in. slit in it. An attempt was made to suture, but the fluid came through the stitched holes. Bleeding from a dural vessel stopped by a piece of muscle, and from bone with bone-wax; flap sutured. Next day a collection of fluid released by inserting probe. No further collection; no more fits.

CASE IX.

Lance-Corporal A. M. Admitted with gutter wound in occipital region aboveinion. Complained of defective vision since being wounded. On examination, found to be suffering from transverse hemianopia, the lower halves of both fields of vision being absent. A skiagram showed a depressed fracture. Wound excised; flap turned down; depressed gutter fracture; trephined. Depressed inner table $2\frac{1}{2}$ in. in diameter found pressing on both occipital lobes; dura not injured. Bleeding from superior longitudinal sinns controlled by piece of muscle. Flap and wound sutured. Vision became normal two days later.

The same methods have been applied in the treatment of the most severe injuries, including several involving the frontal sinns. In 64 cases there have been 5 deaths, a percentage of 7.8. In three of these cases pieces of shell casing had traversed both hemispheres of the brain; in one a gas-containing abscess was present in the brain on admission; and in the last the patient was admitted with spreading meningitis commencing, and though

improvement occurred after drainage, lumbar puncture, and contralateral subtemporal decompression, he ultimately died. The following cases are examples of these more severe injuries.

CASE X.

Private C. A. K. Admitted with two septic wounds of forehead, 5 in. apart, caused by the entry and exit of a rifle bullet. The patient, while not unconscious, was very drowsy, and, when roused, extremely irritable. No paralyses were observed. A skiagram showed fractures of the skull. The two wounds were excised and united across the forehead and extended laterally. Much comminution of bone at both points was found, with laceration of both frontal lobes. Bone was removed until a margin of $\frac{1}{2}$ in. of healthy dura was left. The track through brain and falx was explored with finger. No fragments were found. The wound was sutured with a rubber drain into each end of track in brain. Patient returned to England with wound soundly healed, mentally normal.

CASE XI.

Sergeant H. Admitted with tiny entry wound of rifle bullet in left cheek. Large ragged septic wound of exit over right eye, with cerebral matter protruding. Right eyeball lacerated and collapsed. Very irritable and suffered from delusions. No paralyses. The right eye was excised by Colonel Lister's method. The wound of right eyebrow was excised. Fragments of orbital roof and about $\frac{1}{2}$ in. of vertical plate of frontal bone, including the frontal sinus, removed. Frontal lobe much lacerated, the finger entering $\frac{3}{4}$ in. Liquefied brain matter came away in quantity. Wound sutured with rubber drain into brain. Wound of entry also excised and sutured. For three or four days delusions remained. Patient continually dragging dressings of unless constantly watched. Brain matter ceased to come away about the fifth day. Gradually mental changes improved, and patient returned to England at the end of a month with wounds soundly healed and apparently normal mentally.

CASE XII.

Private J. J. Admitted with two septic wounds due to a rifle bullet traversing the frontal region. Entry wound over left eyebrow, exit through upper eyelid on right. Brain matter protruding from both wounds. Severe wounds of both feet and below one knee were also present. Patient was deeply unconscious with incontinence of urine and absent reflexes in lower limbs. The globe of the right eye was destroyed and the fundus of left eye obliterated by blood in the vitreous. Right eye excised. Wounds excised and enlarged. Both orbital plates, nasal processes of frontal bone and ethmoid, were comminuted. The fragments were removed and several deeply-punctured pieces removed from brain. The wound of entry was sutured and drainage effected through wound of exit, which was partly sutured. The patient eventually recovered completely, returning to England apparently normal mentally. Vision began to return in the left eye after four or five days, and finally became $\frac{1}{2}$.

Another case practically identical in its details with the last one as regards the cranial injuries had the same result; the wound of entry in this case was over the left malar bone and exit through the right eyebrow.

CONCLUSIONS.

To sum up, the methods adopted in this hospital are:

1. Careful preliminary examination.
2. Early operation on every scalp wound, however slight.
3. Complete excision of septic tissues at the commencement of the operation.
4. Removal of all accessible foreign bodies from the brain.
5. Primary suture of wounds.

In conclusion, I wish to thank Colonel H. M. W. Gray for much help and many kindnesses both in my work and in the preparation of this paper, and my colleagues in the hospital for their cordial co-operation in the clinical work, many of the cases having been operated on by them.

THE returns of vital statistics relating to non-native officials in West Africa during 1914 (Cl. 7871) are affected by the war, since of 53 deaths in all 18 were of persons killed in action, while 3 more were directly connected with military operations. Excluding all these, the rate of mortality per 1,000 is 11.6, as compared with 11.3 in 1913 and 20.6 in 1905. The invaliding-rate is also satisfactorily low. Five of the deaths were due to blackwater fever, 2 to yellow fever, and 2 to malaria. The population at risk is, of course, too small to permit of very reliable deductions being drawn, but the facts are consistent with the belief that the conditions of life on the west coast are being steadily improved.

THE TREATMENT OF GUNSHOT WOUNDS OF THE HEAD, BASED ON A SERIES OF NINETY-FIVE CASES.

By CAPTAIN GEO. G. TABUTEAU,
ROYAL ARMY MEDICAL CORPS.

IN the consideration of cases of gunshot wounds of the head, one is struck with the extraordinary discrepancy which frequently occurs in the amount of damage done to the soft tissues as compared with that to the bony skull. In some a small wound is seen on the surface which on investigation is found to have caused most extensive fracture of the bony parts and injury to brain substance. In others an apparently severe superficial wound is found only to have caused a slight local depression of bone with no intracranial damage. Owing to the importance of correct treatment of these head injuries, a brief review of some of the points met with in a series of ninety-five head injuries treated in a stationary hospital with a mortality of 9 (10.6 per cent.), and the conclusions derived from them, may be of interest.

The cases occurred during the period from September, 1914, to July, 1915, and many of us I am sure will agree that during this period we have had to modify considerably our line of treatment in these cases as in other injuries. Preconceived ideas that severe injury inflicted on the skull or brain was bound to be accompanied by definite symptoms have been shown to be wrong. Frequently one sees men with severe damage to the skull and brain walking into hospital. This in itself should make one very careful in the examination of even apparently trivial injuries. It appears almost impossible to be able to diagnose the degree of severity of the injury without carefully watching the patient for some time. I am alluding here mainly to the cases which at first sight appear of very little importance. The percentage mortality in the very severe cranial injuries must of necessity be high, and although from the surgeon's point of view it may be interesting to point to some wretched individual whose life has been prolonged by surgical interference, yet in those that recover there is often some permanent damage left either in the shape of complete or partial paralysis or some interference with the mental perceptions, so that the individual spends the remainder of his life a care to his friends or a burden to the State. It is not for a moment meant that our efforts to save even the very worst of head injuries which come under our care should be lessened by even the smallest fraction; I only wish to put forward a plea for the most thorough examination of every case of head injury, no matter how apparently trivial it may be at first sight. These, to my mind, are the cases that from the wider State outlook are really the most important. It is surely better to make a permanent complete cure of these less obvious cranial injuries, which if overlooked might later on develop Jacksonian epilepsies, etc., than to save the life of some less fortunate creature who will at the best have some more or less permanent defects left.

In several cases of this series it was only after some time in hospital that the man showed any signs of cerebral trouble. In many cases which have shown no critical symptoms—such as localized paresis, headache, optic neuritis, convulsions, etc.—very extensive damage has been found on laying back a flap.

(One case I should like to quote in this connexion:

Private W., wounded some three days previously, walked into hospital. He had a small healed scab over the left temporal bone, apparently a graze. He was kept in bed for ten days. He did not complain of anything till the tenth day and was going to be "marked out"; the temperature and pulse were normal; he complained of some slight headache. There were no eye symptoms.

On the twelfth day he had two fits not localized to any particular group of muscles. Operation was performed on the following day. A flap was turned back and a depressed fracture of the temporal bone found. On removing a circular area the dura was found non-pulsating and discoloured. When incised crucially about 1 drachm of disintegrated pulped brain welled out and was carefully wiped away. The wound was stitched and a drainage tube left in for forty-eight hours. Primary union occurred, and he had no further symptoms. He was discharged to England perfectly normal in every way.

It has now become the rule in this hospital that every case of head injury, no matter of what degree, is put to

bed, a purgative administered on the day of admission, and the entire scalp shaved. The history of the case is carefully gone into with special reference to the characters of the injury which point to the probability of a depressed fracture being present—for example, whether the blow was of sufficient intensity to stun the patient. When the entrance and exit wounds are separated by a bridge of scalp overlying a convexity of bone it is almost certain that a fracture has been produced. Practically all these injuries are inflicted by a local force and must therefore be examined with the mechanical possibilities in view rather than that the decision for treatment should be entirely dependent on a neurological examination.

In two instances where there were several wounds on the head, to one of which the patient directed attention, it was only when the scalp had been shaved that a second wound was found which was really the serious one. The difficulty in saying how much bony damage has been done by the appearance of the wound or by the use of the probe leads me to advocate a more thorough examination in almost every case. By this I mean excising the wound and making absolutely certain of the condition of the underlying structures.

This examination by excision should be done early, usually within a day or two of admission to hospital. If no damage to bone is found and a more extensive operation be not needed, the wound can be sutured and, provided that the technique has been good, primary aseptic union should be obtained. Having completed the excision of the wound, a fresh set of instruments must be employed for any further operative measures. If it is found necessary to trephine, the necessity of turning down a flap may be avoided. Sufficient room can usually be got through the original incision.

Indications for Trephining.

1. Although there may be no obvious depression to be seen, yet if the bone shows bruising or laceration of the periosteum, it is more than likely that some definite damage to the inner table will be found. In these cases a small trephine opening should be made and the inner table examined.

2. In cases in which such external signs are absent, but in which there has been loss of function, even if only temporary, persistent headache, giddiness, vomiting, or other signs of cerebral irritation, trephining should always be done. By so doing serious sequelae are avoided.

After having removed all depressed fragments and extradural blood clot, the condition of the dura mater should be carefully examined. In several cases in which it had been found to be discoloured, non-pulsating, and doughy, I have opened it by a crucial incision and a varying amount of disintegrated brain matter has been extruded, and was carefully wiped away. This brain matter is practically useless, and although some people consider that it may become absorbed in time, I think it is much better that it should be removed, otherwise it may act as a foreign body and give rise to after-symptoms. The risk of the brain becoming infected is considered by some to be sufficiently serious to bar the opening of non-lacerated dura, but if all due precautions are taken, infection should not occur, and certainly in those cases in which an opening was made there was no after-trouble.

One of the most difficult points to decide is the amount of bone that should be removed. Personally I am of opinion that when trephining has to be done, it is quite sufficient that an area of bone should be removed around the injured part until it is quite certain that all the depressed fragments have been removed. In cases in which the dura has been opened it is necessary to remove bone until an area of healthy dura at least $\frac{1}{2}$ in. to $\frac{1}{4}$ in. broad has been exposed all round the laceration.

Transport after Operation.

I feel rather strongly on the subject of the transport of cases after operation. Unless urgently indicated, it would seem better that serious head cases should not be moved for at least three weeks after operation; by this time all fear of danger arising from travelling should have disappeared.

Removal of Foreign Bodies.

The removal of foreign bodies from the brain opens up a very wide field of discussion. Experience in the cases

under review tends to impress on me the advisability of a digital exploration of the track in the brain being made at the primary operation in every instance in which the dura has been torn and the brain apparently pierced by a foreign body.

In some cases it was found that the brain had been pulped quite deeply along a "track" without penetration of a foreign body or piece of bone. A lesser degree of this was seen in those cases in which the brain was pulped without the dura having been open. I can only account for this occurring by its being due to the skull having been struck by a missile which in the first instance had a much greater "striking force" than that which caused the second; whether it be due to vibration set up in the particles of brain substance or not I cannot say.

These head wounds, like those of other parts of the body, almost invariably become septic if not dealt with at an early stage, and it is difficult to follow the arguments for leaving foreign bodies alone. If not removed they are almost certain to give rise to after-symptoms, cerebral abscess, hernia, epilepsy, etc. It frequently happens that the missile causing the injury does not lodge, but the fragments of the inner table may be deeply driven into the brain substance. These may often be found by digital examination with comparative ease. A finger passed along an already existing track, if due care be taken, is very unlikely to cause any additional brain damage. If these foreign bodies are left alone and secondary symptoms develop, the trouble and risk of brain injury are increased tenfold. The use of forceps or a probe for searching for foreign bodies is strongly to be deprecated. In a soft substance, such as brain matter, especially when operation has been delayed, one is only too likely to open up fresh tracks, and to lose that leading to the fragments.

The question arises as to the advisability of making a prolonged search for missiles seen by the *x* rays in the brain, but causing no symptoms. Here one has to be guided by many considerations. If at the time of operation no definite track can be found, and one has to fear damaging a portion of the motor area or some important centre in continuing the search, it would seem better not to risk doing more harm than good. I hope it is sufficiently clear that I consider it is always essential, where there is lacerated dura mater, that a digital examination should be made, and any driven-in particles, be they portions of bone or missile, should be carefully removed as early as possible.

As regards the technique employed in these cases, every case in whom there is the least suspicion of fracture of the skull is given urotropine, grains 10 to 20, four-hourly. A purgative is administered. The scalp is shaved, washed with soap and water, then with ether, and painted with tincture of iodine. Instead of shaving, a depilatory paste may be used, consisting of barium sulphide 2 parts, starch 5 parts, and pulv. orr. rad. 1 part. A thin paste is made, smeared over the scalp, and after ten minutes the hair may be scraped off with the back of a scalpel. The hair should previously be cut short with a "horse clipper." The paste must be thoroughly removed, else a crop of pustules may result. This is a very simple method of removing the hair, and avoids any barbers' cuts. When the patient is on the table a fresh coat of tincture of iodine is applied and a circular area corresponding approximately to the proposed operation area thoroughly infiltrated with a 1 per cent. solution of novocain, to which is added adrenalin chloride. The patient is given a hypodermic injection of morphine, $\frac{1}{4}$ grain, and $\frac{1}{16}$ grain atropine an hour previously. By this means the amount of shock is reduced to a minimum and very little anaesthetic is required. The addition of the adrenalin renders the operation practically bloodless—in fact, several of these cases have been operated on with complete success and with no discomfort to the patient without any anaesthetic beyond the local injection of novocain. If the extent of damage is greater than was thought before exploring the wound, a general anaesthetic may have to be given owing to the injury present necessitating a much larger operation than was at first anticipated. Attached are a few brief notes on some of the more striking cases.

In conclusion, I should like to express my thanks to Colonel Gray, A.M.S., Consulting Surgeon, for all his valuable advice to me in the treatment of these injuries.

CASE I.

Sergeant A., completely unconscious on admission. A deeply furrowed wound of the parietal bone. Operated on, and many fragments of bone found to be driven into the brain. These were removed and injured bone chipped away. The patient regained partial consciousness the following evening, and answered questions slowly in monosyllables, but relapsed again and died in seventy-two hours.

CASE II.

Private K., bullet wound centre of forehead, exit parietal and occipital suture. Admitted with complete right hemiplegia. Operation: Flap turned back, exposing both entry and exit wounds; circular area of bone removed. A definite track found connecting the two wounds. On passing the finger along this track several pieces of loose bone were felt and removed along with blood clot. Wounds closed, and a drainage tube left in each. After-history: Slowly recovered muscle power when discharged to England. Has almost complete power of arm muscles, leg recovering well, but with a certain amount of spasm of the hamstrings.

CASE III.

Private B., admitted unconscious; right hemiplegia, incontinence of bladder and rectum. Unable to articulate, but was intelligible. There was a small punctured wound over the left parietal, apparently caused by a rifle bullet. At the time, no *x* rays being available, it was impossible to attempt to localize the missile. A flap was turned down over the injured area and a circle of bone removed. The dura was found to have been penetrated. Several spicules of driven in bone were removed and a quantity of blood clot extruded. No prolonged search for the bullet was made. After-history: Slow convalescence, when discharged from hospital to England. The patient was able to speak quite rationally; full recovery of bladder and rectum, right arm almost normal, right leg only showing signs of partial recovery with well-marked spasm.

CASE IV.

Private U., admitted with severe injury to occipital region. Semicomscious and completely blind. Operation: Large flap turned down and entire occipital bone found comminuted and the dura mater severely lacerated. Many fragments driven in to the brain substance. Loose portions of bone removed. Torn dura cut away. Brain substances badly damaged and septic. Very little improvement after operation. Lumbar puncture done twice; cerebro-spinal fluid cloudy, and escaped under increased tension. Died fifth day.

CASE V.

Private E., admitted with a furrowed wound of the scalp slightly to the left of the course of the longitudinal sinus. Wound explored the day following admission. No apparent bony injury. Wound excised and edges brought together. Some days later the patient began to show signs of right hemiplegia. Wound quite healthy and healing rapidly. Sixth day: Hemiplegia practically complete. Second operation: Original wound laid open; trephine over the most convex portion of bone. On removing the disc of bone, and enlarging the opening an irregular shaped fragment about the size of a shilling was found detached from the inner table and lying over the motor area. This was removed, also some blood clot. The dura was slightly discoloured, but pulsated normally. Wound closed with silk-worm gut sutures, and a drain left in. The patient rapidly regained motor power. The use of his arm returned in the first week. When discharged to England, eighteen days later, he had almost full use of his limbs and was able to walk with assistance. The various points of interest in this case that strike one are: (1) The apparent absence of bony injury found at the first operation. (2) The slow recovery. (3) The rapid recovery after removal of the cause of pressure.

CASE VI.

Sergeant U., gunshot wound right frontal bone. Injury must have been caused by a glancing blow, as the damage was confined to an area corresponding to the frontal sinus. Flap turned back, and depressed bone removed. Frontal sinus thoroughly opened up and blood clot cleared away; wound sutured and a drain left in for three days. Convalescence normal in every way.

CASE VII.

Sergeant A., gunshot wound right frontal bone. On admission unconscious and vomiting. Brain matter protruding from wound over right frontal bone. Flap turned back and the entire bone found detached and a fracture extending into the temporal. Dura torn and brain substance pulped. All loose fragments removed and bone chipped away clear of injured dura. After-history: Convalescence slow, but when discharged to England had completely healed, and cerebral condition was quite normal.

It is reported from America that an association to oppose the "twilight sleep" movement is being organized by a lady named Olson. She proposes to endeavour to excite the sympathetic interest of wealthy women in the campaign against that method of mitigating the pains of labour, and to raise money for the circulation of literature.

TREATMENT OF SEPTIC WOUNDS BY CONTINUOUS OXYGENATION OR IRRIGATION.

BY

W. ATKINSON WOOD, M.D., M.S. (MELB.),

HONORARY SCROTON, CHILDREN'S HOSPITAL, MELBOURNE;
MAJOR, AUSTRALIAN ARMY MEDICAL CORPS.

I HAVE recently treated a severely lacerated and septic wound about the knee in a child by continuous oxygenation under pressure. I had a rubber bag constructed open at both ends and provided with sleeves at the ends and with a valve through which the oxygen can be introduced.

The bag was slipped over the leg like a stocking and the two ends were rendered gas-tight by firm bandaging or the application of a Martin's rubber bandage, Mead's plaster, or rubber tape. Oxygen was introduced from a cylinder up to the pressure of 3 to 4 lb. which the rubber easily stands; with ordinary bandages the bag will remain inflated with oxygen for about twelve hours, with rubber bandages for longer.

The wound rapidly cleaned and the granulation tissue assumed a most healthy appearance in a shorter time than

one would have expected. The child always asked for the "football" in preference to the dressing, as it was more comfortable.

The discharge collects at the bottom of the bag and can be either drawn off by a drain tube, or the bag can easily be removed, boiled, replaced, and refilled within a short time and without pain.

This method, apart from keeping the wound in an atmosphere of oxygen,

keeps the wound protected and saves the patient the pain of removing and replacing the dressings, to say nothing of the saving in dressings themselves, which, when soaked in discharge and in close contact with a limb, must be most uncomfortable.

The wound must, of course, be opened up to its uttermost recesses, sloughs and dead tissues cut away, and large perforated drain tubes inserted so that the oxygen can get to the growing layer of anaerobes. On a large scale oxygen under pressure could be supplied to each bed by small pipes.

This bag, with slight additions, can also be used for continuous or intermittent saline or antiseptic irrigation; by adding a fairly large sized rubber exit tube at the bottom of the bag, connexion can be made to a vessel under the bed, and when it is in position on the limb saline may be run in from a large elevated vessel, the rate of entrance and exit being regulated by nipping the tubes more or less with clips.

This is the simplest form of rubber bag, but the following improvements, although not necessary, may be added:

1. Make the sleeves large enough to slip easily over the wound, and place inside the sleeves a diaphragm air ring with an air valve.
2. Cover the bag with a linen, canvas, or string net.
3. Make a wound inspection slit in the upper part of the bag which can be made watertight with a clip.
4. Or the bag itself could be made of a waterproof canvas with air-pad sleeves.

Bags of different sizes and shapes are made for different parts of the body.

Advantages.

1. We apply the correct percentage of saline solution to the wound, which can easily be flushed and cleansed at any time, thus removing the dead and toxic lymph and leucocytes without removing the bag.
2. The pain of repeated dressings is obviated.
3. The saving in dressings is enormous.
4. There is no pressure on the limb or soiling of sheets as in the ordinary saline bath.
5. There is no "pus poultice," and the patient is comfortable in all positions; he can move the limb with bag and bath attached.

a. Simple rubber sleeve
b. sleeve with section of air pad; c. entrance tube; d. exit to vessel under bed.

6. It can be used under an interrupted splint in a compound fracture of a limb.

Continuous irrigation is now the accepted treatment for septic wounds, and the bag treatment allows this to be carried out in the simplest manner and without annoyance to the patient or nurse.

Lieutenant-Colonel Norris, at the offices of the Commonwealth of Australia, 68, Victoria Street, London, S.W., will answer any communications as to the supply of the bag.

SANDFLY FEVER AND BACTERIOLOGY:
VACCINE TREATMENT.

BY

C. J. STOCKER, M.B., B.C. (CAMB.), D.T.M. AND H.,
CAPTAIN L.M.S.

WITH regard to the articles in the JOURNAL of July 31st concerning sandfly fever, perhaps the following observations which I had the opportunity of making last year in Rangoon may be of interest. Unfortunately, being on active service, I have not access to the notes I made on the cases at the time, but the interest of the cases to me was such that I can speak fairly accurately from memory.

In March, last year, I was in charge of the 79th Carabio Infantry during their transfer from Bombay to Rangoon. The outbreak began on board ship and continued with increasing severity for some eight weeks, after which it gradually subsided; altogether some 180 cases occurred.

The first case was observed when the ship had left Bombay two days, and as no cases had occurred previously in Bombay, the incubation period, for this particular case, can reasonably be fixed at two days, or less.

The clinical picture presented by the cases was of the usual type, some conforming to the description of "sandfly fever," as given in Colonel Sir Leonard Rogers's book, and some to the description of dengue. The majority of the cases, however, were intermediate in type, and such I cannot pretend to differentiate.

In 35 cases I undertook blood cultures, and in 5 of these a bacillus was obtained identical in every particular with that described by Colonel Rogers in his book. I believe he succeeded in isolating it in 6 out of 110 cases (I speak from memory). The clinical picture in these cases was of the intermediate type.

The bacillus was a difficult one to work with owing to its tendency to auto-agglutination; nevertheless, a goat was immunized by repeated injections with the bacillus until its serum agglutinated in 1 in 800 approximately. With this a sensitized vaccine was prepared and tried in some 20 cases. The results were interesting, but no conclusions can, of course, be drawn from so small a number. In several cases the temperature came down by crisis immediately after the vaccine; in one case it came down in two "steps," each immediately following an injection. In some cases the vaccine had apparently no effect; these were mostly the earlier cases in which smaller doses were given. In no case were there any untoward effects, and in several the patients asked for another dose, as they said it relieved the symptoms. The dose finally decided upon was one of 2,500 × 10⁶, repeated the next day if necessary.

The complement deviation test was tried in 4 cases with serum taken from patients suffering from the disease at different stages. The goat's serum was used as a known serum, and a watery extract of the bacillus as antigen; the result was a definite negative in each case. I do not, however, consider that this absolutely negatives the possibility of the bacillus being a causative agent in one type of the fever, as the duration of the fever was so short that one would not expect a patient to raise a high degree of immunity to the bacillus.

Injection of the bacillus into rabbits and a monkey were also without result. Here again these animals were old inhabitants of Rangoon, and may well have become immune, whereas the scops were all new arrivals.

I do not believe the bacillus to have been a contamination, partly because I have faith in my own technique, and partly because no growth appeared in those cultures which were positive until the second or in one case the third day of incubation.

I also undertook a series of differential blood counts, in some of these cases, from blood smears taken daily during

liness and convalescence. The results were of no particular importance; during the fever there was usually a leucopenia with a relative decrease of polymorphs and increase of lymphocytes and mononuclears; during convalescence there was in some cases, but by no means in all, an eosinophilia. One patient in particular I remember, who had only two days' fever, and whose eosinophilia rose from normal on the first day to 22 per cent. on the fifth. I should mention that in every case malaria was excluded, and in every case of eosinophilia the faeces were examined microscopically.

With regard to the transmission of the disease, I noticed that *Culex fatigans* was the most obvious biting insect about the barracks at the beginning of the epidemic, but that later on *Stegomyia* predominated. Sandflies were present throughout the period, but were never obvious.

Another interesting point about the epidemic was the fact that the first two British officers to be attacked were the only two who did not use mosquito nets, they were both attacked within four days of landing in Rangoon. All the other British officers were attacked later, and one when examined on the first day of illness, showed no less than 42 mosquito bites on the knees, the result of working in "shorts" in the office the night before.

This suggested the possibility of examining mosquitos fed on patients at different stages of the disease; accordingly cultures were taken from the contents of the stomachs of mosquitos (all *Culex fatigans*) fed in this way. I would not have believed it possible to obtain pure cultures in this way, nevertheless in 18 out of 23 cases a pure culture of a bacillus was obtained giving nearly all the reactions of Colonel Rogers's bacillus, but differing from it in its greater motility and smaller tendency to filamentous forms. It was not agglutinated by the serum of the goat mentioned above. I mention this bacillus only as a point of interest.

With regard to the nature of the epidemic itself I am not in a position to judge, as I had not previously seen either dengue or sandfly fever; I take it that the epidemic was a mixed one.

AN ADAPTABLE EYE SHADE FOR MICROSCOPIC USE.

By PROFESSOR S. G. SHATTOCK, F.R.C.S.

My excuse for drawing attention to this device is the advantage (with which I have long been impressed) to be derived from cutting off the access of direct light to the eye above the ocular.

In working in a darkened room with a hooded lamp, the drawback mentioned does not, of course, arise. But when daylight is used the admission of light to the eye above the ocular is a distinct hindrance to the study of fine detail. The difference can be at once brought home by temporarily shading the eye with the hand so as to improvise a dark chamber above the ocular. The ability to see more minute details with an eye shade, and a consciousness of diminished strain, will become so apparent that, once used, I feel sure the device will be afterwards invariably resorted to for any prolonged microscopic study.

Mr. Swift, who makes it to my design, tells me that binocular microscopes were occasionally fitted with shades, but these (as in the case of field glasses) were fixed adjuncts. As the use of binoculars for biological purposes became obsolete, the advantage of the shade appears to have been lost sight of. In some form it seems to be well worth reviving.

The draw-tube of all microscopes at the present time is

made of a standard inside diameter, known as No. 1—namely, 23.3 mm.; and this is the size adopted for the aperture in the floor of the shade through which the ocular drops; but the aperture is made also of a larger size to correspond with standard No. 2—namely, 26 mm.—and it can, of course, be cut so as to take an ocular of any other dimension.

It is hardly necessary to add that the shade can be used for either eye by rotating it so that the higher part corresponds with the outer, receding margin of the orbit. Its cost in black matt brass is 3s. 6d.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE ANTITOXIC POWER OF HYPOCHLOROUS ACID.

For some time past experiments have been carried out with a strongly antiseptic liquid consisting of hypochlorous acid and calcium bicarbonate, in order to determine its antitoxic power. The proportions to use are not yet definitely fixed, but will be given in a fuller account to be published later.

The harmlessness of the liquid in question for guinea-pigs and rabbits is shown in the following table:

TABLE I.

Guinea-pigs.	Quantity of Liquid Injected Subcutaneously.	Effect.
1	1 c.cm.	Slight inflammation at the place of inoculation.
2	2 c.cm.	
3	3 c.cm.	
4	4 c.cm.	
Rabbits.	Quantity of Liquid Injected in Ear Vein.	Effect.
1	1 c.cm. + 4 c.cm. salt sol. 8%	None.
2	1 c.cm. + 1 c.cm.	
3	1 c.cm.	
4	4 c.cm.	
5	5 c.cm.	
6	8 c.cm.	
7	10 c.cm.	

The antitoxic effect of the above-mentioned liquid on diphtheria toxin is demonstrated in Tables II and III.

Neutralization of Diphtheria Toxin in Vitro.

TABLE II.

Guinea-pigs.	Mixture of Toxin and Antitoxic Liquid Injected Subcutaneously.	Result.
1	4 L.D. of toxin + 1 c.cm. of antitoxic liquid	Animals remain healthy.
2	4 L.D. " + 1 c.cm. " " "	
3	4 L.D. " + 1 c.cm. " " "	

Three guinea-pigs inoculated with the same quantities of toxin died after less than forty-eight hours.

Neutralization of Diphtheria Toxin in Vivo.

The antitoxic liquid was injected five minutes after the toxin had been inoculated; further doses were given after twenty-four hours and forty-eight hours. Both toxin and antitoxic substance were given subcutaneously on different sides of the body.

TABLE III.

Guinea-pigs.	Quantity of Toxin Inoculated.	Quantity of Antitoxic Liquid Inoculated—			Results.
		After 5 Min.	After 24 Hours.	After 48 Hours.	
1	4 L.D.	1	1	1	Animals remain healthy.
2	4 L.D.	1.5	1.5	1.5	
3	4 L.D.	2	2	2	
4	4 L.D.	2.5	2.5	2.5	
5	4 L.D.	1	1	1	
6	4 L.D.	1	1	1	
7	4 L.D.	1	1	1	
8	4 L.D.	1	1	1	
9	4 L.D.	1	1	1	+ 5 days. Healthy.
10	4 L.D.	1	1	1	

Guinea-pigs inoculated with 4 L.D. of toxin died after less than sixty hours.

Fig. 1.—A diagrammatic section (natural size) showing the shade *in situ*, as kept in position between the flat upper edge of the draw-tube a, and the rim of the top of the ocular. The form of the upper opening of the shade is indicated by the dotted line.

scopes were occasionally fitted with shades, but these (as in the case of field glasses) were fixed adjuncts. As the use of binoculars for biological purposes became obsolete, the advantage of the shade appears to have been lost sight of. In some form it seems to be well worth reviving.

The draw-tube of all microscopes at the present time is

As far as can be seen, the antitoxic liquid has equally strong effect on tetanus toxin as on diphtheria toxin.

RATÉ FLORES CORDOVA, M.D., D.Sc. Lima
(From the Lister Institute).

TREATMENT OF ABDOMINAL WOUNDS.

With reference to Captain Owen Richards's article (BRITISH MEDICAL JOURNAL, August 7th, p. 213) on abdominal wounds and the administration of drinks, might I venture to suggest that in every abdominal case where it is not considered wise to give drinks by the mouth a large hypodermic saline should be given? If a quart be given every twelve hours in this way, much suffering, and perhaps some deaths, might be avoided. The necessary simple apparatus is in every field ambulance.

V. T. CARUTHERS, Captain R.A.M.C.

Reviews.

SURGERY IN THE BALKAN WAR.

MULTITUDINOUS as will be the books written on the surgery of the present war, interest in the wars in the Balkans is not dead. It is highly probable that if the surgical lessons learned then had been taken more to heart, some of the misapprehensions and difficulties of surgeons in this war would have been less. Professor LAURENT, of Brussels, records his experiences, general and surgical, of eleven months of campaign during the war in Bulgaria and Turkey.¹ He would have preferred to devote a whole year to elaboration of the work, but it is perhaps more fortunate that he published it hot and sharp from his recollections. The book falls naturally into two divisions—the first dealing with general notes and impressions, the second with the wounded. The whole work is copiously illustrated with photographs, those in the first part comprising pictures such as we see daily in our illustrated newspapers—the military train, groups of nurses, soldiers guarding a village, transport wagons, men in trenches, the fight with vermin, and so on. Professor Laurent has a good word for the Bulgarian soldier. In spite of everything, good humour prevailed; the most shocking losses were powerless to suppress it. In quiet hours they amused themselves. The favourite recreations were dancing the "choro," a dance similar to the "farandole" of Provence, and singing national songs round camp fires. This amusement is by no means confined to Bulgarians; our present allies, the Serbian soldiers, dance often with their officers, and many a gladsome reel is danced within the British lines by Highlanders. The Bulgarian ambulance arrangements were at first very faulty, but the sanitary organization was improved with astonishing celerity. In the section dealing with the general effects of projectiles and the treatment of injuries found in war, Professor Laurent says that war surgery is a very different business from ordinary everyday hospital surgery, and that, most important of all, it demands some previous training of the surgeon—"the war surgeon cannot be improvised." "The Balkans are at the present moment peopled with cripples and invalids which a medical education appropriate to war would have spared." The sum of his experience is contained in these seven propositions:

(1) Severe wounds of the abdomen and laparotomy performed in hospital were excessively rare; (2) aneurysms and nerve lesions were relatively frequent; (3) comminuted fractures of the long bones and of the hand were extremely frequent; (4) rifle bullet wounds were greatly more numerous than wounds by shrapnel; (5) injuries of the face were very rare; (6) amputations were rare but troubling frequent; (7) a second operation under chloroform in an infected wound was a serious matter. In attempting to answer the question, Which was the most deadly arm? he made many calculations and comparisons, concluding that on the battlefield the majority of deaths was due to shrapnel, but that the bullet made five times more wounds than shrapnel. "It is the rifle bullet which places most men *hors de combat*; the rifle bullet is the queen of many battles." Another interesting question discussed by Professor Laurent concerns the proportion of wounded to

killed. Since 1896, when the small calibre rifle bullet was introduced, the proportion of killed to wounded on the battlefield has gone up. In 1870 it was 5.7 wounded to 1 killed, in the Russo-Japanese war it was among the Russians 4.9 to 1, and among the Japanese 3.7 to 1, and in the Bulgarian war 3 to 1. The same proportion, 3 to 1, seems to hold in this war for the British forces. Professor Laurent supplies a number of highly interesting tables dealing with relative figures concerning regions wounded, the number of wounds from rifle bullets and from artillery, and the number of fractures in wars during the last sixty years.

The second division of the book deals with the wounds of war, and is fully illustrated by pictures and short sketches of cases. Each region is considered in detail. The wealth of material is enormous, and it is coupled with conscientiousness and industry untiring. The author's advice in regard to operating in injuries of the abdomen is that the following cases demand urgent operation: serious hæmorrhage, wound of bladder with escape of urine, wound of spleen, transverse wound of abdomen in the umbilical region with evidence of intestinal perforation. Wounds of the hands constituted 23 to 25 per cent. of the whole number, and wounds of the left hand seemed curiously common, probably because that hand is well forward holding the rifle. A group photograph shows sixteen men all wounded in the left hand.

This most interesting work is a worthy record of an arduous year of Professor Laurent's life, and probably will endure as the most satisfactory contribution to surgical war literature of that time. The closing pages are in form of an epilogue, "What of War?" War has for its object arrogant domination, brutal gratification of passions, or it is a necessary factor in selection, in renovation of the race. It is a vice, an indelible stain on humanity, or it is a natural consequence of the struggle of all elements in nature and in life, and will cease only with life itself. In ironic commentary, on the same page, is inserted a photograph of a Bulgarian soldier blinded and deprived of both hands by a bomb explosion. One wonders what Professor Laurent's thoughts on war are to-day.

PHYSIOLOGY.

The first edition of Professor STARLING's *Principles of Human Physiology* appeared three years ago. The second edition² contains much new matter in the sections dealing with voluntary muscle, the circulation, the nutrition of the brain, and the innervation of the bronchi. The volume is divided into four parts. The first is given to the principles of general physiology, as exhibited in the structural, material, and energetic bases of the body. The second, 440 pages in length, describes the mechanisms of movement and sensation in all its forms. The third part is the longest, and contains a full account of the mechanisms of nutrition, using the term in its widest sense. The fourth part, of 46 pages, is devoted to the physiology of reproduction and lactation. The book ends with an excellent index by Mr. L. Evans. In writing this volume, Professor Starling has kept in mind the requirements of medical students and practitioners whose previous acquaintance with the subject is of a very shallow variety, or even *nil*. Throughout he has endeavoured to show that the only foundation for rational therapeutics is a proper understanding of the way in which the healthy body works. As he very justly says: "Until we know more about the physiology of nutrition quacks will thrive and food faddists abound. Ignorance of physiology tends to make a medical man as credulous as his patients, and almost as easily beguiled by the specious puffings of the advertising druggist." Hence the book has a special value for the medical practitioner, as well as for the student who has to face examinations in physiology. The different chapters and subsections are written rather in the form of essays on the topics with which they treat, categorically and with abundant use of subheadings to indicate the various aspects from which the subject may be regarded. Professor Starling writes clearly, and has made an excellent choice of illustrations and tracings to illuminate his text. There is nothing of the cut-and-dried formalism so common in

¹ *La guerre en Bulgarie et en Turquie. Onze mois de campagne.* Par Professor O. Laurent. Paris: A. Maloine, 1914. (Demy 8vo, pp. 383; 305 photographs. Fr. 6.)

² *Principles of Human Physiology.* By E. H. Starling, M.D., Lond., F.R.C.P., F.R.S., Hon. M.D. Breslau. Hon. Sc.D. Camb. and Dubl. Second edition. (Roy. 8vo, pp. 1285; 555 figures. 21s. net.)

scientific textbooks about his volume, which is characterized by a broad outlook on the problems of physiology, and an unusual readiness to fall back on other kindred sciences in the endeavour to bring these problems towards a satisfactory solution. The author is to be congratulated upon the production of a sound and stimulating summary of modern physiology as viewed by a chemically minded mechanist with great experience in successful original investigation. The book should be widely read by those for whom it is written, and we wish it all success.

Professor HALLIBURTON is to be congratulated on the appearance of the twelfth edition of his *Handbook of Physiology*,⁵ representing the twenty-fifth edition of Kirke's time-honoured textbook. Two years ago the book was thoroughly revised and brought up to date by Professor Halliburton; the present edition exhibits alterations of a minor character only, such as were necessary to bring it abreast of the times. The book is well recognized as a standard work on physiology for medical students and physiologists, constrained on sound and customary lines, illustrated as one would expect a standard work to be, confining its scope to a workmanlike exposition of the science with which it deals. The success this book has met in past decades is a guarantee of its educational value; the medical student will find in it all he requires for the passage of his examinations in physiology, and we recommend the volume to him with all confidence.

Dr. CRAMER has brought out a second edition of his *Directions for a Practical Course in Chemical Physiology*⁶ within a year of the first. The wise choice of subjects and clearness of diction justify the quick popularity of this little practical book. The author lets the student start with the potato, and prepare starch from that—a much wiser plan than giving him prepared starch to test. So, too, he directs him to examine the phenomena of coagulation of the blood from the start, in place of handing the class plasma, serum, etc., separated by the laboratory attendant or demonstrator. In testing urine for aceto-acetic acid, or acetone, he uses Rothera's modification of the nitro-prusside test: "Take 10 c.cm. of urine in a test tube and saturate it with ammonium sulphate by shaking it with an excess of the solid salt. Then add two or three drops of a freshly prepared 5 per cent. solution of sodium nitro-prusside. Add 2 or 3 c.cm. of strong ammonia. Mix by inverting the test tube once or twice. Allow to stand undisturbed for twenty minutes. A deep perranganate colour is the positive reaction, and the depth of colour roughly indicates the amount present."

TEXTBOOKS OF ANATOMY.

MORRIS'S *Anatomy*,⁷ which has now reached its fifth edition, is sufficiently well known to permit of its being referred to by comparison. The work has always had a strong practical bias, as was to be expected, since the first edition was written by London surgeons. While we think it would not be correct to say that this bias has been weakened, it has, we think, in later editions been obscured by the introduction and expansion of the anatomy of the laboratory as distinct from the anatomy of the dissecting-room. Another striking feature of the book has been the wealth and excellence of the illustrations. The publishers seem to have had the privilege of selecting blocks freely and widely from American and Continental publishers, with the result that the book from the student's point of view is probably the best illustrated textbook in our language. In the present edition large and small type have been largely employed for the purpose of discriminating between the more important and less important facts, a device which makes the book adaptable for a much larger circle of readers than would have otherwise been the case. The embryological part of the subject is still poorly represented, the

chapter on general embryology being insufficient to enable the student to follow the condensed accounts of regional or special embryology which appear here and there throughout the book. It is not without significance that the word "placenta" does not appear in the index. In this respect, but in no other, the work falls below the standard set by such English textbooks as those of Quain, Gray, and Cunningham. It is rather sad to reflect that of the twelve collaborators in the present edition only one is now connected with a London school, and that the book, which was once so representative of London teaching, now prides itself on being the first English textbook to forswear our old traditional terminology and to adopt a new ill-considered nomenclature of foreign origin.

While the necessity of books on applied anatomy may be regretted, since they tend to give the student too partial and broken a view of a subject which should essentially be seen whole, it is idle, in the face of the rapid advances in knowledge and of the persistent increase in size of the more general textbooks, to pretend that such books have not got their sphere of usefulness. In *Medical Applied Anatomy*,⁸ which is a volume of the Edinburgh Medical Series, Mr. T. B. JOHNSON has done for medical anatomy what quite a number of authors have already done for surgical anatomy, nor need he, in our opinion, fear comparison in his work with any or all of them. The judgement which he has shown in both the general plan of the book and in the choice of subjects is alike admirable, while for a first edition the text is singularly accurate. Almost half the book is devoted to the consideration of the nervous system, and within the limit allowed it would, we think, be difficult to suggest any improvement. Of errors, we note that the buccinator muscle is described as arising from the inner alveolar margins of the mandible and maxilla, while the latissimus dorsi is given as inserted into the medial lip, and the teres major into the floor of the bicipital groove. The spinal root of the eleventh cranial nerve is said to arise midway between the anterior and posterior roots of the cervical spinal nerves, whereas it lies definitely behind the ligamentum denticulatum; further, its distribution is not confined, as stated, to the sterno-mastoid and to the upper fibres of the trapezius; it supplies the lower fibres as well, as can be easily demonstrated in the dissecting-room, and as would be expected from a knowledge of its origin. We do not, moreover, subscribe to the dictum, where each is essential, that the axon of a nerve cell is of much greater importance than the dendrites. The illustrations form the feature of the book which lies most open to criticism. Some of the prints are from blocks made originally for a textbook now, we believe, out of print, and published at a time when the art of illustrating was far from being what it has of late years become. Others of the figures are presumably from the author's own pencil, and might, we think, have been brought to a higher state of perfection without any sacrifice of simplicity or without any addition to the expense of reproduction. In Fig. 25 we note that the spino-thalamic tract is placed in the position usually assigned to the rubro-spinal tract; while in Fig. 31 the positions of the internal carotid artery and sixth cranial nerve are not exactly given as they are usually seen and described. For surface markings the author has chosen to go to plaster casts of more or less classical models, and figures of Hercules and Apollo make unexpected appearances as we turn the pages of the book. On the whole we think we prefer our classical art and our applied anatomy separate. Such blemishes as have been noted are, however, slight and do not seriously detract from the value of a book upon which the author is to be warmly congratulated.

ABDOMINAL INJURIES.

*Abdominal Injuries*⁹ is the title of a volume contributed to the "Oxford War Primers" by Professor RUTHERFORD MONSON and Lieutenant-Colonel W. G. RICHARDSON. The book treats of the various forms of abdominal injury met

⁵ *Medical Applied Anatomy for Students and Practitioners*. By T. B. JOHNSON, M.B., Ch.B. The Edinburgh Medical Series. London: A. and C. Black, 1915. (Cr. 8vo, pp. 450; 146 figures. 7s. 6d. net.)

⁶ *Abdominal Injuries*. By Rutherford Monson, Professor of Surgery, Durham University, and W. G. Richardson, M.B., F.R.C.S., Lieutenant-Colonel R.A.M.C.(T.). Oxford War Primers. London: H. Frowde, and Holder and Stoughton, 1915. (Fcap. 8vo, pp. 116; 27 figures. 2s. 6d. net.)

⁷ *Handbook of Physiology*. By W. D. Halliburton, M.D., LL.D., F.R.C.P., F.R.S. Twelfth edition being the twenty-fifth edition of Kirke's Physiology. London: J. Murray, 1915. (Denay 8vo, pp. 942; 577 figures, 3 plates. 18s. net.)

⁸ *Directions for a Practical Course in Chemical Physiology*. By W. Cramer, Ph.D., D.Sc. Second edition. London: Longmans, Green, and Co., 1915. (Fcap. 4to; pp. 110. 3s. net.)

⁹ *Morris's Human Anatomy: A Complete Systematic Treatise by English and American Authors*. Edited by C. M. Jackson, M.S., M.D. Fifth edition, revised and largely rewritten. London: J. and A. Churchill, 1915. (Sup. roy. 8vo, pp. 1553; 1,182 figures. 20s. net.)

with in war, and is based on experience gained in the present campaign. Throughout it is very clearly written, and the diagrams are excellent in their simplicity. Great stress is laid on the need of careful and rapid diagnosis, and the importance of obtaining an accurate history of the injury is explained. In the Boer war statistics showed that though 40 per cent. of cases shot in the abdomen and brought alive to hospital recovered, the death-rate following on operations for abdominal injuries was appalling. In the present war, from the altered conditions of climate, soil, projectiles, etc., together with the possibility of the more rapid removal of patients to suitable hospitals, it is found that early operation may give the best chance of success. The various forms of abdominal contusions are discussed, as are wounds of the abdominal wall and penetrating wounds of the abdomen. Indications are given as to when and when not to spend time in searching for bullets. Surgical technique as applicable to the altered conditions of active service is fully considered. The various operations for the arrest of haemorrhage, closure of perforations, excision of intestine, etc., are clearly described step by step. It is interesting to note that in intestinal anastomosis the authors give a prominent place to Murphy's button. There is a most excellent section on the after-treatment of abdominal cases and the more common complications likely to arise. In conclusion, it may be said that the book should prove of the greatest use to those among us who are at present or who may in the near future be called upon, if not to deal with, at least to help in the treatment of these most serious cases. Further, the book should be helpful to those in civil practice, for nowadays, with rapid traffic and in some places darkened streets, abdominal injuries are by no means infrequent.

FATIGUE.

The issue of a cheap reprint of the English edition of the late Professor A. Mosso's book on *Fatigue*⁸ appears at an opportune moment. The book is written in an entertaining if somewhat discursive style; thus, in the early chapters, there are given interesting facts concerning the flight of quails and other migratory birds, also details of the life-history of Borelli and of Steno, while in the later chapters reference is made to the manner of work of many intellectuals. In the main the book is an exposition of the author's pioneer researches into the subject. His well known ergograph is described, together with its manner of working. Excellent traces are given to show the results obtained under varying conditions. Mosso held that there is only one kind of fatigue—nervous fatigue; muscular fatigue, at the bottom, being an exhaustion of the nervous system.

Various examples are given of the effect upon the organism of cerebral activity, such as lecturing or examining students. The effect varies with the individual; thus in one, an hour's lecturing produced at first increased muscular power; in another, this effect was but transitory, and at the end of the hour there was a marked falling off in the power to do muscular work.

The section dealing with the question of fatigue in muscle suffers somewhat from the date at which the book was originally written; the more recent contributions to this part of the subject are consequently missing. Indeed, throughout it is somewhat disconcerting to find work done in 1883-1890 referred to as "recent." The subject of cerebral fatigue is dealt with largely from the psychological as well as from the physiological side, and should prove of value to educationists. It will serve to emphasize the fact that the young mind should not be unduly fatigued either by work or exercise.

It is somewhat difficult to say how far Mosso's method may be profitably employed in the elucidation of the problem of fatigue in manual workers. His chapter on the law of exhaustion indicates that best results are to be obtained by short intervals of work alternated by short periods of rest. This is undoubtedly true for all forms of manual labour. It cannot be doubted that the fatigue which leads to inattention and accidents is largely of cerebral origin. But in the case of the manual worker performing a reflex act many thousand times a day, often

during its performance chattering gaily about last Saturday's football match, or some such subject, it is probable that the fatigue from his labour supervenes in the lower rather than in the higher centres. In such a case the ergograph may not truly indicate the centres actually involved. To elucidate this problem the method of experimentation upon the workers themselves, as carried out recently in America, appears the more valuable. In such experiments the amount and accuracy of the output of the actual work are used as a measure of the fatigue developed. In dealing with the question of fatigue, it is necessary to bear in mind that it may not be solely due to the actual mental or physical effort, but to concomitant factors, such as ill ventilation, bad lighting, or the din of the surrounding machinery.

The book is one to be studied by all interested in the subject, and may be particularly recommended to those who are concerned with the psychological point of view. It reads well—a sufficient tribute to the excellent work of the translators.

NOTES ON BOOKS.

THE second edition of the *Encyclopaedia Medica*⁹ has now reached its second volume, which contains articles from Aspiration to Chloroform. Among the most important are those on bacteriology, by Dr. Wm. Scott; on injuries and diseases of the bladder, by Professor F. A. Scoville; an account of the blood, by Dr. A. Goodall; on diseases of bone, by Professor Alexis Thomson; and a series of short articles and mere paragraphs are given to such rarities (as should one say commonplaces?) of medical practice as camptodactyly, and to subjects on which medical men can but rarely have to inform themselves, such as canal boats. Brief accounts of all the chief pharmacopoeial and extrapharmacopoeial remedies are included, and so are accounts of the chief eponymic physical signs recognized in practical medicine. The articles are written for the instruction and use of physicians and surgeons alike, and while maintaining a practical character, do not fail to make use of the literature of the subjects with which they deal. A number of illustrations and coloured plates are included, not all of equal merit. It is perhaps surprising to find an account of Blondlot's N-rays still included in a work published in 1915, in view of the fact that their origin in self-deception was proved a good many years ago. The *Encyclopaedia Medica* is a work that should be in every medical library, and contains a vast amount of information that would be of service to practitioners of medicine.

The ninth edition of DORLAND'S well-known *Pocket Medical Dictionary*,¹⁰ containing the pronunciation and definition of all the principal terms used in medicine and the kindred sciences, including dentistry and veterinary medicine, is a book that may be confidently recommended to medical men in search of a medical dictionary of small size. It is well printed and for its size singularly complete, although we find no reference in it to the mitochondria of protoplasm to which so much attention has been devoted in recent years. It is not free from misprints. "Scybalum" is the singular of "scybalæ," not the plural; "Pyrosoma bigemium" should read "bigemum."

Dr. MILLS'S book, *Nursing and Care of the Nervous and the Insane*,¹¹ now in its third edition, is founded on a course of lectures delivered to nurses at Philadelphia. It contains sound practical advice on the nursing of patients suffering from either functional or organic nervous diseases. The first chapter gives a general account of what the nurse's line should be. The next three chapters deal with massage, hydrotherapy, and the various forms of electrical treatment that have proved of service in these cases. The last chapter gives an account of the nursing and care of the insane. The book fills a want, and may be recommended to the attention of those for whom it has been written.

⁸ *Encyclopaedia Medica*. Second edition. Under the general editorship of J. W. Ballantyne, M.D., C.M., F.R.C.P.E. Vol. II: Aspiration to Chloroform. Edinburgh and London: W. Green and Son. (Hoxby Ave., pp. 585; illustrated. Price 20s. net.)

⁹ *Pocket Medical Dictionary*. Edited by W. A. Newman Dorland, A.M., M.D., F.A.C.S. Ninth edition, revised and enlarged. Philadelphia and London: W. B. Saunders Co. 1915. (Fcap. 8vo., pp. 691, with over 60 extensive tables. Leather, 5s. net; with thumb index, 6s. net.)

¹⁰ *Nursing and Care of the Nervous and the Insane*. By C. K. Mills, M.D. Third edition, revised by the author, assisted by N. S. Fawcett, M.D., Philadelphia and London: J. B. Lippincott Co. 1915. (Fcap. 8vo., pp. 142; 12 figures. 5s. net.)

¹¹ *Fatigue*. By A. Mosso. Translated by Margaret Drummond, M.A., and Professor W. B. Drummond. London: George Allen and Unwin, Limited. (1p. 3s. 2s. 6d. net.)

"CONSUMPTION QUACKERY."

UNDER this title *Truth* of September 22nd published an article on a nostrum called "Kasco Tubacyllus," vended by a Nottingham firm named Cassell and Co. The article states that the sale of the nostrum is pushed in the customary manner, "first there is the newspaper advertisement announcing that consumption is positively cured by Kasco Tubacyllus, which is described as 'the consumptive's only hope of life.'" Sufferers who write for further particulars receive a pamphlet, which after some generalities passes on to the announcement that "Cassell and Co. have placed on the market a germicide which 'has been proved—absolutely and conclusively proved'—to be 'a genuine and efficient cure for this terrible disease.'" The "discovery of the specific is ascribed to a man who was himself in the second stage of consumption of the lungs, and who had cured a Leeds sanatorium in the early part of 1914. This unnamed person had the great fortune to stumble across a certain cure which has, within a few months, positively driven away the disease, completely destroying the tubercular germ, and restoring him once again to perfect health. To obtain a similar result the patient is told that he must have the utmost faith in the cure and take it conscientiously. Though somewhat expensive to manufacture, the price has been fixed as low as possible, and a bottle containing 16 ounces is supplied for 4s. 6d., post free. With the pamphlet are sent out copies of some correspondence which has passed between Cassell and Co. and the Secretary of the Brompton Hospital for Consumption. In the first of these letters, signed F. W. Cassell, it is stated:

"So confident are we as to the genuine curative powers of our cure that my son, Mr. H. Cassell, is quite willing to allow himself to be inoculated with the bacilli of tuberculosis under the observation of any member or members of your committee, and no action shall be taken until every indication proves that he is thoroughly in the grip of the disease. He will then undertake to prove how all trace of the bacilli of tuberculosis can be successfully removed from his system.

"The reply from the secretary of the hospital was to the effect that the medical officers were prepared to give the 'cure' a trial on condition that the nature, the mode of preparing, and of using the proposed remedy were unreservedly communicated to them in writing. Needless to say, Cassell and Co. refused to comply with this condition."

Further on our contemporary states that: "In another document the Mr. H. Cassell whose *corpus vile* is offered for the experiment is described as 'our medical expert,' who takes the cases under his personal observation, and will report upon them after studying the charts which patients are requested to fill up at the commencement and during the progress of the treatment."

The editor of *Truth* had obtained through a prospective patient three bottles of Kasco Tubacyllus, and asked the editor of the BRITISH MEDICAL JOURNAL "to submit them to the analysts whose researches into the constituents of quack nostrums have been made public in the well-known book, 'Secret Remedies.' The result is shown in the following report, though it should be mentioned that Cassell and Co. aver in their letter to the Brompton Hospital authorities that the active ingredient of their cure is not ascertainable by analysis:

"Analysis showed that the liquid contained in 100 parts by measure—

Sulphurous acid (H ₂ SO ₄)	...	0.053 part
(Equivalent to 0.82 part of sulphurous acid, B.P.)		
Sulphuric acid (H ₂ SO ₄)	...	0.012 part
Citric acid	...	0.19 part
Cane sugar	...	1.03 part
Invert sugar	...	4.63 parts
Mineral matter (ash)	...	0.008 part

"Slight indications were obtained of the presence of traces of alcohol and formaldehyde, but the quantities of these, if present at all, were so minute as to be impossible of perfect identification. The sulphuric acid found has no doubt been produced by the accidental oxidation of part of the sulphurous acid; similarly, the invert sugar has evidently been produced by the action of the acids on the cane sugar, which is readily inverted by prolonged contact with dilute acid. Substantially, therefore, the liquid is a mixture of—

Citric acid	...	0.19 part
Sulphurous acid B.P.	...	1.03 part
Cane sugar	...	about 5.5 parts
Water	...	to 100 parts by measure

"Very careful search was made for a large number of other substances which might be employed in a mixture intended as a germicide, but in every case with negative results. If any other substance were present at all it must have been in most extreme dilution, so that the quantity obtained by taking the mixture would be practically infinitesimal, but, except for the doubtful indications of traces of formaldehyde and alcohol mentioned above, there was no appearance of any other constituent. The trace of mineral matter may have been partly from the constituents added and partly from the use of ordinary tap water. The formula given above in percentages represents the following quantities in a bottleful and in a dose respectively:

	In one bottle.	In one adult dose.
Citric acid	... 13 grains.	... 0.2 grain
Sulphurous acid, B.P.	... 82 minims	... 1.3 minims
Sugar	... 385 grains	... 6.0 grains

"Taking the prices of these ingredients quoted in a wholesale drug list, the cost (for ingredients alone, without bottle, cork, etc.) would be a little under 1d. for the quantity in one 4s. 6d. bottle."

In commenting on this, after remarking on the contrast between the cost of the ingredients and the price at which the bottle is sold to the public, the editor of *Truth* continues:

Sulphurous acid has, I believe, germicidal properties, but the claim that when a weak solution of this substance is swallowed it enters into the blood stream, and thus is carried into every tiny blood-vessel of the lungs to attack the germs of the disease on their own ground, is preposterous on the face of it and demonstrably false. In fact, any solution of sulphurous acid strong enough to destroy bacilli *in vitro* would, like many other bactericides, do as much damage to the tissues as the bacilli themselves. Its use as a quack nostrum is not even novel. Ten years ago a similar preparation was widely advertised in this country under the name of "Liquozone." In that instance it was offered to the public as a cure for all germ diseases. Cassell and Co., "the great specialists," are, I understand, a father and son who are vendors of a number of quack remedies. They rent a couple of rooms in a provincial town which they call their "laboratories," and where they carry on their correspondence and pack up the bottles of stuff dispensed for them by a local firm. Thence they start an advertising campaign, the sole end and aim of which is to get sufferers from an insidious and too often fatal disease to waste their money on a worthless nostrum.

Truth concludes its article by calling attention to the fact that one of the recommendations of the Select Committee of the House of Commons on Patent Medicines was that advertisements of medicines purporting to cure consumption, cancer, and some other diseases should be absolutely forbidden. The foregoing facts clearly demonstrate, our contemporary considers, that such a prohibition is urgently needed. This, however, does not seem to be the opinion of the Chancellor of the Exchequer, who hopes to raise a quarter of a million a year by doubling the patent medicine stamp duty. It may well be asked whether it is statesmanlike to paler in this way with an evil which must cost the country in loss of health and life tens of millions a year. The British Medical Association, through its JOURNAL, through the two volumes *Secret Remedies and More Secret Remedies*,¹ published in 1909 and 1912, and by the evidence given on its behalf before the Select Committee, has thoroughly exposed the true nature of these businesses. The House of Commons knows the truth through the report of its own Committee, yet it greets with laughing applause the proposal to make a little more money for the State out of this trade. The Government preaches economy, but it does not even go so far as to adopt the recommendation that the nature of the ingredients should be stated on the wrapper of a nostrum. Then the economically minded members of the public would at least know that they were paying 4s. 6d. for a half-ounce of sulphurous acid, or 2s. 6d. for, say, a penny-orth of phosphoric acid, or still more for a few penny-orth of tincture of cinchona bark.

¹ *Secret Remedies: What They Cost and What They Contain; and More Secret Remedies: What They Cost and What They Contain.* London: British Medical Association, 423, Strand, W.C. (Price is each; postage, 3d. each.)

THE third Triennial Conference for the Study of Pellagra is meeting in the city of Columbia in South Carolina, where the conferences of 1909 and 1912 were held. About 175 members, including representatives of the United States Public Health Service, will attend the conference, over which Dr. C. H. Lavinder will preside.

British Medical Journal.

SATURDAY, OCTOBER 2ND, 1915.

HOSPITAL STAFFS AND THE WAR EMERGENCY.

THE War Emergency Committee, at its meeting at the house of the British Medical Association on September 27th, had a very interesting conference with representatives of hospitals in Manchester and Salford. As many of the points raised are exercising the minds of those, both lay and medical, who are responsible for the conduct of the great civilian hospitals in other centres, it will be useful to give some account of the difficulties as they were stated by Sir William Cobbett, Chairman of the Board of Management of the Manchester Royal Infirmary, and his colleagues who represented other hospitals in that great centre of population.

It may, perhaps, be convenient in the first place to state that Major Wilson, chairman of the Medical Board of the Royal Infirmary, said that the 2nd Western General Hospital (Territorial), the head quarters of which are in Manchester, has 3,000 beds in twenty-two different buildings in that town, and that in various other places within the area there were 7,000 more beds in auxiliary hospitals to which patients from the 2nd Western could be drafted, or which could in other ways be used to relieve any congestion there.

In stating the position in which the Manchester Royal Infirmary was, Sir William Cobbett said that it had altogether 974 beds, of which number 248 were now devoted to military purposes. The number of patients treated in 1914 was 13,000, the number of operations was 7,560, and the number of accident cases over 22,000. During the first nine months of this year 6,035 operations had been performed. In normal times the honorary staff numbered 33, including specialists in various departments, and the resident staff 23—namely, 19 at the infirmary, 2 at the central branch, and 2 at the relief hospital. At the present time 27 members of the honorary staff were doing military duty of some kind, and certain among them could not give any time to the infirmary. The resident staff now numbered 8—namely, 6 at the infirmary, 1 at the central branch, and 1 at the relief hospital. They were assisted by senior medical students varying in number from 16 to 20 at different times, who did very useful work, but had, of course, to be under constant supervision. The infirmary dealt with a large number of emergency cases, and for the treatment of such cases had to rely largely on three officers—the resident medical officer, the resident surgical officer, and the accident house-surgeon. These officers were all desirous of enrolling, and he looked forward with apprehension to their leaving at forty-eight hours' notice; in fact, if they did it would be impossible to carry on the infirmary. They desired to do their duty to the country, and if they were told they were serving their country by staying at the infirmary they would be willing to remain. There seemed to be three courses open: one was to leave the infirmary these officers; another was to extend the period of notice from forty-eight

hours to two or three months; and the third was that students newly qualified should be sent to the infirmary to gain experience before being commissioned. It was not business to waterlog the civil hospitals if an arrangement of one of the kinds he had indicated could be made. The three resident officers of the Royal Infirmary who had been mentioned—the resident medical and surgical officers, and the accident house-surgeon—had to be constantly available to meet emergencies, and now more than ever when so many of the honorary staff were engaged in military duties; they were doing work which could not be delegated to general practitioners. Mr. Armitage, who spoke for the Ancoats Hospital, said that it had 150 beds and was situated in the middle of the workshop district of Manchester. In normal times it treated some 20,000 accidents a year and had a resident staff of three, or sometimes four; at present it had two residents, a resident medical and a resident surgical officer; of its visiting staff of three physicians and three surgeons it now had the services of only one physician and two surgeons, and this physician and one of the surgeons were attending also at a military hospital. Dr. Hopkinson, treasurer of the Salford Hospital, said that it now contained 240 beds, more than half of them occupied by soldiers. Every member of the visiting staff was engaged on military duties more or less completely, and all the residents were locum-tenents who held office for short periods. He suggested that no resident should be called away from his hospital until he had served for three or four months. Captain Donald, speaking for St. Mary's Hospital—which really consists of two hospitals, a maternity which admits as many as 115 cases in a month, and a gynaecological hospital—said that of its visiting staff of eight, four were now serving in a military capacity, and whereas in normal times it had seven residents, it now had only two—one in each hospital. It drew its patients from a wide district surrounding Manchester, and most of the maternity cases admitted were difficult. He estimated that the civil hospitals of Manchester, taken together, required, in order to ensure reasonable efficiency, from ten to twelve competent young men as residents.

In the discussion which ensued, Dr. Verrall observed that in some of the smaller provincial towns the hospitals were unable to obtain any residents, and Mr. Bishop Harman expressed the opinion that the civil hospitals had now to face the possibility that in the not distant future every doctor of military age would be required for military service; the way to meet this position would be that, as in ordinary military hospitals, some member of the visiting staff should undertake to act as orderly officer for a day at a time and spend the whole twenty-four hours within the hospital. This had already been done at the West London Hospital, which in normal times had twelve residents, and now had only one. Major Galloway stated that at Charing Cross Hospital, to which he is senior physician, the resident medical officer was a man above military age who had been in general practice. As, in order to deal with surgical emergencies, a hospital must have an operating surgeon in constant attendance, he agreed that it might be necessary for members of the visiting staff to undertake to be on duty for twenty-four hours in rotation. The object of the War Emergency Committee in asking medical men of military age to enrol was that it might be able to advise as to those who could with the least difficulty be spared from civil duties. The War Office had agreed that in hospitals with medical schools a newly qualified man might be

given an honorary commission in the R.A.M.C. and seconded for service for three months as house-physician or house-surgeon. After Mr. E. B. Turner had pointed out that a man who signed the enrolment form was invited to state the date after which he would be ready to go, Dr. Buttar, who was in the chair, thanked Sir William Cobbett and his colleagues for their attendance, and expressed the hope that a War Emergency Committee would shortly be formed in Manchester, and would be able to deal with some of the points raised. Having regard to the call upon the younger members of the profession, it seemed very desirable that the Manchester hospitals should, if possible, liberate some of their residents by obtaining the services of general practitioners, especially for the treatment of out-patients.

In reply to the question whether the military hospitals in Manchester were overstuffed, Major Wilson said that they were not if the hospitals were full, and Professor Donald added that he believed that the average number of military beds under the care of each man doing such work was over 200. This last point, we know, is one that has caused concern to many practitioners, both those who have and those who have not been called on to do duty at the military hospitals in this country. But it is obvious that the state of the hospitals in respect of numbers of wounded under treatment must echo what is happening at the front. For months past there has been, as the saying is, "little doing" in Flanders, but the successes of the last few days have had to be paid for, and already a good many convoys have reached this country and have been distributed, some of them as far as Scotland. One convoy of one hundred, one-third of whom were lying-down cases, were admitted from France into the Edinburgh War Hospital at Bangour on the evening of September 21st, and on the following day one hundred cases reached the Springburn Hospital at Glasgow from the Dardanelles. Many other and larger convoys have arrived—and will be arriving for some time to come—in Great Britain. No one will dispute the claim of these men to immediate surgical attention.

Sir James Barr has written a pungent letter to the West Jersey Board of Guardians, Liverpool, in which, after admitting that the guardians must have difficulty in carrying on their medical work, he says that "this is really not the question for the country now. Everything should be viewed from a military point of view, and the medical care of the civil population must be placed a long way behind that of our fighting men. I hold that all the medical work in the country can be carried on by medical men over military age, and that the young medical men should be set free for foreign service. We must get medical men for the armies that are going abroad; 2,500 are at present required, and only young men can stand the fatigues of a long campaign." The guardians, he urges, ought to get men over military age either for part-time or whole-time service to do the work of the younger men until the war is over, and thus "give them an opportunity of rendering such service to their country as they will never have the chance of doing again." He concludes his letter in the following words: "The War Office has got a large number of medical men from Canada, Australia, and New Zealand, and if this country cannot now produce the men necessary there will be no course open but to apply to the U.S.A. to fill up the necessary complement."

We have received several letters raising various other points, with which we hope to deal in an early issue.

GUNSHOT WOUNDS OF THE HEAD.

THE surgery of war is, alas! receiving ample illumination from experience at the present time, as is illustrated by the three surgical articles with which this number of the BRITISH MEDICAL JOURNAL opens. Our surgeons have been quick to take advantage of the opportunities for study thus offered to them, and the result has been manifest for many months past in the steady flow of valuable original articles published in our columns and in those of some of our contemporaries. Dr. Gordon Holmes and Mr. Percy Sargent, in a paper published this week (p. 493), draw attention to a new type of vascular lesion in the brain, a type brought into prominence by the large number of glancing or shallowly penetrating wounds about the vertex of the skull that have to be dealt with. These injuries result in thrombosis of the superior longitudinal sinus and of its associated lateral venous lacunae and the superior cerebral veins connected with them; in addition, there may be gross injuries of the adjoining cerebral tissue.

Naturally the symptoms and signs vary much with the location and severity of the injury received. Their outstanding features, however, consist in the unusual distribution and type of the palsy induced, in the muscular rigidity always associated with it, in the curious disturbances of sensation observed, and in the relatively slight extent to which the sphincters are involved. As regards the paralysis noted, it was found that out of 78 patients 20 had all four limbs involved, 31 had both legs and one arm affected, 16 had only the legs paralysed; in 6 the signs were mainly hemiplegic, and in 5 one leg alone was touched. The hands were less severely affected than the arms, while the feet were more paralysed than the legs—a most unusual feature when comparison is made with the cerebral palsies commonly met with in civil practice. As the authors point out, this curious distribution finds its natural explanation in the anatomical disposal of the motor centres for these distant parts of the body in the cortex of the brain. The muscular rigidity of the paretic limbs is described as very striking; it occurs early, is generally co-extensive with the paralysis, and usually diminishes in proportion as the power of spontaneous movement returns. Even the muscles of the trunk may be involved, so that the abdomen is rigid and the respiratory movements become feeble. In certain instances reflex spasms have been associated with the rigidity, and in ten patients fits were observed, unilateral in eight instances; the reflexes are increased, and Babinski's sign is present. The sensory changes found are said to be those of pure cortical lesions unaccompanied by any shock effect, as, indeed, is the case with the motor symptoms.

The clinical picture is so novel that the authors hasten to christen it with the title of the "Longitudinal sinus syndrome." It is satisfactory to learn that most of their patients recovered. It is too early yet to give figures that can be regarded as final; only one patient died out of thirty-seven that were not operated upon, while out of thirty-nine on whom operative procedures were taken fifteen died, seven of the fifteen having also some direct injury of the brain. The authors remark on the difficulty of deciding upon the line of treatment that should be adopted in these cases of injury to the superior longitudinal sinus; they characterize the results of surgical interference as extremely unsatisfactory, and emphasize the tendency of cases uncomplicated by laceration of the brain to improve spontaneously. Yet in many cases operation is indicated for fear of septic infection and other

complications, as is set out by Captain Roberts (p. 498), who gives figures proving the remarkable success attending the treatment of soiled and septic scalp wounds on the lines indicated by common sense and the requirements of aseptic surgery. Captain Roberts urges once more, as so many have done before him, that gunshot wounds of the scalp should not be probed. The probe is a deadly weapon here, as it may readily convey a superficial infection into the depths of the wound. He recommends excision of the scalp wound, and of the injured bone beneath it if need be; if the dura mater is uninjured the operation would be sutured and closed without drainage. He reports that out of 118 cases in which this primary suture without drainage was practised, 114 healed by primary union, and only one broke down altogether. Like Captain Tabuteau (p. 501) he recommends that all foreign bodies within reach of the exploring finger should be removed from the brain when that has been penetrated. Captain Tabuteau, on the strength of an experience based upon 95 cases, puts forward a plea for the most thorough surgical examination of every case of gunshot wound of the head, no matter how trivial the injury may be at first sight. The wound should be excised, and the underlying tissues submitted to the most careful scrutiny. A comparatively small wound in the scalp may overlie extensive fractures of the skull and severe lacerations of the brain, a condition of affairs that calls for immediate and thorough surgical investigation. In other instances the contrary is the case, and an apparently severe scalp wound may be associated with no intracranial damage whatever. When it is found that the dura mater has been torn, a digital exploration of the lesion or track in the substance of the brain should be made. Naturally, much help may be gained here by use of the x-rays, when penetrating fragments of metal or bone will be brought into view. Like Captain Roberts, he recommends the administration of urotropin (1 or 2 drachms a day) to patients in whom a fracture of the skull is even suspected. It would be interesting to know how far such internal medication is actually capable of preventing or cutting short intracranial sepsis. The amount of the drug or of its products of decomposition that reaches the cerebro-spinal fluid must be almost infinitesimal.

THE MEDICAL MAN AND THE BUDGET.

A SUMMARY of Mr. McKenna's Budget speech and some specimen income-tax rates on the new scale were published in our issue of last week (p. 480), but in view of its importance we make no apology for returning to the subject in order to discuss the proposals from the point of view of the profession generally.

Modern theory accepts as the chief canon of taxation "equality of sacrifice," and the Budget appears to constitute a successful attempt to achieve that equality; but the sacrifice demanded is no light one. Earned incomes between £700 and £1,000 will under the full operation of the new rates yield to the Exchequer over 10 per cent. as against less than 4 per cent. before the war, and in the case of smaller incomes the rise is relatively even greater, the effect of the all-round increase in the nominal rate of tax being accentuated by the reduction of the abatements of £120 and £150 to £100. These high rates of taxation are accepted by the nation almost without demur, primarily for the simple but sufficient reason that the State urgently requires the money, but also

because in various and rather intricate ways the ultimate effect of those rates is modified with a view to rendering the incidence of the tax more equitable. The claiming of those modifications is, speaking generally, left to the initiative of the taxpayer, and it becomes more than ever desirable that he should understand in what circumstances and to what extent relief is to be obtained.

With the more ordinary forms of relief—namely, in respect of "earned" income, life assurance premiums, and children—our readers are doubtless already familiar, but recent and proposed legislation provides two additional modes of adjustment which are deserving of careful examination.

The dislocation in the professional and industrial world caused by the war has in individual cases rendered the method of assessment by the "three years' average" distinctly harsh. One attempt has already been made, in the Finance Act, 1914 (Session 2), to provide the taxpayers concerned with an equitable remedy, and the Chancellor of the Exchequer has now announced that further provisions will be enacted for the same purpose.

In order to make the proposals clear, it is advisable to explain the effect of the provision already in existence, the more so as the question involved is of special interest to the large and increasing number of practitioners who have accepted commissions in the Royal Army Medical Corps. The hardship inflicted by the three years' average assessment in such cases needs little explanation. If a practitioner, on receiving his commission, can obtain the services of a suitable locumtenent, the receipts of the practice may be maintained, but the expenses will of necessity increase very considerably, and on the other hand, if his partner carry on the practice single-handed, the expenses may conceivably be reduced, but the receipts will almost certainly be reduced still more; in either case the net income of the practice will in all probability fall below the average of the three previous years, and income tax will be assessed not only on the army pay which the officer does receive, but also on civil profits which he does not receive, the extent of the deficit varying according to circumstances such as those indicated above. This hardship was felt the more keenly because officers of the medical service of the Territorial Force now mobilized and serving receive less pay than during an ordinary camp training, and less also than the junior medical officers holding temporary commissions for the duration of the war. The effect of Section 13 of the Finance Act, 1914 (Session 2), is to give an officer the right to claim an adjustment—by way of repayment or otherwise—of his liability from the average to the actual profit of the year of assessment, or, in the case of a firm, to his share thereof. This provision may be invoked by any person serving in the forces of the Crown, or in the British Red Cross or St. John Ambulance service abroad. So far as can be ascertained at present, those lean years will still be available to supply the average basis of assessment in the future when the military service has expired, so that this statutory concession will ultimately bring substantial relief to those in a position to take advantage of it.

The Chancellor has now intimated that the Finance Act, in which the Budget proposals will find their legal force, will provide a special means of relief to all persons whose incomes have been sufficiently reduced to bring them within the scope of the relief. He said: "The whole of the additional duty will be repayable in the event of any individual proving that his actual income from all sources for the year is less

by one-fifth than the income on which he has paid income tax. . . . It is proposed . . . that where the deficiency does not amount to one-fifth, but is more than 10 per cent., repayment of a proportionate amount of the additional duty will be allowed." An example will perhaps make the effect of these proposals clearer. A is a medical practitioner assessed to the tax at £800 on the average of the three previous years, and his actual profits for the year of assessment have fallen to £625. If he has no other income, it is clear that his income is less by one-fifth than the income on which tax has been paid; he is therefore within the scope of the relief, and can claim repayment of the additional tax imposed by the present Budget. On the other hand, if he has other income—for example, dividends or army pay—the percentage reduction will be less, and he may be entitled to repayment of a proportionate amount only, or possibly to no repayment at all. It is fairly clear that though this provision will be of substantial benefit to taxpayers in trades and professions which are suffering acutely from the war, the medical profession as a whole is not likely to be in a position to derive much relief from it, and that it will certainly not supersede the already existing mode of adjustment under the Finance Act, 1914 (Session 2).

An interesting feature of Mr. McKenna's speech was his explanation of the new system of payment of income tax by instalments. The half-yearly system will apply "to individuals and firms who are liable to direct assessment in respect of trade, profession, or husbandry." Public companies are apparently to be excluded, and the system is to apply to tax assessed under Schedule D only. The medical practitioner will clearly be within the arrangement, and as a professional man certainly has a good claim to any advantage which a system of half-yearly payments may carry with it. For the current financial year the tax payable in January is to be calculated on the existing rates, leaving the additional taxes to be collected in July of next year, this temporary arrangement constituting an instalment of the half-yearly system. In this connexion it appears to us to be a matter for regret that, as in the case of the proposed relief for diminished total incomes, adjustments are frequently required to be made by way of repayment. Inasmuch as the additional taxes will not be collected till July, it is obvious that by that time applicants for relief will, as a rule, be in a position to substantiate their claims. It seems strange that in such cases they should be required to pay duties which are then provably returnable to them. Possibly by the time the Finance Act receives the royal assent this anomaly may have disappeared.

Mr. McKenna further announced that for "employees of all descriptions both assessment and collection will be quarterly." Such a system is clearly desirable in the case of workmen on daily or weekly rates of pay, but "employees of all descriptions" is a phrase capable of a very wide interpretation and may be held to cover medical men holding various appointments. Doubtless the precise scope of the proposed quarterly system will soon be made clearer, but in the meantime we may remark that its application to persons holding professional appointments will probably be regarded by them as a doubtful benefit.

In the other chief sources of direct taxation, as, for instance, in the war profits tax, a medical man as such is not interested, but the proposals for additional indirect taxation will not leave him unaffected. The increase of the petrol duty by 3d. per gallon will be felt by a very large number of taxpayers, and the

more so as the increase in the duty may be expected to afford an occasion for a more than equivalent rise in the retail price. Taken in conjunction with the 33½ per cent. *ad valorem* duty on "imported motor cars, motor cycles, and parts thereof," the increased petrol tax must substantially add to the cost of motoring. Where the car is run for pleasure no reasonable complaint can be made, but the case of a country practitioner with a scattered practice is an unfortunate one. At the same time, we may perhaps point out that the motor car undoubtedly fills a very much larger place in the commercial world than when the petrol tax was first imposed, so that if the medical man be in this respect unfortunate, he may extract some consolation from the reflection that on this occasion he has more companions in distress, and that the yield of the tax from which he suffers is correspondingly increased to the advantage of the Exchequer. We assume that the rebate "of half the amount of duty paid" now allowed in accordance with Section 85 (1) of the Finance (1909-10) Act, 1910, will be extended to the further duties to be imposed; this will give the general practitioner an increased interest in preferring such claims.

In closing his speech, Mr. McKenna wisely emphasized the importance of individual economy, saying that "we accept the burdens of taxation partly because they limit our power to consume." In the medical profession, at least, the limitation of individual consumption will be a necessary consequence of the enactment of the new proposals. Heavy as the burdens to be imposed undoubtedly are they will be shouldered in no complaining spirit, but with a cheerful recognition of the necessity for individual self-denial and sacrifice.

WORKSHOP FATIGUE.

PROFESSOR STANLEY KENT'S contribution to the study of fatigue in factories, just issued by the Home Office as a white paper,¹ has aroused considerable interest. The importance of the subject is at all times very great; it is now of supreme importance. That the Minister of Munitions has realized this is shown by his appointment of the Committee on the Health of Munition Workers. Mr. Sergeant Florence presented at the Manchester meeting a valuable report on fatigue to the special committee appointed by the British Association. In it he dealt very fully with the relation of the incidence of accidents to fatigue; accidents were found to increase in the later hours of the shifts, and he suggested that fatigue was the cause, the worker being then less wide awake to danger. Professor Kent has examined various methods of testing fatigue. He has used the ergograph, first exhausting the subject for the particular movement recorded, and then finding what recovery takes place after five minutes' rest. The recovery may be less at the end of the day than it is at the start. Another method used was the reaction time in a complicated form; one or other colour was momentarily exposed, the subject was required immediately to make a signal corresponding to the colour seen, and the time interval was measured. The methods on which he chiefly based his conclusions were a test of visual acuity by Snellen's types, and one of auditory acuity by the watch. He measured also the blood pressure. Using these methods, he brings forward some evidence which tends to show that the workers become fatigued toward the end of the week and recover again by Monday. The number of tests are too few to be decisive, and we are not convinced of their value as a proof of diminution of the worker's efficiency owing to fatigue. The real

¹ Interim Report on an Investigation of Industrial Fatigue by Physiological Methods. Cd. 8055. Price 43d.

test of that is output of work. A man's auditory acuity may and is fatigued by the noise and clang of the machinery, his visual acuity may be lessened by artificial lighting of the shop, and yet his output may be unaffected. There may be a fatigue of higher cerebral centres, and yet lower centres may carry on the reflex habitual acts of a man's trade. So, too, in the matter of accidents. The increase of accidents in the later hours of the shift may be due to diminished alertness of mind, and yet the reflex work may continue to be perfectly performed. The real test for the munition workers is their output, and here we come upon great difficulties, for output in the past has been restricted by trade union customs. A man did as much piece work as he was willing to do for the money offered. The employer cut the price partly for the reason that the worker would not work six days a week if he could earn in three days all the money he found opportunity to spend. The inducements to the worker to spend in ways which will increase his pleasure, happiness, and health need to be enlarged; to secure a larger output, desires must be given him, opportunities for amusement, homes and gardens which he will crave to adorn, holidays he can work for; his wife and children must stimulate him to aim at improving their lot. These, and ambition, are the aims with which most men in the professional classes work. In the munition works the new hands are out to make money while the war lasts, and will not be bound by the old conventions; the old hands are pushed into doing more. The result is, that on a twelve hours shift, and one Sunday off a fortnight, more work is done than on an eight hours shift. The evidence seems to show that the longer a man works the more he will turn out, but manifestly this is absurd. What we want to know is how much will be turned out on the old eight hours shift by men who do their utmost. The evidence derived from scientific management in America goes to show that output is improved by the shorter hours; the high rate of war pay instituted by the Government is, we believe, in some cases limiting output, because the workers have not the opportunity to spend and therefore have no sufficient stimulus to earn more than a certain amount. Give a man a great object of desire to live and work for and his output will go up by bounds. If the chief desire of many at present is to slack and take it easy, we may appeal to their patriotism and manhood, but it is useless to indulge in denunciation, for we have to remember that the housing conditions and confined city life imprison the spirit, and debilitate the energy of millions. War brings the inevitable retribution of the neglect of the governing classes to develop manufacturing England on hygienic lines. The slum and its gin palace, and the scramble to get rich must now be paid for in life and treasure.

MEDICAL STUDENTS IN THE WARS OF THE FRENCH REVOLUTION.

In connexion with the suggestion put forward by Dr. J. E. Robinson, in a letter published in the BRITISH MEDICAL JOURNAL of September 25th (p. 488), that medical students of eighteen months' standing and upwards should be utilized as military surgical assistants, it may be interesting to recall how students were enrolled by the first French Republic for military and naval service in the wars of the Revolution. In its eagerness to destroy every foundation forming a link with the *ancien régime*, the Legislative Assembly dissolved the old faculty of medicine of Paris in 1792; in the following year the Convention swept away the Society of Medicine and the Academy of Surgery, together with the seventeen provincial faculties and fifteen colleges of surgery. It was not long before the fruits of this blind fury of destruction became manifest. The Republic, at war with the whole of Europe, soon found itself in pressing need of surgeons. In eighteen months six hundred medical officers had died on

the battlefield or in the hospitals. The sources of recruiting having been dried up, it was recognized by the wiser minds among the revolutionaries that new institutions for the teaching of medicine must be established to replace the suppressed faculties. Accordingly, in 1794, schools for the training of doctors for the army were created in Paris, Montpellier, and Strassburg. In the meantime medical students were compelled to serve with the forces on land and sea, and in this way many of the men who rose to celebrity in the first half of the nineteenth century spent a part of their student career on active service. Larrey, when scarcely twenty, was surgeon-major on board a frigate; Broussais was a surgeon of the second class in a sloop; Récamier, whose name is associated with the vaginal speculum, was taken from his studies when he was barely twenty and sent to sea as assistant surgeon. These and many others received commissions as *officiers de santé* and took their degrees on the completion of their term of military or naval service. Their training does not seem to have suffered from the interruption of their studies. On the contrary, one may gather that the position of responsibility thrust upon them at an early age bred a quality of hard-bitten self-reliance and a resourcefulness which greatly helped to make them successful practitioners when they returned to civil life.

THE GERMAN CAMPAIGN AGAINST LICE.

In spite of many precautions, the Germans appear to have lost many men from typhus. Among its victims are Jochmann and v. Prowozek, whose claims to distinction, curiously enough, were largely based on their investigations on typhus. The measures adopted to stamp out the disease include the conversion of large factories, notably sugar factories, into stations for disinfecting soldiers and their clothing. Some of these are large enough to cope with 12,000 to 15,000 men with their clothing every day. The men are thoroughly washed with soap in baths, while their clothing is disinfected by steam, and leather articles by dry heat. In many prisoners' camps experiments have been carried out with a view to ascertaining the cheapest and most effective way of destroying lice, and Professor Galewsky has given¹ the following account of his experiments in a prisoners' camp in Königsbruck. A building, used by Russian prisoners, nearly all of whom were infested with lice, was selected for the first experiment. All cracks, crannies, and corners were washed with a 3 per cent. solution of kresol soap, and were then filled up. The clothing was hung up loosely, with the exception of a parcel of shirts, which were tied into a firm bundle. In this building, the floor of which measured 450 square metres, 25 kilos of sulphur were burnt in 16 sulphur stoves. The burning proceeded rapidly, and reached its maximum in 45 minutes. After three hours the doors and windows were again opened, and two hours later the building was occupied by the prisoners, who had meanwhile been washed. The lice and their eggs were found to have been completely destroyed, except in the tightly-packed parcel of shirts. The sulphur stoves used were made on the principle of a Bunsen burner, and the sixteen cost only 300 marks. Experiments carried out by Oberapotheker L. Schlesinger showed that lice and their eggs were killed in two hours by sulphur dioxide vapour, but only in two hours and a half or more by formaldehyde, which was also inferior on account of its irritating smell. Dry heat was sufficient to kill the lice and their eggs in one hour, provided the clothing was hung up loosely. But the dry heat sterilizer used could only accommodate the clothing of fifteen men at a time, and it also had a deleterious effect on leather. The conclusions to which most German investigators appear to have come are that sulphur vapour is the simplest and cheapest as well as the most reliable agent for the destruction of lice and their eggs in clothing and buildings.

HIBERNATION AND THE PITUITARY BODY.

THE prolonged sleep characteristic of hibernation in winter latitudes, and of aestivation in tropical and arid regions, has never been satisfactorily explained. Hibernation has been very generally attributed to two extracorporeal factors—namely, a low external temperature and a diminished food supply. But there is good reason for believing that certain other factors of intracorporeal origin, best summed up in the intentionally vague term "pluriglandular insufficiency," are even more important in the causation of seasonal sleep. A recent paper¹ by Professor Cushing and Dr. Goetsch draws attention to the part played here by the activity or quiescence of the pituitary gland. It has often been noted that the experimental removal of the pituitary body leads to a state of profound lethargy and coma that soon ends in death, producing a cachexia somewhat ponderously termed "cachexia hypophyseopriva." It was observed that injections of pituitary extract would ward off the onset of this cachexia in certain cases. In animals in which the experimental removal of the gland had been incomplete, survival was characterized by adiposity and loss of sexual activity, imitating the syndrome described by Frölich in human beings as "dystrophia adipogenitalis." Drowsiness and even lethargy are seen in both these experimental animals and the human beings exhibiting Frölich's syndrome. Cushing himself has recorded several cases in which extreme torpor was associated with clinical hypopituitarism, and was relieved by the administration of pituitary extracts. It is therefore argued that hibernation may well be due to a wave of seasonal pituitary inactivity, no doubt with similar inactivity of others of the ductless glands as well. Cushing and Goetsch bring forward experimental evidence to show that the North American marmot or woodchuck (*Arctomys monax*), examined in the dormant state, bears out this contention. During hibernation many of the ductless glands exhibit histological changes of a regressive character, as was pointed out in 1906 by Gemelli, and the most notable of these changes are seen in the pituitary body. The gland diminishes in size, the cells of the anterior lobe lose their characteristic staining reactions with acid and basic dyes in certain animals. When hibernation ceases the gland returns to the waking normal, and karyokinetic figures may appear in its cells, which once more appear well differentiated in stained sections—a point made plain in the microphotographs published by these authors. They conclude that hibernation may be ascribed to a seasonal physiological wave of pluriglandular inactivity, and attribute the essential part here to the pituitary body. Not only do the most striking histological changes appear in this structure, but also deprivation of the secretion of this gland alone of the entire series of ductless glands produces a group of symptoms comparable to hibernation.

NEED FOR DENTAL AID TO THE POOR.

ON September 13th the City Coroner held an inquest on the body of a hansom cab driver who had been choked by a large piece of unmasticated beef while eating at a cocoa bar. The man was edentulous except for two stumps on opposite sides of his mouth. In addressing the jury the coroner (Dr. Waldo) drew attention to the dangers of septic teeth, and to the difficulty necessitous people must have in obtaining artificial substitutes. He recalled that two years ago a sum of £5,000 had been given in trust to St. Bartholomew's Hospital to meet this difficulty in the work of the institution, and expressed a hope that an endowment for the same purpose might some day be made to Guy's Hospital. He had, he said, reason to believe that the gift to St. Bartholomew's Hospital was in great measure due to the report of a somewhat similar inquest he had held, and he would like to see the other general

hospital within his jurisdiction similarly benefited. That the City Coroner should use his office publicly to make such an appeal is sufficient evidence of the merits of the case, and it is an appeal which every medical man will endorse. It is often extremely difficult, or even impossible, to induce a patient to part with his own teeth, however foul and poisonous, without the promise of replacement, and many need no other treatment to restore them to health and usefulness. The gift to St. Bartholomew's Hospital has been a great boon, and the extra work entailed has been cheerfully undertaken by the dental staff. We have no doubt that Guy's Hospital would welcome a similar endowment.

CURIOSITIES AND DEFECTS OF SIGHT.

IN a lecture delivered to working men and working women at the Manchester meeting of the British Association last month, Professor Stirling gave a most interesting account of the eye as an optical instrument. Illustrating his remarks with lantern slides of experiments and by cinematograph films, he described the developmental evolution of the eye, and the pitch of perfection to which it has attained in man. For the purposes of our daily life it is indeed a product of singular perfection, and it has been recognized as such from very early days in the history of literature. Professor Stirling described the human eye as a tenfold instrument, and catalogued its separate functions as follows: (1) Microscope, (2) telescope, (3) camera, (4) range finder, (5) photometer, (6) self-adjusting lens, (7) automatic diaphragm, (8) autochrome camera, (9) cinematograph, (10) stereoscope. Little reflection is needed to show that here we have one of Nature's most successful *multum in parvo* instruments. Nearly fifty years ago Helmholtz waxed positively dithyrambic in describing its perfections. "Of all our members," he wrote, "the eye has always been held the choicest gift of Nature, the most marvellous product of her plastic force. Poets and orators have celebrated its praises; philosophers have extolled it as a crowning instance of perfection in an organism; opticians have tried to imitate it as an unsurpassed model. And, indeed, the most enthusiastic admiration of this wonderful organ is only natural when we consider what functions it performs." Such eulogy is well deserved; yet there is another side to the shield, and if it is considered coldly as an optical instrument, the eye has visual defects that cannot be passed over in silence. Here again Helmholtz may be quoted, for he speaks in no uncertain tones: "The eye has every possible defect that can be found in an optical instrument, and even some that are peculiar to itself. . . . it is not too much to say that if an optician wanted to sell me an instrument which had all these defects, I should think myself quite justified in blaming his carelessness in the strongest terms and giving him back his instrument." But we live in an imperfect world, and have to put up with compromise when perfection is unattainable. It is in compromise that Helmholtz saw the chief virtues of the human eye considered as an optical instrument; and so he qualifies his severe strictures, quoted above, by continuing as follows: "Of course, I shall not do this with my eyes, and shall be only too glad to keep them as long as I can, defects and all. . . . The eye in itself is not by any means so complete an optical instrument as it at first appears; its extraordinary value depends upon the way in which we use it. Its perfection is practical, not absolute, consisting not in the avoidance of every error, but in the fact that all its defects do not prevent it from rendering us the most important and varied services." In his lecture Professor Stirling described the importance of the care of the eyesight during infancy and school life, the use of spectacles for correcting errors of vision, the nature of colour vision, and the importance of tests for colour-blindness in the selection of those who have to recognize colour signals at night on land and sea. To emphasize the many points he

¹ *Journ. Experim. Med.*, New York, 1915, xxii, 25.

wished to make he has published a pamphlet containing some hundreds of quotations and some scores of illustrations bearing on the eyes and their uses. Here the reader will find the structure of the eye explained in popular terms, and may see portraits of the chief men of science who have explored the mysteries of its functions, from Descartes to Argyll Robertson. The quotations are drawn from the writing of all ages and many countries, and form a highly instructive series.

DIAGNOSIS OF TYPHOID AND PARATYPHOID INFECTIONS.

In order to ensure uniformity of observation and co-ordination of the results obtained by pathologists and bacteriologists at different military hospitals the Medical Research Committee has arranged for the preparation and supply of sterilized standard agglutinable cultures and standard agglutinating serums for the diagnosis of typhoid and paratyphoid infections by means of macroscopic agglutination tests. The standards are prepared under the direction of Professor Dreyer, and can be obtained free of charge by pathologists working in connexion with military hospitals from the Standard Laboratory, the Department of Pathology, University of Oxford (telegraphic address: "Pathology, Oxford"). To facilitate the preparations of agglutination tests under service conditions or otherwise, a special outfit has been prepared; it can be obtained free by pathologists working for military hospitals from the Medical Research Committee, St. Stephen's House, Westminster, S.W., or may be purchased from Messrs. Baird and Tatlock, 14, Cross Street, Hatton Garden, E.C., price 4s. 6d. The methods proposed and the standardized cultures and serums are already in use at the chief military hospitals engaged in work upon enteric fever cases and carriers with the Expeditionary Force and at home.

EXHIBITION OF FRACTURE APPARATUS AT THE ROYAL SOCIETY OF MEDICINE.

The exhibition of fracture apparatus will be opened at the house of the Royal Society of Medicine, 1, Wimpole Street, on Friday, October 8th, at 3 p.m., by Sir Alfred Keogh, K.C.B., when Colonel Sir Almoth Wright will deliver an address on his recent work dealing with wound infections. He will give demonstrations on that day and on Saturday, October 9th, and Monday, October 11th. Various forms of apparatus found most useful in this war will be exhibited and demonstrated by officers of the R.A.M.C. serving in France and by those attached to base hospitals in England. Officers in London who desire to contribute to the exhibition should communicate with Colonel Fagge, 3, Devonshire Place, W., and others with the consulting surgeons for their command. The exhibition is being arranged by a committee consisting of Lieutenant-Colonel Charles H. Fagge, M.S., Lieutenant-Colonel F. F. Burghard, M.S., Major Robert Jones, F.R.C.S., and Mr. J. Y. W. MacAlister, who is acting as honorary secretary for the committee. The exhibition will be open from 10.30 a.m. to 5.30 p.m. on Saturday and Monday, October 9th and 11th. Medical men who are not Fellows of the society will be admitted, and representatives of firms of surgical instrument makers will be admitted to the exhibition, but not to the lectures, by special tickets issued by the secretary. Visitors will be admitted on Sunday, October 10th, from 10.30 a.m. to 1 p.m., and from 2 p.m. to 5.30 p.m. on presentation of their visiting cards, but no demonstrations will be given.

A NUMBER of sailors on the interned German steamships at Hoboken have suffered from diarrhoea, and for a time it was suspected that some of the German refugees from China who had been cared for on these ships might have carried with them the cholera bacillus, but a bacteriological examination proved that the patients were suffering from diarrhoea only.

Medical Notes in Parliament.

Income Tax and Medical Practitioners' Book Debts.—Sir Hildred Carlile asked the Chancellor of the Exchequer, on September 22nd, whether surveyors of taxes were directed, when making an assessment for income tax, to add to the proved incomes of the medical profession one-third, or indeed any part, of the value of any book debts which might be standing in their books, and which they might never succeed in recovering; and, if so, on what grounds such additions were allowed to be made. Mr. McKenna said that no instructions of the nature suggested had been issued. In the case of medical men, as in other cases, any sum for book debts which had been included for income tax purposes in the profits of any year was, of course, excluded from the profits of the year in which the debts were paid. Should the debts prove to be irrecoverable, they would be allowed as a deduction from the profits of the year in which they were subsequently written off.

Wounded Discharged from Hospital.—On September 23rd, in answer to Mr. Peto, Mr. H. W. Forster, Financial Secretary, War Office, said that with reference to soldiers discharged from hospital he did not think the proposal of appointing county boards to look after them was necessary. On discharge from hospital a soldier, if still requiring medical care, was sent to an auxiliary hospital, which was in the nature of a convalescent home, where he was carefully looked after and his full pay continued. If discharged on furlough to proceed to his home, he received a free travelling warrant and an advance of £1, together with his full pay and also allowances, varying from 1s. to 2s. a day, in addition to any separation allowance previously payable. If he was discharged as permanently unfit, it was the duty of the Chelsea Commissioners to assess and award a pension which varied with the degree of disability in accordance with the scale recommended by the Select Committee and adopted by the House. In the case of an unmarried man, in which no separation allowance was issued, he drew a special allowance of 2s. a day, in addition to his pay. In the course of a reply to another question by Mr. Peto on the same day, Mr. Tennant said that it was desirable, in the interests of the army, that soldiers who had been discharged from hospital as "fit for light duty" should be brought as early as possible up to the standard of "fit for duty," which was the sole object of the recent Army Order.

Military Mental and Nervous Cases.—Mr. Tennant stated, in reply to Mr. Touche, on September 21st, that military mental and nervous cases were treated in the neurological sections of twenty-three military hospitals in the United Kingdom. Accommodation for these cases was also afforded by the Springfield House Hospital, Wandsworth, and the Red Cross Military Hospital, Maghull, near Liverpool. Mr. Tennant informed Mr. Rendall on September 22nd that the subject of the disposal of the more serious mental cases had been receiving consideration, and had caused the authorities considerable anxiety. Owing to the increasing numbers of incurable cases, it would not be possible to continue indefinitely the system of retaining, under the control of the Secretary of State, cases of general paralysis, chronic epilepsy, and chronic insanity which had had previous asylum treatment. Such cases would in future be dealt with in the manner laid down in paragraphs 403, 404, and 408, King's Regulations. This new system would apply to the cases now under the Secretary of State's control in so far as they come within the three categories named.

Casualties in the Dardanelles.—Mr. Tennant informed Captain Amery, on September 28th, that the 87,630 casualties in the Dardanelles up to August 21st included those among the Australian, New Zealand, and Indian Forces.

THE WAR.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[From a Special Correspondent in Northern France.]

SCIENTIFIC MEETINGS.

THE Australian Commonwealth is well represented in France. An Australian hospital was one of the first voluntary medical units raised and equipped for work with the British Army in France, and to this hospital fate has assigned as officers' quarters the premises of a former golf club. This building, unlike any other turned to a like purpose in the area, possesses a very large room, and this fact has assisted the officers of this unit to play a very useful part in the medical life of the hospital base, and, incidentally, to satisfy their hospitable instincts.

Practically all the institutions forming the group are dealing with precisely the same problems, but the natural tendency among them is to do their work in watertight compartments. The fact that the D.D.M.S. and the consultants visit all of them in turn serves, in some measure, to link up their professional work, while individual members of their staffs may be old friends or new acquaintances, and dine with one another occasionally at their respective messes or billets. But, otherwise, and on the whole, there is very little communication between them. The hospitals are, for the most part, situated in hotels scattered over a very wide area, and there is no common resort at which their officers can meet when off duty. In addition, these officers are, as a rule, all busy at much the same hours, so that they cannot visit one another's hospitals at the only time when methods of treatment can be observed without disturbance of patients and nurses—namely, when the surgical work for the day is normally in progress.

To counteract the effect of these conditions the authorities do what they can to encourage the holding of meetings for the discussion of professional topics, but, on account of the lack of accommodation, it very rarely happens that any hospital except the Australian is able to make the necessary arrangements. As already indicated, the Australian Hospital has advantages in this respect, and it has turned them to excellent use. At fairly regular intervals throughout the last eight months—usually about every fourth Sunday—its officers have invited all other hospitals within easy reach to send two representatives, first, to take tea, then to contribute to a symposium on some given subject, and, finally, to discuss all things and sundry at an informal supper.

The subject of the symposium has always been some topic known to be specially occupying men's minds at the time, and the aim of the arrangements has been to secure not a debate but an exchange of experiences in respect of the endeavours made to solve the problem that the topic represents.

As a small contribution to the history of the war the titles of these topics and the order in which they have risen to the surface are perhaps worth putting upon record. The first subject was the treatment of compound fractures of the femur; the second, penetrating wounds of the chest; the third, cerebral injuries; the fourth, wounds of the abdomen; the fifth, gunshot wounds affecting the knee or other joint; the sixth, the treatment of cases of gas poisoning; the seventh, gunshot wounds of the head; and the eighth, the ideal treatment of infected wounds—a subject which had, incidentally, received attention at several previous meetings.

On one or two occasions the reading of a formal paper has formed part of the proceedings, but such contributions have been exceptional. As a rule, the outstanding points of the problem have been briefly outlined by one of the consultants, or by a representative of the hosts, and then each hospital in turn, in the order of its seniority in respect of the date of its establishment in the area, has been called upon to state what its experience in the matter has been and what measures have seemed to it most effective.

At the latest meeting the proceedings were of a different kind. The medical position at the moment allowed of the two ground-floor wards of the hospital being cleared of beds, and of the space thus provided, together with two

marques, being set aside for the day for the exhibition and demonstration of surgical appliances and devices deemed by the staff of any hospital in the area worth bringing to the notice of their colleagues. The greater accommodation available on this occasion rendered it unnecessary to limit invitations to two representatives from each hospital, and the result was a very large gathering and the transaction of a most useful afternoon's work.

The demonstrations were quite informal, each exhibit having its own little section of floor space allotted to it, and those who had devised or were using it standing by to explain the aims in view and the way in which they were deemed to be met by the appliance shown.

The exhibits numbered, in all, as many as 71, and were fairly equally divided between a fracture-apparatus class and a miscellaneous class.

The latter included a series of photographs and casts, as also one or two patients, shown to illustrate possible methods of dealing with gunshot wounds of the face when accompanied by comminuted fracture of the upper or lower jaw, or by more or less extensive loss of teeth and alveolar structure. There were also shown a table specially designed to facilitate the application of plaster-of-Paris splints and some ways of securing effective and continuous irrigation of wounds. The latter object presents a problem which, in the last few months, has received a good deal of attention, and one point that has to be borne in mind in connexion with it is the desirability of preventing the patient's clothing and bedding being wetted. Two methods of attaining this aim were in view; both depended mainly on building a coffer dam around the wound, the material employed being, in the one case, gauze moulded in formalin, and in the other putty and cotton wool.

The class formed by apparatus for dealing with compound fractures of the extremities was very large. It furnished ample evidence of the amount of thought and mechanical ingenuity that has been brought to bear on this subject, and as a whole perhaps suggested that it is injuries of the shoulder or involving the femur above the intertrochanteric line that are now proving most puzzling to splint experts.

But splints for the shaft of the femur predominated. All those described in the BRITISH MEDICAL JOURNAL during the past ten months, or to which passing reference has been made, seemed to be on view, together with a good many others. The number of thigh splints shown was, in fact, a little surprising, for it might have been anticipated that by this time one or two models would have crept into use to the practical exclusion of all others. At all events, in ordinary circumstances the probability would be that appliances which met fewer of the desiderata of a splint than did their rivals, or whose limited degree of utility could be obtained only by the exercise of extreme care, would drop out of use altogether.

The fact that they do not do so, or do so very slowly, may be attributed to several causes or even sets of causes. Into these it is not now proposed to enter, but they will form an interesting subject for some surgical war historian of the future. Meanwhile, however, it may be pointed out that the demands imposed upon splint inventors during the past ten months have gone through several phases which were all more or less well illustrated at the exhibition in question.

The first tendency was to regard immobilization of the fractured bone as the point of primary importance; the second was to set this aim entirely aside in favour of wound accessibility. In the third phase a desire for wound accessibility still predominated, but it was agreed that, quite apart from any consideration of late results, a certain degree of immobilization, whether obtained by extension or otherwise, was desirable in the interests of the wound cleansing itself.

The fourth phase was represented by a persistence of the preceding phase coupled with the claim that, besides allowing the most ample facilities for the treatment of any wound, and a means of applying extension to the fractured bone, a splint ought also to allow of a patient being sent upon long journeys without any disturbance of parts, even when suffering from a compound comminuted fracture of the femur.

The fifth phase was due to looking at the problem from

a somewhat different point of view. It was admitted that the splints of the preceding phase might be regarded as meeting all the positive needs of the situation very fairly; but it was considered that, from the point of view of nurses and patients, matters might, perhaps, be still further improved. The task of the nurse would be facilitated, and the comfort of the patient greatly increased, if the movement of the latter in bed were but very slightly hindered by the fact that he was wearing a splint. This phase became visible only comparatively recently, and despite the exacting character of the programme involved, it has led to the devising of at least one splint which goes a long way towards meeting the full specification. Moreover, the like effort has led, incidentally, to the improvement of splints belonging to the fourth phase, by showing how direct support may be obtained for the whole limb without interfering with their other aims.

As has already been indicated, it is not solely at the Australian Hospital that scientific meetings have been held. The officers of the Meerut Stationary succeeded in organizing, in the late spring, a very useful discussion on the nature and extent of the assistance that surgeons should expect from radiographers; and, quite recently, the results of the work done on the subject of paratyphoid fevers at No. 14 Stationary Hospital were described at a meeting at that hospital, and subsequently discussed by those present.

In addition, meetings for the discussion of scientific subjects have been a fairly regular feature of the medical life of Rouen during the last seven months, and there is reason to anticipate the holding of one or two of the same kind at one of the newer hospital bases.

THE SOUTH-WEST AFRICAN CAMPAIGN.

COLONEL P. G. STOCK, Director of Medical Services in South Africa, has issued a summary of the medical statistics of the Union Defence Forces for the period extending from the beginning to the cessation of hostilities in South-West Africa (August 18th, 1914, to July 9th, 1915). This summary is published in the July number of the *Medical Journal of South Africa*. The number of cases admitted to hospital from all causes was 28,882. The number remaining in hospital at the date of the report was 1,202; the number of officers and men transferred from ports in German South-West Africa to the Union base at Capetown in the hospital ship *Ebani* was 3,754. The admissions included 595 men wounded in action—namely, 277 during the rebellion and 318 in German South-West Africa; the number of cases of enteric fever admitted to hospital was 230, but of these only 69 are reported as having occurred in the area of hostilities; of the remainder, 48 occurred in the S.A.M.R. Training Dépôt, Pretoria, and can in no way be attributed to active service conditions. The average sick-rate during the German South-West Africa campaign was 3.21 per cent. The highest percentage reached during any period of one week was 4.18 per cent., and the lowest 2.59 per cent. Reliable figures are not yet available as to the number of troops in the field during any particular period of the rebellion, and sick rates for this period cannot yet be given. The total number of deaths from all causes to the cessation of hostilities was 415. This figure is made up as follows:—Killed in action: Rebellion, 98; German South-West Africa, 94. Died of wounds: Rebellion, 33; German South-West Africa, 28. Died from accident or misadventure, 57; died of disease, 105. Total, 415. The chief causes of death from disease were as follows: Enteric fever 23, dysentery 15, pneumonia 12, heart disease and other diseases of the circulatory system 6, appendicitis 6, pulmonary tuberculosis 4, abscess and other diseases of the liver 4, malaria 2, all other causes 33. The proportion of deaths from wounds or killed in action to deaths from disease was 10 to 4. In the South African war the proportion was 10 to 17. Over 135,000 doses of antityphoid vaccine were issued. The greater portion of this vaccine was prepared under the direction of Dr. Watkins-Pitchford in the South African Institute for Medical Research, but over 67,000 doses were supplied by Dr. Pratt Johnson from the South African Clinical Research Laboratory. While complete statistics are not yet available, Colonel Stock thinks there can be no doubt as to the very great measure of protection against infection

afforded by inoculation. The *Medical Journal of South Africa* makes the interesting statement that among the first to be inoculated were General Botha and his family.

GERMAN EXPERIENCES OF WAR SURGERY.

WOUNDS OF THE SKULL.

At a meeting of the Hamburg Medical Society¹ Dr. Oehlecker discussed the treatment of wounds of the skull. In almost every case in which recovery ensued the patients had been taken straight by train to Germany, where they were operated on within a few days of the infliction of the wounds. After the relief of compression and the removal of fragments of bone, the patients did well. It was astonishing to find how often extensive unilateral wounds of the cerebrum and cerebellum were unaccompanied by functional disturbances. Injuries to the motor centres were usually followed by rapid and great improvement in the symptoms, and even by complete recovery. Dr. Oehlecker had often found the evidence of the Roentgen rays misleading in gauging the extent and severity of lesions of the skull and brain. It frequently happened that lesions, which appeared to be trifling on examination of the skull by the Roentgen rays, proved far more serious when an operation was undertaken. Not only did the Roentgen rays fail to indicate the extent to which severe wounds had involved the brain, but in the case of slight wounds, with only trifling injury to the inner table of the skull, they often gave no information at all. In cases in which the symptoms were not explained by the Roentgen rays, it was always advisable to trephine. Experience had shown how, in most such cases, the wound was far more extensive than had been supposed before the operation was undertaken. Head-ache and other symptoms, following apparently slight, glancing bullet wounds, should not be treated lightly, and it was often necessary to trephine and search for the cause of these symptoms. The extensive lesions found at these operations were frequently the cause of great astonishment to the operator. Dr. Oehlecker favoured radical operative treatment for apparently slight skull wounds, with a view to preventing late symptoms; and he had never seen any ill effects from this course.

He had frequently found the large occipital nerve divided or injured in wounds of the back of the head, and this lesion was apt to cause the most severe neuralgia. In such cases, when conservative treatment was of no avail, he recommended the extirpation of the second spinal ganglion; and he showed a volunteer, who had received a severe wound of the back of the head penetrating to the cerebellum. The wound had healed completely, and the patient had left his bed, when he suddenly complained of excruciating pain in the back of the head. At first this pain was attributed to the wound of the cerebellum, but it was subsequently traced to the injured nerves of the back of the head. As the pain increased, the remains of the nerves and the second spinal ganglion were excised. The patient was discharged eleven days later with the pain completely relieved. Though the operation had been radical, there was little interference with the movements of the head and neck.

Dr. Boettiger recorded the case of a soldier, wounded on October 5th by a bullet which had entered the skull a fingerbreadth behind the left mastoid process, and had escaped to the left of the middle line, close to the upper border of the tabular portion of the occipital bone. At first he was speechless, and there was slight paresis of the right arm. Both these conditions soon passed off, and on November 19th there were no focal symptoms, although the wound was still suppurating; but next day right hemianopsia and total alexia were observed. His capacity for spontaneous writing was limited to signing his name, while he could write fairly long words from dictation. He could not, however, read these words. He also experienced difficulty in deciphering high figures. On December 3rd the wounds in the skull were opened, and loose fragments of bone, some of which had penetrated to the brain, were removed. As the wound still did not heal, as the focal symptoms showed little improvement, and as the Roentgen rays showed the vault of the skull to be split between the wounds of entry and exit, a large flap of skin and periosteum was made, and a large piece of

¹ *Deut. med. Woch.*, July 15th.

the skull between the two bullet wounds removed. Six sequestra, some fairly large, were abstracted. This operation was rapidly followed by improvement in the alexia, so that the patient could read fairly easily, but not perfectly, owing to the persistence of the hemianopsia. He could also write spontaneously, but he still grew tired on slight exertion. Dr. Boettiger suggested that in this case the bullet had directly injured the optic tract. The alexia, however, was, in his opinion, due to the pressure exerted on the angular gyrus by the wounded vault of the skull.

NERVE INJURIES.

At a meeting of the Medical Society in Hamburg¹ Dr. Saenger gave an account of his experiences of wounds of the peripheral nerves. The left radial and ulnar nerves were most often wounded, and, after them, the median nerve. The distribution of sensory disturbances, following wounds of these nerves, often did not correspond with that usually described in textbooks. Injuries to the median nerve were often accompanied by trophic and vasomotor disturbances. Wounds of the plexus gave rise to the most varied forms of motor and sensory disturbances. Of the cranial nerves, the facial was the most frequently wounded. He advised that operations on wounded peripheral nerves should not be undertaken till the wound had completely healed; when other methods failed to relieve severe pain, neurolysis—by which we understand him to mean the freeing of adhesions—should always be tried. Good results could often be obtained by the use of warm or cold compresses, by bromides and phenacetin, but injections of sodium chloride with eucaine were of little use. As a rule, the treatment of wounds of the nerves had not hitherto been sufficiently energetic; and in many cases a recovery was not effected till neurolysis was performed, and splinters of bone, foreign bodies, and aneurysms, compressing the nerves, were removed.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed.

CAPTAIN BURROUGHS MAURICE HUGHES, of the 4th Battalion Norfolk Regiment, was killed in action on the Gallipoli peninsula on September 15th, aged 43. Though serving as a combatant he was a medical man. He was educated at St. Bartholomew's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1895. He resided at Wymondham, Norfolk. He served in the South African war in 1899-1901, gaining the Queen's medal with four clasps. He attained the rank of Captain on November 25th, 1914, and also held the rank of Honorary Lieutenant in the army from June 17th, 1901.

Captain Walter Rowland Southall Roberts, R.A.M.C. (T.F.), killed in the Dardanelles, was educated at Birmingham, where he was a legible scholar, and in 1906 Queen's scholar, and also at the London Hospital. He took the degrees of M.B. and Ch.B. in 1906, and the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1912. After holding appointments as clinical assistant at the Brompton Hospital and at the City of London Hospital, and as medical officer of the West Ham Town Council industrial school, and medical officer of health at Ongar, he became tuberculosis officer to the Essex County Council, and settled at Braintree. He was an officer of the 3rd East Anglian Field Ambulance (head quarters Walthamstow), in which he attained the rank of Captain on May 1st, 1914.

Lieutenant Patrick Joseph Walsh, Indian Medical Service, was reported as killed in France in the casualty list published on September 27th. He was born on March 17th, 1889, educated at the Medical School of University College, Cork, and took the M.B., B.Ch., and B.A.O. of the National University, Ireland, in 1912. He entered the I.M.S. as Lieutenant on January 25th, 1913, and was medical officer of the 59th Scinde Rifles.

Lieutenant Jeffery Wimperis Parker, R.A.M.C., is now reported as killed in the Dardanelles in August. He was 32 years of age, and the youngest son of the late Professor T. Jeffery Parker, F.R.S., of Otago, New Zealand. He was educated at Dunedin, New Zealand; University College, Cardiff; and University College, London; subsequently he studied at Berlin. He took the diploma of M.R.C.S. and L.R.C.P.Lond. in 1906, and later the

D.P.H.Camb. After qualifying he filled the posts of house-surgeon to the Shadwell Children's Hospital and also to the Addenbrooke Hospital, Cambridge, and was in practice at Penydarren, Merthyr Tydfil, when he took a temporary commission as Lieutenant in the R.A.M.C. on October 7th, 1914.

Note.—In the JOURNAL of September 13th, when noting the death from wounds in Flanders of temporary Lieutenant C. M. Harris, R.A.M.C., we stated that we could not trace his name in either the *Medical Register* or *Army List*. We are informed by a friend that he was educated at Sydney Grammar School and Sydney University, where he took his degree in 1915, and was one of a hundred Australian medical men who came over in May last to take temporary commissions in the R.A.M.C.

Died of Wounds.

Lieutenant Francis Joseph Wisely, R.A.M.C., is reported to have died of wounds in the Dardanelles in the casualty list published on September 27th. He was educated at Belfast and took the B.A. of the Royal University, Ireland, in 1909, gaining a scholarship of the first class, and the M.B., B.Ch., and B.A.O. Belfast in 1911. After qualifying he acted as house-physician and house-surgeon of the Mater Infirmorum Hospital, Belfast, and was assistant medical officer at the City and County Asylum, Powick, Worcestershire, when he took a temporary commission as Lieutenant in the R.A.M.C. on October 10th, 1914.

Died on Service.

Lieutenant Edward Daniell Parsons, R.A.M.C., died at the 3rd London General Hospital, Wandsworth, of illness contracted on active service, on September 21st, aged 37. He was the elder and only surviving son of the late Dr. T. E. Parsons, of Paddock House, Wimbledon, and was educated at St. Thomas's Hospital, taking the M.R.C.S. and L.R.C.P.Lond. in 1903, and the D.P.H. of the London Colleges in 1907. After qualifying he served as house-physician to the Evelina Hospital for Children, as clinical assistant to the Royal Waterloo Hospital for Women and Children, and as assistant medical officer of health and bacteriologist to the Borough of Croydon. When the war began he was tuberculosis officer and deputy medical officer of health to the Borough of Northampton. He took a temporary commission as Lieutenant in the R.A.M.C. on November 2nd, 1914, was sent to Alexandria in June, and was invalided from that station.

Lieutenant Thomas Bond Paul, I.M.S., attached to the Persian Gulf Expeditionary Force, died there on service on September 19th, aged 25. He was the eldest son of Dr. Reginald Paul, of Loughborough, was born on June 30th, 1890, took the L.M.S.S.A. in 1913, and entered the I.M.S. on August 1st, 1914, in the last batch admitted to that service before the war began. Previous to being sent upon active service he was stationed at Poona.

Wounded.

Captain T. W. S. Hills, R.A.M.C. (T.F.), Flanders.
Lieutenant (temporary) L. L. Cassidy, R.A.M.C., Dardanelles.

DEATHS AMONG SONS OF MEDICAL MEN.

McDowel, B. G., Lieutenant 1st Connaught Rangers, son of Dr. McDowel of Sligo, killed in Flanders, aged 21. He got his commission on November 15th, 1914.

O'Neill, Sidney John, Sergeant 6th Light Horse, Australian Imperial Force, eldest son of John O'Neill, M.D., F.R.C.S.E., of Armadale, Melbourne, killed in the Dardanelles, August 7th.

Stewart, Alan Dundas, Second Lieutenant 9th Battalion Royal Sussex Regiment, and Bombing Officer, youngest son of Dr. Stewart of Redcliffe Gardens, London, S.W., killed in France, September 19th, aged 21. His commission was dated November 14th, 1914.

MEDICAL STUDENTS.

Gillespie, Charles, Second Lieutenant 4th Battalion (attached 2nd Battalion), Highland Light Infantry, son of the late Major Gillespie, V.D., of St. Andrews, died on September 26th in No. 1 Casualty Clearing Station, France, of a wound of the chest received on August 24th, aged 22. He was a medical student in his third year at St. Andrews University, where he had already taken the B.Sc. degree, and was a well-known athlete. He ran second in the hurdle race at the last Scottish amateur athletic championship sports at Edinburgh, was captain of the St. Andrews University athletic and hockey clubs, and was the best billiard player in the university. He got his commission on August 15th, 1914.

Munro, Hugh A., Lieutenant 8th Battalion Argyll and Sutherland Highlanders, killed in France by a bomb explosion, aged 22. He was the elder son of the well-known novelist, Mr. Neil Munro, and was in his final year as a medical student at Glasgow when he got his commission on November 24th, 1914.

¹ *Dcut. med. Woch.*, June 1914.

NOTES.

CANADA.

The offer of the Canadian Government to provide a hospital for the treatment of French wounded has been accepted by President Poincaré. The arrangements were concluded during the recent visit to France of Sir Robert Borden. The hospital will be established near Paris; the unit, which left Montreal last May as No. 4 Stationary Hospital (French-Canadian), under the command of Colonel Arthur Mignault, is now in England. It has been enlarged both in numbers and equipment.

Major W. W. Nasmyth, of Youngstown, Alberta, who was wounded at the battle of Ypres, has now so far recovered that he hopes to return to the front at an early date. He has been promoted colonel and is now at Calgary engaged in recruiting and training men for overseas service.

Major C. E. Doherty, of New Westminster, British Columbia, Assistant Director of Medical Supplies for the Canadian Overseas Forces, has returned to Canada. He will be attached to militia head quarters at Ottawa and will direct the arrangements for the care of soldiers invalided from the front, a number of whom have already reached Canada.

A fourth universities' company for overseas service is in process of organization at Montreal. It is in command of Captain A. S. Eve, of the McGill Canadian Officers' Training Corps. The third universities' company, under Lieutenant F. L. Turnbull, has arrived in England. The first and second companies are already with the Princess Patricia's Light Infantry. These companies are composed entirely of university men and have been formed to reinforce the Princess Patricia's.

ANGLO-RUSSIAN RED CROSS HOSPITAL.

The following have been appointed to the staff of the hospital raised in this country to work with the Russian Red Cross:

Commandant and Chief Sanitary Officer: A. M. Fleming, C.M.G., M.B., F.R.C.S., D.P.M., Lond.
Surgeon-in-Chief: H. F. Waterhouse, F.R.C.S.
Physician: Thomas Horder, M.D., F.R.C.P.
Assistant Medical and Surgical Staff: Gould May, M.A., M.D. Cantab.; A. B. Rosher, M.R.C.S., L.R.C.P.; G. A. Jones, B.A. Oxon., L.S.A.; Mark Gardner, M.D. Melb., and H. F. Q. Thompson, F.R.C.S., L.R.C.P.
Dispenser: Mr. Graham Bell.

Nurses: Miss S. I. Irvine Robertson (matron) and a staff of twenty-two qualified nurses and eight V.A.D. workers.

CRIPPLED SAILORS' AND SOLDIERS' ARTIFICIAL LIMBS.

In the JOURNAL of August 7th, p. 227, some account was given of Queen Mary's Convalescent Auxiliary Hospitals at Roehampton, to which sailors and soldiers who have lost a limb are admitted for the purpose of being fitted with suitable apparatus. The hospitals are officially recognized by the Directors-General of Navy and Army Medical Services and the Commissioners of the Royal Hospital, Chelsea. Although some 300 beds have been provided in two houses at Roehampton, over 800 patients are now awaiting admission, and the number increases daily. To meet this large outlay has been incurred at Roehampton in the erection and equipment of new wards, which will shortly be opened. In addition a movement is on foot to establish similar hospitals in Scotland and Ireland, in the immediate neighbourhood of such cities as Edinburgh and Dublin, so that the services of the surgeons on the convalescing staff may easily be available. At Roehampton, with a view to the future employment of the men, and also to provide useful occupation for them while in hospital, workshops fitted with model motor chassis, electrical appliances, lathes, etc., are being organized, with competent instructors. A man who has lost his right hand will be taught to write with his left, and classes for other industries will be arranged. An Employment Bureau, working in conjunction with existing societies and employers' labour, has also been established, and already a number of men have been placed in good situations. From the number of offers received, it is hoped through this medium to find suitable employment for every man on his leaving the hospital.

An appeal for additional funds to carry on the work has been made by Major-General Sir Francis Lloyd, K.C.B., the General Officer Commanding the London District. All contributions may be sent to the Honorary Secretary and Treasurer, Mr. C. H. Kenderdine, St. Stephen's House, Westminster, S.W. It may be added that the patronesses of Queen Mary's Convalescent Hospitals are the Queen and Queen Alexandra, and the presidents the First Lord of the Admiralty and the Minister for War.

KIT FOR MALTA.

Temporary Lieutenant J. C. Walker (Malta) writes: Perhaps one or two hints to officers ordered to Malta may be of service. Full camp kit should be brought from home. Most of the articles required can be purchased here, but the cost is fifty to

sixty per cent. more, and choice is restricted. It is still hot enough through the day to make drill clothing desirable. This can be bought here more economically than at home, and is quite well made up by local tailors. Probably one could save a little by buying the badges and buttons in England. Living is fairly cheap, though this depends partly on the locality where one is stationed. Broadly speaking, drill clothing and tobacco are cheap; all personal effects, toilet requisites, etc., are dear.

ITALIAN RIVER AMBULANCES.

Since July the river ambulances of the Italian Red Cross have been transporting wounded from the front to the hospitals of Cremona, Mantua, and Piacenza. Six of these floating ambulances, which are fitted up with every modern requirement for the comfort of sick or wounded men, are at work on the Po and the Mincio. The service is not free from danger, as enemy aeroplanes are in the habit of dropping bombs on the ambulances. Fortunately so far no damage has been done.

MEDICAL OFFICERS WANTED.

21st Wessex Casualty Clearing Station, R.A.M.C.(T.).
Four or five medical officers are required to complete the establishment of this unit; must be prepared for foreign service, if required. Applications to the Officer Commanding, 21st Wessex Casualty Clearing Station, R.A.M.C.(T.), 71, Holloway Street, Exeter.

32nd West Lancashire Field Ambulance (T.F.).

There are vacancies for medical officers in this unit. Pay and allowances as in the regular army, with promotion to the rank of captain after six months' service. Apply to Lieutenant-Colonel F. J. Knowles, T.D., R.A.M.C.(T.), R.A.M.C., Head Quarters, Croppers Hill, St. Helens, Lancs.

21st South Midland Mounted Brigade Field Ambulance (T.F.).

Three medical officers are required for imperial service with this unit at present under canvas at Holkham Park. Applications to Major D. M. Spring, Senior Medical Officer, The Camp, Holkham Wells, Norfolk.

2nd Line Welsh Border Mounted Brigade.

Two medical officers, willing to undertake the imperial service obligation, are urgently required for service with the 2nd Line Shropshire Royal Horse Artillery and Cheshire Yeomanry. Pay and allowances as in the regular army, also outfit and camp kit grants. Full particulars on application to Lieutenant-Colonel D. C. Leyland Orton, Senior Medical Officer, 2nd Line Welsh Border Mounted Brigade, The Camp, Morpeth, Northumberland.

2nd West Riding Field Ambulance R.A.M.C.(T.F.).

There are vacancies for officers for this unit for service overseas. Applications to the Officer Commanding, 2nd West Riding Field Ambulance, Thoresby Camp, Worksop.

31st North Midland Field Ambulance.

Four medical officers are urgently needed for this ambulance. Applications to Captain Holmes, R.A.M.C.(T.), Officer Commanding, 31st North Midland Field Ambulance, Belton Park Camp, Grantham.

England and Wales.

THE KING'S VISIT TO YORKSHIRE.

DURING his tour in Yorkshire the King was chiefly occupied in visiting munition works, but he found time while at Leeds to go to the university and to visit the 2nd Northern General Hospital in Beckett's Park. His Majesty was received by Surgeon-General W. Kenny, D.D.M.S. Northern Command, and Lieutenant-Colonel H. Littlewood, R.A.M.C.(T.), administrator of the hospital. The King decorated Sergeant A. E. Pendle, 4th Suffolk, and acting Sergeant J. Hogg, 1st Royal Scots, with the Distinguished Conduct Medal, and Corporal Evan Davies, 1st Welsh Regiment, with the Cross of St. George, Fourth Class, conferred upon him by the Emperor of Russia. The King then spent about an hour in the large assembly hall, where some sixty or seventy of the more serious cases were; afterwards he conversed with some wounded men who were in reclining chairs outdoors, and having been photographed among them said: "I am very glad to be with you here to-day. I wish to say how proud I am of the way in which you have done your duty both in France and at the Dardanelles. I trust you will soon be restored to health, and go back to your friends and your homes."

The organization of the 2nd Northern General Hospital was sketched in 1908, when Dr. E. F. Trevelyan became administrator, and the officers appointed were chiefly drawn from the staff of the Leeds Infirmary. On Colonel Trevelyan's death in 1912 he was succeeded as admini-

trator by Mr. J. F. Dobson, who took a large part in the further development of the hospital, which gave it control of the fine new building of the Leeds Education Committee at Beckett's Park. When Colonel Dobson was seized last April with the illness from which we are glad to learn he is now nearly recovered, he was succeeded as administrator by Lieutenant-Colonel H. Littlewood, who had left his retirement to do duty with the hospital. This hospital contains 540 beds, and since May the East Leeds War Hospital, with 520 beds, has been organized; in addition there are under the hospital administration in auxiliary hospitals and convalescent homes 1,837 beds, making a total of 2,897. The following summary of the work of the hospital was presented to His Majesty:

	Cases.	Deaths.
Expeditious Force (West)—		
British	6,625	50
Canadian	172	2
Belgian	402	2
Expeditious Force (Mediterranean)...	220	0
Home Force	5,173	22
	12,592	76

The King then went to Sheffield, where he was received by the Lord Mayor; he visited the university and went over the Applied Science Department, where he saw the students in training in the workshops.

UNIVERSITY OF LONDON OFFICERS' TRAINING CORPS.

The University of London Officers' Training Corps, under the command of Lieutenant-Colonel D. S. Capper, will begin its eighth year of training under exceptional conditions, as the colleges of the university are largely depleted of students. In the infantry unit—the largest in the contingent—the training, since the outbreak of the war, has been mainly of a continuous character, cadets being accommodated in premises in London. As a rule a few months of training under these conditions have been sufficient to qualify cadets for commissions. The artillery and engineer units of the contingent are also in active training. Their work is especially important at the present time, as facilities for the training of technical officers are few. The artillery unit has been permitted to keep its guns and equipment for training purposes. In the medical schools of the university a considerable number of students are completing their medical training with a view to taking commissions as soon as qualified. The strength and training of the Medical Unit of the University O.T.C. have therefore not been much affected by the war, and the cadets attended camp as usual.

Since the outbreak of war the number of commissions obtained by cadets and ex-cadets of the contingent down to the end of August, 1915, amounted to 1,521, and 189 commissions were obtained before the war, giving a total of 1,710. In addition, 245 commissions have been obtained down to the same date, upon the recommendation of the university, by graduates and students who were not cadets or ex-cadets of the University Officers' Training Corps. Before the end of September the university will have supplied well over 2,000 officers to the army through the Officers' Training Corps or by direct recommendation, and many other graduates and students have obtained commissions through other channels. Distinctions obtained by ex-cadets of the University Officers' Training Corps include: Military Cross 6, Médaille Militaire 1, mentioned in dispatches 14.

Under War Office Regulations membership of the University of London Officers' Training Corps is not restricted to members of the university, and other men of suitable education desirous of qualifying for commissions are accepted. Candidates for enrolment should apply personally to the adjutant at the head quarters, 46, Russell Square, W.C.

THE PROPOSED COMMERCIAL TARIFF IN MANCHESTER.

Throughout Manchester and Salford many strong expressions have been heard of objection to any proposal that the cost for drugs should be a first charge on the medical benefit fund. All the panel practitioners seem to be agreed that the tariff stands in urgent need of revision, and the tariff suggested in the report of the Departmental Committee, if it stood alone, would have been welcomed at removing many anomalies, though perhaps in a way that might injure the chemists unnecessarily. But the feeling

is very decided that if the adoption of the commercial tariff is dependent on the doctors agreeing to guarantee the chemists payment of all their bills in full, it ought to be rejected. It is felt that the chance of a deduction from the practitioners' fund in order to pay the chemists is not at all remote, and no one seems able to understand why the doctors should be in any way called on to bear the liability, because they may not be able to treat patients efficiently with a sum of money which is now only barely sufficient for the country as a whole, and which in the hard times that will follow the war may be altogether inadequate. To agree to accept such liability is held as equivalent to agreeing that the doctors are being paid too much at present, and if the scheme is forced on the profession it is practically certain that there will be trouble.

The Salford Panel Committee has decided strongly to oppose any scheme put forward which would make the practitioners' fund liable to be called on to make up any deficiency in the drug fund. Inquiries have been made, too, as to the opinions of a number of the panel chemists, and without exception—though, of course, they would like the discounting of bills to be prevented—they consider the proposed tariff an utter subversion of all their trade principles and a desperate attempt to eke out an insufficient fund in the first place at the expense of the chemists though ultimately to the detriment of the insured patients. During the last year the working of the medical part of the Insurance Act has been gradually but certainly improving in the district, but if an attempt is made to force on the doctors and chemists the proposals of the Departmental Committee in their entirety, many who have been doing their best to make the Act a success will be forced into an attitude of active opposition.

Ireland.

TRINITY COLLEGE, DUBLIN, AND THE WAR.

Address by the Vice-Chancellor.

SPEAKING at a meeting of the Senate of Dublin University on September 24th, the Vice-Chancellor, Mr. Justice Madden, said that a year ago an extraordinary meeting was held to enable some students in the medical school who were fully qualified for the medical degree to proceed at once to active service without waiting for the ordinary examination, and now when the Senate met again with the same object in view it seemed to be an occasion on which some detailed information as to the part taken by their students in the service of their King and country might be given. As to the medical school, 650 past and present members of the school were serving in various parts of the world in which the war was waged, in the R.A.M.C., the Indian Medical Service, in Red Cross Hospitals, or otherwise. Of these, they deplored the loss of 24 who had laid down their lives, 26 were among the wounded, 3 were missing, and 10 had been made prisoners of war.

It was pleasing to be able to record that many distinctions had been obtained by medical men of Trinity College, and the splendid work done by them had been mentioned in dispatches on no less than twenty-eight occasions. Several medical officers had been commended for gallant and distinguished conduct in the field, 5 had been granted military crosses, 3 had received the Distinguished Service Order, 2 the Order of St. Michael and St. George, and 3 the Order of the Bath (C.B.). That the Army Medical Service was tonnd adequate to the extraordinary demands made upon it was largely due to the arrangements made by that distinguished Irishman, Sir A. Keogh, on whom the university recently conferred the honorary degree of M.D. In the present war the British troops had enjoyed almost complete immunity from disease, which caused such terrible mortality in South Africa. This has been due to the system of preventive inoculation introduced by a former student of their medical school—Sir A. Wright.

The Vice-Chancellor also referred in eulogistic terms to the work being done by their women students in the present crisis. Many were now engaged at work in which men were formerly employed, and several had offered their services for munitions work. As to the Officers' Training Corps, he said the number of Trinity College students

serving with the colours was 1,500. Of these 707 had obtained commissions. The total who had joined from Trinity College since the war broke out was 970. Of these 74 had been killed, 67 wounded, and military crosses had been conferred on four, two of whom he would mention—Lieutenant Stubbs, son of a former Senior Fellow of Trinity, and Captain Moore, son of Sir John Moore.

The response of the medical graduates of the University of Dublin in the national crisis has been a splendid record, and it is only true to state that an equally good record is supplied by the medical graduates and licentiates of the National University (Ireland), the Queen's University (Belfast), the Royal Colleges of Surgeons and Physicians, and the Apothecaries' Hall, Ireland.

COMPLIMENTARY DINNER TO DR. DENIS WALSHÉ,
CO. KILKENNY.

Dr. Denis Walshé, (Graigu, co. Kilkenny, who has received the degree of M.D. (Honoris Causa) of the National University, Ireland, was entertained at a complimentary dinner by his colleagues of the South Eastern of Ireland Branch of the British Medical Association at the Club House, Kilkenny. The dinner was very largely attended by Dr. Walshé's colleagues, who travelled long distances from the adjoining counties to be present to do him a well deserved honour.

Scotland.

ESK RIVER PURIFICATION.

SOME years ago the purification of the water of Leith, which is, strictly speaking, Edinburgh's only river, was carried to a successful issue at very considerable cost but with the greatest benefit, especially to the large district of Murrayfield. Now another large piece of work aiming at the purification of another river, the Esk, which runs to the south of Edinburgh by Dalkeith and reaches the sea at Musselburgh, has, after sixteen months and at a cost of a little over £9,000, been brought to a conclusion by Messrs. Gilbert Thomson and Ferguson, civil engineers, Glasgow, for the town council of Dalkeith. On September 22nd the Dalkeith Sewage Purification Works at Newmills were opened by Provost Brown. As a result of these works the sewage of Dalkeith will be diverted from the Benbught burn; they will take also that which reaches the South Esk by other channels, and a considerable part of that which goes to the North Esk. Two main sewers unite at Newmills, and the sewage then passes through grit chambers and screens into the main sedimentation tanks, which are in duplicate, and have special provision for storm water. From the tanks the liquid is collected into two long troughs, which deliver it to distributors, four in number, acting independently, travelling back and forward over the filter, and driven by the weight of the liquid itself. After passing through the filter the liquid is taken to the "innus tanks," after being collected by under drains, so that the fine suspended matter may be intercepted before it is discharged into the river. The health benefit not only to Dalkeith and its residential suburb, Eskbank, but also to Musselburgh and other places lower down the Esk, cannot fail to be considerable.

WINTER SESSION AT EDINBURGH UNIVERSITY.

There can be little doubt that the medical classes in Edinburgh University will be much depleted this winter; indeed, the Edinburgh Students' *Handbook*, which has just been published, by its reduced bulk gives unmistakable indication of this depletion. The book is brought out by the Students' Representative Council, and gives much useful information upon all matters which interest the undergraduate. Special attention this year is given to the claims of the Officers' Training Corps, and it is stated that between 850 and 900 cadets and ex-cadets have received commissions during the past twelve months. It is interesting to note that about thirty former presidents of the Students' Representative Council are on active service, and that about twelve former presidents of the University Union and a thousand former members of the Students' Representative Council are with the forces; medical's form a considerable proportion of these numbers. The

Edinburgh University *Calendar* has also made its appearance for the session 1915-16. It contains, as usual, all information regarding university matters, and shows that about fifty students, taken from the merit list of last session, had taken advantage of the privileges given last November on account of the war. The statistics furnished indicate that 4,009 members of the university were in July last serving in one form or another with the colours, and that 64 had died *pro patria*; it is calculated that the number now on service has increased to 4,500, or thereabout. Details are also given of two new scholarships—the James Cropper and the Waldie Griffith—both of which are for the benefit of women students of medicine.¹ The session opens on Tuesday, October 5th, in the University, in the Edinburgh School of Medicine for Women (whose lecturers are the only ones recognized by the University Court for students preparing for the university examinations), and in the Extra-mural School of Medicine of the Royal Colleges.

Correspondence.

THE WAR EMERGENCY.

Poor Law Medical Officers and the Cost of Drugs.

SIR,—There must be many senior practitioners like myself who are also Poor Law medical officers and who, when the appeal came from the War Office through the War Emergency Committee of the Association, willingly agreed to take up again the work of their younger days to release their junior partners and allow them to take commissions for the war.

The tax on us, both physically and financially, will be heavy if we have to do our own dispensing with drugs at war prices.

By the National Insurance Act the Government established the principle of writing prescriptions to be dispensed by chemists and paid for by the Insurance Committees, and I suggest that representation be made to the Local Government Board pointing out what a great help it would be to the Poor Law Medical Service if a general order was made that Poor Law medical officers should be relieved of that part of their contracts which requires them to do their own dispensing and provide the drugs. This request should be made through the medical press and by a deputation to the Local Government Board if need be.

The profession has responded to the demands made upon it in a way which has met with the approval of all classes, and I feel confident that my suggestion has only to be made to the authorities for them to recognize that it is reasonable, practicable, and in the interests both of the sick poor and of the Poor Law medical officers.—I am, etc.,

Emsworth, Sept. 27th.

LOCKHART STEPHENS.

MEDICAL EDUCATION OF WOMEN.

SIR,—Under the above heading you have published a letter from Miss R. Mary Barclay, M.A., M.B. Edin. It could not be expected that you should know your correspondent as we know her here. The authorities of this school and others are familiar with her epistolary activities. On these I do not propose to enlarge, but in her letter to you there are statements and innuendoes with regard to this school which cannot be allowed to pass without correction and contradiction. This school is conducted by a body of lecturers who have had long experience in teaching, and whose names come before the University Court annually for reconsideration; while the teaching arrangements and the teaching premises are inspected annually by members of the court. Clinical teaching is conducted in the Royal Infirmary by members of the staff of the infirmary in the wards set apart by the infirmary for that purpose, and to which men students are not admitted; instruction is also given in the Royal Hospital for Sick Children from the whole staff of that hospital; at the City Hospital for Infectious Diseases; and at the City Asylum. The statement by Miss Barclay that women do not get "Edinburgh training" is absurd. The whole secret of the Edinburgh system is that the individual teachers devote themselves loyally and

¹ See the JOURNAL, May 1st, 1915, p. 782.

diligently to their teaching duties, not allowing other duties to interfere with their performance, and that the lecturers both inside and outside the university are trained and experienced teachers before they seek recognition as lecturers. The lecturers in this school are the Extra-Academical Lecturers in Edinburgh, and nothing but praise is due to them for the high spirit and efficiency with which for years they have carried on the medical education of women in Edinburgh. That the teaching has been efficient is shown by the number of passes, our list of graduates, and the good work the qualified women who have studied at this school are doing all over the world. Miss Barclay's attempts to decry the training in her own school are not taken seriously by those who know and understand all the circumstances. Here, as in London, the problem of how to deal with increasing numbers is emerging, but in due time that will be solved.—I am, etc.,

Edinburgh School of Medicine
for Women, Sept. 27th.

WILLIAM RUSSELL, M.D.,
Dean of the School.

THE ADMINISTRATIVE CONTROL OF MEASLES.

SIR,—I have read with interest Dr. Ralph M. F. Picken's article in the JOURNAL of September 18th, and agree with him that notification is essential in any direct effort to control measles, and, further, that when followed by active measures, experience justifies it.

Dr. Picken is apparently not aware that measles is compulsorily notifiable in Greenock, and on this basis he compares with Greenock the adjoining town of Port Glasgow, where measles has been notifiable since 1898. Greenock has had compulsory notification of measles by householders since 1885 under local Acts, and for thirty years the provision has been vigorously enforced. There are good reasons for believing that notification in the case of measles is as complete under this system as under the Notification Act, for there is no divided responsibility to notify, and the householder does not rely on the doctor attending to send in the notification; moreover, a very large proportion of cases are at the time of notification without medical attendance. In the five years 1910 to 1914 there were 7,192 cases of measles notified by householders in Greenock, and of these no fewer than 3,602 were without medical attention. I question if all these would have been notified under any other system than that which places the duty upon the householder alone to notify.

Dr. Picken refers to a chart showing the mean biennial death-rates from measles in Greenock and Port Glasgow for the period 1891-2 to 1909-10. That Greenock had compulsory notification of measles for a considerable number of years earlier than Port Glasgow probably explains why the curve in Port Glasgow is steeper from 1893-4 onwards. It also supplies a reason for the larger drop in Port Glasgow of 60.9 per cent. in the mean of the annual death-rates from measles in the second decennium compared with the first, as contrasted with 49.2 per cent. in Greenock.—I am, etc.,

W. M. S. COOK, B.Sc., M.B., D.P.H. Camb.,
Greenock, Sept. 22nd. Medical Officer of Health.

INFANT FEEDING.

SIR,—I do not think it would be found that the views held by Dr. Cameron and myself upon the subject of infant feeding are essentially different; at any rate, our aims are directed towards the same object—the improvement of the methods of artificial feeding and the reduction of the present rate of infantile mortality. On one point we certainly appear to differ, although I hope that even in this the difference is more in words than in reality. In Dr. Cameron's opinion, the results of feeding with whole citrated milk and with diluted milk plus sugar are very much the same, while, in my opinion, they are quite different, my contention being that the cause of a good deal of infantile health is the almost universal use of diluted milk by the poorer mothers of this country.

In one particular Dr. Cameron is not quite fair to me. He accuses me of having found a diet that is universally and invariably successful. Such is not the case. My suggestion is that whole citrated milk can be used with benefit as a routine measure instead of diluted milk, but

that it, or any other form of feeding, could be always universally and invariably successful is no claim of mine.—I am, etc.,

Leeds, Sept. 26th.

C. W. VINING.

Obituary.

SIR LIONEL SPENCER, K.C.B., M.D.,
SURGEON-GENERAL I.M.S. (RETIRED).

SURGEON-GENERAL SIR LIONEL DIXON SPENCER, K.C.B., one of the most distinguished officers on the retired list of the Bengal Medical Service, died at his residence in London, after a long illness, on September 22nd, aged 73. He was born at Gateshead on June 16th, 1842, educated at the Newcastle Medical School, and took the degree of M.D. St. Andrews in 1862, and the diplomas of M.R.C.S. and L.S.A. in 1864 and 1865 respectively. When the I.M.S. was again thrown open to competition, after admission to that service had been closed for four and a half years (1860 to 1865), he entered as assistant surgeon on April 1st, 1865, along with Surgeon-Generals Cleghorn and Harvey and Colonel Kenneth McLeod. He became surgeon on July 1st, 1873, surgeon-major on April 1st, 1877, brigade-surgeon on January 27th, 1889, surgeon-colonel on October 24th, 1892, and surgeon-general on October 25th, 1898; he retired on attaining the age of 60, on June 16th, 1902. Most of his service was spent in political employment under the Foreign Department of the Government of India. After a few years as medical officer of the Central India Horse he served successively in many of the Indian native states as Residency Surgeon, Eastern Rajputana States 1871, Kasauli 1877, Bhaatpur 1878, Jodhpur and Jaisalmer 1879, and from March, 1881, as Agency Surgeon and Superintendent-General of Vaccination and Dispensaries in Rajputana. On attaining to administrative rank in October, 1892, he was appointed Principal Medical Officer of the Punjab Frontier Force, and held that post for five years, during which he served as P.M.O. in the Waziristan campaign of 1894-5, on the north-west frontier of India, was mentioned in despatches (G.G.O., No. 473 of 1895), received the frontier medal with two clasps and the C.B. on August 27th, 1895. In October, 1898, he was appointed surgeon-general of the Punjab Command, and in 1901 he officiated for some months as director-general of the I.M.S. On March 29th, 1895, he received a good service pension; on January 27th, 1906, was appointed honorary surgeon to the King; and on June 25th, 1909, he was promoted to K.C.B. His funeral took place, after cremation, at Brookwood Cemetery on September 27th.

Sir Lionel Spencer was a most popular officer, both with those of his own age and standing and with the juniors who served under him, who always found him just, kindly, and considerate. He married the daughter of Professor Alexander Harvey, M.D., of Aberdeen, a sister of the late Surgeon-General Harvey, I.M.S., and her death cast a shadow over the closing years of his life.

GILBERT CAMPBELL, M.B.,

PARTICK, GLASGOW.

It is with regret that we announce the death of Dr. Gilbert Campbell, which took place at Bishopton, Renfrewshire, on September 13th. Dr. Campbell was in his 75th year, and for the past twelve months at least had been laid aside from active practice. He was born and educated in Ayrshire, and his earlier professional years were spent in the teaching profession. Ambition directed his energies towards medicine, and he became a student in Anderson's College, Glasgow, in those days and still a well known medical school, and later graduated in the University of Glasgow. His first practice was established in the east end of Glasgow, in the Bridgeton district, where his professional ability, coupled with a genial, kindly manner, soon gained for him wide popularity. He then moved to Partick, in the western end of the city of Glasgow, and again proved his acceptance as a practitioner. He held the post of local Poor Law medical officer, and was one of the founders and chairman for fourteen years of the Scottish Poor Law

Medical Officers' Association. To him and to the labours of the secretary of that association, Dr. W. L. Muir, the Scottish parochial doctors are indebted for many benefits.

Dr. Campbell represented a type of practitioner seldom met with in present days. He was a staunch member and elder in the Church of Scotland, a trusted family adviser in many affairs other than medical, and a keen follower and critic of progress in medicine. In the east end of Glasgow his somewhat burly figure, unconventional dress, and happy free style earned for him the affectionate nickname "the farmer." The writer's father practised in the same district, and used often to speak of Dr. Campbell's stories told to enliven the night toings of midwifery, and of the good heartening of his genial imperturbability. He is survived by his wife and two sons and two daughters. His elder son fills his place, and is an equally popular medical practitioner.

SIR JAMES M. MOODY, medical superintendent of the London County Asylum, Cane Hill, died suddenly on September 20th at the age of 62. He was the son of the late Fleet Surgeon John Moody, R.N., and was born in county Tyrone in 1853. He studied medicine at St. Thomas's Hospital, and obtained the diplomas of M.R.C.S. Eng. in 1874, and L.R.C.P. and L.M. Edin. in 1878. For some time he acted as clinical assistant at St. Luke's Hospital, and was afterwards assistant medical officer at Brookwood Asylum for six years. In 1882, at the early age of 29, he was appointed medical superintendent of the Cane Hill Asylum on the opening of that institution, and this position he occupied until his death. On two occasions he was offered, but did not accept, a commissionership in lunacy. A few years ago he was selected by the Newfoundland Government to report on the administration of lunacy in that colony. He was an excellent administrator, and introduced many improvements in the care and treatment of the insane. No fewer than fifteen of his medical staff became superintendents of other asylums, and one was subsequently appointed a member of the Board of Control. He received the honour of knighthood in 1909. He was a member of the Caravan Club and the Japan Society, an enthusiastic collector of antiques, and an authority on bees. Sir James Moody married in March, 1885, Alice Harriet, daughter of the late Mr. Freud of Worplesdon, Guildford, who survives him.

THE LATE MR. JOSEPH SMITH.—A correspondent has kindly furnished us with the following additional information about Mr. Joseph Smith, an obituary notice of whom appeared in the JOURNAL of September 25th. He was the son of Mr. John Smith, solicitor, of York, and was educated at Sedgley Park, Boulogne, and King's College, London. He practised successively in Notting Hill, Guildford, and Bedford Park. He was one of the first to obtain the Diploma of Public Health at Cambridge. He was president not only of the Society of Members, but also of the now dissolved Incorporated Medical Practitioners' Association. In 1903 he was chairman of the Chiswick Urban District Council. Mr. Joseph Smith, until three years ago, was present at every annual meeting of the College of Surgeons, and advocated to the last the cause of the Members.

Universities and Colleges.

UNIVERSITY OF LONDON.

ENTRANCE SCHOLARSHIPS.

St. Thomas's Hospital.—The entrance science scholarships for 1915-1916 at the medical school have been awarded to A. S. J. M. Huggett (£150) and H. S. Le Marquand (£60).

St. Mary's Hospital.—The following awards have been made:—University Scholarship of 50 Guineas (Open): Mr. H. T. Prys Jones. Open Scholarships in Natural Science: (£100) Mr. A. S. Wright, (£30) Mr. R. M. H. Newbery. Frederic John Palmer Scholarship, £25: Mr. B. W. Roffey. The Epsom College Scholarship of 50 guineas was, on the nomination of the Head Master, awarded to Mr. T. S. North.

St. Bartholomew's Hospital.—The competitions for entrance scholarships at the medical school have resulted in the following awards: Senior in Science (value £75 each) to Mr. L. P. L.

Firman-Edwards, Whitgift School and Trinity College, Cambridge, and Mr. I. G. Williams, University College, Bangor; the Junior in Science (value £150) to Mr. Campbell Shaw, Monmouth Grammar School.

UNIVERSITY COLLEGE.

Students of the Faculty of Medical Sciences other than first year students will be received by the Provost and Dean on the afternoon of Monday, October 4th. On October 8th Professor W. M. Bayliss will give a public introductory lecture at 5 p.m. on the physiological action of light.

UNIVERSITY OF DUBLIN.

At special commencements held in Trinity College, on September 24th, the following degrees in medicine, surgery, and midwifery were conferred:

M.B.—Amy F. Nash.

M.B., B.Ch., B.A. O.—Clara B. M. Adderley, G. Bateman, E. Boyers, A. G. Fisher, R. H. Graham, W. Hunt, M. B. King, E. J. Manix, H. Mitchell, Geraldine Murphy, J. M. Ryan, C. G. Sherovitz, T. W. Sweetnam, J. H. C. Walker, W. B. Walker, C. M. L. West, W. F. Wilson.

UNIVERSITY OF GLASGOW.

THE number of candidates at the preliminary examinations held this week was in arts and science 265 as compared with 362 last September, and in medicine 127 as compared with 97 last year. The number of candidates at these examinations does not represent the total number of students intending to enter, as others are admitted by school-leaving certificates or after passing certain examinations held by other bodies.

Medical News.

BY a recent decree of the Government anticholera vaccination has been made compulsory in the Italian army.

PROFESSOR J. A. LINDSAY will give an address on eugenics and the doctrine of the superman before the Eugenics Education Society at the Grafton Galleries, Grafton Street, W., on Thursday next, at 5.15 p.m.

THE seventy-fourth session of the School of Pharmacy of the Pharmaceutical Society of Great Britain will be opened on Wednesday, October 6th, at 3 p.m., by an address by Sir Rickman J. Godlee, Bt.

THE sixth Norman Kerr memorial lecture of the Society for the Study of Intoxication will be delivered in the hall of the Medical Society of London on October 12th, at 4 p.m., by Sir William J. Collins, M.D., M.S. The subject is the ethics and law of drug and alcohol addiction.

LIEUTENANT HENRY WYNDHAM GOODEN, M.D., R.A.M.C., sometime house-surgeon and resident medical officer at the Bristol Royal Infirmary, who was killed in action while attached to the 2nd Royal Irish Regiment, on May 9th last, left unsettled property valued at £14,621.

THE Governor of the State of Indiana has issued a proclamation declaring October 1st disease prevention day throughout the State. Exercises were to be held in the public schools on that day, and municipal, civic, and other organizations were co-operating to make the effort a success.

THE *Journal of the American Medical Association* states on German authority that salvarsan is being manufactured at Dairen where the Southern Manchurian Railway has a laboratory. The chemical research preliminary to its production was completed, it appears, in Japan.

AMONG the leaflets issued recently by the Board of Agriculture and Fisheries is an appeal to country people on economy in food. It urges them, among other things, to store their crops properly, to bake their own bread, and to cook vegetables by steaming. This leaflet and various others bearing on the subject can be obtained gratis and post free from the Secretary, Board of Agriculture and Fisheries, Whitehall Place, London, S.W.

FOLLOWING the example of England, France, and Germany, Italy is making provision for the special treatment of soldiers suffering from nervous disorder caused by the shocks of warfare. In June a department for this purpose was opened in connexion with the Ospedale Maggiore at Milan. It is under the direction of Professor G. Medea, director of the neuropathological section of that institution, who has the rank of captain.

The British Fire Prevention Committee, 8, Waterloo Place, London, S.W., asks us to state that it has various fire warning posters adapted to different kinds of institutions, including military and auxiliary military hospitals, convalescent homes, and hospitals, and in French, Flemish, Panjabi, and Urdu for hospitals admitting Belgian and Indian wounded. It also has special posters as to air raids for schools and householders. In most instances the posters will be sent free on application from a duly authorized official of an institution, accompanied by a large stamped envelope.

The usual monthly meeting of the Executive Committee of the Medical Sickness and Accident Society was held on September 17th, when Dr. F. J. Allan was in the chair. The accounts presented showed that the sickness claims experienced were under the expectation, in spite of the sums paid to members wounded on active service, which might be classed as an additional risk. The new business had been well up to the average, the combined tables for sickness and endowment assurance still being popular. The rise in the fees of locumtenents had caused many members to increase their sickness benefit in the society as a precaution in case of illness. Prospectus and all information can be obtained from Mr. Bertram Sutton, Secretary, Medical Sickness and Accident Society, 300, High Holborn, W.C.

DR. SANGUINETTI of Genoa declares that there is a strong reaction against German "Kultur" in Italy. He notes in the *Annales de gynécologie et d'obstétrique* for July-August, 1913, that Professor Bossi of Genoa had recently spoken about the victims of Tontonic gynaecology. He began with the case of Semmelweis, the pioneer of antiseptic surgery, persecuted because he was a Hungarian. He showed how Krönig's practice of subcutaneous and spinal anaesthesia had given rise to grave abuses, and how the trade in tuberculin had profited professors as well as pharmacists. Bossi had himself taught and practised conservative operations on the uterus, accepted by British, French, and Russian obstetricians, yet the Germans still insisted on castration and Caesarean section under the same conditions. Lastly, the Germans have been guilty of the grossest plagiarism. Scipione, Mercurio, and Melli, writing in 1605, La Torre in later years, and Gigli as well as Bossi, still living, have alike been victims, their innovations being ascribed in Germany to Walcher, Momburg, Döderlein, and Dührssen.

MESSERS. ERNEST GREYHER AND COMPANY, of 5, Blackfriars Street, Manchester, ask us to state that the "Manchester electrolyzer" of their manufacture is an apparatus which produces a solution of a salt of hypochlorous acid from common brine. It has, they claim, proved to be of considerable value for general sterilizing and disinfecting purposes. The whole process consists in the electrolyzing of the brine, thereby causing the production of sodium hypochlorite. One type of this electrolyzer works with a direct current of 110 volts and requires 8 to 10 amperes; it passes 4 per cent. brine solution through at the rate of 13 gallons an hour, giving about 4 lb. active chlorine in ten hours. One of these instruments has, we are informed, been installed at the London County Asylum, Bexley, and Dr. E. Fanles, assistant medical superintendent of that institution, read a paper on the subject of this electrolytic chlorine bleach at a meeting of the Medico-Psychological Association in 1913. This was briefly noticed in the *BRITISH MEDICAL JOURNAL* at the time (December 27th, 1913, p. 1629), and the complete paper was published in the *Journal of Mental Science* for January, 1914. In it some interesting descriptions are given of tests carried out upon the bactericidal properties of this bleach, and its capacity for removing blood, faecal and menstrual stains from clothing. The use of chlorine in bleaching is, of course, very old, and the sodium hypochlorite contained in disinfectants depending upon chlorine action is regarded with a good deal of suspicion on account of its liability to rot certain common fabrics. It is claimed by the makers in this instance, however, that their hypochlorite, being neither alkali nor acid, acts very rapidly and without detriment to clothes, and this seems to be the experience at Bexley, so far as it has gone. We are informed that the liquor is used for flushing drains, ridding reservoirs of green weed, disinfecting slaughterhouses, and for similar purposes. In this connexion readers may like to be referred to the account given in the *BRITISH MEDICAL JOURNAL* of July 3rd last, p. 38, of the electrolytic disinfectant made, under the superintendence of the M.O.H., Dr. F. W. Alexander, by the Metropolitan Borough of Poplar.

Letters, Notes, and Answers.

THE telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are: (1) EDITOR of the *BRITISH MEDICAL JOURNAL*, *Aldwych, Westrand, London*; (2) GENERAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medicover, Westrand, London*; telephone, 2634, Gerrard. The principal office of the British Medical Association is 16, South Frederick Street, Dublin.

Series, answers, and communications relating to subjects of which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

ANSWERS.

SPINAL OR LOCAL ANAESTHESIA FOR REMOVAL OF PILES. In reply to "G. A. D." (*BRITISH MEDICAL JOURNAL*, September 25th, p. 492), Mr. J. D. Mortimer (London, N.W.) writes: The danger of a fatality or permanent after-effect, such as paralysis of the sphincter ani, is inconsiderable, provided the injection is done with proper precautions as customary with experts. Spinal anaesthesia alone is not, however, to be recommended for "nervous" patients; they are likely to interfere with the operation and to be at its close and long afterwards in a very unsatisfactory condition. For the removal of piles a combination of spinal anaesthesia with light general anaesthesia is excellent in most cases.

THE CIGARETTE HABIT.

DR. WILLIAM BEAMWELL (Liverpool) writes: Recent correspondence in the *BRITISH MEDICAL JOURNAL* has made it sufficiently clear that sudden cessation of alcohol in confirmed inebriates will in some cases either induce or intensify delirium tremens, and "Junk," who asks for suggestions for the cure of the cigarette habit, has probably made the mistake of sudden withdrawal of tobacco in the case which he tells us suffers from great mental depression on attempts at complete cessation from smoking. I learnt years ago the folly of this method of dealing with the tobacco victim, and I have generally got over the difficulty in extreme cases of advising the patient to graze, to diminish the number of cigarettes smoked by at least one less every day. One patient, an English lady, who had been taught to smoke in Russia, and who usually smoked from thirty to forty cigarettes a day, managed, to her own great astonishment, to get down to four a day in the course of a few weeks, but declared that nothing would ever induce her to relinquish this small luxury. The habit of smoking cigarettes right to the end, either by a holder or on the point of a penknife, is a danger which should be pointed out to the patient, the heat driving the nicotine in strong concentration to the end of the cigar or cigarette, and consequently intensifying its toxic effect with each inhalation. The injuries of smoking, therefore, would be greatly lessened if only three-fourths of the cigar or cigarette were smoked and the last quarter thrown away. The long churchwarden pipe has gone out of use, but its absorption of nicotine was its great advantage, and its modern substitute—the pipe with a well—should be suggested to the tobacco lover as the most harmless method of smoking.

DR. L. R. H. P. MARSHALL (Peebles) writes: Many of the soldiers coming under one's observation, whether invalided home from active service or requiring medical treatment while undergoing their course of training at home, show obvious signs of "tobacco poisoning." I have found that the popular remedy, soda mint in tablet form, alluded to dispassionately in the mouth, dispels the immediate and urgent desire for a smoke more efficiently than anything else I have tried. Men are so conscious themselves of the aid it is to their endeavours to control the habit that they come and ask for the tablets. This in no way interferes usually with other treatment being used at the same time. So useful have I found this simple expedient that I think it is worth trial by others, and I would go further and suggest a generous supply of the remedy being included with each consignment of cigarettes sent by liberal donors for the use of the troops at the front. Perhaps it might save many a man's wud when the day came for him to leap out of his trench and charge.

All remittances by Post Office Orders must be made payable to the British Medical Association at 11, General Wellington Street, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post, Wednesday morning. Proof sheets, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-*restante* letters addressed either in initials or numbers.

THE VALUE OF HYPOCHLOROUS ACID IN THE TREATMENT OF CASES OF GAS GANGRENE.

BY JOHN FRASER, M.D., CH.M., F.R.C.S. EDIN.,
CAPTAIN R.A.M.C.,
BRITISH EXPEDITIONARY FORCE.

(Report to the Medical Research Committee.)*

In June of this year I was interested to learn that the professor of pathology and the staff in the Department of Pathology at Edinburgh University were investigating the value of hypochlorous acid as an antiseptic. This information came to my notice before any publication had been made. I was anxious to test the value of the application in the treatment of recent and infected wounds, and Professor Drennan was good enough to place a quantity of the material at my disposal; and, further, he gave me very useful directions as regards its preparation and properties.

Since that date I have given the treatment a very thorough trial, and its value in the special class of case herein noted has so impressed me that I have decided to publish a brief account of the results.

This paper, therefore, deals only with the value of hypochlorous acid as an application in cases of gas gangrene. And it is well at the outset to make clear what is meant by the term. It is applied to cases in which the wound has become infected with a gas-producing organism; the further progress of the infection is associated with local tissue necrosis, and ultimately with general collapse and death. The affection has been attributed to various organisms. According to Fleming,¹ it would appear that the most common occurrence is a combined infection by the *Bacillus aerogenes capsulatus* with the streptococcus.

Granting that infection with these or other organisms is the chief etiological factor, there are also certain important accessory conditions. The situation of the wound is important; I have never seen a gas infection follow a wound of the scalp or face, and only on one occasion have I seen it follow a wound of the trunk. The lower extremity is a more common site than the upper, and in the lower limb the seat of election for an infection is certainly below the knee.

The nature of the wound is the second consideration. The infection pre-eminently occurs in a punctured wound, and more especially in a wound which has been associated with extensive extravasation of blood into the tissues. There are other subsidiary etiological factors, but those mentioned are of outstanding importance.

It is possible in this paper to refer to the pathology of the condition only in the briefest terms. From the wound opening a scanty, foul-smelling discharge appears; it is largely composed of broken down blood clot; it is of a brownish colour, and mixed with it there are bubbles of gas. The skin around the wound becomes of a faint purplish colour. In the subcutaneous tissues there is an accumulation of lymph-like fluid. There is a similar infiltration throughout the intermuscular septa and connective tissue planes. Muscular tissue rapidly loses its healthy red appearance; it becomes pallid and avascular, and disintegrates into a foul-smelling necrotic mass; it is always extensively infiltrated with gas; if the muscle is exposed to the air its surface becomes dry, brown, and leather-like. In consequence of the muscle changes bands of fascia stand out prominently, and they undergo early necrosis. Throughout the precincts of the wound there is an infiltration of gas, and it extends to further limits along certain lines—the subcutaneous tissues, the perivascular tissues, and the planes of intermuscular connective tissue. In addition to these local changes there have been found alterations in the brain, the suprarenals, and the liver: the cortical cells of the brain disintegrate; chromaffin substance disappears from the cells of the suprarenal; and in the liver there is actual destruction of the cells.

I shall refer to particular clinical features in describing individual cases. Locally there are the changes which

have been mentioned above. The general effects are the phenomena of fever, rapid pulse, increased respirations, restlessness, sweating, delirium, unconsciousness, and death. Ultimate death would appear to depend upon the structural changes which are found in the brain, the suprarenals, and the liver.

These elementary facts have been stated as an introduction to the account of the method which I have employed in the treatment of these cases. The method has been the application of the 0.5 per cent. solution of hypochlorous acid known as *eusol*, occasionally intermitted with one of two other procedures—the application of the powder known as *cupad* (bleaching powder and boric acid) and the use of baths of hypertonic salt solution. For details regarding the composition and experimental value of *eusol* and *cupad* the reader is referred to the paper by Professor Lorrain Smith and others in the BRITISH MEDICAL JOURNAL of July 24th. Briefly the method of preparation was as follows:

Into a Winchester quart bottle 27 grams of dry bleaching powder were placed, and to this 1 litre of water was added; the mixture was shaken, and 27 grams of boric acid were added; the bottle was now filled with water, the solution was thoroughly shaken, allowed to stand for a few hours, and then filtered through cotton-wool. The clear solution is *eusol*; it is slightly alkaline to litmus and contains approximately 0.5 per cent. hypochlorous acid. *Cupad* was made by finely grinding the dry bleaching powder and adding an equal weight of boric acid powder. Both *eusol* and *cupad* were stocked in airtight black bottles.

Whenever a case of gas gangrene was recognized as such the *eusol* treatment was immediately begun. The local wound from which the infection had apparently commenced was opened up thoroughly, and as far as possible all free blood clot was removed. Whenever an emphysematous sensation could be detected an incision about 2 in. long was made, but such an incision was never carried deeper than the subcutaneous tissues. Each wound was now thoroughly irrigated with *eusol*, and if the wound was of any depth irrigation was carried out under considerable pressure by means of a Higginson's syringe; frequently the nozzle of the syringe was forcibly inserted through a superficial wound and a small quantity of the *eusol* injected into the subcutaneous tissues all around the wound. From the last procedure was seen no ill result, but, on the other hand, considerable benefit has repeatedly accrued.

Grossly infected muscle or skin was cut away. Gauze soaked in *eusol* (0.5 per cent.) was lightly packed into the wound and as far as possible into all the crevices. If the wound was of considerable depth, it was found advantageous to insert a medium-sized drainage tube provided with numerous large lateral openings; around the tube gauze wrung out of *eusol* was lightly packed. This procedure had the advantage that the gauze packing could be easily re-soaked by injecting a quantity of fluid along the rubber tube from which it escaped by the lateral openings into the dressing. Over the surface of the wound and covering a large area of the surrounding skin gauze wrung out of *eusol* was laid; this was covered with a layer of dry gauze, wool, and bandage. The end aimed at was to make the dressing as light and airy as possible. In only two instances could it be said that the dressing had produced any irritation of the surrounding skin. In both cases the slight irritation which appeared occurred around the edge of the dressing; it was easily counteracted and speedily alleviated by the application of a thick layer of zinc ointment. During the first forty-eight hours an attempt was made, where possible, to change the dressing every four hours; after that period it was found sufficient to change the dressing every eight hours. On the fourth day of treatment experience taught one that granulation tissue was improved and the separation of the slough stimulated by the application of *cupad* to the wound; this was dusted on from a dredger in a thin layer, and the dressing with gauze *eusol* continued as before. This modification was followed throughout the fourth, fifth, and sixth days; it was not adopted earlier because observations seemed to show that in the earlier stages of treatment the application of a solid tended to retard the wound secretion. On the seventh and subsequent days, until granulation was complete, the treatment was further modified by immersing the part for four hours each day in a bath of hypertonic salt solution; a double

* The report was illustrated by coloured drawings, not here reproduced, showing the underlying sloughing tissue exposed in two cases by incisions made on the patients' admission, and the healthy granulating tissue after applications of *eusol*, or *eusol* and *cupad*, for five and ten days respectively.

purpose was answered—the granulations were further stimulated and any remaining slough separated, and the surrounding skin, which had become very dirty after repeated eusol dressing, was thoroughly and efficiently cleaned.

Observations of the wound from day to day show some interesting features. During the first twenty-four hours the foul smell of the wound entirely disappears; the discharge as such also disappears, but is replaced by a lymph-like secretion, which soaks the dressings with a glairy, gelatinous looking fluid. After the third day this lymph-like discharge tends to cease, granulation tissue begins to make its appearance, and slightly blood-stained serum escapes from the wound. Sloughs separate with extraordinary rapidity, and the healthy granulation tissue which remains completes the process of healing at a more rapid rate than I have previously observed.

At no time was any complaint made of pain or irritation being produced by the eusol. This could not be said of the eucod; its application was always followed by a stinging, burning sensation, which lasted usually for about thirty minutes.

Details are added of nine cases of undoubted infection with a gas-producing organism, ending in tissue necrosis, which were treated successfully with eusol. Many of the cases were of intense severity. These cases have not been selected, but form a consecutive series coming under my care. It was interesting to note that the general condition of the patient responded and improved synchronously with the improvement in the local condition.

CASE I.

Private, admitted June 23rd, 1915.

History and Operation.

As a result of a shell explosion the right foot was blown off, and there was a deep lacerated wound of the left thigh. In regard to the wound of the right foot, the edges were trimmed and converted into flaps, the surfaces were washed with eusol, and the stump was partially closed with interrupted silkworm gut sutures. The wound of the left thigh was dressed with a warm solution of hydrogen peroxide.

Progress.

The amputation did well, and proceeded to heal without further complication; the wound of the left thigh developed the clinical features which are associated with a moderate gas infection—that is to say, the general condition altered by a rise in temperature, pulse and respiration-rate. The patient complained of general debility and restlessness, and had the facial appearance of undoubted illness.

Locally the wound had altered; the surface appeared to be covered with coagulated albuminous substance; the exposed muscle had a brown leathery appearance; the surrounding skin was beginning to be discoloured with a faint purplish tinge. When the fingers were gently laid on the part, the typical emphysematous crackling could be detected in the surrounding tissues, and also in the exposed muscle. On light percussion a faintly resonant note could be detected.

Case I.—A, Date of admission.

With the discovery of the development of these features the treatment was altered; generally stimulants were pressed as thoroughly as possible; locally several incisions were made into the subcutaneous tissue around the wound; the wound itself was loosely packed through all its interstices with gauze wrung out of eusol. Over the wound and the surrounding tissues gauze saturated with eusol was laid. The dressing was changed at intervals of eight hours, and after the primary eusol dressing the wound was thoroughly syringed out with eusol. Twenty-four hours after the original application of eusol no gas could be detected in the surrounding tissues. The exposed muscle still crackled on pressure, and from it bubbles of gas could be expelled, but there was no suspicion of any spread of the infection. On the fifth day the greater part of the necrotic muscle came away as a slough, leaving behind it clusters of red and healthy granulation.

After-History.

Both general and local conditions were so thoroughly improved that we were able to send the patient to the base on the sixth day (June 29th). We followed the principle of keeping as far as possible in touch with the patients who passed through our hands. Thus we were able to ascertain their ultimate condition, and we received from this patient a letter written from Chichester on July 27th. Special interest centres around the following remark: "The thigh wound is got on wonderful, the hole has fill right up and the skin is grown about half an inch all round it and it's gone so small."

CASE II.

Sergeant, admitted August 30th, 1915.

History.

This man was wounded in a bomb explosion. The chief injuries were localized to the right leg below the knee. There was an extensive wound, which passed through the

Case II.—A, Date of admission; E, eusol dressing; S, saline bath.

leg, associated with a compound fracture just below the knee-joint. On the outer aspect of the leg there were several non-superficial wounds of varying size and depth. On the anterior aspect of the leg there were several small punctured wounds.

On admission the patient was found to be suffering considerably from collapse; the pulse was 120, small and irregular; the temperature reached 100°. The various wounds were dressed with a eusol dressing; they were dirty and sloughy, but at this, their first examination, they showed no evidence of a gas infection.

The following morning, August 31st, the general condition of the patient gave rise to some anxiety; the pulse-rate had increased, but more alarming were the restlessness and air of impending collapse. On examining the limb the source of the change was evident—there was an extensive infection with a gas-producing organism throughout the leg from the knee to the ankle. There was considerable swelling; the limb was tense and resonant on percussion; there was crackling on palpation all over, but especially marked on the anterior surface of the limb.

Gas Gangrene: Treatment.

Free incisions were made all over the limb into the subcutaneous tissues. With each incision there was a distinct escape of gas; the incisions into the front of the leg showed that the muscles and subcutaneous tissues were of a greenish-black colour, very foul-smelling and crackling with gas; there was, in fact, an acute infection of emphysematous gangrene. The limb was treated with eusol; gauze soaked in it was loosely packed into all the crevices of the wounds and incisions.

After-History.

The further progress of the case need not be entered into in detail; briefly it was as follows: The eusol dressing was changed at intervals of four hours. From the date of operation there was no further spread of the gas infection. Emphysema remained in the muscle until the muscle separated as a slough. Sloughing occurred in the entire group of anterior tibial muscles, leaving exposed the tibia, fibula, and interosseous membrane; the slough extended from the upper attachments of the muscles to the upper border of the anterior annular ligament. The treatment throughout consisted in the application of eusol; from this there were two divergences—during the third and fourth days of treatment dry eucod was powdered over the area in addition to the eusol dressing; during the fifth, sixth, and seventh days, while the slough was separating, the limb was immersed in a bath of hypertonic saline for intervals of eight hours in the twenty-four.

The patient was discharged on the tenth day with the leg wounds in a healthy granulating condition.

CASE III.

Private, admitted August 10th, 1915.

History.

This man had been wounded three days previously by a rifle bullet through the right thigh. Military exigencies had prevented his transfer to the clearing hospital until this date.

Condition on Admission.

His condition was such as to give rise to considerable anxiety. He was restless and, to some degree, collapsed; there was pro-

Case III.—E, Eusol dressing; O, operation.

Treatment.

Under a general anaesthetic the wound was opened up for an extent of about 9 in.; a quantity of foul-smelling blood clot was removed, and also several portions of clothing which had been dragged in by the projectile. The bullet had passed through the substance of the semimembranosus muscle, and this muscle was apparently the main site of the gangrenous process; its surface, when exposed, was perfectly dry and of a greenish-brown appearance; when handled it cracked in the fingers. When cut into it did not bleed and the cut surface was of a salmon pink colour, quite different from the red of a healthy muscle; moreover, it was a foul-smelling mass. By enlarging the incision the muscle was followed throughout the greater part of its course; it was severed at its origin and at its insertion and entirely removed. It was interesting to note that the necrotic process was so closely limited to the position of the muscle. The wound was syringed out with eusol, and afterwards lightly, but thoroughly, packed with gauze wrung out of eusol.

Thereafter the wound was dressed at intervals of eight hours. After the second application of eusol all foul smell disappeared, and actually on the third day healthy red granulation tissue became apparent in the wound.

CASE IV.

Private, admitted August 24th, 1915.

History.

This man was wounded through the soft tissues of the right calf five days before admission to hospital.

Condition on Admission.

His condition was found to be extremely serious. He was restless, collapsed, and occasionally delirious; his temperature was 100.4, his pulse 120, and his respirations 30; he had the appearance which is associated with an intense toxæmia.

The local condition was even more alarming than the general condition.

The right leg below the knee was swollen to almost twice its natural size. The skin showed the purplish-red discoloration of moist gangrene. Up to within 3 in. of the knee-joint there were several large superficial vesicles containing foul-smelling blood-stained fluid; the surface temperature of the limb below the knee was stone cold; no trace of a pulse could be detected in either anterior or posterior tibial vessels. From the bullet wounds a quantity of foul-smelling blood clot was protruding; the entire limb below the knee cracked with emphysema. From the knee to the groin, although the skin temperature was maintained, and there was no discoloration, yet the presence of gas could be detected by palpation and percussion.

The treatment of such a case presented a great problem; one was faced with three possibilities of treatment:

1. To adopt no greater operative interference than that of simple incision, risking the very remote possibility of the gangrene becoming localized.
2. To disarticulate the limb at the hip-joint by a flapless amputation, and thus get above the infected tissue.
3. To amputate through the centre of the thigh—in other words through the less infected gas area—in this way getting rid of the actual necrotic part, and trusting to localize

Case IV.—A, Date of admission; E, eusol dressing; X, amputation.

and protect the less infected part by free incision and the application of some antiseptic. After due deliberation the last course was adopted.

Operation and After-History.

The operation was performed under spinal anaesthesia. The amputation was carried out in the middle of the thigh and anterior and posterior flaps were formed. The cut surfaces were thoroughly washed with eusol and a few sutures were inserted to bring the surfaces together. Above the site of amputation a number of incisions were made into the subcutaneous tissues.

The further progress of the case was one of uninterrupted recovery. No further evidence of a gas infection appeared; the stump surfaces quickly granulated, and on the fifth day it was found possible to insert additional sutures, and so facilitate the healing and closure of the stump.

CASE V.

Private, admitted August 26th, 1915.

History and Condition on Admission.

Twenty-four hours before admission to hospital this man had been wounded by a rifle bullet. It had passed through the left

thigh, producing a compound fracture of the junction of upper and middle thirds of the bone. It had then passed across the front of the right thigh immediately below the groin. In its passage it had torn away the coverings so completely as to leave Scarpa's triangle exposed in its entirety, as though by a dissection; in the floor of the triangle the pulsating femoral vessels were lying clearly visible. From its origin the wound had been grossly infected. There was a mass of adductor muscle at the inner side of the wound in a condition of necrosis and infected throughout with a gas-producing organism; there was a similar mass of necrotic and gas-infected muscle—portions of the sartorius and rectus femoris muscles—lying at the outer edge of the wound. The surface had the coagulated, gelatinous-looking appearance which one had by this time begun to associate with gas-infected wounds.

Treatment.

The question was considered whether it would not be advisable to amputate the limb immediately; it was decided to

Case V.—A, Date of admission; E, eusol dressing; X, amputation.

vasi, as any immediate amputation would certainly result in infection of the stump surfaces. The wound was carefully cleaned up, syringed, and afterwards lightly packed with gauze wrung out of esoul; the dressing was changed at six-hourly intervals. For three days repeated dressing with esoul solution was persisted in. During that time the gangrenous process was entirely mastered, the infection disappeared from the substantial tissues; the emphysematous crackling remained in the necrotic muscles until these separated as sloughs.

On the fourth day the continued exposure of the femoral vessels apparently led to a coagulation of the blood stream, and gangrene appeared in the tissues of the foot. It was therefore necessary to perform amputation in the upper part of the thigh.

In performing this amputation one had an opportunity of observing in the tissues of the stump how completely the original necrotic process had been localized. It had not extended into the posterior thigh muscles, and it had not infected the tissues of the thigh above the wound. It was our opinion that the remarkable localization of the infection was the result of the action of the esoul application.

CASE VI.

Sergeant, admitted August 4th, 1915.

History and Condition on Admission.

There was a bullet wound of the right thigh. The injury had been sustained some forty-eight hours before, and there had

been a considerable amount of bleeding into the deep tissues of the thigh. The bullet had entered the centre of the thigh posteriorly, and it remained just beneath the skin anteriorly; the bone of the leg was not damaged. From the wound fluid and discoloured blood were escaping; it was distinctly foul smelling. Around the wound the typical crackling infection associated with infection by

Case VI.—A, Date of admission; E, esoul dressing.

a gas-producing organism could be detected; the outline of the thigh was considerably swollen. Small bubbles of gas could be expelled with the blood from the bullet wound. As regards the general condition, the temperature was 100°, the pulse 90, and there was a distinct degree of general illness.

Obviously one was dealing with a case in which, if there was not a tissue necrosis due to the gas-producing organism, there was at least the infection which is preliminary to such a change.

Progress.

The wound was thoroughly opened up and drainage established. Among the tissues of the thigh a quantity of blood clot had accumulated; this was removed. The cavity was syringed out with esoul. A drainage tube was inserted, and the space around the drainage tube was loosely packed with gauze wrung out of esoul. In about eight hours the wound was dressed. The packing was removed; it still retained a trace of the foul smell possessed by the discharge the evening before; the cavity was again syringed out. There was no evidence of any gas infection of the surrounding tissue. At the third dressing the foul odour had entirely disappeared; the interior of the cavity was covered with a thin brownish slough. In about four days the slough had separated, leaving a cavity lined with healthy granulation tissue.

CASE VII.

Sapper, admitted September 2nd, 1915.

History and Treatment.

The patient was admitted on the afternoon of September 2nd with a bullet wound through the calf of the left leg. On examination the wound appeared sloughy and gas was found to be present in the surrounding tissues extending upwards to the knee-joint and downwards as far as the ankle-joint. The wound was enlarged under a general anaesthetic and syringed and dressed with esoul; the dressing was changed every six hours.

Progress.

On the following day (September 3rd) the swelling had diminished, and only the faintest traces of gas could be detected.

On September 4th there was a considerable extension of the infection, gas could be detected throughout the greater part of the leg between the knee and the ankle. Fresh incisions were made into the leg; the original wounds were further opened up

Case VII.—A, Date of admission; E, esoul dressing; o, operation.

and some blood clot removed. The wounds were thoroughly syringed out with esoul and esoul wet dressings were applied and changed at four-hourly intervals as before.

On September 5th no gas was detectable; the patient generally was much improved. On September 7th, locally the wounds were clean and beginning to granulate; the pulse and temperature were normal, and the general condition was thoroughly satisfactory.

On September 10th, the improvement being maintained, the patient was discharged to the base.

CASE VIII.

Sergeant, admitted August 30th, 1915.

History and Condition on Admission.

This man was wounded in a bomb explosion about two days before admission. On admission he was scarcely conscious; he was delirious, and after a short period of delirium and talking nonsense he lapsed into complete unconsciousness. On the outer side of the left thigh there was a deep lacerated wound; it had all the appearances of a wound infected by a gas-producing organism. The tissues in the floor and side of the wound were brown and sloughy in appearance; there was a scanty foul-smelling discharge. The skin at the edges of the wound was faintly discoloured with a purplish-red discoloration; throughout the muscles exposed in the wound and throughout the surrounding tissues there was the distinctive crackling of a gas infection.

Other wounds present were superficial and not affected with gas gangrene.

Treatment and Progress.

The local treatment consisted in freely opening up the infected wound. As much as possible of the necrotic muscle was cut away. The wound was washed out with esoul, and later it was loosely packed with gauze saturated in the same solution.

The further progress of the case, as far as the infected wound was concerned, was one of progressive recovery—the gas infection was entirely arrested, the sloughs of necrotic muscle had begun to separate, and healthy granulations were beginning to appear.

The general condition of the patient was unfortunately not so favourable. Complete consciousness was never regained; the features were all those of a progressive oedema cerebri, and after lingering for five days he died.

Post-mortem examination showed that he was the victim of a specific leptomeningitis, which apparently was responsible for the fatal oedema cerebri.

CASE IX.

Private, admitted August 25th, 1915.

History and Condition on Admission.

A rifle bullet had passed through the soft tissues of the back. On admission the general condition was satisfactory; the wounds were dressed, and, while they were undoubtedly infected, nothing unusual was noticed.

Case VIII.—A, Date of admission; E, esoul dressing.

Operation.

On the morning after admission the general condition was less reassuring; the temperature remained high—100°; the pulse-rate had increased; there was a complaint of pain in the wound and general restlessness. On dressing the wound, the cause of the change was apparent—the wound was infected with a gas-producing organism; there was the typical emphysematous crackling of the surrounding parts; gas could be displaced from the wound.

Case IX.—A. Date of admission; E. eusol dressing; O. operation.

trance and exit wounds; and the discharge was foul smelling. Under a general anaesthetic the wound was thoroughly opened up. The subcutaneous tissues had a dry gelatinous-looking appearance, as though infiltrated with coagulated lymph; gas could be displaced from this situation. The depth of the wound contained foul-smelling blood clot; the muscles which were cut in the opening up of the wound had the pale avascular appearance of commencing necrosis. Gas originating in the wound had infiltrated downwards in the retroperitoneal tissues as far as the anterior superior spine of the ilium. The wound was syringed out with eusol; its interstices were lightly packed with gauze wrung out of eusol; drainage was secured by means of two large rubber tubes passing downwards into the depths of the wound.

Progress.

As regards the subsequent progress of the case, the dressing was changed at intervals of six hours for two days and thereafter at intervals of eight hours. From the date of operation the condition improved and the improvement was progressive. After the first twenty-four hours all trace of foul smell disappeared and no further evidence of gas could be found. On the fourth day healthy granulations had already made their appearance.

A HOSPITAL SHIP IN THE MEDITERRANEAN.

BY
HUBERT CHITTY, M.S., M.B.LOND., F.R.C.S.ENG.,
R.N.V.R.,
ASSISTANT SURGEON TO THE BRISTOL ROYAL INFIRMARY.

This article is somewhat discursive. My aim has been simply to give a description of the kind of work with which a hospital ship is called upon to deal, and of the conditions under which this work is carried out.

The ship is extremely well fitted, and is capable of carrying, without undue crowding, 350 cot cases, and an equal number of "walkers."

There are two excellent theatres—the one large and containing two operating tables, the other smaller and provided with one table. Our medical staff at present consists of a fleet surgeon, a consultant surgeon, and nine surgeons. One of the last belongs to the R.N., the remainder are drawn from the R.N.V.R., or hold temporary commissions. We carry four nursing sisters. There is also a sufficiency of sick bay ratings, and of St. John Ambulance men.

Fortunately our work has been carried out in security. It has never been hampered by any disregard, on the part of the enemy, of the Geneva Convention. The Turks are, from all accounts, remarkably clean fighters. They certainly respect hospitals and hospital ships, and they never put any impediment in the way of the rapid evacuation of our wounded from the shore. Hospital ships are allowed to anchor quite close to the land, and embark their cases unmolested. Of course if they get in the line of fire shells may burst unpleasantly near them, and they may have to clear out. Similarly, in certain situations, spent bullets from the nearest trenches create a certain element of danger. Shrapnel fired at aeroplanes occasionally falls on

board, or a floating mine may prove a menace. These are, however, unavoidable incidents of warfare, and no fault of the Turks.

Having anchored, then, in a convenient spot, the ship is ready to take in wounded. Cases are usually brought off from the shore in barges towed by picket boats. When these come alongside, the walking cases are first taken off; the cot cases are then placed, stretcher and all, in "cot-carriers" and are hoisted on board. As a rule the majority of the "walkers" are only received for a few hours. They are fed, dressed, and then taken off in trawlers to the shore hospitals. Those of them who are likely to require lengthy treatment are, however, retained on board.

The more severely wounded men are nursed in swing beds and service cots. Any requiring immediate operation or dressing under an anaesthetic first pass through the theatre.

When as many cot cases as possible have been taken on board, the ship may complete her complement with walking cases, or she may proceed to one of the nearest hospitals and fill up there. The ship then goes on to Alexandria, Malta, or England, discharges her patients, takes in stores, coals, cleans ship, and returns to the scene of action.

When there is much activity ashore, and casualties are heavy, every available ship may be required on the spot. In these circumstances the routine may be modified, and all the cases discharged at the nearest hospital. This enables the hospital ship to return to the scene of action within a short time of leaving it. When things are quiet a ship of our size may take four or five days or even longer to fill up. On the other hand, we have taken in our full complement in eighteen hours, while during that time more than four hundred additional walking cases were dressed, fed, and sent away. Between seventy and eighty of these patients passed through the theatres, many of whom required multiple operations.

The condition in which the wounded arrive on board depends almost entirely upon the distance of the firing line from the beach, and upon the nature of the intervening terrain. Where the front trenches are within easy reach of the shore the wounded are received within a few hours of their having been injured. In these circumstances wounds when irrigated and, if necessary, freely opened up and drained, do quite as well as similar injuries treated in a civil hospital at home. Severe sepsis is the exception and spreading gangrene practically unknown. On the other hand, where the trenches are some miles from the shore, there is inevitably considerable delay in evacuating the wounded. Often this cannot be effected for twenty-four hours or more. When this is the case septic infection in a very large proportion of the wounds is firmly established, and has spread widely. Amongst such patients spreading gangrene, both with and without gas formation, is common, and many of the wounds are maggoty. Flies are incredibly numerous, especially at the southern end of the peninsula. Immediately a trace of blood is spilt down they come in swarms. In a moment a wound, unless protected, is lost to sight beneath a black crawling mass of these insects, and the same applies to a soiled dressing. One can only hope that things may improve with the advent of the cooler weather.

I feel considerable diffidence in speaking of individual injuries and their treatment, as so much has been written on the surgery of the war by more competent pens than mine. I will touch, however, lightly upon a few classes of injury, mentioning any points which have appealed to me personally. In military surgery every medical man suffers from the disadvantage of being unable to follow his cases up. In a hospital ship the cases upon which one individual operates may get scattered through several wards, and lost to his sight. On the other hand, he may have to undertake the after-treatment of cases originally under the care of his colleagues. At best the cases are seldom under his supervision for more than a few days before they are transferred to a shore hospital.

In spite of this I will endeavour to give a brief account of some injuries as they appear during the short time they remain on board.

Of the different kinds of wound, those inflicted by shell are comparatively rare except at Cape Helles. Shrapnel and bullet wounds largely preponderate everywhere. Injuries inflicted by bombs are very common where the

opposing trenches lie close together. We met with them chiefly at Anzac. Bayonet wounds are very uncommon. The Turk does not seem to love the bayonet.

Head Injuries.

Let me commence my account by referring to cerebral injuries. Penetrating bullet wounds inflicted at short range are generally quickly fatal, and are rarely seen on a hospital ship. Injuries by partially spent bullets, on the other hand, are common, the bullet usually remaining lodged within the cranium.

When seen such patients frequently present signs of compression. When such cases are met with the scalp and wound should be thoroughly cleaned and the edges of the latter excised. The wound is then enlarged, or a flap of scalp is turned down. The opening in the skull is increased with the aid of nibbling forceps, and any loose fragments of bone are removed. This is followed by a rush of blood and disorganized cerebral matter. Patients thus treated often improve markedly, and life is undoubtedly prolonged. Unfortunately, I understand that the majority of them succumb later to septic complications.

Tangential wounds of the skull are much more amenable to treatment. The skull when exposed may present an appearance of bruising only; a slight groove may be apparent, or a linear portion of the skull may have been carried away. Cases in which the entry and exit wounds of a bullet lie close together in the skull may be included in the same category.

Even in the first cases trephining almost invariably reveals a depressed fracture of the inner table, while in the remainder the dura is torn, and pieces of bone may be found driven into the cerebral substance. In some cases the dura must be opened, even if it has not been torn, owing to the presence of a large haematoma beneath it. As long as the cases remain aseptic their prognosis is favourable. They usually present signs of cerebral irritation and are very troublesome to nurse in a crowded ward. The same principles govern the treatment of injuries due to pieces of shell or bomb.

Spinal Injuries.

In cases of spinal injury one can rarely hope to do any good by surgical interference.

Wounds of the Face.

Wounds of the face often present a terrible appearance, but if thoroughly cleansed and carefully stitched up, with provision for adequate drainage, they do well. I have seen nothing of the ultimate results. These are almost the only wounds into which one dare insert sutures.

Shattered jaws are frequently met with. Here again I am unable to speak of final results. In the early days the whole mouth becomes very foul. The only treatment consists in frequent irrigation. Such patients are difficult to feed, but can almost all swallow fluids given to them in a feeder to which a rubber tube has been attached. This tube must be passed well to the back of the tongue.

Wounds of the neck when septic are liable to be followed by oedema of the larynx. This sometimes manifests itself with alarming suddenness, and may necessitate the performance of a hurried laryngotomy.

Wounds of the Thorax.

Bullet wounds of the chest are common. When the heart or big vessels have been injured the patient rarely reaches the ship alive. Patients with wounds of the lungs who have lived long enough to reach the ship usually do well. Haemothorax and haemoptysis are of frequent occurrence, but all the symptoms subside quickly, save in rare instances, if the patient is kept sitting up in a restful position. Morphine is invaluable in these cases. Operative interference is rarely justifiable. Occasionally a large haemo- or pneumo-thorax may require to be tapped in order to relieve dyspnoea.

Abdominal Injuries.

On the subject of the treatment of abdominal injuries I cannot pretend to speak with authority. Few patients have reached us who were not already moribund, either from internal haemorrhage or general peritonitis. A few have, however, arrived in a rather better plight. They

have almost all been treated by starvation, opium, and rectal saline infusion, and have been kept propped up in Fowler's position. Of these a fair proportion have made a complete recovery. In a very few cases of recent injury operation has been deemed advisable, but the results have proved very discouraging. Unfortunately, I can give no statistics in the case of either operative or expectant treatment. I am, however, strongly of opinion that the latter holds out a better prospect of success in all but exceptional cases.

Injuries to the Limbs.

Clean bullet wounds of fleshy parts, uncomplicated by other injuries, give little trouble. The skin round about should be painted with iodine and a simple dressing applied. They almost invariably heal by first intention. Shrapnel wounds frequently become septic. Should any signs of inflammation develop they must be opened up, irrigated, and freely drained. Shell wounds are almost invariably infected, and must be freely drained and washed out from the first.

When nerves are injured early interference is not indicated. Many cases recover completely without operation. Nerve suture cannot safely be performed till the wound has completely healed. Occasionally a bullet presses on a nerve, causing intense pain, and may require early removal.

Large vessels are frequently wounded. Many such cases bleed to death on the field. Those which reach the ship may present signs of a large haematoma, or may be bleeding freely from an external wound. Even if the bleeding has temporarily ceased it is apt to recur later. Finally, if the vessel has not been tied, aneurysm, or arterio-venous aneurysm, frequently develops. Early operative interference gives excellent results. As the wound has been well flushed with blood it may almost always be closed, and usually heals by first intention. Bleeding is commonly found to proceed from one of the main arteries which has been button-holed. A free incision, good light, and good retraction greatly facilitate the operation. Many patients are collapsed from loss of blood, so that speed in operating is essential, while intravenous infusion may be required.

One of the most frequent and troublesome complications of penetrating wounds of the limbs is a compound fracture. When the wounds of entry and exit are small and aseptic the fracture may be regarded as of the simple variety and may be treated as such.

Unfortunately such cases are rare. When the bone has been hit its fragments, together with the bullet, usually act like an explosive and tear a large hole in the soft parts. Any such extensive wound tends to become septic, and is generally markedly so by the time the patient arrives on board. Such cases should be given an anaesthetic and treated in the theatre at once. The wound must be opened up freely and thoroughly irrigated. Any completely detached fragments of bone are removed. My endeavour always is to convert such wounds as far as possible into craters, in which every part is freely accessible and pocketing of pus an impossibility. To secure this end muscle may be freely divided—transversely if necessary—and any bruised or lacerated portions cut away.

I shall not speak of the various ways of putting up compound fractures, as so much has already been written upon this subject. There are only three things to consider—the comfort of the patient, ready accessibility of the wound, and immobilization of the fractured bone. Correct apposition of the broken ends is of little importance in the early days, as no union can take place till much later.

Sepsis in a badly drained compound fracture is a most deadly complication. It is in such cases that one sees so much spreading gangrene. Particularly in septic compound fractures of the femur the mortality has been very high. Undoubtedly this is due to the difficulty in securing free drainage. There must be no hesitation about sacrificing a large amount of muscular tissue in order to secure this end.

This leads me to speak of spreading gangrene, though I am afraid I can add little of interest to what has already been written upon this subject. Whether accompanied by gas formation or not it has proved, in my experience, to

be a most hopeless condition. By the time the patient has developed an anæmic toxic appearance I believe he always dies, whatever surgical treatment is adopted. Gangrene is usually either present when the patient reaches the ship, or makes its appearance within the first twenty-four hours. In gangrene of the upper limb, which has not spread much above the elbow, a few lives are saved when circular amputation is performed through the shoulder-joint. The wound is left absolutely open without a single stitch. In the case of the lower limb our results have been bad. A thoroughly toxicæmic and exhausted patient, such as a gangrene patient generally is, seldom seems to survive the shock of a high amputation through the thigh. I am inclined to think that in these cases free incision, followed by frequent deep injections of hydrogen peroxide, is a more hopeful line of treatment. So far spreading gangrene has never occurred in the case of a patient who has reached the ship within eight hours of the receipt of his injury.

One cannot fail to be deeply impressed with the way in which the whole clinical aspect of the wounded varies with the length of time they have taken to reach the ship. When they come late they are absolutely exhausted on arrival, and withstand the shock of operation very badly. Almost all the wounds are extensively infected, and surgical treatment consists almost entirely in incisions and amputations. The mortality from septic infection and from shock is high. When they come early, the mortality from sepsis is low, and the cases, as a whole, run a much more benign course. The difference in the general condition of the patients in the two cases must be seen to be believed.

Before I close I must make some reference to the use of "antiseptic paste." I approached the question with an open mind, having met and talked with Sir Watson Cheyne. I used it freely on our first two trips, and I have come to the following conclusions: If a wound is freely drained, it does not require paste. It will do all right without it. When a wound is once obviously septic, paste is powerless to clear up the infection. I have met with no evidence that it can prevent septic infection occurring, while, once it has developed, there is plenty of evidence that the use of paste is unjustifiable.

In conclusion, I wish to pay a tribute to the energy and organizing power of Fleet Surgeon Dalton. He alone has made it possible for the work on board to be carried through, even in the busiest times, without a hitch. I must also express my personal gratitude to him for much valuable advice and assistance.

ACUTE RENAL DISEASE AMONGST THE TROOPS IN FRANCE.

A CLINICAL NOTE BASED ON NINETY-FIVE CASES.

By R. G. ABERCROMBIE, M.D.CAMB.,
TEMPORARY LIEUTENANT R.A.M.C.

The health of our troops serving in France is at present fortunately excellent; there have, however, occurred a number of cases of acute renal disease, the causation of which is not at present fully understood. The whole subject is undergoing thorough investigation; pending the results of this inquiry, it may be of interest to give a brief clinical account of 95 cases which have come under the writer's personal care.

General Characters.

The disease exhibits the features of an acute nephritis; it presents œdema, the passage of albuminous urine containing granular casts, febrile reaction, and uræmic symptoms.

The majority of the cases occurred in previously healthy young or middle-aged men, in whom no evidence of pre-existing renal disease could be found. In a small minority of cases the previous history or the presence of cardiovascular changes led one to suppose that the condition was superimposed upon previously damaged kidneys.

Symptoms.

Onset.—In some cases the onset was sudden; in others the symptoms were little marked during the first few days, but became progressively worse. Swelling of the face,

especially of the eyelids, was one of the earliest symptoms; it was usually accompanied by headache and pain in the back and limbs; sometimes febrile symptoms preceded the swelling of the face by several days. Bronchitis with irritative cough occurred in many cases; in others abdominal pain, diarrhoea, and vomiting. Of the initial symptoms headache was the most constant; shortness of breath was also frequent. In only very few cases was tonsillitis present.

Oedema was constantly present; it was absent in only one doubtful case. The face was always markedly affected; the trunk and limbs frequently so. Pleural effusion was present in two cases; ascites in four. The usual duration of the oedema was one or two weeks; in only three cases was it obstinate, rendering it necessary to transfer the patients to England in an œdematous condition. The last relics of the disappearing oedema were usually to be found in the parotid and lumbar regions. The cases with ascites ran a severe course, probably owing to the injurious pressure of the fluid on the renal vessels.

Uræmic Symptoms.—Headache, often severe, was a constant symptom. Convulsions occurred in three cases; amaurosis in one. Vomiting and paroxysmal nocturnal dyspnoea occasionally occurred. The tongue was usually furred, sometimes dry and brown.

Febrile Reaction.—Many of the cases exhibited a temperature of 100° or 101° for one or two days after their admission to hospital; in others the history suggested that fever had been present at the onset. Two cases relapsed while in hospital; in each the temperature rose to about 101°. One case ran a febrile course for about a fortnight. Shivering was sometimes complained of, but an actual rigor was not witnessed. Since the cases were not generally admitted to hospital until several days after the onset, it was not possible to say whether fever was invariably present at the commencement.

Urine.—The volume passed was much diminished in the bad cases; complete suppression was present in several instances. The amount of albumin varied from a light cloud to a quantity sufficient to render the urine nearly solid on boiling. The amount diminished under treatment, but only in a very few cases did it clear up altogether prior to the patients' transfer to England. Granular casts were constantly present during the acute phase; hyaline and blood casts were also found. Red blood cells were present microscopically in the large majority of cases; obvious hæmaturia was frequent, and sometimes persisted when the patient was approaching convalescence.

Blood pressure was usually high during the acute phase, as evidenced by an accentuated aortic second sound. Means were not at hand for obtaining an exact record of the arterial tension.

Other Symptoms.—The bronchitis occasionally proved persistent and troublesome. Severe epistaxis occurred in several cases. Rarely did nephritic œdemata show itself.

Diagnosis.—Various forms of albuminuria were distinguished by the absence of œdema and uræmic symptoms and by the characters of the urine. In several cases not included in this series the symptoms were due to an infection of the lower urinary tract by the *B. coli communis* or a related organism. So far as the writer's observations go, only in a very few cases could the condition be regarded as an exacerbation of a chronic nephritis.

Prognosis.

None of the patients died. After a stay in hospital of from one to three weeks, 92 of the patients were transferred to England free from œdema. In a few of these cases the albumin had also disappeared, in several others it was reduced to a trace, but the majority were still passing a fair amount of albumin. Three cases assumed a chronic aspect, and were transferred to England with persistent œdema. Only time will show how far the condition will lead to chronic renal disease.

Treatment.

The patients were nursed between blankets and were warmly covered up. They were given milk, barley water, and lemonade; these were administered warm every two or three hours, a total of 7 or 8 pints being given in the twenty-four hours. A daily morning purge of half an

ounce of magnesium sulphate was given, and repeated during the day, if necessary.

The effect of this treatment was immediately seen in the re-establishment of the urinary flow, the rapid subsidence of the oedema, the clearing of the tongue and the return of the appetite. The progressive increase in the volume of urine, as shown by daily measurement, afforded an index of the patient's improvement. In cases with much gastric disturbance it was necessary largely to substitute barley water for the milk for a few days. Solid food, with the exception of fruit, was, as a rule, withheld until after complete disappearance of the dropsy; a little bread-and-butter and milk pudding were then given. In cases tending to chronicity, salt-free diet was tried, but not for a period long enough for its value to be ascertained. Suppression was treated by sinapisms to the loins and hot packs, the patient being plied with warm lemonade while in the pack. Packs were also employed for uraemic symptoms and for obstinate dropsy; they were not repeated too often, as they were found debilitating. Diuretics and diaphoretics were not as a rule employed, except when the dropsy was obstinate; in such cases caffeine and salines were tried without much apparent benefit. Urinary antiseptics, in the form of boric acid and urotropine, were given in a few cases; it was difficult to estimate their value; they were not given as a routine, in the absence of direct evidence of infection of the urinary tract, and from fear of irritating the kidneys. Bromides were given for severe headache and for convulsions, and a sedative cough mixture ordered when necessary.

When the urinary flow was fully re-established, the oedema completely absent for several days, and all uraemic symptoms relieved, the patients were warmly wrapped up and transferred as cot cases to England.

Causation.

Most of the cases came from the front, but some had been in comfortable quarters at the base. The disease appears sometimes to occur in small localized outbreaks; thus three cases occurred amongst the orderlies of one hospital. Exposure to cold in itself cannot be the causative factor, for the writer saw no cases at a general hospital during the severe weather of January and February, whereas in the warm months they have been frequent. The diverse conditions under which the men had been living makes it difficult to incriminate any particular food or drink. Most of the patients had drunk Flemish beer, some had drunk French wine, and some had been practically teetotalers.

From the motley symptoms of the onset and the irregular incidence, the writer at first judged the cases to be an anomalous form of influenza; but though organisms resembling *Bacillus influenzae* were found in the sputum of the bronchitic cases, they could not be recovered from the urine. Cultures of the urine proved sterile, except in a few cases in which staphylococci were grown, probably due to contamination. Blood cultures also proved sterile.

Reviewing all the circumstances, the writer is inclined to the belief that the disease is an infection by a definite organism, the nature of which is at present undiscovered.

The writer expresses his thanks to Lieutenant-Colonel J. H. Campbell for permission to publish the cases treated at No. 11 General Hospital; to Colonel Sir John Rose Bradford, for his ever-ready help and advice in difficult cases; and to Temporary Captain S. W. McLellan, for a large amount of pathological investigations.

THE IMPORTATION OF BACILLARY DYSENTERY.

By A. E. CARVER, M.D., CANTAB., M.R.C.P. LOND.,
HONORARY PHYSICIAN, WESTERN AUXILIARY MILITARY HOSPITAL,
TORQUAY.

THE immunity from epidemic disease enjoyed by our troops during almost twelve months of trench warfare is a striking testimony to the efficiency of our Army Medical Services; but it is now evident that cases of dysentery are to be expected from the front, and it is open to question whether the necessity for the adoption of stringent methods of precaution and prevention, in the

interests of the population at home, has been fully appreciated.

The grounds for fearing that dysentery amongst our soldiers is likely to be followed by similar epidemics amongst the civil population are not purely theoretical. Such a sequence, with disastrous results, occurred in North London in 1902, an account¹ of which was read before the London Medical Society. Dr. Cantley² also described an outbreak amongst women and children which occurred at a London barracks in June, 1900—that is, nine months after the opening of the Boer war—and during the autumn of the same year other outbreaks occurred in the Home Counties. Although in none of these cases, I believe, was the *Bacillus dysenteriae* (Shiga) isolated, it is probable that this was only because search was not made for it, and there can be hardly a doubt that these cases were in fact acute bacillary dysentery, from which disease the symptoms, course, and pathological findings were indistinguishable; and in some at least of the cases the infection was traceable to soldiers recently home from South Africa.

Confirmatory evidence of the view expressed in a thesis³ in 1903 that the supposed varieties of acute and ulcerative colitis, as occurring in this country, are identical with the disease known as dysentery when occurring abroad, has been adduced independently by Dr. Eyre⁴ and by Professor Robert Saundby,⁵ the latter in an illuminating address delivered in 1906; and it would be interesting to learn whether sporadic cases of ulcerative colitis have of late years appeared in the wards of our large hospitals with as great frequency as during the years immediately following the late South African war.

Until quite recently there seems to have been no repetition in this country of dysenteric diseases occurring in epidemic form, but at the present time circumstances appear to be assuming a more threatening attitude.

During the autumn of last year a virulent epidemic, exactly resembling that of 1902 in North London, broke out in an institution in the West of England. At first two nurses were attacked, children under their charge becoming subsequently affected, and from the stools of these patients the *B. dysenteriae* was isolated in almost pure culture. After diligent search it was found that a child admitted about a fortnight previously had suffered from stomach-ache and diarrhoea, and was at that time passing visible pus and mucus in his stools. He was, in fact, convalescent from dysentery, and upon questioning him it transpired that his father had lately returned home from India and was still suffering from the disease. The child recovered, but others succumbed, and the epidemic threatened to assume very serious proportions.

At the present time I have under my care a soldier who was sent home convalescent from enteric fever. Five days after his admission to the Western Auxiliary Military Hospital he developed acute dysentery, a bacillus indistinguishable from the *B. dysenteriae* being present in the stools. The onset of the dysentery occurred eighteen days after he left the military hospital abroad, and the inference is that the disease was contracted on the ship in which he spent thirteen days on the voyage home, in company with scores of men who were suffering from dysentery.

Notwithstanding that it is accepted upon all sides that bacillary dysentery is an acute infection, the disease is not notifiable, and there seems to be but little general recognition of the established fact that it is capable of assuming epidemic aggressiveness even in this country.

Moreover, experience would seem to indicate that when the disease does gain a foothold it proves to be of a virulent type, the rate of fatality, amongst children especially, being extremely high.

HASSELLTINE publishes in the *New York Public Health Reports* for July 30th, 1915, two cases of paralysis during antirabic treatment in addition to two others which he made public in 1913. In one of the patients facial palsy developed on the twenty-first day but it passed off. The second case died on the eleventh day of treatment, six days after the development of ascending paralysis. It is not clear that this complication was really an abortive rabies.

A CASE OF MOLLUSCUM FIBROSUM

(VON RECKLINGHAUSEN'S DISEASE).

BY

A. WILSON GILL, M.D. EDIN.,

BANLEY, STAFFS.

The case described below illustrates the usual features of molluscum fibrosum, and little is to be added to the original description of the disease published by von Recklinghausen in 1882. Several cases have been described and investigated since that date, and have all corroborated his discovery that the multiple growths occurring in the skin are of the nature of fibromata growing from the connective tissue of the terminal filaments of the cutaneous nerves. The standard work on the subject in this country is the exhaustive monograph by Alexis Thomson, *On Neuroma and Neurofibromatosis*, published in 1900. Therein will be found a full description of the two cases recorded by von Recklinghausen, a complete account of symptoms, diagnosis, prognosis, etc., and a list of all the recorded cases of neurofibromatosis up to that date. Rolleston and Macnaughton² in 1912, in their paper on hereditary and familial types of the disease, give a further list of familial and hereditary cases published after 1900.

The patient here described is a man aged 60, a potter's slip-maker by occupation, who confesses to no previous illnesses, but who for the last few years has suffered more or less from chronic bronchitis. He is somewhat poorly nourished, but active both physically and mentally. He exhibits none of the mental dullness often associated with cases of von Recklinghausen's disease. There is no history of bilious attacks which have been described by some observers, nor can I find any evidence of pulmonary tuberculosis.

History.

He states that he first noticed small lumps on the skin of the chest about thirty years ago. These lumps appeared painlessly, and steadily increased in size, while fresh growths continued to appear. Some appeared to collapse after a time, but none of them have ever completely disappeared.

On several occasions he has pricked them, thinking they were little bladders with fluid contents. One continued to grow from the region of the lower costal margin on the right side until it reached almost to Poupart's ligament. This tumour was removed at the North Staffordshire Infirmary twenty-two years ago. It weighed 5½ lb. Following on the operation, he states that the tumours increased rapidly in size and number, especially on the chest.

Although the disease was painless at the onset, he now states that he can tell for several days beforehand where fresh growths will occur, by a sensation of intense pricking suggesting "the bite of a gnat" which causes him to rub the part. There then appears a small violet-blue spot under the skin, which gradually becomes a small growth about the size of a small pin's head; it steadily increases in size or may remain stationary. On the scalp there is a large oval soft swelling measuring 5 in. by 3½ in. covered with a few hairs, and suggesting a bald patch in the accompanying photograph. This tumour, he has been informed, was present at the time of birth. Apart from bronchitis, his only complaint is cramp in the right leg after walking.

Distribution of the Growths.

The greater number of the growths are found on the trunk itself and especially on the back and chest. On the top of the head is the large soft tumour already mentioned. The face and forehead are dotted over with numerous small growths and there are innumerable small pin-point growths on the neck. There is one on the chin the size of a hazel nut, pedunculated, but hidden by the beard. The arms, thighs, and legs are comparatively free from growths. There are none on the palms of the hands, but on the sole of the left foot there are two small ones along the inner border, and several small ones on the sole of the right foot. Over the coccyx there is a tail-like appendage. The majority are sessile, but a few have a tendency to be pedunculated.

There is no pain on pressing over any of the tumours. They are generally of soft consistence, some giving the sensation of empty bags of skin, but over the site of the operation scar they tend to be firmer and give a feeling of containing a convoluted plexus. In most of the larger tumours this plexiform arrangement is distinctly palpable.

Areas of pigmentation are usually found associated with the tumour growth. In Alexis Thomson's series of 76 cases, pigmentation was present in 19—a proportion of 25 per cent. Harbitz³ found pigmentation present in all the cases examined by him. In many cases, as in this, the skin surface generally is dark with a diffuse brownish pigmentation. In addition to this general discoloration, more definite areas of pigmentation are to be found. Three distinct varieties of pigmentation occur and are present in this case similar to those described by Rolleston and Macnaughton:

1. Functiform pigment spots, resembling freckles.
2. Café-au-lait patches.
3. Violet-blue spots—the first stage of the molluscous tumours.

In this man the café-au-lait patches are found only on the back and especially over the scapulae. The largest is seen over the right scapula. Smaller patches occur on the back generally and over the buttocks. The arms and legs are comparatively free from pigmentation, and there are no patches on the buccal mucous membrane.

The actual diagnosis of von Recklinghausen's disease must, of course, rest on the histological examination of the tumours. This has not been agreed to in this case, and owing to the rapid increase which took place after the operation twenty-two years ago, I have not pressed him very hard to submit to any operation, however slight.

I have been quite unable to trace any hereditary or family tendency in this patient, but it is well known that such cases are not infrequent, and are fully described in the literature. As Feindel has said, "Generalized neurofibromatosis is always congenital, often hereditary, and sometimes familial."

The treatment for the condition is purely surgical, but should only be adopted in the case of very large tumours, if there is pain, or where ulceration has occurred over the tumour. It has repeatedly been observed that operation has been followed by an increase in the size and number of the tumours.⁴

Death may occur from exhaustion, loss of weight, and anaemia, if the disease is progressive, and the occurrence of sarcoma is not uncommon.

The special points of interest in this case are:

1. The intense itching preceding the appearance of the tumours. This symptom is not a common one, but was noted by Malcolm Morris and Wilfred Fox⁵ in a case described by them.
2. The congenital nature of the disease, as shown by the presence of the tumour on the scalp at the time of birth.

3. The presence of tumours on the soles of the feet—an uncommon situation.

4. The presence of the three types of pigmentation.

5. The rapid increase in the size and number of tumours after operation.

ACUTE ACTINOMYCOSIS OF THE PAROTID GLAND.

By E. D. TELFORD, F.R.C.S.,
SURGEON, MANCHESTER ROYAL INFIRMARY.

THE course of events after infection by the ray fungus is usually slow; the swelling and induration are of gradual development without acute local or general reaction, and the subsequent softening and discharge are long drawn out and tedious.

There occur, however, rarer cases in which the disease assumes a much more acute form. Two such cases have come under my notice within the last ten years, and they seem worthy of mention since there are but few reports of the acute forms of actinomycosis. In view of the fact that the ordinary chronic variety is still frequently missed, and a diagnosis, often of tuberculosis, sometimes of sarcoma, is wrongly made, the acuter cases of actinomycosis are, owing to their greater rarity, still more likely to be a source of error in diagnosis.

The two cases on which this note is based presented a remarkable similarity in onset and symptoms. In each case the route of infection was by the parotid duct, and from this point of entry the disease rapidly infiltrated the gland itself. The infection was, in the one case, derived, no doubt, from the habit of chewing corn whilst engaged in feeding poultry; in the other case the patient had, a week before the onset, played with some children in a field of ripe corn, but no more exact source of infection could be discovered. In both cases the outline of the gland, including the very distinct *socia parotidis*, was plainly marked, but within seven days of onset the barrier of the glandular capsule was broken down, and a most acute diffuse cellulitis of the face resulted. The nature of the infection was determined in each case by the examination of portions of the infiltrated subcutaneous tissue in the Pathological Department of the University of Manchester.

The features of this acute form of actinomycosis would appear to be as follows. The fungus enters by the parotid duct and, within a few days of entry, gives rise to an acute parotitis; the *socia parotidis* is seen to be enlarged and tender. The disease then bursts through the limits of the gland, whereupon a very acute cellulitis develops which may extend far over the scalp and well down the neck. There is great constitutional disturbance and marked evidence of septic absorption. At this stage the swollen parts are likely to be incised, when the incisions will be found to yield no pus, but merely a sanious debris. The cut tissue will be seen to be diffusely infiltrated, of a dirty grey colour, flecked with points of yellow. The fluid and debris obtained may be extremely foul, indicating a mixed infection of organisms from the mouth. The incisions, although they may ameliorate the acute condition, will probably fail to arrest the disease and the further spread of the lesion with fresh points of softening will be seen. These, when in turn incised, will tend to assume a chronic course until, ultimately, the diagnosis is trusted upon the observer by the yellow granules of the fungus.

The practical lesson is that any acute cellulitis of the face of obscure origin, or of unnoted appearance on incision, should excite suspicion of actinomycotic infection. The discharge from such lesions, or, better, a small portion of tissue, should be examined, and, since the fungus is not always easy of identification, a single negative result should by no means be accepted as final.

Once the diagnosis is established, appropriate treatment in addition to the incisions should be given. Iodine has appeared to yield good results in the more common chronic forms of the disease, and should certainly be used freely

in these more acute cases. It has often been given in too small a dose; it should be pushed very freely in all forms of actinomycosis. One of my acute cases took no less than 240 grains of potassium iodide each day for several weeks with distinct benefit and no ill effect. In addition, iodine should be given locally. A 10 per cent. solution of iodipin may be injected into the infiltrated area at several points to the daily amount of 10 c.c.m. The incisions and sinuses should be irrigated freely with a weak mixture of tincture of iodine and water.

In my second case a dose of 0.3 gram neo-salvarsan was given as soon as the diagnosis was established on the twelfth day of the illness. Although this case was a very acute one, with extremely foul discharge, there was within twenty-four hours of the administration a very marked increase in the amount of discharge and a rapid improvement in the local and general condition. This improvement was so well maintained that a further injection which was contemplated was not given. An isolated observation of this kind is of small value, but from my experience of its effect in this instance I would certainly be disposed to use salvarsan in cases of actinomycosis.

The problem of securing good drainage by incision of the face without leaving very obvious disfigurement is not easy. In my second case I attempted it by making a free incision above the hair line of the temple, and by blunt subcutaneous dissection I made a large tunnel, out of which a tube was drawn through a small vertical incision in front of the ear. Another incision, concealed behind the angle of the jaw, enabled a similar subcutaneous tunnel to reach the first one and provided good dependent drainage by a second tube. In this patient all the parts were soundly healed within two months and the cosmetic result was particularly fortunate.

In these more acute instances of facial actinomycosis early diagnosis is much to be desired. Unless the true nature of the disease is recognized, the condition is likely, after numerous incisions, to drift into the ordinary chronic form with multiple and tedious points of softening causing gross disfigurement. It would seem that much may be done to obviate this unfortunate result by energetic treatment early in the disease.

My first case had been treated as "mumps" and had been in existence for three weeks when brought to my notice. This case, in spite of energetic treatment, took five months to heal, and resulted in very marked disfigurement. The second case, which had a history of only seven days, was, by the help of free drainage, of much iodine, and probably of salvarsan, well healed within eight weeks, and the subsequent facial appearance of the patient was not the least satisfactory feature of the case.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF ACETYL SALICYLIC ACID POISONING.

ACETYL SALICYLIC ACID being so extensively prescribed at the present time leads me to publish the following as possessing some features of interest in that the patient showed a marked idiosyncrasy to the drug on a number of occasions.

A gentleman, aged 34, was suffering from a slight attack of influenza. I advised him to take 10 grains of acetyl salicylic acid every six hours. The first dose was taken about half an hour after a light lunch, and by mistake he took only 5 grains. Within an hour his throat commenced to swell, and the mucous membrane of the tongue shortly afterwards became involved to a marked degree. Severe pain, situated over the middle of the sternum, ensued. The oedema spread to the neck, which became much enlarged equally on the two sides, and the swelling quickly extended upwards over the face. The eyelids participated in the general oedema, but the involvement was not sufficient to close the palpebral fissures. A dull red urticarial rash now appeared over the chin and both cheeks. The roof of the mouth was dry and the speech thick. The oedema of the tongue was sufficient to embarrass somewhat respiration by the mouth, but the act was unimpeded by the nasal route. Slight deafness and tinnitus and a sensation of fullness in the head were present. There was no palpitation, and the urine was normal in appearance. Gastro-intestinal symptoms, with the exception of the sternal pain mentioned, were absent. Two hours after the onset the symptoms commenced to abate, and an hour later had all disappeared. Although the discomfort

attendant on the infiltration of the connective tissues was marked, the severe sternal pain, which lasted two hours unabated, was the greatest cause of alarm to the patient. Alcohol, asthma, rheumatism, and gout have no place in his past history, but there is a tendency to the last-mentioned disease in the family. There is no trace of augeoneurosis in the family history.

When I saw him later he informed me that he had had a number of similar attacks in the past. The first occasion was two years previously, when he was given 5 grains of acetyl salicylic acid for a chill. Toxic symptoms commenced within half an hour, and lasted in all about eight hours. The sternal pain on this occasion was not so severe, but otherwise the phenomena were exactly comparable to those enumerated above.

About twelve months later a doctor gave him acetyl salicylic acid in cachets, one to be taken every night immediately before retiring to bed; the dose is not known. Twelve doses in all were taken, and on each occasion exactly the same symptoms commenced within a period of half an hour to an hour, and lasted from two to three hours. He continued taking the acetyl salicylic acid every night, as he thought the symptoms "were part of the disease and the treatment."

The toxicity of the drug has been attributed to the impurities existing in salicylic acid, and the phenomena of salicylism are very like those produced by quinine, but inquiry elicited the fact that the patient has always been able to tolerate full doses of quinine.

The marked idiosyncrasy of this patient for acetyl salicylic acid is well shown. In all, the drug has been taken on fourteen occasions, and each time has been attended by the same toxic phenomena, the individual symptoms following each other in similar order. The degree of severity has gradually increased, particularly as it relates to the lingual oedema and the sternal pain.

PEPPER IN THE PROPHYLAXIS AND TREATMENT OF FILARIASIS.

AFTER several months of observation and experiment I have discovered that pepper is an excellent prophylactic against filaria.

A study of the diets peculiar to the various races in this colony reveals the important fact that where much pepper is used in the food filaria is less evident in direct proportion. For example, (a) the aboriginal Carib Indians use an enormous amount of pepper in their food and drink, and filariasis is almost unknown among them; (b) the East Indian immigrant and those "Creole" East Indians who adhere strictly to their national dishes, in which pepper enters largely, seldom, if ever, suffer from filariasis. On the other hand, filariasis is most common in those races, like Portuguese, negroes, and other inhabitants, who make use of very little pepper in their food.

From the above observations I concluded that pepper, or piperine, its active constituent, was no doubt the prophylactic against filaria.

Probably the knowledge of the prophylactic properties of pepper, like most other things in primitive peoples, was lost in the centuries, and what was once based on scientific principles was handed down and followed blindly as a habit or custom.

To prove my theory that pepper has something to do with the prevention of the manifestation of filariasis, I experimented with tinctura capsici in cases of acute filarial fever and lymphangitis, and found that the fever and lymphangitis yielded promptly to the administration of the drug. Probably piperine would act in the identical manner.

The discovery promises to have very far-reaching results; therefore I hasten to record my observations, and hope to prove their value and accuracy later.

J. A. ROBERTSON, L.R.C.P. and S.E.,
Medical Officer, Alms House,
Georgetown, Demerara.

The authorities in the capital of Pennsylvania, which has been troubled recently with rainy weather, have acted with great vigour in preventing the multiplication of mosquitos. A special mosquito brigade has treated more than 353,000 sq. ft. of standing water with oil, filled up approximately 300 pools, and dug 50 miles of ditches to drain marshes where the pests breed. All weeds on vacant lots have been cut down. It is proposed that the marsh lands shall be cleared and trenched in January when they are frozen.

Reports

ON MEDICAL AND SURGICAL PRACTICE IN HOSPITALS AND ASYLUMS.

PERTH HOSPITAL, WESTERN AUSTRALIA.

GRANULOMA PUDENDI: CAESAREAN SECTION.

(By ARTHUR J. NYLANS, M.R.C.S.Eng., Gynaecologist to the Hospital.)

Mrs. X., aged 20 years, white, but born in a district in Western Australia in which infective granuloma occurs among the aborigines, was admitted to the Perth Hospital about seven months pregnant with her first child on August 3rd, 1913. About six months earlier small nodules appeared on the perineum, and soon broke down into ulcers. The labia majora were found much enlarged, firm, and rough on the surface, and about 2½ in. in diameter. The labia did not pit on pressure. Ulceration, with irregularly heaped-up granulation tissue on the surface, was seen to extend from a little behind the anus about 1½ in. on each side of it and involving it, and passed along the outer and inner sides of the labia majora; also from the clitoris up the anterior vaginal wall. The edge of the ulcerated surface was clean cut, not markedly raised, and rather serpiginous. The vaginal introitus was narrowed by dense scar tissue occupying its posterior margin. Outside the local condition described no lesions could be discovered in any other part of the body, but the patient was decidedly anaemic. The Wassermann reaction was negative, and salvarsan, mercury, and iodine without evident effect.

On October 15th, 1913, the patient, being in labour, was transferred to me for Caesarean section. She was intensely anaemic, the blood from incisions giving a remarkably pale stain. The placenta was found immediately under the uterine incision and completely separated, there being no adhesions, polypoid decidual endometritis, or other evidence of syphilis. The abdominal incision was only a little over 6 in. long, and the child was extracted without withdrawing the uterus from the abdominal cavity. The child could not be revived, but the mother progressed satisfactorily up to a week after operation. The skin clips were then removed, and a few hours later the whole abdominal wound was found to have completely opened up into the peritoneal cavity, exposing the intestines. The vitality of the patient had been so low that there had not been the slightest attempt at repair of the abdominal wound. In spite of this, however, the uterine wound had united quite satisfactorily, supplying excellent evidence of the healing capacity of the highly vascularized pregnant uterus. The abdominal incision was resutured, and the patient placed in the open air and given iron and ammonia. Thence onwards the progress to recovery from the operation was uninterrupted.

The granulomatous condition remained little if at all influenced by iodides, mercury, arsenic, and iron internally, and antiseptic local treatment. On December 21st the whole ulcerated area was scraped, the heaped-up granulation tissue coming away with great ease, as if it were an overlying moss. The surface was then brushed over with carbolic acid. The cervix uteri was felt on this and on a subsequent occasion (January 7th, 1914) to be very friable, breaking down readily with the gloved finger-nail. A vaginal speculum could not be used on account of the contracted condition of the introitus, so that one had to depend entirely on the sense of touch. The cervix was curetted, and carbolic applied. X-ray treatment was given twice a week, and after a few months the patient left the hospital. Mr. Hancock, the radiographer to the hospital, who carried out this treatment, informs me that the ulceration had almost healed, and the labia were almost their normal size when the patient went home.

Dr. Shearman, Government Bacteriologist to Western Australia, who examined specimens from this case, states that they consisted of granulomatous tissue, but that he could discover none of the spirochaetes referred to by some writers on infective granuloma. Dr. Cleland, of Sydney, has contributed valuable papers on this disease, in one of which he figures a spirochaete.

Infective granuloma pudendi is quite common among the

aborigines of the north of Western Australia, seventy or eighty cases being as a rule under the care of Government medical officers. As far as I can discover, however, the case here recorded is the first instance in Western Australia in which the disease has occurred in a white woman. How she became infected could not be determined, although sexual congress is the usual method of propagation. The husband presented no evidence of the disease.

Reviews.

MORE OXFORD WAR PRIMERS.

MAJOR L. BATHE RAWLING, in his Oxford War Primer on *The Surgery of the Head*,¹ treats of the subject with the authority to which his experience of the present war entitles him. The work, which is well and profusely illustrated, deals in detail with the various injuries and diseases of the head which may have to be treated—not only with wounds of the scalp, skull and brain, with fractures of the vault and base of the skull, with concussion, compression and irritation of the brain, and with intracranial hæmorrhage, but also with injuries of neighbouring regions, such as the orbit, the jaws, and the mastoid process. There is, in addition, a chapter on infections of the brain and meninges, the whole giving a complete, if not very exhaustive, account of the injuries dealt with. The book opens with a chapter on the clinical applied anatomy of the head, its physiology and its topography—information important for the student of brain surgery. In his reference to the physiology of the optic nerve, he points out that the experience of the war has established the fact that the great majority of head injuries with increase of intracranial pressure are associated with some degree of papilloedema, not true optic neuritis. The whole appearances are those of oedema due to pressure, not those of inflammation. These observations have been confirmed by other workers in cerebral surgery during the war. The author lays great stress on the importance of head injuries at the present time, on account of their frequency, owing to the method of trench fighting, and also on account of the serious nature of the sequelae, many of which may be prevented by proper treatment. Quoting Teewan's law that the aperture of exit is caused by the penetrating body only, whilst the aperture of exit is larger, inasmuch as it is made by the penetrating body plus the fragments driven out of the proximal table and diploë, he applies it to the bullet wound fractures of the skull, urging that it cannot be too repeatedly stated that every fracture of the external table, however trivial at first sight, is associated with a much greater comminution and depression of the internal table, with all the associated danger of damage to dura mater, meningeal vessels, and venous sinuses. We heartily agree with the author that these observations cannot be too frequently and too strongly impressed on all those surgeons who have to deal with cases of head injury, however trifling and simple they may seem to be. The chapter dealing with the technique of operations on the skull and brain is good, though the detail given would not be sufficient to guide an inexperienced surgeon in performing any but the simplest operation. The great importance of the control of hæmorrhage from the scalp in brain operations is dealt with, and the author describes a simple tourniquet devised by himself for controlling such hæmorrhage. It consists of a frontal metal piece, through which holes are bored for the passage of a rubber band. The rubber is of greater calibre than the hole through which it passes, and consequently, when tightened up, locks automatically. The tourniquet is passed over the head so as to be low down over the occipital region, above the level of the ears, and low down again over the forehead. In such a small work as this it is obviously impossible for the author to have dealt very fully with a subject so extensive as the whole of the surgery of the head, but the primer may be recommended to the beginner on the subject as strictly up to date and accurate.

¹ *Surgery of the Head*. By L. Bathe Rawling, M.B., B.C. Cantab., F.R.C.S. Eng., Major R.A.M.C. (T.F.), Oxford War Primers, London: H. Frowde, and Hodder and Stoughton, 1915. (Fcap. 8vo, pp. 150; 21 figures. 3s. 6d. net.)

Lieutenant-Colonel D'ARCY POWER's small work on *Wounds in War*,² another of the Oxford War Primers, has a somewhat misleading title, for it deals with war wounds in a very general sense only, with no reference to wounds of the chest, spine, or abdomen, and no account of gunshot fractures of the limbs or skull. Colonel D'Arcy Power belongs to the school which believes that the principles of aseptic surgery are not applicable to the treatment of wounds received on active service, a school whose principles most war surgeons have now adopted. He advocates the thorough and immediate cleansing of gunshot wounds, swabbing them out very liberally with pure carbolic acid, and following this by free incision and thorough drainage. The vaccine therapy of wounds is treated at length in a chapter contributed by Mr. Mackenzie Waller, who advocates the use of antiserum combined with vaccine as preferable to either alone. The chapter on secondary hæmorrhage is good, though exception might be taken to the view that in cases of this nature it is useless to attempt to isolate and ligature the artery in the wound, and that therefore the vessel must always be tied in its continuity. Many experienced surgeons advise that in many cases at least an attempt should be made to tie the artery in the wound, and we have seen many instances in which this treatment has been quite successful. This little work, though not very ambitious, may serve as an introduction to the beginner in war surgery.

In his excellent little volume of *Medical Hints*³ Colonel J. E. SQUIRE gives a first-rate summary of the information likely to prove useful to medical officers in charge of troops. He recognizes, and, still more, would act upon the principle that prevention is better than cure; with the result that his pages are full of hints as to the early detection of troubles of a medical nature that may be nipped in the bud, or at any rate cut short, by immediate recognition or treatment. The first chapter deals with the acute infectious fevers to which the soldier is liable, including such foreign diseases as cholera and plague. Then follows a brief account of the diseases of the digestive system; here Colonel Squire remarks that a toothbrush should form part of every man's kit on service, and is more important to him than his razor—to which we would say "Hear, hear," under our breath, so that the C.O. shall not hear. Subsequent chapters deal with heart disease, rheumatism, tonsillitis, body parasites, frost bite, gassing, and other such subjects, with some excellent pages on the uses and abuses of tobacco. Marching, and discipline in hospitals are also discussed in a very helpful manner. Colonel Squire's book may be warmly commended to the attention of the medical officers for whom it has been written.

Dr. G. M. DUPUY's illustrated manual of stretcher-bearing, designed as a companion to the R.A.M.C. *Training Book*,⁴ contains a series of 138 photographs showing exactly how stretcher-bearer squads should perform their evolutions, and how the wounded should be cared for on the field of battle. The present war has proved what a great asset the regimental stretcher-bearer is to his wounded or disabled comrades; experience has shown that the collection of the wounded in the actual firing line must be largely the work of the regimental men rather than of the R.A.M.C. men, who have all their work out on the collecting stations. The photographs are good, and are clearly explained. The book may be commended to the attention of all who are going in for stretcher work and have no experience of military or ambulance training.

GERMAN ATROCITIES.

In the early stages of the war the civilized world was appalled by the records of German "frightfulness" in Belgium and France. Later, similar stories came from Poland. The advance of the German

² *Wounds in War, their Treatment and Results*. By D'Arcy Power, M.B. Oxon., F.R.C.S. Eng., Lieutenant-Colonel R.A.M.C. (T.F.), Oxford War Primers, London: H. Frowde, and Hodder and Stoughton, 1915. (Fcap. 8vo, pp. 108. 2s. 6d. net.)

³ *Medical Hints for the Use of Medical Officers Temporarily Employed with Troops*. By J. E. Squire, M.D. Lond., F.R.C.P., D.R.C. (amb.), Lieut.-Colonel R.A.M.C. (V.), etc., Oxford War Primers, London: H. Frowde, and Hodder and Stoughton, 1915. (Fcap. 8vo, pp. 128. 2s. 6d. net.)

⁴ *The Stretcher Bearer*. By G. M. Dupuy, M.D., Oxford Medical Publications, London: H. Frowde, and Hodder and Stoughton, 1915. (5s x 3s, pp. 149; 138 figures. 2s. net.)

army in these countries was marked by the wholesale slaughter of prisoners and wounded, among them women and children; the burning of villages; the wanton destruction of historical buildings and monuments; rape, robbery, and murder, with every conceivable circumstance of torture and brutality. When outraged humanity sent up a cry of horror at these atrocities the Germans replied by saying "War is war," the formula with which they justify the violation of every law and agreement made among civilized nations, and accepted by themselves, for the mitigation of the inevitable cruelties of war. Later, when they began to realize that the German army had clothed itself with a garment of infamy that would make the very name of the nation to which these savages belong a fixed figure through all time for scorn to point his slow, unmoving finger at, they said the charges were lies. Exaggeration, and even invention, there may have been. But there is a large mass of evidence which bears the stamp of official authority, and cannot be waved aside by a simple denial. Not counting reports in newspapers and in books about the war by writers who profess to describe only what they saw, there is a considerable body of literature containing the results of carefully sifted inquiries made by Commissions appointed by the Belgian, Russian, British, and French Governments. All these contain ample proof of outrages such as are summarized in the report of Lord Bryce's Committee on Alleged German Outrages, published as a Blue Book. It is there stated that it was proved:

(1) That there were in many parts of Belgium deliberate and systematically organized massacres of the civil population, accompanied by many isolated murders and other outrages. (2) That in the conduct of the war generally innocent civilians, both men and women, were murdered in large numbers, women violated, and children murdered. (3) That looting, house burning, and the wanton destruction of property were ordered and countenanced by the officers of the German army; that elaborate provision had been made for systematic incendiarism at the very outbreak of the war, and that the burnings and destruction were frequent where no military necessity could be alleged as being the cause of a system of general terrorization. (4) That the rules and usages of war were frequently broken, particularly by the using of civilians, including women and children, as a shield for advancing forces exposed to fire, to a less degree by killing the wounded and prisoners, and in the frequent abuse of the Red Cross and the white flag.

It is strange that in the face of all this weighty evidence there should still be pacifist cranks in this country who, in their zeal to defend the Germans, declare these charges to be not proven. To all who, either from a misguided philanthropy or from the characteristic English way of taking it for granted that everything British must be wrong, may be inclined to take this view of the conduct of the Germans, we recommend an attentive study of the French official report on German atrocities, an English translation of which has just been issued.⁵ The book is free from any tinge of sensationalism; its tone is throughout judicial. The pledges given by Germany in treaties and in conventions of the Hague are confronted with instances of their deliberate violation proved by documentary evidence, mostly of German origin. About a hundred documents are quoted, said to be taken "almost at random from amongst hundreds of others no less convincing"—reports by French officers and soldiers, sworn statements by French citizens, proclamations and orders of the day by German commanding officers, and the proofs and admissions supplied by the diaries and letters of German soldiers. "All these documents," it is truly said in the preface, "possess in themselves a kind of authority to which, generally speaking, there is no possible reply." The genuineness of the extracts from the notebooks, diaries, and letters of German soldiers is shown by photographs of the originals. The indictment is thus all the more crushing inasmuch as the Germans are condemned out of their own mouths.

A few quotations will give an idea of the nature of the evidence. In a notebook written in Belgium by a German non-commissioned officer there is the entry "Mutilation of

the wounded is the order of the day." In another the writer says:

Alas, how quickly one sees the *l'ête humaine* revealing itself in many a soldier. It was not long before we could tell whether our kultur was a mere surface varnish or something more deeply rooted. . . . They ransacked the houses looking for arms without the least regard for social rank.

Further on the writer says, "All moral sense is deadened." And again:

All rights of property are abolished. We are doing infinite injury to our reputation.

In the notebook of another non-commissioned officer there is the following entry:

It was given out at first that we would take up our quarters at Billy, from which place the entire civil population had already been expelled, and all household effects either removed or destroyed. This method of making war is absolutely barbarous. I wonder how we can have the face to rail at the conduct of the Russians when we are behaving much worse in France; at every opportunity on one pretext or another we pillage and burn.

The writer seems to have a foreboding of a day of retribution, for he adds:

But God is just and sees everything. "His mills grind slowly, but they grind exceedingly small."

A private soldier writes:

There is really some truth in all the talk about German barbarians.

Lieutenant Wilhelm Peters, of the 8th Bavarian regiment of infantry (reserve), in a sworn deposition, stated that he had seen brutalities perpetrated by various soldiers who had strayed from their company. But he attributes the crimes committed at Nomeny on August 20th and 21st, 1914, to "abnormal brutes." Several instances of the murder and wounding of medical officers engaged in the discharge of their duties are given. A typical example of the contempt in which the Germans hold the Red Cross is contained in a report by Surgeon-Major Rigaux, who describes the bombardment of a regimental first-aid post stationed at the farm of La Pécherie, in the Department of the Aisne:

After the bombardment of November 27th, acting on the advice of the General commanding the second division, the Red Cross pennons, which it seems had been scarcely visible on the front of the house and on the roof, were replaced by two large flags two yards by three, mounted upon flagstaffs eight yards high. From that date forward shells fell without ceasing. After some firing from the direction of La Miette, which sent shells right into the courtyard of the farm (evidently tank shots), we were treated every morning from nine o'clock till noon to a systematic bombardment with the range evidently established commencing at the outskirts of the farm and ending on the building. Seventeen of our people were wounded.

Other statements show that prisoners were treated with great cruelty. Among them may be noted the deposition of a French hospital orderly, named Martin, who was interned in the Alten-Grabow camp. The prisoners were hustled and struck with the butt-end of rifles; a man who dropped from exhaustion was shot out of hand, and twenty-three civilians were dispatched for no cause known to Martin. The food was abominable in quality and insufficient in quantity. There was no doctor to attend the wounded among the prisoners. Badly as the others were treated, Martin testifies that he remarked that the English prisoners were the objects of quite special brutality.

There are chapters on the use of burning liquids and asphyxiating gases, but these need only be mentioned.

We have already called attention to the absence of sensationalism in the book. As Mr. Bland says in his introduction, "The reader will find herein no elaborate weaving of arguments, no sentimental appeal to the emotions, no fine writing or *ex parte* pleading; nothing but a methodical statement of damning facts." If the book has something of the baldness of General Joffre's *communiqués*, it in this reflects the changed temper of the French nation which makes it formidable by its very moderation.

Burke said it was impossible to indict a nation, but this book is a contradiction of that assertion. It may be said that the blame for the atrocities set forth in it lies on the shoulders of the rulers of Germany. But the German people—who, to judge from their newspapers, glories in the fact that they are called barbarians by the rest of the world—must share in the responsibility.

⁵ *Germany's Violations of the Laws of War, 1914-15*. Compiled under the auspices of the French Ministry of Foreign Affairs. Translated and with an introduction by J. O. P. Bland. With facsimiles of documents. London: William Heinemann, 1915. (Demy 8vo, pp. 373; illustrated. 5s. net.)

NOTES ON BOOKS.

DR. PERCIVAL NICHOLSON'S little book on *Blood Pressure in General Practice*⁶ gives a sketch of the subject designed for general practitioners. The author incorporates in his text many quotations from American writers on the subject, and a few from the British literature. Beyond mentioning Poiseuille (whom he calls Poisselli), and von Bosch and von Kries (whom he calls von Posch and von Ptoin), and Tigerstedt, he pays no attention to Continental writers on the subject. The book contains the views of numerous writers, with which those of the author are co-ordinated with varying success. Many of the statements made are erroneous, and others go beyond the facts upon which they are based. The author cites an interesting pronouncement by the North-Western Life Insurance Co. (U.S.A.). In a letter to its examiners it says: "The statistics on 1,247 cases at all ages, in which there was a blood pressure of 150 mm. mercury and over, show a mortality two and one-half times greater than the general average mortality of the company covering the same period."

Written to supply a want in connexion with schools for mothers and maternity centres, Dr. HILDESHEIM'S little book on *The Health of the Child*⁷ is a very successful performance. The author has no particular fads or fancies to push, but gives a clear and concise account of the general lines upon which mothers and nurses should regulate the feeding, clothing, and regimen of the children they have to look after. He gives reasons for his statements, and explains, where possible, the principles upon which his advice is given, so that the book appeals to the intelligence as well as to memory. The rules and directions are conveyed in the simplest terms and should be intelligible to all; from the point of view of medicine they leave nothing to be desired. Dr. Hildesheim is to be congratulated upon the production of a most serviceable little book. It may be recommended with confidence to the attention of the many mothers and nurses who would be the better for instruction in the best ways of caring for their little charges. It deserves a large circulation.

⁶ *Blood Pressure in General Practice*. By P. Nicholson, M.D. Third edition. Philadelphia and London: J. B. Lippincott Co. 1915. (Cr. 8vo, pp. 194, 8 figures, 6s. net.)
⁷ *The Health of the Child*. A Manual for Mothers and Nurses. By O. Hildesheim, M.D., B.Ch., Oxo. With an introduction by G. F. Still, M.A., M.D., Camb., F.R.C.P., Lond. London: Methuen and Co., Ltd. 1915. (Fcap. 8vo, pp. 121, 1s. net.)

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

A MEETING of the Executive Committee was held on September 23rd, when the reports on the position of the Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés were considered. A financial statement showed a substantial sum of money in hand and on deposit in the bank and bearing interest. For the greater part of the Belgian medical men, refugees in England, positions have now been found.

THE WEEK'S SUBSCRIPTIONS.

The subscriptions to the Belgian Doctors' and Pharmacists' Relief Fund received during the week have been as follows:

£	s.	d.	Dr. Pierre Haupt	£	s.	d.
			Major C. E. Southon ...	2	2	0
Dr. G. D. H. Carpenter			West Kent Medio-Chi-			
(seventh donation,	1	0	urgical Society (per			
total 47)			Dr. W. H. Payne,		5	0
Western Australia			Hon. Sec.)		3	0
Branch, B.M.A. (per			Dr. S. G. Sloman			
Dr. J. E. Ramsay,	83	9				
Hon. Treas.)						

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE APPEAL FOR SURGICAL INSTRUMENTS.

Surgical instruments should be sent to the Master of the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C. The Master acknowledges gifts from:

Mr. C. J. Heath, London.
Mr. Alfred Freer, Stourbridge.

Mr. James Nourse, Calcutta.

MEDICAL AND SURGICAL APPLIANCES.

Apparatus for Rectal Administration of Saline Solution.

DR. C. HAMILTON WHITEFORD has designed an apparatus for the administration per rectum of saline solution by Murphy's method. This apparatus consists of a wide-based metal stand containing a night light, an open tin with a platform, on which stands a thick glass reservoir (a 3-lb. jam jar), with a capacity of 1½ pints. Surrounding the platform is a gutter or ditch, which has a slight fall towards the nozzle, with tap (C), which carries the rubber tube leading to the rectum. A thermometer, in a fenestrated metal case, slides into a metal loop on the inside of the tin, its bulb lying in the solution in the ditch. The rubber cork is perforated by three metal tubes: In the centre a tube with tap (A) and funnel for filling the jar; on one side an air tube, projecting into the jar and carrying a rubber tube which terminates in a metal tube, whose end is cut obliquely. The upper edge of this oblique opening lies at the level of the solution in the ditch when full. On the other side is a siphon tube, which reaches to the bottom of the bottle. Its outer end has a tap (B), beyond which is a rubber tube with metal ending, which lies in and just clears the

bottom of the ditch. The rubber tube which connects the ditch with the rectal nozzle is 4 ft. in length, of large lumen, with thick walls to prevent kinking. The rectal nozzle supplied with the apparatus is of vulcanite, bent at an angle of 75 degrees, and terminates in an olive-shaped head, the distal surface of which has four lateral perforations. The bottle should first be lifted out of the stand with all the taps shut and the cork firmly inserted. Tap A is then opened, the bottle filled with 1½ pints of saline solution at 105° and the tap shut. A lighted night light, covered by the metal cap, is placed with a little water in the basement and the thermometer slid into its loop. The ditch is then partly filled with 5 oz. of saline solution at 105° F. Tap B is now opened and siphon action started by blowing down the air tube with an enema syringe with 3 in. of tubing; the air tube is replaced by the side of the bottle. During administration, as soon as the level of the solution in the ditch falls below the end of the air tube, air passes into the bottle and restarts the siphon action, which continues until the end of the air tube is again closed by the rise of the solution in the ditch. The height of the apparatus above the rectum is calculated from the surface of the solution in the ditch, and when this has been ascertained no further regulation is required. Tap C being opened, the solution is allowed to run through the rectal tube and nozzle till it comes out warm. The tap is then closed, while the nozzle is inserted into the rectum and then opened again. The rate of the flow is regulated by the height of the ditch above the rectum. In order to refill the bottle the tap B is shut, tap A opened, the solution poured through the funnel, tap A shut, B opened, and lastly the siphon is restarted, with the syringe applied as before to the end of the air-tube. Among the advantages Dr. Whiteford finds in this apparatus are that the solution, being drawn from the ditch in which the fluid is at a constant level, is delivered into the rectum at a uniform pressure; the patient strains back into the ditch instead of into the reservoir through the siphon tube; the solution passes into the rectum along a channel of ample width by gravity alone; the temperature of the solution in the ditch is maintained at near 100° F., and loses but little when it reaches the rectum; no jacket or cover is needed. The apparatus is almost indestructible, and its broad base makes it difficult to upset. The price complete with enema syringe is £3, and the makers are Messrs. Reynolds and Branson, Ltd., Leeds.

THE late Dr. James Ryley, Ophthalmic Surgeon to the Great Yarmouth Hospital and sometime mayor of that town, left estate valued at £18,351.

THE WAR EMERGENCY.

AN OPINION FROM THE BRITISH ARMY IN FRANCE.

The following communication, forwarded by the Director-Generals Army Medical Service, was read to the War Emergency Committee at its meeting at the house of the British Medical Association on October 6th:

We have observed with some regret that in recent *Gazettes* there have appeared the names of many medical men who have resigned their temporary commissions in the Royal Army Medical Corps. It is of course certain that a considerable proportion of these are recalled to Great Britain by personal and public claims on their services which they could not neglect, but at the same time we think that the claims of the army and of the nation are perhaps scarcely sufficiently considered by those at home, at whose call some at least of the officers have resigned their commissions. It may well be that, after the past few months of comparative quiet, medical men at home may hear from those who have been serving in France that some of them have found the work monotonous. And, while this no doubt is perfectly true, we would ask those who contemplate applying for commissions to consider the matter in another light.

Every one recognizes more or less that in order to ensure a successful issue to the war our army and navy must show the greatest patience and tenacity of purpose, and that without these mere bravery in battle is of but little value.

The same is true of the work of the medical profession. A similar tenacity of purpose and an equal patience are required in addition to the skill and energy which every battle calls forth. The excitement of great and moving events is necessarily transient, and men must be prepared to do their duty steadfastly during long periods of dullness. Yet it is during these dull periods that the services of the army surgeon are really of the greatest value, though they may be dull and uneventful to himself, and it is during these intervals that the regimental medical officer gets into that close touch with officers and men alike which gains their confidence and gives him an influence without which mere professional knowledge is not of much avail.

The medical officers who are attached to regiments, batteries, motor convoys, etc., are each responsible for the health and well-being of many hundreds of men, and it is not too much to say that the strength of our army has been largely maintained during the past year by the work of these officers.

It is no doubt monotonous to be constantly watchful of the cleanliness of billets, to supervise food, to prevent parasitic infections, to treat sore feet, diarrhoea, or muscular rheumatism, and to do the thousand and one things which help to keep the soldier an efficient fighting man. But the medical officer who does these things is doing at least as much for his country as the man who performs operations or treats enteric fever.

The staff of the field ambulances have also to deal with many minor ailments of but little interest, but every division is dependent on them for the rapid return to the regiments of those whose illnesses are too slight to justify a return to England. Rest stations and convalescent depôts in charge of the field ambulances are also dull, but the good they do in maintaining the health of the troops is almost incalculable, and we would urge on all medical men who wish to serve their country that the performance of all such duties is essential for success in the present war.

The work of the casualty clearing stations and of the general hospitals at the base is characterized by periods of comparative idleness and of excessive work, but it must be

evident to all that, unless the staff was too large for periods when there is but little fighting, it would be far too small for dealing with the crowds of wounded which follow in the wake of every great battle. And, hard though it may be to remain comparatively idle during months of comparative peace, it must be remembered that the lot of the medical officer is in this respect identical with the lot of the cavalry soldier or the artilleryman.

The country needs the service of men who are prepared not merely to brave the dangers of a battlefield, but also to endure with patience and cheerfulness the dull routine of daily work and waiting. The coming winter may well prove a severe trial to those whose duty it is to fight, and there can be no doubt that if our army is to be kept healthy and ready for action, the medical profession must supply it with men who will show the same determination and patience in their own field of work as have distinguished the British soldier throughout this campaign.

LETTERS.

THE NEED FOR SERVICE.

SIR,—The British Medical Association has lately been putting pressure upon the one remaining member of my staff eligible for service to take up military duty. The medical staff of the County Council consists of ten men, eight of us are serving and one has lost his life. Of the two remaining men who are not serving, one is physically unfit, and the other is our tuberculosis expert; so that 90 per cent. of those eligible to serve are serving, and the Association is putting pressure on the man who makes the remaining 10 per cent.

At the present time I am engaged on military duty as officer in command of the 5th Laboratory. I am acting as radiographer for the V.A.D. hospitals in the county, and am doing in addition to my own work the work of some of my colleagues who are on active service. Before the British Medical Association make any communication to the one remaining member of my staff they ought to inquire of me as to whether the officer in question could be spared.

I have before me the panel list of Derbyshire doctors. On that list there are 294 medical men, of whom 37, or just over 12 per cent., are on active service. We officials have had no holiday since the war began, and some of us have been working continuously twelve hours a day, and generally seven days a week. I see panel doctors taking their holidays as usual, and for this I do not blame them; but surely it would be more dignified if the British Medical Association put pressure upon the practitioners in the county to go on active service before they attempted to break the back of the willing horse by putting pressure upon my one remaining assistant who is of military age.

The army must have its medical service, and the proper thing for the Government to do is to take over the whole of the practitioners in the country as a controlled service, the same as they are doing with certain manufactures. If the country were divided into districts of suitable area and one practitioner was left in each area, it would be an easy matter to release at least one-third of the general practitioners. To prevent any hardship arising to them when they come back, the practitioners remaining should be transferred to other districts not their own.—I am, etc.,

SIDNEY BARWISE, Major R.A.M.C.(T.),
County Medical Officer; School Medical Officer, Derbyshire;
Medical Adviser, Derbyshire Insurance Committee.
County Offices, Derby, Oct. 4th.

SURGEONS FOR FOREIGN SERVICE.

SIR,—Two thousand five hundred more medical men are wanted for the army before Christmas. Where some of them may be found is indicated in the report, published in

the JOURNAL of September 18th, of the meeting of the War Emergency Committee on September 15th. As indicated in that report, the War Office is encouraging men of military age to volunteer for foreign service, and the War Emergency Committee is strongly backing the movement. The appeal will not be in vain, for a large number of the junior members of the home service staffs have declared themselves ready to go.

The liberation of these men from their posts at home will entail yet another modification in the working arrangements of the territorial hospitals and the "a la suite" commission scheme. The working arrangements of these hospitals have already undergone various modifications and improvements during the past year, and the present movement on the part of the War Emergency Committee towards liberating the junior members of the staffs must introduce further alterations. Amongst medical men and laymen there has been for long an opinion that these hospitals could be efficiently and economically run by employing the "whole-time" services (for the period of the war or in relays of six months at a time) of a number of our senior surgeons and physicians, and of medical men who have been "invalided" home (unfortunately an ever-increasing number), and who, while not able again to face the hardships of active service, are capable of any amount of home work. Our seniors are no less patriotic than our juniors, and, if the latter are to be called to foreign service, should be willing to take up at home "whole-time" service in relays, and so keep the necessary work going. If the present call on the juniors should lead to a necessary radical modification of the working arrangements of the territorial "a la suite" system, there are not wanting those who think it might be all to the good.—I am, etc.,

Glasgow, Oct. 5th.

JAMES H. NICOLL.

MEETINGS. METROPOLIS.

A WELL ATTENDED meeting of the practitioners of Hampstead was held on October 1st, in response to an invitation from the Division, to ascertain what steps should be taken to raise the necessary number of doctors for the army. Dr. COLLINGWOOD ANDREWS acted as chairman. Dr. COX, from the War Emergency Committee, addressed the meeting. He outlined the excellent work already accomplished by the committee—the formation of local committees throughout the kingdom, thus placing the whole of the country in touch with the Director-General. Dr. TURNER, a member of the War Emergency Committee, also addressed the meeting. He emphasized the urgent need of men of military age accepting commissions in the R.A.M.C. without delay, and advised men to enroll, and so place the Director-General in the position of being able to fulfil the needs of the R.A.M.C. as the occasion arose. The necessity for a preliminary training was pointed out; certain routine work was absolutely necessary for the smooth working of the medical service. If any practitioner who had previously applied and had received a refusal would again apply his chances were that he would be accepted, provided his application was sent to the proper quarter. Refusals arose from lack of knowledge of the proper quarter to apply to. A War Emergency Committee was appointed and its members given power to co-opt others.

A meeting of the Hendon Division was held on September 30th at Finchley, to which all practitioners resident in the area were invited. Dr. HICKS was in the chair; seventeen members and sixteen non-members were present. The War Emergency Committee's circular appealing for eight more men for commissions in the R.A.M.C. was read and discussed. The CHAIRMAN reported that since August 1st, 1915, four medical men in the area had taken commissions, and as a result of the meeting one practitioner intimated his intention of applying for a commission, and one signed the enrolment form (W. 2). A scheme for conducting the practices of men absent on full-time service was agreed to on the basis of half private and confinement fees, and insurance receipts and other contract money to be pooled and divided pro rata among the men acting as deputies. Separate War Emergency Committees were elected as follows:—*Finchley*: Drs. Hicks, Baker, T. Godfrey, Barker, and Orr. *Hendon*: Drs. Andrew, Steel, M. Baker, Hunt Cooke, and Hargraves.

IRELAND.

County Monaghan.

A MEETING of the resident medical practitioners of the County Monaghan was held on September 22nd in the Town Hall, Castleblayney, when Dr. WILSON occupied the chair. The meeting was well attended, and all parts of the county represented.

Dr. McKENNA, J.P., Carrickmacross, brought before the meeting the call of the War Office for medical men, and the scheme put forward by the British Medical Association and the Irish Committee to answer the demand for suitable doctors. He described the urgent need at the front for medical aid, so that the men, and especially their Irish fellow-countrymen, fighting the battle for civilization against barbarism, and being wounded and injured in foreign lands—to protect us from outrage and ruin—should at once receive that skilled assistance necessary to restore them to health and strength. He appealed to all medical men of military age, or whom the War Office would accept, to place at once their names on the Roll of Volunteers, and to do their duty by Ireland and humanity.

The following resolution, proposed by Dr. McKENNA, seconded by Dr. M. R. WHITLA, and supported by the CHAIRMAN, was passed unanimously:

That we, the medical practitioners of the County Monaghan, hereby band ourselves together to facilitate any of our members who may answer the country's call in bringing aid to our soldiers who are at present engaged in the fight for civilization against barbarism. And in furtherance of this resolution we hereby agree to protect and preserve, to the utmost of our ability, the practice and appointments of any such member or members while so engaged. And we urge upon the various departments and local bodies the necessity of assisting us in the faithful carrying out of this resolution.

OPENING OF THE MEDICAL SCHOOLS.

THE winter session in most of the medical schools has been opened this year without much ceremony beyond that attending the distribution of prizes.

At the Middlesex Hospital the DEAN said that in spite of the difficulties due to the war the work of the school had proceeded satisfactorily, and it had received its fair share of new students. Almost all the members of the medical staff were engaged in some kind of medical service, and so were very many former students. Mr. W. E. GILBERT, who was in the chair, said that the traditions of the school had not only been preserved but strengthened by the devotion of past and present members; the country could never repay the debt which it owed to the medical profession. Sir JAMES KINGSTON FOWLER, after distributing the prizes, gave a short address, in the course of which he said that after the war there would be a new spirit in the universities. Men would feel the necessity of always maintaining themselves in a condition to serve their country. They would not play less, but work harder. The profession had done its duty well, and many doctors had made great sacrifices. The Royal Army Medical Corps had done magnificently, and a great debt was owing to Sir Alfred Keogh, who, in peace, foresaw the necessity of establishing the system of military general hospitals which had worked so well.

At Charing Cross Hospital Medical School the prizes were distributed by Dr. RONALD M. BURROWS, Principal of King's College, who said that he believed that the University Training Corps and university men had given to the new army 80 or 90 per cent. of its officers. Universities, colleges, and hospitals throughout the kingdom had placed the brains of their scientists at the service of the Government to deal with the special problems of the moment. It was for the universities to show that they could make their education flexible, and, while welcoming every opportunity to do definite war work, they should lay stress on the general principle that no nation went under except through a lack of brain power, and that financial and military successes were so much dependent on education as literature or science.

At the opening ceremony of the London School of Medicine for Women there was a large attendance, which listened to a most interesting address by Dr. FLORENCE WILEY, on the war and the medical education of women. The number of entries at this school exceeds any previous record.

British Medical Journal.

SATURDAY, OCTOBER 9TH, 1915.

GROUSING.

IN another column will be found a letter signed by six of the consulting physicians and surgeons with the British army in France, expressing their very decided opinion on the duty of medical men at the present time towards that army. Of the signatories the majority have been with the army in France for over a year, and all for many months, so that they know of what they speak. They freely recognize that for long periods at a time the work of medical officers of regiments or attached to other units may be monotonous and that there are long periods of dullness, but they enumerate the duties of these officers, and urge on all medical men who wish to serve their country that the performance of such duties is essential for success in the present war. That there is still a very great deal of misunderstanding with regard to the work of military medical officers is shown by a letter signed "Surgeon" published in the *Edinburgh Evening Dispatch* of September 28th, copies of which have been sent to us by several correspondents. One describes it as libellous and treasonable—libellous, as we understand, because it speaks very disparagingly of the "ordinary medical practitioner," and treasonable because, whether intentionally or not, it must, so far as it has any influence, tend to discourage recruiting for the medical service. But it seems hardly worth while to apply such grandiose terms to so sorry a production. We should have labelled the letter ignorant and put it in the waste-paper basket, but that it has caused other correspondents some distress of mind. "Surgeon," were he a wounded soldier, would shudder to think, knowing what he does of "the ordinary country practitioner," so he writes, that he had been brought under such care. Feeling, apparently, that the width and depth of his own knowledge of his "ordinary" brethren may be defective, he fortifies himself by quoting what he has "been told by professional nurses." Having thus disposed of all "ordinary" persons, he proceeds to demolish "Sir James Barr and other prominent officials of the British Medical Association," and asserts that they would be better employed in looking over the names of the members (and non-members) of the British Medical Association and advising the War Office that they, meaning the War Office no doubt, "might communicate with the best men of the country and so enlist their services," than in doing something else not clearly specified.

We must assume that "Surgeon" is really a qualified member of the medical profession, because we do not believe that the *Edinburgh Evening Dispatch* would otherwise allow an anonymous correspondent so to sign himself. We have, then, two alternatives: either he has had so unfortunate an experience of the postal service that he has not received any of the letters and circulars issued by the Scottish War Emergency Committee, or by the Committee formed in London on its model, nor any of the medical journals for some months past; or—and this is the other alternative—having received them, he has failed to read them, wherein he would be the more blameworthy, as

he sets himself up to condemn in a public newspaper what he supposes the committees to state and propose. Had he read, he would have known that what he says they ought to have done is exactly one of the many things they are doing by the circulation of the form of enrolment which "Surgeon" by some strange accident has failed to receive, or, by regrettable negligence on his part, has failed to read. He thinks that "those in authority" should "seek out the good average surgeons of the country; let them," he says, "guarantee to such surgeons that they will have responsible and proper work to do, and I am sure that there are few surgeons in the country to-day who will refuse service." "Surgeon" may set his mind at rest; few surgeons in the country have refused service—none so far as we know. He thinks that "no doctor who feels himself of great use to the community in which he is placed should enlist in the army to find that he will be used to render 'first aid' to the injured. A good ambulance pupil can do that well." One correspondent who is troubled by the letter of "Surgeon," says that he "would be pleased and proud to render first aid to Tommy," but as he has no experience of surgery beyond what is met with in general practice, and no practical knowledge of laboratory methods as applied to medicine, he asks "what use am I likely to be to the army, and am I likely honestly to earn the salary the War Office offers?" We have no doubt that a man who takes this conscientious view will earn his salary very well, for he will soon find that surgery, first aid or other, forms only a small part, a very small part, of his daily duties. He will probably have to render first aid, and in spite of what "Surgeon" insinuates will do it much better than an ambulance pupil; in doing it he will detect those apparently slight cases which require further surgical assistance, and will send them to the casualty clearing station or hospital where they will find "the eminently skilful men" that "Surgeon" chooses to assume are not now present in sufficient numbers.

The main duties of the regimental medical officer when his regiment is actually fighting are to see that the first dressing is properly applied so as to arrest haemorrhage and mitigate as far as possible the risk of infection, to put up fractured limbs so that the man may be carried away or walk away with the minimum of suffering; to diagnose conditions such as wounds of the head which may seem trifling but which are really serious; and to treat men suffering from the shock of chest and abdominal wounds while dispatching them as quickly as possible with a note of the gravity of their condition to the nearest casualty station. Here it may be observed that these stations are at varying distances from the firing line, some perhaps four or five or six miles, others eight or ten. The surgeon of the regiment or field ambulance shows his judgement, where he has a choice, in directing the man to one or other place, according to the nature of his injury.

But for how many hours in a month is a regiment actually fighting? True, in trench warfare such as until the other day prevailed for so many months in Flanders, casualties occur every day, but relatively to the whole British army in the field—a French statesman said the other day that we had a million men in Flanders—they were few.

From the humanitarian point of view no work could be finer, and we should have supposed it well worthy of the best devotion of the "ordinary medical practitioner"; but from the point of view of the Commander-in-Chief, who has to look on his army as a machine for breaking the enemy, its importance

lies, first, in the rapid evacuation of the wounded who encumber the machine, and, secondly, in the speedy return of the lightly wounded to their places in the machine. Far more important to him is the result of the regimental medical officer's daily round of work, the aggregate of small duties conscientiously done, which means a healthy army. We apologize for the commonplace, and will spare ourselves and our readers the repetition of the fifty-times-told tale of the great and gallant armies brought to ruin and defeat by disease. Always hitherto the bacilli have slain their ten thousands where the bullets have slain their thousands.

The grievous part of the business is that such abysmal ignorance as to the real duties of a military medical officer should be paraded in public print by a surgeon—even an "average surgeon." The very name of the corps ought to have saved him from so foolish a blunder. In this country we speak of the Royal Army Medical Corps and the Army Medical Service; the French, Germans, and Austrians make the point still clearer by speaking of the sanitary or health service of the army.

From the military point of view the main duty of the medical services of an army is to keep the men who compose the army healthy and physically fit. The duties of a medical officer of a regiment are concerned with the health and training of the men from the day of their enlistment, and are all the more exacting if he be the medical officer of a newly formed unit. He ought to know every officer and man in the battalion and his capabilities. He should be present at gymnastic exercises, watching what the men can do and looking out for those upon whom the strain may be telling unduly. He must give constant attention to the state of the feet of the men and see that his chiropodist department is working conscientiously. He must look to the state of the men's teeth and see that their food is of good quality and properly cooked. He must see that they have proper means of washing and that they know how to avoid vermin, or if they have become infested, how to rid themselves of the pests. He must continually be taking care to keep his own sanitary cadre in the highest state of efficiency and in camp must be continually supervising the sanitary arrangements. In billets he must take care that his men are living in sanitary conditions and must equally attend to conservancy. He must also become expert in keeping all the necessary forms and statistics, a wearisome work, no doubt, but essential to the smooth working of the machine, and essential also, should the man be wounded or go sick, to his being traced for the information, not only of the army administration, but also of his relations. This last point is important; it is our first concern when our own sons or brothers are hit, and failure throws great discredit on the medical service and the medical profession.

The battalion medical officer is, in fact, the most important individual in the medical organization, and the letter from which we have quoted at the beginning of this article states that "it is not too much to say that the strength of our army has been largely maintained during the past year by the work of these officers." All that we have said here has been said in that letter much better and with much greater authority. "The country," the writers say, speaking from an unequalled experience, "needs the service of men who are prepared not merely to brave the dangers of a battlefield, but also to endure with patience and cheerfulness the dull routine of daily work and waiting." "If," they continue, "our army is to be kept healthy and ready for action, the medical profession

must supply it with men who will show the same determination and patience in their own field of work as have distinguished the British soldier throughout this campaign."

THE OPTOQUIN TREATMENT OF PNEUMOCOCCAL INFECTIONS.

QUININE is a drug that has received a vast amount of attention from both clinicians and chemists. From the clinical point of view its therapeutic actions may be said to be well known. The chemist, however, has hitherto been baffled in his study of its chemical structure, and its constitutional formula still remains an unsolved problem. All that can be said as to the structure of the molecule of quinine is that it contains a quinoline molecule with a methoxy group in the p-position, $C_9H_7N.OCH_3$, and a complex residue $C_{12}H_{19}NO$ containing the atomic group $-CH=CH_2$ as a side-chain, and also a hydroxy group.

A great deal of work has been done on the pharmacological properties of quinine and its derivatives. Four years ago Morgenroth and Levy published some interesting and promising studies in the destructive action of ethylhydrocupreine, one of the near relatives or derivatives of quinine, on the pneumococcus. Ethylhydrocupreine, known for short as optoquin in German, optoquin in English, may be derived from South American cuprea bark (*Remijia pedunculata*). This bark contains a small percentage of homoquinine; on treatment with caustic soda, five parts of homoquinine yield two parts of quinine, which has the formula $C_{19}H_{20}N_2.OH.OCH_3$, and three of cupreine, $C_{13}H_{19}N_2(OH)_2$. From a chemical point of view, quinine may be regarded as either p-methoxycinchonin or methylcupreine, and cupreine as either p-oxycinchonine or a naturally occurring demethylated quinine. Both are far more effective in the treatment of malaria and pyrexia than is cinchonine, $C_{19}H_{21}N_2.OH$, which lacks the p-methoxy group in the quinoline nucleus it contains, and is a much more strongly convulsant drug than either quinine or cupreine. The alkaloid optoquin, or ethylhydrocupreine, of the formula $C_{12}H_{19}N_2.OH.OCH_2$, is actually made from hydroquinine, $C_{19}H_{20}N_2.OH.OCH_3$, and not from cupreine. The experiments of Morgenroth and Levy were made on mice, and it was found that the subcutaneous injection of optoquin solutions were both protective and curative for mice exposed to infection with Fränkel's pneumococcus. Arguing from mice to men, it was hoped that optoquin would be a specific against pneumonia in human beings. But Fränkel, in 1912, tried it in 21 cases of pneumonia, with results that were disappointing; in addition, 3 of the patients developed amblyopia while they took the drug.

Quite recently Moore¹ has published some experiments on the action of optoquin hydrochloride on the four chief serological types of pneumococci as described by Cole and by Dochez and Gillespie, and on various strains of streptococci. The action of the optoquin salt on the latter was relatively slight. But on all four strains of pneumococci Moore found the bactericidal action of the optoquin salt so vigorous as possibly to be usable as a test for a true pneumococcus; growth *in vitro* was inhibited by the presence of from 1 part of the drug in 500,000 to 1 in 10,000,000; and the cultures were killed by the drug in a concentration of from 1 in 20,000 to 1 in 10,000,000 in different instances. Quinine hydrochloride killed or inhibited the growth of either the pneumococci or streptococci only in much stronger

¹ H. F. Moore, *Journ. Exper. Med.*, New York, 1915, xxii, 269.

concentrations than these, and was without any selective action on the pneumococci. The base optoquin was found to have a well-marked protective action against the experimental infection of mice with all four pneumococcal type-strains. Thus out of 85 mice inoculated intraperitoneally with one hundred times the minimal lethal dose or less of pneumococci, and treated by the hypodermic injection of a 2 per cent. solution of the free base in olive oil (0.5 c.c.m. per 20 grams of mouse), 57 survived, only 15 died of pneumococcal septicaemia, and 13 died of the toxicity of the drug or some obscure cause. In other words, 81 per cent. of the mice treated with optoquin were cured of their pneumococcal infection. If, however, enormous doses of virulent pneumococci were employed—a thousand times the minimum lethal dose, for example—the ethylhydrocuprein appeared to afford no protection in the case of certain pneumococcal strains; while in other instances it might protect against a dose even ten times as large.

So far as pneumococcal infections are concerned, therefore, it looks as if we possessed in optoquin a strongly bacteriostatic drug with a parasiticide action comparable to that of quinine in malarial infection. It is unfortunate that, so far as our present knowledge goes, optoquin should be so highly organotropic in man as Fränkel found it to be, because this quality would appear to render it unsuitable for the treatment of pneumococcal infections in human beings. Even in mice, as Moore's experiments indicate, it seems to be unduly organotropic, if it was responsible for the deaths of 13 out of 85 mice treated with it, as appears to have been the case.

THE POSITION OF GENERAL PRACTITIONERS TAKING COMMISSIONS.

THERE has come into our hands an extraordinarily interesting document, penned by a country practitioner who responded recently to the call of duty, and took a temporary commission in the R.A.M.C. Before he joined the army he counted the cost; and though his calculations showed a certain loss and many possible risks which might make that loss greater, he has taken his chance bravely and made the necessary sacrifices. He gives full details of his financial position, of the difficulties which had to be met, and of the arrangements which it has been possible to make. With the financial details we need not trouble our readers, although they are admirably worked out. Suffice it to say that by careful adjustment of expenses our correspondent has been able to reduce the loss anticipated in running his practice during his absence to £8 a year. Thus he is left with rather less than his army pay wherewith to support himself, his wife, and his child during his term of service; and with a practice, guarded so far as the sense of honour of his colleagues can guard it, to return to when he is free. It may be of interest to sketch some of the arrangements made, and to record a few of the difficulties met with in applying the principles accepted by the Division to which he belongs, for it is possible that these difficulties and the manner in which they were overcome may furnish some guidance for other districts. The practice includes private and panel and club patients. With regard to the private patients, fees are divisible in the proportion of two-thirds to the acting practitioners and one-third to the absentee. Accounts will be sent out by a representative from priced returns received from the acting practitioners. All moneys will be paid into a bank and a division made from time to time. On the doctor's return from service the amounts still due to the acting practitioners will be paid to them within three months, less 10 per cent. deduction for bad debts. This is to be done in order to close the arrangement as soon as possible. The absent practitioner will

not be responsible for bad debts. Prescriptions and measurements for appliances, etc., can be obtained at his house, but are not to be given to patients. A circular has been addressed to all private patients on the ledger, explaining the practitioner's absence; and a notice has been posted on his surgery door asking inquirers to select any doctor they please. With regard to panel patients, an equal division of fees has been arranged; one moiety to be distributed proportionately amongst the other panel doctors on the evidence of the record cards. Patients are directed to go if possible to the nearest doctor, but dispensing is to be done by the panel practitioner for all patients more than one mile from the absentee's house. Records are to be fetched thence by the patients themselves, and a notice is affixed to the surgery directing any new patients desirous of being placed on the absentee's list to apply to the nearest panel doctor. The neighbouring practitioners have agreed not to attend any of the patients—club, panel, or private—for the space of one year after the end of the military service; and this provision is to be binding in the event of a successor taking the practice. Only in this way was it found possible to preserve the capital value. The difficulties noted are as follows: It is doubtful whether the army pay will suffice to meet the medical officer's expenses in some districts as well as support his wife and child. The payments for work done prior to joining the army must be kept back against the day of return to civil practice, for no money will be coming in until new book debts accumulate. The fact that the practice was purchased with borrowed money is a source of anxiety, the more so as the death of the practitioner would cause serious loss in selling value. Hence the clause in the agreement with regard to a successor. Another point which needs stating clearly is that the absent practitioner should be responsible only for the collecting and distributing portions of the expenses connected with the practice. Finally, it is noted that during absence no new patients will be added to replace those who die or move from the district, so that for two or three years after his return the practitioner is bound to have to face a reduced income. We hope that this summary may convey to our readers some sense of the courage shown by our correspondent in facing the difficulties met with in responding to his country's call, and that his example may be followed by many who are still doubtful which way their duty lies. It is possible that his case shows how much might be gained by the full acceptance of the scheme of enrolment now being carried out by the War Emergency Committees, though there can be no doubt about the finer instinct displayed in his voluntary self-sacrifice. For those not cast in heroic mould, perhaps too as a means of avoiding waste to the community, the method of enrolment to take service when called upon by those in touch with both the military and the civil position, offers the soundest means of satisfying every need. This is, we think, an answer to the plaint of Dr. Sidney Barwise (at p. 539). The object of the enrolment is to get a complete list of the medical men in all districts who are of military age and capacity, and then to ask those who can best be spared to hold themselves in readiness, after a date they are invited to specify, to take a commission in the Royal Army Medical Corps. That this is the object in view has very often been stated, and an endeavour to make the matter clear with respect to one particular difficulty was made in the article on hospital staffs and the war emergency published in the last issue of the JOURNAL at p. 509.

MEDICAL CERTIFICATES FOR MUNITION WORKERS.

WE have several times expressed the opinion, and most recently only last week, that the way to get the highest output of efficient work in munition works was not by encouraging an undue amount of overtime and discouraging reasonable holidays. We have advanced this

opinion not only on general physiological principles but also on the result of experiments and observations both in the laboratory and in the workshop. We believe it to be a matter calling urgently for the serious attention of employers and managers of works, and it will, no doubt, be considered by the Committee which the Minister of Munitions has appointed on the health of munition workers. In a controlled establishment one of the rules is that workpeople must not absent themselves without permission, and in the case of sickness must furnish a doctor's certificate. This throws a great responsibility on the doctors practising in areas in which such controlled establishments exist, a responsibility very similar to that which the War Office places on the civilian doctor with respect to soldiers on furlough. A few months ago a circular was issued by the Insurance Commission in Scotland calling attention to this matter in the following terms: "In view of the large number of soldiers who, having been granted short terms of furlough, obtain extensions thereof on medical certificates given by insurance practitioners, the Scottish head quarters command desire that the necessity should be impressed upon practitioners of exercising the closest scrutiny of cases coming before them, and of bearing in mind that, when the question of a soldier's fitness to return to duty is in doubt, the military authorities are entitled to the benefit." This seems to put the matter very neatly; obviously it has its application to workers in munition factories, although the conditions under which they work are very much less favourable to health than those enjoyed by the soldier, who for the most part lives an open-air life, and for the preservation of whose health the Army Medical Service exists. We fully appreciate the fact that the doctor may often be placed in a very difficult position when a munition worker who complains of illness applies for a medical certificate, and we recognize also that if he were to make a mistake he must expect very little consideration from a coroner or his jury; at the same time the doctor should—and we have no doubt, as a rule, does—take care not to allow himself to be used merely to ensure that a workman may secure a holiday which he might otherwise find it difficult to obtain. We have no doubt that those medical men who have not yet considered the matter only need to have their attention called to it to recognize its importance. At the same time we would repeat what we said at the beginning—namely, that the real remedy lies largely with the persons responsible for the management of controlled establishments. They ought to recognize the physiological limits of useful work, and should take care to make it possible that a man who really stands in need of a holiday can get it without resorting to subterfuge.

DIARY OF NAPOLEON'S UNDERTAKER.

Two years ago (January 11th, 1913, p. 53) we published a lecture by Professor Arthur Keith, in which he sought to show that two specimens in the museum of the Royal College of Surgeons were, as Sir Astley Cooper had alleged, authentic parts of the great Napoleon. Distinguished Napoleonic scholars, such as Lord Rosebery and M. Frémeaux, regard them as spurious because of the strict watch kept over the Emperor's body both during and after the *post-mortem* examination by Antommarchi on May 6th, the day following Napoleon's death. We learn from the Literary Supplement of the *Times* (September 30th, 1915) that Major M. F. Foulds, who is at present in medical charge of the troops stationed in St. Helena, has unearthed the diary of Napoleon's undertaker, Andrew Darling, which he copied and transmitted to Dr. Arnold Chaplin, the leading authority in all that pertains to Napoleon's last and complex illness. The diary, Dr. Chaplin states, was printed in the *St. Helena Advocate* in 1851, but no copy was known to exist in Europe. Unfortunately, it does not help the historian very much. We find that Dr. Rutledge relieved Dr. Arnott

in the watch over the body—thus explaining the discrepancy between the statements of some recorders, who said that watch was kept by the first, while others give only the name of the second. "Dr. Rutledge had orders not to let his heart be taken out of the room, I having received the same orders, the reason of this, as I was informed, was owing to Dr. Antro Marchi (*sic*) wishing to have his stomach in his own possession to take to Europe with him." It is quite evident that Antommarchi—whom Professor Keith suspects of having abstracted the pieces of bowel now in the College of Surgeons—had no scruples about taking *post-mortem* specimens—when it was possible. The undertaker also gives two other items which are of interest. Dr. Burton accused Antommarchi—probably on good grounds—of having stolen the mould of the well-known mask of Napoleon from him, but that he (Dr. Burton) retained a part. One suspected that a complete mould of the head had been taken, Antommarchi taking away the face part and leaving merely the occiput with poor Dr. Burton. From the diary just published we find that such was the case; a mould of the whole head was taken. We believe that the occipital part—which was in Dr. Burton's possession—is now lost. It is said to have been broken by him in a moment of irritation after he had failed to compel Antommarchi to restore the cast of the face. As plaster-of-Paris was not to be got in St. Helena at the time, Antommarchi attempted to make a mould with the powder obtained by grinding down some small images. This attempt failed for the reason mentioned by Dr. Chaplin in his interesting letter published in this issue (p. 552). The cast was actually made by Dr. Burton with powder prepared from a gypsum rock native to St. Helena. St. Helena records are notoriously contradictory, and Mr. Darling's diary forms no exception.

CEREBRAL HAEMORRHAGE AND THE CORONERS ACT.

Mr. J. CROSE, the Derby Borough Coroner, has lately, according to a newspaper report, made certain rulings which are not, in our opinion, in conformity with the Coroners Act. An inquest was held upon the body of a man, aged 56, who had, according to the evidence, met with an accident about three years before, and being in consequence unable to work, had received compensation from the company by which he had been employed. His condition was duly certified week by week by his medical attendant, and upon these certificates he received his pension. He died rather suddenly from cerebral haemorrhage, and Dr. J. Anderson, who had seen him during life, gave a certificate of death. Dr. Anderson, in his evidence at the inquest, stated that the symptoms he observed were typical of cerebral haemorrhage, and that having heard the history of the case he did not hesitate to certify. The coroner stated that Dr. Anderson had acted wrongly in giving a certificate because he had only seen the deceased whilst he was unconscious, and death ensued within a few minutes. After showing a regrettable tendency to browbeat the witness, the coroner said that he was liable to a heavy fine. We do not know of any legal enactment which limits the power of a medical practitioner to give a death certificate in any case. It is for the registrar who receives such certificate to decide whether it shall be accepted or referred to the coroner. It is no part of the legal duty of a practitioner to make any report to the coroner or to any other authority, although circumstances may arise in which he will be well advised to do so. Provided that his certificate discloses the cause of death and is given bona fide, his legal responsibility ends, and it rests with the registrar to either register the death or to decline to do so. It is interesting to note that the jury gave a verdict in this case in accordance with the medical evidence, and thereby fully endorsed the certificate which had been given. It is a great pity that some coroners should seem to seek to aggrandize their office by casting

reflections in public on the actions of medical practitioners and the procedure adopted by them. The law relating to medical certification should be within the knowledge of every coroner, especially if, as in this case, he be a solicitor. It is the only excuse for appointing lawyers to be coroners. It is quite clear that in this instance there was no necessity whatever for an inquest to have been held. There was, therefore, a waste of public time and public money which, always indefensible, is particularly reprehensible at this time.

Medical Notes in Parliament.

The Discussion on the Budget.

THE Chancellor's proposals, which were summarized in our issue of September 25th, were received as a whole with general approval, but in the course of the discussion they were subjected to considerable criticism in matters of detail, and some of the points dealt with in the debate on the resolutions are of special interest to the medical profession.

Hitherto medical practitioners have received a rebate of one-half of the existing motor spirit tax, and some interest has not unnaturally been shown in the question as to whether they are to receive any rebate in respect of the increase proposed in the rate of duty. The question was raised on a resolution moved by a private member the effect of which, if carried, would have been to restrict the allowance to one-half of the old petrol duty. The Chancellor adopted a strictly non-committal attitude on the subject, and moved that the House should negative the resolution, on the ground that unless this was done the question of these abatements could not be considered in future. The resolution was negatived accordingly, but it is to be noted that on October 4th a deputation of the Commercial Motor Users' Association was informed by the Commissioner of Customs and Excise that Mr. McKenna had, after consideration of the arguments advanced by the association, introduced into the Finance Bill the necessary clause to secure a 50 per cent. rebate of the new petrol tax to all commercial motor users who had previously been exempt to the extent of 1½d. per gallon when the full tax was 3d. per gallon.

The proposed import tax of 33½ per cent. *ad valorem* duty on motor cars, motor cycles, and parts thereof, is to be subjected to extensive modifications. Mr. Lough, in opposing these taxes, said that of the motor cars imported into this country 65 per cent. were for the purpose of trade and the war, and most of the remaining 35 per cent. consisted of cheap cars used by doctors and other professional men. Mr. McKenna defended the tax as being advisable on several grounds in the special circumstances of the present moment, but at the same time announced that he was prepared to concede exemption to "motor vehicles, chassis, and parts thereof used exclusively for trade purposes." He expressly refrained from giving a more precise definition, but it will be noticed that in any event he does not seem to be committed to any exemption of cars, etc., used solely for "professional" purposes. On the other hand, some of his remarks in this connexion might lead to the belief that the exemption may be intended to apply to such cases, inasmuch as he intimated that one of the chief purposes of the tax was "to limit the import of an article which is extensively used solely for purposes of luxury." This aspect of the proposed import duties was later emphasized both by the Prime Minister and Mr. Bonar Law. If these duties are to be regarded in some measure as constituting a sumptuary tax, and traders are accordingly to be relieved, it is difficult to conceive how the relief can equitably be withheld from professional men.

On the income tax resolution several protests were made against applying the high rates of income tax to officers in the army and navy. The extent of the feeling on this subject is shown by the fact that the protest was made by a Liberal member, was supported by a Unionist, and later by a Labour member, who roundly declared that it would be a mean thing to tax the incomes of young

officers in the new armies. The Chancellor said that if, in view of the incidence of the tax, the officer was insufficiently paid, the relief ought not to be by way of abatement of the income tax, but ought to be graded right through the army. In the subsequent discussion reference was made to the enormous number of officers who had left professional and business occupations, and it was intimated that the question would again be raised when the Finance Bill came before the House.

One member urged that the law governing the income tax ought to be made intelligible to laymen. Mr. Montagu, speaking on behalf of the Government, explained that the consolidation of the income-tax laws was already proceeding; the Government, he said, was pledged to institute a Committee to examine into existing income-tax inequalities, and he suggested that the simplification and codification of the law would be better dealt with when that Committee had made its report.

It will be seen that at present several matters of considerable interest to the medical profession remain open questions. Only when the Finance Bill, based on the resolutions now agreed to by the House, is published will it be possible to deal more definitely with the considerations which will arise.

Military Mental and Nervous Cases.—Mr. Tennant informed Mr. Touche, on September 30th, that so long as accommodation was available hospital treatment was provided for soldiers suffering from nerve disturbance and less of mental balance in the neurological sections of the twenty-three military hospitals of the United Kingdom in which uncerifiable cases amongst the rank and file were treated. In reply to a further question by Mr. Touche on the same day, Mr. Tennant stated that Springfield House Hospital, Wandsworth, to which uncerifiable cases of soldiers suffering from nerve disturbance and less of mental balance were sent, was a block of the Middlesex County Asylum at Wandsworth, and was under the same management as the rest of the institution. Any civilian admitted to the county asylum would have been certified as insane. Cases were not sent to Springfield House Hospital until after a period of treatment in the neurological section of a general hospital.

Invalided from Navy.—Commander Bellairs asked the First Lord of the Admiralty, on September 30th, in view of the admitted facts in regard to the case of Surgeon David Vickery, who was invalided from the navy on a mistaken diagnosis, whether he would now communicate the decision of the Admiralty on his claim for the surgical and medical expense in which he was involved, bearing in mind that the grievance was of many months' standing. Dr. Macnamara said that as an act of grace it had been decided to make a grant of £20.

Hospital Ships at Gallipoli.—Mr. Tennant stated, in reply to Sir Henry Craik on September 30th, that the medical arrangements for dealing with the sick and wounded at Gallipoli were entirely in the hands of the Royal Army Medical Corps. The transport of the sick and wounded involved the co-operation of the naval authorities, who had the control over the working of the ships, which was exercised through a naval hospital transport officer. There were fifty ships regularly engaged on this service; this number, it was hoped, would prove adequate, but as an emergency measure other transports could be utilized in addition. In reply to a subsequent question, Mr. Tennant said he thought he was correct in saying that of the fifty ships referred to forty-nine were hospital ships.

Wounded Medical Officers and Rewards.—Mr. T. M. Healy asked the Under Secretary of State for War, on September 21st, whether doctors wounded while attending to soldiers under fire would receive, or were entitled to, any special recognition for their bravery. Mr. Tennant said that the mere fact of being wounded while attending to soldiers under fire did not entitle a medical officer to special recognition for bravery, but these officers received full recognition for valour shown, their cases being considered on the same lines as those of other officers. Any exceptional circumstances would be given their proper weight.

Medical Inspection of Scholars.—In replying to Mr. Peto, on September 30th, Sir John Simon said that the medical examination under the Factory Acts was for the purpose of testing the fitness of the child for employment in a particular factory, and imposing any necessary conditions as to the precise kind of employment. The requirement applied to all persons under the age of 16, and the bulk of the examinations took place after the child had left school. The question of linking up this examination with the school medical inspection had not been overlooked, but no change in the requirements of the Factory Acts could be made without an amendment of the Acts, and that could not be undertaken at present.

THE WAR.

THE FRENCH ARRANGEMENTS FOR THE WOUNDED FROM RECENT ACTIONS.

As we noted at the time, defects in the medical service of the French army were recently made the occasion of a violent attack on the Government through the Minister of War. The spokesmen of the Government and of the Committee of Hygiene, while admitting that last year defective organization led to many delays and mistakes, alleged that matters had been put into order. This assertion has been tested during the last fortnight, and the results have justified it. M. J. Godart, the new Under Secretary of State for War charged with the supervision of the medical arrangements, has been to watch the work of evacuating the wounded from the front in Champagne and Artois, and has given *Le Journal* an account of his observations.

The medical service had, M. Godart said, two problems to solve: first, to transport the wounded rapidly, and, secondly, to distribute them suitably. The number of automobiles actually in the field has been increased, and they go up as far as the *poste de secours* whenever that is possible. They worked without stopping day or night, so that the time a wounded man was left on the field was reduced to a minimum. The ambulances from the first line to the railway stations are worked in the same way. By an arrangement with the railway companies the speed of the ambulance trains has been increased to from 30 to 45 kilometres (18 to 27 miles) an hour. The trains are heated and ventilated, and are not kept waiting more than an hour in the railway stations. They are completely disinfected after each journey. The distribution of the wounded has been arranged by regions, and the number of wounded each region can receive is known. Each region has a distributing railway station with an experienced surgeon in charge. When the wounded arrive they bear labels indicating the nature and gravity of the wound; the surgeon in charge of the distributing railway station knows the surgical resources of his region, and therefore where to send the wounded. At each such station there is an ambulance where urgent operations can be performed. Before his arrival each wounded man has, as a matter of routine, received an antitetanic injection. The general result of these arrangements has been that the wounded sent to Brittany arrived there twenty-four hours after receiving their wounds, in Paris within fourteen hours, and at Fontainebleau within sixteen hours. The longest period before a wounded man had reached the hospital to which he was assigned was thirty hours.

The automobile surgical ambulances had been so far useful that a considerable number of operations had been performed in them under excellent conditions, but on the whole, as at present organized, their position was found to be ill defined. If they are allowed to be too mobile they are not able to do enough, and if stationary they really duplicate the stationary ambulances. They ought, in M. Godart's opinion, to be replaced by operating and sterilizing cars without any surgical personnel, which could be sent to ease points at which there was special pressure. The radiological cars had worked perfectly, and had rendered it possible to make rapid diagnoses and to undertake early operations, which had been greatly to the advantage of a number of wounded men.

The means taken for preventing the effects of poisonous

gases had been satisfactory, as was proved by the fact that very few cases had occurred in spite of the enormous quantity of those gases employed by the Germans. The soldiers could be well protected by masks and helmets, but in the excitement of an assault it was very difficult to get them to wear them. Nevertheless, during these particular operations the men got through the poisonous zone so quickly that they did not suffer. The British masks and helmets have also, we understand, proved very efficient, and are adapted to neutralize gases the Germans are known to have employed, or are suspected of proposing to employ.

M. Godart said that the new metal skull-cap had proved useful, and had prevented a considerable number of wounds; shrapnel bullets did not penetrate it. Similar metal caps have, we believe, been issued to the British, and probably we are as much indebted to the French in this respect as they are to us with regard to the gas helmets.

The general sanitary condition was good; tetanus had very nearly disappeared and gas gangrene had greatly diminished. The serum of Leclainche and Vallé had given good results. The general sanitary state of the troops was good; this was due to the strict orders given by General Joffre with regard to the removal and incineration of refuse in the camps and the disinfection of places, and as to the war against flies. Soldiers in camps were not allowed to lie directly on the ground, but were provided with wicker hurdles to sleep on. The senior medical officers of regiments were instructed to come to an understanding with the municipalities with regard to the strict scavenging of towns, and the regiments were also provided with laundry carts in which linen could be washed and dried. The result was that the murderous epidemics of previous wars were unknown.

M. Godart concluded as follows: "Things are, it is true, not yet perfect. Our task is heavy. This is as true for the health service of the army as for the manufacture of guns and munitions. Our labour never ends, but we are putting all our energy into it. The prime right of the soldier who has shed his blood on the field of battle is to be well treated and quickly treated."

We are enabled by the kindness of a correspondent to reproduce here a diagrammatic form used by Dr. Baradat in one of the regions—the region of Privas, the chief town of the Department of the Ardèche, which borders the Rhone below Lyons on the western side. With this diagram properly filled up the medical officer in charge of the distributing railway station at Lyons knows how many beds are available in each town, and Dr. Baradat, who is the responsible officer at Privas, the centre of the region, knows in what hospitals the men are, how many are in the convalescent *dépôt* at Privas, and how they have been disposed of when they leave that institution. As will be seen, the number of beds and formations varies very much in the different towns according to the facilities, including in particular the number and size of suitable buildings, available. At Annonay there are eight formations with 511 beds; at Aubenas-Vals there are six formations with 356 beds; at Privas, the county town, five formations with 376 beds. It would, of course, make the work very much simpler to have all the men in one big building—one formation—but this is seldom possible. The difficulty exists also in this country, and was illustrated by the case of Manchester, mentioned last week, where the 3,000 beds available had to be distributed through twenty-two different buildings.

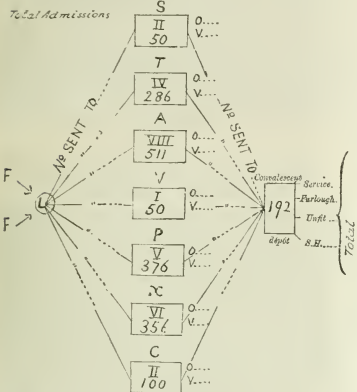

The British system for distributing wounded men to hospitals at home, which has been at work for the last year, resembles that described above as now organized in France, but owing to the sea transit it is rather more complicated. The work of distribution has to be done twice, first at a point on the lines of communication from the front, where the officer in charge has a daily statement showing the number of beds vacant in France, and the number of hospital ships available; with this in his hand he has to decide whether a man shall be sent to a British hospital in France, and if so which, or sent home direct, and in making his decision he must have regard to the man's condition and the nature of his wound. The second sorting takes place at the home port of disembarkation, where information in tabular form, but similar to that in Dr. Baradat's diagram, is in the hands of the officer

responsible for dispatching the ambulance trains to the military general hospitals established in various towns in this country.

Table for recording the distribution of wounded and sick from the distributing railway station to the several towns in a "region" in France, and the manner in which they were finally disposed of from the convalescent depot.

Movement of sick and wounded in the district of Privas from (date to date).

Total number in hospitals in the district
Total number of vacant beds

F = convoys of wounded coming from (the front) to L (Lyons). Number sent to S = Serrieres, T = Tournon, A = Aumont, V = La Voulte, P = Privas, X = Aubenas-Vals, C = Cruas.

The Roman figures within the squares give the number of formations, the Arabic the number of beds. O = the number of beds occupied; V = the number of beds vacant in each place; S, H. = special hospitals.

For purposes of reproduction the diagram has been compressed laterally; the actual diagram was about 12 in. in the horizontal and 8 in. in the vertical measurement.

As to the disinfection of ambulance trains, Professor F. Bordas, a member of the Council of Public Hygiene for France, gave to the Society of Public Medicine in Paris a short time ago an account of the method of disinfecting railway carriages followed for the Paris zone.¹ The trains were disinfected at convenient stations on each railway a short way out of Paris. He points out that any process adopted must be effective both against micro-organisms and parasites. Experiments showed that spraying with mercury perchloride, the vapour of formaldehyde, and cresol were not effective against these parasites, and this fact governed the procedure adopted. The plan eventually worked out consisted of two stages; the first was cleansing. In first and second class carriages the cushions were beaten unless a vacuum cleaner was available, and the compartments thoroughly brushed out, the refuse being immediately incinerated. The woodwork in all classes of carriages was scrubbed out with soft soap and washing soda, and the compartments thoroughly washed out. For disinfection a solution of calcium hypochlorite (chloride of lime, bleaching powder) was preferred to sodium hypochlorite ("autretois", "liqueur de Labarraque," depuis faussement appelee "Eau de Javelle on Javel"), because it was found impossible to determine the chlorine content of the latter without laboratory tests. A solution of calcium hypochlorite (2 degrees chlorometric, a degree being the number of litres of chlorine gas furnished by 1 kilogram of calcium hypochlorite) was pulverized in a Bertraud apparatus under a pressure of 6 kilograms. This filled the com-

partments with a fog which persisted for more than an hour. The compartments or carriages were kept closed for twenty-four hours. If, however, there was reason to suppose that cushions were infected with human parasites it was considered preferable in the interests of the workmen to reduce the amount of manipulation and to fumigate the carriages with sulphurous acid, using 40 or 50 grams of sulphur to the cubic metre. In first-class carriages, sleepers, and restaurants, this was replaced by benzination, using 13 c.c.m. of benzine to each cubic metre. Benzine was found to be so toxic to each cubic metre, a small proportion in the air destroyed them rapidly. Cushions and bedding soiled by blood or pus were first of all cleansed with warm water and then soiled. The water used for washing was treated with calcium hypochlorite before it was run away. The straw of soiled palliasses was burnt, and the ticking washed in a solution of calcium hypochlorite (two degrees chlorometric). Some of the railway companies had tanks specially designed for heating the soft soap; but in one particular case, where such an appliance was not available, the boiler of an old locomotive was mounted on bricks and used for the purpose. To the solution of soft soap in water a sufficient quantity of sodium carbonate was added to give a strength of 5 per cent. The pulverizer used is the invention of M. Bertrand, engineer to the Nord Railway Company. It consists of a cylindrical receiver (a Westinghouse receiver serves well) having a tube going down to the bottom. The hypochlorite is put in through a funnel, and the receiver must not be completely filled. The air, under pressure of 6 to 8 kilograms, is admitted above. Two india-rubber tubes, the one carrying air under pressure and the other the liquid, meet in a nozzle, and in it the liquid is pulverized. The necessary pressure is obtained either from the engine of the train or from a stationary engine. Benzine vapour is obtained by pouring the liquid into a tub and putting into it another smaller vessel containing hot water. The compartments must be kept closed for twenty-four hours, and must not be entered during that time.

On the arrival of the train at the disinfecting station the medical officer of the train gives to the disinfecting foreman a special note indicating any carriages which have been occupied by men suffering from infectious diseases or infested with parasites. It is the duty also of the medical officer to see that the personnel of the train takes all utensils out of the carriages, all bedding, and any stretchers soiled by blood, pus, or dejections.

GERMAN EXPERIENCES OF WAR SURGERY.

WOUNDS OF THE AEDOMEN.

Dr. H. Boir,¹ in giving an account of his experience of abdominal wounds, did not say where his experience was gained, but stated that as the majority of the cases did not reach hospital within twenty-four hours of the infliction of the wounds, and as there was little time for operating on those rare occasions when the patients were admitted early, the treatment of abdominal wounds was invariably and of necessity conservative. While the mortality among the patients suffering from wounds of the intestine was very high, the mortality from wounds of the stomach was surprisingly low.

Altogether 72 cases of abdominal wounds, not including wounds confined to the abdominal wall, were observed. The diagnosis of wounds of the abdominal cavity was made by locating the wounds and detecting symptoms of peritoneal irritation. In 14 cases the diagnosis was confirmed by necropsy. The spleen was wounded in one case and the liver in eight, and though two of the wounds of the liver were complicated by wounds of the lungs and kidneys, only one of these nine patients died.

Wounds of the Intestine.

Among the 50 cases of bullet wounds of the intestine, there were 30 about which exact information was available. Of these 30 patients 27 died, and judging from the course of the bullet, it was evident that in every case the small intestine, and in a certain proportion of cases the large intestine also, had been wounded. The necropsies showed that the perforations of the intestine were most

¹ Rev. d'Hygiene, T. xxxvii, p. 727.

¹ Deut. med. Woch., June 10th.

numerous when the bullet travelled in the long axis of the body, and in one case as many as fourteen perforations were counted in the same body. The wounds of the intestine were most extensive when they had been inflicted by bullets fired at close range or striking sideways. In about one-third of the necropsies it was evident that the wounds were so serious that a satisfactory operation was technically impossible. In the remaining two-thirds the conditions were such that an early operation in favourable circumstances might well have saved the patient's life. In some cases the intestines were wounded but not perforated, the bullet having incised the serous and muscular coats, but not the mucous lining of the intestine. Such cases showed that the intestine was sometimes displaced by the bullet without being perforated; and this was the explanation also given by Enderlin, who failed to find wounds of the intestine in 3 cases in which the bullet had passed transversely through the abdomen. Of the 30 cases of wounds of the intestine, 14 presented wounds of entry only, while 16 presented wounds of exit also. Among the latter were the 3 cases terminating in recovery. Curiously enough, in 3 cases both the wounds of entry and of exit had been inflicted by bullets travelling sideways. In a considerable number of cases in which the bullet remained in the body, it had either struck the body sideways or had been turned into this position after entering the body. The tendency of the modern infantry bullet to turn sideways was, in Dr. Boit's opinion, largely responsible for the high mortality from abdominal wounds.

Wounds of the Stomach.

Of the 13 cases of wounds of the stomach, 12 were due to rifle bullets and 1 to a fragment of shrapnel. Only 2 patients died, both being wounded by bullets, which remained in the body. In the first case death was due to haemorrhage from a branch of the middle colic artery. The bullet had shattered the seventh rib on the left side in the nipple line, and the severity of the wound of the stomach was largely due to its laceration by fragments of rib. In the second case death was due to diffuse peritonitis. The bullet had entered in the mid-axillary line, below the ninth rib on the left side, and had perforated the stomach at two points. The patient had crawled back a distance of 300 metres to have his wound dressed. It was considered that the low mortality from wounds of the stomach in this series of cases was due principally to the fact that the stomach was empty. In practically every case no food had been taken within five to twelve hours of the infliction of the wound. Another important factor was the level at which the stomach was wounded; in the second fatal case the stomach was perforated in the most dependent part of the fundus, whence the escape of its contents was most easy. The prognosis was best when the stomach was wounded in the lesser curvature, and near its cardiac end; and it was worst when the stomach was wounded in the fundus or near the pylorus. The symptoms were very variable. In some cases vomiting occurred at once, and in others it supervened a few hours later. In other cases, again, the wound provoked nausea only. There was every degree of shock, but only in one case was the wound immediately followed by haematemesis. Many of the patients remained lying where they were wounded, while others walked a considerable distance. The pulse was at first almost invariably rapid, and intestinal peristalsis was either reduced or totally inhibited. Rigidity of the abdominal wall was a constant sign. All the symptoms improved with astonishing rapidity, and usually disappeared in two to four days.

Treatment of Wounds of the Stomach and Intestine.

The favourable course of these cases confirmed Dr. Boit in his view that conservative treatment was the best for wounds of the stomach. Operation should be attempted only when there was severe haemorrhage, and also possibly when there were signs of extensive laceration of the stomach. It was more difficult to decide how to treat wounds of the intestine. It was obvious, however, that a man with an abdominal wound should be kept as quiet as possible, and should not be moved before the fourteenth day after the infliction of the wound. Dr. Boit had made a *post-mortem* examination in two cases in which, owing to the transport of the patients, in one case on the sixth day and in the other on the tenth day, limited peritonitis was converted to a general peritonitis by the breaking

down of adhesions. Motor cars for the transport of the severely wounded had not been available for his patients till the seventh month of the war. Previously they had been, as a rule, transported on straw in primitive carts. When a case of wound of the intestine was admitted to hospital within eight to twelve hours of the infliction of the wound it was, in Dr. Boit's opinion, advisable to operate if other conditions were favourable.

It was, he said, unfortunate that, as a rule, in a field hospital there were many other casualties competing at the same time with the abdominal casualties for the surgeon's help; and as these other casualties promised better results from immediate operative treatment, the abdominal casualties were apt to go to the wall. For this and other reasons it was advisable that field hospitals should be established for abdominal casualties only at points where severe battles were anticipated. They should not be more than 15 to 20 kilometres behind the front, and their position should be notified to the stretcher-bearers so that the abdominal casualties could be transported direct to the special hospital without having to be drafted there from a general field hospital.

THE DIAGNOSIS OF TYPHOID AND PARATYPHOID INFECTIONS.

It was mentioned briefly last week that the Medical Research Committee had made arrangements to supply to bacteriologists and pathologists standard agglutinable cultures and standard agglutinating serums for the diagnosis of typhoid and paratyphoid infections by means of macroscopic agglutination tests, as well as a special outfit for the performance of such tests. The object in view, which cannot but commend itself to every physician and pathologist, and to all engaged in public health work whether for the army or civil population, is sufficiently expressed in the following memorandum issued by the Medical Research Committee:

Memorandum on the Diagnosis of Typhoid and Paratyphoid Infections.

With a view to the convenience of bacteriologists at military hospitals, and the co-ordination of results obtained by different observers at different times and places, the Medical Research Committee have made arrangements for the preparation and supply of sterilized standard agglutinable cultures and standard agglutinating sera, for the diagnosis of typhoid and paratyphoid infections by means of macroscopic agglutination tests.

The standard cultures and sera for *B. typhosus*, *B. paratyphosus* A, and *B. paratyphosus* B will be prepared in the Department of Pathology, Oxford, under the direction of Professor Dreyer, and they will be supplied by the Medical Research Committee free of charge to pathologists working in connection with military hospitals.

Applications for the standard cultures or sera should be addressed to the Standards Laboratory, Department of Pathology, University of Oxford (telegraphic address, "Pathology, Oxford"); telephone, Oxford 467.

To facilitate the performance of agglutination tests under service conditions or otherwise, a special outfit has been prepared. This consists of a special stand, dilution tubes, agglutination tubes, and two dropping pipettes, which can be obtained free of charge by bacteriologists working for military hospitals upon application to the Medical Research Committee, St. Stephen's House, Westminster, S.W., or may be purchased from Messrs. Baird and Tatlock, 14, Cross Street, Hatton Garden, E.C., price 4s. 6d. each set.

Full directions for use will be sent out with each set. In these directions details will be given which will enable bacteriologists in suitably equipped laboratories to prepare their own killed agglutinable cultures, and to standardize them against the standard serum issued. But where such facilities are absent, and under service conditions generally, standard agglutinable cultures will be supplied in quantities sufficient for all ordinary routine work. When application is made for standard cultures, the probable weekly number of agglutination tests to be made should be stated.

The standard agglutinating sera for *B. typhosus*, *B. paratyphosus* A, and *B. paratyphosus* B will be provided either for the identification of these several forms or for the purposes of comparison with any given killed agglutinable cultures. The use of the standard agglutinable cultures, with the set of apparatus as provided, is believed to offer the following advantages:

1. The procedure is simple and rapid.
2. The materials are always ready, and no cultures have to be incubated and prepared.
3. The culture is killed and all risk of infection is absent.
4. The reaction can be carried out at any temperature between 35° C. and 55° C., or even at room temperature if necessary.

5. No microscope is needed.

6. The killed cultures are as sensitive to agglutinins as fresh living cultures, or even more sensitive.

7. Owing to the precise quantitative determination which it allows, the method enables the worker to follow the course of the agglutination curves obtained by successive examinations, and thus facilitates the differential diagnosis between agglutination due to inoculation and that due to active disease.

8. The results obtained possess standard uniformity even in relatively unpractised hands, and are strictly comparable from case to case and from day to day, wherever the tests are performed. The expression of the results in standard agglutinin units will allow the comparison of extensive series of observations in different laboratories and at various times for statistical or other purposes.

The methods proposed and the standardized cultures and sera provided are already in use at the chief military laboratories engaged in work upon enteric fever cases and carriers with the Expeditionary Force and at home.

It is hoped that in the interests of the unification of records the standards now made easily available may be generally adopted.

St. Stephen's House, Westminster, S.W.
July 8th, 1915.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

CAPTAIN ARTHUR ERNEST BULLOCK, R.A.M.C., was killed in Flanders on September 27th, 1915, aged 26. He was the elder son of Dr. Bullock, of St. Leonards-on-Sea, was educated at St. Mary's, and took the licence of the Society of Apothecaries in 1912. After serving as clinical assistant in the ophthalmic department, resident obstetric officer, and house-surgeon at St. Mary's, when the war broke out he took a temporary commission as Lieutenant in the R.A.M.C. on August 10th, 1914, and was recently promoted to Captain. He was attached to the Middlesex Regiment at the time of his death.

Captain Ernest Cotton Deane, R.A.M.C., was killed in Flanders between September 25th and 28th, 1915, aged 28. He was the third son of T. Stanley Deane, of Bank House, Rathcalle, co. Limerick, was educated at Corrigan School, Kingstown, and at the Adelaide Hospital, Dublin, and took the licences of the two Irish Colleges in 1909. He entered the R.A.M.C. as Lieutenant on July 28th, 1911, and was promoted to Captain, with all the other lieutenants in the corps, on March 30th, 1915. In his case this special promotion came only four months earlier than he would have been entitled to it in the ordinary course of events. Before the war he was serving in India, at Lucknow; he came to Europe with the Garhwal Brigade, and was attached to the second battalion of the Leicester Regiment when killed. He was a well-known Rugby football player, having been captain of the Monkstown and Adelaide Hospital fifteens, and an Irish International. The announcement that the Military Cross had been conferred upon him appeared in the *London Gazette* on October 2nd, the same day on which his death in action appeared among the obituary notices. It was in the following terms:

Captain Ernest Cotton Deane, R.A.M.C. (attached 2nd Battalion the Leicestershire Regiment).

For conspicuous gallantry on August 22nd, 1915, near Pausissart. A standard patrol 120 yards in front of our line was bombed by the enemy at about 10 p.m., the only notification being two loud bomb explosions. Captain Deane, without any knowledge of the enemy's strength, at once got over the parapet and ran by himself to the spot, under rifle and machine gun fire. Finding four wounded men, he returned for stretchers and got them back into safety. This is not the first time that Captain Deane's gallantry under fire has been brought to notice.

Lieutenant Kenneth Robinson, R.A.M.C., was killed in the recent advance in Flanders on or about September 25th. He was educated at Manchester, took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1907, the degrees of M.B. and B.S.Lond. in 1912. He had been honorary medical officer to the Girls' Home, Bramley Cross, Lancashire, and was in practice at Llandudno when he took a temporary commission in the R.A.M.C. on March 5th, 1915. He was attached to the 12th Battalion Manchester Regiment when he met his death.

Lieutenant Edgar Faulks, R.A.M.C., killed in action between September 25th and 27th, was 38 years of age and was the second son of Mr. and Mrs. Arthur Faulks of

Loughborough. He received his medical education at Guy's Hospital, where he was house-surgeon and house-surgeon to the throat department. He took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1902. At the time of his death he was senior assistant medical officer at the Bexley Asylum, Kent. He joined the R.A.M.C. three months ago. He had only been at the front a few days before the action took place in which he lost his life.

Wounded.

Captain H. M. Pope, R.A.M.C., Flanders.
Lieutenant G. Millar, R.A.M.C., Flanders.

DEATHS AMONG SONS OF MEDICAL MEN.

Carless, Albert Wilkes Buchan, Lieutenant 1st, attached 5th Battalion Middlesex Regiment, eldest son of Professor Albert Carless, F.R.C.S., Major R.A.M.C. (T.), died of wounds in Flanders on or about September 26th. He was educated at St. Clare School, Upper Walmley; at Caius College, Cambridge; and at King's College, London, where he gained the Warneford entrance scholarship, and was for three years a medical student, and a member of the University O.T.C. He went to the front in November, 1914.

Collison-Morley, Harold Duke, Lieutenant-Colonel, the Buffs, commanding a battalion of the Middlesex Regiment, son of the late Dr. L. Collison-Morley, Medical Officer of St. Paul's School, killed in Flanders, September 25th, aged 37. He was educated at St. Paul's School, the Slade School, and Julien's Art School, Paris. At an early age he contributed sketches to the *Graphic*, and last year he exhibited etchings at the Society of Arts. As a young man he went to Australia, and served with the Queensland Bushmen in the South African war in 1900-01, when he was present in operations in the Transvaal and Orange River Colony, including the action at Rhenoster Kop, gaining the Queen's medal with three clasps, and a commission as Second Lieutenant in the Lancashire Fusiliers, from May 19th, 1900. He became a Captain on July 16th, 1901, was transferred to the Buffs, or East Kent Regiment, on May 20th, 1908, and became Captain on March 13th, 1911. He was appointed Adjutant of the 7th Battalion, London Regiment, on December 15th, 1911. In 1905 he married Olive, daughter of the late Horace Wood, of Clairmont, Natal, and leaves one daughter.

Coward, Leslie G., Captain 1st, attached 5th Battalion, Middlesex Regiment, youngest son of the late Dr. Coward, of Park Lane, Stock, Lewington, killed in Flanders on September 25th. He was educated at Owen's School, London, got a commission as Second Lieutenant on January 1st, 1915, and became Captain in June.

Dunlop, Kenneth Strickland, Second Lieutenant 4th Battalion South Staffordshire Regiment, youngest son of Andrew Dunlop, M.D., Belgrave House, Jersey, killed in Flanders between September 25th and 28th, aged 35. He got his commission on April 3rd, 1915.

Greenhalgh, Maurice Lomax, Second Lieutenant King's Liverpool Regiment, youngest son of the late Thomas Greenhalgh, M.R.C.S., M.R.C.P., killed in France on September 25th. He was educated at Helm Leigh, Buxton, and at St. Bees, and at the beginning of the war enlisted in the United Public Schools Battalion, getting a commission on October 23rd, 1914.

Handfield-Jones, Neville, Lieutenant Royal Field Artillery, only son of Dr. Handfield-Jones, of 36, Cavendish Square, London, killed in Flanders September 25th. His commission was dated April 22nd, 1915.

Herbertson, William Gray, Lieutenant 8th King's Own Scottish Borderers, killed in action in France, was the second son of Dr. James Herbertson of Johnstone, Renfrewshire. He first joined Lochiel's Camerons, and was afterwards promoted and transferred to the K.O.S.B., where he acted as bomb officer. He was 25 years of age, and a well-known Rugby football player.

Nelson, Cecil, Captain 3rd Essex Regiment, attached 69th Punjab, eldest son of Surgeon-Major Nelson, of Downpatrick, Ireland, killed in the recent advance in France. He was born on September 2nd, 1879, educated at Armagh High School and in Germany, and joined the Royal Irish Rifles as Second Lieutenant on November 15th, 1899, serving with that regiment in the South African war in 1899-1900, when he gained the Queen's medal with two clasps. On August 30th, 1902, he joined the Indian army, being posted to the 3rd Buffs, and became Captain on November 15th, 1908. Before the war he was Station Staff Officer and Cantonment Magistrate at Rurki. He then accompanied his regiment to Egypt, and later on was sent to the western front.

Stiven, Ronald Walker Sutherland, Captain 1st Battalion Royal Scots Fusiliers, younger son of the late E. W. Stiven, M.D., died of malaria as a prisoner of war at Majiza-Ishin, between September 15th and 18th, aged 27. He joined the army as Second Lieutenant in September, 1908, became Lieutenant in April, 1911, and Captain on January 31st, 1915.

Tracey, Geoffrey Engene, Lieutenant 9th Battalion Devonshire Regiment, who was killed in action in France, was the eldest son of the late Dr. H. P. Tracey and Mrs. Tracey of Willand, Devon, and was 19 years of age.

Treharne, Leslie Llewellyn, Second Lieutenant 9th Battalion Welsh Regiment, youngest son of the late Dr. Edward Treharne, J.P., killed on September 9th. His commission was dated November 13th, 1914.

Wilson, D. J. R., Second Lieutenant Welsh Regiment, elder son of Dr. Wilson, of Haverfordwest, Pembroke, killed in France on September 25th, aged 22. He got his commission on October 3rd, 1914.

Wilson, Geoffrey, Captain Wiltshire Regiment, son of Dr. Mervyn Wilson, of Chippenham, killed in the recent advance in France. He was educated at Marlborough, and became Captain on February 2nd, 1915.

MEDICAL STUDENTS.

Fawcett, Richard Wilfrid, Second Lieutenant South Staffordshire Regiment, only son of the late Charles Fawcett, of Rawdon and Bradford, died of wounds in France on September 26th, aged 23. He was educated at Haileybury, at Caius College, Cambridge, and at the London Hospital, where he was a medical student. In the early part of the war he served for some time in the navy as a surgeon-probationer on H.M.S. *Ferret* in the North Sea, then got his commission on March 26th, 1915.

Allan, James Grant, Lieutenant 9th Gordon Highlanders, who has been killed, was the elder son of Rev. W. G. Allan of Edinburgh. He was 20 years of age, and held the degree of B.Sc. of Edinburgh University, where he was studying medicine. He received his commission on November 19th, 1914.

THE ARMY NURSING SERVICE.

The casualty list published on October 2nd contained the names of no less than eight members of the Army Nursing Service as having died on service. This list, however, appears to refer to the whole period of the war up to date, for Miss Cole died at Boulogne so long ago as February 21st (BRITISH MEDICAL JOURNAL, March 6th) and Miss Pearce at Havre on April 29th (BRITISH MEDICAL JOURNAL, May 15th). The names are as follows:

Queen Alexandra's Imperial Military Nursing Service—Miss E. H. Cole, France; Miss P. A. Pearce, France; Miss M. A. Walshe, Mediterranean; Miss L. M. Swaine, Mediterranean; Miss M. H. Johnston, Mediterranean; Miss E. Fearnley (Reserve), France.

Canadian Army Nursing Service—Master J. B. Haggard, Mediterranean; Miss F. E. Munroe, Mediterranean.

NOTES.

A HINT TO REGIMENTAL MEDICAL OFFICERS.

A REGIMENTAL MEDICAL OFFICER sends a suggestion which he thinks may be useful to those newly commissioned in the R.A.M.C.: In my work (he writes) I have found a simple shilling rubber lettered printing outfit of inestimable value. It has saved me many weary hours of clerical work, and gained for me an unmerited reputation for business methods. Of course, a specially made stamp with one's appointment and medical qualifications is common. The objections to such are the lack of adaptability, cost, delay in delivery, and the not uncommon changes in one's appointment to units. With a printing outfit and a couple of extra type holders a number of stamps can be made immediately. I have one for heading the official "memo" forms, printing:

From the Medical Officer,
to 17th Westshire Fusiliers.

another for all sick reports, letters, memos, and so on, printing:

Captain, R.A.M.C.,
in Medical Charge 17th Westshire Fusiliers.

I have also put together two or three others for special purposes. I was suddenly called on to enter in a thousand soldiers' active service pay books the date of their typhoid inoculation. From my predecessor's returns I found he had only given the dates when he commenced giving each dose to the battalion. I merely had to put together the orthodox symbols and dates as:

T.V. 8 Dec. 1914.

I

T.V. 18 Dec. 1914.

J

X. Y. Z.

leaving the place X. Y. Z. for my initials. In this way I saved many hours' work completing that duty. Again, when I had to enter in the active service pay book the dentures which had been supplied, I put up the type in the required form:

D or D
L or U 10. AUG. 1915.

according as to whether an upper or lower denture had been issued at the date of my inspection.

The printing outfit can be obtained from any stationer for less than two shillings.

THE VESTAL VIRGINS.

Flanders is at the best of times a fly-ridden country, and, of course, the huge accumulation of men and horses

in the area has given the flies an extraordinary chance. The responsible officers of the Army Medical Service realized at an early date that special methods would be necessary; and, as we mentioned some time ago, Sir Arthur Sloggett, in the memorandum which he issued last April as Director-General A.M.S. in France, said with regard to trench latrines that they should be of the shallow variety whenever possible, and constantly supervised to ensure that the excreta are kept covered with earth. "Less than 1 ft. of dry earth over excreta will not infallibly prevent flies from emerging if eggs have been deposited before the faeces were covered." In these circumstances incineration was mentioned as a possible alternative. Shortly afterwards a commission of three—Professor Newstead, of Liverpool; Mr. R. W. Jack, Government entomologist, Southern Rhodesia; and Captain E. E. Austen, the well known entomologist attached to the Natural History Department of the British Museum—studied the subject on the spot and made further recommendations. In the early summer special instructions were given with regard to incineration, and where it was found possible to build incinerators—and it would seem that this has generally been found possible in any large collection of men behind the lines—everybody, officers and men alike, were required to see that excreta were put into the incinerator. These never-dying flies have got, among the officers at least, the name of "the Vestal Virgins," and the meaning and importance of their work seems to be thoroughly understood. Sometimes, no doubt, when the wind was in the wrong quarter the odours were not quite agreeable, but this inconvenience was cheerfully put up with, since it was well known that the vestals were designed to obviate the greater inconvenience of a plague of flies, and the serious risk of the conveyance of disease. It is generally recognized, we gather, by officers of all corps that sanitary work has never been done anything like as well in any previous campaign as in this, and they are taking a professional pride in the fact, which makes for greater efficiency in the future.

MEDICAL OFFICERS WANTED.

21st Eastern Mounted Brigade Field Ambulance, R.A.M.C.(T.F.). Three officers are required by this unit. As the 11st Eastern Mounted Brigade Field Ambulance is abroad, medical officers will be required from this unit for service overseas. Application to Major C. G. Kay Sharp, Commanding 21st Eastern Mounted Brigade Field Ambulance, R.A.M.C., Tadworth Camp, Epsom.

2nd Line Welsh Border Mounted Brigade.

Two medical officers, willing to undertake the imperial service obligation, are urgently required for service with the 2nd Line Shropshire Royal Horse Artillery and Cheshire Yeomanry. Pay and allowances as in the regular army, also outfit and camp kit grants. Full particulars on application to Lieutenant Colonel D. C. Leyland Orton, Senior Medical Officer, 2nd Line Welsh Border Mounted Brigade, The Camp, Morpeth, Northumberland.

England and Wales.

THE MANCHESTER UNIVERSITY.

PERHAPS the most interesting event in the academic year 1915-16, which commenced on October 7th, is the assumption of office by Sir Henry Miers, the new Vice-Chancellor. At a meeting called by the Council of the Workers' Educational Association, and held on September 25th at the Students' Union, a hearty welcome was accorded to the new Vice-Chancellor, Mr. H. Pilkington Turner presided, and, in responding to the cordial vote of welcome, which was carried with acclamation, Sir Henry Miers expressed his fullest sympathy with the aims and objects of the Workers' Educational Association, and said that one of the things that made him feel at home in Manchester was that he was coming among people who shared the ideals of those among whom he had worked in London. A resolution was also carried expressing appreciation of the work done by Professor Weiss as Vice-Chancellor. In reply, Professor Weiss took the opportunity of welcoming Sir Henry Miers on behalf of the members of the University.

The new Vice-Chancellor, coming from the Principalship of the London University, assumes office in Manchester at a time when the whole work of the university cannot fail to be unusually difficult. It is noteworthy that in the

prospectus of the different faculties for the coming session the arrangements are in nearly every case issued with the special proviso that the number of lectures in the courses may have to be diminished owing to rearrangements necessitated by the war. Last year the number of students entering the university was between three and four hundred less than the average, and the authorities appear to expect that in the coming session there may be a still further decrease in the number of entrants taken as a whole. In the Medical Faculty, however, judging from the number of inquiries, a large number of entrants are expected; as a rule medical students commence their five years' course before attaining military age.

MANCHESTER ROYAL INFIRMARY.

In normal times before the war the work of the Manchester Royal Infirmary was divided among three establishments: the Royal Infirmary in Oxford Street, the out-patients' department in Parker Street, and the accident and out-patients' department in Roby Street. Owing to the demands of the war, the out-patients' section at Roby Street had some time ago to be discontinued, as sixty beds had there to be set up for sick and wounded soldiers. These beds were in addition to the large number at the infirmary itself set apart for the wounded. Practically the whole of the staffs of the three institutions are now engaged in war work, though some of them only as part-timers; as so large a proportion of the staff have either already gone away on active service or have volunteered and expect to be called on at any time, it is announced that the Board of Management has decided to close the Parker Street out-patient department from October 11th; after that date all out-patients will have to attend at the infirmary itself. This will, of course, cause some amount of inconvenience, as the distance to the infirmary from the centre of the city is considerable; but with the depleted staff (which, in addition to military cases, has to attend all the ordinary cases as usual) the temporary change in arrangements appears to be unavoidable. At a meeting of the Board of Management held on September 29th under the chairmanship of Sir William Cobbett, the position of secretary and general superintendent of the institution, which had become vacant by the resignation of Mr. W. G. Carnt, was filled by the appointment of Mr. Frank Hazell. Mr. Hazell has been for the last fifteen years secretary of the Norfolk and Norwich Hospital at Norwich, and before that was for nine years assistant secretary of the St. Luke's Hospital for the Insane, London.

THE LIVERPOOL MILITARY HOSPITALS.

The territorial military general hospitals established so rapidly a year ago, in accordance with the scheme elaborated by Sir Alfred Keogh during his first tenure of office as director-general, have been extended from time to time as further demands were made by the army so quietly that it is difficult to grasp the magnitude of the work that has been done. The *Liverpool Daily Post* published the other day an article on the military hospitals of Liverpool, and was clearly surprised to realize how extensive the provision has now become. The City Hospital at Fazakerley—to which, it is stated, stretcher cases are, as a rule, most conveniently drafted—has 500 beds. It is a pavilion hospital surrounded by airy grounds. Highfield, lent by the Select Vestry, is an almost new hospital with 500 beds, in a healthy situation. At the Mill Road Infirmary, West Derby Union, there are 400 beds, and at the Toxteth Union 100. The Royal Infirmary, the Royal Southern Hospital, and the David Lewis Northern Hospital each offer 40 beds, the Stanley Hospital 20, and the Bootle Borough Hospital 25. The tropical school at the Royal Infirmary has been adapted to provide 200 beds, and the old hydropathic home at Woolton has been taken over to provide as many more. In addition the orthopaedic centre for wounded soldiers at the Alder Hey Hospital provides 500 beds in a new building on an agreeable suburban site. There are also a number of hospitals maintained by private beneficence. At various Southport hospitals about 600 beds are provided, while Birkenhead furnishes 250, and Wallasey about 100. Lastly, there are a number of convalescent hospitals. Altogether the Liverpool district contains provision for over 5,000 military patients.

Scotland.

We regret to notice that the son of Sir Edward Schafer is reported as wounded and missing, and the son of the Principal of Aberdeen University as killed in the recent fighting.

TREATMENT OF TUBERCULOSIS IN EDINBURGH.

At a meeting of the Edinburgh Insurance Committee, held on September 23rd, the terms of agreement between the Corporation and the Insurance Committee regarding the scheme for the prevention and treatment of tuberculosis in the city were submitted and approved.

By this agreement the medical officer of health, Dr. Maxwell Williamson, will be the chief administrative officer in carrying out the whole scheme for the prevention and treatment of tuberculous disease in the city. The assistant medical officer of health, Dr. John Guy, will act as a tuberculosis officer. His chief duties will be in connexion with cases of tuberculosis in insured and uninsured persons. His services will be placed at the command of the Insurance Committee. He will attend the meetings of the Insurance Committee and the Sanatorium Benefit Subcommittee, and will act as medical adviser to the committee. In the event of the appointment of tuberculosis officer becoming vacant, any new appointment shall be made by the Corporation in consultation with the Insurance Committee. Sir Robert William Philip, M.D., will continue to act as consultant or expert adviser in connexion with the prevention or treatment of tuberculosis in all its forms, whether in the case of insured or uninsured persons. The Corporation agrees that the Royal Victoria Dispensary and its staff shall be available for the treatment of tuberculous cases, whether insured or uninsured, including medicines. The Insurance Committee agrees as from February 26th, 1915, to pay to the Corporation annually in quarterly instalments the following sums: First, a proportion, amounting to £200 per annum, of the salary of the assistant medical officer of health acting as tuberculosis officer; and secondly, the sum of £200 per annum in respect of the Royal Victoria Dispensary, with its nursing staff being made available for the treatment of insured tuberculous cases. The Insurance Committee will make monthly payments to the Corporation for the treatment of insured persons in any hospital administered by the Corporation, for whom the Insurance Committee or the Sanatorium Benefit Subcommittee shall have agreed to provide such treatment. The rate of such payments will be agreed upon annually between the Corporation and the Insurance Committee as at December 31st each year. The agreement is terminable on three months' notice on either side. Early stages of the negotiations were noted in the *JOURNAL* on June 6th, 1914, p. 1265, and July 31st, 1915, p. 195.

Ireland.

ULSTER AND PROVISION FOR SICK AND WOUNDED SOLDIERS.

ON October 1st the Marquis of Londonderry and Lady Londonderry opened the new block of the Ulster Volunteer Force Hospital. The original hospital was an adaptation of the old exhibition buildings, near the Botanic Gardens Park, kindly given by the City Corporation. The university authorities granted the use of their adjoining ground, and on it a new L-shaped block has now been completed, and is continuous with the old; a broad verandah runs along the inside of the L, which faces south, and the contained ground is rapidly being planted with shrubs and flower beds. The arrangement and equipment are excellent and up to date, and the general feeling at the public opening was one of surprise and delight that such a bright and useful building could spring into being in such a short time. Counting the verandah, the full buildings will now be able to accommodate over 200 patients. The honorary treasurer said that the total subscriptions amounted to £14,417, and since he had ascended the platform he had received a further promise of £150. Several batches of

patients had already been received, and all did extremely well; in a few days the administration would be ready for double the number.

At a well-attended meeting in the City Hall, Belfast, on September 21st, a public committee and many subscribers handed over to the military authorities twenty-two motor ambulances for the use of the Ulster Division; most of these are ready and fully equipped. The sum of £10,560 has been subscribed throughout Ulster for this object.

Dr. Joseph Fulton, one of the visiting medical officers of the Poor Law Infirmary, Belfast, has returned the £50 for attendance on the invalided soldiers of the Ulster Division during their stay in one of the blocks of buildings given by the guardians to the military authorities, asking them to spend the sum in comforts for the men.

Correspondence.

NAPOLEON'S FUNERAL.

SIR,—The publication in the *Times Literary Supplement* of the diary of Andrew Darling, the upholsterer who acted as undertaker at Napoleon's funeral in 1821, is an event of considerable interest to Napoleonic students. Although it was known that this document had been published in the *St. Helena Advocate* in 1851, all trace of it had been lost, and its contents were unknown. Fortunately, however, Major M. F. Foulds, R.A.M.C., who is at present in medical charge of the troops in St. Helena, is interested in the subject, and is devoting his spare time to a methodical search among the records deposited in the Castle at Jamestown for any facts regarding the captivity of Napoleon that may have been overlooked. Major Foulds happened to be reading a *St. Helena Who's Who*, and he noticed on p. 62, under the heading "Darling," that a document had been written by that person, in which was recorded the dispositions made for the funeral of Napoleon. He therefore prosecuted his search, and amid a mass of records very much un-eaten, found Darling's diary in an excellent state of preservation. Major Foulds sent the document to me with the request that if deemed of sufficient interest, steps should be taken to secure its publication in the *Times*.

From the historical point of view the diary is of great value, for, unlike so much of the St. Helena evidence, it is untinged with political bias; indeed, it is a plain and minute statement of the way in which the "undertaker" carried out his work. In addition, the document brings to light some facts which were unknown, and, as collateral evidence, confirms several points which were in doubt. Some of these may be mentioned. Darling gives us the exact measurements of Napoleon's height, breadth of shoulders, and depth of chest, as he lay dead (length, 5 ft. 7 in.; only 18 in. barely across the shoulders; and scarcely 10 in. deep). In common with all others who saw the dead Emperor, Darling, the undertaker, was struck with the extraordinary beauty and youthful appearance of the face. Then Darling gives us an exact account of the way in which Napoleon's private apartment was fitted up as a "chappelle ardente," and he describes with minute care the making and furnishing of the coffins and the manner in which the heart and stomach were enclosed in their respective silver receptacles. His version of this last duty tallies with that of Dr. Rutledge, who was in medical charge of the body, and with that of Abraham Millington, the armourer, who soldered up the coffins. Finally, Darling gives us some new facts concerning the much-debated question of the death mask. Thanks to the labours of Mr. G. L. de St. M. Watson, in his recent book, *The Story of Napoleon's Death Mask*, the claim of Dr. Burton as the author of the famous mask now rests on irrefutable evidence, and Antommarchi's pretensions are for ever disposed of. Darling informs us that he purchased 150 small plaster figures in Jamestown and had them ground down to serve as plaster for the cast. Of course this material was bound to be ineffective, for he had neglected to have it calcined. No wonder that when Antommarchi made the attempt he failed, and it was not until Dr. Burton had obtained some crude gypsum from deposits found on the island that a satisfactory cast could be obtained. Darling

also mentions that the mattress on which Napoleon rested in death was much "marred by stains of blood from him when he was turned round to shave the back part of his head for the bust." This mattress with the stains can be seen in Madame Tussaud's. All these and many other interesting details will be found in the document, which is well worthy of perusal.

In connexion with this document it is interesting to record the fact that there is still living in London a lady in her 95th year who was present at the funeral of Napoleon in 1821. It is true that she was only 3½ months old at the time, and, of course, remembers nothing of the occurrence, but she is nevertheless the last surviving link with the Great Emperor in St. Helena.—I am, etc.,

London, E.C., Oct. 4th.

ARNOLD CHAPLIN.

MEDICAL SERVICE IN THE HIGHLANDS AND ISLANDS.

SIR,—In the discussion on the above by the Scottish Committee at Perth on September 10th some most important points appear to have been entirely overlooked.

The Committee, apparently, assumed that the Highlands and Islands Board guaranteed to the medical officers of the remote parishes a minimum income of £300 per annum plus travelling and other working expenses. The Highlands and Islands Board have done nothing of the kind; nor is any such guarantee referred to in their proposed agreement with the doctors.

The medical officers, in the proposed agreement, are to charge a fee of 5s. for the first visit and 2s. 6d. for each subsequent visit during the same illness, and moderate charges for medicines supplied. Should the doctor fail to get his fees—he will never get cash payment in a Highland parish—the Board refuse to take any responsibility for the bad debts, and in the proposed agreement nothing whatever is said as to the Board making up the doctor's income to £300 per annum free of all working expenses.

Again, there is no check on patients who call the doctor long distances for trifling ailments and no extra fee for night visits.

Above all, there is no intention to put the parochial medical officer of the remote Highland parishes on a similar footing to his brethren in England and in Ireland, by making him eligible for a fair pension. Many medical men have "existed" in the Highlands and Islands on beggary salaries, doing, practically, Government work single-handed for twenty years and over, and now the Treasury steps in and objects to these poor men being allowed a decent superannuation. It appears as if these medical men are being practically asked to clear out, go to the poorhouse, or rely on charitable relatives or friends in their old age for support.

If the Highlands and Islands (Medical Service) Board have not sufficient funds to institute pensions for the older or disabled members of the Highlands and Islands Parochial Medical Service, then the Highland members of Parliament and their constituents must see to it that the grant is increased, if only for ensuring this mere matter of common fairness and justice.

Had these medical officers elected to enter the army or the navy, they would now be entitled to a pension of at least £1 per day. Instead, they have been all along doing much harder work, receiving much less in pay, and left to retire when unfit for the work without a penny.—I am, etc.,

September 21st.

GUARANTEE.

THE DANGER OF SACCHARINE.

SIR,—The increased taxation of sugar and its substitute, saccharine, thus again increasing their price, seems to be a good opportunity of drawing the attention of the profession to the danger of the latter drug when it is consumed in large quantities. Sugar is a food, saccharine is not; it is a chemical made from coal-tar derivatives having a sweetening property, volume for volume, of about 500 times that of cane sugar. In spite of the fact that before the new taxation its price had already risen by about 25 per cent., it is still consumed in large quantities by the general public in this country, being taken chiefly for obesity. It can be obtained *ad libitum* from druggists, for, although it is chiefly made in Germany and Austria, it is also manufactured in Great Britain.

Recent research at the McFadden Laboratories at the Lister Institute has shown that saccharine is a powerful auxetic like several other constituents and derivatives of coal-tar; and there is now strong evidence that it is these auxetics in tar and pitch that give rise to the predisposition to the epithelioma known as pitch and sweep's cancer. Saccharine, therefore, should be taken internally with caution, and not for long periods, unless the patient is suffering from diabetes or other really serious complaint.

In the United States the sale of saccharine was prohibited by law in 1912, on the grounds that in daily doses of 0.3 gram or more it causes "disturbances of digestion," and also that as a sweetener in canned foods and preserves it is a deception, the public believing "saccharine" to be a form of sugar.

Judging by the verbatim report of the inquiry, the absolute prohibition was enforced chiefly because of the second reason, which does not apply so much in this country, where the industry of canning foods is not such a large one, although, owing to its small bulk, saccharine is used here, especially in tinned infants' foods. But the first reason is also an important one, in that saccharine, after prolonged administration, evidently acts as a chronic irritant to the stomach. This point was demonstrated at the inquiry held by the United States Department of Agriculture¹ in 1911, when the exhaustive experiments of Hörter and Folin² were published. From these investigations it appears that saccharine causes an increased secretion of hydrochloric acid in the stomach, and, after prolonged administration, gives rise to nausea. The sweetening effect of the drug is also lost after a time, and patients frequently take a dislike to it.

From the foregoing facts, therefore, especially as saccharine is a coal-tar auxetic, it appears justifiable to utter a warning against its indiscriminate use as a drug or substitute for sugar. Whether it is actually a predisposing cause of cancer of the stomach is a point impossible at present to determine by any statistics, as the drug has been in use for nearly thirty-five years; but still, knowing the effect of the coal-tar auxetics in the tar and pitch trades, the risk hardly seems worth running unless its administration is essential. In cases of diabetes, when its advantages may outweigh its disadvantages, saccharine can be ordered judiciously by prescription. It is to be hoped that some day the public will be educated not to obtain it in any other way.—I am, etc.,

Lister Institute, S.W., Oct. 1st.

H. C. ROSS.

THE ADMINISTRATIVE CONTROL OF MEASLES.

SIR,—I have to thank Dr. Cook for correcting my reference to notification of measles in Greenock. I knew that householders notified measles in Greenock, but I was not aware that they were compelled to do so. Fortunately the error does not affect the argument, if any conclusions from such figures are justifiable, since the comparison depends on the existence of a stable condition of things in one town, and changing conditions during the same period in another town adjacent. Indeed, if the chart in question gave any support to notification, the argument is now strengthened.

It is questionable, however, if the system of compulsory notification by householders, as practised in Greenock, is quite an efficient means of discovering cases of the disease. The percentage mortality among the known cases of measles for the five years 1910-14, instanced by Dr. Cook, was 2.49 in Greenock, 1.32 in Port Glasgow, and 0.50 in Renfrewshire. These rates are calculated on figures taken from the annual reports of the Medical Officers of Health. Renfrewshire and Port Glasgow represent for this district the extremes of health conditions and weighting of the population at the earlier years of life, and the rate for Greenock should theoretically fall somewhere between theirs. The Greenock rate exceeds that of Port Glasgow by more than three times the standard error, and the excess may fairly be attributed to a deficiency in the recorded cases of measles in Greenock rather than to greater fatality of the disease.—I am, etc.,

Glasgow, Oct. 4th.

Obituary.

EDWARD A. MINCHIN, M.A., F.R.S.,

PROFESSOR OF PROTOZOOLOGY IN THE UNIVERSITY OF LONDON.

The world of medicine, as well as that of biology, to which he more properly belonged, is the poorer by the early death of Professor E. A. Minchin, F.R.S., at the age of 49 years.

Although his fame will no doubt rest upon his zoological work, yet the fact that he did a considerable amount of work also upon those protozoa which are the cause of disease will connect his name with medicine. He was educated at Westward Ho and Keble College, Oxford, where he became a Fellow of Merton College, and was for many years demonstrator of comparative anatomy and held also a Radcliffe Travelling Fellowship. His early work at Oxford was zoological, principally on sponges, knowledge of which he advanced considerably. After holding the appointment of Lecturer on Biology at Guy's for one year he became, in 1899, Jodrell Professor of Zoology in University College, London; in 1905 he went to Uganda as a member of the Sleeping Sickness Committee of the Royal Society to study the tsetse fly in its relation to sleeping sickness and the life-cycle of *Trypanosoma gambiense* in its relation to the fly *Glossina palpalis*. Although these researches were comparatively barren of direct results, an admirable account of the anatomy of the fly was written and much collateral information obtained. In 1906 he was appointed Professor of Protozoology in the University of London. A later development of his African work soon followed in a series of papers on the question of the structure of trypanosomes in relation to microscopic technique, an important and necessary piece of work, showing how structures may be altered, obliterated, or manufactured by imperfect technique. In 1912 he published his most important work, *An Introduction to the Study of the Protozoa*, one of the best books on this very difficult and ever-moving subject. It is full of the most careful criticism, and is, what is too rare in a book of this type, also full of generous appreciation of other men's work; it will probably remain for a long time the best presentation of our knowledge on this subject up to its date. Then last year appeared a monograph, written in conjunction with Dr. J. D. Thomson, on the rat trypanosome in its relation to the rat flea; in this, which was the result of five years' work, although every problem presented by the transmission of the trypanosome and its development in the flea is not solved, a mass of the most careful work is contained, carrying the subject as far as it can go at present. His last piece of actual work was the thoughtful address which he was unable to deliver before the British Association at Manchester a few weeks ago.

He was elected a Fellow of the Royal Society in 1911, and the Linnean Society conferred the Trail award and medal on him in 1910.

As a teacher he was clear, patient, and extremely careful, and as a colleague loyal and sincere.

THE LATE LIEUTENANT T. A. PEEL, R.A.M.C.—A notice of the short career of Lieutenant T. A. Peel, R.A.M.C., killed in the Dardanelles, was published in the JOURNAL of September 11th. His father, Mr. J. E. Peel of Arnhall, has now received a letter from Captain A. C. W. Vincent of the Dorsets, to which regiment Lieutenant Peel was attached, relating the circumstances of his death. The regiment was one of the first to land at Suvla Bay; they had a large number of casualties on August 9th. They and to many men of other regiments Lieutenant Peel was uniting in his attentions. On the day of his death, August 19th, part of his regiment was in support of an attack, which was repulsed with loss, and the stream of wounded men who came through the Dorsets' trench were treated by Lieutenant Peel. About midday he went out to men lying between the trenches to give them morphine. Having exhausted his stock he went back to the trench for more, and then went out again; during the whole time he was being sniped at, and on this second occasion a bullet passed through his body. Two men of the Dorsets went out and brought him in on a blanket, but the wound was quickly fatal. Captain Vincent adds

that Lieutenant Peel's name had on several occasions been sent to head quarters for his continued good work, and was again sent on on the day of his death.

INSPECTOR-GENERAL HENRY THOMPSON COX, R.N. (retired), died on September 16th, aged 64. He was the son of the late Henry Rix Cox, of H.M. Board of Public Works, Ireland, and was educated in the medical school of the Royal College of Surgeons, Ireland, taking the diploma of L.R.C.S.S.I. and the L.R.C.P. in 1871, also that of M.R.C.P.J. in 1881. He entered the naval medical service in 1872, and reached the highest rank, that of inspector-general of hospitals and fleets (now surgeon-general), on January 25th, 1906, retiring in 1909. He served in the Ashanti campaign of 1873-74, with the naval brigade on shore, receiving the medal. He was also serving on board H.M.S. *Anchylus* as medical officer when that ship and H.M.S. *Shah*, two old unarmoured vessels, successfully fought the Peruvian ironclad, *Huascar*, in the hands of rebels against the Government, off the South American coast in 1877.

SURGEON-MAJOR CHARLES GRAY, Army Medical Department (retired), died in London on September 25th, aged 78. He was educated at St. Thomas's, took the M.R.C.S. in 1858, and entered the Army as assistant surgeon on April 22nd, 1858, becoming surgeon on April 22nd, 1870, and surgeon-major on April 1st, 1873, and retiring on November 13th, 1874. His war services are not given in the *Army List*, though the crossed swords against his name in the retired list show that he had seen service in war.

MAJOR GEORGE THOMAS MOULD, Bengal Medical Service (retired), died suddenly in London on September 13th. He was born on November 25th, 1864, took the diplomas of M.R.C.S. and L.R.C.P. (Lond.) in 1888, and entered the Indian Medical Service as surgeon on March 30th, 1888, becoming major on March 30th, 1900, and retiring, as soon as he had qualified for the earliest pension, on July 28th, 1905. He put in his whole service in military employ, being for many years medical officer of the 1st Duke of York's Own Lancers, better known as Skinner's Horse. He served on the north-east frontier of India in the Manipur expedition of 1891, medal and clasp; in the north-west frontier war of 1897-98, in the Tschai valley campaign, medal and clasp; and in the third China war in 1900, when he took part in the relief of Peking, and in the actions of Peitsang and Yangtsun, gaining a third medal and clasp.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are: Dr. C. H. Bradley, sometime clinical instructor in medicine in the University of Minnesota, aged 50; Dr. Marco Luzzato, physician to the Ospedale Civile, Venice, for more than thirty years, one of the founders and sole editor of the *Rivista Veneta di Science Mediche*; Dr. Alphonse Péchin, President of the General Syndicate of French Oculists, and author of numerous writings on the neurology of the eye and other subjects connected with his speciality, aged 63; Dr. Rigal, formerly physician to the Necker Hospital, Paris; Dr. Ugo Schiff, professor of chemistry at Florence, author of valuable papers on subjects within the province of physiological chemistry, and one of the founders of the *Gazzetta chimica Italiana*; and Dr. Horatio N. Spencer, founder of the *American Journal of Otolaryngology*, which he edited during a period of four years, and professor of diseases of the ear in the medical department of Washington University, St. Louis, from 1881 to 1911, aged 73.

V. ZACHARY COPE (*Brit. Journ. Surgery*, vol. iii, No. 9) considers that actinomycosis is by no means so rare in man as is generally believed, and that many cases are diagnosed incorrectly. In the course of the ten years preceding 1912 only 136 cases were admitted into seven of the largest hospitals in London. Yet while the four largest together only reported a total of 50 cases, two of the smaller hospitals admitted respectively 61 and 21 patients subject to actinomycosis. Cope has detected this disease in 13 cases during the last three and a half years.

Public Health

AND POOR LAW MEDICAL SERVICES.

POOR LAW MEDICAL OFFICERS' ASSOCIATION.

The council of this association at its meeting on September 23rd considered the case of Dr. Denning of Epping; he had been suspended by the guardians, but was entirely exonerated as the result of an inquiry by the Local Government Board. Subsequently the guardians had endeavoured to determine Dr. Denning's appointment by giving one month's notice in accordance with the terms of the contract he had originally signed. Thereupon a further appeal was made to the Local Government Board, which ruled that the guardians' action determined only that particular contract and did not affect Dr. Denning's tenure of office as workhouse medical officer. This, it was considered, was an important decision, showing that no contract made by Poor Law medical officers with boards of guardians could over-ride the conditions laid down in the Poor Law Orders. It was reported that Dr. Denning complained that the guardians were now endeavouring to insert in the new contract conditions as to hours of attendance at the workhouse which would seriously interfere with his private practice. The council advised Dr. Denning to insist on the retention of the old terms in the new contract, believing that unless the guardians could show that the interests of the sick inmates of the workhouse demanded a change in his hours of attendance he would be supported by the Local Government Board. The Poor Law Orders gave the guardians no right to fix arbitrarily the hours of attendance of the workhouse medical officer.

The Honorary Secretary reported that a request had been made to the Local Government Board by the Poor Law Medical Officers' Association for permission to give evidence before a departmental committee appointed by that Board to revise existing Poor Law Orders. The Chairman of the Committee had invited the association to present a memorandum; such a memorandum, prepared by the Honorary Secretary, Dr. Major Greenwood, with the assistance of Major Thackray Parsons, R.A.M.C., was approved.

In reply to an inquiry, the council expressed the unanimous opinion that the giving of certificates in the case of mental defectives was no part of the ordinary duties of Poor Law medical officers, who were entitled to the same fee as laid down in the Lunacy Acts for lunacy certificates.

It was reported that Sir Arthur Downes had notified that it had been decided to allot two representatives to the Central Council for District Nursing (London) to the Poor Law Medical Service of the metropolis, and the association was invited to appoint another representative; it nominated Dr. A. Withers Green.

Universities and Colleges.

UNIVERSITY OF GLASGOW.

The following candidates have been approved at the examinations indicated:

M.B. and Ch.B.—Fourth Professional Examination, Medical Jurisprudence and Public Health—New Medical Ordinance: J. Alston, T. Blackwood, C. Buchanan, C. Brown, H. D. Brown, J. A. Buchanan, D. Campbell, D. Clyde, D. H. Coats, W. K. Connell, V. G. Cook, J. Cremer, J. F. Duthie, J. Ewing, T. Gray, S. J. Henderson, A. R. Hill, N. Johnstone, F. C. Logan, A. F. McMillan, F. B. Martin, V. H. Marshall, R. Rodgers, J. Steel, J. A. Smeale, A. R. Steinberg, G. C. Swanson, H. W. Torrance, R. N. Walker, R. S. Weir, K. J. T. Wilson, Jean L. Hamilton, Margaret Service, H. Rourke, Alison E. Wilson. *Third Professional Examination, Jurisprudence and Public Health—Old Medical Ordinance:* M. N. Bhattacharjee, J. W. Dalglish, G. del P. M. Devers, T. B. Fulton, T. P. Hutchison, W. F. Kitchin, W. A. MacDonald, D. B. McIntosh, W. W. Morrison, W. O'Brien, J. A. Paterson, T. M. S. Wilson, Margaret O'Rourke Gallagher, Mary Scott.

UNIVERSITY OF LONDON.

ENTRANCE SCHOLARSHIPS.

Guy's Hospital Medical School.—The following entrance scholarships have been awarded: Senior Science Scholarships for University Students: C. W. W. Armstrong (£75); H. G. Barford (£25). Junior Science Scholarships: E. H. Roche (£120); R. C. B. Ledlie (Certificate). Scholarships in Arts: H. J. Selby (£100); K. H. Hugh Jones (£50).

Middlesex Hospital.—The following scholarships have been awarded: Entrance Scholarships: Mr. D. S. Muir (£25); Mr. E. W. Riches (Secomb); Mr. P. S. Coleman (Thurs); Freer Lucas Scholarship: Mr. R. M. McLoyle-Jones. New Zealand Scholarship: Mr. R. Fulton.

University College.—The following elections have been made: Bucknill Scholarship (135 guineas): Mr. J. P. Padsham. Medical Entrance Exhibition (55 guineas each): Mr. H. L. Heimann and Mr. A. B. Saunders. Epsom Free Medical Scholarship: Mr. D. C. Corry.

VICTORIA UNIVERSITY OF MANCHESTER.

The following candidates have been approved at the examinations indicated:

FIRST M.D. (Part I, Inorganic Chemistry and Physics).—Kathleen Doyle, Georgiana M. Duthie, E. Pickett, A. H. Sudek (*Chemistry*);—H. D. Preston. (*Physics*).—Elizabeth C. Davies, J. G. Nolan. **Part II, Elementary Biology.**—J. N. Laing, F. L. Pickett, H. D. Preston, Edna Ratner.

CONJOINT BOARD IN SCOTLAND.

The following candidates have been approved at the examination indicated:

D.P.H.—Mary A. B. Murphy, J. Crockett, W. S. H. Campbell, J. C. Drysdale, K. A. Maclean.

The Services.

INDIAN MEDICAL SERVICE.

The *London Gazette* of September 17th announced the appointment of eight medical men to the Indian Medical Service as lieutenants.

In the *London Gazette* of October 5th these eight appointments are cancelled, and the eight officers concerned are gazetted to temporary commissions instead, as follows:

E. A. M. J. Goldie, May 20th; S. N. Forbes, M.B., June 9th; M. B. Patel, June 9th; N. R. K. Ubhaya, June 14th; C. P. Fernandez, June 19th; A. P. Pestonji, F.R.C.S., June 21st; N. B. Mehta, June 21st; S. S. Malasani, M.B., June 24th.

EXCHANGES DESIRED.

TERRITORIAL FORCE.

CAPTAIN A. R. PATERSON, R.A.M.C.(T), attached 14th Dorset Regiment, Ambala, India, wishes to find substitute so as to enable him to transfer to a unit at home or in France. Communications should be addressed to Dr. Le Fleming, Wimborne, Dorset, who will give all details.

TWO LIEUTENANTS attached to the 21st Highland Casualty Clearing Station stationed in Aberdeen, desire exchange with two officers serving in France with Clearing Station, Field Ambulance or Regiment. Apply to Major Limes, 21st I.L.C.S., R.A.M.C., Fonthill Barracks, Aberdeen.

Medical News.

SIR ALMROTH WRIGHT will repeat, on Saturday and Monday, October 9th and 11th, at 3 p.m. each day, his demonstration given at the Royal Society of Medicine after the opening of the exhibition of fracture apparatus. The exhibition will remain open until Wednesday, October 13th.

FOUR cases of plague and four deaths occurred in Mauritius during the fortnight ending September 30th. In Hong Kong during the week ending October 2nd two cases of the disease and two deaths occurred.

At a meeting of the Royal Sanitary Institute to be held in the Council House, Salisbury, on the evening of Friday, October 22nd, Dr. Fison, M.O.H. Salisbury, will open a discussion on the recent epidemic of cerebro-spinal meningitis in the city.

The annual commemoration of the benefactors of the Royal College of Physicians of London will take place on Monday, October 18th, when the Harveian Oration will be delivered by Dr. Sidney Coupland, at 4 p.m. The usual dinner will not be held.

OWING to the enforcement of the so-called engenes law, there has been a notable decline in marriages in the State of Wisconsin. In consequence, the *Boston Medical and Surgical Journal* informs us, the law has been amended to make its requirements less rigid, and to allow physicians greater liberty in granting certificates.

OWING to the temporary closure of the Hall of the new Worshipful Company of Barbers, the first meeting for the new session of the Hunterian Society will be held at the home of the Royal Society of Medicine, Wimpole Street, W., next Wednesday, at 9 p.m. The first Hunterian Society lecture will be delivered by Dr. Samuel West on "Bright's disease in some of its clinical aspects." To this and to all other meetings of the society all members of the medical profession are cordially invited.

The first meeting of the session of the Medical Society of London will be held on Monday next at 8 p.m., when the incoming president, Dr. William Pasteur, will give a short address, and Professor J. T. Morrison of Birmingham, for some time Surgeon-in-Chief, Third Military Hospital, Skopje, will relate his experiences in Serbia in 1914-15. Among the arrangements for the coming session are discussions on gunshot wounds of the peripheral nerve on October 25th and on gunshot wounds of the head on November 15th.

THE annual report of the Chief Medical Officer of the Board of Education for 1914 (Cd. 8055; to be obtained of any bookseller, price 1s. 3d.) has been issued, and will call for further notice on a future occasion. Meanwhile, we may say that among the subjects dealt with are the school medical service, education and infant welfare, tuberculosis in school children, medical treatment and a special chapter on such treatment in rural areas, dental disease, open-air education, physical training, and the education and care of the crippled child.

EVERY one must admire the courage of Miss Mary Davies in inoculating herself with a cultivation of the bacillus of gas gangrene, and then asking Dr. Kenneth Taylor, of the Ambulance Americaine, Neuilly-sur-Seine, to test a method of treatment by quinine hydrochloride which he had devised. Although the injection was made into the muscles of the leg, Miss Davies was fortunately quite well again in twenty-four hours. Miss Davies is the youngest daughter of the late Sir Henry Davies, K.C.S.I., of Pumpsaint, Carmarthenshire, and for the last five years has been working as a bacteriologist at the Pasteur Institute. Since that time she has assisted Dr. Taylor in his study of gas gangrene. Dr. Taylor came from America some time ago with the intention of joining the staff of the Imperial Cancer Research Fund, but was diverted by the war. We suspect that had he considered it proper to make an experiment on a healthy human being he would not have chosen this particular form. A full account of his investigations would be welcome.

UNDER the auspices of the Chadwick Trust Dr. D. Noel Paton, Regius Professor of Physiology in the University of Glasgow, commenced a course of lectures on food in war time at the Hauptstead Central Library on October 4th. The first lecture dealt with food and work; the second, to be given on October 11th, will deal with good and bad food; and the third, on October 18th, with food and drink. The lectures are given on each day at 8.15. On October 20th Dr. R. O. Moon, recently physician to the Serbian Isolation Hospital at Skopje (Uskub) will begin a course of three Chadwick lectures at the Royal Society of Medicine on typhus in Serbia, in which he will deal with the lessons from previous epidemics, the relation of typhus to plague, relapsing fever, and enteric fever, and will discuss prophylaxis and treatment. Other Chadwick lectures will be given in November by Mr. A. Saxón Sueli, F.R.I.B.A., on emergency military hospital construction; and by Mr. W. E. Riley, F.R.I.B.A., on the housing of workers.

SIX demonstrations on the anatomy of the human body, designed to meet the needs of first aid and ambulance students, will be given in the theatre of the Royal College of Surgeons of England, Lincoln's Inn Fields, at 5 p.m., by Professor Arthur Keith, Conservator of the Museum, on the following dates: Fridays, October 15th, 22nd, 29th, November 5th, 12th, and 19th. The demonstrations are open to all men attached to companies of the Royal Army Medical Corps, and to members of ambulance and Red Cross classes. Professor Shattock and Mr. Colyer will also give some demonstrations intended for advanced students and medical practitioners. Professor Shattock's will be given on Mondays, October 18th and 25th, and November 1st, at 5 p.m. They will deal with rickets and cretinism, with foreign bodies, and with actinomycosis and leprosy respectively. Mr. Colyer's demonstrations, at 5.30 p.m. on Wednesdays, October 20th and 27th, to which dental students are specially invited, will deal with injuries and diseases of the teeth of the anthropoid apes, and with irregularities of the teeth in man.

AMONG the many periodical publications published by military units of one sort or another are some issued by the staffs of hospitals. The *Craigleith Hospital Chronicle* was, we believe, the earliest of these periodicals to be founded. It has reached its tenth number and second volume; it presents quite an imposing appearance with its quarto page and its bright cover bearing the Union Jack and Red Cross flags, and a sketch of the building which was the Craigleith Poorhouse until it was taken over by the 2nd Scottish General Hospital. Among the contributors is some one who knows how to make excellent initial letters and tail-pieces. The first number of the *Chronicle of the 3rd London General Hospital, Wandsworth*, was published this month. Lieutenant-Colonel Bruce Porter, the officer in command, begins in it a history of the hospital, telling how it came into being. The number contains a considerable admixture of the humorous and possesses more than one artist of unusual ability. It is edited by Private Ward Muir, R.A.M.C.(T.), and while we do not wish it a long career, we hope it may never fall behind the promise of the first number.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Attingham, Westward, London*; telephone, 2531, (Gerrard). (2) FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westward, London*; telephone, 2530, (Gerrard). (3) MEDICAL SECRETARY, *Medicera, Westward, London*; telephone, 2534, (Gerrard). The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

N. asks for advice in the treatment of a male patient who for eight years has suffered from leucoderma on the back of the hands and on the soles. The patient resides in India, and the spots disappear or fade so as to be hardly visible, when he goes to Europe.

THE PRICE OF BROMIDES.

W. P., M.D., asks: Can any of your readers say what is the best substitute for bromides? I am a parish doctor to a district of nine or 20,000 inhabitants, and as such I have at present seventeen epileptics who must have their full dose of bromide. Lately I have received a parish order to attend another very severe case who in the ordinary way would not have been granted an order at all; now one has been given because they say they cannot afford to buy the medicine at its present price.

WEIR'S VACCINATION INSTRUMENT.

VACCINA asks if any reader could inform him whether the instrument bearing the above name in dealers' lists was invented by Dr. Alexander McCook Weir (M.D., Queen's University, Ireland) of Nottingham, who wrote a work called *Vaccination Reform* in 1878. This book is mentioned under Dr. Weir's name in the *Medical Directory* of 1888, but our correspondent cannot find any review of it in the medical papers of the date when it was published, nor any note of it, or of the instrument in question, in the catalogue of the United States Surgeon-General's Library. If Dr. A. McC. Weir did not invent this instrument, which bears a lancet at one end and a scarifier consisting of four steel needle ends at the other, who was the Dr. Weir who invented it? Is it described, as well as figured, in any medical work? A sample of Weir's instrument is to be seen amongst Lord Lister's instruments now preserved in the museum of the College of Surgeons.

INCOME TAX.

Superannuation Allowances.

PALINURUS receives £65 superannuation allowance as a retired district medical officer. He inquires whether income tax would be paid by him at the "earned" or "unearned" rates.

The income is to be regarded as "earned"—*vide* Sec. 19 of the Finance Act, 1907—and should be assessed at the lower rate of duty provided "Palinurus" has complied with the statutory requirement to make a claim to that relief before September 30th. If no such claim has been made he is liable for the current year at the full—that is, "unearned"—rate of tax. If the total income of himself and wife should be less than £700 he can still claim to have the "abatement" of £70 to be set against the £65 assessed.

PHENOLPHALEIN COLOUR REACTION.

DR. C. DE R. (Gnarathuque, Brazil) asks for an explanation of the following colour reaction: A mixture of phenolphthalein and magnesia was ordered; when the chemist was triturating the two powders together they assumed a light pink colour, which became crimson when some drops of water were added.

* * * This colour is due to the formation of a small quantity of the magnesium salt of phenolphthalein. Although magnesia is only very slightly soluble, it is sufficiently so to interact with phenolphthalein when the two are triturated together, and the magnesium salt of phenolphthalein is red, as are its sodium and potassium salts. We have not heard that the salts of phenolphthalein differ in action from the substance itself.

ANSWERS.

PRESIDENT of a DISTRICT NURSING ASSOCIATION.—Measles must undoubtedly be classed as an infectious disease, and the infection can be carried by a nurse to other patients, but with reasonable precautions it is unlikely. Our correspondent would do well to obtain a copy of a report on district nursing in relation to measles and whooping-cough, presented to the meeting of the Central Council for District Nursing in London, as reported in the *JOURNAL* of July 24th, p. 156. (London: P. and S. King and Son, Limited. Price 3d.)

LETTERS, NOTES, ETC.

PARON'S *List of Schools and Tutors* (London: J. and J. Paton, 1915. Cr. 8vo, pp. 1107; illustrated, 2s.), now appearing for the eighteenth year in succession, is a book for parents. It gives particulars and pictures of many of the best English schools for boys and girls, with lists of the scholarships and exhibitions obtainable, and information as to the curricula and fees. The book circulates in England, India, the Dominions and Colonies, so that it makes a wide appeal. The second half of the volume contains information as to the occupations and further educational studies that may be taken up by adolescents when schooling days are done—engineering, agriculture, the civil services, the medical profession, domestic science, music, and the like.

SHIP SURGEONS AND THE WEARING OF UNIFORM.

NAUTICUS writes: From the number of advertisements appearing in the *BRITISH MEDICAL JOURNAL* I gather that there is a serious difficulty in obtaining ship surgeons. One of the obstacles in the way of applicants is the wearing of uniform. I know several men who would like to take a voyage, but will not go to the expense of providing, or face the indignity of wearing, a uniform which places them in the same category as a purser or second engineer. The uniform is the distinguishing mark of the mercantile marine profession, to which the medical man does not belong. A surgeon on board is a person without any authoritative status; he is there to treat illness and give advice as to the health of the ship; therefore the uniform is meaningless beyond that of a badge of servitude to the company. Now that ship surgeons may charge fees for the treatment of passengers, thus bringing the relationship between them purely to that of doctor and patient, the wearing of uniform is all the more unnecessary. If shipping companies would abolish the rule, they would receive more applications, as most self-respecting practitioners would prefer to be regarded as the "doctor on board" rather than a member of the ship's crew. Conversely, if applicants would emphatically state their objection to wearing uniform, I feel sure that the companies would appreciate the point.

FOREIGN WINES AND TOBACCO.

DR. C. BARRIE TAYLOR (Manchester) writes: I appeal to the medical profession to support the Coalition Government in their endeavour to check the vast importation of foreign luxuries. Medical men can largely assist in the diminution of the consumption of foreign wines and tobacco by their patients. In the case of tobacco, it is well known, particularly amongst the working classes, that there is a considerable amount of nicotine poisoning from the use of cigarettes, and it is my belief that the Government should check the import of tobacco only allowed or prescribed in cases of pain and in a comparatively few other cases. Only this morning I had a patient in my consulting-room who smokes five packets of cigarettes a day, and he seemed glad to know that he would improve if this practice were discontinued. When wine or a stimulant is considered advisable I think most authorities will agree that a good old British whisky diluted with water or effervescent mineral water is equal if not superior to the foreign stimulant. British ales and stout are superior to the foreign production. Even brandy should be greatly diminished in its use. I have attended the recent debates in the House of Commons, and it was particularly impressed upon me that the increase of the tobacco duty by 50 per cent. was made in order to diminish the foreign imports. Some have the mistaken view or excuse that when they are purchasing tobacco they are helping the Government, but the latter is far better assisted by the non-purchase of the foreign article. We cannot have much influence in the cases of other luxuries, faxes, articles of toilet, cars, watches, musical instruments, hats, etc.—but we have with tobacco and foreign wines. Will the 25,000 medical men help the Government and the country to check the stream of gold that is flowing to the U.S.A., and so help the foreign exchanges in our favour, and at the same time benefit their patients?

GAS POISONING: A CORRECTION.

IN Dr. Aitchison's letter on gas poisoning, published in the *JOURNAL* for September 25th, after the word "overflowing" (p. 489, col. 1, line 6) add, "and then perhaps was obliged to open the chamber doors and empty it into the open air."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 425, Strand, London, not later than the first post on Wednesday morning preceding publication, and if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

URETERAL CALCULUS: ITS SYMPTOMS AND TREATMENT.

WITH A FEW ILLUSTRATIVE CASES.

BY
DAVID NEWMAN, M.D., F.R.F.P.S.G.,
CONSULTING SURGEON, GLASGOW ROYAL INFIRMARY.

In the great majority of cases met with in practice, by means now at our disposal, little difficulty is experienced in discovering a stone in any part of the urinary tract, and in defining its size, shape, composition, and location. In some instances its presence may be detected by one method alone—by vaginal palpation (Case iv), by the cystoscope (Cases ii and iii), or by x rays (Cases v and vi); in others, and these are not few, on account of the absence of symptoms or physical signs, not one, but all our methods of investigation must be employed before a diagnosis is arrived at and the surgeon is placed in a position to advise for or against an operation.

The surgeon who has but a limited experience in renal work is often too readily convinced of the presence of stone. He is misled by what he believes to be clear evidence: he undertakes an operation: he exposes the kidney, opens the pelvis, and examines the ureter, but no stone is found. On the other hand, when the symptoms are atypical, a case of stone is liable to be mistaken for lumbago, appendicitis, perityphilitis, pleurisy, cystitis, lumbar abscess, or spinal disease. No one symptom or physical sign is free from fallacy.

At a time when the diagnosis of calculus in the ureter depended upon a consideration of symptoms, helped by a chemical and microscopic examination of the urine only, great difficulties and uncertainties presented themselves to the surgeon, but now, in almost all cases, with our modern physical methods of inquiry, the surgeon knows beforehand what he will require to do in operating.

Many other lesions of the urinary tract may present all the symptoms of calculus, so that when the surgeon had subjective phenomena as his guide, helped only by palpation and an examination of the urine, the cases were very rare where even an approximately correct diagnosis could be made, and he approached an operation with considerable solicitude, and his active intervention required some courage. The problem now is greatly simplified and the diagnosis reduced to a certainty. With the aid of x rays, the cystoscope, wax-tipped and metallic ureteral bougies, and palpation of the terminal portions of the ureters, exact information can be gained. But even with all these valuable physical aids, in a goodly number of cases patience and careful watching are necessary, and not one but frequent examinations may be required before a definite course of treatment can be determined.

Conversant with the recent advances both in scientific and practical urology, the surgeon knows how valuable all the physical corroborative evidence is in helping him to

gain a full knowledge of the lesion. It must, however, always be carefully borne in mind that the diagnosis of a case is not simply locating and understanding the nature of the local disease demanding the aid of the surgeon, but the possession of a full knowledge of the patient's general condition. The surgeon must be a physician, a physiologist, and a pathologist as well as an operator. The actual operation is the smallest part of his work. After knowing the patient and all about him the two problems to be solved are: (1) Are the symptoms due to a stone in the ureter, and, if so, where is it situated? (2) Is the function of the suspected kidney and its neighbour interfered with, and are there any secondary lesions?

These questions can only be answered by making a very complete examination involving the general clinical history (haematuria, pain, anuria), examination of the urine, palpation, cystoscopic inspection, ureteral catheterization, the use of wax-tipped bougies, and x-ray photography and the fluorescent screen. The symptoms depend upon whether the morbid processes involve one or both kidneys.

When one organ is free from disease, and a stone becomes embedded in the ureter of the other kidney, the phenomena are regulated by the amount of obstruction caused by the impacted body. If the plugging is complete the indications are generally acute but short in duration, and unless the obstruction is speedily relieved the corresponding kidney is rapidly destroyed. The blocking of the ureter is generally preceded by symptoms of stone in the corresponding kidney, renal colic on one side coincident with the presence of blood in the urine. The injury produced by an im-

Fig. 1 shows distension of the renal pelvis and of the ureter throughout its whole course, from impaction of a calculus in the duct as it passes through the wall of the bladder. Fig. 2 shows the stone caught just outside the bladder; Fig. 3 at the brim of the bony pelvis, and Fig. 4 a little below the point where the renal pelvis contracts to form the ureter. The lumen of the ureter is smallest as the duct passes through the bladder wall.

acted calculus seldom causes much bleeding, but in some instances considerable haematuria may occur. The following case is an example of this, due to a stone impacted in the ureter at the point where it passes over the brim of the pelvis.

CASE I.—Renal Colic on Three Occasions from Impaction of Renal Calculus in the Left Ureter: Transitory Hydronephrosis and Haematuria.

A lady, aged 28, who had suffered from two attacks of acute renal colic, consulted me during the third onset of the pain. The patient was thin and the abdomen extremely lax. On palpating the left kidney the renal pelvis was found to be occupied by a hydronephrosis, and on passing the hand along the tract of the left ureter on deep pressure a very painful spot was discovered, just at the point where the ureter passes over the brim of the pelvis (Fig. 5). The distended ureter could be traced down to the same point, and an examination per vaginam in the elbow-knee position showed the lower segment of the left ureter to be normal; the bladder and orifices of the ureters were also healthy. After the calculus had been impacted for five hours relief was obtained and 16 oz. of blood-stained urine was passed, the colour being like dark port wine. When a week had elapsed after the onset of the last attack the left ureter was carefully massaged three times daily, and nine days after this treatment had been instituted a smooth uric acid calculus, the size of a lentil seed, dropped into the bladder.

Sometimes the loss of blood is considerable, and the blood

comes away immediately after the relief from the acute colic (Case vi).

In other cases the quantity of blood present in the urine may be very small; this is generally so when the calculus is little and its surface smooth, and when it is impacted close to the orifice of the ureter. When the patient is suffering from an attack of renal colic there may be little or no blood in the urine, but if there is even a little it may be taken as evidence that the ureter is not completely obstructed by the stone, unless possibly the blood is escaping from the ureter of the unaffected side. When the attack passes off, either as a consequence of the escape, or from displacement of the calculus, a small quantity of blood is almost certain to be found in the urine if a careful watch is kept for it.

The dull and aching pain is for a time localized in the lumbar region only, but suddenly it shifts to the groin, and on pressure with the hand over the line of the ureter the suffering of the patient is markedly increased; at the same time it may be observed that the hæmaturia is suddenly stopped. Disappearance of blood from the urine coincident with sudden shifting of the locality and an increase in the severity of the pain are symptoms strongly in favour of the diagnosis of a stone fixed in and completely plugging the ureter. While the ureter on one side is blocked and no urine is being excreted by the corresponding kidney, the organ on the opposite side may be over-active and secreting a large quantity of urine of low specific gravity.

Figs. 1, 2, 3, and 4 show the ureter as seen when the stone is impacted in various parts of its course. In normal conditions the ureter is found to be narrowed in three places (1) at a point $1\frac{1}{2}$ to 2 in. below the pelvis of the kidney; (2) as it crosses the common iliac artery; and (3) just as it enters the wall of the bladder. These, consequently, are the points where a stone is liable to be delayed in its descent or impacted. Above the impacted stone the duct is dilated, elongated, and its walls are thickened. I have seen instances where the ureter had a lumen as large as the normal small intestine, and at the operation difficulty was experienced in recognizing it, until it was traced to the kidney.

The duct is always dilated on the proximal side of the obstructing body, so that at an examination the calculus may be readily pushed up from the spot where it has been impacted, and so may be found not always in the same place at different examinations by x rays or by the finger (Figs. 1, 2, 3, 4).

With calculus in the ureter alone the urine seldom gives any significant indications. Certainly the presence of blood may attract attention, but as a rule it is so small in amount that as a sign it is not of much value. Pain and suppression of urine are the important symptoms. The conditions other than calculus which may cause obstruction to the ureter are numerous.

Table showing the Causes of Acquired Hydronephrosis in 665 Cases (from Neuman: "Lectures on Surgical Diseases of the Kidney," p. 114).

	Hydronephrosis.	
	Double.	Singl.
Simple or malignant tumours of pelvic organs causing pressure on ureters	143	41
Stricture of the urethra, enlarged prostate with hypertrophy of the bladder	195	39
Tumours or abscesses of pelvic organs leading to torsion of the ureters	23	9
Tumours or abscesses of abdominal organs ...	17	7
Displacement of pelvic organs, causing torsion of ureters	23	20
Bands and adhesions	7	5
Renal calculi	17	51
Displacements of the kidney	1	16
Tuberculous disease of the bladder	13	17
Tumours of the bladder	3	7
Ureter entering pelvis	6	5
	448	217

One important distinction between the course of events in calculous obstruction and that due to pressure from

without is that while the latter is gradual and almost always produces considerable dilatation of the pelvis of the kidneys, the former is sudden, and on one side at least is unassociated with hydronephrosis. It is unnecessary to discuss in detail the points of distinction between pressure symptoms as induced by the diseases above enumerated and the obstruction produced by calculus.

As a general rule, the disease causing pressure upon the ureters is itself so prominent that it is not likely to escape observation. But while a lesion may be discovered in one of the pelvic organs which may reasonably account for the obstruction, the surgeon must not conclude that a ureter is not also impacted by a calculus. A very striking example of this came under the observation of the writer. A woman with a large uterine fibroid complained of symptoms resembling renal colic, followed by suppression of urine, which lasted on several occasions for more than twenty-four hours, after which came relief with the escape of a large quantity of urine of low specific gravity. The conclusion came to was that the hydronephrosis and anuria were due to pressure of the tumour upon the ureters, but after death a calculus was found impacted in the left ureter as it passed over the brim of the pelvis. The most important cases to distinguish from calculous obstruction are those in which the flow is impeded by kinking of the ureter, as in movable kidney, or where the impediment arises from angular insertion of the ureter. Transitory hydronephrosis is met with in cases where the ureter is occluded only occasionally. Sudden accumulation and rapid subsidence of the swelling is an important characteristic of transitory hydronephrosis produced in this way, and while on the affected side the pelvis is still filling and becoming more and more tense, on the healthy side there may be complete inhibition of the function of the kidney. But while anuria may last sometimes for days, it is hardly ever so prolonged as to endanger the life of the patient. Calculus of considerable size may be present in the ureter for many months without producing any symptoms, or the local symptoms may be referred entirely to the bladder or urethra, giving all the classical signs of stone in the bladder.

Calculi in one ureter causing complete occlusion, the other kidney being incompetent, leads very soon to complete suppression of urine. Before suppression occurs the patient experiences in the region of the affected kidney pain which may be limited to the lumbar region, or it may extend along the line of the ureters to the bladder or down the thighs. This may be associated with considerable vesical irritation and a desire to micturate, even although the bladder is empty or nearly so. The course of events that follows depend upon the nature of the obstruction and the degree to which the function of the kidney on the opposite side is impaired. Calculous anuria may last for many days without the development of symptoms of toxic poisoning, and if the kidney has previously been the site of hydronephrosis the period will be more prolonged than if the organ is not so affected. This delay in the development of so-called "uraemic symptoms" is the feature which distinguishes obstructive anuria from suppression of urine due to disease of the renal parenchyma; indeed, in calculous anuria death may occur without the occurrence of any of the ordinary symptoms of uraemic poisoning. The early appearance of symptoms of toxic poisoning in the anuria of organic disease of the kidney is explained by the circumstance that during a long period prior to the actual suppression of urine there has been a steady impairment to the elimination of waste products and a gradual storing up of toxins in the system, so that when the kidneys stop working the poisoned state of the circulation cannot be relieved sufficiently by the complementary action of other organs, such as the skin, the lungs, or the alimentary tract.

In a few instances the employment of all the special methods may be necessary; in other cases one may suffice. Such easily diagnosed cases are not met with every day; it is only with very good fortune that an observer can have easy success, consequently all methods which throw light on the diagnosis are of use.

Considered in order of their relative value, they are:

I. Radiography.

For the detection of stone x-ray photography was first used in 1896 by Dr. John Macintyre in the Glasgow Royal

Infirmary, when calculous matter was discovered in the pelvis of the kidney of a patient under the charge of Dr. James A. Adams. When first employed many difficulties had to be met: the thickness of the parietes, the chances of the stone being overshadowed by bone, and the movement of the kidney during respiration are all difficulties which have been overcome by improvement in technique. The subject was carefully worked out by Albarán, Ringel, Braatz, Wagner, and others at an early stage in the development of this method, and they showed that even with the most careful attention to detail the results from radiography were valuable only in exceptional cases, where probably the diagnosis could have been made without the aid of the rays.

This was the general opinion and experience regarding the value of the Roentgen rays in the diagnosis of urinary calculi to begin with, and for a number of years after their general introduction. Now this method of investigating the urinary tract has been wonderfully improved and has become indispensable to the urologist, but it must not be allowed to exclude other methods of investigation. The danger is that it may become a short cut to diagnosis, and so lead to serious errors.

It is now so perfect that even a small uric acid stone in the lower segment of the ureter can easily be discovered. This field of diagnosis has been extended by the use of stilettered ureteral catheters, and by the injection into the ureter and kidneys of certain metallic salts which throw a shadow, and maps out for us the position of the renal pelvis and the line of the duct.

There are certain points the surgeon requires to attend to, and others should be looked after by the skiagrapher.

The surgeon should see that the bowels are clear of any substance likely to throw a shadow, and for this purpose a mild aperient should be given on two successive nights prior to the examination, and the patient should have only light diet the day before, and should fast on the morning of the examination.

In searching for ureteral calculus we use both the fluorescent screen and the photographic plate. These methods have the advantage that they not only demonstrate the presence of stones, but they also afford valuable information as regards their number, position, shape, and size.

There are many dangers of obtaining shadows which are liable to be mistaken for those of stone, and we must admit that the difficulties of obtaining a shadow of calculi *in situ* in the kidney or ureter are due to many causes. It is by recognizing these difficulties that we have practically overcome them, and steadily the percentage of our failures have become less and now are very few indeed. In each individual case the tension of the rays and the length of the exposure must be carefully considered, and before the shadow photograph is taken, or, better still, while it is being taken, the penetrating power of the rays must be observed through the fluorescent screen. Before taking a photograph the position of the stone as seen by the screen should be marked by cross wires which come out in the radiograph. The wire can then be removed and the relationship of the stone to the cutaneous surface fixed by marking with ink.

Errors in diagnosis may be considered in two divisions: (1) Those in which the shadow is given, and believed to be due to stone, but the surgeon fails to find one, and (2) those in which a stone is removed by the surgeon, but no shadow betrayed its presence. The most common causes of false shadows are the presence in the abdomen or in its walls of substances with a high absorptive index, such as faecal accumulations, fruit stones, the presence of bismuth salts, enlarged and calcified glands, old purulent accumulations, gastritis, and phleboliths.

The most common and characteristic position for a stone is in the angular space formed by the eleventh rib and the spinal column. Very often the shadow of the stone is covered by the last rib. A clearly-defined shadow in this position is almost certainly due to calculus; it is when shadows are found in other regions that doubt arises. Those due to calculus may, of course, be found in any part of the urinary tract, and the more closely the situation of the shadow corresponds with the anatomical position of the pelvis of the kidney and the ureter the greater the suspicion of stone. It is therefore useful in doubtful cases to pass a soft metal bougie into the ureters and photograph

it along with the stone; but, on the other hand, a shadow well outside the line of the ureter may be caused by a calculus in a diverticulum (Cases VI and VII, Figs. 11 and 12).

The employment of boudges charged with metallic salts or injection of the pelvis and ureter with innocuous solutions of metallic salts furnish an additional shadow picture of the structures under examination, and afford valuable information in certain cases.

Ureter boudges made of fine-wire are easily introduced and are superior in many ways to others. They mould themselves easily to the duct. On account of contortion of the duct causing variation in the course of the ureter it is difficult to judge from a skiagram whether a shadow is in the course of the ureter unless the x-ray picture is taken with a bougie in the ureter. In operations on the ureter, or on organs in close proximity to it, it is important to determine the topography of the ureter throughout its entire course.

By injecting a warm solution of collargol (10 per cent.) or an emulsion of silver iodide in emulsion of quince seed (5 per cent.) into the pelvis of the kidney through a ureteral catheter the urinary tract can be silhouetted on the x-ray plate. Great care is required in using this method, and it is not always free from danger, as shown by Rorsing of Copenhagen, Geraghty and Zachrisolms. A very good review of this method is published by Lequeux, Papin, and Maingot.¹ As far as the diagnosis of stone in the ureter is concerned the ureter catheter fulfils all that is required. It is arrested by the stone and the radiogram shows the stone shadow at the tip of the bougie or in close relationship to it, whereas if the shadow is away from the line of the bougie the shadow is either caused by the stone being in a sac (Cases VI and VII and Figs. 11 and 12), or it is thrown by a foreign body outside the urinary tract.

An x-ray plate should be marked clearly with the patient's name, the date, and the *right* and *left* sides should be shown by L and R. This may seem a very elementary instruction, but it is an important one, and failure to carry it out gives rise to endless trouble. To avoid all possible error, metal letters R and L should be fixed to the patient's skin. The edge of the psoas muscle and the lower poles of both kidneys should be seen unless the liver is unusually dense or enlarged. The bones should be distinctly outlined, particularly the transverse processes of the lumbar vertebrae. A large plate should be taken showing the whole region of the urinary tract, and, if a shadow is seen anywhere, a smaller plate should be used to bring out detail.

II. *Sounding of the Ureters and the Use of Wax-tipped Boudges.*

In cases of stone impacted at the lower end of the ureter the ureteral catheter may fail to pass more than a short distance into the duct, but on introducing a ureteral resonator the sound of the metal coming in contact with the stone can be detected by the ear, as well as by the hand, of the observer. The instrument consists of a probe which is fixed in a small flat handle and prolonged into a hollow brass globe or resonator. One end of an india rubber tube is fixed to the proximal end of the resonator; to the other end of the tube is fixed a wooden ear tube, made to fit the external auditory meatus of the observer. The probe is introduced into the ureter, and when an obstruction is met with the ear tube is fixed in position and the instrument is rotated slightly. If a calculus is present the sound produced by the probe grating upon it is easily heard.²

A method proposed by Kelly is to introduce a ureter catheter or sound coated with wax. When the smooth wax coating comes in contact with the rough stone its surface is scratched, and this, when carefully carried out, gives not only corroborative evidence of the presence of a calculus, but the distance of the stone from the urethral orifice can be measured. While this method may be employed with advantage in women through Kelly's speculum, it is not so easily employed when direct illumination cystoscopes are used. When the waxed catheter has to be introduced through the shaft of the cystoscope scratch marks may be made by the catheter canals, and consequently lead to erroneous conclusions. Kelly, in

¹ Made for the writer by Messrs. J. Gardner and Son, surgical instrument makers, Edinburgh.

referring to his own method, says: "There are three sources of error which must be borne in mind in order that they may be avoided. In the first place, the contact of the wax with the side of the speculum may produce a facet. This should never be taken for a scratch, and the wax need not touch the edge of the speculum if the catheter is introduced with a steady hand and the inner rim of the speculum utilized as a fulcrum. In the second place, the catheter should be introduced into the ureteral orifice with one direct forward movement; any to-and-fro movement near the vesical rim of the speculum is liable to produce scratches. In the third place, when withdrawing the catheter, the speculum having been already removed, the vulva must be held open, so that there is no contact with the genital hairs."

This method was employed with advantage prior to the introduction of x-rays and even for a number of years thereafter, but now that the technique of skiagraphy is so thoroughly understood it is seldom used. All stones are discovered by the experienced skiagrapher.

Sounding the ureters also only marks an advance in physical diagnosis, but is a method I have not resorted to for many years.

III. The Cystoscope.

The cystoscope may prove the existence of complete obstruction to the ureter by the fact that, even although the mouth is patent and the duct admits a catheter, no

Fig. 5.—A sound in the bladder and the left index finger in the vagina, as seen when the stone is in the ureter outside the bladder wall.

CASE III.—*Repeated Attacks of Renal Colic from Ureteral Calculus, which ultimately became impacted in Orifice of Left Ureter and was clearly seen by Cystoscope; Removed by Suprapubic Route: Cure.*

A lady, aged 31 years, was suddenly and without any warning seized with a severe pain in the left lumbar region associated with suppression of urine, on November 10th, 1907. After twelve hours of agony the pain gradually passed off, and almost immediately she passed a few ounces of dark-coloured urine, but as no medical attendance was sought at the time it is not known that the coloration was due to *bi-oxi*. She enjoyed good health for over four months, when a second attack seized her, and I was asked to see the patient six hours after the onset of the pain, which had all the characteristics of renal colic. The attack lasted for eight hours but recurred the following day. A cystoscopic examination was made, when the bladder was found to be practically normal, but from the orifice of the left ureter the point of a phosphatic stone protruded, and by palpation through the vagina the stone was made out to be the shape of a horse bean but about one-half larger. It was removed by a suprapubic operation.

IV. Abdominal Palpation and Palpation through the Vagina or Rectum.

By palpation through the abdominal parietes much information may be gained when the stone is situated above the brim of the pelvis, provided the walls are flaccid and the patient thin; but when the muscles are rigid, which is often the case, or the patient is corpulent, the detection of a stone in the upper part of the ureter is almost impossible. Pressure with the hand, however,

Fig. 6.—When the stone is simply covered with mucous membrane of the bladder.

fluid escapes. This is most accurately observed after a hypodermic injection of indigo-carminé or of aniline blue and the patient has taken a full drink of warm fluid. Coloured shoots are seen escaping from the patent ureter only.

When a stone is situated close to the orifice of the ureter it may appear in the bladder as a distinct projection of the mucous membrane, or it may protrude through the mouth of the ureter, exposing its surface.²

In some instances the calculus may pass along the ureter through the muscular portion of the bladder wall, and become gripped only by the mucous membrane at the orifice of the ureter, so in place of passing through into the cavity of the bladder, the calculus, by obstructing the flow of urine, leads to the mucous membrane being pushed away from the muscular portion of the bladder, and a rounded tumour-like mass presents itself in the bladder which may be mistaken for a tumour (Fig. 6).

From a number of cases two may be selected where I was fortunate in diagnosing the presence of a stone impacted at the orifice of the ureter by a cystoscopic examination only:

CASE II.—*Renal Calculus Impacted at Orifice of Ureter and pushing Mucous Membrane in front of it; Calculus Movable; Removed by Ilio-inguinal Operation.*

At the first examination the stone itself was not visible, being covered by the mucous membrane of the bladder, but the appearances were so exactly a replica of a view I got in a previous case³ that I felt satisfied that I had to deal with a modernized calculus included in the mucous membrane of the bladder; and after I had expressed my opinion to Dr. J. Souttar McKendrick, who sent the patient to me, he told me that he had an x-ray plate taken, and a shadow was found in the situation I had indicated (Figs. 1 and 6). The calculus was mobile, and was removed easily by the ilio-inguinal route.

generally elicits tenderness in the locality of the stone, or may even induce acute pain.

When the calculus has passed to the lower third of the ureter, examination with the finger in the rectum or in the vagina, according to the sex, may lead to the detection of the stone and the exact situation occupied by it. A sound should be passed into the bladder, and with the left index finger in the vagina or rectum, the back of the instrument is made to press upon the line of the ureters and their orifices (Figs. 5 and 6).

Simply by digital examination a stone may be found, as illustrated in Case IV. By palpating the vagina or rectum the surgeon can, by pressing the point of the finger backwards against the pelvic wall, make out a hard body. During the examination the patient usually complains of pain and irritation of the bladder, with a desire to micturate.

CASE IV.—*Old History of Renal Colic from Calculus at Lower End of Ureter, the Movement of which was Limited; Removed by Ilio-inguinal Route; Ureter not Sutured; Good Recovery.*

Recently I was asked to see a lady who had suffered from symptoms of ureteral calculus for several years. Her husband, a doctor, suspected a stone, and on digital examination I found a hard body impacted just behind the cervix and a little to the left, which slipped upwards on pressure against the sacrum. I felt sure it was a stone, and the diagnosis was confirmed by a cystoscopic examination, the calculus causing a bulging at the orifice of the ureter (Fig. 1). On exploration the stone was found at the lower end of the ureter, but while movable it could not be pressed up more than 2 in. from the ureter orifice, and therefore could not be brought into view through the ilio-inguinal incision. I had therefore to make the incision through the ureter wall by touch, and press out the stone through the opening, and as no sutures could be applied, the wound was packed with gauze. The lumen of the ureter being large the uretro-

drained freely into the bladder, and the gauze packing was almost dry when removed on the fourth day. Uninterrupted recovery.

REMOVAL OF A BULLET FROM THE RIGHT VENTRICLE OF THE HEART UNDER LOCAL ANAESTHESIA.

REPORTED BY

LIEUTENANT L. H. C. BIRKBECK, R.A.M.C.(T.C.),

AND

LIEUTENANT G. N. LORIMER, R.A.M.C.(T.C.).

With Remarks by

COLONEL H. M. W. GRAY, A.M.S.(T.C.),

CONSULTING SURGEON TO THE BRITISH EXPEDITIONARY FORCE, FRANCE.

PRIVATE A. was admitted to a general hospital on July 19th, 1915, having been wounded eight days previously. The bullet had passed through and killed a man in front of him. A. was knocked down, but did not lose consciousness, and had not had any discomfort other than slight pain from the wound. There was a small dirty wound ($\frac{1}{2}$ in. diameter) just below and to the right of the xiphi-sternal junction, and also a painful swelling of the right parotid gland, which disappeared next day. The patient showed no other symptoms during the first few days. He was kept in bed. The heart appeared to be normal and regular. The pulse varied between 80 and 90. The evening temperatures rose to 100° to 101° F.

X-ray Report by CAPTAIN S. F. McDONALD, R.A.M.C.

July 21st, 1915.

"There was an entry wound in the right epigastrium, but on examination no shadow could be seen in the abdomen.

"The lungs and pleural cavities were normal. The diaphragm moved well and evenly on both sides. The heart was normally situated, but there was some slight increase of cardiac shadow on the right side. In the lower portion of the heart shadow was a very sharply defined dark shadow moving with the heart, and also apparently laterally in relation to the heart. This last movement suggested that the object was free in the pericardial cavity, but on turning the patient over it was seen to lie quite definitely in the substance of the heart. It had a distinct rocking movement. No antero-posterior movement was visible in relation to the heart.

"The object seemed to be in, or close to, the lowest portion of the wall of the right ventricle. Its shape and size, so far as could be made out, were those of a rifle bullet. Attempts to take radiograms were unsuccessful."

Colonel Gray, consulting surgeon, saw the patient first on July 25th, and again on July 26th, on which day a sharp pain developed suddenly in the left leg. As the pulse during the night of July 26th had shown some irregularity, rate 65 to 95, and the heart had occasionally dropped beats, an operation was decided on and performed on the morning of July 27th. Veronal, gr. v, was given on the evening before, and three doses of morphine, amounting in all to $\frac{3}{4}$ gr., during the morning before operation. The patient was not unduly under the influence of morphine. He was screened again just before the operation and conversed, sat up, and turned himself smartly when asked to do so.

Operation.

Under local anaesthesia (eucaine 1 per cent., potassium sulphate $\frac{1}{4}$ per cent., and adrenalin) Colonel Gray made a wide horseshoe-shaped incision, convexity upwards, extending along the sixth costal cartilage on each side and across the sternum at the level of the attachment of the fifth cartilage. This incision was used so as to make an

exposure of the track of the bullet in the depth. The perichondrium was separated from the left sixth cartilage, which was cut across at the costo-chondral junction and used as a lever to elevate the sternum while the triangularis sterni, pericardium, etc., were being separated off the posterior aspect of the flap. A small portion of the right sixth rib was removed close to the costo-chondral junction. The sternum, at the lower border of the fifth costal cartilages, was grooved deeply with a gouge and divided with bone forceps. The soft parts were then separated from the sternum and ribs so that the flap could be turned downwards and forwards. When the flap was pulled forwards a hole about an inch long appeared in the pleura on the right side, in the track of the bullet. The right lung collapsed. The respirations became laboured and quick, the patient coughed jerkily; he became anxious and complained that he was breathless. The colour remained good, and he settled down in about one minute, after being reassured by the surgeon. Except for this disturbance there was apparently no discomfort during the entire operation.

The flap was held forward by hooks, and the pericardium opened obliquely from the base to near the apex of the heart. About a drachm of slightly bloodstained fluid was noticed in the pericardial cavity. The heart looked normal. No wound could be seen. On digital exploration the bullet was felt to be lying, apparently fixed, at the back of the heart, either in the wall or cavity of the right ventricle. The point of the bullet was near the apex of the ventricle. During the manipulations the heart was noticed to miss a beat occasionally—when touched at the upper and back part of the interventricular septum.

The right ventricle was seized with a pair of catch forceps near the apex. When it was seen that this caused no disturbance a suture was passed through the muscle adjacent, and by these the heart was held forward. This in no way agitated the patient. On further exploration the bullet was definitely located by probing with a needle, and was thought to be fixed in the right ventricle near the posterior coronary vessels. After manipulation, the bullet was felt to change position and to be free inside the ventricle. It was worked away as far as possible from the coronary vessels and grasped between the thumb and finger. Two stitches were inserted into the muscle wall over the bullet. The wall of the ventricle was incised for half an inch, and the bullet removed with forceps. While the wall of the ventricle was still being held firmly between the finger and thumb the stitches were tied.

On removing the catch forceps there was brisk bleeding, which was stopped quickly by an under-running stitch. The pericardial cavity was wiped free of blood-clot and was filled with normal saline to expel the air; it was then sewn up. The right pleural cavity was next filled with saline and the injured pleura sewn up. While the wound was being closed the chest was aspirated to remove the saline. This aspiration was the only part of the operation which seemed to cause the patient any pain.

The patient was wonderfully comfortable on being taken back to bed, but about four hours after the operation the respirations rose suddenly to 48 a minute, and remained at about that level till he died, except for part of the day of July 29th and 30th, when, the patient being deeply under the influence of morphine, they dropped to 28 a minute.

He was much troubled after this occurred by mucus collecting in large quantity in the throat and the upper part of the trachea. Various remedies were tried for this, with little avail. He took nourishment fairly well. Cardiac stimulants were used after the first two days.

On July 29th his mind began to wander, and he was often delirious till the time of his death on July 31st. He lived nearly four and a half days after the operation.

There was never any indication that the operation on the heart had interfered with its action, which, though quick (average 120 to 130), was wonderfully strong up to within a few hours of his death. No dropping of beats was noticed after the operation.

Necropsy.

At the post-mortem examination it was found that the external wound had healed well; there was no sign of any

inflammation. There was no fluid exudation of either blood or pus in the pericardial cavity, but the heart was covered by a shaggy layer of lymph about one-sixth of an inch thick. The wounds in the heart had healed perfectly.

There were several shredly, *ante-mortem* clots entangled in the chordae tendineae of the right ventricle and a long narrow clot in the pulmonary artery extending into its right branch, besides the usual *post-mortem* clotting. There was an abrasion of the endocardium of the posterior wall of the right ventricle where the bullet had been lying, but the cavity looked normal otherwise. No wound of entrance was discovered. The heart was sent to the Royal College of Surgeons of England for further investigation.

There were several small clots in the branches of the pulmonary artery with corresponding infarct areas in the lungs. The right lung had expanded to about two-thirds the size of the left. There were about two pints of blood-stained serous fluid in the right pleural cavity.

The cause of death was judged to be multiple pulmonary infarction from clots derived from the right ventricle.

REMARKS BY COLONEL H. M. W. GRAY.

I should like to add to the notes of Lieutenant Birkbeck and Lieutenant Lorimer that the irregularity of the pulse-rate (65 to 95) without extraneous cause, the occasional dropping of a beat, and the sudden pain and swelling in the right parotid and left leg (due possibly to small emboli) made me decide to operate. The patient was otherwise extraordinarily well, and showed no distress whatever. One did not care to risk postponing operation till the patient could be transferred to England.

The method of using the local anaesthetic was by infiltration of the line of incision and blocking of the intercostal nerves on each side from the fourth to the seventh. No anaesthetic was injected into or around the pericardium or pleura.

Interesting points about the operation are:

1. The complete success of the local anaesthetic. So far as I can gather, this is the first occasion on which any operation on the exposed heart has been done with local anaesthesia alone. The patient was not deeply under the influence of morphiae. He responded to questions, requests, or suggestion at once.

2. The evanescent nature of the distress when the right lung collapsed.

3. The absolute absence of sensation of the pericardium, both parietal and visceral, and of the heart itself, to squeezing, pulling, pricking, cutting, or suturing. These manipulations caused, apparently, no interference with the cardiac action. During the extraction of the bullet at least one half of the right ventricle was firmly grasped between the fingers and thumb. The heart missed a beat repeatedly whenever the upper and back part of the interventricular septum was pressed, but began to beat again at once when this pressure was removed. I could not assure myself that the ventricles alone were implicated. The patient denied having any discomfort during these times, or indeed at any time during the operation, except when the right lung collapsed, and when the aspirating needle was being introduced into his chest, when he complained loudly of pain. Even swabbing out the pericardial cavity caused no pain. All these observations are very interesting when one thinks of the effect of similar manipulations of either bowel or parietal peritoneum.

4. There was a little difficulty in being certain of the position of the bullet, owing to its proximity to the interventricular septum, which, when contracted, gave a similar sensation on palpation. Therefore, a straight needle was used to locate the bullet definitely.

5. The method used to obtain rapid distension of the lung at the end of the operation—in the absence of a positive pressure apparatus. On account of commencing respiratory distress, aspiration was stopped after about 25 ounces of the saline solution were removed. It was thought that the remainder would be rapidly absorbed.

6. The possibilities of future successful operations for intracardiac conditions which are conjured up by the virtual success of this one. I understand that a French surgeon recently removed, with permanent success, a rifle bullet which had lain in the right ventricle for five months. Unfortunately, I cannot meantime give a reference to the account of his operation.

OBSERVATIONS ON THE DRAINAGE OF GUNSHOT WOUNDS.

By C. MAX PAGE, M.S., F.R.C.S.,
CAPTAIN R.A.M.C. (S.R.).

ONE of the prominent features of the surgery of the present war has been the necessity for the use of some form of drainage in a large proportion of the wounds met with.

It must at once be admitted that the practice is an undesirable one. Any drain inserted into the tissues has the irritant effect of a foreign body, and in the cases in point, an infective one. However, no means has yet been devised by which the evacuation of discharges and the prevention of the spread of infection can otherwise be secured. This being so, till the ideal method of treatment comes to light, one must employ the type of drain which most efficiently serves its purpose.

In civil practice, when drainage is necessary, standard rubber tubing has been commonly adopted, and in general the same material has been applied in the treatment of gunshot wounds. In this latter work I do not think that simple rubber tubes, either perforated or split, have proved entirely satisfactory, and I propose to describe a type of drain which, when it is a question of maintaining of wound track open in its whole extent, appears to have certain advantages over these.

It is difficult to form a judgement of such an appliance, as the standard of effectiveness does not admit of exact measurement. I will therefore merely attempt to present the reasons which suggested its design.

PRINCIPLES CONTROLLING WOUND DRAINAGE.

The first action of any drain is to prevent obliteration of the cavity by adhesion or apposition of its walls. The introduction of any foreign body effects this purpose, and it is the second action—namely, the evacuation of discharges from the wound track—which determines the surgical value of any particular pattern.

Supposing that no outside hydrostatic or pneumatic force be brought to bear, the movement of wound discharges is effected by two forces—namely, gravity and capillary tension.

1. *Gravity*.—The action and value of gravity in wound drainage is so well accepted that it need not be enlarged upon here.

2. *Capillary tension* is the only force effecting drainage in the reverse direction. Its activity is directly proportionate to the capillary surface in action, and is affected by the viscosity of the fluids in question. The coefficient of capillarity is higher for water than for any other fluid; it becomes lower in proportion to the albuminous material added.

The condition and nature of the surface dressing also controls the movement of fluids in the subjacent wound—thus, when the dressing is completely saturated, no further movement of fluid along the capillary column abutting upon the dressing will occur.

The value of the above forces will vary in respect of different kinds of wound; three main types may be recognized, namely:

1. A cavity—for example, an empyema or a definitely localized abscess.

2. A potential cavity—for example, the track of the wound caused by a missile which has lodged.

3. A potential tubular space—for example, the track formed by the passage of a missile through the substance of a limb.

The method by which drainage is effected in these three types may now be considered.

1. A Cavity.

In the case of a cavity the volume of fluid to be removed will be relatively large, and the drainage of the track about the surface will be usually of little importance. In these circumstances a simple tube placed so as to reach the inner surface of the cavity will, if acting in the direction of gravity, give ideal results.

2. A Potential Cavity.

In the case of a blind track there may be a foreign body or dead material at the end which cannot be completely

removed, and, as far as the drainage of this part is concerned, the above considerations hold good. Drainage of the track, however, is also probably necessary, and the observations made below on the third type of wound will then apply.

3. A Potential Tubular Space.

The track formed by the passage of a missile will contain blood clots and debris; the collapse of its walls will in most cases obliterate the cavity. The injury will have opened up a series of connective tissue planes, and the aim of drainage is to prevent the spread of infection along them. As the exact position of the openings of these planes cannot be determined, the ideal drain should evacuate discharges from the entire inner surface of the wound track. Thus a simple tube lying in the track will permit discharge in the capillary space between its outer surface and that of the wound track; but when, as rapidly occurs, this space becomes clogged by clots or the viscosity of the discharge, the movement will cease. In this instance the action of gravity is acting at a disadvantage in the small capillary space.

If a rubber tube with side holes be used, its action will not be very different. The perforations are rapidly filled in with granulations and intruded tissue. The discharge which there may be in the direction of gravity from the lumen of the tube will come from these buds of half-strangulated tissue, and satisfactory drainage from the connective tissue planes is impossible. The same observation holds in relation to a perforated metal or glass tube.

A gauze wick acts ideally for a time, but it becomes so rapidly saturated and put out of action that it is of no value in practice.

In general it will be admitted that drainage is rapidly inhibited in all wound tracks, whether a drain is inserted or not, either by the clotting of the discharges or by the obstructive action of the surrounding tissues.

The aim must therefore be to overcome this tendency to stagnation. The hypertonic saline advocated by Sir A. Wright induces a fluid discharge which does not clot. Its use, therefore, facilitates as well as increases wound discharge. But to obtain the best results this solution must be brought into contact with the entire surface of the wound, either by continuous irrigation or by frequently repeated lavage.

The above-mentioned types of drainage tube do not allow this purpose to be fully effected, but I think the form I describe below fulfils this requirement, and also increases the capillary drainage surface in action.

THE GUTTER DRAIN.

The tube should be made of rubber. In section it is star or pinion shaped (Fig. 1). The outside diameter should be the same as that of full-sized ordinary drainage tube.

For certain cases the drain should be provided with a central lumen (Fig. 2). The tube is passed through the entire length of the wound track; the upper projecting extremity is capped by a piece of thin rubber tubing (shown in Fig. 2)—for example, a cut rubber glove finger—which extends just into the entry of the wound.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 1.—Section of gutter drain. Natural size.
Fig. 2.—Section of gutter drain with a central lumen. The section also shows the cap. Natural size.
Fig. 3.—Gutter drain externalized from sections of ordinary rubber tubing sewn together centrally. The cap is not shown. Natural size.

It will be seen that, as a result, a series of gutters lying against the wound surface extend the length of the track. When fluid is syringed into the cap, it passes down each gutter, so as to bring the solution into contact with practically the whole wound surface, at the same time clearing away from the same area all debris. After lavage, the maximum capillary surface in proportion to the size of the drain is in action. When this type of tube is employed

for blind wounds (Type 2), the provision of a central lumen (Fig. 2) allows the fluid to be syringed to the bottom of the track, whence it will return along the various gutters.

Theoretically, it might be expected that this drain would give good results with continuous irrigation, but in practice relatively forceful periodical washing out of the gutters has proved more satisfactory.

It has not been possible to obtain drains quite in the form depicted, but I have for some months used a substitute made from ordinary rubber tubing. The tube is halved longitudinally; three lengths are then lightly sewn together to form the drain. It is capped as described above.

The appearance of a section is shown in Fig. 3. As stated above, whatever drain is put in the tissues the reactionary tissue formation round it soon leaves only a capillary space between wound surface and drain; for this reason, if it is necessary to leave the drain in place for more than a few days, and, in addition to lavage, periodical movement of the drain of the gutter type is desirable.

Conclusion.

In conclusion, it should be repeated that the above drain has only been used in its extemporized form. It is not suggested that it affords an ideal method of wound treatment, but in two respects it appears to be an improvement on the patterns in common use—namely:

1. The drain forms with the surface of the wound track, in proportion to its diameter, the maximum capillary space, along which the evacuation of fluids can occur.
2. It admits of lotions being brought into general contact with the surface of the wound track while the drain is in place.

THE RECRUIT'S HEART.

A MEMORANDUM FOR MEDICAL EXAMINERS.

BY

SIR JAMES MACKENZIE, M.D., F.R.S.,

LECTURER ON CARDIAC RESEARCH AT THE LONDON HOSPITAL.

SINCE the outbreak of the war I have seen a large number of healthy young men rejected as recruits because of some manifestation of the heart which the examiner took to be abnormal and a sign of weakness. I have also seen a number who have been invalided out of the army because of these manifestations.

At the request of the War Office I drew up recently a memorandum upon this subject to serve as a guide to medical examiners of recruits, and as this memorandum may not come before all the examiners, Sir Alfred Keogh has asked me to call attention to it. It is as follows:

THE SIGNIFICANCE OF ABNORMAL SIGNS IN THE RECRUIT'S HEART.

It should be understood that the healthy heart in the young can exhibit murmurs, and variations in rate and rhythm, which are perfectly physiological in origin and indicative neither of disease nor of impairment.

The Functional Efficiency of the Heart.

Before examining the heart, find out the functional efficiency by ascertaining how it responds to effort. This is shown by finding out the amount of exertion the candidate has been accustomed to take in the past in his work or play, and if he can undergo severe bodily exertion without distress.

Murmurs.

The physiological murmurs are always systolic in time, and the situation of the greatest intensity may be at the apex, mid-sternum, or base of the heart. If the candidate's response to effort be normal, and the heart normal in size, the murmur is negligible, for it is manifest that, if the cause which produces the murmur hampers or embarrasses the heart in its work, the size of the embarrassed chamber will increase, and its functional efficiency be impaired.

Irregularities of the Heart.

There are only two forms of irregularity that need be considered. Irregularities indicating serious mischief will be associated with such diminution of the functional efficiency that the candidate would not seek to recruit—such as the irregularity of auricular fibrillation or of heart-block.

Youthful Type of Irregularity.

The most common irregularity is that which occurs in the healthy heart of the young. It is characterized by a lengthening and shortening of the pauses between the beats; it will often be found to vary with the respiration, the beat increasing in rate during inspiration and decreasing during expiration. When it does not have the characteristic respiratory character it can be made to take on the character by getting the candidate to breathe slowly and deeply for a few minutes. It is frequent in perfectly healthy hearts, and is therefore of no importance, and candidates should not be rejected on account of its presence.

Extra-systoles.

In rare cases the pulse may be found intermittting more or less frequently. If the heart be auscultated, two short sharp sounds rapidly following one on the other may be heard during the pause. If this is the only sign present—that is, if the functional efficiency of the heart be good and the size normal—then these extra-systoles are of no significance and the candidate should not be rejected.

The Effects of Excitement.

Many candidates whose hearts are perfectly healthy suffer from palpitation or excited action of the heart during examination. The beat becomes forcible and rapid and a systolic murmur may be present. If such a candidate be told to lie down and breathe slowly and deeply for a few minutes the heart's action becomes less violent and the rate slows during expiration. With a history of good functional efficiency the candidate may be considered suitable for enlistment.

Memorandum

ON

THE EMPLOYMENT OF BANDAGES FOR THE IRRIGATION OF WOUND-SURFACES WITH THERAPEUTIC SOLUTIONS, AND THE DRAINING OF WOUNDS.By COLONEL SIR ALMROTH E. WRIGHT, M.D.,
F.R.S., C.B.,

A CONSULTANT PHYSICIAN TO THE EXPEDITIONARY FORCE IN FRANCE.

THE irrigation of wounds has over the application of wet dressings the following advantages.

We can bring our therapeutic solution continuously into application, maintaining its concentration unaltered. I have elsewhere, in my lecture, emphasized that this is, in treatment with saline solutions, of fundamental importance.

We can, given proper arrangements, apply our therapeutic agent to all the internal and external surfaces of the wound, and at the same time obtain ideally effective drainage.

I propose in this Memorandum to describe a series of simple arrangements which, I think, satisfy all requirements.

In the ordinary arrangement in which the irrigating fluid is supplied in the form of a "drip" falling into the wound—and it is the funnel-shaped wound I have in view—the fluid makes its way down along the side of the wound in a rannel, and we thus treat only one small sector of the wound. We have, in fact, the conditions of a rock valley or cove, where a thread of water flows to the bottom in a single channel, leaving all the rest dry.

Let me show you that by an arrangement of bandages the water can be led into the wound where we require it, that it can be distributed so as to wash down all the walls,

and that it can then be carried away without any leakage into the bed.

It will be convenient to begin by considering the properties of bandages and strips of gauze as conduits for carrying water. They may be regarded as conduit pipes

Fig. 1.

Fig. 2.

with porous walls—pipes which will convey water uphill by capillary attraction, downhill by gravity, and first up and then down hill when arranged as siphons.

We may, as a matter of fact, confine our consideration to bandages, for the ordinary bandage is, as comparative experiments bring out, a more effective water carrier than a strip of gauze cut to the same width.

The first point which comes up in connexion with the employment of bandages in supporting wounds is their liability to be obstructed by the lodgment of particles in the meshes. The method which is employed when the dependent opening of a wound is plugged with a strip of gauze would seem specially designed for the purpose of compassing such obstruction. Here gravity carries the undiluted pus directly down into the wick, and we obtain instead of a drain an impermeable bung which effectually confines the discharges.

The arrangements shown in the models (Figs. 1 and 2) show how these difficulties can be circumvented and the wick be kept free from obstruction. We have in these—we may call them "mud-funnel" experiments—funnels filled in with a glutinous mixture of flour and water and in each case a bandage arranged as a siphon. In the first model (Fig. 1) the siphon is a simple loop of bandage carried over the rim of the funnel. In this model a wick carried up into the stalk of the funnel. In the second model (Fig. 2) we have a rubber tube introduced through the stalk of the funnel and standing out above the surface of the fluid. This rubber tube is threaded with a bandage, and its end has been cut into two strips which hang down into the muddy fluid. The siphons are here, as you will appreciate, working in what would correspond to wounds standing full of pus, and they have, as you see, in each case carried over a very considerable volume of muddy fluid. And if they were continually refilled they would—for only the distal ends of the ascending limbs of the siphon bandages can here be obstructed and put out of functioning—continue to siphon over indefinitely through the upper segment of each ascending limb. You will also note that the wick in Model

Fig. 3.

No. 1 has become obstructed and has carried out only very little fluid. Finally, in connexion with Model No. 2, I would like, in passing, to call your attention to the principle that we can always, as occasion may require, reinforce the one or the other limb of the siphon; and that in this model we have in the two strands of bandage which compose the ascending limb of the siphon two streams of fluid which are tributary to the descending stream.

I pass on to certain further points having also a general application. You will appreciate that though water will, when it has a clear fall, run down a bandage without leakage, it will, as soon as contact is made with any surface, flow away over that surface. Again, it will leak out at any point when we constrict the bandage, or at any point where we loop up the bandage. For water refuses to run quickly uphill.

To prevent trouble from these sources we must, where our irrigating fluid has to be carried through obstructions

Fig. 4.

Fig. 5.

in the wound, or uphill, substitute rubber tubing for bandage. If, however, we have to resort to a siphon arrangement for drawing off our irrigating fluid from the reservoir, it will be of advantage to thread a bandage into the ascending limb of the siphon, and to carry it sufficiently far in to pass down some little way into the descending limb. It will also be advisable to leave in position the wire which we have used for threading in the bandage, and to bend it round into the form of a narrow U, so as to prevent the end of the rubber tube kicking itself out of the water. The great advantage we get from the use of a wick in our delivery tube is that we cut down the delivery from what the rubber tube would carry (which would be excessive) to what the wick will carry (which will be amply sufficient). Moreover, the siphon, when furnished with a wick, will start itself automatically, and also restart itself when the reservoir comes to be refilled.

I pass on to consider the factors upon which the efficacy of bandage siphons depends. The volume of fluid delivered is determined (a) by the height to be climbed in the ascending limb; (b) by the length of, and weight of water in, the descending limb; and (c) any obstacle to delivery encountered at the distal end of the descending limb.

In addition to these the rate of delivery will be affected (d) by the nipping of the bandage when it rests upon a knife-edge, this factor coming seriously into account in experiments with a long length of descending limb heavily weighted with water.

The experiment here set up (Fig. 3) shows the influence of factors (b) and (c); these being the factors we have to take special note of in connexion with the drainage of wounds. It will be seen that where other conditions are the same it is always the siphon with the longer descending limb which gives the more efficient drainage. Again, it will be seen that, other conditions being the same, a larger volume of water is delivered from a bandage whose end is immersed in water than from a bandage suspended in air. In the case of water dripping off from a bandage into air, consideration will show that the bandage will, just before the drop falls, be overfull of water, and that the inflow into it will for that moment be suspended, to be accelerated as soon as the drop has fallen off. As a result, we have in the bandage which is dripping off into air a cyclically interrupted flow. In contrast to this we have, where the descending limb of the bandage goes down into water, a continuous unobstructed delivery.

The practical application of this in connexion with wounds is that the siphon bandages which carry off the washings from wounds ought to pass down from the patients' beds into water in vessels placed on the floor. And if any bandage happens to be too short to dip into

Fig. 6.

the water the drip from it will be accelerated if it is torn into tails.

Where only little water is flowing off through bandages draining a wound evaporation must be guarded against, for this will, by diminishing the load of water, retard the outflow into the descending limb.

Up to the present we have considered only siphons formed from a single loop of bandage—that is, drainage carried out through conduit-pipes very much smaller in calibre than the vessel they are draining.

One may in many cases—in particular in wounds where the bandages may be obstructed by pus—desire to provide an ampler outflow. This can be done by packing the wound full of bandages, but there is here a right and a wrong way.

In this model (Fig. 4) I have packed a test tube in the ordinary method by taking a strip of bandage and coiling it up into the wound, and I have then taken the loose end of the bandage and, leading it out of the test tube, have employed it as the descending limb of my siphon. Side by side with this I have packed a test tube (Fig. 5) by taking a number of loops of bandage, laying them one above the other over the mouth of the tube, and then pushing them down so as to form with the strips outside a sort of rough letter M. We may call this the *multiple loop method of packing*. When I now turn on the water and fill up these companion test tubes you see that while the one which is packed with a single strand of bandage coiled up inside it empties itself only very slowly, the one

which is packed with multiple loops empties itself almost as fast as I can fill it in. You will note in connexion with the first system of packing that it is quite effective, really more effective than the second so far as relates to the conveyance of fluid along the tube. In point of fact, the contiguous coils of bandage fuse together, and give us all that a full calibre wick could. The real fault of the system lies in the out-flow. It is as if we had a large

Fig. 7.

main running out into a small pipe. Holding these principles before us, we may now consider how we can in each particular type of wound arrange for feeding in the therapeutic solution, for distribution,

irrigating it all over the walls, and effectively draining the wound.

Wounds may for our purposes be classified into cylindrical wounds disposed horizontally; funnel-shaped wounds with the funnel opening disposed upwards, downwards, and laterally; and finally ascending or descending cul-de-sac wounds. We may take these in order.

Arrangement for Irrigating a Cylindrical Wound which Perforates a Limb Horizontally.—Here, as shown in the model (Fig. 6), the irrigating fluid is conveyed into the interior of the wound in a narrow rubber tube. The wound is drained by two leashes of loops, which go down on either side into vessels of water. These

Fig. 8.

are pulled into position in each case by a strand of bandage fastened, as shown in the figure, round the bight of the loops.

In actual practice, when we want to verify that the irrigation is working properly, we do so by the following devices.

We test the effluent by drawing a line across one of the bandages with a stylographic pen, and note that the ink is carried down in streaks by the current. We test the inflow by piercing the rubber tube with the needle of a hypodermic syringe and driving in a bubble of air just above the point where the glass union provides an inspection chamber. Then holding the piece of glass tubing horizontally we see the bubble of air carried along. Where we want to test the condition in the interior of the wound, we aspirate into the syringe while pinching the rubber tube proximally to the insertion point of the

needle. Where we want to see the effect of the irrigation in prospectus we cut transverse strips from the bandage at different levels, and prepare microscopical preparations from these by streaking them out one by one over the

surface of the microscopic slides. We then, if the wound is getting progressively cleaner, see the microbes falling off, and if the wound were getting dirtier should see the microbes increase, as we travel inwards towards the wound.

Arrangement for Irrigating the Inverted Funnel Wound.—The kind of wound here in view (Fig. 7) is that produced when a projectile entering the thigh from in front fractures the femur and drives it before it, making an extensive wound of exit.

A strip of bandage tied loosely round the bight of a leash of bandages is passed up from below through the stalk of the funnel. This is now drawn tight, and then the strips of bandage hanging bunched up in the centre are one by one looped up over a framework fitted just below the mouth of the funnel. The irrigating stream is now carried through the upper bandage into the neck of the funnel, and here divides up into a whole system of separate streams which together irrigate the whole interior face of the funnel. In connexion with the actual wound we should loop up the bandages, not as in the model through a circular framework of wire, but as in Fig. 8, over a light aluminium cradle placed astraddle over the limb.

Arrangement for Irrigating the Upright Funnel Wound.—The wound here in view (Fig. 9) is that seen in connexion with a compound fracture of the femur with wound of entrance behind and the wound of exit in front. Instead of dividing after entering the wound the irrigating stream must here divide outside the wound and enter in a number of separate streams. We can get this by dividing up the end of a bandage into a number of tails and planting these about the wound.

The arrangement shown in the model embodies improvements suggested by my fellow worker, Lieutenant H. H. Tanner. It will be seen that we have here fitted to the delivery tube which conveys the fluid into the wound the upper end of a test tube. This serves as a receptacle for the bandage. Fitted to the mouth of the test tube we have a rubber cap traversed by a number of small rubber tubes. Into each of these is inserted one of the tails of the bandage. Finally, each of the rubber tubes is stiffened with wire. This enables us to direct its stream in any direction and to ensure the tubes maintaining any position which we give them in the wound.

Fig. 10.

Fig. 11.

Fig. 12.

Arrangement for Irrigating a Funnel Wound which is Disposed Horizontally.—Except only in the detail of the disposition of the irrigating tubes and the provision for carrying off the washings the arrangement is the same as in the upright funnel wound.

Arrangement for Irrigating an Ascending or Descending cut-de-sac Wound.—Both these wounds are irrigated by the arrangement shown in Fig. 5. In other words, the irrigating fluid is conveyed in a fine rubber tube upwards or downwards to the blind end of the wound, and the washings are carried away by multiple loops of bandage.

Method of Preventing the Irrigating Fluid running away over the Patient's Skin or Clothing and Soaking into the Bed.—It has already been emphasized that bandages resemble tubes with porous walls and that fluid leaks out whenever on entering or leaving a wound they make contact, as they inevitably must, with the external surface of the body.

We need not here concern ourselves with leaking from the inflowing stream. We have already provided against that by feeding the irrigating fluid into the wound through rubber tubes. There remains the leakage from the bandages which carry the outflowing stream. It is a form of leakage which is always liable to occur except where the wound of exit occupies, as the patient lies in bed, the most dependent portion of his body surface. The only method of dealing with this very serious inconvenience is by damming back the water which escapes. We can do this by means of what I may call *irrigation flanges*. Where we are dealing with a wound situated on a limb, what we require is a *ring-flange* above or below the wound (Fig. 11); or, better, irrigation flanges both above and below. Where we are dealing with a wound opening on the outer aspect of the trunk or limb, with, for instance, a wound on the lateral aspect of the shoulder, we require a *horseshoe flange* (Fig. 12) round the opening of the wound.

Such flanges are built up upon the patient's skin in a very simple manner. We first prepare some formalin gelatin. We do this by dissolving 20 grams of gelatin in 100 c.cm. of water—or better, so as to have plenty, twice that quantity in double as much water.

We now, pouring the gelatin solution out into a bowl, add to it one-tenth of its volume of the ordinary 40 per cent. formalin. Then taking a number of short lengths of bandage, previously laid ready to hand, we immerse these in the formalin gelatin. This done we take a roll of cotton-wool and encircle the limb with it, or, as the case may be, bend this round in the form of a horseshoe and then apply it, with the opening of the horseshoe disposed upwards, to the skin round the wound. Going back then to our strips of bandage lying in formalin gelatin, we take them one by one from the bowl, paste one end down on the skin, carry the middle over the ridge formed by the roll of cotton-wool, and then paste down the other end on the far side, taking care always to overlap one strip of bandage by another. When we have covered in our roll of cotton-wool we have completed our task, and we have now, as soon as the formalin gelatin sets—and it sets in a few minutes—a light stiff watertight confining dam firmly fixed down upon the patient's skin.

Let me say in conclusion that I am indebted to my fellow-worker, Lieutenant A. H. Tanner, for setting up and drawing the models, and also for valuable assistance in elaborating the above system of irrigation and drainage.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE PREVENTION OF DEFORMITIES DUE TO ADHESION OF TENDONS AND MUSCLES.

We have had a fair number of cases of deformity due to adherent tendons and muscles at the Cliff Hospital, Felixstowe. Most of the scars were situated on the forearm, but some were on the arm or thigh.

The worst feature of cases of old forearm scars is the inability to flex or to extend the fingers and wrist. Flexion is greatly diminished in cases of scars involving the extensor surface of the forearm, and extension is similarly diminished in cases of scars on the flexor surface. In addition to this loss of movement, the soldiers complain

a great deal of a sensation of inconvenience due to the pulling on the scar by the muscles involved. A similar complaint is made in cases of scars on the arm and thigh.

The cases we have had have resisted all attempts for their improvement by massage and movements, and on operation it has been found that in the majority the condition has been due to the failure of the surgeon to sew up the deep fascia after making an incision for the removal of the bullet. The exposed muscles or tendons become adherent to the skin. The condition can easily be cured by suturing the deep fascia after separating the adhesions, putting up the forearm on a splint in a suitable position, and having recourse to movements and massage some twenty-four hours after the operation. The success attending these steps has been very great. The condition can be still more easily avoided by suture of the deep fascia in every case in which it is opened, following this up by early massage and movements.

Other cases are due to the tendons and muscles becoming adherent in the scar following a wound. The adhesion is, as in the last class, to the skin, and is due to the division of the deep fascia. These contractions can be avoided by early massage and movements, and when the contractions have already taken place, can be cured by similar measures. Too much stress cannot be laid on the importance of suturing the deep fascia in every case in which it is opened by the surgeon.

P. L. GIUSEPPI, M.D. Lond., F.R.C.S. Eng.,
Surgeon to the Cliff Military Hospital, Felixstowe.

THREE-PLY WOOD FOR SPLINTS.

In these times of scarcity of skilled labour any device which will enable comparatively unskilled persons to make efficient surgical appliances is worthy of record, and I therefore offer no apology for drawing the attention of surgeons to the advantages of three-ply wood as a material for splints.

This substance consists of three very thin layers of tough wood which are superimposed, so that the grain of the middle layer runs at right angles to that of the two outer ones. The three layers are then cemented together under pressure. The resulting material is very strong for its weight, has no tendency to warp, and can only be split with great difficulty. It is made of various thicknesses, of which I have hitherto used three, namely: $\frac{1}{8}$ in., $\frac{1}{4}$ in., and $\frac{1}{2}$ in. Owing to the absence of any tendency to split, windows may safely be cut in the splints to allow access to wounds. After softening the wood by soaking it in hot water, it can be bent into any moderate curve, but naturally it is easier to mould the thinner varieties than the thicker. It must be held in the desired shape during drying by bandaging or other means, after which the curve becomes fixed, and there is no tendency to spring back.

For many of the smaller splints, such as those for the forearm, even when windows are cut, no reinforcement is necessary if they are made of the $\frac{1}{4}$ in. stuff, but when using the more easily bent thinner material, or making longer splints, it is wiser to strengthen them by nailing a strip of wood, $\frac{1}{2}$ by $\frac{3}{8}$ or $\frac{1}{2}$ in., along either edge, or wherever it may be seen to be needed. Small $\frac{1}{4}$ in. brass tacks, which do not rust and can be easily clinched, are very suitable for this purpose.

A number of these splints have been and are in use at the Royal National Orthopaedic Hospital in the treatment of wounded soldiers, and have given satisfaction on account of their strength and lightness. This latter quality makes them acceptable to patients and also less likely to shift their position. The cost of a square yard of three-ply wood is about half a crown. Out of this twenty-four forearm splints can be cut, costing for materials, including nails and strengthening strips, not more than 1½d. each. Adjustable jointed splints are made of the same material, with the addition of metallic hinges of various kinds, such as will readily occur to any one of a mechanical turn of mind.

Of course these splints cannot be sterilized by boiling, but if they are given a coat of shellac varnish they will not absorb discharges, and they can easily be cleaned with cold water and soap.

London, W.

E. MURHEAD LITTLE.

Reports

ON

MEDICAL AND SURGICAL PRACTICE IN
HOSPITALS AND ASYLUMS.COLONIAL HOSPITAL, PORT OF SPAIN,
TRINIDAD.A CASE OF FIBROSIS UTERI: VAGINAL HYSTERECTOMY:
RECOVERY.(By R. SEHEULT, M.D., Resident Surgeon, Colonial
Hospital, Port of Spain, Trinidad.)

A WELL-NOURISHED, slightly anæmic woman, aged 37 years, was admitted on April 27th, 1914, with the following history:

She had been married for thirteen years, and had four children, all healthy, and no abortions; the last child was born in 1907. During the past six years she had a more or less continuous and rather profuse white vaginal discharge, which at times became creamy and offensive; the menses had been quite regular until August, 1913, when they began to appear more frequently than usual; the loss of blood, however, had never been excessive, and the periods lasted generally four days. There was occasionally pelvic pain irrespective of the periods. In October, 1913, I was asked to see her in consultation; there was then an offensive sanguineous vaginal discharge; examination yielded evidence of endometritis; the cervix was intensely indurated, and exhibited a small nodule about a quarter of an inch in diameter, which aroused a suspicion of malignancy, but microscopic examination of a small excised portion dispelled this idea. The uterus was curetted, and it was observed at the time that the organ was hard and tough. Relief followed the operation for a short time only, the symptoms reappearing in an aggravated form; for seventeen days in April, 1914, there was a more or less continuous sanguineous, foul-smelling discharge.

When admitted the condition of the cervix noted above was again observed, and uterine hæmorrhage was readily provoked by the introduction of the uterine sound. Suspicions of a malignant affection of the uterus were revived, and scrapings from the uterine cavity were submitted to microscopic examination; sufficient tissue, however, does not appear to have been removed for that purpose. It was again noticed at this curetting that the uterus was exceedingly tough; this may account for the failure to obtain the necessary material for microscopic examination.

After careful consideration of the case I advised vaginal hysterectomy, under the impression that the patient had cancer of the uterus. Accordingly on May 5th, 1914, I removed the uterus by the vaginal route; it was uniformly enlarged and weighed 5½ oz.; its walls were considerably thickened, hard and tough, and cut almost like cartilage. The mucous lining appeared to be very thin. Dr. Dickson, the pathologist to the hospital, kindly made sections of the organ for microscopic examination, and reported as follows:

Microscopic examination of the body of the uterus showed atrophy of the endometrium and absence of the tubular glands; the muscular coat was very largely replaced by dense fibrous tissue. There were scattered about in the fibrous tissue small bands and strands of non-striated muscular tissue. The walls of the vessels were thickened. The nodule on the cervix showed the structure of a myoma.

There was no evidence whatever of general arterio-sclerosis; the renal function was quite normal.

The patient made an uneventful recovery.

The clinical features of the case in association with the pathological changes found in the uterus appear to correspond with the interesting and rather uncommon condition described by Sir John Bland-Sutton some years ago, and named by him "fibrosis uteri."

THE New York *Medical Record* announces that the American Association of Workers for the Blind and the American Association of Instructors of the Blind have appointed a commission for preparing a uniform raised-letter system. A conference will be held with the British Uniform Type Committee before any final action is taken.

Reports of Societies.

MEDICAL SOCIETY OF LONDON.

THE President (Dr. W. PASTEUR), in his opening address on October 11th, referred to the difficulties connected with the holding of meetings during the war. One-third of the total number of the members were engaged on active service either abroad or at home. The war was providing plenty of material for investigation, but there was considerable difficulty in making adequate use of the material available. At the advanced bases it was no easy matter for notes to be taken, especially during periods of rush, and even those taken might fail to get through to England. Moreover, patients who were under observation were often, when they improved, drafted to convalescent homes before their cases had been completely investigated. It was inevitable, therefore, that much of the experience gained by individual workers should be fragmentary. He then referred to two groups of cases which had been under his personal observation. The first were cases of *pulmonary tuberculosis*. The special features of this condition, as he had observed it in the soldiers invalided from the service, were the prominence of hæmoptysis, and the rapid improvement which occurred when they were placed under favourable conditions. In the great majority there was a previous history of pleurisy or of actual tuberculosis of the lung. Some had undergone sanatorium treatment, even within a period of two years before they joined the service. Some of the cases followed pneumonia. The physical signs of the condition were very indefinite, moist sounds, especially, being scanty or absent. The second group, which provided material of the greatest interest, was the *enteric group*, including typhoid, paratyphoid, dysentery, trench diarrhoea, and intestinal protozoal diseases. Most of these came from the Near East, but some also from France. They were indefinite in type and benign, for recovery was almost invariable. In the modified typhoid class pyrexia of varying intensity and duration was often the only symptom or only prominent system. The onset was sudden. The pulse-rate, as in ordinary typhoid, was relatively low. There was malaise, but the headache was slight. The abdominal symptoms were indefinite, or perhaps altogether wanting. Spots were not uncommon, but were often indefinite and not always easy to distinguish from the many forms of spots seen on the skins of these patients. The spleen was not usually enlarged. The characteristic toxic appearance of a typhoid patient was little in evidence. The fever ended by lysis and convalescence was often ushered in by a few days of subnormal temperature. The typhoid met with was modified by inoculation; bacteriological tests were difficult to carry out; a single agglutination test was of no use in such cases, but it was necessary to obtain a curve from repeated tests in the early stages of the disease, using very considerable dilutions. It was open to question whether trench diarrhoea represented relapses of modified typhoid fever. Some cases of that disease failed to react to any agglutination test. The suppression of the abdominal symptoms was the chief distinction of the modified disease. It comprised only a small fraction of a large class of enteric diseases, all of which required careful investigation.

Professor J. T. J. MORRISON, F.R.C.S., of Birmingham, related his experiences in Serbia, 1914-15. He outlined the steps leading to the formation of the first British hospital expedition to Serbia in connexion with the war. Under the joint auspices of the Order of St. John and the Serbian Relief Fund, a unit of fifty members was appointed, including medical men, dressers, nurses, and orderlies, with Mr. Morrison as surgeon-in-chief. Their destination was Skopje, the chief town of southern Serbia, better known by its Turkish name Uskub. Here the mission transformed the buildings of a high school into a surgical hospital of 280 beds, equipped with operating theatre, x-ray department, and dispensary. The deplorable plight of the first batch of 160 patients was described. Suppurating wounds and septic compound fractures had not been dressed for many days; gangrenous limbs were common; there were cases of typhoid and dysentery; and all were swarming with lice under their tawny clothing. Serbia was then at her lowest ebb, the army being in retreat after the battle of Shabatz, and there was an

almost complete absence of hospital stores, besides a great shortage of surgeons. In the early period the pressure of work in the hospital was so heavy that the day's work was not always finished by midnight. The strength of the staff was reduced by illness, due to scarlatina, relapsing fever, and typhus, and one nurse died. An account was given of the overcrowding of sick and wounded in insanitary factories, barracks, and stables, which were used as hospitals throughout the country. When the surgical demand lessened, after the Austrians were defeated, Professor Morrison was invited to join the Typhus Commission appointed by the Skupstina to cope with the epidemic then rising to its height. Reference was made to visits to Nish, Belgrade, Kragujevatz, and other towns. A tribute was paid to the members of other British and foreign units, and the heroic deeds of Dr. Esther Kadisch and Madame Yankovitch mentioned. Commenting on the Oriental attitude of mind of native officials, a cause of frequent inconvenience and delay, the explanation suggested was the centuries of Turkish domination which found and left Serbia mediaeval. The unit was appointed for a term of three months, extended later to five. Professor Morrison's surgical colleagues were Mr. W. M. Paton and Mr. E. F. Eliot. He spoke in high terms of the competence and comradeship of these gentlemen. The address was illustrated by a series of lantern slides and photographs.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

The opening meeting of the thirty-fourth session was held at the society's rooms, West London Hospital, on October 8th, when the new President, Dr. LEONARD DOBSON, presented the Keesley Memorial medal to Mr. Aslett Baldwin, and afterwards delivered an address on *Progress in treatment*. In the course of it, after references to the profound influence of the discoveries of Lister on medicine as well as surgery, he observed that the procedure of aseptic surgery was so complicated that it could be carried out only under the conditions found in a modern hospital, and raised the question whether the ideal arrangement was not a judicious combination of the antiseptic and aseptic methods. Experience had rendered it possible to estimate the value of certain operations with some degree of accuracy—notably those for the displacements of the uterus and kidney, gastro-entostomy, and appendicostomy. In malignant disease early operation was the only hope of cure, though the action of radium and the x rays was remarkable in many ways. In the domain of medicine equally important advances had been made, resulting in great changes during the last thirty years, and, speaking generally, the use of drugs had given way to other means to a great extent. There was too strong a tendency to follow fashion in the practice of medicine. At one time most patients were put on soured milk; then came the turn for vaccines, and at the present time every patient is said to be suffering from pyorrhoea alveolaris—a craze which was responsible for the needless sacrifice of innumerable sound teeth. After a reference to the discovery of the Wassermann reaction, Dr. Dobson said that he thought there was some cause to deplore the neglect of most physicians to make a serious study of dietetics. Finally, reference was made to the great developments in the applications of electricity and the x rays in the diagnosis and treatment of disease, and to the changes that have taken place in medical practice through the influence of preventive medicine.

DR. NELSON M. BLACK, in the New York *Annals of Ophthalmology*, asserts that face powder sets up a distinct type of conjunctivitis specially marked by very stringy mucilaginous secretion and intolerable itching. When the dust is applied to the face a portion of the fine rice flower which is driven upwards and lodges in the moist conjunctiva, where it forms a mucilage, which is not dislodged from the conjunctival cul-de-sac by the lacrimal secretion. The woody cells of the hard exterior of the rice grain swell, and the angular corners produce an irritation which is aggravated by rubbing. The cul-de-sac should be flushed with a normal salt or boric solution and an ointment of equal parts of lanoline and vaseline applied; it causes an agglutination of the cells, which can then be more readily washed out.

Reviews.

THE TONSILS.

The mystery that appears to surround the function of the tonsils must in no small measure be held responsible for the opposition to their complete removal for the relief of septic conditions brought about by the absorption of bacteria or the poisonous products of their growth sealed up within the tonsillar crypts.

Dr. HARRY A. BARNES'S monograph on *The Tonsils*¹ should considerably assist in clearing up the mystery. The book is the outcome of a patient and painstaking research into the lymphoid tissues of the throat. Facts ascertained concerning the lymphoid tissues can alone form a reliable basis for any theories about the surgery of the tonsils. The book accordingly opens with a chapter on the general nature of lymphoid tissue, which is followed by chapters on the development, anatomy, histology, function, pathology, bacteriology, diseases and neoplasms of the tonsils. The two concluding chapters are given up to the surgery of the tonsils and its complications and sequelae.

In practical medicine, the more important questions relating to the tonsils concern their function, the indications for their removal, and the best method of removal. Hitherto the lack of certain knowledge, obtainable only by patient research, of the function of the tonsils has led, on the one hand, to a great variety of functions being thrust upon them, and, on the other hand, to a denial that they have any function at all. Of the attributions to them, many, as the author says, are little better than speculations, advanced without apparent knowledge of their histologic structure—as, that they absorb the products of salivary digestion; that they secrete mucus that aids deglutition; or that they secrete an amyolytic ferment. These theories ignore the lymphoid character of the organs, and scarcely need refutation. Histologically, the structure of the tonsils is identical with that of the other lymphoid bodies throughout the alimentary and respiratory tracts and their physiological significance is probably the same.

Dr. Barnes sums up as follows: "That the tonsils are important physiological tissues during childhood; that they should never be removed without adequate cause, but that when such cause exists their function is either permanently impaired or is easily taken up by the other lymphoid tissues. There should therefore be no hesitation on that score in totally removing diseased tonsils." It may be added that there should be no hesitation in accepting the view expressed when it is remembered that among the infections which have been attributed to this source are acute and chronic arthritis, endocarditis, pericarditis, acute or chronic nephritis, osteomyelitis, appendicitis, peritonitis, pulmonary gangrene, infectious jaundice, cervical adenitis of simple inflammatory or tuberculous origin, and chronic toxæmia without localized lesions other than those in the tonsils themselves. Although—as Dr. Barnes goes on to say—in many of them the relation of the tonsils to the disease has not been placed above question, nevertheless, as septicæmia of a high or low degree of virulence may be of tonsillar origin, it follows that the infection may manifest itself by the most varied localizations. In this respect septic tonsils are on the same footing as septic gums. It is reasonable, therefore, to conclude that cutting off the supply of organisms tends to limit the extent of the process, and to advise the complete removal of the tonsils with this end in view.

In the chapter dealing with the surgery of the tonsils Dr. Barnes points out that the partial operation, which consisted in the removal of those portions only that protruded beyond the faucial pillars—the so-called tonsillectomy—has, with the increase of knowledge and experience, been superseded by the operation of tonsillectomy, or complete removal of the tonsil, and, thereby, of the source of infection. Within the limits of this notice enough has been said to show that the partial operation of tonsillectomy

¹ *The Tonsils: Faucial, Lingual, and Pharyngeal; with some Account of the Posterior and Lateral Pharyngeal Nodules*. By HARRY A. BARNES, M.D., Instructor in Laryngology, Harvard Medical School, London: Henry Kimpton; Glasgow: Alexander Sutherland, 1914. (Roy. 8vo, pp. 168; 39 plates. 12s. 6d. net.)

is entirely inadequate in those cases in which the symptoms depend upon absorption from the crypts.

Dr. Barnes makes out a good case for tonsillectomy. The fact is brought out that it is the so-called buried tonsil with the extensive and almost closed supratoruscular fossa which is not reached by the old operation of tonsillectomy that causes systemic infection, and not the large petunulated tonsils which so readily lend themselves to tonsillectomy, and which might easily be spared. It is to be hoped that a study of Dr. Barnes's monograph may be the means of bringing relief to many suffering the ill effects of chronic toxic absorption, or of recurring acute inflammatory conditions, when all that is needed is tonsillectomy.

THE FOUNDATIONS OF PSYCHOLOGY.

In a day when psychology is used as a word to conjure with, and all sorts of crazy notions are put forward as psychological, in a day when the feeble-minded are to be discovered and classified by psychological tests, novels are recommended because they are said to be psychological, and business men are taught to advertise on psychological principles, it is a rest and a comfort to come across a book on psychology¹ whose author knows the meaning of the word, and treats the subject in a manner that is sane and reasonable. Dr. Boris Sidis has much to say that arrests attention and provokes thought. He has original views, and he states them for the most part clearly and well. Whether they will commend themselves to the world of psychologists and become accepted, time alone will settle, but in any case they are well worthy of consideration, and when so much that passes as psychology is mere repetition of what has been said before or is meaningless verbiage, this is a conspicuous merit. There is no subject that novices find so difficult to grasp as psychology, and now that it has become a compulsory subject for diplomas in mental diseases it is important that medical men should have at their command books on the subject that are intelligible to novices, and are adapted to the study of disease. Most textbooks on psychology are badly arranged, badly proportioned, and badly written. They impose on the student a very disproportionate amount of labour, they devote a very disproportionate amount of space to sensation and perception, they are very deficient in their descriptions of the higher capacities of mind, and their teaching has no bearing at all on the vagaries of mind that are discovered in the lunatic asylum and the consulting room. Dr. Boris Sidis is a practising alienist, and recognizes, as few writers of textbooks do, that the processes of sensation and perception are not the only, nor even the chief, processes of mind, nor are they the processes whose disorders are most frequent and most grave.

He starts by disentangling psychology from the other sciences on which it touches at various points, and with which it is often confused. Some there are, who call themselves "mechanists," and would make psychology a branch of physiology, or even of physics; others confuse it with metaphysics. These errors are exposed by Dr. Sidis. While he reduces sensation and perception to their proper position of subordination, he yet propounds a theory of perception that has indeed been foreshadowed by others, but that has never been put so well as he puts it. It is not possible to criticize it here—that must be left for the special reviews—but it must be said here that his criticism of the current view is destructive and telling, and if his substitute does not captivate the judgement, at least it must be reckoned with. One of the best points in his book is his criticism of The Unconscious, that phantom which is just now attracting so much attention and support from amateur and would-be psychologists. The task is perhaps not very difficult, but Dr. Boris Sidis performs it very thoroughly, and leaves the theory without a leg to stand on, and without a rag to cover its naked absurdity. His theories of the thresholds of consciousness and of reserve energy are less convincing, and he has not emancipated himself from some current beliefs that are certainly erroneous—as, for instance, that the child at birth is a purely reflex being. This is curious, for, as a

rule, he hangs but little on authority, but sees things for himself as they appear to him, and he has been an observer of infantile behaviour. It is odd, therefore, that he should have failed to notice, what he must often have witnessed, the spontaneous jerks and sprawlings of the infant, without any provocation from impressions. With all of us a preconceived notion will blind the eyes to the most conspicuous fact, and so it is with Dr. Sidis.

That which is evidently in his own eyes the most important contribution to psychological doctrine is the theory of "moment consciousness," an unfortunate term which handicaps the estimation of the theory, for even after a careful examination it remains doubtful whether the term "moment" is to be understood in its temporal or in its dynamical sense, or in some other sense which is not defined. The theory is important, and would modify very seriously our notion of the constitution of consciousness. It has much to commend it, but it is not explained with the clearness that characterizes most of the book, and it would be out of place to discuss it here. We have said enough to show that the book is an important one, and one that cannot be neglected by the student of psychology.

The printing is bad. On many pages the face of the type is not square with the face of the paper, and consequently the upper or the lower ends of the letters are deeply indented and heavy, while the opposite ends are faint and scarcely impressed at all. Otherwise the book is well produced.

POVERTY AND WASTE.

MR. HARTLEY WITHERS is a cheery soul, who, having set out as an exponent of economic philosophy, finds himself to be the proud discoverer of the philosopher's stone. Starting with the belief that the poverty of the workers is a thing that can and must be abolished, Mr. Withers, in his book *Poverty and Waste*,² dismisses various panaceas such as Socialism, and at the end of each chapter reveals to us that the one thing necessary in order to improve social conditions, is the abolition of luxury. Thus luxury checks the production of necessaries. Luxury causes scarcity and dearth of capital. Luxury keeps wages low. The risks of the middleman might be reduced if luxury were diminished. Against luxury Mr. Withers makes out a plausible case, and incidentally exposes the fallacies of many kinds of social reformer. Apart from the suspicion aroused when a single cause is alleged in explanation of some defect in anything so manifold as human nature, we have an uneasy feeling throughout the greater part of this book that all is not well with the argument. Gradually it dawns on the reader that it is the old, old story of a lack of definition of terms. What is luxury? The question seems as difficult as the famous query, "What is truth?" In the earlier chapters it is only possible to gather that £10,000 spent on fireworks or the keeping of three motor cars would be luxury. But in the last chapter Mr. Withers supplies his answer. "What I mean by luxury is anything that we can do without, without impairing our health of mind and body." Truly we agree that this is an "elastic definition," showing "that luxury varies according to the circumstances and upbringing of every individual." Is it an answer to the question, and if so, whither does it lead us?

However, the book is eminently readable, furnishing much food for thought; and if Mr. Withers is sometimes hard on existing institutions, at least he has the merit of seeking to show that there is good in them as well as evil. Herein he differs greatly from most of our enthusiasts for reform.

NOTES ON BOOKS.

ORIGINALLY published in 1897, MALLORY and WRIGHT'S well-known laboratory manual of *Pathological Technique* has now reached its sixth edition.³ The book is so well known in this country, as it is in the United States of America, that no detailed account of its contents need be given. It contains full accounts of all the more useful and

¹ *Poverty and Waste*. By H. Withers. London: Smith, Elder and Co. 1914. (Post 8vo, pp. 189. 3s. 6d.)

² *Pathological Technique: A Practical Manual for Workers in Pathology, Histology, and Bacteriology*. By F. B. Mallory, A.M., M.D., and J. H. Wright, M.D., of Harvard University Medical School. Sixth edition, revised and enlarged. Philadelphia and London: W. B. Saunders Co. 1915. (Roy. 8vo, pp. 536; 156 figures. 13s. net.)

³ *The Foundations of Normal and Abnormal Psychology*. By Boris Sidis, A.M., Ph.D., M.D. London: Duckworth and Co. 1915. (Post 8vo, pp. 423. 7s. 6d. net.)

trustworthy methods of preparation that may be employed by either beginners or professors working in pathological laboratories. Among the additions to this edition are Bielschowski's silver impregnation stain for nerve fibres, connective tissue fibrils, and reticulum; Bensley's fixation and staining to show the presence of cytoplasmic mitochondria; and G. Herxheimer's new method of staining fat with Sharlach R. The illustrations are well chosen, but the reproduction of many of them leaves much to be desired; there is a good index. The book is indispensable for use in pathological laboratories.

The ABBÉ FÉLIX KLEIN became chaplain to the American Hospital at Neuilly in September, 1914, and has recorded his impressions as a non-combatant down to the close of last year in the simple form of a diary.² The Abbé sets out his daily impressions, his observations, hopes, and fears in a most straightforward manner, with tales to illustrate the faith and virtues of the wounded soldiers and others with whom he was brought in contact. He found much to encourage his belief in the good qualities of human nature, and quotes many an incident to show the depths of religious feeling touched by experience of trench and battlefield in soldiers of the Allied forces. There is a directness and naïveté of soul about the Abbé that makes a strong appeal to the reader. No very profound views of life may be unfolded in his narrative, which deals mainly with the more obvious and superficial emotions of the natural man. These, however, the Abbé reflects and transcribes with great clearness, and the result is a human document of no little sentimental interest. The translator, nudly bound within the fetters of French idiom, has done her work indifferently.

EXPERIMENTS ON LIVING ANIMALS.

The report showing the number of living animals during the year 1914 under licences granted under the Act 39 and 40 Vict., c. 77, has just been issued.

England and Scotland.

The Chief Inspector, Professor Thane, states that, owing to the great stress of work thrown upon the Home Office by the war, it has not been possible to prepare the report in the usual detailed form. The names of all places registered for the performance of experiments during 1914 are given in a table. Nine new places were added to, and one removed from, the register during the year. The names of all persons who held licences during 1914 are given in three other tables; the total number was 673. Reports have been furnished by—or, in a few cases, on behalf of—nearly all those licensees, but in eight instances it has not been possible to obtain a report owing to the absence of the licensees on war service. The reports show that 188 licensees performed no experiments. A table (II) gives the names of the licensees, and shows the number of experiments returned by each. It is divided into two parts, A and B, which contain respectively experiments done without anaesthetics and those in which anaesthetics were used.

Number of Experiments.

The total number of experiments in Table II (A) is 4,889. Of these were performed:

Under licence alone	2,772
Under Certificate C	263
Under Certificate B	1,550
Under Certificate B+E	304

Table II (B) is devoted entirely to inoculations, hypodermic injections, and some few other proceedings, performed without anaesthetics. It includes 82,364 experiments, whereof there were performed:

Under Certificate A	81,891
Under Certificate A+E	383
Under Certificate A+F	90

The total number of experiments was 87,253, being 905 less than in 1913; the number of experiments included in Table II (A) showed a decrease of 1,460, and that in Table II (B) an increase of 555. The returns show that during the year 1914, 22,371 experiments were performed by nineteen licensees in the course of cancer investigations. Of these, 625 are in Table II (A) and 21,746 in Table II (B). The latter were almost entirely inoculations into mice.

² *Diary of a French Army Chaplain*. By Abbé F. Klein. Translated from the French by M. Harriet M. Capes. London: A. Melrose, Ltd. (Cr. 8vo, pp. 288. 3s. 6d. net.)

Ninety-four licensees reported over 24,000 experiments performed for Government departments, county councils, municipal corporations, or other public health authorities. Twenty-one licensees reported over 15,000 experiments for the preparation and testing of antitoxic serums and vaccines, and for the testing and standardizing of drugs.

Inspections.

During the year the several registered places had been frequently visited by the inspectors, and a large number of experiments were witnessed. For the most part visits were made without previous notice. The animals were found suitably lodged and well cared for, and the licensees were generally attentive to the requirements of the Act and the conditions attached to their licences by the Secretary of State.

Irregularities.

The irregularities which had come under notice during the year were few and not of a serious character. They were as follows:

In a case where two adjoining laboratories, belonging to different authorities, are registered separately, a licensee whose licence was available for one of these laboratories performed inoculation experiments in the other laboratory for which his licence was not available. It was explained that he was a newcomer, and had not understood that the two places, which communicate together, are registered separately. The Secretary of State accepted this explanation, but pointed out to him that the irregularity would not have occurred if he had taken steps to inform himself exactly as to the premises in which he was authorized to perform experiments.

A licensee holding certificates B, E, E, for certain experiments on cats, performed an operation of a similar character, which was, however, not covered by the terms of the certificate. He explained that the experiment lay entirely within the scope of the work that he proposed, and that it did not appear to him that the experiment went beyond the limit of his certificates. In view of this explanation the Secretary of State did not take any further action, but caused the licensee to be warned that the terms of certificates must be interpreted and observed strictly.

A licensee holding Certificate A, for abstraction of blood, reported that he had performed eight inoculation experiments under that certificate. He explained that he had inadvertently overstepped the limits of the licence, as he thought that the certificate covered these experiments. His explanation was accepted, and he was cautioned as to the necessity of attending strictly to the terms of certificates.

A licensee performed eight experiments on rabbits under a certificate B which had not been allowed to come into operation by the Secretary of State. He explained that from the correspondence that took place he supposed that the certificate had been allowed for rabbits, but not for cats. As it was clear that he acted under a misconception, he was admonished as to the necessity for strict attention to, and compliance with, the terms of the Act and the conditions imposed by the Secretary of State, and his licence was continued.

A foreign professor on a visit to this country performed an experiment on a frog while not holding a licence. As this was evidently done under a misunderstanding of the directions given to him, the Secretary of State did not refuse to grant a licence to him when it was applied for.

Ireland.

The inspector, Dr. Joseph O'Carroll, states in his report that the number of places in Ireland registered for the performance of experiments during 1914 was seventeen. The physiological laboratory of University College, Galway, had been added to the list. The number of persons holding licences at the end of 1914 was 30, an increase of 5 new licensees. A table is given which shows that 340 experiments were performed by 20 licensees, 92 being under licence alone and 248 under certificate; 210 were simple inoculations under Certificate A, of which 86 were made for the investigation of diseases of the lower animals. In 132 the object of the research was physiological; in 198 it was pathological, with either a diagnostic or a therapeutic aim; and in 8 cases the experiment was made for a medico-legal purpose. Ten licensees performed no experiments. Dr. O'Carroll suggests that experimenters dealing with problems of public health should be invited to include in their annual reports a brief note of any definite results to which their research had led them. If such results were recorded in the returns the reports of licensees would acquire a scientific value, while subsequent fuller publication of methods and results would be promoted rather than prejudiced. In conclusion, he states that he has every reason to believe that the holders of licences had obeyed the spirit as well as the letter of the Act, and that experiments had not been unnecessarily multiplied.

OPENING OF THE MEDICAL SCHOOLS.

UNIVERSITY OF LEEDS.

At the opening session of the Faculty of Medicine of the University of Leeds Sir WILLIAM OSLER delivered an address, in which he discussed the relation of science to war. In these islands, he said, which in fruitful ideas, inventions, and discoveries had had the lion's share, there had been a failure to grasp immediately their practical importance. The leaders of intellectual and political thought were not awake when the dawn appeared. The oligarchy, who ruled politically, were ignorant, and the hierarchy, who ruled intellectually, were hostile. Yet the seed was abundant and the soil good; it only needed the cultivation given so freely by members of the past generation, to yield the results to be seen to-day at Oxford and Cambridge and in the new universities, where, as in Leeds and in Sheffield, the problem of linking university work with the scientific industries was being solved. Turning to the contributions of science to the increase of military power of destruction, he said that from 1790 to 1913 there were 18,552,200 men engaged in the great wars, of whom 5,498,097 lost their lives. In the Balkan wars of 1912-13 there were 1,230,000 men engaged, of whom 350,000 were killed; in the Russo-Japanese war there were 2,500,000 men, of whom 555,900 lost their lives. It was estimated that in the present war more than 21 millions were engaged. As weapons had improved, the losses would be yet greater, and it might be expected that at least five or six millions of men in the prime of life would be killed. On the other side—its mission of salvation amid the horrors of war—science had done three things. The first was the organization of the transport and care of the sick and wounded; the second victory of science in war was the prevention of disease, and here the old experimental method, combined with the new chemistry applied to disease, had opened a glorious chapter. The knowledge so gained had been translated into practical effect as never before in history. In a larger army than Britain had ever before had in the field the incidence of disease had often been lower than in times of peace. In the West there had been no great epidemic, and in the East, though dysentery and forms of typhoid were troublesome, the grave camp diseases, such as cholera and typhus, had not prevailed, and were not likely to prevail. The third achievement of science was the great advances in the treatment of wounds. He believed that the methods of treating wounds infected with gas gangrene were giving increasingly good results, and no single aspect of preventive medicine had been more gratifying in the war than the practical stamping out of tetanus by preventive inoculation. In concluding his address he said: "To one who was by temperament and education a Brunonian and free from 'common antipathies' and 'national repugnances,' one sad sequel of the war would be, for this generation at least, the death of international science. An impassable intellectual gulf yawned between the Allies and Germany, whose ways were not our ways, and whose thoughts were not our thoughts. That Germany had made herself a reproach among the nations of the earth was a calamity deplored by all who had fought against Chauvinism in science, and a bitter regret to those who had had close affiliations with her, and lifelong friends among her professors whose devotion to science had made every worker in every subject, the world over, their debtor." In moving a vote of thanks to Sir William Osler, the Vice-Chancellor, Mr. M. E. SADLER, expressed his regret that British universities had neglected scientific study and methods in the training of the young men who passed on to high positions of influence in the Civil Service. If Oxford had cared more in the study of humanity for science and less for philosophical dialectics, the country might have had in its Civil Service men who were so alert to the real drift of things, and so alive to the possibility of the destructive power of science, that they would in trumpet tones have aroused their countrymen, and prevented this war by being more prepared. British universities had helped to provide the remedy, and there was nothing the members of the Leeds University had admired more than the part their colleagues in the medical school had borne in the care of the wounded and the sick.

UNIVERSITY OF EDINBURGH.

The effect of the war was very evident in diminished numbers of students, especially of seniors, attending the medical classes in the opening days of the present session of the University of Edinburgh, which began on Tuesday, October 5th. From the ranks of the teaching staff, too, Mr. Alexis Thomson, the Professor of Surgery, and Dr. Lovell Gulland, the newly elected Professor of Practice of Medicine, were absent, the former serving as consulting surgeon to the Third Army in France, and the latter as consulting physician at Malta, each with the rank of Colonel in the Army Medical Service. Professor Thomson's place in the surgery class has been temporarily supplied by Mr. Alexander Miles, F.R.C.S. Edin. and Lond., whilst Dr. William Russell, the Professor of Clinical Medicine, has taken on Professor Lovell Gulland's work in addition to his own.

EDINBURGH SCHOOL OF MEDICINE FOR WOMEN.

Two years ago there was a notable increase in the number of women studying in the Edinburgh School of Medicine for Women, and this was more than maintained in the following year. In the past summer session there was again a marked increase in the number of students, and to judge from the crowds in Surgeons' Hall on the opening days of the present winter session there is an indication that the accommodation there provided may be strained and that further extension may be required. The number of new students in the summer session was 23, and in the one just begun it is 43, so that the *annus medicus* contains 66 names.

LONDON SCHOOL OF MEDICINE FOR WOMEN.

DR. FLORENCE WILBY, in her address at the opening of this school, discussed the influence of the war on the medical education of women.

The summons to women to fill up the ranks had, she said, come from all kinds of professions and trades, but from none, perhaps, more urgently than from the medical profession. The ever-increasing number of medical men and women employed in military service abroad, together with the number employed in either whole or part time military service at home, had taxed the resources of the medical profession to the utmost. But in more indirect ways the war was creating a future need, since young men who would otherwise now be entering upon a training for some professional career were enlisting for naval or military service, and thus the supply of medical students in the men's schools was seriously diminished; this meant for years to come decreasing numbers of men in the profession of medicine. Women must make good this deficiency, and that they were willing to do so was made clear by the facts that the usual entry of the school had been doubled and that there was a largely increased entry of women medical students in Scottish and other schools. Any national demand which called women from indoor semi-inert habits to lives of activity and usefulness must raise and not lower the standard of general development, so that there was on this account no need to fear that the response to the call was incompatible with fulfilling the country's great need of a sane and stalwart race.

The proportion of women to men entering the medical profession was after all of minor importance; the really serious question was whether the result of the changes would be a total loss or gain in numbers to the profession as a whole. There was very good reason to think that the tendency for some years would be towards a shortage of the total number of men and women required, and it was incumbent upon men and women alike to look to the needs of the future with a vision cleared through our close acquaintance with the tragedies and demands of this strenuous time, and with a desire, freed from all prejudice and self-seeking, that the coming generation of doctors, whatever the proportion of men and women, should be worthy of the best traditions of the past, equipped for their work as no generation had been before, and inspired with high resolve to build on the ashes of a world disaster a healthier, sounder, and wiser humanity. There were many signs that this duty was already making itself felt, and was, indeed, prompting different groups of people to serious consideration and to action. One illustration was the very considerable extension of the premises of the school now in progress—an extension which included not only more lecture rooms and laboratories, but also accom-

modation for the prosecution of research such as it had never been possible to arrange before. Closely associated with this development for primary subjects was the plan for doubling the resources of the Royal Free Hospital to enable it not only to meet more effectively the needs of the poor, but also to provide very complete clinical facilities for the training of students. The extending outpatient work of the hospital was provided for in the building completed just before the war began. It contained, also, modern equipment for the first instalment of development in maternity work, which must play so large a part in the preventive medicine of the future, as well as for extensions in pathology and in x-ray, electrical and massage treatment. The building was handed over to the War Office just after its completion, and was in use for wounded officers. When it reverted to the work of a civil hospital it would allow of greatly extended work in medicine and surgery, and in the special departments, with extension of the facilities through consultative work to the doctors in private practice in the neighbourhood. The special training in nose, throat, and ear work and in the ophthalmic and children's departments prepared students for future work under the Board of Education, and in the clinics for gynaecology, midwifery, and for antenatal and infant care the knowledge necessary for preventive work could be acquired. It was an open secret that the opening of other schools and hospitals to women students was now a matter of careful consideration, but they were faced with certain problems and difficulties. Some questions they had to consider were: How will co-education in medicine work? Will the presence of women drive away the men? Will the presence of men students prevent women from coming to the school? Will women expect, after student days are ended, to occupy posts of responsibility? Might they aspire to staff appointments? Might they even at some time outnumber men on the staff? The other schools which desired to help in the education of women students would, she believed, naturally open appointments, from the lowest to the highest, to men and women alike, for the post-graduate education which experience and responsibility gave was more important than any student work, and no hospital could be said to truly educate which withheld such experience.

Dr. Willey then enumerated some branches of medical work, preventive in character, which would repay all the vitality and enthusiasm the coming race of medical women could give. They were: (1) The study and care of pregnancy, including pathological research into the causes of antenatal death; (2) the study of the art of obstetrics, which should include all that made for skilful delivery on the one hand and relief of pain on the other; (3) the study of those conditions which lead to a high infant mortality and a low standard of health in childhood; (4) the prevention of such diseases as hinder conception, kill the unborn, maim childhood, and produce chronic invalidism in women.

By the generosity of the Duchess of Marlborough a maternity hospital to accommodate twenty patients would be opened in Endsleigh Street, where students of the school would have the opportunity of doing some of their obstetric work under hospital conditions, while the maternity department was required for wounded officers. In considering how to save infant life, the large proportion of illegitimate children untraceable after the first year of life must be remembered. Serious effort had been made to combat this loss, both in the inspection of singly boarded out children since the Children's Act, and in the recent extension of the Notification of Births Act. But mother and child should be kept together. Efforts in the past had been directed towards suitably boarding out children and providing the mother with other work, but medical knowledge should point out to the ardent sociologist that the child needed the mother and the mother needed the child, and no arrangements for their true welfare could contemplate their separation. With regard to the prevention of disease which killed child life and invalidated women, medical women must do their part in the abolition of a national scourge as it affected their own sex; both in the preventive work of education, and in the curative work, which was also preventive, in hospitals arranged for the purpose. This was work yet waiting for medical women to do—to cure disease, and at the same time to restore self-respect to spirits which had been broken for lack of it.

EXHIBITION OF FRACTURE APPARATUS.

The exhibition of fracture apparatus, arranged by officers of the R.A.M.C. to illustrate methods which have been found most useful in this war for the treatment of fractures, was opened on Friday afternoon, October 8th, at the Royal Society of Medicine.

Dr. FREDERICK TAYLOR presided over a very large meeting in the library, and explained that the response to the invitation had been so wide that it had been found difficult to find room for all the apparatus offered, so that the exhibits had overflowed the large Robert Barnes Hall.

Sir ALFRED KEOGH said that if the course of military surgery in the last year were considered, it would be recognized that great progress had been made, and that surgeons in France, in the Mediterranean, and at home had achieved remarkable successes. Nevertheless much difference of opinion as to the best methods of treatment of injuries and of the complications of wounds still existed; for instance, there was as yet no agreement as to how best to treat tetanus, as to whether antitoxin, if it were used, should be injected intravenously, subcutaneously or intrathecally, and as to the value of carbolic acid and other methods of treatment. The object of the exhibition was not to attempt to teach surgeons what they ought to do, but to afford an opportunity for comparing notes, especially as to the indications for operation and the best methods of treating gunshot fractures. The formation of definite opinions on these points was hindered by the difficulty of following up cases; a system of communication was wanted between surgeons at home and in France, so that those in France might learn what happened to their patients afterwards, and those at home might know the nature and object of the treatment to which the men had been subjected. He was anxious that a method should be found, but none of those yet submitted had been found practicable. Whether the apparatus in the exhibition would be applicable to civil conditions was not the immediate question, but he felt confident that for military surgery a system of splinting fractures had been worked out which marked a permanent advance. The objects had been to allow the patients to make those spontaneous movements which would not be detrimental to the fracture, to ensure freedom from pain during transport, and to provide ready access to the wounds, especially for irrigation, which was the rule of the day in France. He appealed to those whose bent was towards research to devote themselves exclusively for the present to researches in medicine and surgery applicable to this war, so as to ensure that treatment was conducted on scientific principles.

Sir ALMROTH WRIGHT then gave an address on the results and practical applications of recent researches in what he called the physiology of wounds. It was, in a sense, a continuation of the address delivered in April¹ and arrangements have been made to publish it in full in a subsequent issue. He began by observing that the wounded men were to be regarded as sick men, since practically all wounds received in this war were infected. He then went on to indicate the principles by which he considered surgeons should be guided in planning a line of treatment. After holding his audience for an hour Sir Almroth Wright offered to stop, but, it being evident that the general desire was that he should continue, he added a little epilogue, in which he returned to the consideration of the question with which he concluded his previous address—namely, whether it would not be proper that some one line of treatment thoroughly thought out, and resting upon physiology, experiment and experience, should be generally followed.

At the conclusion of the address a vote of thanks to Sir Almroth Wright for his address, and to Sir Alfred Keogh, was moved by the PRESIDENT, seconded by Colonel BERGHARD, and carried with acclamation. Afterwards Sir Almroth Wright gave a demonstration, a full report of which will be found at p. 564.

The Robert Barnes Hall was filled with exhibits, and it was interesting to note that the various officers who exhibited apparatus for the treatment of compound fractures had all devised splints which can fairly be described as modifications of the well-known Thomas's knee splint—adapted, in some instances, for use in injuries of the upper limb. The dominant feature,

¹ BRITISH MEDICAL JOURNAL, April 10th, 1915, p. 625; April 17th, p. 655; April 24th, p. 720; and May 1st, p. 762.

however, was that in all the modifications the Thomas skeleton frame was adopted for two reasons: First, because it gave free access to a septic wound for frequent dressing, free drainage, and copious irrigation of the infected wounds; and, secondly, because it gave a means of direct extension with counter-extension from the groin or axilla, so that the patient could be moved without detaching the extension apparatus applied to the limb. Major Sinclair demonstrated the appliances in use in No. 7 Stationary Hospital at Boulogne, which he described in an article published in the *BRITISH MEDICAL JOURNAL* on September 18th. He showed skeleton splints for the upper and lower limbs, designed on the plan of the Thomas knee splint, and the method of suspension of the limb and splint, shown in the drawings at pp. 430, 431, and 432 of the issue of the *JOURNAL* just mentioned. This is an interesting illustration of how history may to some extent repeat itself when men at different times set themselves to solve the same problems. Those familiar with the history of the Thomas splint for the treatment of fractures will remember that thirty years ago, when surgeon to the Stanley Hospital in Liverpool, Mr. Robert Jones suspended the splint from a similar truck running on rails above the bed, in order to increase the comfort of the patient. The use of this means of suspension was abandoned at the Stanley Hospital because it was found that the patients often asked the nurse to arrange pillows and sandbags to prevent the limb from swinging when they moved, as they were more comfortable if it was kept steady. The other main object of raising the limb—to allow of room for some vessel with a waste pipe to receive overflow from irrigation—could probably be arranged on some other method. The other part of this exhibit consisted of methods of irrigation by small delivery pipes which, in the case of bullet tracks, were introduced into the interior of perforated flexible wire or metal drainage tubes, or in spiral coils; in the case of surface irrigation the irrigated fluid splashed through a perforated wire gauze contained in a large metal box like a biscuit-box; the supporting framework was made of the aluminium rods supplied in the regulation field fracture box. The efficiency of the apparatus for continuously splashing a considerable portion of the surface of the limb without splashing the surrounding parts of the bed was only equalled by the simplicity and ingenuity of its construction. Putty or plasticine with which cotton-wool was incorporated was advocated as an improvement on formalized gelatin for making flanges to prevent the irrigating fluids from running along the limb and overflowing into the bed. A compound spiral irrigator with a bore of one-sixteenth of an inch, drilled with holes and closed at the end, was shown by Captain E. K. Martin, R.A.M.C.(T.).

From the same hospital Sir G. H. Makins showed a splint for exerting traction on the soft parts of an amputation stump; it consisted of a short Thomas's knee splint to which the flaps were attached by strapping. Sir G. H. Makins also showed, in association with Major H. G. Pinches, R.A.M.C., the "Boulogne box" for the transport of fractures of the femur.

Captain Max Page had an exhibit of splints brought from Abbeville, made from the aluminium rod materials supplied in the regulation field fracture box, after the manner described and illustrated by him in the issue of the *BRITISH MEDICAL JOURNAL* for May 15th, 1915, p. 839. Here again the splints were designed on the model of the Thomas splint, and were specially designed for easy transport of the wounded back to hospitals. Though rough in appearance they have proved efficient in practice.

Dr. Ogier Ward's exhibit consisted of aluminium rods and specially prepared sheets of aluminium which could easily be twisted and fitted together to make splints to fit any limb. With the addition of perforated aluminium sheets prepared on Dr. Ogier Ward's principle, the field fracture box materials might be made still more useful in the rapid manufacture of emergency splints combining the advantages of both exhibits.

The dominant characters of Major Robert Jones's exhibit of various forms of Thomas splint and its modifications were simplicity of design and excellence of finish. Commencing with splints for minor injuries of the fingers, the importance of using dorsiflexed splints at the wrist and the method of treating Colles's fracture

were demonstrated. Splints were shown for the ambulatory treatment of compound fractures of the upper limb, and demonstrations were given of the use of the Thomas knee splint in its original form for all fractures of the lower limb between the small trochanter of the femur and the middle of the tibia and fibula. The use of the modified Thomas's abduction frame for fractures of the femur above the small trochanter and the importance of the abducted position in securing good functional recovery were specially emphasized. The point of view put forward was that of the orthopaedic surgeon, who looked beyond the immediate difficulties of treatment to the ultimate functional result which might be expected.

In the department of dental surgery Lieutenant Valadier showed a beautiful series of casts of jaws and of mechanical apparatus for retaining fractured jaws in correct position, and for forcing back jaws which had been displaced, so that the remaining teeth articulated correctly, and defects might be remedied. The large number of cases figured in photographs and skiagrams served to show how important a part the dental surgeon played in the military hospital of the present day.

Captain C. H. Barber, I.M.S., exhibited a splint for compound fracture of the leg, which he described and illustrated in the *BRITISH MEDICAL JOURNAL* of July 10th, p. 47.

Captain Thomas Warrington, R.A.M.C.(S.R.), showed an extension splint the principle of which was that the weight of the leg resting on a movable inclined plane produced extension. The principle could be applied to the femur, knee, or tibia.

Mr. Herbert J. Paterson, M.C., honorary surgeon-in-charge, Queen Alexandra's Hospital for Officers, Highgate, showed an extension splint for the treatment of compound fracture of the humerus and a splint for compound fracture of the radius.

Colonel C. W. Cathcart showed an extension apparatus as a substitute for wire splints, and Mr. B. Sangster Simmonds sent from the Graylingwell War Hospital, Chichester, an exhibit illustrating a method of treating septic compound fracture to facilitate the use of plates. Colonel Culbert Wallace and Captain Maybury showed an extension leg splint designed by them for use in the treatment of gunshot wounds of the femur and capable of producing powerful extension of the leg during the process of plating fractures of the femur or tibia. The splint consisted of a Thomas crotch ring with two lateral steel rods fitted in sockets and two transverse bars, the upper being fitted with wooden footplate, and the lower carrying a long screw for producing extension.

Captain F. Arthur Hepworth, R.A.M.C.(T.), surgeon to the Wharfedale War Hospital, showed a tripod folding leg sling and cradle for use in fractures of the lower limb, and Captain P. B. Roth, R.A.M.C.(T.), a Thomas sling for treating gunshot wounds of the humerus.

From the 3rd London General Hospital, Wandsworth, Captain Gosse, R.A.M.C.(T.), sent casts of limbs for moulding splints, and from the Kitchener Indian Hospital Major A. Neve, R.A.M.C., sphagnum moss pads and sawdust pads for dressings.

There can be no doubt the exhibition fulfilled one of the objects mentioned by Sir Alfred Keogh in his opening remarks. The men who have been doing work in different ways in different hospitals have met and interchanged ideas and experiences and talked of them to hundreds of surgeons who came to see and to learn, and out of this must grow a better understanding of how there may be established a continuous and uninterrupted systematic treatment of cases of compound fractures as they pass from one surgeon to another from the field dressing station to the base hospital at home.

It is reported that the Vienna Academy of Sciences has made a grant of £160 to Professor R. Foech to enable him to conduct anthropological researches among the various races represented by the Russian prisoners of war.

The *Journal of the American Medical Association* announces that on a Sunday in August coloured physicians from all parts of the States addressed audiences in the coloured churches of Chicago on topics relative to public health. On the three following days clinics conducted both by white and coloured doctors were held in three hospitals in Chicago.

British Medical Journal.

SATURDAY, OCTOBER 16TH, 1915.

WAR ORTHOPAEDICS.

A SHORT discussion took place last week in the French Chamber of Deputies on the provision of artificial limbs and other appliances for wounded soldiers. A deputy, M. Caudace, complained that the State had been made to pay high prices for defective apparatus, and that there had been great delays. He proposed, therefore, that the factories where such apparatus were made should be included among those controlled by the State. M. Charles Bernard, a member of the Commission on Hygiene, said that that body was concerned to establish types of apparatus, those hitherto supplied having been found worthless. M. Godart, the Under Secretary for the Medical Department of the War Office, after stating that the most ingenious improvements in apparatus had in most instances been designed by men who had themselves been injured, said that one Government factory had already been established (at St. Maurice), that another was being installed at Lyons, and that others had been sanctioned at Bordeaux and elsewhere. In other places efforts had been made which he desired to encourage. The establishment of these factories would put an end to the opposition of the trade and to the technical incompetence that had been shown, for he believed that France was behind other countries in this respect—a conclusion which will seem surprising to many who know the very high excellence of the operating instruments turned out by French makers. M. Godart went on to say that he had had a conference with the makers of apparatus, and had appointed a special orthopaedic committee, which he proposed to enlarge; it was instructed to settle types which the makers could then copy. Until the supply of proper apparatus equalled the demand temporary apparatus would be issued so that the men might go home.

In this country the subject of what may be called war orthopaedics is being carefully studied by a few surgeons. There is the Queen Mary's Auxiliary Hospital at Roehampton where, with the cordial co-operation of the medical departments of the navy and army, men are admitted to be fitted with artificial limbs. Each case is carefully studied by the surgical staff, and a great deal of most useful work has already been done. There is also the military orthopaedic centre at Alder Hey, near Liverpool, of which we have some reason to think sufficient use is not being made.

With the best stump in the world the designing and fitting of an artificial limb is no easy matter, as any one who has had an ill-fitting boot will be ready on reflection to believe. But all stumps are not as good as they might and would be if operating surgeons at the time of the operation could give more thought to the apparatus that will eventually have to be fitted, and during the after-treatment always had the same

point in mind, taking pains to prevent contractions and adhesions in the stump and in the joint above, which must limit movement in the future. In this connexion we will venture to quote the sentences with which Major Robert Jones concludes his recent primer on injuries to joints: "During the recovery of stumps after amputation, care should be taken to procure a free range of movement in the neighbouring joints. Otherwise difficulties will arise when the time comes for fitting artificial limbs. This is especially important in the hip and shoulder. Quite a large proportion of cases are returned with flexion at the hip, which can only be accurately detected by flexing the sound limb on the patient's chest, when it will be found that the stump cannot be fully extended; in other instances there will be limitation in abduction, adduction, or rotation. The shoulder may be similarly handicapped after amputation through the arm. To prevent this, the position of the stump should be frequently changed during healing—a process so often delayed by suppurative—and, in addition, the joint should be put through its full range of movements two or three times a week. Deformities which have been allowed to take place during recovery will require complete correction before an artificial limb can be effectively worn. If deformity is threatened by contraction of scar tissue, it is imperative that the limb be placed for an extended period in a position opposed to the pull of the scar."

But there is more to be said on this head in relation to wounds which fortunately do not call for amputation. One such point is very opportunely raised by Dr. Giuseppe of Felixstowe in a memorandum published in this issue. He says that he has met with a number of cases in which the functions of a limb have been seriously embarrassed owing to the adhesion of muscles or tendons to the skin scar. They can be treated successfully by a secondary operation to sever the adhesions and close the fascia over the muscles and tendons, but he thinks that the condition could be prevented if the surgeons into whose hands such cases first come were to take care to suture the fascia. The suggestion seems worthy of consideration and discussion, but we suspect that it may often be impossible of realization. The surgeon dealing with an infected wound involving the muscles is mainly concerned to prevent the dire consequences of the infection by ensuring adequate drainage. He may well consider it wiser to leave the future functional integrity of the limb to be procured by a secondary operation.

However this may be, facts of this kind seem to emphasize the wisdom of the observations made by Sir Alfred Keogh in opening the exhibition of fracture apparatus at the Royal Society of Medicine last week, to the effect that it was very desirable to get established a good working system of communication between the surgeons at the clearing stations and hospitals abroad and those working in the hospitals at home. He said that he was anxious to see such a system established, but that no practical plan had yet been devised. There is nothing like leather, and for our own part we believe that in matters of general principle there is no medium of communication which approaches a medical journal in width of reach, and particularly—with all proper humility let it be said—this JOURNAL. But Sir Alfred Keogh had in mind also the tracing of the cases of individual wounded men, so that the surgeon abroad could tell his colleague at home what he had done and why, and the

colleague at home could tell the surgeon abroad how things had turned out, when there had been success, or why and how there had been failure.

MIGRATIONS OF EARLY CULTURE.

To state that scientific opinion is constantly changing is to give utterance to a truism. Some persons have indeed thought that the so-called exact sciences are not subject to this law, and Macaulay remarked that "nobody ever heard of a reaction against Taylor's theorem"; by so saying he laid himself open to the sarcasm of Professor Whitehead, who observed that it was a fairly safe assumption to make that Taylor's theorem was both enunciated and proved wrongly in every English textbook in existence at the time Macaulay wrote his essay. These revolutions of thought are, however, naturally more obvious to the non-expert in the case of the descriptive sciences, and in particular that dealing with the customs and beliefs of primitive races. Most men past the age for military service can recall the disputes of the rival schools of comparative mythologists, Max Müller and his followers on one side, and such writers as M. Gaidoz and the late Mr. Andrew Lang on the other. The spirit of these controversies is discernible in the works of many living anthropologists, and is not absent from a most interesting memoir recently contributed by Professor G. Elliot Smith to the *Proceedings of the Manchester Literary and Philosophical Society*, and now published in book form.¹

In opposition to the view, now widely held, that similar or even identical rites and customs connected with the disposal of the dead have been independently evolved, Professor Elliot Smith's thesis is to maintain that a highly complex culture compounded of a remarkable series of peculiar elements, including sun worship, the custom of building megalithic monuments, and that of mummification, was developed in Egypt between 4000 and 900 B.C. This culture-complex, which may be described as "heliolithic," began to be disseminated somewhere about 800 B.C., travelled eastwards, and eventually reached the American coast, being modified in transit by various local accretions. Professor Elliot Smith's general method of reasoning is as follows. If a certain practice A, flourishing in a certain country X, be in that country associated with certain other practices B, C, D, etc., the association being purely dependent on local circumstances, there being no essential connexion between A, B, C, and D; then if in some other country, Y, at a later period we find A still associated with B, the presumption that the practice has been communicated from X to Y is created, and the larger the number of extraneous elements of the B, C, D, etc., series retained, the stronger the presumption. *A fortiori*, if in X we find a custom, a, associated with A, such custom owing to local peculiarities being really helpful to A, then if a is retained with A when the conditions of Y are such that a is meaningless or harmful to the success of A, the case for importation is established.

As an example of the former method, Professor Elliot Smith adduces the blending of the sun's disc with the uræus, often combined with the wings of the horus-hawk, a symbolism originally attributable to the dominance of the sun-god Ré in the northern capital of Egypt, which also happened to be the seat of serpent worship. This composite symbolism has

encircled the world. As an illustration of the latter method may be cited the practice of ancient Egyptian embalmers of making circular incisions around the fingers and toes, the aim being to prevent the finger and toe nails being carried off with the general epidermis first scraped off and the vestiges shed when the body was steeped for weeks in a preservative brine bath. The same incisions were made by Torres Straits natives, but they neither scraped off the general epidermis nor used a brine bath. Further, they deliberately removed the skin thimbles and nails, thus defeating the very object the operation was designed to carry out.

Professor Elliot Smith meets the apparently cogent argument that if the practice of mummification were really derived from Egyptian sources by the various tribes that practised it, the latter would also have acquired certain useful arts well known to the Egyptians, of which they were and have remained ignorant, by an appeal to Rivers's important researches, which demonstrate that all knowledge of an art or craft once practised may be completely lost by the tribe's posterity.

Professor Elliot Smith naturally puts stress upon the combination of customs the independent evolution of which, each taken by itself, is no unlikely event. No doubt this argument is open to certain criticisms. Even if we assume that the associated customs or beliefs are strictly independent, in the sense of the mathematical statistician, the improbability of their concurrence can only be used as an argument in favour of interdependence, with full recognition of what is implied thereby. Dr. Venn, in his well-known treatise on the logic of chance, called attention to the popular fallacy often involved in arguments from statistical improbability. Thus, the chance that a six will be thrown twenty times running with a single die is very small, but if we regard the particular set of throws as a member of an enormous series of throws comprising all those made since dice were first used, the event ceases to be extraordinary or abnormal in the sense popularly attaching to the words. This caution is applicable to the interpretation of cultural associations unless we possess an absolutely exhaustive knowledge of all the combinations which have occurred, and still occur, throughout the "universe" under consideration. This caution becomes of still greater importance if one remembers that such cults as sun and serpent worship may not arise independently, but both take their origin in the observation of natural phenomena coexisting in different and remotely separated quarters of the globe. In this connexion Sir J. G. Frazer's observations on serpent worship² are deserving of notice.

We do not think, however, that the other line of argument adopted by Professor Elliot Smith, namely, the persistent performance of a stage in the technique of an operation which has ceased to subserv the function to which it was adapted, can be criticized in this way, and it will be interesting to see how his opponents endeavour to meet him on that ground. The case seems identical with that established by Sir J. G. Frazer and others in favour of the importation into modern religious rituals of ceremonies forming a natural or even logical part of older religions, but now devoid of meaning and usually supported by their votaries on wholly fictitious grounds.

We have said enough to prove that Professor Elliot Smith's work is of great interest and must be carefully considered by all anthropologists. The monograph is provided with a good bibliography.

THE RECRUIT'S HEART.

SIR JAMES MACKENZIE has done a very useful piece of work in calling attention to the unconscious skill with which the young recruit may simulate heart disease in his anxiety to pass his medical examination. The memorandum in which Sir James does this is printed at page 563. Its issue has been occasioned by the fact that its author has met with many cases in which recruits have been rejected, or soldiers have been invalided out of the service, for cardiac abnormalities that actually in no way impaired the heart's functional efficiency, however much they have impressed the imagination of the medical examiner. These abnormalities fall naturally into two classes, namely, those characterized by the presence of murmurs and those exhibiting abnormal cardiac rhythm; both are likely to lead astray the over-conscientious medical man. The murmurs described by Sir James as "physiological" have in the past received a great number of names, and may be found in the literature described as "haemic," "cardio-pulmonary," "inorganic," "functional," or, best of all, "accidental," for the term "accidental" commits its user to no theory as to the murmur's genesis. In brief, cardiac murmurs without cardiac enlargement may be disregarded. The study of the cardiac irregularities to which Sir James refers owes more to himself than to anyone; here again he puts the matter in a nutshell by emphasizing the fact that irregularity of the heart is negligible so long as its functional capacity remains good and its size normal. In the same way undue rapidity of the heart, such as is frequent in recruits or soldiers who are nervous or unduly fond of tobacco, may be disregarded if there is a history of good functional efficiency of the heart to be obtained. In fact, so far as the heart is concerned, any candidate is fit for the army if he can undergo severe bodily exertion without distress. So long as this is the case, and there is no great cardiac hypertrophy, compromising physical signs may be bidden go hang.

PENSIONS FOR SOLDIERS AND SAILORS.

THE Naval and Military Pensions Bill, having been amended in the House of Lords, now awaits consideration in the House of Commons. The amendments include an alteration in the name of the central committee, which it is proposed to call the War Allowances Committee, and also its constitution. The financial provisions seem still rather vague, and liable to break down between the two stools of the State and private benevolence. The question of pensions and compassionate allowances is under consideration also in France. A Select Committee appointed some time ago has settled its report, which will come before the Chamber at the end of this month. M. Pierre Masse, the reporter of the committee, has given some indication of its recommendations. He points out that the matter of military pensions, which hitherto has concerned a relatively small number of persons, chiefly officers or professional soldiers, will in future affect the whole nation. Every little village will have its pensioners, or persons claiming to be pensioned, and the law governing the matter will become one of the most important on the statute book, since it will most nearly touch everyday life, as happened in the United States after the War of Secession. The law at present in force dates from 1831, and its provisions cannot equitably be applied to an army representing the nation in arms as France now is. It made no provision for parents or other relatives who had been dependent on a wounded man, nor for illegitimate children; the classification of wounds was bad, and the provisions with regard to invaliding for sickness opened the door to many abuses. The temptation to make a clean sweep had to be resisted, as it would have involved the reconsideration of a large number of instances in which persons were already in the enjoyment of allowances, but the Committee proposes a number of important amendments. With regard, in the

first place, to widows and orphans, it appears that hitherto the pension has been an unchanging minimum, irrespective of the number of children; this is to be remedied, and the right of a child is to be recognized without detriment to the widow. Illegitimate children are to benefit to the same extent. Hitherto small pensions given to a father or mother dependent on a son were subject to review every eighteen months; in future a life pension will be given to them as well as to widows and orphans; the amount and the conditions will be determined by the civil court without fee. The Committee recommends that wounded men shall in future have a claim in respect of each child, and that the scale of allowances for various degrees of invalidity shall be revised in accordance with the experience gained in respect of workmen's compensation. It will be proposed to take power to give a supplementary pension to the very seriously wounded who require the constant help of an attendant. Under the old law, any man invalided for sickness, or his heirs, had to show that the disease which caused his invalidity or death was contagious or endemic, or had been contracted in the execution of military duties. In future the onus of proof is to be on the other side, and it will be assumed, unless evidence can be brought to the contrary, that diseases contracted or aggravated during the war were due to the conditions of service. Other matters with which the Committee has dealt are the need for the reconsideration of pensions already enjoyed in respect of new services rendered, the ease of soldiers returned as missing, and the position of railway men and all persons mobilized for civil work. A society called the "Orphelinat des Armées" has been established, under the patronage of the President of the Republic, to supplement pensions granted by the State to widows and orphans. Its main objects are to ensure that the child shall be left in charge of its mother, to board out children without mothers or with incompetent mothers, and only to send them to orphanages in the last resort.

THE AMERICAN RED CROSS IN ENGLAND.

DR. HOWARD BEAL, an officer in the medical service of the United States army, who for the past year has been in charge of the Red Cross hospital established by American women in England at Paignton, Devonshire, is about to return to America, and was entertained by Sir William Osler at a farewell luncheon in London on October 15th. Dr. Beal came over with the first American Red Cross units in September, 1914. The two units then allotted to England each consisted of three surgeons and twelve nurses; one unit was sent at once to Paignton; the other was for a time attached to Haslar Naval Hospital, but afterwards it also went to Paignton, and the hospital there then had a staff of six surgeons and twenty-four nurses, with an equal number of British and Australian nurses. Later on Dr. Crumley, of the Mayo Clinic, was attached as pathologist and bacteriologist. Sir William Osler proposed a composite toast to the American women in England who had achieved a fine piece of organizing work at Paignton, to the American Red Cross which had supplied the staff, and to Dr. Beal. Sir Alfred Keogh bore testimony to the admirable work done by the American Red Cross at Paignton, and by the Harvard and other units in France. In the name of the R.A.M.C., he thanked Dr. Beal and the American women in England, who, headed by Mrs. Harcourt and Lady Randolph Churchill, had made the enterprise possible. Dr. Beal gave some particulars of the hospital, stating that it now possessed 250 beds, with 20 others in an isolation block. During the year which had just been completed it had treated over 1,900 patients with so much good fortune that it had had to record only five deaths. The staff had greatly valued the visits of the consulting physician, Sir William Osler, and those who had not yet attended one of his ward visits had a most interesting experience ahead. Americans who, like himself, were of English ancestry, felt the call of the blood,

and he was confident that if the British War Office wanted to widen the scope of its medical service he could get a corps of Americans with British blood in their veins who would be delighted to come over. Among Sir William Osler's other guests were the Director-General R.N., Sir Arthur May, Surgeon-General Carleton Jones, Colonel Adams, professor of pathology in the University of Montreal, the Hon. Dr. Pync, and other representatives of Canada and the United States.

A SURGEON ON PHARMACY.

THE opening of the new session of the School of Pharmacy in association with the Pharmaceutical Society of Great Britain took place on October 6th, when Sir Rickman Godlee delivered an inaugural address, in the course of which he said that last August, wishing to destroy the wasps which threatened his fruit garden, he went to a chemist in a neighbouring country town and was supplied unhesitatingly with 2 oz. of potassium cyanide. The incident served to impress upon him the heavy responsibility which rested upon the dispensing chemist. The difficulty of avoiding mistakes seemed enormous, and if it was true that death was ever flitting about the point of the surgeon's knife, it was also true that death was ever hovering about the chemist's shelf. No doubt the chemist, from his study of repeated prescriptions, did learn a great deal as to the medical use of drugs, and when people, who should have consulted a doctor, came to get something from the chemist, he might be tempted to use his accumulated knowledge and accept a patient's diagnosis, or even make a diagnosis himself. It was a dangerous and immoral thing to do, and it had to be remembered that ordinary sore throat might mean diphtheria, and ordinary stomach-ache appendicitis, and the delay of a few hours, due to the assumption by the chemist of a doctor's function, might involve a fatal issue. The last excuse for this kind of thing had vanished with the passing of the National Insurance Act, but only by setting his face rigorously against it could the chemist keep a clear conscience and deserve that epitaph which was still to be seen in a country churchyard: "He was a man without guile, and an apothecary without ostentation." There had always existed a kindly relationship between pharmaceutical chemists and doctors, and the introduction of medical students to pharmacy began at an early age. Under the direction of the dispenser he had himself made up many a bottle of medicine, and always had marvelled at the ingenuity shown in concocting a pharmaceutical blunderbuss, though even this was loaded with a far less promiscuous charge than in the days of their ancestors. He did not know whether physicians ordered such elaborate medicines now. Surgeons certainly did not, unless it was some old favourite of their youth from which they could not cut themselves adrift. In his earlier days the giving of minute globules became the vogue, and he remembered the practice being compared to putting an ounce of Epsom salts into the Sea of Marmora and then drinking the water of the Mediterranean. But it was not surprising if the homoeopathic dose engendered a certain scepticism:

If it be good in such complaints
To take a dose so small.
It surely must be better still
To take no dose at all.

The advent of the compressed tablet must have saved the pharmacist considerable time and trouble; he often wondered how it had affected his income. The manufacture of patent medicines had led to the piling up of enormous fortunes, but it was equally possible to make great incomes out of the legitimate pursuit of pharmaceutical chemistry. Much of this had been taken out of our hands by our friends the enemy, who before the war sent 270 tons of fine pharmaceutical products annually to our markets. Sir Rickman concluded

with a tribute to Ehrlich, whose methods of investigation opened up a new field for the science of pharmacology. They suggested that the knowledge of the living cell and the living microbe increased, the chemist and physiologist, working in concert, might be able to predict the action of any drug when once its chemical composition was known. Sir William Tilden moved a vote of thanks to Sir Rickman Godlee, and the other business of the afternoon was the award of the Hanbury Gold Medal for research to Mr. Edward M. Holmes, the society's curator, and the presentation of prizes to students, when it was announced that for the first time in the history of the school the number of women students equalled that of men.

DISEASES OF ANIMALS.

THE Annual Report of the Chief Veterinary Officer of the Board of Agriculture and Fisheries for the year 1914¹ is a very interesting document, and makes a strong appeal to students of epidemiology. The opening pages describe a series of minor outbreaks of foot and mouth disease in various parts of the country. One series, consisting of eleven outbreaks, occurred in and near Lindsey, Lincolnshire, during August and September. The origin of this outbreak seems obscure. Another instance was traceable to the landing place of Irish cattle at Birkenhead, and it may be remarked that a much more serious outbreak arising in this landing place was the subject of a special report. Swine fever was very prevalent in 1914, no less than 1,785 more outbreaks having been confirmed than in 1913. Glanders was less and anthrax more prevalent than in 1913. Sheep-scab gave rise to slightly fewer outbreaks in 1914 than in 1913. Special attention is directed to the prevalence of tuberculosis among swine, and it seems clear that not less than 3.5 per cent, and possibly more than 11 per cent, of swine are affected with this disease. A special section is devoted to the subject of swine erysipelas, a disease often confused with swine fever, and various inferences are suggested by the statistics. Since the data are necessarily based upon the findings on premises reported as under suspicion of swine fever, we doubt whether epizootiological conclusions can safely be drawn without concurrent analysis of the swine data, for the material is not a random, but a biased sample of the true distribution. The report includes two scientific papers. One, by Sir Stewart Stockman and Mr. W. G. Wragg, makes it probable that *Piroplasma bigemimum*, the cause of tropical redwater, and *Piroplasma ateygens*, an organism found in the blood of certain British cattle suffering from redwater, are not only morphologically but also physiologically distinct, cross immunization being impracticable. The second paper, by Sir Stewart Stockman, deals with epizootic abortion. The author points out that it is necessary to distinguish between bovine, equine, and ovine abortion, describes the bacteriological and epizootiological differences, and records the results of extensive immunizing experiments. The results achieved by immunization with live bacilli in bovine abortion are decidedly promising. A more extended report on the matter will be published later on. The whole report testifies to the zeal and efficiency of the Board of Agriculture's scientific staff.

A STUDENT OF INSECT LIFE.

JEAN HENRI FABRE, the entomologist of Provence, has died at the age of 91. He was a village schoolmaster for the greater part of his life, although at one time he had taught natural philosophy at the College of Ajaccio and the Lycée of Avignon. It was in and near Sérignan in the Vaucluse, the department which has Avignon for its capital, that he made most of the observations which have rendered his name so well known. As an observer of the

¹ Annual Report of the Chief Veterinary Officer for the Year 1914 (Board of Agriculture and Fisheries). C. 8013.

habits and mode of life of certain classes of insects, their larvae and pupae, he was probably unequalled. He was endowed with infinite patience; it carried him through many long days in the field under conditions of personal discomfort which would have deterred most men. He was also exceedingly ingenious in devising experimental conditions for studying the life-history of insects. In this way he threw light on the insect parasites of insects, illuminated many dark places, and showed the extraordinary complexity of the arrangements of Nature and the interdependence of one insect upon another. Some of his observations, as he was himself ready to point out, put great difficulties in the way of the evolutionist; he was content to state the problems and to leave their solution to the future. But had he been no more than an observing naturalist his name would probably not be known to one in a thousand of those to whom it is familiar. He possessed a happy power of popularizing scientific facts in a style which was at once clear and graphic, and selections from his writings, recently published in an English translation, have charmed many who have not had the opportunity of reading his *Souvenirs Entomologiques* in the original tongue.

EXTIRPATION OF THE PINEAL BODY.

We are still very much, if not completely, in the dark as to the functions of the pineal body. In a recent exhaustive account of its histology, Krabbe¹ has developed the theory that it may have a sensory function, that of regulating and keeping constant the pressure of the cerebro-spinal fluid secreted by the ependyma of the choroid plexuses. Flesch, in 1888, had supposed that it might regulate the production of heat, a view unsupported by any evidence; Walter, in 1913, described it as a sort of reflex organ, whatever that may be, and a year later wrote of it as a regulator of the pressure of the cerebro-spinal fluid. From the developmental point of view the pineal body is said to be homologous with the parietal eye of cyclostome fishes, though not with that of saurians. From the point of view of comparative anatomy, Crenzfeldt showed, in 1912, that the pineal body is best developed in animals with relatively thin skins. Histological examination of the pineal body leaves us quite uncertain as to its functions, according to Krabbe; it is probable, though not proven, that it has an internal secretion, and that is all that can be said, for the results of injections of pineal extracts have been quite inconclusive so far. The feeding of children and animals with pineal extracts has led to very ambiguous results at the hands of different observers. Another line of investigation that might throw light on its functions is the pathological; observation, that is to say, of the systemic disturbances associated with disease of the pineal body. According to Krabbe, about 70 cases of pineal tumour have been recorded up to the present time, and in 5 of these premature development of the sexual organs was noted, while in a few others the patient was obese. These few exceptional observations are hardly enough to base hypotheses upon, or to justify the attribution of sexual precocity to hypopinealism, for example, and of obesity to hyperpinealism. One more method of investigation remains for consideration, and that is the experimental ablation of the pineal body, followed by prolonged observation of its results. A contribution to this study has been made by Dr. Dandy,² who notes the extreme difficulty of the operative removal of a structure so deeply seated in the brain. His experiments were made upon young puppies; the chief difficulty surmounted was the tendency to haemorrhage from the veins (particularly Galen's vein) in the immediate neighbourhood of the organ. It is reached from in front, through the third ventricle, rather than

from behind, after free division of the splenium of the corpus callosum, in the latest and most successful method of operation devised by Dr. Dandy. One puppy survived the operation fifteen months, several others survived it for from three to eight months, another died of distemper after a year. The pineal was also removed in several adult dogs and bitches, and three of them were still alive four months after the operation. Dr. Dandy comes to the following conclusions. Removal of the pineal produces no sexual precocity or indolence, no adiposity or emaciation, no somatic or mental precocity or retardation. The pineal is apparently not essential to life, seems to have no influence upon the dog's well-being, and appears to have no active endocrine function of importance in either the puppy or the adult dog. What, then, are we to suppose is the function of the pineal gland? Dr. Dandy refers incidentally to what he calls "the anatomical evidences of its involution after the early years of life." This view of the gland's obsolescence is stoutly combated by Krabbe, whose extensive histological studies have convinced him that the fibrosis and calcareous concretions commonly found in the adult pineal are not to be taken as evidence of degeneration or involution. If, as appears to be the case, the pineal body has no internal secretion capable of individual recognition by the action of either its excess or its defect, Krabbe's view that it serves to regulate the pressure of the cerebro-spinal fluid is not without its attractions.

HYPOCHLORITES AS ANTISEPTICS.

The revival of the use of hypochlorous solutions for treatment of wounds in war, marked by the publication in this JOURNAL of the paper by Professor Lorrain Smith and his colleagues at Edinburgh, giving the results of their experimental observations on the antiseptic action of hypochlorous acid (July 24th), and that by Dr. H. D. Dakin on the use of a particular hypochlorite solution (August 28th), which he considers, and Dr. Carrel appears to agree with him, presents certain advantages, is one of the interesting developments of military surgery brought about by the experiences of the present war. A report by Dr. John Fraser on the value of hypochlorous acid in the treatment of cases of gas gangrene, published last week, contains striking evidence of the remarkable effect of the Edinburgh hypochlorite preparations to which the names "eusol" and "eupad" have been given. We understand that the Medical Director-General, R.N., has arranged with Sir Watson Cheyne, one of the consulting surgeons to the navy, to test the value of the hypochlorite solution devised by Dr. Dakin, and that they are now working together in a hospital ship employed in the Mediterranean. We hope that the medical profession as a whole may shortly have an opportunity of learning the results of their investigations and experiences.

THE NEW TAXES.

A copy of the Finance (No. 3) Bill, which incorporates the recent proposals of the Chancellor of the Exchequer, reaches us as this issue goes to press. Next week we shall deal more fully with the questions involved, but in the meantime we note that while the existing rebates on petrol duty will be extended to apply to the increased rates of duty now in force, no allowance in respect of the new import tax on motor cars will, as the bill stands at present, be made where cars are used for professional purposes.

The second meeting of the Pan-American Scientific Congress, which is to be held at Washington, will open on December 27th, 1915, and adjourn on January 8th, 1916. Among the nine sections into which the work of the Congress will be divided is one devoted to public health and the medical sciences. The chairman of this section is General William C. Gorras.

THE WAR.

THE WOUNDED FROM THE RECENT FIGHTING.

WORKING OF THE MEDICAL ARRANGEMENTS.

THE following extracts are from a letter written by an officer in France which has been placed in our hands. They show how the arrangements for the evacuation of the wounded after the recent fighting have worked. They will, we feel sure, interest many readers.

September 23th, 1915.

My dear —,

The medical arrangements are once more proving excellent. Everybody and every part of the machinery must, like the rest of us, have been working at very high pressure, but at the same time the system has been, and still is, working smoothly and with very effective results. In other words, the wounded are being picked up as rapidly as the operations in progress at the moment permit, and carried to the regimental aid posts by stretcher bearers, whence they are passed steadily through the field ambulance advanced dressing stations and field ambulance head quarters (being carried by the field ambulance's own vehicles) to the casualty clearing stations, which they reach by the motor convoy ambulances. At the casualty clearing stations they remain until fit to proceed further, and are then placed on the hospital trains (which are provided with nurses and doctors) and taken to the various hospital bases.

All this sounds, perhaps, rather complicated, but that the process is rapid you will agree when I tell you that I was talking this time yesterday (that is, about lunch time) to some men who had been wounded the previous evening and were already in the hospital train on their way to a base.

Another detail will emphasize the same point. I timed the loading of one particular hospital train. It reached the railroad at 12.45 p.m. and by 2 p.m. was ready to start on its return journey. Meantime, 450 patients had been placed in its beds, the actual time occupied in transferring them from the ambulances being less than an hour—to be precise, fifty-eight minutes. I was astonished when I found the total was so high, as throughout the process of loading there was no appearance of hurry. This was the day before yesterday, and by now many of these patients have probably been installed in hospitals on your side for several hours at least. They had all had their wounds overhauled at a casualty clearing station and any early operation desirable had already been performed; so many are likely to have been shipped across straight away.

I judge this to be probable even in the case of some of the more severe injuries, since the thigh and other splints now being used at the front, the fashion in which the wounds are dressed, the skill with which the patients are handled, the comfort of the trains, and the splendid equipment of the hospital ships all combine to make it possible to send a patient on a long journey without increasing his sufferings or interfering with his progress towards recovery.

The rapidity with which the evacuation of casualties goes on day by day seems to be due to several factors, of which the most important, perhaps, is that the medical authorities are not relying on a single route. In effect they have split up the country behind the active fighting line into three evacuating zones—a northern, a central, and a southern zone—each of which has its own means of access to the hospital bases. Each zone includes a proportionate number of casualty clearing stations, lying at varying distances from the actual fighting line, the majority of these being billeted, that is to say installed, in permanent buildings, such as schools, monasteries, and the like.

With the fighting line progressing as it now is, it is impossible to make any precise statement as to the distance that intervenes between any given casualty clearing station and the field ambulances which it serves, but in no case is it great. Taking, for instance, one of the more distant, an officer in charge of the Motor Ambulance Convoy connected with it told me yesterday that unless the road were really blocked with traffic he could go out

with his section of twenty motor ambulances, take his sick on board, return at loaded ambulance pace, unload, and be ready for another journey all within the space of three hours.

But even this statement is possibly a little misleading, for the casualty clearing stations are not being filled and emptied haphazard. Whenever possible the patients are classified, I find, at the field ambulance head quarters and the more serious cases sent to the nearest casualty clearing stations, the less serious to the more distant.

A good many serious cases, indeed, are not being sent to a casualty clearing station at all, but evacuated by means of large ambulances. Experimentation with these has been going on during the past few months, and there is now quite a number of them. The tendency to increase them is not remarkable, considering the degree of comfort they present. Three days ago I looked up a man on one of them, and found it difficult to realize that the thirty patients I saw had all been fighting the previous afternoon in the pouring rain. They were spotlessly clean and lying in real beds, which were even provided with mosquito curtains. They were bound for a port where they would be placed straight on board a hospital ship. The majority of them seemed to be chest cases.

Another point worth noting is that there are special arrangements for the treatment of abdominal cases. At several of the casualty clearing stations there are surgeons who in civil life take a special interest in abdominal work, and as many as possible of the patients with gunshot wound of the abdomen are being sent to these stations, one at least of which is very close up indeed. Such patients do not reach the casualty clearing stations concerned in what may be called the ordinary course, but are sent straight in by a field ambulance wagon as soon as picked up. The arrangement has been in existence for some little time in the area of the army now principally engaged, but this will be the first time on which it has been tried on a large scale. It will be interesting, therefore, to learn later on whether the results obtained have proved superior to those secured elsewhere. Should this not be the case, it may of course be objected that the arrangement does not satisfy the ideal, this apparently being that abdominal cases should undergo operation practically where they fall in mobile operating units. I doubt if the notion has ever been seriously entertained by persons really conversant with the conditions of twentieth century warfare, but should there be any one out here who has clung to it until now the events of the last few days must surely have sufficed to disabuse his mind.

The enemy aeroplane observers direct fire on any and every place where they see men to be collecting. For instance, the day before yesterday, an acquaintance of mine who is in administrative medical charge of a division, and therefore further away than would be a "mobile operating theatre," saw the building he had just been using as an office destroyed by shell fire. It was out of reach of rifle and field artillery fire, and shells from very heavy guns should have passed harmlessly hundreds of yards above it and a mile or two beyond; but a German aeroplane having managed to cross the line for a few moments spotted that the place was occupied and caused three high explosive shells to be plumped in its neighbourhood. The A.D.M.S. himself was not hurt, but several privates and a padre were killed.

I am afraid, indeed, that among officers and men of the R.A.M.C. the casualties during the last few days will be found to have been as heavy as in the same corps in the Dardanelles. Anyhow, I know of several casualties among medical officers of my own acquaintance, and I do not suppose that it is only my acquaintances who have been unlucky. Losses in the R.A.M.C. are inevitable when battalions are advancing. If they are very fortunate their medical officers may be able to comply with the standing order, which is, to establish their aid posts in a sheltered position, but it is not always possible. Besides this, when looking for such a place the medical officers are certain to be exposed to rifle fire, and when established they cannot be protected from shell fire. In "peace times" they can dig themselves in under cover of night, or otherwise contrive to secure for themselves and their patients a fairly safe position, but when an advance is being made little attention can be paid to the point. Indeed, even in the case of field ambulance head quarters the best that can

often be done is merely to keep them in a position where it is only to heavy artillery fire that they are exposed. Consequently, if you see that the casualties among the R.A.M.C. are as heavy on this occasion as I expect, do not conclude that they are due to inexperience or foolish recklessness on the part of the men concerned. Medical officers being both costly and valuable, it is part of their job not to get hit if they can help it, but, if they cannot, why "Quo fiero?" as we say in the lingua franca of the front. Anyhow, I hope I have now set your mind at rest to some extent. I have tried to make things plain, but have necessarily scribbled this letter at a great rate.

P.S.—An accident prevented my sending this off, so I am now able, three days later, to add a postscript which will bring you right up to date. The medical work has gone on as successfully as it started and that, as you will have already gathered, is in top-hole position. We already knew that the arrangements had been perfected to meet every contingency of the siege-like operations of the past few months, and we now see that the organization is so skilfully arranged that it can be transformed at a moment's notice and without a hitch to meet the conditions prevailing during a real advance. To know this will be consoling not only to you and your people, but is so even to ourselves, for at the back of our minds we know that the R.A.M.C. may any day have us in their hands. We do not think about it more than possible; we always think it is going to be the other fellow, but I know all the same how much reliance we place on the R.A.M.C., and the R.A.M.C. knows it, too. That is one reason why, even in "peace times," its officers get hit. The medical officers come along into the trenches while fighting is in progress, instead of staying at battalion head quarters, and I know how he backs up a wounded man when he finds he is getting first aid from a medical officer instead of from only a trained regimental orderly.

To complete what I told you in the first part of my letter, I now add that the evacuation of the whole of the casualties incurred during the four or five days that the recent fighting may be considered to have lasted has now, I hear, been completed. When an official statement is made as to their number, you will be able to gauge what a fine performance this represents. For evacuation does not merely mean getting the sick and wounded out of the way of the fighting troops. It means getting a wounded man off the battlefield and out of the field hospitals, which, although they have never been equalled in any previous war, are not ideal places for a badly wounded man, down to the splendidly equipped hospitals at the bases, where every comfort is available, where everything that modern knowledge can suggest is done for the men, and where, if their cases are unusually serious, they can even be seen by their friends. What the actual number of casualties has been I do not know; but whether it be two thousand or twenty times that number, their successful evacuation will always mean that the said number of helpless men have not only been skilfully treated by medical officers at the front, but, in addition, have been fed and transported a long distance by the same corps—in other words, a triumph of professional organization.

THE MEDICAL SERVICE OF THE AUSTRALIAN IMPERIAL FORCE.

THE defence forces of the Commonwealth of Australia are strictly, what the term implies, for home defence. The Commonwealth is divided into six military districts, and each district into military areas. The medical service is under a Director-General, and each district under a P.M.O., while each area has its medical officer. The various brigades have their full equipment of field ambulances and medical officers, while regimental service is also provided for. In addition a reserve of medical officers has been formed, consisting for the most part of the staffs of the various hospitals, for service in time of war.

When the war broke out the Commonwealth sent an Australian contingent, composed of men who volunteered for service abroad, and the troops so formed were called the Australian Imperial Force. With the first contingent went, as D.M.S., Surgeon-General W. D. C. Williams, the

Director-General of Medical Services, and as A.D.M.S., Colonel C. Ryan, P.M.O. of the third military district; three field ambulances, under the command of Lieutenant-Colonel Sutton, Newmarch, and Sturdee respectively; one light horse ambulance under Lieutenant-Colonel Sutherland; and the requisite number of regimental medical officers. Practically all of these men were already in the Australian Army Medical Corps. After the first contingent had been mobilized it was decided to send further medical units for lines of communication—namely, two general hospitals, two stationary hospitals, and one clearing hospital.

The 1st Australian General Hospital was commanded by Lieutenant-Colonel Ramsay Smith, of Adelaide, and its staff was formed largely of the leading surgeons and physicians of Melbourne and Brisbane, with x-ray specialist, pathologists, and bacteriologists of high standing. It consisted originally of 250 beds, but has been greatly expanded. The 2nd General Hospital was under the command of Colonel Martin, of Sydney, with a staff of leading practitioners from Sydney and New South Wales. The 1st Stationary Hospital, commanded by Lieutenant-Colonel Bryant, of Melbourne, had on its staff some of the leaders of the profession in Adelaide. The 2nd Stationary Hospital was under the command of Lieutenant-Colonel White, of Western Australia, with one surgeon from Melbourne and well-known West Australian practitioners on its staff; the Clearing Hospital, commanded by Lieutenant-Colonel Gblin, of Hobart, had one Melbourne surgeon and a leading Tasmanian practitioner on its staff.

All these hospitals were very fully equipped with up-to-date instruments, appliances, and laboratories. They were conveyed to Egypt by a specially fitted ship, the *Kyarra*, which was subsequently used as a transport for taking invalided soldiers back to Australia. All the hospitals remained in Egypt for about three months. When the Australian divisions went to Gallipoli the two stationary hospitals and the clearing hospital went with them, while the two general hospitals remained at the base in Egypt. Before this occurred, however, a fourth field ambulance, under Lieutenant-Colonel Downes, and another field ambulance, with the third brigade, under Lieutenant Colonel Beeston, had been dispatched from Australia. With the various reinforcements a great number of medical officers of varying ranks have been sent, and more recently the third general hospital has gone to the front, with a large staff of leading surgeons and physicians from Sydney and Melbourne, under the command of Colonel Fiaschi, of Sydney. Still more recently the staff of another general hospital has arrived in England, under the command of Lieutenant-Colonel Hayward, of Adelaide. In England an auxiliary hospital of 500 beds (which it is proposed to increase to 1,000) has been established at Harefield Park, and the medical staff for it, and for 500 beds (to be increased to 1,000) at the convalescent home at Woodcote Park, Epsom, and for 500 beds at the City of London War Hospital, Epsom, have been supplied from Australia. Finally, two Australian hospital ships have been staffed and equipped, each carrying 40 officers and 1,400 other ranks. A transport for invalids has been fitted up and staffed, carrying 15 officers and 450 other ranks, and is now on her way to Australia, taking back men permanently unfit for war service. She will be followed by similar transports at suitable intervals.

It may be mentioned further that besides what has been done by the Commonwealth Government, the Australian Voluntary Hospital, under the command of Lieutenant-Colonel Eames, of New South Wales, and staffed by Australians and ex-Australians, left London for France on August 21st, 1914, and has been situated in turn at Havre, St. Nazaire, and Wimereux. Lieutenant-Colonel Bird, lecturer on surgery at Melbourne University, volunteered at the beginning of the war with the staff of his private hospital. He was given a commission in the R.A.M.C., was for a time consultant surgeon to the forces in Egypt, and then on the hospital ship *Sicilia*. In response to a request from the War Office 150 medical men from Australia have joined the R.A.M.C.

An unfortunate incident has unhappily occurred in connexion with the 1st Australian Hospital. From a report in the *Age*, we learn that on the motion for the adjournment of the House of Representatives on August 19th,

Mr. Mathews said that he understood that as a result of an investigation Dr. Ramsay Smith and others were returning to Australia; he asked for further information. The Minister for the Navy, in reply, said that the chief medical officer, Dr. Fetherston, was proceeding to Egypt to inquire and report on the matter. The *Adelaide Advertiser* of August 25th contained an article purporting to explain the incident. It stated that the High Commissioner in London had telegraphed early in July to the effect that the Director-General of the Army Medical Service at the War Office had reported that complaints received regarding the administration of the 1st Australian General Hospital, Cairo, were of such a nature as to justify an immediate investigation. The High Commissioner concurred with the proposal, and the Army Council, which had expressed its willingness to undertake an inquiry, was invited by the Commonwealth Government to investigate the complaints and submit recommendations. An inquiry was accordingly instituted, and recommendations made to the Commonwealth Government that certain changes in the personnel should be made which involved the recall of Lieutenant-Colonel Ramsay Smith and the matron to Australia.

Lieutenant-Colonel Newmarch has, we understand, been appointed commandant of the hospital, and Lieutenant-Colonel Barrett will act as ophthalmic consultant with the force in Egypt, an appointment which he had held concurrently with that of registrar of the hospital.

THE HOSPITALIZATION OF THE CANADIAN EXPEDITIONARY FORCE.

(From a Canadian Medical Officer.)

IN connexion with the Canadian Expeditionary Force it is well to make a sharp distinction between the care of the Canadian wounded and the Canadian Medical Service. It is true that at the beginning of the war this distinction was not by any means fully realized, even by those at head quarters. The Canadian Army Corps was part and parcel of the British Expeditionary Force and, Naomi-like, felt that "my people are thy people." So it still feels. It is proud that its field ambulances, casualty clearing stations, and general and stationary hospitals overseas are of service to lend and treat all branches of the service and all divisions of the forces of the Empire; proudest of all that no less than five Canadian hospital units are either at the present moment with the Mediterranean Forces or on the way there—and this wholly irrespective of the presence or absence of any Canadian troops in that field of operations. But, granting this, the last few months have made it more and more evident that here in Great Britain, when Canadian invalids return from overseas, it is best that, instead of being scattered throughout the length and breadth of the British Isles, they should be collected together in hospitals and convalescent depôts of their own, and this not merely as a matter of discipline but as most conducive to the content and good spirits of the wounded and to their more rapid recovery. At first it seemed good policy that the men from across the ocean should be scattered through the old land, should be cared for as special—and most often, as it happened, as honoured—guests, should come to know the old home people and the old homeland. And as a matter of fact, innumerable letters to Canadian homes, which have found their way into Canadian papers, have revealed how the beauties of the English countryside, the treatment received in little country towns, and the kindly, not to say wonderful, hospitality lavished in many a luxurious country house on our convalescing soldiers have left an ineradicable impression.

There is, however, another side to the picture. When, a few weeks ago, Sir Robert Borden, being in Manchester or its neighbourhood, wished to visit the Canadians in hospital there, it was found that twenty-seven Canadian soldiers were distributed between twenty-four hospitals! It is not surprising that many of these men felt isolated and depressed; after the long months of intimate comradeship they, or many of them, felt wholly adrift from their battalions, longed to be with other Canadians, to swap

stories and find friends with whom to live over again the unforgettable days. So many petitions in fact have been carried at head quarters in London from individual soldiers asking to be transferred to the Duchess of Connaught's Red Cross Hospital at Cliveden or other centre where they might be with other Canadians, that evidently it is for the good of the Canadian Expeditionary Force as a whole that distinctively Canadian hospital centres should be established. It is interesting to note that both Australia and New Zealand have come to a like conclusion and have taken steps in the same direction.

So this policy is in the course of being carried out. With great consideration Mr. Waldorf Astor has consented that the hospital in his grounds at Cliveden be not only Canadian as regards its staff, but Canadian also as regards its patients. The hospitals in the Shorncliffe area are becoming more and more Canadian as regards their occupants. The Moore Barracks Hospital, Shorncliffe Military Hospital, and the Tent Hospital at St. Martin's Plain, are staffed by the C.A.M.C., and have almost exclusively Canadian patients; the Canadian War Hospital at Walmer also takes in only Canadian patients, and the Helena Hospital at Shorncliffe has wards devoted exclusively to the members of the same Expeditionary Force. All tuberculous patients from the C.E.F. are sent to Pinewood, Wokingham. What is more, arrangements are being made for other special hospitals for nervous patients, for eye, ear, nose, and throat cases, and the likelihood is that in the course of the next few months these special hospitals and special "clinics" will be considerably augmented. The Granville Hotel at Ramsgate will shortly be opened as a hospital for special conditions.

For a considerably longer period the advantages of this policy have been realized in the case of convalescents, and this because numbers of Canadian patients treated in convalescent homes throughout the country were granted furlough indiscriminately without notification to the Canadian authorities, and were as a consequence lost sight of for months, many being proceeded against as deserters. Thus ever since early summer non-commissioned officers and men from the hospitals in the London district have been gathered together at Bromley Park, those from the rest of England at the larger hospital at Monks Horton, near Shorncliffe. Now, as autumn is advancing, and tent life is becoming uncomfortable for invalids, a series of other Canadian convalescent hospitals is being thrown open. There are already close upon 600 Canadian convalescents in the huts at Woodcote Park, Epsom. Hillingdon House, Uxbridge, is being used as the convalescent annexe for Cliveden, while the Friendly Society's Convalescent Hospital at Dover, the Glack Convalescent Hospital at Deal, Mrs. Flemming's Convalescent Hospital at Luton House, Selling, and Lady Northcote's lovely home at Eastwell Park, Ashford, are all devoted to Canadians—this last since the early part of June. Bearwood Park, Wokingham, will be opened within the next few days with the same object. Many homes have been thrown open specially for Canadian officers—more, in fact, than can be utilized. Among these, special mention must be made of Nuneham Park, Oxford, the home of the late Colonial Secretary and Mrs. Harcourt; Holme Pierrepont, offered by Lord Manners; Merlewood, Virginia Water, the home of Mr. Donald Macmaster, M.P.; and the Moorings, Sunningdale, offered by Mr. Wills.

While these preparations are under way, the people in Canada have not been idle. With the active support of their Royal Highnesses the Duke and Duchess of Connaught, from one end of the continent to the other there has been an enthusiastic movement to provide convalescent hospitals for the wounded; that where healing is likely to be a lengthy process, Canadian soldiers may be returned home and there undergo recovery. By private generosity and public subscription numerous well-appointed homes or hospitals have been offered and accepted by the local Governments, one or more in each province, so that at the present moment it is likely that at least eleven such institutions, capable of caring for 2,000 or more wounded, will, when this appears in print, be ready to receive patients. At Quebec the Immigration Building, admirably adapted for the purpose, acts as a receiving hospital, from which the patients are distributed throughout the Dominion. When the St. Lawrence becomes closed to

navigation in November this will be replaced by a similar receiving hospital at Halifax.

At first thought all these preparations may seem excessive, but when it is remembered that competent authorities have placed the casualties in the present campaign at something well above 100 per cent. per annum, it is seen that even now more may have to be accomplished.

CANADIAN MILITARY HOSPITALS.

From our Correspondent in Montreal.]

THE MCGILL MILITARY HOSPITAL IN FRANCE.

THE McGill Hospital, No. 3 Canadian General Hospital, has been at work in France since August 10th last, when it received its first two convoys of wounded. The hospital is well situated on sandy soil, and in the immediate vicinity are four other general hospitals of 1,000 beds each, among them No. 1 Canadian General Hospital, under Colonel Murray MacLaren, and the Harvard unit, No. 2 Stationary Hospital, under the command of Colonel Shillington, is also situated near by. With the exception of the operating-room, which is a wooden structure, the McGill Hospital is under canvas. The Durbar tents in use were supplied by the British Government, and are part of a presentation made to the War Office by the Begum of Bhopal and other Indian magnates. Some of these tents hold nearly 50 beds; they are floored, and are to be lighted with electricity. Each tent has an outer shell, and a narrow corridor from 2 to 3 ft. wide runs between it and the inner tent, thus securing shade and coolness in summer and warmth in winter. The covering of both outer and inner tent is composed of three layers, the innermost being a soft yellow cotton beautifully decorated in Oriental style; the tent poles and other wooden fixtures correspond in colour. Some of the nursing sisters who left Canada with the unit were scattered for a time amongst other hospitals, for instructional purposes chiefly, but all have now rejoined the hospital.

THE LAVAL MILITARY HOSPITAL.

No. 6 Stationary Hospital, which has been organized by the medical faculty of Laval University, Montreal, has been recruited in Montreal under Lieutenant-Colonel G. E. Beauchamp, who is in command. The officers are: Major J. O. D. LaCroix, Major J. P. Décarie, Major Georges Bourgeois, Captain J. A. Lussier, Lieutenants J. U. Gariépy, J. de G. Joubert, J. E. Lorrain, L. D. Collin, Henri M. DuHamel, and Honorary Lieutenant E. R. LaMontagne, Quartermaster. The unit will probably spend a few weeks at Valcartier before leaving Canada about the beginning of November. A few days ago a special convocation was held at Laval University, at which members of the different faculties were present, when the following resolution was passed: "We learn with pleasure of the initiative of the Faculty of Medicine in organizing the Laval Stationary Hospital."

CANADIAN MILITARY HOSPITALS IN EGYPT.

No. 5 Stationary Hospital, Canadian Expeditionary Force, is in Egypt. This unit was supplied by Queen's University, Kingston, and is under the command of Lieutenant-Colonel Etherington. No. 1 Stationary Hospital, which left Canada with the first contingent of the Expeditionary Force, and is under the command of Lieutenant-Colonel S. Hanford McKee of Montreal, is also reported to have gone to Egypt, as well as No. 3 Stationary Hospital, commanded by Colonel Casgrain of Windsor, Ontario.

THE ST. JOHN'S BRIGADE HOSPITAL.

The hospital known as the St. John's Brigade Hospital, erected at Etaples by the St. John Ambulance Association, was projected last February, and has now been at work for some three or four weeks. It is a 520 bed hospital, consisting entirely of huts. The huts are of wood both inside and outside, the outside being stained or painted dark brown. Each hut is 20 ft. wide and 100 ft. long. The end of each hut furthest from its main entrance is partitioned off to provide space for a bathroom and a ward scullery; between these is a passage leading to a

sanitary annexe. The short corridor between annexe and ward has cross ventilation. The ward units are connected to one another and to the administration block and reception block, as also with the huts containing the kitchen, the dispensary, the x-ray room, and the life, by wooden corridors provided with roofs but open at the sides. All the ward units are disposed in lines parallel with the central corridor, but at varying distances from it. This central corridor forms a spine to the whole building, and has at one end the kitchen and the store-rooms and at the other the administration block and the reception department. At intermediate distances along the central spine and opening straight on to the corridor that forms it are various huts arranged as dining-rooms for the patients, for the sisters and medical staff, each provided with a large anteroom, as a pathological laboratory and dispensary, as a dental department, and as a splint-room, etc. The operation block contains two operation rooms with natural overhead and side lighting, as well as with electric lamps. They are so arranged that the operation table can, if necessary, be run into the adjoining x-ray room and the operation then completed. The upper halves of the ward windows drop inwards from the bottom, but are built in at the sides, so as to secure an upward inlet of air without draught. The beds are not of the pattern generally used in field hospitals, but of the pattern commonly employed in civil hospitals at home. They have a fairly high head rail and all are bored for the reception of an arm to support a pulley. The ward doors are sufficiently wide for the beds to be wheeled on to the corridor.

In one of the huts at the kitchen end is a very large dynamo which provides current both for the x-ray department and for a refrigerating machine. The same room contains a soda-water manufacturing plant. The sleeping quarters for the officers are divided from the hospital by a road, and stand under a small grove of pine trees. They consist of two huts divided up into a number of separate rooms or cubicles. It is the kitchen end of the hospital that faces this main road; lorries bringing supplies are thus able to unload without causing disturbance. The reception room at the other end faces a private road for ambulances. The reception block consists of several rooms of which the central one is provided with four tables, opposite each of which is a movable stretcher stand. The whole of one ambulance load can therefore be dealt with simultaneously, the process consisting in taking down particulars as to the patient's name and regimental number and pinning on to him a brass disc showing the number of his ward, as soon as the reception room medical officer has settled with which ward the patient is to be sent. These preliminaries completed, the patient and his stretcher are placed on a bicycle-wheel stretcher-carrier, and he is wheeled off to his ward. The whole process is rapid. At one end of this central reception room are benches for walking cases, who are dealt with on much the same lines, but before being sent to the wards they pass into rooms adjoining the main room, and there they get rid of their uniforms and other clothing and then pass into another long room, provided with a dozen or more baths.

All the huts, as also the corridors, are raised on piles to a distance from the ground varying from 6 in. to 2 ft. The height varies because the site is a sandy slope with an irregular surface. It is possibly the character of the surface which first suggested not only raising the whole of the buildings on piles, but also the provision of connecting corridors. The corridors are very useful, for owing to them nothing need be carried by hand; anything can be wheeled about on light trolleys—patients' meals, medicine baskets, ward linen.

The solid excreta and refuse of the hospital are burned in a Horsfall incinerator. The liquid refuse is removed by drains to catchpits on waste ground lying a considerable distance below the slope on which the hospital stands. The hospital is very well equipped, but there is no evidence of extravagance in its outfit. The general appearance suggests that everything has been thought out in minute detail and in advance. The distinctive features of the hospital are: (1) Its erection upon piles which make the state of the weather a matter of indifference; (2) easy communication with all parts of the hospital by covered corridors, which, as already indicated, greatly facilitate

work; (3) the arrangement of the reception room; and (4) the carrying away of all refuse water by easily controlled drains.

WAR MEDICAL MOBILIZATION IN FRANCE.

(From an Occasional Correspondent in France.)

In France all medical men in good health, under the age of 50, are mobilizable, but a large proportion of valid men over that age volunteer for service, and are accepted, though they are not sent to the front unless they expressly solicit the privilege. Their uniform comprises a cap (*képi*) bearing a broad band of crimson velvet, which serves to identify them as belonging to the *service de santé*. The civil practitioner enters as *aide-major* with one or two stripes, but most practitioners have done their military service, and already have the grade of lieutenant or captain. When mobilized, practitioners are not allowed to undertake private practice, though their services are available on an emergency. In fairness to all, it has been decreed by the Minister that no practitioner in charge of a hospital or *formation sanitaire* shall be allowed to take a post in the district in which he normally resides, but this is a rule which apparently admits of numerous exceptions, though of late an outcry on the part of those who have been distinguished under it against those who have contrived to elude its operation, has led to a reshuffling of the cards.

All wounded whose injuries entail functional disturbances likely to be benefited by thermal spa treatment are sent to one or other of the famous watering places and given a course of baths, douches, and massage, etc., the maximum duration of the treatment being fixed at three weeks. Similarly, advantage is taken of the various mechano-therapeutic institutes to restore mobility to damaged or stiffened joints. At the termination of the course of treatment the men are returned to their regimental *dépôt*, thence to be sent back to the front, or to be accorded a furlough of from one to three months. If permanently disabled, they are discharged from military service. Men not strong enough to return to the front but still capable of discharging less exacting duties are drafted into the auxiliary departments—hospitals, secretarial duties, and the like.

The *formations sanitaires*, or auxiliary hospitals, distributed all over France, are placed in charge of one or more mobilized medical men with, as a rule, one *chirurgien de carrière* in each district for the big operations. An average number for each surgeon in charge would be about 150 beds, inclusive of medical cases. Inasmuch as at least 15 per cent. of the patients have serious wounds necessitating protracted dressings, this means that the surgeons have their hands full, especially when allowance is made for operations, x-ray research, etc. Each town or district is provided with a *médecin en chef de la place*, whose function is to see that the accommodation is sufficient for a specified number of wounded, to keep a record for transmission to the central authorities of the number of beds vacant each day, to provide medical assistance, and to superintend arrangements generally. These *médecins en chef* are usually elderly professors from the universities or practitioners who have passed the age for active service. I may add that no surgeon is authorized to perform any grave operation without previous consultation with a colleague.

One noteworthy shortcoming is a lack of provision for enabling the wounded to take baths, with the unavoidable consequence that they are usually very dirty, especially round about the feet; indeed, it could hardly be otherwise. In a certain *dépôt* where seven or eight hundred soldiers are interned the only bathing accommodation is a washing tub (half a wine barrel), the water for which has to be heated over the gas or brought a distance from the kitchen.

One great difficulty in France is the provision of nurses—I am not referring to the properly trained nurse, because she is, to all intents and purposes, non-existent. Those we have are, for the most part, young women drawn from the middle classes, who have had a few weeks' prefactory training (not comprising any practical hospital training) in bandaging and the principles of antiseptic. Even so, there is a decided lack of adequate assistance, and advantage has to be taken of English, American, and Swiss

volunteers. *Infirmières* are never paid; at most they are given their meals, washing, and, in some instances, sleeping accommodation; consequently the choice is restricted to young women not dependent upon their earnings for a living. This may account for the difficulty experienced in obtaining an adequate number of recruits. Nurses are expected to take their turn at night duty without relinquishing their daily duties in the wards, and their hours are unmercifully long, from 8 a. m. to—well, until there is nothing left to be done, say, 9 or 10 o'clock at night.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

CAPTAIN THOMAS HENRY STANLEY BELL, R.A.M.C., was killed in France on October 1st. He was the eldest son of Dr. A. Lees Bell, of Ballochmyle House, Dunfermline, was educated at Dunfermline High School and at the universities of Glasgow and Edinburgh. He graduated M.B. and Ch.B. at Edinburgh in 1914. He was for four years a member of the Edinburgh University Students' Representative Council, and served in the Serbian Army Medical Corps during the war in the Balkans. He joined the Special Reserve of the R.A.M.C. as Lieutenant on September 3rd, 1914, and was promoted to Captain on completion of a year's service.

Captain Sydney Francis Macalpine Cesari, R.A.M.C., was killed in France on October 3rd. He was the second son of the late Edward Cesari of Inverness and Birnam, and was educated at Perth Academy and at Edinburgh University, where he graduated M.B. and Ch.B. in 1913, and afterwards filled the posts of house-surgeon at Greenock Infirmary and house-physician at the Royal Infirmary at Edinburgh. He was a keen football player, and was a member of the Edinburgh University and Greenock Wanderers fifteens successively. He joined the R.A.M.C. Special Reserve on April 8th, 1913, was called out for service on August 12th, 1914, and was recently promoted to Captain on completion of a year's embodied service. His death was due to a bullet fired by a German sniper.

Captain Edward Worsell Carrington, R.A.M.C., was killed in France on September 25th or 26th, 1915, aged 26. He was the youngest son of the late Sir J. W. Carrington, of Avenue House, Reading; was educated at Marlborough, at Keble College, Oxford, and at King's College, London, and took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1913. He joined the R.A.M.C. as a temporary Lieutenant on August 10th, 1914, was sent to the front soon after, and had been attached to the 2nd Battalion Worcester Regiment for over a year. He was promoted to Captain on completion of a year's service, and last February received the Military Cross for gallant behaviour.

Lieutenant Edward Henry Pollock Brunton, R.A.M.C., was killed in France on October 8th, aged 25. He was the younger son of Sir Lauder Brunton, M.D. F.R.S., was born in January, 1890, and was educated at Fettes, at Trinity College, Cambridge, and at Bart's. After taking the M.R.C.S. and L.R.C.P. Lond. in 1913, he served as house-surgeon to the Royal Portsmouth Hospital, and as house-physician at Bart's, took a commission as temporary Lieutenant in the R.A.M.C. on April 2nd, 1915, and in July was attached to the 4th Battalion Grenadier Guards, with which he was serving when he was killed.

Lieutenant Robert Montgomery, R.A.M.C., was killed in the recent advance in France on September 26th. He was the son of Mr. Robert Montgomery, schoolmaster, Broxburn, and took the M.B. and Ch.B. at Edinburgh in 1913. Afterwards he acted as medical officer to the garrison of Edinburgh Castle, and then as an assistant in Leith. He joined the Special Reserve of the R.A.M.C. as Lieutenant on July 11th, 1913, and was called out on August 12th, 1914.

Lieutenant Edward Jocelyn Nangle, R.A.M.C., attached 1st Battalion Royal North Lancashire Regiment, was killed in the recent advance in France. He was a native of East London, Cape Province, South Africa, was educated at Cambridge, where he took the B.A., and at St. Mary's, where he was a member of the Rugby football fifteen, and served as house-physician and house-surgeon. He took the M.R.C.S. and L.R.C.P. Lond. in 1912, and got a

temporary commission as Lieutenant in the R.A.M.C. on August 14th, 1914.

Lieutenant James Richardson Spensley, R.A.M.C., attached 8th Battalion East Kent Regiment (the Buffs), was killed in the recent advance in France. He was educated at the London Hospital, and served as house-surgeon there, after taking the M.R.C.S. and L.R.C.P.Lond. in 1901. He then settled at Genoa, where he was port surgeon. He was a keen supporter of the boy scout movement, of which he was chief commissioner for Italy. He had only recently taken a temporary commission in the R.A.M.C.

No less than eleven officers of the R.A.M.C. have now been reported as killed in the recent advance in France since September 25th.

Died on Service.

Captain Gurney White Buxton, R.A.M.C.(T.F.), died at the Dardanelles in September. He was educated at St. Bartholomew's Hospital, took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1891, and was in practice at Fenny Stratford, Bucks. He was an officer of the 2nd South Midland Mounted Brigade Field Ambulance, in which he attained the rank of Captain on November 13th, 1911.

Wounded.

Captain E. Gordon, R.A.M.C. (temporary), Flanders.
 Captain C. Robertson, R.A.M.C. (temporary), Flanders.
 Lieutenant C. T. Bishop, R.A.M.C. (temporary), Flanders.
 Lieutenant W. S. Martin, R.A.M.C. (temporary), Flanders.

DEATHS AMONG SONS OF MEDICAL MEN.

Allan, Marshall T., Lieutenant 6th Battalion Royal Scots Fusiliers, son of the late Dr. George R. Allan, of 19, Woodside Place, Glasgow, killed in France September 25th to 28th, aged 26. He was educated at Glasgow University, where he was a medical student, was in the Officers' Training Corps for four years, and was in the university football, cricket, and hockey teams. He got a commission as Second Lieutenant on September 1st, 1914, went to France in the spring, was bomb officer of his battalion, and was promoted to Lieutenant in August.

Allen, Herbert Thomas, Captain 9th Battalion Seaforth Highlanders (Ross-shire Buffs), youngest son of the late Brigade-Surgeon W. E. Allen, I.M.S., killed in France on September 25th, aged 32. He had served as a civil engineer in Africa, India, and Trinidad, was an A.M.I.C.E. and F.R.G.S. In the early part of the war he held a commission in the Royal Naval Reserve, and served for four months of his service in the North Sea; joined the army in January, and became Captain on February 1st.

Cameron, Roy Douglas, Lieutenant 6th Battalion Cameron Highlanders, second surviving son of Lieutenant-Colonel C. S. Cameron, I.M.S. (retired), killed in France September 25th or 26th. He was educated at Exeter College, Oxford, and got a commission on August 29th, 1914.

Carswell, John Jamieson, Second Lieutenant 10th Battalion Cameronians (Scottish Rifles), younger son of Dr. John Carswell, Commissioner, Central Board of Control, Scotland, 25th to 27th. He was born in Glasgow in 1889, educated at Glasgow Academy, the Glasgow School of Art, and the West of Scotland Technical College, and held a scholarship as apprentice architect with Mr. James Millar, A.R.S.A. He enlisted in the 9th (Glasgow Highlanders) Battalion of the Cameronians at the beginning of the war, got a commission on October 24th, 1914, and went to the front in July.

Cordeux, Edward Henry Noble, Second Lieutenant 7th Battalion Sherwood Foresters, only son of the late Dr. Robert Henry Cordeux, of Burton Park, Nottingham, killed in Flanders on September 30th, aged 19. He got his commission on September 26th, 1914.

Cressley, George E. L., Lieutenant 2nd Battalion Yorkshire Regiment, younger son of Dr. Cressley, of Tunbridge Wells, killed in France on September 26th, aged 20. He was educated at Tunbridge School, where he held a Junior Scholarship, and left school in July, 1914, with a scholarship at Cambridge. Called up in the 2nd Battalion of the 2nd South Midland Regiment in the Kent Cycle Corps on August 6th, 1914, went through the special war course at Sandhurst in spring, and was gazetted to the Yorkshire Regiment on May 12th, 1915. He went to France in July, was employed there on special trenching work, and joined his regiment shortly before his death.

Dobson, Montague Charles, Major, Royal Garrison Artillery, second son of Nelson C. Dobson, F.R.C.S., of Clifton, killed in France on September 25th-28th, aged 38. He was born on February 26th, 1879, joined the Artillery as Second Lieutenant on February 26th, 1898; became Lieutenant on February 16th, 1901; Captain on October 24th, 1905; and Major on October 30th, 1914. He served in the South African War in 1899-1902; took part in operations in the Transvaal, Orange River Colony, and Zululand; was twice mentioned in dispatches; and gained the Queen's medal with three clasps and the King's medal with

two clasps. After the war he was employed for four years in surveying Basutoland, and in the early part of the present war was assistant embarkation officer at Southampton.

Donaldson, Denis Harrison, Second Lieutenant 7th Battalion London Regiment, elder son of Dr. T. C. Donaldson, the Elms, 19. He was educated at Epsom College, and at the City and Guilds Engineering College, London, enlisted in his battalion early in the war, went to France in March, served in the action at Festubert, and was gazetted to a commission from September 24th, the day before his death.

Duirs, Morris Williams, Second Lieutenant 7th Battalion King's Own Scottish Borderers, youngest son of the late Dr. D. E. Duirs, of Johannesburg, South Africa, killed in France, September 25th to 27th, aged 22. His commission was dated December 12th, 1914.

FitzMaurice, Richard, 1st Battalion London Scottish, fourth son of Dr. Richard FitzMaurice, of Littlehampton, Sussex, late of Lindfield, killed in France, September 25th-28th, aged 25.

Gillett, Edward Francis, Second Lieutenant Royal Field Artillery, eldest son of Dr. Jermyn Francis Gillett, Elvin House, Audover, killed in France on September 28th, aged 21. He got his commission on January 23rd, 1915.

Hare, Bernard Crumston, Second Lieutenant First Battalion Middlesex Regiment, youngest son of E. H. Hare, F.R.C.S., of Aylesford Lodge, Hornsey, killed in France, September 25th-28th, aged 22. He was educated at Highgate School, where he was in the Officers' Training Corps, and joined the Artists' Rifles before the war. He took an interest in social work, and was Scoutmaster of the 66th North London section, and a commission in the 14th Battalion of the Middlesex Regiment on November 23rd, 1914, but was senior in command of the bombardiers of the 1st Middlesex when killed. His eldest brother, Amys, was killed at Neuve Chapelle, the second is serving in the Indian Army in command of a destroyer, and the third, Jack, a Lieutenant in the 210th Middlesex, has been wounded at Gallipoli.

Hopkins, Lewis, Second Lieutenant, 8th Battalion Somerset Light Infantry, youngest son of the late Surgeon-Major Nathaniel Hopkins, I.M.S., killed in France, September 25-27th, aged 29. His commission was dated March 1st, 1915.

Lloyd, Cecil D., Norton, Second Lieutenant, 8th Battalion West Kent Regiment, second son of Dr. Hugh Lawson of Chislehurst, killed in France, September 25th, aged 19. He was educated at Halesbury, enlisted in the Public Schools Battalion at the beginning of the war, and got a commission on September 22nd, 1914.

Moore, William Henry Walker, Second Lieutenant, 6th Battalion Wiltsire Regiment, son of Dr. Moore of Walton Grange, Stroud, killed in France, September 23rd, aged 18. His commission was from September 23rd, 1914.

Moran, Herbert James, Lieutenant, 8th Gurkhas, younger son of the late Lieutenant-Colonel James Moran, I.M.S. (retired), killed in France, September 25-28th, aged 24. He was born on January 17th, 1891, joined the army as Second Lieutenant on January 20th, 1912, and joined the Indian army on March 11th, 1914.

Moran, William Paul, Lieutenant, 10th Gurkhas, eldest son of the late Lieutenant-Colonel James Moran, I.M.S. (retired), died at Malta on July 8th of wounds received in the Dardanelles. He was born on January 23rd, 1887, educated at Bedford, joined the East Surrey Regiment as Second Lieutenant on January 29th, 1906, and the Indian army on October 5th, 1907, as Second Lieutenant on November 29th, 1908.

Myddleton-Gavey, Francis Edward, Captain, 2nd, attached to 4th, Battalion Worcester Regiment, only son of Major E. H. Myddleton-Gavey, R.A.M.C.(T.F.), late of Eastbourne, killed at the Dardanelles on September 26th, aged 27. He was born on January 24th, 1888, became Second Lieutenant on September 9th, 1908, joined the Indian army on November 7th, 1909, being posted to the 1st Gurkhas, became Lieutenant on December 9th, 1910, and resigned in 1913. He returned to the Worcester Regiment as Lieutenant on February 9th, 1915.

Paramore, Charles Gordon, Captain 8th Battalion Royal Berkshire Regiment, fourth son of the late Dr. Paramore of Gordon Square, London, killed in France on September 25th, aged 30. He became Captain on February 18th, 1915.

Ryan, James H. A., Captain 1st Battalion King's Liverpool Regiment, younger son of Dr. W. H. Ryan, of Road, Northamptonshire, killed in France, September 25th. He was educated at Downside School and at Sandhurst, which he represented at Association football, cricket, and athletics, and also won the half-mile at the army athletic meeting at Aldershot in 1913. He joined his regiment in February, 1912, became Captain on August 5th, 1914, went to France in August, 1914, and served in the 1st Regiment from 30th to 31st of August at the end of which he was the only officer of the battalion who went out in August, 1914, still unwounded. He won the Military Cross early in the war. As a cricketer he had also played for Northamptonshire.

Treameane, Arthur John Newman, Major 8th Battalion Seaforth Highlanders (Ross-shire Buffs), eldest son of the late Mr. John Treameane, M.R.C.S., of Melbourn, Cambs., killed in France, September 25th, aged 38. He was educated at Geelong School, Ormonde College, and Melbourne University, and had the degrees of M.A., M.Sc., and LL.M., and was also a barrister-at-law of Gray's Inn. In 1899 he went with the first Victorian contingent to South Africa, where he served in the operations in Cape Colony, including the action at Colenso, was wounded, and received the Queen's medal with two clasps.

He went from the Cape to West Africa, where he was on special service in the Ashanti campaign of 1900, receiving another medal and clasp. He subsequently served as Adjutant of the West African Regiment at Sierra Leone, as Superintendent and Staff Officer of Police in North Nigeria, and as Political Officer on the Boundary Commission. He acquired a thorough knowledge of the Hausa language, for which he got a scholarship at Christ's College, Cambridge, and was appointed lecturer in that language to the university. On December 25th, 1909, he was appointed Major and second in command of the 22nd (Queen's) Battalion of the London Regiment, but was transferred to the Reserve on taking up work in the Hausa colony in Tunis and Tripoli. When he broke out he was in Australia. He came home at once, and was reappointed Major on October 24th, 1914, this time in the Seaforths. He was the author of several works on the Haussas.

MEDICAL STUDENTS.

Calder, George M., Second Lieutenant 8th Battalion Seaforth Highlanders (Ross-shire Buffs), youngest son of George M. Calder, of Pressley, Forres, killed in France September 25th-28th, aged 24. He was educated at Aberdeen, where he had taken the M.A., and had completed his second year in medicine when the war broke out. He then enlisted in the Gordon Highlanders, and went to France as a sergeant in that regiment. He got a commission on February 25th, 1915.

Cruikshank, Harold A., Lieutenant 2nd Battalion Royal Scots Fusiliers, only son of the late William Cruikshank, of Kimberley, South Africa, killed in France on September 28th, serving as machine gun officer of his battalion. He was in his third year of medical study at Glasgow University. His commission was dated April 1, 1915.

Finlay, Thomas Pressell, Captain 3rd, Attached 2nd Battalion Gordon Highlanders, killed in France September 25th-28th. He was the only son of the late Robert Finlay, of Blackhill, Bonnybridge. He was in his final year of medical study at Glasgow University, and in the O.T.C. there when the war broke out. He got a commission as Second Lieutenant in the 4th Battalion of the Argyll and Sutherland Highlanders from August 15th, 1914, later was transferred to the Gordons, where he got his Company in July.

Harley, George Melven, Captain 12th Battalion Highland Light Infantry, killed in France on September 25th, aged 25. He was a medical student at Anderson's College and the University, Glasgow, and in the O.T.C. there. Three years ago he joined the Special Reserve of Officers, on May 18th, 1912. He became Lieutenant on October 15th, 1914, and Captain on February 1st, 1915.

James, Douglas Charles, Second Lieutenant South Staffordshire Regiment, died in France on September 30th, of wounds received on the 25th, aged 20. He was the second son of Charles Henry James, Esq., J.P., of Ingledene, Plymouth, and was a medical student at Bart's. His commission was dated November 4th, 1914. His elder brother, Lieutenant William Douglas James, Royal Garrison Artillery, was also killed on September 25th.

NOTES.

THE MOTOR LABORATORY OF THE WELSH DIVISION.

The equipment and personnel of a divisional bacteriological laboratory has been sanctioned in connexion with the 38th Welsh Division. The war establishment is one captain, one lieutenant as assistant bacteriologist, one laboratory attendant (a sergeant or corporal), and one driver A.S.C. (mechanical transport). The transport consists of the motor laboratory (five tons), with one driver provided from the divisional supply column, and one motor cycle for the use of officers for inter-communication. The laboratory, it may be remembered, was presented by Mr. and Mrs. Lynn Thomas. The bacteriologist is Captain Emrys Roberts, professor of pathology and bacteriology in the University of Wales, and pathologist and bacteriologist to the King Edward VII Hospital, Cardiff. The laboratory has been working with the division for some months.

THE LORD DERBY WAR HOSPITAL, WARRINGTON.

The Lord Derby War Hospital, Warrington, has been established in the asylum buildings of the Lancashire County Council at Winwick; it provides accommodation for over 2,500 men. Within five weeks of being taken over it was ready to receive patients. Three operating theatres, each with anaesthetic and x-ray apparatus, have been established. In addition to services rendered by surgeons in Warrington and Manchester, there is a staff of twenty-one resident medical officers. The hospital is under direct War Office control and regulations, but there is also a visiting committee. The number of patients in the hospital is about 1,700, and since it was taken over as a war hospital nearly 3,500 patients have been admitted. The administrator is Lieutenant-Colonel Alexander Simpson, who was medical superintendent when the buildings were used as an asylum, and the deputy administrator is Major F. M. Rodgers, previously assistant medical officer.

THE SOUTH-WEST AFRICAN CAMPAIGN.

In the BRITISH MEDICAL JOURNAL of October 2nd we published a summary of the medical statistics of the Union Defence Forces for the period covered by the duration of hostilities in South-West Africa. This was taken from a report by Colonel P. G. Stock, Director of Medical Services, which was published in the *Medical Journal of South Africa* for July. In the August number of our contemporary there is a letter correcting an error in the number of doses of antityphoid vaccine supplied by Dr. Pratt Johnson from the Clinical Research Laboratories, Johannesburg. The figure should have been 67,580 doses, and not 33,000, as originally stated.

BLIND SOLDIERS.

Following the example of Great Britain and France, Italy is establishing institutions for the training in new lines of work of soldiers blinded in the war. One has been set up in Florence for some time under the direction of Dr. Bartolomeo-Iloli and Professor Pietro Landriani, both of whom, being blind themselves, are specially qualified to understand the difficulties of persons who have lost their sight. The municipality of Milan has appointed a committee, of which the Sindaco, Signor Caldera, is chairman, to study the best means of organizing means of enabling blinded soldiers to earn their living. The Council of the Pie Istituto dei Ciechi has placed its services at the disposal of the committee.

MEDICAL OFFICERS WANTED.

2nd 1st City of London Field Ambulance (T.F.).

There are vacancies for medical officers in this unit. Pay and allowances as in the regular army, with promotion to the rank of captain after six months' service. Apply to Major C. S. Brebner, 2nd City of London Field Ambulance (T.F.), Ipswich.

2nd West Riding Field Ambulance (T.F.).

There are vacancies for officers of this unit for service overseas. Applications to the officer commanding 2nd West Riding Field Ambulance, Thoresby Camp, Worksop.

67th (H.-e. Counties) Division.

Commanding officers are wanted for the Divisional Sanitary Sections of the First and Second Lines of this Division. Medical officers of health or medical men possessing the D.P.H. preferred. Applicants should not be above 45 years of age. Further particulars can be obtained from Colonel William R. Smith, Divisional Sanitary Officer, Head Quarters Tumbridge Wells.

Ireland.

DUBLIN CASTLE RED CROSS HOSPITAL.

A REPORT recording the steps which led to the transformation of Dublin Castle into a Red Cross hospital has been issued, and its new aspects are illustrated by excellent photographs. The wards were equipped for the reception of 250 officers and men, and were ready for the reception of patients on January 27th. On February 17th the first convoy of wounded soldiers numbering 100 arrived; on March 19th 162 arrived, on April 30th 142, on May 28th 96, and on June 27th 119. The number discharged convalescent was 588. The radiographs taken numbered 304, and the operations 212.

The Committee of Management states that no grant has been received from the War Office, nor any aid from the British Red Cross Society, towards equipment. While the War Office agreed to pay the clinical hospitals of the city at the rate of 4s. a day for each bed occupied, the Committee had not been able to get any claim, beyond 3s. a bed occupied a day, acknowledged. The Committee claims equality of treatment, and regards the situation as particularly illogical when it is considered that the cost of the staff and much of the running expenses have to be incurred whether the wards are occupied or empty, whereas in the hospitals existing before the war only a small addition to the staff was needed to meet the requirements of the number of wounded soldiers that they take in. In these circumstances the Committee is satisfied that, to carry on the work of conducting the affairs of the hospital and ensuring that all supplies shall be promptly paid for, it will be necessary for the City of Dublin Branch to make a strong effort to augment the fund for the maintenance of the Castle Hospital. The statement of income and expenditure from December 12th, 1914, to June 30th, 1915, shows receipts of 46,000 from the Red Cross Branch and 22,791 from the War Office, and expenditure of 24,433 on furniture and equipment, 11,374 on salaries and wages, and 22,568 on supplies. It is stated that the cost of maintenance during May, with 182 beds occupied, was 3s. 5d. a bed, and during June, with 121 beds occupied 3s. 11d. a bed.

In a leaflet issued with the report of the Red Cross Branch it is stated that a working margin of £1,000 is required to relieve the financial strain. The Committee has been asked to equip 50 additional beds for open-air treatment, to be placed on a long balcony temporarily roofed over. The additional cost would be £1,000 and, if the funds were available, the equipment would be undertaken. A letter acknowledging the receipt of the report has been received from the Queen, who expresses the pleasure with which she has learnt that the Branch is in an efficient state of organization and is doing such excellent work.

ARRIVAL OF HOSPITAL SHIP AT DUBLIN.

The hospital ship *Oxfordshire* arrived off Dublin about midnight on Sunday, October 3rd, with about nine hundred men and officers on board. Owing to a fog she was not able to land the men until the evening, when some twenty units of the Irish Automobile Club ambulance service and about forty private cars were ready to receive them and squads of the R.A.M.C. and St. John Ambulance Brigade were in attendance. Nearly three hundred of the wounded were sent to Belfast in two trains. One man died on the journey. A large number of the men came from the fighting round Loos, and many regiments were represented.

SCALE OF FEES FOR PRIVATE PRACTICE.

At a recent meeting of the Swinford Board of Guardians Dr. J. M. O'Reilly, Salford Royal Hospital, was unanimously elected medical officer of the Charlestown dispensary district, subject to his signing a scale of fees not exceeding 5s. for all visits on patients under £5 valuation, and over £5, 10s. for the first visit, and 5s. for succeeding visits; maternity cases not to exceed £1 is. Several attempts have been made recently to induce doctors to sign such an undertaking, which is not only unreasonable but illegal.

Scotland.

SIR ALEXANDER OGSTON AND THE GENEVA CONVENTION.

A LARGELY attended meeting was held at Inverurie on October 9th in connexion with the County of Aberdeen Branch of the British Red Cross Society. Sir Alexander Ogston, who has been doing valuable work among the sick and wounded in Serbia, delivered an address on the Geneva Convention. That Convention, he said, was signed by all the European powers and also by the United States, Japan, and other ex-European nations, and it was thought that the horrors of war were to be enormously mitigated. He was afraid, however, that all their dreams of humanity were very much the same as they were in the days before benevolence began to be preached as a doctrine, and aimed at as a principle. They saw two of the leading nations of Europe throwing over by the first part of their military work the whole of the Geneva Convention. These nations no longer regarded neutral men as neutrals; they were prisoners; cruelties could be exercised upon them, and that with zest. Those who attended upon the wounded could no longer go free, taking all their materials with them. They were all made use of by those two unscrupulous nations who had rent the Geneva Convention into fragments, and no one would ever in future believe in the Geneva Convention. Who could? After the example they had had, it seemed an impossibility that any one without ridicule could hold up the idea of the Geneva Convention. It seemed that in the future it would be quite recognized as one of the features of the war that the non-combatants should be made prisoners, ill-treated, shot, executed, and that the individuals of the country where the war was being carried on—however helpful they might be to the sick and wounded of either army—would be looked upon as enemies, and all their efforts under the Geneva Convention would amount to nothing whatever. After some severe remarks on the conduct of individuals among ourselves whom greed had led into a course of action which meant a betrayal of their own country, Sir Alexander Ogston went on to say that long before the crisis came there were persons who perceived that there was at home an avenue open to them for good in connexion with possible war work in the future. Although Voluntary Aid Detachments and the Red Cross Society did not meet with a vast number of

supporters, they met with a few, and that of the very first quality, and he thought those who had joined the Red Cross Society before the war broke out, or undertook the work of Voluntary Aid Detachments, could not help feeling a pride in what they did. When they started the little voluntary hospitals the idea was entertained that a check must be put upon the soldier patients by having a sergeant or constable in supervision over them in case they might break out of the ward. But a very few weeks of actual experience showed that that was all nonsense, especially in the case of the Territorials, who were absolute gentlemen. A word from a nurse was sufficient restraint, and a remonstrance was sufficient to make them do anything.

Canada.

PROPOSED RESIDENTIAL COLLEGE AT MCGILL UNIVERSITY.

The athletic sports of the McGill Auxiliary Battalion of the Canadian Officers' Training Corps were held on September 18th on the new camps, which is beautifully situated at the foot of the Montreal Mountain. The property was purchased by Sir William Macdonald and presented to the university a few years ago. A stadium, capable of seating 8,000, the funds for which were subscribed by graduates of the university, is almost completed. In the future it is proposed to erect residences for the students, and towards the funds required for this purpose 150,000 dollars has just been given by Dr. James Douglas of New York, son of the late Dr. Douglas, a well-known practitioner in Quebec. Dr. James Douglas took the degree of B.A. at Queen's University, Kingston, and is an honorary LL.D. of McGill University, of which in the past he has been a generous benefactor; he was recently elected Chancellor of Queen's University.

A MEDICAL LIEUTENANT-GOVERNOR OF ALBERTA.

Dr. R. G. Brett, of Banff, Alberta, has been appointed by the Dominion Government to be the next Lieutenant-Governor of the province of Alberta. He was born at Strathroy, Ontario, in 1851, and graduated in medicine from Victoria University, Toronto, in 1874. After practising for some time in Ontario he went to Winnipeg, and became one of the founders of the Manitoba Medical College. In 1886 he established the Banff Sanatorium, of which he became medical director. From 1889 to 1892 Dr. Brett served on the Advisory Council of the North-West Territories (now the provinces of Saskatchewan and Alberta), and from 1892 to 1900 was a member of the Assembly. He was also President of the College of Physicians and Surgeons of the North-West Territories, and is now a member of the Medical Council of the Province of Alberta.

Correspondence.

THE WAR EMERGENCY.

A QUESTION OF UNIFORM.

SIR,—In view of the heavy demands which are about to be made on the medical profession to furnish medical officers to the navy and army, it is important that the reasonable requirements of those who may elect to serve should be at once stated to the Admiralty and War Office, and, if possible, given effect to while there is yet time.

Every medical man who now signs himself willing to serve when called upon is placing his future on the cast of a die and conferring an obligation on the nation. He is virtually enlisting, yet seems to be promised nothing in return for his devotion.

The meanest man who enlists in the navy or army receives a uniform—a token to the world that he is serving the nation—and medical men who give their promise to join when required ought, after being found physically fit, to be required to wear a uniform and receive a bounty of, say, £10 to purchase it.

No one who knows the inducements that lead men to serve can doubt that this, more than anything, would induce a large number to offer themselves. The whole

subject might be argued out at length, and I think the reasonableness of what I suggest would be admitted, but I abstain from encroaching on your space, as probably all who know the feelings of the profession, as I am convinced I do, will at once admit it.—I am, etc.,

October 10th.

A. O.

THE NEED FOR SELECTION.

SIR.—As Chairman of the War Emergency Committee of the Chesterfield Division of the British Medical Association, I cannot allow the letter from Dr. Barwise in this week's JOURNAL to pass without some explanation from me, although the enrolment of all junior men has to some extent done away with the necessity for his letter and my reply.

Our Committee recently received a communication from the Central Committee in London, stating that more men were urgently needed for the R.A.M.C., and that our area should produce six more men.

After discussion it was decided to send a circular letter to men under 40 years of age, pointing out the urgency of the call, and appealing to them primarily as coming within one or more of the following classes: Unmarried, in a partnership, on whole time service, assistants, or hospital residents. There was a strong feeling that the men who stood to lose least should be asked to join first.

Now the tuberculosis officer resident at the Chesterfield Sanatorium, which has only been opened a few months' certainly fulfilled these conditions, for he could return to his post at the close of the war without loss of capital or income. The Committee, I understand, were willing, if necessary, to close this sanatorium for the duration of the war; moreover, they actually offered the use of this sanatorium to the War Office, who refused it, saying that they did not need the sanatorium, but they did want the staff. In any case, there should have been no great difficulty in finding a man over military age to do this work, or a medical lady, many of whom are specially qualified. A copy of our letter to this medical officer was forwarded to Dr. Barwise also, with a request that no barrier should be put in his way if he desired to enlist. No special pressure was, so far as I am aware, put upon the particular officer in question.

At the same time, the Committee here realize that medical men in general practice with much to risk both in capital and in income are not encouraged to join when they see suitable whole-time officers still in their posts.

Dr. Barwise, in his letter, refers to the fine response made by his staff in general, for which the Committee heartily applaud them, and it may be of interest to know that most, if not all, of these men have been replaced; but I fail to see that these statistics alter the fact that an eligible man is not being encouraged to go.

Dr. Barwise makes some ungenerous remarks about the recruiting returns of panel doctors in the county of Derby. He should know that these men deal with the urgent and constant needs of the civil population in a large colliery area, with many thousands of munition workers. Unless this class of people have an efficient staff of doctors there will certainly be the risk of an outcry in the country. Another grievance against the panel doctor is that a few of us have been fortunate enough to secure a holiday. Let Dr. Barwise be thankful that he at any rate goes to bed every night secure against any disturbance of that holiday.

His Utopian scheme to divide the country into areas and compel each doctor to limit his energies to his own little corner would kill the free choice of doctor with a vengeance, and could only be suggested by a man who knows nothing at all of the work of a general practitioner. This letter has been submitted to the War Emergency Committee, who unanimously approve.—I am, etc.,

ARTHUR COURT,
Chairman.

Chesterfield, Oct. 12th.

SIR.—In a letter from Dr. Barwise in your last issue there appears to be a veiled imputation against the patriotism of the panel doctors in Derbyshire. He fails to realize that a large number of assistants to panel doctors have undertaken military duties, thus in many cases doubling the work of practitioners. His statement that the panel doctors have been able to take their holidays as

usual is absolutely incorrect. I am sure we are all very interested to hear the amount of work that Dr. Barwise is doing, but although we do not advertise the fact in the medical papers I feel convinced that the majority of panel practitioners in Derbyshire do more hours' work in a week than Dr. Barwise, and a large percentage of that work is on dependants of men on active service, for which we receive nothing, thus differing from the patriotic work performed by Dr. Barwise, for which he receives remuneration from the State.—I am, etc.,

Alfreton, Oct. 11th.

RAYMOND G. BINGHAM.

Dr. H. E. LITTLEDALE (Charing, Kent) writes to express his entire agreement with Dr. Barwise's suggestion that the entire medical profession should be taken over by the Government, and that practitioners left at home should be removed from their own to other districts. He has, he adds, already made this suggestion to the War Emergency Committee.

GROUSING.

SIR.—Your editorial under the above heading is a timely call to—let us say—the less thoughtful of our profession.

I had the honour of serving in France for over six months, my position being such as to bring me in contact with some hundred or more medical officers. After the rush in October, November, and December of 1914 I was frequently asked by my colleagues if I could not do something to break the monotony of "having nothing to do." My reply to one and all was this:

"I am very pleased to hear it, for it means that our poor chaps up at the front are not being smashed up. We did not come out here for experience at the expense of our pals, so carry on and wait for the next rush, when you will be busy enough."

"I never looked at it in that light," one and all replied, and I heard no more grouching.—I am, etc.,

A. MACBETH ELLIOT, M.D.,

(Temporary) Lieutenant-Colonel, R.A.M.C.

London, W., Oct. 10th.

ABSENT CONSULTANTS.

DAKRYON asks for suggestions for the "solution of a problem serious to me and to others similarly situated if they should join the R.A.M.C. A large part of my income is derived from consultations with neighbouring practitioners. Even supposing that my friendly rivals did not wish to profit by my absence, I do not see what scheme could be arranged which would be feasible and just."

INFANT FEEDING.

SIR.—At a time when faddism is rife in the artificial feeding of infants, and alternative methods, each of which is lauded by its own particular adherents, are abundant, I own it is with some temerity that I write to support any one of them. But my experience with whole citrated milk bears out so exactly Dr. C. W. Vining's contention that I feel his protest should not go altogether unsupported. To me, as to him, the infant fed by this method bears little resemblance to the majority of those who receive diluted milk. When I began to advise with regard to infant feeding in an out-patient department I thought, as I had been taught, that diluted milk with certain definite proportions of sugar and cream added would satisfy all needs. Disillusionment soon followed, for I found that diluted milk in the case of the poor meant literally milk and water, with perhaps some sugar. Cream or any substitute for it was seldom added, despite the most detailed instructions. The hospital babies fed on diluted milk I found were listless, pale, and pasty, with flabby muscles and loose joints, prominent abdomens, and unhealthy motions, and were not seldom rickety. My conception of them fits Dr. H. C. Cameron's description fairly closely.

With some scepticism and misgiving I tried whole citrated milk, for it seemed to me that even if such a method attained no more than an equal degree of success, the absence of the need for adding sugar and fat would be greatly in its favour. I was agreeably surprised by its results, and now after a trial extending over some nine years, I am led, like Dr. Vining, to the opinion that as a routine method for infants without gastro-intestinal

disorders it surpasses all others. Infants fed on whole milk, to my mind, contrast most definitely with those fed on diluted milk, and show to an unusual degree for artificially fed babies those criteria of good nutrition—healthy skins, firm muscles, taut joints, physical vigour, and mental alertness.

I use 2 grains of sodium citrate to the ounce of milk, not 1 grain as advocated by some writers, and regard the difference as important. When, however, the time arrives for giving more than 4 oz. feeds, the citrate may often be reduced to the lesser amount. The milk is always brought to the boil; there appears to be some special advantage in boiling the milk in this method of feeding, in addition to those which are usually claimed for it.

No hard-and-fast rule can be made with regard to the amounts suitable for each feed, varying as they do, not only with the age of the baby, but with its weight, vigour, previous feeding. As a rule, a satisfactory amount is one which is slightly in excess of that of the milk, which would be given in a diluted milk feed. As in other methods of feeding, it is wise to give a small amount at first, and to increase it gradually, using as guides the baby's weight chart, appetite, and general condition.

The dietetic treatment of exceptional infants and those with gastro-intestinal disorders is another chapter.

Dr. Vining has made his attitude quite clear. No more than he should I regard whole citrated milk as the key to all the difficulties which surround this complicated but important subject. I agree with Dr. Cameron that there is no room for dogmatism, but much for careful and systematic observation. Whether from the work of the school of Finkelstein and Meyer, of which Dr. Cameron is such an able exponent, there will emerge a principle from which a method, or methods, of feeding will be devised as generally applicable as whole citrated milk remains to be seen.—I am, etc.,

London, W., Oct. 6th.

FREDERICK LANGMEAD.

BOYS IN RECRUITING RALLIES.

SIR,—Yesterday afternoon in the company of many thousands of the inhabitants of this health resort somewhere on the English seacoast, I was a spectator of a great recruiting rally and march-past. From a medical standpoint I observed several matters that I think require readjustment. As the whole subject hinges upon one fact—namely, the introduction of children into the ranks of adult marching troops, to take on muscular strain for which their immature limbs are unfitted—I shall not take up space with unnecessary detail. What I saw yesterday was a considerable body, of whom, at a low estimate, 30 per cent. were boy scouts, boy cadets, and boy non-descripts. Although one could not avoid admiring the pluck many little fellows of 4 ft. and less displayed in striving to keep up with the long quick strides of their seniors, yet one could see that the strain was excessive and in some cases was doing the children positive harm. The conditions were accentuated in the case of the boys who played the wind instruments and who marched along discharging sweet music as they went, but at what a cost!—I am, etc.,

October 11th.

M.D.

THE WAR REFUGEES' DISPENSARY.

SIR,—For nearly a year, with the express sanction of the Government, the Committee of the War Refugees' Dispensary, 265, Strand, W.C., has been providing domiciliary medical attendance for refugees residing in the London area. It has been able to do this solely by the devoted and enthusiastic co-operation of Belgian doctors, themselves refugees. Owing, however, to various causes, the number of Belgian medical practitioners available for this work has diminished almost to vanishing point at the moment when the colder weather is daily increasing the calls for domiciliary attendance, and the Committee finds itself confronted with many more such appeals than it is able to meet. It has occurred to it that even in these days of unusual stress there are probably many English practitioners with a sufficient knowledge of French who would be willing, if not eager, to help it by undertaking in case of need to visit sick refugees living in their immediate neighbourhood. It is not likely that any doctor would be asked to undertake more than two or three such cases at

a time. The Committee does not offer any remuneration, and all its work up to the present date has been entirely gratuitous, but it would pay for all necessary medicines and appliances. The areas in which help is most needed are those lying to the south of the river, in the East End, and in the Finsbury and Hammersmith districts. The Committee would be glad to receive the names of any doctors willing to help it, addressed to the War Refugees' Dispensary, 265, Strand, W.C.—I am, etc.,

J. H. PHILLOP,
Chairman of Committee, War
Refugees' Dispensary.

October 12th.

Obituary.

SURGEON-GENERAL SIR CHARLES MACDONAGH CUFFE,
K.C.B., LL.D.,

ARMY MEDICAL STAFF (RET.).

SURGEON-GENERAL SIR CHARLES CUFFE died at 2, Cadogan Gardens, S.W., after a short illness, on October 4th, aged 73. He was born in Dublin on April 15th, 1842, the son of the late D. B. Cuffe, was educated at the Catholic University, Dublin; at the Richmond Hospital; and in the medical school of the Irish College of Surgeons, Dublin; and took the diploma L.A.H. (Dubl.), and the double qualification of the Edinburgh Colleges, in 1863. He became F.R.C.S. (Edin.) in 1893. He entered the army as assistant surgeon on September 30th, 1863; became surgeon on April 1st, 1873; surgeon-major on September 30th, 1875; brigade surgeon in 1888; surgeon-colonel in 1893; surgeon-general on November 30th, 1896; and retired, on attaining the age of 60, on April 15th, 1902. From 1867 to 1874 he served in the 11th Prince Albert's Own Hussars, and, after attaining administrative rank, was principal medical officer successively at Belfast, 1893-94, of the Allahabad and Narbadá Divisions 1894-95, and at Rawal Pindi 1895-96. He served in South Africa in 1877-79, in the Kafir war of 1877-78, the operations against Galekas; and in the Zulu war of 1879, including the battle of Ulundi; he was mentioned in despatches in the *London Gazette* of August 2nd, 1879, and received the medal with a clasp and the C.B. He saw active service also in Burma in 1887-88, receiving the medal with a clasp. In 1905 he was promoted to K.C.B. He was also an honorary associate of the Order of St. John of Jerusalem, a J.P. for London, and a vice-president of the Irish Medical Schools' and Graduates' Association. He had been a member of the Kensington Borough Council since 1906 and had served on a number of committees, including the Public Health Committee. He had also been a member of the board of guardians for St. Mary Abbots', Kensington, since 1907.

Sir Charles Cuffe was for several years a member of the Naval and Military Committee of the British Medical Association; he was vice-president of the Section of Public Medicine at the annual meeting at Portsmouth in 1899, was vice-chairman of the Kensington Division from 1908 till 1911, and represented that Division at the annual meeting at Sheffield in 1908.

DR. AUSTIN FLINT, of New York, who died suddenly on September 22nd, was born in 1836, and was therefore in his 80th year. He was the son of a well-known physician. He received his literary education at Harvard, and then studied medicine at the University of Louisville, and afterwards at Jefferson Medical College, Philadelphia, where he graduated in 1857. He settled first in Buffalo, where he was visiting surgeon to the General Hospital and professor of physiology in the university of that city. He was also editor for three years of the *Buffalo Medical Journal*. In 1859 he was appointed professor of physiology in New York Medical College. He was one of the founders of Bellevue Hospital Medical College, and the first professor of physiology in that institution. In 1898 he became professor in Cornell University Medical College, where he remained till the end of his active career. Dr. Flint was well known as the author of several valuable works. Among them may be mentioned the *Physiology of Man*, in five volumes, of which two editions have been published; *Chemical Examination of the Urine in*

UNIVERSITY OF ABERDEEN. SPECIAL WAR GRADUATION.

THREE medical students were capped at a graduation ceremony on October 9th. They had completed the final part of the special war examination for the degrees of M.B. and Ch.B., and are already members of the Royal Army Medical Corps. They were: J. Ewen Cable, Maternity Hospital, Aberdeen; B. Landridge Davis, Kingseat Asylum, Newmachar; and Claude C. Hargreaves, Royal Asylum, Aberdeen.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Fifty Years Librarian and Secretary.

AT the monthly meeting of the Royal Faculty, Dr. John Barlow, the president, made reference to the interesting fact that Mr. Alexander Duncan, LL.D., completed fifty years of service as librarian and secretary on August 12th last. The President moved the following resolution, which was seconded by Dr. Robert Perry, the oldest Fellow, and unanimously approved: "The Fellows of the Royal Faculty of Physicians and Surgeons of Glasgow, in meeting assembled, resolve to place on record their sincere appreciation of the services of Alexander Duncan, B.A., LL.D. For over fifty years Dr. Duncan has been a faithful secretary and librarian, devoting himself unsparingly to the various duties of his office, a trusted and sagacious adviser in matters of difficulty, and the true helper and friend of all the Fellows. That he may be long spared to come among us, free from pain and sorrow, is the hearty wish of all the Fellows of the Royal Faculty." A copy of the resolution was instructed to be sent to Dr. Duncan.

At the same meeting John Forbes Webster, L.R.C.P., L.R.C.S. Edin., L.R.F.P.S., L.D.S. Glasg., 19, Newton Place, Glasgow, was admitted (after examination) as a Fellow of Faculty, *qua* surgeon, qualified to hold office.

CONJOINT BOARD IN ENGLAND.

THE following candidates have been approved at the examination indicated:

SCISSOR COLLEGE (*Anatomy and Physiology*)—K. E. Attenborough, E. J. Blair, W. A. Flynn, M. Girgis, W. H. Grace, D. V. H. Harcourt, J. Harvey, C. E. P. Heston, C. P. Hines, C. V. Ince, G. J. James, Evelyn H. Johnson, W. A. Johnson, H. G. Joyce, A. E. A. Khsir, L. K. Ledger, J. G. McCune, C. H. Mackie, C. L. Mason, A. Y. Massouda, G. Meadows, F. Morcos, W. W. Newson, R. F. Pantou, J. C. Paw, M. C. Perch, C. F. Reiner, R. H. Reitz, A. W. Reitz, A. S. Szymanski, C. E. A. Shepherd, B. C. W. Simpson, N. Synn, I. H. Zortman.

THE late Mr. Edmund Owen left estate valued at £14,749.

THE sixth Clinical Congress of Surgeons of North America will be held in Boston during the week beginning October 25th. It is expected that 1,500 surgeons will be present. Dr. John B. Murphy of Chicago is president and Dr. Charles H. Mayo of Rochester, Minn., president-elect of the Congress.

THE trustees of the British Museum have issued from the Natural History Museum, Cromwell Road, S.W., what appears to be the first of a series of economic leaflets. It deals in simple terms with the danger of disease from flies and lice. The leaflets can be obtained, price (post free) 1d. for six copies; 1s. for 100 copies, at the Natural History Museum, Cromwell Road, London, S.W., only.

THE Duchess of Marlborough, Mr. Walter Long, M.P., Sir Thomas Barlow, Sir J. Crichton-Browne, and Mr. Benjamin Broadbent will address a public meeting to be held at the London Guildhall on October 26th to promote the campaign of the Central Committee for National Patriotic Organizations (29, Cockspar Street, S.W.) and the National Association for the Prevention of Infant Mortality (4, Tavistock Square, W.C.). The chair will be taken by the Lord Mayor at 3 p.m.

THE Central Midwives Board, at its meeting on October 7th, decided to ask the Privy Council to request the Local Government Board to call the attention of local supervising authorities to the prevalence of the practice of midwifery by unqualified persons and to advise them to institute legal proceedings against such women and bring before the General Medical Council any medical practitioners "covering" such women. Three women were disqualified from examination on account of tampering with birth and marriage certificates.

ACCORDING to the *American Underwriter*, which publishes a consideration of the relative death-rates of abstainers and moderate drinkers from the actuaries' point of view, in the United States, the United Kingdom, and the British Colonies, the probable difference between the death-rates of abstaining and non-abstaining life insurance policy holders is still problematical. It appeared that the death-rates from rheumatism and Bright's disease were lower among beer drinkers than amongst consumers of whisky.

THE International Health Commission of the Rockefeller Foundation was established in June, 1913, for the purpose of fighting the hookworm disease, not only in the Southern States of America, but in other countries. From a report of the foundation recently issued we learn that the area of infection extends around the globe in a zone about 66 degrees wide, having its centre at the equator. Practically all countries in this belt are infected. Work was begun in British Guiana, Antigua, Trinidad, St. Lucia, Grenada, the Malay States, Panama, Nicaragua, Costa Rica, and Guatemala, and also in Egypt and Ceylon. Up to December 31st, 1914, the Commission had treated 19,425 hookworm sufferers throughout the world. In addition it had instituted an educational system by which many thousands were instructed in the dangers and means of fighting the disease.

THE Incorporated National Union for Christian Social Service, founded some sixteen years ago by the Rev. Dr. Paton of Nottingham, and now presided over by the Dean of Manchester, has, in addition to two farm colonies for "unemployed," two colonies for epileptics. One of the latter is situated at Lingfield, Surrey, and accommodates nearly 300 patients in ten homes. There is a large open-air school for children epileptic under the Board of Education, which receives epileptic children from education authorities and others, and appears to be doing very good work. The medical superintendent, Dr. Hume Griffith, in referring to the recent establishment of a sanatorium, pleads for the equipment of an operating theatre, and of a laboratory for research work, so much needed in connexion with epilepsy. The society's second epileptic colony is at Starthwaite, Westmorland, and receives patients from the North of England. Much has yet to be learnt as to the pathology, causation, and treatment of epilepsy, and we are glad to find that an effort is being made at Lingfield to obtain by subscription such equipment as may be necessary for the carrying on of research.

ANALYSIS OF CASES OF TETANUS TREATED IN HOME MILITARY HOSPITALS FROM AUGUST, 1914, TO AUGUST, 1915.

BY
SIR DAVID BRUCE, C.B., F.R.S., F.R.C.P.,
SURGEON-GENERAL, A.M.S.

The object of this paper is to give medical officers serving in military hospitals at home the result of various methods of treatment in cases of tetanus.

In December, 1914, a return of cases of tetanus was called for from home military hospitals, and an army form issued. Up to the present, notes on 231 cases have been sent in: of these, 98 recovered and 133 died. This gives a mortality of 57.7 per cent. In the *Memorandum on the Treatment of Injuries in War* (July, 1915)¹ it is reported from overseas that 179 cases of tetanus have been treated. Of these 179 cases, 140 died, a case mortality of 78.2 per cent.

The death-rate in untreated cases is stated to be 91 per cent. in those of short incubation, 50 per cent. in those of delayed incubation.

On examining the rate of mortality at the various hospitals where cases of tetanus have been treated, it is seen that at Netley it stands at 81 per cent. This is probably due to the fact that as this hospital is near the port of disembarkation the most serious cases and those already showing symptoms of tetanus would naturally be sent there.

There were 6 cases at Aldershot with 6 recoveries. As this result is very satisfactory, it may be useful to describe the method of treatment employed.

Cases of Tetanus treated at Aldershot.

Case 40.—The wound was in the right arm and caused by a shrapnel bullet. Five days after the wound, on his admission to Aldershot Hospital, he had 1,500 units of antitetanic serum injected subcutaneously as a preventive measure. Symptoms of tetanus occurred nine days after this injection, fourteen days after the date of wound. He now had 3,000 units injected subcutaneously and intrathecally on two days. Recovered.

Case 41.—Gunshot wound of middle finger of the left hand. On his admission to Aldershot Hospital he received 1,500 units as a preventive measure. Symptoms of tetanus occurred fourteen days after this injection and nineteen days after wound. Same treatment as in Case 40. Recovered.

Case 42.—Gunshot wound, scrotum and right thigh. He received 1,500 units on admission, five days after wound. Four days after this symptoms of tetanus appeared, and he received 4,500 units intrathecally in three doses on two days. Recovered.

Case 43.—Shell wound in left hip. On admission, three days after wound, 1,500 units were injected. Symptoms of tetanus appeared seven days after this injection, about ten days after the wound; 3,000 units subcutaneously and intrathecally. Recovered.

Case 44.—Gunshot wound, thorax. No preventive dose was given in this case on admission to the Aldershot Hospital. Symptoms of tetanus appeared six days after wound; 4,500 units in three doses, all intrathecally; 1,500 each, two on one day and one the day following. In addition, 2 c.cm. of a 25 per

cent. solution of magnesium sulphate were injected into the spinal canal with each injection of serum. Recovered.

Case 45.—Gunshot wound of left hand. A preventive dose of 1,500 units was given on admission and thirteen days after wound. Symptoms three days after this injection and sixteen after wound; 3,000 units in one day subcutaneously and intrathecally. Recovered.

It may be that these cases were slight, and would have recovered spontaneously, but two things must be remarked. In five of the cases a prophylactic dose of serum was given immediately on admission to hospital at Aldershot, and in the curative treatment the direct injection into the spinal canal was always used. In England resort to this preventive use of serum seems to have been rare, and it is suggested that in suspicious cases it seems a sound line of treatment. After onset of symptoms the intrathecal way of approach appears also to be by far the most effective.

At Aberdeen there were 3 cases with 3 recoveries. None of these had a preventive dose on admission to the Aberdeen Hospital. One had 147,000 units (140,000 subcutaneously, 4,000 intravenously, and 3,000 intrathecally), another 18,000 units (16,500 subcutaneously, and 1,500 intrathecally), while the third had only 3,000 subcutaneously.

Colchester also had good results—7 cases with 5 recoveries. Here also there was no prophylactic treatment on admission, and nothing noteworthy in the manner of curative treatment.

THE DISTRIBUTION OF CASES OF TETANUS BETWEEN AUGUST, 1914, AND AUGUST, 1915.

The first cases occurred in August, 1914, and the following diagram represents as nearly as possible the number of cases which occurred in each month until the following July. It is impossible to show the proportion of cases of tetanus to the number of wounded, as the information is not at present obtainable.

Diagram I.

From Diagram I it will be seen that most of the cases occurred during September, October, and November, 1914. This may have been due to the fact that the wounded

¹ BRITISH MEDICAL JOURNAL, August 2nd, 1915, p. 305.

TABLE I.—Particulars of the Six Cases treated at Aldershot.

No. of Case.	Date of Wound.	Prophylactic Injection of Serum.			Onset of Symptoms.		Curative Treatment by Antitetanic Serum.					
		Date.	No. of Days after Wound.	Method.	Units.	Date.	No. of Days after Wound.	No. of Days after Prophylactic.	Date.	Subcutaneously.	Intrathecally.	Result.
40	1914, Oct. 18	1914, Oct. 23	5	Subcutaneously	1,500	1914, Nov. 1	14	9	1914, Nov. 2 Nov. 3	— 1,500	1,500	Recovered.
41	Oct. 18	Oct. 23	5	Subcutaneously	1,500	Nov. 6	19	14	Nov. 6 Nov. 7	— 1,500	1,500	Recovered.
42	Oct. 18	Oct. 23	5	Subcutaneously	1,500	Oct. 27	9	4	Oct. 27 Oct. 28 Oct. 28	— — 1,500	1,500	Recovered.
43	Oct. 26	Oct. 29	3	Subcutaneously	1,500	Nov. 5	10	7	Nov. 5	1,500	1,500	Recovered.
44	Oct. 25	—	—	—	—	Oct. 31	6	—	Oct. 31 Nov. 1	— —	3,000 1,500	Recovered.
45	Oct. 20	Nov. 2	13	Subcutaneously	1,500	Nov. 5	16	3	Nov. 5	1,500	1,500	Recovered.

were more exposed to contamination of their wounds at that time, which included the retreat from Mons; that there was less opportunity of receiving surgical treatment as rapidly and as effectually as later on; that during this time the preventive use of antitetanic serum had not been developed, as it has during the last six months, when it is reported that, wherever possible, every wounded man has received a prophylactic dose; and generally that experience has taught medical officers how better to cope with the conditions obtaining in time of war, to unlearn the lessons of modern aseptic surgery, and to revert to the older methods of free incisions, thorough drainage, and constant removal of septic products by baths or irrigation. At the present time it is impossible to say which of these factors has been the most important.

RELATION OF THE NUMBER OF DAYS WHICH ELAPSED BETWEEN THE DATE OF WOUND AND THE ONSET OF SYMPTOMS, AND THE RATE OF MORTALITY.

It is well known that the rate of mortality depends on the length of time which has elapsed between the date of the wound and the onset of symptoms, and the following diagram shows that the cases of tetanus under consideration follow the same law.

Diagram II.

Diagram II shows that in the cases dealt with, if the symptoms of tetanus appeared within ten days of receiving the wound, the mortality was 66.6 per cent.; if between the eleventh and twenty-fifth day, 39 per cent.

The Incubation Period, or Number of Days which Elope between the Date of Wound and the Onset of Tetanus Symptoms.

The following curve shows the number of cases which occurred on each day from the third day after date of wound.

Curve I.

From Curve I it will be seen that, in the cases of tetanus under consideration, more occur on the tenth day after the wound than on any other. The incubation period may be as short as three days and as long as 157.

TREATMENT OF TETANUS BY ANTITETANIC SERUM.

A.—Preventive Treatment.

Among the 231 cases, only 37 are noted as having been treated with antitetanic serum before the onset of symptoms: 20 in France, 7 in England, 10 not specified. Of these 37, 18 recovered and 19 died, giving a mortality of 51.3 per cent.

The usual dose was 1,500 units (8 records), but 1,000 were given in 3, 500 in 8, and 4,000 in 2.

TABLE II.

	Recovered.	Died.
8 cases inoculated on day of wound	3	5
3 " " one day after wound	2	1
3 " " two days after wound	2	1
2 " " three days after wound	1	1
2 " " five days after wound	1	1
3 " " six days after wound	3	0
2 " " seven days after wound	0	2
1 " " eight days after wound	0	1
3 " " nine days after wound	2	1
1 " " eleven days after wound	1	0
9 cases were unaccounted for.		

The average incubation period of 17 fatal cases was thirteen days; of 15 cases which recovered, 18.5 days.

B.—Curative Treatment.

Out of the total of 231 cases the numbers treated with antitetanic serum after the onset of symptoms was 215 (93 per cent.). Sixteen cases did not receive curative treatment with antitetanic serum in England. Of these, 3 recovered and 13 died; mortality, 81.25 per cent. Of the 3 which recovered all had been treated prophylactically in France. Of the 13 who died 6 had been treated prophylactically in France.

Of the 215 cases 116 were treated by subcutaneous injections alone; 46 recovered, 70 died. Mortality, 60.3 per cent.

Of the 215 cases 7 were treated by intravenous injections alone; 1 recovered, 6 died. Mortality, 85.7 per cent.

Of the 215 cases 14 were treated by intrathecal injections alone; 8 recovered, 6 died. Mortality, 42.8 per cent.

Of the 215 cases 27 were treated subcutaneously and intravenously; 5 recovered, 12 died. Mortality, 70.9 per cent.

Of the 215 cases 41 were treated subcutaneously and intrathecally; 23 recovered, 18 died. Mortality, 43.9 per cent.

Of the 215 cases 2 were treated intravenously and intrathecally; 1 recovered, 1 died. Mortality, 50.0 per cent.

Of the 215 cases 16 were treated subcutaneously, intravenously, and intrathecally; 3 recovered, 8 died. Mortality, 50.0 per cent.

Of the 215 cases 73 were treated intrathecally with or without subcutaneous or intravenous injections; 40 recovered, 33 died. Mortality, 45.2 per cent.

It would appear from Diagram III, which represents this graphically, that injections of antitetanic serum into

Diagram III.—Treatment of tetanus by antitetanic serum, showing rate of mortality in subcutaneous, intravenous, and intrathecal methods of injection. S, Subcutaneous; I, intravenous; S.I., subcutaneous and intravenous; T, intrathecal; T.S., intrathecal and subcutaneous; S.I. & T., all three; W., intrathecal with or without others.

the spinal canal are more effective than subcutaneous or intravenous injections.

The Influence of Dosage on the Curative Action of Antitetanic Serum.

It is generally held at the present time that success in the treatment of tetanus by antitetanic serum depends on the use of big doses.

Out of the 231 cases under review, in 200 only was the amount of serum recorded. In analysing these 200 cases it must be noted that the amount of serum given is the total amount, not the daily amount or the amount of each dose. For example, if a serious case came into hospital, received 10,000 units, and died at the end of one day's treatment, this would be put down as 10,000, whereas a milder or more chronic case receiving the same treatment for ten days would be returned as having had 100,000 units. It would be false to argue that as the one got ten times as much serum as the other and recovered, the result was due to the larger amount of serum given.

In the returns sent in the daily amount is seldom given; what is recorded is the total amount given from the beginning to the end of treatment.

It is suggested that in the returns sent in future the daily amounts should be specified, and the mode of injection, intrathecal or otherwise, carefully recorded.

Out of the 200 cases 4 received 1,000 units or under; 2 recovered, 2 died. Mortality, 50 per cent.

Out of the 200 cases 61 received from 1,001 to 5,000 units; 24 recovered, 37 died. Mortality, 60 per cent.

Out of the 200 cases 50 received from 5,001 to 10,000 units; 14 recovered, 36 died. Mortality, 72 per cent.

Out of the 200 cases 20 received from 10,001 to 15,000 units; 12 recovered, 8 died. Mortality, 40 per cent.

Out of the 200 cases 19 received from 15,001 to 20,000 units; 6 recovered, 13 died. Mortality, 68 per cent.

Out of the 200 cases 19 received from 20,001 to 30,000 units; 10 recovered, 9 died. Mortality, 47 per cent.

Out of the 200 cases 14 received from 30,001 to 40,000 units; 9 recovered, 5 died. Mortality, 36 per cent.

Out of the 200 cases 13 received from 40,001 to 147,000 units; 9 recovered, 4 died. Mortality, 38 per cent.

The main conclusion to be drawn from a study of these cases of tetanus treated therapeutically by antitetanic serum is that it seems highly probable that the serum has little or no effect on the course of the disease. There is a little evidence that, if the serum has any effect at all, then the intrathecal method of injection is the most effective. It hence arises that, if serum is to be used at all, then it should first and foremost be injected intrathetically in as large dose as possible, and repeated as often as safe and practicable, as long as symptoms persist. If there is any likelihood that tetanus toxin is still being absorbed into the blood stream from the wound, then, in addition to the intrathecal injection, a further quantity of serum may be introduced intravenously and subcutaneously. In this way 3,000 to 5,000 units could be injected into the spinal canal and 10,000 to 20,000 into a vein and under the skin.

On account, doubtless, of the ease of giving serum by subcutaneous injection, this method is most used. In 116 cases out of the 215 under consideration (54 per cent.) it was the only method used. In 190 cases (88 per cent.) it was one of the methods used. The intrathecal method was only used in 73 cases out of the 215 (33 per cent.).

Now the contention is that the intrathecal path should be used in every case where serum is used, either alone or in conjunction with the other methods.

OTHER THERAPEUTIC REMEDIES.

1. Carbolic Acid Injections.

The treatment of tetanus by carbolic acid injections was described by Baccelli in 1888, and consists of the subcutaneous or intramuscular injection of carbolic acid. It is generally used in a 1 in 20 solution, and from 3 grains to 12 grains of the acid constitute a daily dose.

In the present series 33 cases were treated by this drug; 12 patients recovered and 21 died (63.6 per cent.).

In Table III the single injections and daily quantities are expressed in grains of carbolic acid. The cases are arranged according to the amount of carbolic acid given per diem, from 0.45 grain in Case 75 to 80 grains daily in Case 206.

From a study of the table it would appear that there is no evidence that carbolic acid has any favourable therapeutic effect on cases of tetanus. It is also suggested that

small doses, such as half a grain a day, are quite inadequate.

TABLE III.

No. of Case.	Single Dose, in Grains.	Quantity per Diem, in Grains.	Total Quantity Injected.	Recovered.	Died.
75	0.45	0.45	2.25 gr. in 5 days	R	
92	0.2	0.6	1.2 gr. in 2 days		D
214	0.22	5.2	?		D
51	0.9	5.4	5.4 gr. in 1 day	R	
219	0.9	7.2	27.0 gr. in 4 days		D
10	2.6	7.8	?		D
14	0.7	8.4	94.5 gr. in 18 days	R	
20	0.75	9.0	18.0 gr. in 2 days		D
223	0.9	10.8	42.0 gr. in 3 days		D
13	1.0	12.0	?	R	
229	1.1	13.2	36.0 gr. in 2 days		D
231	2.25	13.5	108.0 gr. in 14 days	R

6	1.5	18.0	?	R	
9	0.75	18.0	75.0 gr. in 4 days		D
46	0.75	18.0	144.0 gr. in 18 days	R	
47	0.75	18.0	?	R	
48	0.75	18.0	?	R	
50	0.75	18.0	93.0 gr. in 5 days		D
164	1.5	18.0	?	R	
225	1.5	18.0	36.0 gr. in 4 days		D
228	1.5	18.0	20.0 gr. in 1½ days		D
16	1.0	24.0	72.0 gr. in 3 days		D
216	1.5	35.0	85.5 gr. in 4 days		D
205	10.0	80.0	900.0 gr. in 21 days	R	

Case 206 received altogether 900 gr. of carbolic acid subcutaneously during a period of twenty-one days. The strength of the solution was 2 per cent. He received 10 gr. every 3 hours for 48 hours, every 4 hours for 96 hours, and every 6 hours for 48 hours; then 20 gr. every 12 hours for 9 days, and afterwards every 24 hours for 3 days. At no time were there any symptoms of carbolic acid poisoning. In addition, he had the chloral and bromide by the rectum three times a day, the effect of which was augmented by hypodermic injections of heroin and morphine whenever he was restless. The longest general spasm lasted for about two hours, but throughout the course of the illness the spasms were always well under control; the last occurred fourteen days later than the first. The patient developed tetanus six months after the date of wounding. No focus of infection was discovered.

2. Magnesium Sulphate.

This method of treatment seems to have been first used in America, and its value depends on its powerful sedative or anaesthetic action on the spinal cord. Few of the cases under treatment in England have received this treatment. One case was given 2 c.cm. of a 25 per cent. solution intrathetically; another, one injection (amount and strength not given) subcutaneously; another received 2 c.cm. of a 25 per cent. solution with each dose of serum intrathetically. Three doses were given, and the patient recovered. Two cases received intrathecal injections, one of them 7 c.cm. of a 25 per cent. solution. In other cases it was given by the mouth and by the rectum, but in these it could not have been intended to exert its action on the spinal cord. Nine cases in all were treated with magnesium sulphate; of these 7 died and 2 recovered.

It would appear that this method of treatment is powerful and not without danger, so that great caution ought to be used in its exhibition. Stromeyer treated 5 cases, giving an injection of 8 c.cm. of a 15 per cent. solution. In 2 of these there was marked anaesthesia of the trunk and lower extremities; in the other 3 no anaesthesia was noted. In all 5 cases after the injection there was a cessation of the spasms and muscular rigidity, the patient slept, and respiration was slowed.

CONCLUSIONS.

The conclusions to be arrived at by this analysis are as follows:

1. In the 231 cases of tetanus under review the mortality was 57.7 per cent.
2. Cases with a short incubation were more fatal than those of longer incubation.
3. Most cases occurred on the tenth day after the wound.
4. There are few allusions to the use of antitetanic serum as a prophylactic.
5. In regard to the therapeutic effect of antitetanic serum, the evidence would go to show that this action is not well marked.
6. If antitetanic serum is used—and in such a fatal disease it would seem wrong not to give the patient the benefit, even if doubtful, of the antitoxin—it ought to be injected in the first place intrathecally, as this method would seem to possess advantages over the intravenous and subcutaneous methods.
7. There is no evidence that any benefit accrued to the cases treated by carbolic acid or magnesium sulphate injections.
8. To sum up, the treatment of a case of tetanus might be as follows:

- (a) Place in a quiet, darkened room under care of a sympathetic and capable nurse.
- (b) The best surgical treatment of the wound should be thoroughly carried out to ensure the prompt and complete removal of all septic products.
- (c) The intrathecal injection of at least 3,000 units of antitetanic serum. At the same time 10,000 to 20,000 units may be injected intravenously and subcutaneously. This procedure to be repeated as frequently as the course of the disease seems to demand.
- (d) In addition to this the patient should receive sedative drugs, such as chloral or chloroform, in full doses.

ON THE HAEMOLYTIC ACTION OF THE URINE IN CERTAIN CONDITIONS.

By C. S. MCKEE, M.B.,

VANCOUVER, B.C.; CAPTAIN C.A.M.C. No. 5 GENERAL
HOSPITAL, CANADIAN EXPEDITIONARY FORCE.

This article is a summary of two papers read before the Vancouver Medical Association in April, 1914, and April, 1915, and not yet published. The work is based upon material obtained from the Vancouver General Hospital, while Director of the Laboratory of Clinical Pathology in that institution. Since arrival in England, with the concurrence of Surgeon-General Carleton Jones, D.M.S., Canadian Expeditionary Force, and thanks to the help given me by the National Research Committee, facilities have been granted to me to continue the work at Cambridge, under Professor Gowland Hopkins. I had, however, been able to do little more than demonstrate some of the main phenomena here recorded to Professor Hopkins, and, I may add, in the laboratories at St. Bartholomew's and Guy's Hospitals (to which hospitals I would express my gratitude for the opportunity given to obtain material), when I was called to active service overseas.

I would here express my sincere thanks to Professor A. B. Macallum, of Toronto; Principal Westbrook, of the University of British Columbia; Lieutenant-Colonel Adams, C.A.M.C.; and Professor Hopkins, for the encouragement they have given me in this research.

It seems fitting to place on record the following observations, since a careful search through the literature at my command, and also a search by interested friends through that contained in much larger libraries than were at my disposal in Vancouver, has failed to show that the reaction here described has been noted before, or, if noted, published. The only mention made of the action of urine upon the red blood corpuscles is the loss of shape and colour that these cells undergo after standing for some time in urine which tends to become alkaline, together with certain incidental notes upon changes observed in the red corpuscles in some (but by no means all) cases of haematuria.

It is unnecessary here to detail in full the sequence of observations and deductions which led me to this

particular line of inquiry. It will suffice to say that for the last few years I have interested myself particularly in the various forms of anaemia, and after not wholly successful endeavours to find some reaction whereby to separate sharply the conditions of so-called primary and secondary anaemia, it appeared worth while to test whether change in the blood plasma led to change in the corpuscles, whether these changes, if any, were due to the loss of some protective material, to the presence of toxins, or to the presence of something passed into the plasma for the purpose of neutralizing circulating toxic elements—a something which, while neutralizing these toxic bodies, exerted a coincident deleterious action upon the erythrocytes. Should there be bodies of any of the above types in the circulating blood, it seemed deserving of study whether they undergo excretion and are to be detected in the urine; and the first question to be answered was, Can any difference be made out between the action upon the red corpuscles of normal urine and that of urine from cases of grave (pernicious) anaemia?

METHOD EMPLOYED.

The solution of this first problem was not so simple a matter as it might seem. In fact, for a long time I failed to note any difference between them as far as the action on red corpuscles was concerned, red cell emulsions of different strengths and amounts being mixed with varying quantities of urine. The intention was to note if, after the red corpuscles had been exposed to the action of urine, there was any increase or decrease in the resistance of these to the action of a haemolytic serum, or any other change, which could be noted and followed up. Eventually I adopted the following technique by which, while ordinary urines have so far exhibited a complete absence of haemolytic power, those from cases of grave pernicious anaemia show at some period, often daily for a long time, a marked haemolytic activity. I have so far noted it in all cases studied, except in cases of the aplastic type.

The method is as follows:

1. Make an emulsion in the proportion of one drop of blood to 4 c.c.m. of 0.85 per cent. salt solution.
2. Collect a dozen or more urines from various cases and take a series of test tubes, 3 in. by $\frac{3}{8}$ in. in size. In each place 15 drops of the urine to be tested.
3. To each tube add 1 c.c.m. of the blood emulsion and mix with the urine.
4. Place the tubes in the incubator at 37° C. for two and a half hours, shaking several times during this period, examining at each shaking for evidence of haemolysis.
5. If haemolysis occurs in any of the urines, a series of 1-2-4-6-8-10 drops, added to 1 c.c.m. of the emulsion, can then be made up for the purpose of measuring the haemolytic value of the urine giving the reaction.

Notes on Method.

There are certain notes which it is well to make regarding this technique.

I. To make up the cell emulsion I add the blood—10 or 15 drops—to 15 c.c.m. centrifuge tubes filled with 0.85 per cent. salt solution, wash once by centrifuging the cells, and make up the bulk to 40 or 60 c.c.m., corresponding to 1 drop of blood to 4 c.c.m. of the salt solution, as in the Noguchi-Wassermann system. I have, however, gained the impression that unwashed cells are somewhat more resistant, this being noted best in those cases where very small amounts of urine, say 1 or 2 drops, lake the corpuscles, and it is intended to use both washed and unwashed cells in a series of observations on this group.

II.

For the purpose of dropping the urines into the test tubes I use a dropper made from opsonic tubing drawn out in the flame to a capillary of medium bore, and drop with the tube held almost horizontally. After the first 15 drops are measured a mark may be made on the pipette with a grease pencil, and a sufficiently accurate amount of each grease pencil, and a sufficiently accurate amount of each pipette.

III.

I mention 15 drops as the amount chosen, because experience has shown me that whereas with some urines

1 drop added to 1 c.cm. of cell emulsion will induce haemolysis, I have not yet found, where 15 drops of urine do not haemolyse, that 30 drops will. In other words, if 15 drops do not haemolyse, doubling the amount has no effect. While stating this it must be emphasized that a marked difference occurs between urines. With some, 1 or 2 drops added to the cell emulsion will cause almost instant haemolysis. This phenomenon is seen most frequently with urines having an alkaline reaction; although by no means all alkaline urines haemolyse, even in an amount of 15 drops. It has therefore been made a rule, whenever a strongly haemolytic urine is encountered, to test for the smallest amount which will give the reaction. But clearly the laking action is not purely a matter of quantity, for in testing a urine which has been reacting daily, a very curious thing is often noted, in that 1 or 2 drops cause laking before 10 or 15 drops, and indeed 30; and at times the 15-drop doses may require two and a half hours to completely lake the corpuscles, and the 30-drop dose may cause no laking whatever.

And also, if the minimum laking dose of the urine is ascertained, and several doses added to the cell emulsion—where, for example, 1 drop lakes 1 c.cm. of blood cell emulsion—take 3 drops of the urine instead of 1 and add to the 1 c.cm. cell mixture. When complete laking has taken place, add 1 c.cm. more emulsion. This last remains not laked, the excess of haemolytic substance all having been taken up by the first lot of cells. This in alkaline urines.

IV.

Subjection of the blood cell-urine mixtures to incubator temperature of 37° C. is essential, and I am inclined to believe that neglect to consider this one detail is responsible for this simple phenomenon not having been observed long ago. It is true that at ordinary room temperature, haemolysis, notably with alkaline urines, does at times occur, but a parallel series of tests at room and incubator temperatures shows that warmth is an essential factor in the majority of the reactions, and in all of those in acid urines. Repeatedly no haemolysis occurs in 18, or 24, and often 48 hours in the cool of an ordinary room, when it is decisive in 2½ hours at 37° C.

V.

So far I have never observed haemolytic activity in the urine of healthy persons.

I hope in a later paper to attempt to go more fully into the cause or meaning of this phenomenon.

RESULTS.

As already noted, if carefully studied, the urine from cases of pernicious anaemia will be found to give this reaction. Just as the disease itself has its periods of remission, so is it with the haemolytic activity of the urine; but no relation has been made out between the two, nor do I pretend that I am calling attention to a test which will be of diagnostic or prognostic value in this disease, because this haemolytic action of urine is by no means confined to pernicious anaemia, as was ascertained when urine from other types of disease was studied.

Briefly, this appearance of a body or bodies in urine of a more or less actively haemolytic nature, is a fairly frequent accompaniment of grave disturbances of metabolism. In severe chronic anaemia the reaction is frequent, but not of daily occurrence, and after having tested and cross-tested the red cells of several pernicious anaemia cases, it appears that some patients' cells are much more resistant than others, but also that all are less resistant than normal cells.

The reaction is obtainable in erysipelas, gout, acute rheumatic fever, advanced tuberculosis, and certain cases of syphilis. In acute rheumatic fever, as so far studied, the urine was found to lake blood cells in all cases at some period during the course of the disease, in most cases all through the acute stage. The same has been true of severe erysipelas and streptococcal throat cases. In syphilis the reaction depended on the severity of the symptoms.

In all severe burns the urine has been regularly haemolytic and has remained so until death, or recovery was well assured. In some cases of skin disease, where a large part of the skin surface has been involved laking by the urine has been common and persistent. In two cases of

carbolic acid poisoning the urine, twenty-four hours later, was intensely haemolytic and remained so till death; here possibly other factors may have been at work.

In starvation the reaction appeared to depend upon the severity of the symptoms. In cancer with wasting, the reaction has always, so far, been present. In septic cases also it is common.

To see if possible whether this reaction was the result of some definite acidosis, urine from cases where this condition was well defined was studied—in children and certain post-operative states—and the haemolytic action obtained; so, again, it obtains in diabetes, if coma is approaching, or if after a period of well-being the condition becomes aggravated. Possibly associated with this group of cases I may note that in only four cases of pregnancy did I obtain this reaction (during the last week of pregnancy) and, curiously, all these four cases became eclamptic.

There is also a group of kidney and heart cases which exhibits urinary haemolysis. In so-called chronic Bright's disease laking is uncommon, but if acute nephritis supervenes, then in many cases haemolysis shows itself. In acute nephritis two groups have apparently become manifest, in one of which I have not noted this reaction, and another in which the reaction is present. All the cases of this last group succumbed. In heart cases with broken compensation the reaction is very regularly present, varying apparently directly with the clinical symptoms. One case with ascites was very interesting; the urine was daily haemolytic over a long period, except for a few days following each paracentesis.

Yet another order of cases I am inclined to regard as of importance. In the routine examination of all new cases entering hospital (and altogether I have now tested urine for this reaction from 5,000 cases) I have often observed that the urine obtained the first day following the patient's entry was haemolytic, but never again during his stay of days or weeks in hospital. So also in shock following accidents urinary haemolysis is frequently present in the same way. These observations led me to examine urines from post-operative cases, with the result that this reaction was found the day following operation in many cases; in some only once or twice, in others persisting for days or weeks. I am hoping to continue this study in connexion with the important group of cases of grave shock developing under shell fire.

FACTORS INFLUENCING THE HAEMOLYTIC PHENOMENON.

To gain, if possible, some understanding of the nature and significance of this reaction I have instituted a detailed study into the haemolytic activity of the various urinary constituents. This study is not yet complete, but is being continued by Mr. S. W. Cole at the Bio-chemical Laboratory at Cambridge. We hope to publish the results later. At most I would lay down:

1. Haemolytic action does not depend upon the acidity or alkalinity of the urine alone, although it is true that the majority of the most powerfully haemolytic urines are alkaline.

2. A urine with alkaline reaction does not increase in haemolytic power when kept at room temperature for twenty-four or forty-eight hours. Many lose markedly in strength. Paradoxically, a urine which is alkaline on passing I have never yet found to haemolyse at once, but only after standing for three or four hours after having been passed.

3. Acid urines tend to lose their haemolytic power on standing twenty-four or forty-eight hours, although the reaction remains acid. In this connexion the study has revealed a fact which I have not seen noted elsewhere: that urines seem to be of two orders—(1) one which is alkaline on passage or becomes so in a short time; (2) an acid group which remains acid despite bacterial contamination and fermentation. I have, indeed, incubated this type of urine for twenty-four hours without causing an alkaline change. As these observations have proved of interest and application outside this particular research, it is thought best to bring forward this study in a separate note later.

4. Bringing the urine to the boil appears to have different effects. It has no action on some urines, and in others weakens or inhibits the laking power. I have still to study the effects of boiling for longer periods.

5. The results of a study of the haemolytic powers of

the various urinary constituents may be summed up by saying that although alkalis like ammonia, acids such as acetic acid, and acid salts such as acid calcium phosphate, possess haemolytic powers, it is evident that these are not responsible for the phenomenon seen in actively haemolytic urines. The amounts of all these necessary to induce a similar haemolytic effect when added to (a) NaCl 0.85 per cent, solution, or (b) normal urine, being far greater than exist in urines that are found to haemolyse.

My observations during this work yield, as might be expected, different results as regards alkaline and acid haemolytic urines respectively, and must be left for full discussion later. Here I would only call attention to the protective action of sodium bicarbonate.

It was found, in the first place, that normal sodium bicarbonate solution, when added to a haemolytic urine in varying amounts, from 10 to 40 drops per 10 c.cm. of urine, prevented the haemolytic action, and this whether the urine was previously acid or alkaline, more being required in the case of a very powerfully haemolytic acid urine than in a correspondingly powerful alkaline urine. Following this observation, it was discovered that in patients affording a haemolytic acid urine the administration of sodium bicarbonate by the mouth in sufficient dosage caused the haemolytic action of the urine to disappear. This was tried only in a few cases with very powerful haemolytic acid urines, and never in a case with alkaline urine, and although in my few cases the administration seemed to be of clinical value, they are far too few to use as a basis for treatment.

6. The attempts at removing or neutralizing by the various absorbents, precipitants, filtration, etc., and the influence, if any, of the H ion concentration, as well as other studies, will be left for future discussion.

SUMMARY.

1. A phenomenon of fairly constant occurrence in certain morbid states, which apparently has hitherto escaped notice, is here described, namely, the rapid laking of blood corpuscles by the urine.

2. It has never been noted in the urines of normal individuals.

3. The agent causing this haemolysis is left an open question, but there seems no doubt that it is not a normal constituent of the urine.

4. Save in the case of certain strongly haemolytic alkaline urines, of which one drop sometimes causes instant laking of the blood emulsion at room temperature, the haemolytic process requires incubator temperature of 37° C.

5. Sodium bicarbonate definitely influences the reaction *in vitro*, and possibly when administered to patients by mouth.

6. A curious and apparently definite grouping of stable and unstable urines, so far as change of reaction from acid to alkaline is concerned, has been remarked. This group of unstable urines may perhaps be found of prognostic value.

URETERAL CALCULUS: ITS SYMPTOMS AND TREATMENT.

WITH A FEW ILLUSTRATIVE CASES.

BY

DAVID NEWMAN, M.D., F.R.F.P.S.G.,

CONSULTING SURGEON, GLASGOW ROYAL INFIRMARY.

(Continued from p. 561.)

TREATMENT.

Expectant Treatment.

THE treatment must depend upon an exact appreciation of the state of the patient and of the morbid condition present. If there is reason to believe that one ureter only is blocked, and that the kidney on the opposite side is healthy, it is advisable to wait the course of events, as in many instances the obstruction is relieved spontaneously within a short time and no permanent harm results. This is especially to be recommended when there is evidence that the obstruction is incomplete or transitory, or when the patient is suffering little pain and the stone is known to be a small one.

While a stone in the ureter is certainly a source of danger, being liable to cause obstruction and its consequences—sepsis, haematuria, and hydronephrosis—it does not necessarily demand operation. Whenever a stone is suspected, x-ray detection is used, and, as a consequence, we find that a goodly proportion of ureteral stones are evacuated spontaneously. By having an x-ray plate taken from time to time its progress can be watched, care being taken to keep the patient under supervision. At regular intervals a thorough examination must be made, including a cystoscopic inspection, to ascertain that there is no blocking of the ureter. The following case is a good illustration:

CASE V.—Repeated Attacks of Renal Colic during Nine Months : Descent of Calculus Watched: Ultimately passed per Urethram.

The history was that of repeated attacks of renal colic, with the passage of gravel on several occasions. With x-ray a stone was discovered in the first instance (January, 1904) at the level of the transverse process of the fourth lumbar vertebra. The patient was examined at intervals of two months, and on September 9th, 1905, an x-ray photograph was taken, when the shadow of stone was found corresponding in position to the union of the lower and middle third of the left ureter—that is to say, well below the brim of the true pelvis. On some earlier examinations the stone was seen much lower down; there, was, freely movable. On September 10th a cystoscopic examination was made, when the mucous membrane of the bladder was found to be practically normal, but, on account of the enlargement of the middle lobe of the prostate, the examination was difficult. The orifice of the right ureter was normal; that of the left was considerably dilated and the shadow of a median stone. The margins were very slightly thickened, and on the left lip the line of the mouth was obscured by a trickle of blood escaping from it, so that the whole contour was not clearly seen. The line of the ureter was very distinctly marked, and the mucous membrane covering it was pigmented and congested. On September 11th I received a letter from the patient saying that he had passed the stone on the evening of September 10th, and that he "felt alright now," but should I wish him to do so he was willing to undergo another cystoscopic examination.

A second x-ray photograph was taken on September 11th, and failed to show the shadow seen in the first plate, proving that the shadow seen was due to the stone which had been passed. A second cystoscopic examination showed the same appearances as formerly presented, with the addition that close to the middle of the upper lip there was a small submucous haemorrhage, and a similar spot was seen on the margin of the lower lip, but no blood was found escaping from the orifice. The stone passed was the size of a horse bean, but very irregular in shape and distinctly nodulated. It is worthy of remark that the passage of this concretion caused no laceration of the lips of the ureter or other injury recognizable with the cystoscope further than the minute submucous haemorrhages just described.

I have occasionally found that the ureter stones escape soon after a cystoscopic examination, which, I suppose, may be explained by the manipulation inducing a certain amount of muscular contraction or spasm of the muscular fibres of the ureter, which are often greatly hypertrophied in the presence of calculus.

While the patient is under observation attacks of colic may be prevented or relieved. In such cases the use of massage, shampooing, and the application of fomentations sometimes relieves the spasm. Pain may be alleviated during an attack by the administration of anodynes such as morphine, belladonna, and opium, but the latter drug must be employed with great care, as even a small dose may produce alarming effects when there is any interference with the proper action of the kidneys. It is much safer to employ hot fomentations, emollient enemata, and hot baths; should the pain be extreme, it may be necessary to place the patient under the influence of an anaesthetic, which not only has the advantage of relieving the suffering of the patient for the time being, but may also, by abolishing spasm, facilitate the passage of a calculus from the ureter. Under similar circumstances, warm diluents and diuretics have been given with the view of forcing the calculus down by an increased secretion of urine, but probably the beneficial action of these remedies is due more to the power they possess in reducing the irritating qualities of the urine than to any mechanical effect the increased flow of urine may exert. Changes in the position of the patient sometimes give relief from suffering by altering the situation of the stone, by dislodging it from the position where it causes most complete obstruction; in the same way external manipulation in the renal region or along the course of the ureters has been

recommended. If the calculus is known to be close to the bladder, manipulation through the vagina or rectum may immediately relieve the pain by pushing the stone upwards into the dilated portion of the ureter and so allowing the pent-up urine to escape. Unless during the attacks, the patient should not be kept in bed. Large quantities of fluid should be given to increase the excretion of urine and promote the downward passage of the stone.

With careful treatment directed to promote the progress of the stone into the bladder in many cases we have been able to avoid an operation. When one stone has passed successfully from the ureter we must be assured that no others remain. The stone may pass into the bladder and be seen with the cystoscope, but fail to escape. Dilatation of the urethra with a large bougie may facilitate matters, if not it must be removed. If the stone escapes, well and good, but it must be remembered that in other respects the patient is in the same position as he occupied before the calculus showed itself. Another one may form unless precautions are taken.

Operative Treatment.

If the attacks of pain are frequent or severe; if the patient requires to lead an active life and is likely at times to be beyond the reach of an operating surgeon; if there is any evidence of hydronephrosis or of sepsis; if the stone is fixed in one place or is large in size; if there is only one working kidney; if the patient's general health is becoming impaired and the kidney excretion is not efficient, the stone should be removed as early as possible.

When the ureter of the only working kidney is sealed, it is evident that the first point to attain is immediate relief of the obstruction. In most cases there is a short period during which medicinal remedies may be employed, but unless relief is very speedy valuable time must not be wasted in waiting for the action of drugs. The only working ureter is plugged, and the obstruction can be removed by the surgeon, or an artificial exit can be made in the loin so as to provide a channel for the passage of urine. In this way the immediate danger to life may be averted, and later on a careful search can be made for the stone, and a method devised for its removal.

The operative procedure depends upon the position occupied by the stone:

- (a) When the stone is in the upper third of the ureter.
- (b) When the stone is too high up to be felt by the finger, but occupies the middle third of the ureter.
- (c) When the stone is sufficiently low down to be detected by digital examination in the vagina or rectum.

The stone may be removed without opening the peritoneal cavity by any of the following routes:

1. The lumbar route prolonged extraperitoneally.
2. The paraperitoneal route used in exposure of the kidney by stripping the peritoneum from the abdominal parietes.
3. The hypogastric route, opening the bladder above the pubes.
4. The sacral route.
5. The perineal route.
6. The vaginal route.
7. The vesical route.

The extraperitoneal route is the one now almost exclusively employed in exposing the ureter. During the early stages of the operation the position of the patient is similar to that for renal operations, but it is well to have him placed upon his back with the legs flexed and the thighs brought well up over the abdomen while exploring the pelvic portion of the duct.

The lumbo-ilio-inguinal route is the only one to be recommended in the great majority of cases, the exceptions being those in which the calculus is known to be in the pelvic segment of the ureter.

The incision usually employed commences an inch below the last rib at the outer edge of the erector spinae muscle, and extends inwards and downwards in front of the anterior superior iliac spinous process. The distance to which the incision is extended inwards depends upon the necessities of the individual case. If the patient be short and stout the space may be increased by making a T-shaped addition to the above, or by incising a portion of the quadratus lumborum.

When the fascia transversalis has been exposed and divided the colon is seen. It should be retracted and the hand introduced through the wound behind the peritoneum, when the kidney can be felt embedded in its adiposo capsula. The soft fat is easily separated from the kidney,

and after the organ has been fully exposed a systematic examination must be made before it is disturbed from its bed. The ureter should be searched, and if a stone be found it may sometimes be pushed up into the pelvis and removed by an incision through the convex border of the kidney; generally this is easily accomplished, as the ureter is dilated above the point of impaction of the stone, but if it be firmly fixed an incision should be made through the wall of the ureter above the level of the stone, and after the calculus has been extracted the incision may be closed by sutures.

If the kidney is diseased and the tissues around it are indurated and adherent, it is very difficult to detect the ureter. Under such circumstances it is necessary to trace the ureter from below upwards, beginning at the point where it passes over the brim of the pelvis, or where it crosses the iliac vessels. In disease it is usually more easily discovered than in health, but on account of prolonged irritation the peritoneum is more firmly adherent to it than under normal conditions. When the duct is

discovered by the forefinger the intestine and the peritoneum should be gently pressed aside with a thin gauze pad held by an assistant, in such a way as to leave the ureter freely in view (Fig. 7). The serous membrane should then be carefully dissected from the duct as far down as may be necessary. Whether to separate the ureter upwards or downwards from the point in view is easily determined by its lumen; the duct is always distended above the point of obstruction.

The pelvic segment can only be seen by extending the incision in the parietes well forwards, but before doing this it is well to pass the forefinger down into the pelvis and explore, and not infrequently, when the obstruction be due to stone, the concretion can be displaced and slipped upwards so as to be brought into view without enlarging the opening.

A difficulty occasionally met with which should be kept in view is the lodgement of the stone in a diverticulum of the ureter, so that while the concretion is not in the lumen of the duct its presence causes distortion of the passage and obstruction to the escape of urine.

In opening the ureter, an oblique incision should be employed rather than a longitudinal one, which is liable to produce diminution in the lumen of the duct by the suturing, while a transverse incision is likely to be followed by a fistula.

When only the pelvic portion of the duct requires to be exposed, the incision through the parietes may be limited.

Fig. 7.—The right ureter exposed in the ilio-inguinal region, and drawn downwards and forwards, so as to be fully seen. With a little manipulation the stone can be slipped up to the most easily exposed segment of the ureter before being removed.

Instead of starting from a point an inch below the last rib, the incision may be made as for tying the common iliac artery, commencing immediately outside the centre of Poupard's ligament, and $\frac{1}{2}$ in. above it; this incision is carried outwards towards the crest of the ilium, then upwards and slightly inwards. The abdominal muscles are cut through till the fascia transversalis is reached; it is picked up and divided, and the extraperitoneal fat is exposed to view. The peritoneum is then separated, and, with the bowel, is held to one side by an assistant while the surgeon explores the posterior wall of the bladder for the ureters. Owing to the small size and depth of the wound, it is necessary to throw light into it with an electric forehead-lamp or a mirror.

When the ureter is exposed for the removal of a stone, if it be found that the calculus can be displaced from its bed and pressed upwards, the opening in the duct should be made in the dilated ureter well above the point of impaction. By adopting this plan the incision is made through comparatively healthy tissue, whereas if the cut is made directly over the concretion the line of incision passes through unhealthy tissue, the mucous membrane is apt to be eroded, and the walls of the ureter diseased. After the ureter has been opened and the stone removed it is difficult to adjust the edges of the wound in the flaccid duct. To obviate this difficulty in recent operations I have adopted the following plan, which has given perfect results.

Before the incision is made six catgut sutures should be passed through the wall of the ureter parallel to the line of incision, and one-sixth of an inch away from the cut. Three on each side (Fig. 8, *a, a', b, b', c, c'*) pass through the ureter wall outside the mucous membrane. These are used as braces to steady the wall of the ureter while the incision is being made, and to draw the lips of the wound apart (Fig. 9). When the stone is freely

Fig. 8.

Fig. 9.

Fig. 10.

Figs. 8, 9, and 10 illustrate a method of applying strands of gut to keep the wound apart during the operation (Fig. 9) and utilized as sutures later. Fig. 10 shows the suturing of the mucous membrane with a continuous fine catgut. The strands *a, a'* are passed parallel to the line of incision, but when used as sutures *a* on the right-hand side is tied to *a'* on the left side and *a'* to *a*, and so on, *b* to *b'* and *b'* to *b*.

movable and well down the ureter the operation is simple, but in actual practice many difficulties are encountered, the more common of which I may illustrate by the following cases:

CASE VI.—*Old-standing Calculous Hydronephrosis with Diverticulum in which Calculus usually lodged: When displaced the Stone blocked the Ureter and caused Symptoms: Stone removed by Lumbar Incision: Good Recovery.*

The history dated back over a period of twenty years. The patient was the colonel of an Indian cavalry regiment, and consequently lived in the saddle. The first attack of renal colic

came on while playing polo, and lasted for over thirty-six hours. From then till he consulted me he had severe attacks of renal colic, the pain being limited to the right lumbar region; at one period they were frequent, at another time many months passed free from pain. Within the last few years the attacks have been more severe, and always associated with hæmaturia; these are now brought on by any sudden movement while lying, and the patient says that the only thing that relieves the pain is a cross-country ride. This, he says, is a certain cure, but relief from pain is always followed immediately by a considerable hæmaturia. A long shadow was seen close to the body of the third lumbar vertebra on the right side.

At the operation, by a lumbar incision, the kidney was found to be hydronephrosed, and very firmly adherent, so that much difficulty was met with in exposing the ureter and pelvis. The stone could be felt in the thick mass of connective tissue, but when the pelvis and dilated ureter were opened the stone could not be reached. It was found, however, in a diverticulum (Fig. 11, *a*) communicating with the upper end of the ureter (*b*) and was removed, but by cause of the adhesions the diverticulum could not be dealt with. The condition found clearly explains the history that while the stone was in the sac and the patient maintained the erect posture the calculus caused no trouble and was not likely to be displaced, but when he suddenly moved in bed, from lying on his left to lying on his right side, the stone was liable to drop into the diverticulum into the dilated ureter, and so cause obstruction. Jolting on horseback, while it caused bleeding, evidently pitched the stone back into its pouch, and at once relieved the colic, also no doubt the long periods of freedom from pain were due to the calculus remaining at rest in its receptacle outside the ureter.

Another instance of a stone lodged in a diverticulum may be of interest. In this case the pouch is level with the brim of the bony pelvis.

CASE VII.—*Renal Colic of Old Standing, becoming lately Less Acute: Hæmaturia and later Pyuria from Right Kidney: Stone just below Brim of Pelvis: Hydronephrosis: Stone found in Diverticulum, and removed by Ilio-inguinal Incision.*

A lady aged 40 years had attacks of renal colic during several years, but no severe pain had been complained of for two years.

There is, however, constant dull pain in the right kidney, occasional slight hæmaturia, and moderate pyuria.

When I first examined the patient in August, 1908, the quantity of pus deposited was moderate. The urine was acid and contained *Bacillus coli*. The temperature was normal and the pulse good, but the general health was poor, and she said that she was becoming weaker. The bladder was normal, but the orifice of the right ureter was dilated. A shadow was found a little below the level of the brim of the pelvis, and the right kidney was considerably enlarged. The left kidney normal. Both kidneys were working well, but all the pus came from the right. On account of the enlargement of the kidney, the pyuria, and the failing health, an operation was advised.

On exposing the ureter, which was easily done by an ilio-inguinal incision, a diverticulum (Fig. 12) was found in which the stone was lodged. The sac was opened, the stone removed, and the diverticulum excised. A curious circumstance was that the lumen of the ureter above the level of the stone was very little greater than normal and suggested the

Fig. 11.—Rare case of diverticulum of ureter (*b*) which contained a long finger-shaped stone

Fig. 12.—Diverticulum at level of brim of pelvis containing a stone. The ureter was not much dilated, but a moderate hydronephrosis developed.

idea that the diverticulum existed prior to the formation of the stone or that the stone had increased in bulk greatly after it had become lodged in the pouch. The opening of the diverticulum (Fig. 12) was much smaller than the stone. The edges of the wound in the ureter were brought together, and the patient made a good recovery.

After the stone has been brought to the opening in the ureter, difficulty may be found in removing it, as, if smooth and rounded, it may repeatedly slip away from the grasp of sequestrum or dressing forceps. In such cases the writer has used cup-shaped forceps similar to Mackenzie's laryngeal forceps, or a small lithotomy spoon. Again, in cases of phosphatic concretion associated with *Bacillus coli* infection, the stone may be so friable that it breaks into small fragments as soon as it is grasped with forceps. Here again a spoon is useful. After the stone has been removed, the ureter sound should be passed upwards and downwards to make sure that the duct is patent, that all concretions have been removed, and that no stricture remains. The mucous membrane is separated from the outer wall of the ureter so that it may be sutured separately with a continuous fine catgut suture (Figs. 8, 9, and 10). This completed, the sutures used as braces are tied, *a* to *a*, *a'* to *a'*, *b* to *b*, *b'* to *b'*, and so on. In some instances the opening in the ureter is so low down that sutures cannot be used (Case IV). Then the wound should be carefully packed with gauze and a free drain established.

The Paraperitoneal Method.

This is carried out in the following way: The patient is placed on his back and an incision is made $\frac{1}{2}$ in. to the outer side of the linea semilunaris, beginning close to the border of the ribs and descending to the anterior superior spinous process of the ilium. The parietes are divided down to the peritoneum, the cavity of which is not opened, but the membrane is separated from the abdominal muscles gently by the hand of the operator and, along with the abdominal contents, is dragged towards the middle line by an assistant. The kidney, with its surrounding fat, is then brought into view and the ureter exposed and examined as described above.

Should the patient be short and stout it may be necessary, in order to gain sufficient room, to make an incision at right angles to the first one, possibly as far as the quadratus lumborum. The advantage of this method is not so evident in operations upon the ureter as when lesions of the kidney require to be dealt with, but it is certainly to be preferred to the transperitoneal route.

When old adhesions have formed the peritoneum is very liable to be torn, and, should this accident occur, the wound must be carefully sutured before the ureter is opened.

The Hypogastric Route.

This has been occasionally employed by the writer for the removal of calculi. If the stone has passed through the muscular wall of the bladder and pushed the mucous membrane in front of it the appearances presented by the cystoscope are liable to be mistaken for those of a tumour. In employing this method the bladder is opened by a suprapubic incision and the intramural segment of the duct is examined with one finger in the bladder, the other in the vagina or the rectum. It may be possible to grasp the impacted body with forceps and by careful manipulation drag it away without making any incision in the vesical wall, but if the stone be too large for this it is well to make a small incision and dilate the ureter with sinus forceps before attempting to extract the calculus.

The Sacral Route.

This method has been employed by Sir Henry Morris⁴ for the removal of a calculus impacted $2\frac{1}{2}$ in. from the orifice of the ureter. He describes the method as follows: "I employed a straight incision parallel with the median line and 1 in. from it, 5 in. in length, commencing about 2 in. above the border of the gluteus maximus muscle, and extending nearly to the transverse level of the anal aperture, but a little behind it. The edges of the gluteus maximus and great sciatic ligament were divided, and the rectum and vagina were pushed towards the opposite side by breaking through the cellulose-fatty tissue between them and the pelvic wall by means of the forefinger and a few touches with the scalpel. In one of these cases the dorsal position, with the haunches well raised on a firm pillow placed beneath the loin, was found to facilitate the identi-

fication, isolation, and removal of the lower end of the ureter; in the other case the patient had to be turned upon her back before it was possible to fix the calculus. This was done by the forefinger in the vagina, and the patient was again placed on her opposite side with her face downwards and the calculus cut down upon and extracted."

The Perineal and the Vaginal Routes.

These routes also are used for the removal of stones impacted close to the bladder.

Ceci has removed a ureteral calculus through the rectum, and Fenwick has employed a perineal incision; removal through the vagina has been employed by Kelly, the writer, and others. In such cases the ureter is dilated above the point of obstruction, so that it can be easily felt with the finger. The patient is placed in the knee-breast position. The bladder is fully distended with air and the posterior wall of the vagina is retracted backwards so as to give a good view of the anterior wall. The stone having been located with the finger, an incision is made through the vesico-vaginal septum between the orifice of the ureter and the cervix, large enough to admit the forefinger. The mucous membrane covering the stone is now incised and the lips of the wound are held apart, and the stone is pressed into the bladder through a finger in the vagina and a finger in the bladder. The use of forceps should be avoided. The ureter being dilated above the level of the stone, the introduction of the forceps is liable to push the calculus upwards, and once it is loosened it is very difficult to get hold of.

Another method may be used without opening the bladder. The ureter and the stone should be fixed by a small sharp hook, and an incision is then made through the vaginal wall, cutting on the stone; when this is completed a rush of urine takes place and the calculus escapes along with it. A catheter or sound should be passed up the ureter to the pelvis of the kidney to see that no other stones are impacted higher up. The opening may be closed with sutures, but probably it is safer to keep it open for a time by passing a drainage tube into the dilated ureter.

Vesico-Uretero Lithotomy.

In the male, when the stone becomes arrested where the ureter enters the bladder wall, by doing a suprapubic cystostomy the calculus may be removed. The patient is placed in the Trendelenburg position. With the finger in the rectum the stone is fixed in position by an assistant, the bladder is opened, and a small probe-pointed grooved director passed into the ureter from the bladder; the ureter is slit up for a third of an inch, fine sinus forceps are inserted, and the stone is extracted.

As the ureter is always distended above the obstruction it may be found difficult to fix the stone, which is apt to recede upwards and evade the grasp of the forceps. But this may be done by the assistant gripping the ureter above the stone with dressing forceps introduced into the bladder, helped by the finger in the rectum.

A Transperitoneal Operation.

This operation is now only adopted when the surgeon is uncertain as to the situation and nature of the obstruction, or is doubtful as to whether one or both ureters are involved. A median incision may be employed under such conditions, but if there be no doubt as to which ureter is affected, the incision should be made along the semilunar line, and curved towards the middle line at its lower end. There are many objections to the transperitoneal method. Unless the ureters be considerably altered by disease they are difficult to find behind the abdominal viscera. The peritoneum is opened both behind and in front, and in the event of any leakage of urine from the ureter may become infected; the position of the wound does not permit of free drainage; and, finally, no additional information can be gained which cannot be ascertained by other and safer methods.

After the abdomen has been opened, the first point is to ascertain the position of the kidney and find the hilum; then, passing the fingers downwards in front of the psoas muscle, the ureter may be traced as low down as the bifurcation of the common iliac artery. When diseased and distended the ureter is more easily traced than in

health, and often the stone can be felt occupying its lumen, while above the obstruction the greatly distended ureter is easily traced behind the peritoneum; indeed, it may be so dilated that, were it not outside the peritoneal cavity, it might be mistaken for small intestine. When the ureter is not the seat of serious pathological changes, when the subperitoneal fat is abundant and the intestine is over-distended with gas, much difficulty may be experienced in tracing the course of the duct. The point at which it is most easily detected is where it crosses the brim of the pelvis.

With the improvements in the operating cystoscope attempts have been made to extract calculi from the orifice of the ureter by dilating the duct with a catheter and removing the stone with McCarthy's flexible forceps passed through the cystoscope. Such an operation may be very nice if it succeeds, which is very questionable, but it is not surgery. It is very true that there are many operators but few surgeons. If a stone is so small that it can be picked out of the orifice of the ureter by forceps passed through a cystoscope, the strong presumption is that if a little more patience and a little less zeal for operating had been exercised the stone would in a short time have found a way out for itself.

The case is a very exceptional one where the Jumbo-ilio-inguinal operation is not the most suitable operation to employ. It has many advantages over all the others; when any unusual features present themselves, as, for example, in Cases VI and VII, they can be dealt with easily.

EPIDEMIC JAUNDICE IN WAR TIME.

BY

S. MORITZ, M.D., M.R.C.P.LOND., M.Sc.VICT.,

SENIOR PHYSICIAN TO THE MANCHESTER HOSPITAL FOR CONSUMPTION;
LECTURER IN THE VICTORIA UNIVERSITY, ETC.

JAUNDICE has been known to occur epidemically in peace time among the civil population, affecting then preferentially children. More frequently it has been observed in barracks, prisons, etc., but the largest epidemics have occurred in armies in war time—thus in the American war of 1862, in the Franco-German of 1870, and the Boer war. Its occurrence in this war seems probable.

The etiology of epidemic jaundice is still obscure. Jaeger described, as the cause of the disease, a micro-organism, the *B. proteus flavescens*, which he separated from the urine of patients affected with infectious jaundice.

There is no doubt that epidemic icterus is a disease *sui generis* due to some infective agent. Rainy and damp weather are mentioned by some authors as predisposing causes, but these might be excluded, for we find that the epidemics of jaundice have occurred more frequently in the summer and not in the rainy season. The supposition that the infective agent might be introduced into the human system by food or drinking water seems to be controverted by the fact that in several of the epidemics which have occurred only those men in the army were affected who had been digging dykes or trenches or had been engaged in earthworks. The infection seems to be due, therefore, rather to a virus or organism which develops in the soil during the decay of organic matter (excrements and dead bodies) and which is either swallowed or inhaled. There is no doubt that bad camp conditions were the principal cause of the large epidemic in the American war. In this war, in round numbers, out of 1,087,000 men in the Atlantic army 22,000 men fell ill with icterus; of 1,100,000 men of the central army 20,500 became affected, while of the 30,000 men of the Pacific army only 100 became icteric. The troops most affected were those of the Potomac Camp before Washington (1861-62), those before Yorktown (April, 1862), and those on the Chickahominy (January, 1862).¹ The total number of cases of jaundice among the white troops observed in that war amounted to 71,691.²

The accumulation of huge masses of men, bad drainage and ventilation, the superficial interment of the bodies of the fallen in the immediate neighbourhood of the camps, gave rise to this, the largest of all known epidemics.

Similar causes no doubt prevailed in the siege of Paris (1870), where 2½ per cent. of the troops of the Bavarian army corps were affected with icterus.

The course of epidemic icterus is generally benign. Out of 10,000 cases affected in the first year of the American war, only 40 died from this disease. Sometimes the symptoms are very slight, but usually the illness runs a characteristic course.

The illness usually commences suddenly with rigor and rise of temperature without premonitory symptoms. At the same time there is lassitude, vertigo, and headache, due no doubt to the fever. In severe cases there is soon some stupor or delirium, and these symptoms occur much earlier than they do in typhoid fever. The tongue is furred, and diarrhoea is usual. The liver and spleen enlarge moderately. Between the third and the fifth day, rarely earlier, the icterus commences, so that until then the diagnosis may appear doubtful. The liver and spleen are found enlarged on percussion, the edge of the liver may be distinctly felt, and is sensitive on pressure. The urine often contains moderate quantities of albumin, hyaline and epithelial casts, sometimes blood corpuscles.

The bowels usually become more and more relaxed, and the stools clay-coloured. The temperature remains high, often up to 104°, with irregular remissions during four to eight days; it then goes down quickly, and becomes normal in further four to six days, and simultaneously the hepatic and splenic enlargements and the albuminuria disappear, whilst the jaundice may last ten or fourteen days longer and then fade slowly.

In about 25 to 40 per cent. of the cases a relapse takes place three to eight days after the temperature has become normal. The relapse is usually less severe than the first attack.

There is usually great loss of strength, loss of weight (to 20 lb.), and prolonged convalescence. In most cases severe muscular pains, principally in the calves or in the back, are felt from the commencement of the illness, and these pains may persist even during the period of convalescence. Occasionally a spotty erythema of the skin of the thorax and abdomen is seen, in others herpes labialis, rarely an erythema of the fauces and tonsils. Occasionally hæmorrhages in the skin, conjunctivæ, or retinae have been observed. Coryza, hæmaturia, melæna, or hæmoptysis may occur; still rarer complications are parotitis, laryngeal paresis, neuritis, and iridocyclitis.

The duration of the febrile attack is from eight to ten days, that of the relapse from five to eight days; the whole duration of the illness from three to four weeks.

In regard to differential diagnosis, simple catarrhal jaundice, recurrent fever, and bilious typhoid come into question. Until the micro-organism of epidemic jaundice is found it will be impossible to distinguish slight cases of this illness from simple catarrhal jaundice. In some of the epidemics of recurrent fever many of the cases (25 per cent.) are affected with jaundice; the presence of spirillæ in the blood will clinch the diagnosis.

As icterus is said to interfere with Widal's reaction, the differential diagnosis from typhoid may be difficult.

The "bilious typhoid," described by Griesinger fifty years ago as endemic at Cairo, as well as the epidemics of febrile icterus described by Kartulis in Alexandria (1838) and Diamanthopolus in Smyrna (1886), were probably of the same nature. Though records of epidemic jaundice can be traced back at least to the year 1699, and perhaps to Hippocratic times, Weil of Heidelberg, in 1886, described a small number of cases, and since then "epidemic jaundice" has been described under the name of "Weil's disease," not only in German, but also in English textbooks (*vide* Clifford Allbutt, Osler, etc.).

STATISTICS published by the Bureau of Preventable Diseases of the Department of Health of the City of New York show that the number of cases of rabies found in animals examined in the laboratory of the department decreased from 64, recorded for the second quarter of the year 1914, to 15 in the corresponding quarter of 1915. There was also a reduction in the number of persons examined for dog-bite, and in that of dogs examined for rabies.

MALARIA CONTRACTED IN FLANDERS.

BY

LIEUTENANT J. MCG. H. REID, R.A.M.C.,

AND

LIEUTENANT H. E. HUMPHRYS, R.A.M.C.

THE following cases were admitted to a general hospital from various parts of the front:

CASE I had lived in Hull all his life and never previously left England. He came out to France in July feeling very fit, but on August 28th had pains in the head, followed next day by shivering fits. This continued every second day, and he was admitted to hospital on September 9th. The blood, examined the following day, showed the presence of a typical benign tertian parasite. He said that he had never been near Indian troops, but that he was encamped beside a river.

CASE II had lived in London and had never been out of England before. On August 29th he had an operation for appendicitis, which was followed three days after by shivering attacks. He had been in excellent health before. He had never been in close proximity to Indian troops, but said there was a small pond near where he was billeted. The blood film showed benign tertian.

CASE III had lived in Suffolk and had never previously been out of England. He said that he had attacks of shivering two months ago in France, but did not report sick. On August 24th he again had had shivers, which occurred every other day. He said that he was in close contact with Indian troops. The blood showed benign tertian.

CASE IV belonged to Fifeshire. He had never previously left Scotland. He came to France in May feeling very fit and was only in contact with Indian troops one day. He had shivering attacks and vomiting a month ago. These attacks had continued ever since and occurred at night. He was admitted on August 28th; the blood film showed benign tertian.

CASE V lived in Staffordshire, and had never been out of England before. He was in close contact with Indian troops for three months. He was taken ill with shivering attacks and headache on September 5th; the shivering attacks occurred every day. The blood film showed benign tertian.

CASE VI, a native of Birmingham, had never previously been abroad. About the middle of June he was stationed at Ports-mouth for about four weeks, and then proceeded to Bulford. After he had been there about a month he had a very severe shivering attack. He left for France about July 17th, and kept quite fit till the middle of August, when he had a severe shiver similar to the first. From that day to September 9th he had similar shivers every day. He was sent to hospital as "query enteric," but examination of the blood showed benign tertian. He was stationed near Indian troops.

The probable explanation of these cases seems to be that infection was conveyed by mosquitos either from Indian troops or troops who had been abroad. The last case is rather more interesting than the others, inasmuch as the patient is quite certain that his first attack occurred while stationed in England. The fact that for some time he was in a large seaport town where he was likely to come in contact with troops from abroad is to be noted. On the other hand it is possible that infection may be conveyed by some other means.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

RECURRENCE OF LOCAL SEPSIS.

The most interesting article by Mr. Bond on the recurrence of local sepsis in completely healed wounds¹ reminds me of a number of cases I have come across in ordinary surgical practice. Here are, in outline, four of them:

1. An appendix abscess was opened; the patient's condition did not warrant search for the appendix. When the gridiron incision had healed the appendix was removed through Battle's incision; this healed by primary union, but the gridiron scar broke down and suppurated.

2. A man was admitted to hospital for obstruction due to adhesions eighteen months after a gangrenous appendix had been removed. The new incision healed; the old appendix scar suppurated, although the operation was an absolutely "clean" one, and the old scar was not touched.

3. A man had eczema of the foot. Weeks after it was healed he stood at a football match on a very cold day, drank more than was good for him, and went home fagged. The foot became red and swollen, and a small collection of fluid formed which was aspirated, and a pure culture of staphylococcus grown. The condition cleared up rapidly during the exhibition of an autogenous vaccine.

4. A man who ten months previously had had suppurative appendicitis developed croupous pneumonia. Just after the crisis the temperature went up, and the old appendix scar suppurated, discharging offensive smelling pus resembling in a mild degree that coming from the original abscess, and did not heal for five or six weeks. Here there was no traumatism, surgical or otherwise, to account for the suppurations.

Cases like these suggest that for long periods after a wound has healed organisms remain in the tissues—it hardly seems to depend on the presence of foreign bodies; there was no foreign body present in any of my cases—and that the recrudescence of suppurations depends upon some lowering of resistance or of the quantities of antibodies, or whatever happens to be the popular phrase of the moment to indicate that the soil is favourable to the growth of pus germs.

It would seem, *a priori*, that increasing the immunity by such means as autogenous vaccines prior to any further surgical interference would be the most likely way to prevent the recurrence of sepsis.

ALTRINCHAM HOSPITAL.

INTUSSUSCEPTION OF THE BOWEL: OPERATION AFTER FOUR DAYS: RECOVERY.

(By E. L. LUCKMAN, M.R.C.S., L.R.C.P., Surgeon to the Hospital.)

A BOY aged 10 years was playing at school, when he was suddenly seized with pain in the right iliac region, and was taken home. When I saw him he complained of very acute pain in the region above mentioned, which after a time became continuous. Hot applications were applied, but with little benefit. As he was constipated, warm enemata with soap and oil were administered, and there was a slight action of the bowel. There was some vomiting, but this did not relieve his pain. On inquiry I found that he had had a similar attack two years previously, which simulated intussusception. I gave him medicine to relieve pain, glycerine and belladonna fomentation to the abdomen, and warm oil enemata.

It was not until the fourth day that the parents gave consent to an operation. He was then cyanosed, with subnormal temperature and weak pulse. There was stercoraceous vomiting, and the abdomen was tympanitic and greatly distended, and there was some dullness in the right iliac fossa. The symptoms all pointed to intussusception.

He was removed to the hospital and put under an anaesthetic. I performed laparotomy and found 6 in. of the ileum invaginated; by gentle pressure the inner tube was squeezed out, the intussusception being thereby relieved.

We had to hurry with the abdominal sutures on account of his condition. It was with difficulty that the two sides of the incision were brought together on account of the bowels being distended with flatus. Two hours after the operation he passed flatus and the tension was relieved. His temperature and pulse afterwards ran a normal course, and he made an uninterrupted recovery.

The chief points to note are: (1) That the operation was on the fourth day; many authors state that it is hopeless to operate after the third day. (2) Six inches of bowel were intussuscepted.

The Journal of the American Medical Association states that an action has been begun before the Supreme Court by Attorney-General Woodbury to determine the right of the State to sterilize defectives. The individual on whom the State Procreation Commission proposed to perform the operation is a young man, 22 years of age, one of a family of sixteen, practically all defective. To date, this family has cost the State 10,000 dollars (£2,000) for hospital care and maintenance. On the decision in this case depends whether the Procreation Commission will enter on its work of sterilizing mentally defective persons in New York.

Reports of Societies.

DISCUSSION ON THE TREATMENT OF CEREBRO-SPINAL MENINGITIS.

In opening a discussion at a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on October 19th, when Dr. W. HALE WHITE was in the chair, Sir WILLIAM OSLER said that the features of the recent epidemic resembled those of previous ones in that there was a low case incidence; that it was widespread; that there was a high case mortality, a high incidence among soldiers—especially young soldiers—and that the epidemic declined with the end of the winter. During the first year of the war there had been 462 deaths from this disease, and it was the second highest cause of death from infectious diseases. From the Registrar-General's report during twelve months, 9,269 deaths were certified as due to meningitis. In 3,819 of these the cause of the meningitis was not specified. There was need for more information concerning this group. The meningococcal variety was the only one from which recovery could be anticipated. He had never personally seen a recovery from tuberculous meningitis, and only once from streptococcal. Two points called urgently for discussion in connexion with treatment of the meningococcal form: (1) The prophylactic measures which should be taken in view of the probable recurrence of the epidemic this winter; (2) the value of serum treatment. An increase of the disease must be expected during the winter months; how was it to be combated? Many observers held that the epidemic was in the carrier; in this it resembled pneumonia. Two truths stood out prominently—one, the correlation between its seasonal prevalence and that of naso-pharyngeal catarrh; the other, the influence of overcrowding. He advised that three steps should be taken: (1) That the young soldier should be guarded from over-fatigue; (2) that naso-pharyngeal catarrh should be reduced to a minimum; (3) that good ventilation should be procured for the sleeping quarters, combined with comfortable warmth of the bed. Anti-meningococcal serum was still on its trial. In the present state of knowledge specific therapy combined with lumbar puncture was the rational treatment. The value of the specific treatment was much debated, and in many quarters disappointment had followed its use. The epidemic had been unusually severe and the mortality high. In an outbreak among the Canadian forces, of 40 cases treated 26 had died. The progress of a few treated with Mulford's serum suggested that some improvement had taken place, but no benefit had followed other serums. The results at Haslar and elsewhere had been no better. The main cause for this want of success was, he believed, inert serums. Another possibility was infection by parameningococci. The contrast was great between the results in this country and those obtained by Flexner and others in America.

Dr. A. G. ROBB gave his experience of the severe epidemic which occurred in Belfast, and contrasted the mortality before and after the use of Flexner's serum. At first the mortality in hospital was 72 per cent. Flexner's serum was then used, and the death-rate fell at once. For the three months before its use the death-rate was 85 per cent.; for the three months after, 26 per cent. A like disparity occurred between the death-rates of the cases treated in hospital by serum and those treated outside without serum during the same period. It was important that in published statistics the gross mortality should always be given. He had hoped for better results during the last epidemic, but they had been worse. Of exactly 100 cases treated 36 ended fatally, although the cases, he thought, had not been more severe. So far as he could ascertain no single case in the north of Ireland not treated by serum had recovered. The greatest benefit from serum treatment had been noted in young children. Before its use the mortality among them was 90 per cent.; in the last epidemic only 4 out of 17 children under 5 years old had died; there were two cases in children under 1 year old, and both recovered. Possibly another strain of organism might be responsible for the disappointing effects of serum. He

had taken strains from various sources to the Rockefeller Institute, and although the investigation was not complete, no radical difference had been found between them. In some, however, lower dilutions had been necessary to produce agglutination. Serums obtainable in this country from various sources had been tested by Flexner, who had shown that much of it was unsatisfactory. At the outbreak of war large quantities had come from America, where little was being prepared. Few horses had previously been immunized, and, as a result of the demand, these were bled far too often. At the present time, however, it was thought that a serum even better than the original one had been prepared. He discussed the views of Sophian, who insists on the importance of noting the blood pressure during the intrathecal injection and on the inadvisability of giving a general anaesthetic. Dr. Robb had, however, come to the conclusion that no additional anxiety need be felt if a general anaesthetic were given, and that in such circumstances no sudden fall of blood pressure need be feared. He had tried the new serum in 8 cases, only one of which had ended fatally.

Dr. H. D. ROLLESTON (temporary Surgeon-General R.N.) gave the results obtained in the navy from the beginning of the war to the end of last August. There had been 170 cases, mostly in dépôts, and he had abstracted the notes of 163 of them. Serum had been tried in 105. The death-rate of the whole series was 53 per cent. Cases treated by serum fell into two groups: (1) Those treated by lumbar puncture and serum alone; and (2) those which received both serum and other forms of treatment. Of the 105 serum-treated cases, 64 died. The mortality of those receiving serum alone was 70 per cent.; the mortality when other treatment was also used, 46 per cent. When serum had been used before the third day of the disease the mortality was 60 per cent.; when between the fourth and seventh day, 58 per cent.; when after the seventh day, 73 per cent. The failure was not due to the serum being given too late in the disease. It had been procured from many different sources. Afterwards the serum treatment had been combined with soamin, or vaccines, or hexamine. The results of the serum compared badly with those obtained by almost any other method. Of 21 treated by soamin alone 33 per cent. died; of 18 treated by soamin and serum 61 per cent. died. It almost appeared as though the administration of serum had done harm rather than good. He did not think that the gravity method (Sophian) was necessary, nor had there been any serious anaphylactic symptoms. In a few cases autogenous vaccines had been used, with a mortality of 25 per cent. Hexamine appeared to be inert.

Captain MICHAEL G. FOSTER, R.A.M.C., said that as he had lost a high percentage of cases treated with serum he had abandoned it for lumbar puncture only. Of 42 cases so treated 14 died, a result which would bear comparison with those obtained by serum. The advantages of lumbar puncture were the striking relief from symptoms, especially if the puncture were fairly frequently repeated, and the possible prevention of hydrocephalus. Lumbar puncture was a safe operation; a general anaesthetic was advisable. He removed the amount which would run off, and had never met with ill effects.

Captain J. F. GASKELL, R.A.M.C., gave further details of the same cases. He had found that in those which were unresponsive to treatment the meningitis was chiefly verticillate, the base of the brain being comparatively little affected. A table of the cases showed that it was important to commence treatment early. In certain fatal cases the theca was distended with tough adherent pus not removable except with a scalpel. In a group of hydrocephalic cases it was found that the patients could be kept alive by artificial respiration, denoting that death was due to intraventricular pressure. *Post mortem*, in such cases tough adhesions were often found, which had made it impossible to remove the excessive fluid by puncture. In one case the patient's own serum had been used, the symptoms improving immediately, but similar sudden improvement had been noted in other cases not so treated. In his opinion, patients did as well with daily lumbar puncture if as much fluid as possible was run off, as with serum treatment.

THE late Sir Thomas Clouston, for many years physician-superintendent of the Edinburgh Royal Asylum, Morningside, left personal estate of the value of £27,453.

Reviews.

SANE PSYCHO-THERAPY.

A SANE and well-reasoned method of investigating and treating the multitudinous manifestations of neurasthenia, hysteria, and the allied maladies that are grouped together under the somewhat questionable title of psycho-neuroses, comes as a refreshing dip into a cold bath after stifling in the heated and unwholesome atmosphere of psycho-analysis and the unpleasant mystification of the new German school. Such a method is provided by the teaching of Professor DEJERINE.¹

Psycho-therapy is a word of many meanings. It may mean suggestion, either hypnotic or non-hypnotic; it may mean Christian Science, so-called; it may mean psycho-analysis; it may mean the influence of a strong character on a weak one; and may have other meanings. To Professor Dejerine it means first a thorough understanding of your patient, and a recognition of his point of view, his fundamental weakness, and, as far as possible, of the origin of his malady; it means, in the second place, an attitude of cordial sympathy with the patient; it means, in the third place, the winning of the patient's confidence by sympathy and by candour; and it means, lastly and mostly, persuasion, by which is meant the combined influence of sympathy, reasoning, and authority. Professor Dejerine examines, one after another, the usual methods of treating these maladies, and one after another he condemns them upon grounds that are well and carefully reasoned, and carry the reader's assent. Treatment by drugs, whether they are active or are mere vehicles for suggestion, he condemns unreservedly. He admits that by giving the patient bread pills under a high-sounding title, and with the positive assurance that they will do him good, the patient will very likely improve; but he argues that in the first place we have no right to deceive our patients and to practise on their credulity, even for their own good; and in the second, that although the patient may improve in this way and in that, yet some day he will wake up to the fact that, taking all together, he is as bad as ever, and his last state will be worse than his first. No one who has practised this method can deny that this is very often the result. Suggestion is called by Professor Dejerine a medical trick, and he very justly says that it is not enough to abolish the symptoms; it is necessary to change the whole mental state of the patient, or the symptoms will infallibly recur. Hypnotic suggestion is very carefully examined. It is no small problem for a physician to determine whether he has the right to suppress the free will of his patient, and make him act against his own volition. We cannot with impunity accustom a subject to accept suggestions from others. Very few of those who have been used as experimental mediums have ever been able to return to normal life. The effect of hypnotism is not towards development and strengthening of the character, but towards deterioration and weakness. Moreover, Professor Dejerine is convinced that a deeply-hypnotized person may be induced by suggestion to commit any act, even crime; and this objection has often been urged against hypnotism, and has never been answered. Finally, hypnotic suggestion deals with but one isolated mental state, and can never produce the general mental revolution that is required. This reasoning seems unanswerable. Direct suggestion without hypnosis is less dangerous than hypnotic suggestion, but as it is less powerful, so it is less efficacious, and it has special dangers of its own.

In therapeusis by persuasion there is no more stage-setting, no more drawn curtains, no more closed shutters, no more over-riding the will of the patient. It consists in establishing the complete confidence of the patient in the physician by a thorough investigation of the case and a candid explanation of it to the patient. Appeal is made to the patient's reason, but not to his reason alone; no hysterical or neurasthenic was ever cured by syllogisms. He is led on to cut his own way through the tangle, and to save himself by his own efforts. His self-confidence and self-reliance are developed, and his character

strengthened. The method appeals no less to the reason than to the conscience, and altogether the book is fascinating reading.

The translation is more literal than into idiomatic English, and bears many marks of its American origin; it is, however, clear and intelligent. The book is printed upon the heavily loaded paper that for some reason is general in America, and in consequence needs a bookstand for comfortable reading, and is expensive to send by post. This is the less reasonable as it contains no illustrations, which are the usual excuse for selling books by the pound *avoirdupois*.

STEREOROENTGENOGRAPHY.

THE hybrid and repulsive term "stereoroentgenography" is employed by Dr. J. T. CASE² as the name for the illustration of pathological and normal conditions of the viscera and other tissues by the use of stereoscopic skiagrams, a method that has been in use for nearly twenty years. During the last few years the technique of the method has been vastly improved, particularly by Dr. Case himself, and he is now in a position to take the two skiagrams that are required within the space of a single second; as he points out, the greatest speed obtainable is advisable in work of this kind. As for the apparatus employed, Dr. Case uses an intensifying screen for taking stereoscopic skiagrams of the intestine. The interrupterless type of transformer, operated on a 110 or 220 volt direct or alternating current circuit, is advised; the exposures given vary from one-twentieth to one-fourth of a second. The second photographic plate must occupy exactly the position of the first; before exposing the second plate the x-ray tube should be shifted laterally a distance of six centimetres, which is the average interpupillary distance. The distance between anode and plate recommended is usually sixty-five centimetres for chest and abdominal work. The use of tubes with two anodes, in place of shifting the tube before the second skiagram is taken, has hitherto proved unsatisfactory. The photographic plates employed should be of large size, in the case of gastric skiagrams measuring 11 by 14 inches.

Dr. Case has published an *édition de luxe* of a hundred double stereoskiagrams of patients with disorders of the alimentary tract. The book is in four volumes, with loose leaves, in folders and cases, and is published under the aegis of Dr. Howard Kelly of Baltimore. There are 205 leaves in the four volumes, each leaf consisting of text, or text and diagrams, or text and a stereoskiagram. The stereoskiagrams are apparently bromide prints, reduced to 3 by 2½ inches; a stereoscope for looking at them is given with each set of volumes. The cases illustrated are for the most part gastric and intestinal cases of all sorts, illustrating both organic and functional diseases of the alimentary tract, as well as the normal condition of affairs. The text gives an ample description and discussion of both the cases and the skiagrams, so that the reader is able to profit fully by the detail of the excellent pictures reproduced. One of these gives a very interesting view of a pelvis containing two calcified uterine fibroids (p. 199). Dr. Case finds that acute intestinal obstruction gives quite a diagnostic x-ray picture; the gas-distended small intestine here shows a pathognomonic reticulated appearance, and the use of a bismuth meal is unnecessary (p. 117). In many cases he gives two bismuth meals, at intervals of from six to twenty-four hours, particularly when it is desired to visualize the entire alimentary tract for observation at one or two sittings (p. 129). Dr. Case believes that when gall stones are present they may be demonstrated on the skiagram in nearly half the cases (p. 102). We have nothing but praise for the contents and the get-up of these sumptuous volumes. Neither care nor expense has been spared in their production. There is no skiagrapher who would not learn much from their study, and they cannot be too widely made use of.

OXFORD WAR PRIMERS.

THE amazing number of explosive missiles used in the present war have produced a vast variety of injuries to the chest and its contents. The experience gained in the treatment of them has enabled some very definite lines to

² *Stereoroentgenography: The Alimentary Tract*. By J. T. Case, M.D. In four parts. Troy, N.Y.: The Southworth Co. 1915. (Cr. 4to, pp. 205, and 100 stereograms in the four parts.)

be laid down, more especially as regards the injuries to the internal organs. Many of the leaders of surgical teaching have already published their views, and a useful handbook, in which the whole subject is considered in detail, has recently been compiled by Staff Surgeon J. KEOGH MURPHY, R.N.V.R.³ His own experience, derived from naval as well as from military practice, has enabled him to form some very definite opinions, which are set forth in interesting form and deserve close attention. The modern rifle bullet is a merciful missile so long as it encounters soft tissues only in its course. It becomes terribly destructive if its course is obstructed by any hard tissue such as bone. The hard envelope of the bullet may split and break up into a vast number of sharp fragments which may cause widespread laceration.

In spite of the fact that the thorax contains so many vital parts, the mortality from chest wounds is not so great as might be expected. Very many of the injuries are inflicted in the sides and in the back. The prone position, which has to be so much used, lays the head, neck, and back open to rifle fire, and many longitudinal wounds are thus inflicted which are very fatal in their ultimate results. The shock produced by wounds of the chest is often very severe, but is sometimes surprisingly small, nor is there usually much hæmorrhage, unless a large vessel has been injured. Pain, too, is seldom severe, except in superficial injuries to the back, and dyspnoea, which may be very severe at first, tends to pass off fairly soon. Injuries to the pleura and their results form a large proportion of the conditions calling for special care and caution. Hæmorrhage, so seldom met with in civil practice, is common in military surgery, and the writer devotes much attention to the questions arising as to treatment under varying conditions. The great danger of a collection of blood in the pleural cavity is that it should become septic. If a hæmo-pyo-thorax should be thus set up, its free drainage is obviously indicated, but so long as the blood remains uninfected the less it is interfered with the better. Even the use of the exploring syringe is deprecated. Simple pleuritic effusion as a result of a wound is not often met with. Some form of infection usually takes place from the beginning. In dealing with penetrating wounds of unknown depth and extent the processes of nature should not be interfered with by the introduction of a probe or by the injection of antiseptic fluids. The use of the latter in general seems to be regarded with disfavour, as being useless as a disinfectant and only too liable to interfere with the normal protective action of the lymph that has already begun the healing process. The cleansing of the external wound and the removal of any dead tissue or foreign bodies, a gentle sponging with hydrogen peroxide or 5 per cent. carbolic, and a light inunction with iodox, a preparation with which the writer expresses great satisfaction, should be followed by fomentations of boracic acid, the greatest care being taken to avoid sepsis. By such means the natural flow of lymph is assisted with as little interference as possible.

The treatment of shock in deep thoracic injuries is often urgent, and of all the methods hitherto employed the writer expresses his strong preference for slow injection of hot saline into the rectum. An ingenious application of the siphon and the thermos bottle enable this to be done at a uniform temperature. The difficulty of applying bacterial therapeutics in military practice is great, but a good deal can be done to supply autogenous vaccines which in some cases have proved useful and are always worth trying, as they are not productive of any evil results.

Mr. Murphy's little handbook will be found of real value to the very large number of young military surgeons who may be called upon to treat thoracic injuries. It is full of detailed information of the kind that is most needed in actual practice.

The war primer on *Nerve Injuries and Shock* by Captain HARRIS is divided into two parts. The first of these deals with direct injuries of the central and

peripheral nervous system; the second with the nervous shock and loss of moral so commonly met with in the present day of high explosives, and characterized by many of the nervous manifestations irrationally known as "hysterical." Captain Harris gives a brief but clear exposition to cover the ground of the title of his book, describing the nature of the cases likely to be met with and giving fairly full instructions as to their treatment, but leaving pathological and theoretical considerations severely alone. The little manual should be of service to those for whom it has been written.

During the last twelve months both civil and military practitioners of medicine have seen relatively large numbers of cases of epidemic and sporadic cerebro-spinal meningitis, although the disease has not, fortunately, shown anything like the extensive spread noted in American and Continental epidemics occurring in the last twenty years. A full, scientific, and lucid account of the disorder has been written by Major T. J. HORDER.⁴ His *Cerebro-spinal Fever* is quite the best book on the subject we have seen, and it should be in the hands of all medical men who have to do with the disease. The descriptions of the symptoms, diagnosis, treatment, and prophylaxis given are admirable, and leave nothing to be desired. Should cerebro-spinal fever re-emerge in epidemic form again during the coming autumn and winter months, the practitioner could hardly have a better guide in his dealings with the disease than Major Horder's little volume.

BEHIND THE LINES.

The title *War Pictures Behind the Lines*⁵ expresses well the scope of the book which Mr. IAN MALCOLM, M.P., has written, describing his experiences, chiefly in France. For about eight months—beginning in October, 1914—he worked for the department of the British Red Cross Society now known as the Inquiry Department, and was specially engaged in tracing the fate of men returned as "missing." The system established of examining the hospital registers and questioning the wounded and the lists of prisoners furnished weekly by the International Red Cross Society in Geneva afforded a great deal of information, but there were always some not accounted for, and the prosecution of inquiries with regard to them led Mr. Malcolm into almost every part of France where the British have fought in this war. A sad part of his task was to attempt to identify graves, and he pays the warmest possible tribute to the sympathetic attitude of the French, including the humblest peasants, towards the dead of their ally. To most readers the most novel part of his book will be the chapter on the Red Cross work which is being done by Switzerland. The International Committee of the Red Cross at Geneva is international in the sense that it operates as a clearing house between nations, not that it is composed of representatives of all nations, for each of its members must be a Swiss resident in Geneva. It has established an *Agence des prisonniers de Guerre*, and twelve hundred voluntary workers have organized a card-index system, in which every man whose name reaches the agency as a prisoner (whether military or civil), or as missing, or as killed, is registered. From October 15th, 1914, to June 30th, 1915, this agency corresponded with 234,731 families; received 1,800,000 letters and 50,000 visitors, and forwarded about 71,300 letters and 11,500 telegrams to various destinations. In addition to this work a *Bureau des Repatriés Civils* has been established, and on its lists are nearly 20,000 names of exchanged civilians of all nationalities who have passed through its hands, and of no fewer than 65,000 poor refugees from French territory. When the refugees arrive there is an inspection of clothing, and in most cases it has to be renewed. Bathrooms and changing rooms have been fitted up in a large gymnasium, and in three or four hours each convoy is ready to be sent off in tractors to the French frontier. In Berne there is a committee of ladies supplying prisoners in French, German, and British camps with comforts of various kinds: from the French section bread and clothing

⁶ *War Pictures Behind the Lines*. By Ian Malcolm, M.P. London: Smith, Elder, and Co. 1915. (Fcap. 8vo, pp. 242; illustrated. 6s. net.)

are sent to French prisoners in Germany and distributed under the superintendence of neutral delegates, and the British section dispatches vast consignments of loaves and other articles to our own prisoners; the Russian section is well supplied with money to buy comforts and necessities for the thousands of captive Russians whose families are too far off to send separate parcels. "*Inler arma caritas*, the Red Cross motto, is certainly the guiding principle of Swiss life to-day; generous and indiscriminately kind to the helpless and fallen victims of the German War." Mr. Malcolm's book is very modestly written and well illustrated by photographs of places and incidents and reproductions of official documents.

NOTES ON BOOKS.

C. J. S. THOMPSON'S *Compendium of the Pharmacopoeias and Formularies*⁷ has now reached its fifth edition, and has been brought thoroughly up to date. It includes the alterations made in the last edition (1914) of the *British Pharmacopoeia*, and contains tables and abridgements that make it a serviceable handbook of reference for medical practitioners, pharmacists, and students.

R. R. BENNETT'S *Materia Medica and Pharmacy*⁸ is one of the small books on the subject written for the benefit of medical students, and supposed to contain as much as they require to get them through their examinations in these subjects. It has been altered so as to conform with the *British Pharmacopoeia* (1914); dosage is given in both the newly adopted metric system and the older imperial system to which we are all accustomed.

THE NEW TAXES.

As the Finance (No. 3) Bill was issued so late last week our comments upon it must necessarily appear belated, but it still seems worth while to examine those provisions which have some special interest for medical men more closely than was practicable when the only reliable source of information available was contained in Mr. McKenna's Budget speech.

Section 10 of the bill deals with the duty on motor spirit, which is to be increased from 3d. to 6d. a gallon. The existing rebate of 1½d. per gallon will be raised to 3d.—presumably only to the extent to which the spirit purchased has borne the full rate of duty. In these days the taxpayer is often exhorted to suffer in silence and to be thankful for any mercies the Exchequer can afford to distribute by way of mitigation. Nevertheless, while the medical profession may be suitably grateful for the rebate of 3d. per gallon, the remaining moiety of the duty falls on the individual practitioner with peculiar severity. The fact is undeniable, even though the consequences be accepted, if not exactly with cheerfulness, at any rate without serious complaint. It is to be remembered that no other professional man uses motor spirit to the same extent as the medical practitioner. The position of the latter differs also from that of a trader paying a similar duty on the petrol used in the conveyance of goods, for economic theory and recent experience alike bear testimony to the fact that such general trade taxes slide with remarkable facility from the shoulders of the trader to those of his customers through rising prices, whereas the medical man has not the opportunity—even if he has the desire—to pass on the incidence of the tax in similar fashion.

These remarks apply also to the 3½ per cent. *ad valorem* import duties on motor cars, accessories, and component parts, which are dealt with in Section 12, passed in Committee on October 20th by 78 to 26. Whatever may be the origin and final outcome of these taxes, their effect will certainly be to cause an early and substantial rise in the price of the cheaper varieties of motor cars. These duties have more than once been defended as constituting a "sumptuary tax," and in accordance with that aspect of the question Section 12, Subsection (7), provides for the exemption of

trade motor vans. The phraseology of this clause is so important that we quote the first two paragraphs in full:

§12. (7) Motor cars which are proved to the satisfaction of the Commissioners of Customs and Excise to be constructed and adapted for use, and intended to be used solely, as motor omnibuses, or bona fide motor ambulances, or in connexion with the conveyance of goods or burden in the course of trade or husbandry, and chassis, component parts, and accessories, which are so proved to be intended to be used solely for any such motor cars, shall not be charged with duty under this section.

Provided that in such cases as the Commissioners of Customs and Excise direct, cars, chassis, accessories, or parts, as the case may be, shall not be exempted unless they are marked or stamped in such manner as the Commissioners direct or approve with some distinctive stamp or mark showing that they are only to be so used.

If reference be made to the fifth schedule of the Finance (1909-10) Act, 1910, which deals with the original rebate on motor spirit, it will be found that it bears a considerable resemblance to the above-quoted subsection, but it will also be found that a further clause extended the rebate to motor spirit used for a car "kept by a duly qualified medical practitioner while it is being used by him for the purposes of his profession." The position therefore appears to be that in 1909 the medical practitioner was considered to have an equal right with the trader to partial exemption from a motor tax, whereas now the trader is to have full exemption from the import tax and the medical practitioner no allowance at all. For this we can find no reason based on equitable grounds. The Legislature has already admitted—and in the bill under discussion repeats the admission—that, so far as the petrol duty is concerned, the medical practitioner is entitled to the same relief as the carrier of goods; surely the principle should apply, *mutatis mutandis*, to the tax on the car in which the petrol is consumed. The use of a motor vehicle by wholesale and retail traders may be advantageous, but to the medical profession it is essential. If it be urged that the motor van should be encouraged in the interests of the community as being ultimately more economical, and therefore tending to reduce prices, it can be urged with at least equal force that nothing should be done which might have the effect of reducing a practitioner's ability to visit his patient immediately, and with the least possible cost in time and money, for the services which he brings to his patient are more urgent than the trader's goods, and his time is more valuable than that of the motor-van driver.

We are forced to the conclusion that the reason is to be found in the practical difficulties which may be feared rather than in the realms of economic theory, and this conclusion is borne out by the manner in which the bill seeks in the section quoted above to safeguard the revenue from the subsequent adaptation of imported cars to suit private purposes. There must of necessity be a difficulty in discriminating at the port of entry between chassis for light commercial cars and chassis for private cars; in fact, the only adequate safeguard would seem to lie in subsequent periodical examination of all those foreign chassis which have been exempted from the new import duties. So far as the petrol tax is concerned, periodical consideration of each case occurs automatically when each repayment claim is made. The difficulty of applying some such system to the car itself does not appear to be insuperable. Organization already exists for granting the yearly motor licences, and it would seem that a reasonably simple solution of the problem would be to raise the licence rates on foreign cars imported after October 1st, 1915, or some other convenient date. The chassis of such cars could be stamped on importation and be subject to inspection on the renewal of the yearly licence. A system of taxation on these lines would effectively check the evasion which the authorities appear to regard as at any rate a possibility, and at the same time obviate the practical difficulty which seems to prevent the application of the equitable rule that professional, as well as commercial, users of a motor car shall be relieved—to some extent, if not entirely—from the "sumptuary" tax aimed at the private user, whose car is an article of comfort or luxury, and not part of the equipment by means of which his income is earned. We fear, however, that such a radical alteration is not now possible, and the only way by which the medical profession can receive equitable treatment in this matter is by the

⁷ A *Compendium of the Pharmacopoeias and Formularies*, Official and Unofficial, with Practical Aids to Prescribing and Dispensing. By C. J. S. Thompson. Fifth edition. London: J. Bale, Sons, and Danielsson, Limited, 1915. (Fcap. 8vo, pp. 800, 5s. net.)

⁸ *Materia Medica and Pharmacy for Medical Students*. With an Appendix on Incompatibility. By R. R. Bennett. B.Sc. Lond., F.I.C. Third edition. London: H. K. Lewis, 1915. (Fcap. 8vo, pp. 270, 4s. 6d. net.)

extension of the proposed exemption to cars "kept by a duly qualified medical practitioner" . . . and "used by him for the purpose of his profession"—the language of the petrol rebate section seems suitable for the purpose.

Section 23 needs little comment, inasmuch as it merely provides for the increase of the income tax relief in respect of children from £20 to £25 for each child. It is noteworthy that the allowance remains the same for all incomes not exceeding £500, and ceases at that limit, whereas the expenses actually incurred undoubtedly rise with the growth of the parent's income. If £25 for each child is a reasonable allowance where the total income of the parents does not exceed £200, then it is not sufficient where that income is £400 or £500. An allowance of 10 per cent. of the total income for each child would appear to be more equitable, with possibly a fixed minimum allowance.

It is apparent from Section 24 that the system of quarterly collections is to be applied to all employees, though the bill proposes to give the Commissioners of Inland Revenue authority to exclude any "class" by regulation. Medical men holding appointments from local authorities or hospital boards under "wholtime" conditions will probably prefer a half-yearly to a quarterly payment. If that should prove to be the case, it may be possible to obtain the exclusion of that "class" of case from the quarterly system. In any event the question cannot arise at present, as the system does not operate till 1916.

Section 26 provides, in effect, for the limitation of time for making a claim to relief in respect of earned income to be extended to cover the whole of the year of assessment and the three subsequent years, instead of the period to September 30th only. Strictly construed this section would appear not to relieve persons already assessed at the "unearned" rates on account of the late delivery of a claim to the "earned" rate, though it would operate to grant such relief where the assessment is made after the bill becomes law—that is, subsequent to the Royal assent. This is clearly anomalous, and it is to be hoped that the authorities will recognize the anomaly and avoid it by applying the extension of time to all assessments made or to be made for the current year. The difference between the two scales of duty has increased from the original 3d. to 1s., and the effect on the tax payable is accordingly so substantial that the penalty for procrastination is more than the offence warrants. A general amnesty for this year would suitably accompany the disappearance of the more restricted limitation.

The Excess Profits Duty has attracted a large share of the attention given to the bill by the daily press, but, except in circumstances rather difficult to imagine, it could not affect the medical practitioner, and we need not consider it here at any length. Section 35 exempts, *inter alia*, "any profession the profits of which are dependent mainly on the personal qualifications of the person by whom the profession is carried on and in which no capital expenditure is required, or only capital expenditure of a comparatively small amount." We can conceive of few professions to which the words of this clause apply more clearly than they do to the medical profession. In any case there would probably be few practitioners caught in the intricately woven net of the Excess Profits Duty, but it is none the less satisfactory to have the exemption established on general grounds, leaving individuals free from the obligation of making complicated calculations as to their profits for various years—a freedom especially welcome in these strenuous times.

The proposals detailed in the bill differ in some respects—notably in connexion with the motor car import duties—from those outlined by the Chancellor in his Budget speech, and they may be still further amended. Whatever burdens the State may impose on the medical profession will be borne in the spirit of true and quiet loyalty, but that task will be lightened if it can be felt that the taxes are levied equitably and without unfair discrimination between the various classes of the community. From our point of view, we regard the claim of the medical profession to share in the exemption from the motor import duties as not only proved, but admitted, and we hope that the Chancellor will be able to extend that exemption in the same manner as the motor spirit duty allowance was extended in 1909.

CONFERENCE OF THE NATIONAL SPECIAL SCHOOLS UNION.

The seventh biennial Conference of Teachers, Medical Officers, Managers, and others interested in special schools for defective children, promoted by the Special Schools Union, was held in London from October 14th to 16th, and was largely attended by representatives from all parts of the country. On October 14th typical London County Council special schools were open for inspection, and numerous visitors had the opportunity of inspecting the results of manual training, which, in the case especially of the elder boys' and girls' schools, were simply wonderful considering the infirmities of the pupils who had produced the wood-work, metal-work, clothing, and other specimens.

On October 15th the sittings at the Guildhall commenced under the presidency of the Chairman of the London County Council (Mr. CYRIL JACKSON). After a State opening by the Lord Mayor, the first paper was by Sir W. P. BYRNE, K.C.V.O., C.B., Chairman of the Board of Control, its subject being "Teaching in institutes for defectives." He urged the importance of careful classification for teaching purposes; the slighter and more educable cases were, he considered, alone appropriate for day schools; the graver and permanent cases of mental defect required institutional treatment. He also referred to schemes in progress for training teachers for mental defectives. Mr. J. T. LEGGE (Director of Education, Liverpool), in a paper on "The education of the mentally defective," referred to the scheme outlined by the Royal Commission on the Blind, Deaf, and other exceptional children as long ago as 1869, which he described as excellent in dealing with the needs of the mentally defective—a scheme, indeed, to which we have only been approximating in recent years." An interesting discussion followed, in which Dr. SHUTTLEWORTH (London), Dr. PEARSON (Leeds), Mrs. BURGWIN (Superintendent of Special Schools, London), Miss JAMES (Superintendent of Liverpool Special Schools), Miss DENDY (Commissioner of the Board of Control), and others took part.

The afternoon session, under the presidency of Major WALDORF ASTOR, M.P., was occupied with the consideration of physical defects. Major Astor, in some opening remarks, said that evidence had accumulated that cow's milk was frequently responsible for non-pulmonary tuberculosis; the ideal was a tubercle-free milk supply, but it would be very many years before dairy herds were free from tuberculosis. He advocated pasteurization and the grading of milk into (a) children's milk, (b) adults' milk, (c) cooking milk. Such grading of milk in New York had coincided with the reduction of infantile mortality by over 4,000 a year. Papers were read by Dr. ARTHUR LATHAM on "The prevention of tuberculosis in childhood"; by Mr. C. ELSLIE, F.R.C.S., on "The problem of the physically defective child"; and by Mr. A. C. COFFIN, B.A. (Director of Education, Bradford), on "Special school work in Bradford." The Saturday session was under the presidency of Mr. F. R. ANDERTON, Chairman of the L.C.C. Special Schools Subcommittee, and papers were read by Major LEONARD DARWIN on "Feeble-mindedness in its racial aspects," and by Mr. J. W. BURN (Head Master of the Clondesley L.C.C. school for elder mentally defective boys) on "The practical side of special school work." Major DARWIN urged the importance, on grounds of heredity, of the mentally deficient not being allowed to marry, and asked the aid of teachers in instructing the parents of their pupils as to the risks to progeny attending such unions. The trend of scientific opinion, he said, was that innate, and therefore transmissible, mental defects were irremovable by education or environment. In the discussion which followed Mr. Bunn's paper, questions were raised as to the respective duties of the doctor and of the teacher in the selection or certification of pupils for the special schools, Mr. H. HOLMAN (late H.M.I.) remarking that the co-operation of both was necessary in coming to a satisfactory conclusion.

At its annual meeting, recently held at Washington, the Association of Military Surgeons of the United States passed a resolution by 75 to 1 in favour of compulsory military training.

British Medical Journal.

SATURDAY, OCTOBER 23RD, 1915.

ABORTIVE TREATMENT OF WOUND INFECTION.

DR. ALEXIS CARREL has communicated to the Académie de Médecine¹ the results of experiments and observations made by MM. Dakin, Daufresne, Dehelly, Dumas, and himself, at the Rockefeller Laboratory and Temporary Hospital 21 at Compiègne, on the use of the hypochlorite solution devised by Dr. Dakin. Dr. Carrel began by quoting Professor Tuffier's statement that of 1,000 amputations at Maison-Blanche, the operations had to be done in about 800, not on account of the gravity of the wound, but owing to complicating infection. He complained that no new doctrine had been formulated to replace that held at the beginning of the war, though at a very early stage it had been proved to be wrong. Like Sir Almoth Wright, he asks that some single method of treatment shall be established and followed by all, even though, in its turn, it may eventually be superseded by something better. In this way, he said, the wounded would be protected to some extent from "therapeutic fantasies" which are now allowed full play for want of a directing principle.

Carrel sees in the proper use of an antiseptic the method which should be universally followed at present. He starts from the position that all wounds due to shells, mines, or grenades are infected, and supports this statement by the results of bacteriological examination, which, when made even as early as about six hours after the wound was received, had in all cases revealed the presence of a varied microbial flora, aerobic and anaerobic. The bacteriological examination brought out certain other facts of importance: first, that the microbes at this early stage were generally present in small numbers, for in a smear preparation several microscopic fields might have to be examined before a micro-organism was found; and, secondly, that they were in the main localized round about the projectile or scraps of clothing; they had not had time to spread through the wound. In a smear examined twenty-four hours after the wound, or later, the appearance was very different; the micro-organisms were so numerous that often they could not be counted in the smears and were found in smears from every part of the wound. Bacteriology, clinical observation, and common sense, Carrel maintains, combine to justify the opinion that during the first few hours it is easy to clear a wound of microbes, but that it becomes more and more difficult if they are allowed time to multiply, to spread over the surface of the wound, and to infiltrate its walls. For an analogy he turns to acute appendicitis, in which experience proves the wisdom of operation within the first twelve hours. He urges that treatment to abort the infection in gunshot wounds of all kinds, even those which appear trivial, should be begun at the earliest possible moment. The first thing—and a relatively easy thing—is to remove foreign bodies, but

it is not possible to remove mechanically all the smaller fragments, nor to get rid of all the microbes lodged in the walls of an anfractuons wound. It is, he said, with a graphic touch which lightened a rather matter of fact paper, no more easy to clean a wound with a gauze swab than to clean a greasy bottle by the same means. As it is not possible to clean away the microbes entangled in the minute fragments of foreign bodies, and in the walls of a wound, it is advisable, he considers, to use some liquid which will penetrate everywhere and can with impunity be left in contact with the tissues for a sufficient length of time.

Dr. Carrel vigorously repudiates the view that antiseptics are useless. He admits that they have been abused, ill chosen, and badly applied, but for him the conclusion to be drawn is not that they should be discarded, but that they shall be better chosen and better applied. Dr. Dakin's search for an antiseptic solution effective, unirritating, and cheap, resulted in the special solution of sodium hypochlorite which he described in this JOURNAL on August 28th. Carrel's contention is that if this solution be caused to penetrate into every corner of the wound, and if it be constantly renewed, complete sterilization of the wound can be achieved. He would have the skin disinfected with tincture of iodine at the first dressing station, and the wound, if its aperture be small, injected with the solution of hypochlorite; he would cover a large wide wound with gauze wet with the hypochlorite solution, but would not have any impermeable material put over this. He does not consider this rapid provisional disinfection essential, though he thinks it improves the prognosis. The essential point is to get the wounded to an ambulance or clearing station as quickly as possible. For him the future of the patient depends upon the rapidity of his transport to some place where his wound can be treated by an effective antiseptic method, so that it may be put on the way to become in a few days an aseptic wound. At the ambulance or clearing station foreign bodies, including scraps of clothing, should be removed at once, usually with a finger of the gloved hand or with dissecting forceps. The object of any operation then done should be to open up the wound sufficiently to allow it to be thoroughly cleaned; it should not be mopped, brushed, or everted, and particular attention should be given to the arrest of hæmorrhage. Having opened up the wound and arrested hæmorrhage and having ascertained the situation and extent of every recess, the next step is to employ an efficient antiseptic. Carrel recommends that devised by Dakin, on the grounds that it is effective if properly used, cheap, and easily made by any ambulance dispenser.²

² Dr. Dakin's directions for the preparation of a 0.5 to 0.6 per cent. solution of hypochlorite are as follows (BRITISH MEDICAL JOURNAL, August 28th, p. 319): "One hundred and forty grams of dry sodium carbonate (Na_2CO_3), or 400 grams of the crystallized salt (washing soda), is dissolved in 10 litres of tap water, and 200 grams of chloride of lime (chlorinated lime) of good quality is added. The mixture is well shaken, and, after half an hour, the clear liquid is siphoned off from the precipitate of calcium carbonate and filtered through a plug of cotton; 40 grams of boric acid are added to the clear filtrate, and the resulting solution is ready for use. A slight additional precipitate of calcium salts may slowly occur, but it is of no significance. The solution should not be kept longer than one week. The boric acid must not be added to the mixture before filtering, but afterwards." We may add that the cost of making this quantity of the solution would be, approximately, 2s. 4d. if ordinary commercial washing soda were used, and about 5s. 4d. if a comparatively pure variety of sodium carbonate were employed. In the first instance the cost would be about 1s. a gallon, and in the second, a little over 2s. 4d. If the chemicals were bought in fairly large quantities, the cost would be slightly diminished in both cases. A little variation in the hardness of the water would not be likely to produce any appreciable effect on the strength of the solution.

¹ *Bull. de l'Acad. de Méd.*, T. LXXV, No. 40.

In the strength of 0.5 per cent., while strongly antiseptic, it causes no irritation even when applied to the skin or tissues for several weeks. But though its antiseptic action is highly effective, it is of short duration, for it is destroyed when in contact with albuminous substances; therefore it must be renewed frequently by injection or continuously by irrigation. At the first dressing it may be injected into the wound with an ordinary syringe, great care being taken to see that it penetrates into every part of the wound, and arrangements must be made that this penetration everywhere shall continue. Carrel uses india-rubber tubes about six millimetres in diameter: a hole half a centimetre from one end, or several holes, as the nature of the wound requires, are cut in the tube, which is then covered with bath towelling, in the manner described in the JOURNAL some time ago. In a narrow wound one tube may suffice, but in a large wound with pockets several may be required. In fracture cases he lets the end of the tube lie among the fragments. The fluid is absorbed by the towelling, and so kept in contact with the surface of the wound. At the first dressing the wound is filled with gauze and the surgeon assures himself by testing the tubes that the liquid can come into contact with every part of it. Over all is placed a layer of non-absorbent cotton through which the india-rubber tubes project. Every hour, or every other hour, a sufficient quantity of the liquid is injected into the tubes unless continuous irrigation can be arranged.

When this plan of treatment attained its maximum success, bacteriological examination showed that the wound had been cleared of microbes and was aseptic; it might then be closed, not with sutures, but with strips of plaster on the surface, and in the depth by efficient compression by proper pads. In the first trials two suppurating wounds of the same kind and in the same patient were treated the one with and the other without the hypochlorite solution; it was observed in the former that the discharges dried up and the number of microbes diminished, while the condition of the latter did not change. Phagocytosis and cicatrization went on in the wound treated with hypochlorite, notwithstanding the continued employment of the antiseptic solution. Gradually the treatment was extended to more recent wounds, and finally to a series in which the interval between the receipt of the wound and the application of the treatment was from six to twenty hours. In all these cases fragments of shell or scraps of clothing had to be removed, and the presence of microbes in greater or less abundance, according to the interval between the receipt of the wound and the commencement of treatment, was established by bacteriological examination. After being irrigated with the hypochlorite solution for from three to five days, microbes had generally disappeared from the discharges which were not copious, and meanwhile any portion of necrosed tissue had disappeared.

When the wounds had been proved to be aseptic, the sides were brought into apposition with strips of plaster, and union was generally obtained from a week to a fortnight after the wound had been received; the scars were small and supple. Carrel went so far as to say that fractures produced by fragments of shell, although infected, could by this method be brought into a condition so thoroughly aseptic that they recovered like simple fractures. The conclusion, therefore, is that infected wounds can be sterilized by the use of a hypochlorite solution, and that then they may be treated as aseptic wounds; the essential thing is to ensure that every part of the

wound is reached by the antiseptic. Even in cases in which it was not possible to achieve asepsis the severity of infection was greatly diminished, the healing of an infected wound was hastened and most of the complications which cause death, render amputation necessary, or produce deformity were prevented. In the long run, according to Carrel, the adoption of a hypochlorite method will largely increase the number of wounded who can be returned to service.

It will be seen that Dr. Carrel's results very closely parallel those recorded by Captain John Fraser in the JOURNAL of October 9th (p. 525). Captain Fraser used the solution of hypochlorite as devised in Edinburgh. Even in cases of gas gangrene he observed that during the first twenty-four hours the foul smell of the wound entirely disappeared; that by the third day the lymph-like discharge set up tended to cease and granulation tissue to form; that sloughs separated with extraordinary rapidity, and that healing proceeded at a very rapid rate.

The observations of Dr. Carrel and Captain Fraser will be studied with interest by all surgeons engaged in the present war, and we hope to publish next week the text of the address given by Sir Almoth Wright, who, if we understood his verbal statement correctly, does not consider the use of antiseptics in this elaborate manner necessary.

MIXED VACCINATION AGAINST TYPHOID FEVER AND PARA- TYPHOID A AND B.

LAST August the members of the French Academy of Medicine began an interesting discussion on the method and value of protecting soldiers and sailors against typhoid and paratyphoid A and B infections by the use of a mixed vaccine. As Chantemesse pointed out, the question is one that has only recently acquired any practical importance. It is only recently that these three varieties of what has long been known as "typhoid fever" have been generally discriminated; and it is only during the present war that paratyphoid fever has proved to be an infection of wide dissemination requiring any specific prophylaxis. The two forms of paratyphoid fever distinguished as A and B in accordance with the variety of *Bacillus paratyphosus* causing them are not, it may be said at once, of equal practical importance. Paratyphoid B fever is rarely fatal, and not a single death occurred among 447 cases of it in the Japanese navy, as Kabeshima recorded (1914); while out of 289 patients with paratyphoid A fever, 7 died. Similarly, it may be noted, among the 70,000 European troops in India during 1913 there were 79 cases of paratyphoid A fever, with 2 deaths, but no cases of paratyphoid B fever. The mortality of typhoid fever among the Japanese sailors was much greater, 45 out of 367 patients succumbing to the infection.

In a general review of the prophylaxis of these three closely connected fevers, Vidal¹ said that the use of mixed bacterial vaccines to protect experimental animals against a number of infections was first described by himself and Sicard in 1897, assuming that protection and the acquisition of agglutinating powers went hand in hand. The subject was further discussed in 1902 by Castellani,² and in 1905 he was using a mixed typhoid + paratyphoid A + paratyphoid B vaccine, among other complex vaccines, for the protection of human beings. In 1910 a

¹ Bull. de l'Acad. de Médecine, Paris, 1915, lxxiv, p. 1248.

² See BRITISH MEDICAL JOURNAL, 1915, i, 445, 758; and ii, 230.

similar triple antityphoid vaccine was employed by Vincent in Morocco, but he appears to have discontinued its use a year later. The use of analogous compound antityphoid vaccines has subsequently been described by a number of authors, and it may be said that their employment has a sound experimental and clinical basis at the present time.

But there are several practical points about their use that require further definition. Is a mixed vaccine to be injected, or are the three component parts of it to be administered successively? In what proportions are the three bacterial strains to be employed in the mixed vaccine? Does the mixed vaccine confer as high a degree of immunity to infection as its component parts do when used separately? Is it necessary to immunize against paratyphoid B at all? On several of these points Castellani has no doubts. He believes that the mixed vaccine, containing the full doses of each of its constituents, does not in practice produce unduly severe local and general reactions. Widal, on the other hand, recognizes the danger of producing severe reactions by the injection of adequate doses of mixed vaccines, and he seems inclined to counter this danger by reducing each individual dose and by giving a series of four injections rather than any smaller number.

Vincent goes still further in the same direction. His experience in Morocco leads him to advise the administration of two large doses of antityphoid vaccine, and to follow these up with two or three subsequent injections of a mixed paratyphoid A + B vaccine whenever circumstances and time allow this course to be taken. As for the relative importance of typhoid and paratyphoid vaccines, Widal describes the use of the former as a necessity, the use of the latter as a matter of local exigency and good fortune, in the military conditions that now obtain; he foresees great practical difficulties in the application of Vincent's method of giving five (or better six) separate inoculations. He would therefore use a triple vaccine, sterilized by heat, and give for choice a course of four injections with it. He holds that an infection with paratyphoid B is not without real danger to soldiers exhausted by the labours of a campaign.

It seems generally agreed that the triple vaccine is as efficient in producing immunity as its components are when used separately. Vincent, in conclusion, added to the discussion the fact that a triple vaccine—known for short as T.A.B.—has been used in the Italian army for three years with excellent results, particularly in Cyrenaica and the Tripolitan, where paratyphoid fevers A and B are both endemic and epidemic.

CENTRAL MEDICAL WAR COMMITTEE.

At a meeting of the War Emergency Committee, held at the house of the British Medical Association on October 20th, Dr. Frederick Taylor moved a resolution to the effect that a more appropriate title would be the Central Medical War Committee, and this was adopted. A deputation from the Committee which had had an interview with Sir Alfred Keogh having made its report, the Committee reviewed the present situation and adopted a resolution to the effect that it should continue to use every endeavour to complete the quota of medical men originally called for by January 15th, 1916, having regard, however, to any modifications in the number asked for wherever the civil needs of any district suggest such modification, and that the enrolment scheme should be modified so that practitioners should be asked to engage definitely for service at a fixed date after January 15th, 1916. This resolution, which was passed unanimously, emphasizes

two facts—first, that a large number of medical men is still required to satisfy the demands of the military authorities for the armies already in being; and secondly, that a further large number will be required later for the new armies now being formed. It cannot be too strongly impressed upon the profession that the military necessities require that every man of military age who is physically fit should be prepared to enter the military service of the country in the present emergency. The only way in which this can be done while properly safeguarding the interests of all concerned, is by every available man placing himself at the disposal of a committee with expert knowledge. It is found that eligible men often express their willingness to go if and when conscription becomes an accomplished fact. This policy, however, must almost inevitably place the medical profession in a far worse position, inasmuch as under conscription the calling up of men would probably be left in the hands of Government officials not fully informed as to the needs of the local community, and totally unacquainted with the difficulties of the practitioners called upon. It was mentioned during the meeting that the number of local medical war committees had been increased to 149, and that in some of the remaining seventeen areas the work was being done by the Executive Committees of the Divisions of the British Medical Association. Before the meeting adjourned a letter was read from a well-known medical agent, suggesting that it might be worth while to call a meeting of agents to discuss questions connected with the putting on their lists of locumtenents fit men eligible for service with the R.A.M.C. It was resolved in reply to this letter to express general approval of the proposal to hold such a meeting.

FASTING TREATMENT FOR DIABETES.

The daily press, misinformed and optimistic as ever in matters of medical and surgical treatment, has quite recently announced a "reported cure for diabetes," alleged, as is so often the case in such matters, to have emanated from America. The cure is said to be based on "bicarbonate of sodium with a small amount of salt." It is added that "in extreme cases the treatment is given hypodermically." This, we take it, is a reference to an interesting article on "prolonged fasting in diabetes" recently published in America by Dr. F. M. Allen.¹ As the result of the treatment of 44 patients suffering from severe forms of diabetes mellitus at the Rockefeller Hospital in New York Dr. Allen is able to speak highly of the treatment of the condition by prolonged periods of fasting. Fasting is not a new thing in the cure of diabetes, having been recommended empirically by many writers in succession, from Nannyn to Guelpa. In the present instance, however, its utility was foreshadowed by certain experiments upon animals, and its application to man was based directly on these experiments. Dr. Allen's experience indicates that the glycosuria in cases of even the severest type of diabetes may with advantage be cleared up by one initial fast, lasting, if necessary, as long as eight or ten days. In one instance it was found that a diabetic patient's total metabolism was 8 per cent. above normal, and that no sugar was being burned in the tissues at all. After a nine days fast the total metabolism had fallen to 20 per cent. below normal, and the respiratory quotient showed that the sugar formed from the tissue protein was being burned. This shows the great improvement that may take place in a weakened metabolic function—namely, the utilization of sugar—when a course of complete rest is prescribed to that function. When the fast is over, the next step is to introduce protein, fat, and carbohydrate into the diet in such a way as to maintain freedom from glycosuria and urinary acidosis,

¹ Amer. Journ. of Med. Sciences, Philadelphia, 1915, cl. 480.

a matter of careful experimentation in each patient. The reappearance of glycosuria is an indication for a day of fasting; indeed, routine fast days once a week may be prescribed with advantage, even in the absence of glycosuria. Two main principles are enunciated by Dr. Allen here: the patient should be kept permanently below weight, and the fat in the diet should be restricted. Both are new ideas, comparatively speaking, in the dietary treatment of diabetes; both are designed to minimize the strain placed on the weakened pancreatic function by the taking of food. Both from his own experience and from that of other medical practitioners who have adopted this starvation treatment in diabetes, Dr. Allen is able to speak very highly of the new method. Its immediate results are most encouraging. As for the remote results, a longer experience is naturally required before any authoritative statement can be made: the cure is yet in its infancy. It removes glycosuria and acidosis more quickly and more surely than has been the practice heretofore, and it is common knowledge that diabetic patients do better when glycosuria and acidosis are removed than when they are allowed to continue. Dr. Allen gives no specific indications as to the particular articles of diet given when the fasting is over, or their quantities; these details are to be stated in a later publication. No mention is made of the administration of either "bicarbonate of sodium" or "small quantities of salt" in the treatment, whether by the mouth or hypodermically, in the American journal. But it is clear that the fasting treatment of diabetes has a rational experimental basis, and its further exposition and developments will be awaited with interest.

THE WAR AGAINST FLIES IN FRANCE.

DR. R. BLANCHARD, professor of parasitology and medical natural history in the Faculty of Medicine of Paris, has written an essay on the fight against the fly for the *Ligue Sanitaire Française*, which the *Ligue* has published in a pamphlet.¹ It begins by describing the different kinds of flies, their habits and their metamorphoses, and then discusses the diseases transmitted by the non-biting and the biting flies. The greater part of the pamphlet is concerned with the methods of preventing the dissemination of disease by flies, which resolve themselves practically into the methods for the destruction of the insects. Dr. Shipley, in his article on the house-fly,² said that the eggs, which are laid a little beneath the surface of the dung-heap in batches of 100 to 150, hatch out at suitable temperatures in something under twenty-four hours. The maggot (larva) undergoes three moults, the third when it is half an inch long, being reached on the fifth or sixth day. "Now," he said, "it leaves the moist situation in which it has flourished, and, crawling through the manure, seeks some dry or sheltered corner," where it is transformed into the pupa which immediately precedes the perfect insect. It appears, however, that although the larva can pupate in a dry corner it prefers to bury itself in the ground. However this may be, the important fact in the present connexion is that the full-grown larva, when about to pupate, has an impulse to migrate from the manure heap, and the method of destroying it devised in Canada and the United States by Hewitt and Hutchison is designed to turn this habit to the discomfiture of the insect. Professor Blanchard is evidently greatly taken with the plan; partly because it demands only a modification of a method of treating manure recommended in France for quite another reason by Dehérain and Ringelmann. Their object was to prevent the loss of ammonia and other nitrogenous bodies by catching the drip from the heap in a tank of water underneath it. A shallow concrete tank is made and a grid of stout laths placed over it; the manure is put on this platform, and if it is dry it is watered from time to time until the

tank is full. When full a pump is fitted, and the liquid in the tank is again pumped over the manure. To make this into a larva trap the only modification necessary is to see that the platform is rather narrower than the tanks, so that not only the larvae which come out at the bottom but also those that wander out at the sides will drop into the water and drown. In this method no antiseptic is used, its success depending wholly upon the fact that it takes advantage of the instinct of the larva to work itself out of the manure when it is going to pupate. Professor Blanchard, however, seems to think that the migration is due not so much to a rooted instinct as to the circumstance that the fermentation which is going on in the manure makes it too hot for the larva. It may be remembered that in the *JOURNAL* of September 18th was published a short note on a paper communicated to the *Académie des Sciences* by M. Roux. The point of this paper was that the eggs of the house-fly could not withstand a temperature of 60° C., and that during fermentation of manure the temperature might rise to between 60 and 70° C. Blanchard states that the larvae object to manure that is kept thoroughly moist, and also that the migration takes place chiefly at night. It is necessary to maintain a certain amount of fluid in the tank and to keep it thoroughly cleaned out from accumulations of straw, which might enable the larvae to climb out. Hutchison estimated that in this way 98.5 per cent. of larvae were destroyed. The method has the advantage that it not only does not deteriorate the value of the manure, but, almost automatically, supplies a quantity of liquid manure; the saving thus effected by preventing the loss of ammonia more than repays the small amount of labour required. The objection is that the tanks afford a breeding place for mosquitos. This disadvantage may be obviated by applying paraffin in the proportion of 15 to 20 c.c.m. to the square metre. In an appendix M. H. G. Richter, secretary of the *Ligue*, who is an architect, gives a plan and section of a construction for a manure grid and tank on the principle described.

THE NEW ENGLISH DICTIONARY!

SINCE the notice of the summer instalment of the *New English Dictionary* appeared in these pages (July 17th, p. 104), the veteran editor, Sir James A. H. Murray, has passed to his rest. In the prefatory note to that fasciculus the editor in chief spoke of his "long and serious illness," but he continued manfully at his beloved labours till almost within a week of his death, which took place on July 26th, 1915. To quote from a short sympathetic note, appearing as an inset in the present portion of the *Dictionary*, "Sir James Murray's great wish that he should live to finish the *Dictionary* on his eightieth birthday, in 1917, has not been fulfilled; the unceasing labour of three and thirty years has ended when less than a tenth part of the work remains to be done." The notice continues: "Almost within a week of his death he was still hard at work, showing, as Dr. Bradley wrote of a visit made to him, 'not a little of the mental zest and lucidity that I remembered of old.' In the preceding months, while barely convalescent from an illness that seemed to bring him to the gates of death, he had prepared, and at the appointed date of July 1st published, his usual 'double section.' For some years Sir James was aided in the editorial work by Drs. Bradley and Craigie, and more recently by Mr. Onions; but, as the inset reminds the students of the *Dictionary*, "it has always been the rule that each of the editors should be exclusively responsible for the portions

¹ *A New English Dictionary on Historical Principles*. Edited by Sir James A. H. Murray, Henry Bradley, W. A. Craigie, and C. T. Onions. Vol. IX. Sp. Pl. Standard-Seed. By Henry Bradley, Hon. D. Litt. Oxford: At the Clarendon Press; London, Edinburgh, New York, Toronto, Melbourne, and Bombay: Humphrey Milford, October, 1915. Price 2s. 6d. (6d. each).

¹ Paris: *Ligue Sanitaire Française*, 72, Rue de Rome. Prix, Fr. 2.

² *BRITISH MEDICAL JOURNAL*, October 17th, 1914, p. 662.

of the work issued under his name. The sections in the hands of Dr. Bradley, Dr. Craigie, Mr. Onions, and their staffs, will not be affected by Sir James's death). But Sir James Murray at the beginning laid the lines and drew the plan; in the prosecution of the work, when it became clear that it must be shared, his amazing capacity for unremitting labour enabled him to take more than an equal part, and the volumes produced by himself show characteristic excellences which cannot be exactly matched, though they may be rivalled by merits of another kind. He will not write the last pages, but more than that of any other man his name will be associated with the long and efficient working of the great engine of research by which the *Dictionary* has been produced." To those words of whole-hearted recognition from his co-workers we add our full consent, for not once only, but many times in the quarterly notices of the *Dictionary* which have appeared in these pages, have we drawn special attention to the thoroughness of Sir James Murray's knowledge of medical terms, to the scholarly manner in which he always dealt with them, to the new light which he not rarely shed upon them, and to that peculiarly rich interest with which he was constantly able to invest them in his happy choice of illustrative quotations. Indeed, sometimes it almost seemed as if the unusual phenomenon of the infusion of a piquant kind of humour in the selection of the quotations was being witnessed, and as if Sir James were enjoying a quiet dig at the doctors. Although unusual, this character was not without precedent in lexicography, as the fortunate possessors of the early editions of Johnson's *Dictionary* know to their delight. Whether he would or no, Dr. Johnson had much for which to thank the Scots. His own biography, which some have not hesitated to call the greatest life of an Englishman ever written, came from the pen of Boswell; and now another Scotsman, Sir James Murray, has borne the biggest burden in producing the greatest English dictionary which the world has seen and one which would have gladdened Dr. Johnson's eyes to behold. The present section, which carries the alphabetical rubrics from *Standard* to *Stead*, does not contain many medical terms; but a glance through its pages reveals a few which are of interest and also shows the usual carefulness in the registering and illustrating of medical meanings of ordinary words. Thus, on the first page, under *standardize* there is a reference to the pharmaceutical meaning of the term and an illustrative quotation regarding "standardized laudanum." *Materia medica* is likewise represented in this section by carefully prepared articles on *starch* (with references to *starch-bananas*, *starch baths*, and *starch-sugar*), and on *stavesacre*, with many illustrative quotations, including one (of 1630) which says: "Mix'd with *Stavesacre* and *Argentum vivæ*, it will not leave a man a *Louse* alive," and so explains why the plant has been called *Lousewort*. An interesting group of medical terms begin in *Staphyl* (from the Gr. *σταφύλη*, bunch of grapes), and includes *staphyle* (a rare synonym for *uvula*), *staphyline*, *staphylococcus* (first used apparently in 1887), *staphyloma* (protrusion of the cornea), *staphyloplasty* (a plastic operation for the closure of cleft palate), *staphylo-rhaphy* (surgical closure of a cleft palate), *staphylo-tome*, and *staphylo-tomy* (amputation of the *uvula*). Two new words, *staphylolysin* and *staphylo-toxin*, are supplied with one illustrative quotation each, and both are taken from the BRITISH MEDICAL JOURNAL, the former from the number for September 10th, 1904, and the latter from that for April 12th, 1902. Another little group of terms circles round *Stapes*, and includes *stapedectomy*, *stapedial*, *stapediform*, and *stapedius*. *Starblind* is a word which seems to have troubled Dr. Bradley not a little; it would seem to have relations with *stark blind* and through it with *stark dead* and *stark naked*. Other terms are *status*, *stasis*, and *static* (in their medical senses).

ANAESTHETISTS AND INFECTION.

THE subject of the dangers run by anaesthetists in the course of their practice has been little studied in this country. While patients who suffer from syphilis or from tuberculosis would appear to be a source of infection to the administrator of an anaesthetic to them, no reliable statistics exist from which to estimate the real danger. Anaesthetists are at the present time called upon to deal rapidly with a large number of men, many of whom are probably in an infective stage, although any definite history is lacking. There is little doubt that in hot, ill-ventilated rooms the anaesthetist runs a certain risk in respect of tuberculosis, and more than one hospital anaesthetist has been attacked with pulmonary phthisis, although we are not aware if any causal nexus has been established between the work and the infection. Again, both in this disease and in syphilis the sputum of patients often finds its way to the hands and even the face of the anaesthetist. The modern routine method of protecting the mouth and nares by gauze should, if the latter be sufficiently thick, safeguard the anaesthetist from the patient as well as vice versa. The eyes, however, remain as a vulnerable area. The anaesthetist's hands are probably a real source of danger. The necessity of opening the mouth, dealing with sharp snags of teeth, mopping the fauces, seizing the tongue and arranging the lips over a gag, offer a fruitful field for the buccal flora, and the hands readily carry infection to the anaesthetist. Obstreperous patients—and experience has proved that many soldiers belong to this type—have bitten fingers engaged in opening and dealing with the mouth. Although complete manual asepsis is impossible the use of thick rubber gloves is a precaution of which the prudent anaesthetist will make use. The modern plans of employing open masks for the liquid anaesthetics do not act as a wholly efficient safeguard. Salivation is commonly present during the induction of anaesthesia, alike with chloroform and ether, and this usually induces the patient to spit vigorously. To secure cleanliness and safety a second mask should be at hand to be used as soon as unconsciousness has supervened, and the soiled mask should be stripped of its gauze and boiled before further use. When nitrous oxide is given to doubtful patients an all-metal mask should be preferred. The gas bag is safeguarded by efficient inspiry and expiry valves, although it is a wise precaution to rely upon the reversible red rubber bag of Vernon Knowles, which is readily cleansed and disinfected with a mercuric solution. It need hardly be said that in operations about the mouth, nose, and air passages in general the dangers of infection are most likely to arise, and to minimize them careful cleansing by tooth scaling, sprays, mouth washes, and so on, may be systematically pursued. The record of Continental cases of infection is of little value, since many possible sources of infection were present which render futile any attempt to trace the cause to the effect.

DRUG AND ALCOHOL ADDICTION.

SIR WILLIAM COLLINS delivered the sixth Norman Kerr Memorial Lecture before the Society for the Study of Inebriety on October 12th, Dr. Mary Scharlieb presiding. The subject which, as the lecturer said, had been dictated to him, was "The ethics and law of drug and alcohol addiction." In dealing first with the nature of addiction to noxious agents, he said that the pathology of inebriety, which in its confirmed form was indistinguishable from moral insanity, had been too materialistic in accentuating the physical aspect of its causation with its implied irresponsibility. When dealing with agencies which abrogated consciousness and subordinated conscience to appetite, we had passed outside the range of histology, physiological physics, and even of biochemistry. He believed that alcohol and drug addiction ought to be regarded as examples of the surrender of self-control in favour of self-indulgence, of the voluntary preference for the lower

in the presence of the higher alternative of volition, exercised in obedience to appetite rather than to the higher command of conscience. Those who, on the other hand, were committed to the physical causation of inebriety, and to determinist philosophy, must, it seemed to him, flounder in the quicksands of responsibility and irresponsibility, and would "continue to search in vain for something out of a bottle or, maybe, a hypodermic injection, wherewith to redeem the sot and rehabilitate the will." In discussing the part legislation might play, and more particularly the spirit in which Governmental intervention should be undertaken, Sir William referred to the principles of the law of equal liberties as enunciated by Spencer and Mill. Their doctrines, he said, might sound somewhat out of date in the ears of the social reformers of to-day, and eugenists and sociologists now presented a new principle wherewith to inspire legislation—namely, that the social instincts were to be conceded preference over individual instincts, and that where there was conflict between social action and self-regarding action the law was to step in and forbid that which was inimical to the cohesion of society. This read like a resuscitation of Rousseau's *Contrat Social*, and with easy descent would lead to the odious dictum that minorities, and a *fortiori* individuals, had few or no rights at all. A safer path would be to follow the line indicated by Mill in the fifth chapter of his *Essay on Liberty*, in which he enumerated the principles that had been adopted as the basis of the pharmacy and poisons Acts, and justified the State in imposing restrictions on drink dealers, although, apart from the justification arising out of the interest of these dealers in promoting intemperance, such restrictions would be infringements of legitimate liberty. The kernel of the whole matter was in the restraint of liberty to secure a larger and truer liberty; the limitation of self-will in the interests of free-will and self-control; the repression of self in the cultivation of self-hood—principles which needed to be safeguarded alike against undue application and undue neglect. Finally, the lecturer passed in review recent legislative action, urged certain radical reforms in the pharmacy and poisons laws, and suggested also that it would be salutary if medical men would think, not once or twice, but many times, before prescribing potent drugs of addiction for internal exhibition if, as often happened, simpler and non-abusable remedies would meet the case. He referred to the prohibition of vodka in Russia and absinthe in France, and expressed himself convinced that little progress towards individual and national sobriety would ever be effected unless our statesmen took their courage in both hands, and either by heavy duties or penal restrictions, confined to medical and legitimate purposes all drugs of addiction, of which alcoholic beverages containing more than a moderate proportion of spirit were most widely resorted to and most pernicious in their total effects. A vote of thanks to Sir William Collins was warmly supported by Sir Arthur Downes, Dr. Armstrong-Jones, and Major McAdam Eccles.

CHILBLAINS.

A MEDICAL correspondent who describes himself as a healthy, active man—"a first-class life"—aged 45, in practice on the north-east coast, and hardened to exposure, has no trouble in keeping his body warm and glowing, yet has his fingers covered with chilblains during the winter, and asks what he can do. Sometimes he has one or two chilblains on the toes, but this is unusual. His hands, he says, are extremely sensitive to cold, and no treatment that he has tried—and this has included calcium chloride and calcium lactate in full doses—is of any avail. A question of this kind comes to us every year as surely as the swallows go. Increased importance is given to it this year, for undoubtedly some of the cases in the army in Flanders last year, perhaps the majority, were of the

nature of chilblains and were not frost-bite, though at first so called. Chilblains are rare in Canada, where in many districts snow commonly lies for months on the ground during the winter, though, of course, frost-bite easily occurs if proper precautions are not taken. We believe that in this country many sufferers find that chilblains do not develop during frosty weather, but begin to be troublesome so soon as a thaw sets in. In a changeable climate such as ours alternate frosts and thaws may keep up the affection throughout the winter. This suggests that it is damp rather than cold which is the determining cause, and the more susceptible victims begin to suffer as soon as the mists of early autumn set in. Again, a tendency to develop chilblains undoubtedly runs in families, and, although the textbooks of dermatology speak of it as occurring most commonly in children of the strumous diathesis, it is certain that it occurs also in others, especially, perhaps, in those who would formerly have been spoken of as of the nervous temperament. The books, in fact, give very little help, for the suggestion that erythema pernio (chilblains) is in some way related to lupus erythematosus does not help. Yet the disease is common, very distressing to the sufferer owing to the intense itching at night, and, when the chilblain "breaks," indolent ulceration may ensue, which is very difficult to cure until the season changes. Cod-liver oil is recommended, and may be of use in children, and tonics also are spoken of; but, as in the case of our correspondent, who says that he feels no need of a tonic since he is very healthy, they seldom seem called for by the general condition. He suggests that ionic medication might be of some avail, but, if so, what drug should be used?

THE ENTRIES AT THE MEDICAL SCHOOLS.

THE number of students entering at Edinburgh this term to begin the study of medicine is 95; there were between 40 and 50 entrants last May, so that the total number for the year is only a little below the average. The number of women students who have entered this year in Edinburgh is unusually high, as is also the case at the London School of Medicine for Women. In the other London medical schools there is a general decline as compared with 1913 in respect of the entry of full students. This, however, seems to vary very much in different schools, but averages probably about 20 per cent. Everywhere there appears to be a decrease in the number of men entering for special classes, such as those for the F.R.C.S. and D.P.H.

LOAN EXHIBITION OF JAPANESE WORKS OF ART.

A REMARKABLE loan exhibition of Japanese works of art and handicraft is being held at 127, New Bond Street, in aid of the funds of the British Red Cross Society and the Order of the Hospital of St. John. The collection—which includes exhibits lent by Her Majesty the Queen and His Excellency the Japanese Ambassador—has been selected by experts from seventy collections in this country. The exhibition will be open every week-day until November 13th, and affords a unique opportunity of seeing choice specimens of the beautiful art work of our Eastern ally.

THE University of Edinburgh has appointed Professor Harvey Littlejohn, Dean of the Faculty of Medicine, to be its representative on the General Medical Council, in the room of Sir Thomas Fraser, whose second term of office has expired.

THE names of Lieutenant-Colonel John Murray (ret.), Army Medical Staff, Ashburn Gardens, London; Dr. David Rorie, Cults; Dr. James Harvey Stewart, Hatton, Cruden; and Dr. James Davidson Wynnes, Aberdeen, have been added to the Commission of the Peace for Aberdeenshire.

Medical Notes in Parliament.

Housing of Munition Workers.

On the motion for the adjournment on October 14th, Mr. Yeo raised a short discussion on the raising of rents by landlords in certain areas; it had been postponed at the request of the Minister of Munitions. He said that the trouble already existed in a number of places, and this statement was confirmed by Mr. Rowlands and Mr. Barnes.

Mr. McKinnon Wood, Secretary for Scotland, in replying with reference to that country, said that he agreed that the matter should be considered carefully and treated as a temporary emergency. An emergency had been brought about because the men engaged upon munitions had been aggregated in certain districts; the district most affected in Scotland was Glasgow. The matter was one of some complexity as the charges on the landlord had increased, and if he was a person with a very small margin he was undoubtedly in a position of difficulty. Mr. Wood proposed to appoint a small impartial committee to inquire into the matter promptly and rapidly; it would, he hoped, deal first with the district of the Clyde. He hoped that meanwhile the factors and owners of Scotland would hold their hands.

Dr. Addison, Parliamentary Secretary to the Ministry of Munitions, who also replied, said that the Minister welcomed the appointment of the committee in Scotland, since whatever other cause of unrest there might be on the Clyde, this was a contributory cause which should be cleared away quickly. In England the Ministry recognized the difficulties of householders in munition areas, and a scheme was under consideration which would be quite undreamed of in times of peace to deal with cases of the most pressing kind in munition areas. The officers of the Ministry throughout munition districts had been instructed to collect complaints, and when the Ministry had obtained a clearer vision as to how extensive they were it would be better able to determine what was the right thing to do. Attention, however, had already been given to the matter. In the first place, new factories were, as far as possible, placed in districts where there was an existing population able to supply both the skilled and unskilled labour without requiring additional accommodation. It would be misleading at present to give figures, but, as a matter of fact, the scarcity of skilled labour was such that it could not be expected that it would be possible to bring from other places the mass of workers required; in such a place as Sheffield, for instance, workers must be obtained by spreading those already there. The total number of workers required in any particular factory would not necessarily indicate the total of those who would need to be housed. With the aid of the Local Government Board an inquiry had been made in every area where there was an extension of munition work. The areas fell into two classes: First, places in which, apart from the extension of munition works, there was congestion at the present time. In such a district it would be more justifiable to provide additional permanent houses than in a district where after the war there was not likely to be any increased pressure on the present available accommodation. In some places, therefore, a considerable increase in the permanent houses was required, in other places temporary accommodation would suffice, and the present emergency could be met to a considerable extent by making use of many existing buildings. Steps had been taken to requisition a considerable number of institutions and other places, and it was hoped that satisfactory accommodation would thus be provided within a very short time for a very large number of workers. Secondly, in places where there was at present a pressure upon the existing housing accommodation, the co-operation of the local authority had been invited, and schemes had already been arranged, entirely apart from the temporary accommodation, for the provision of a considerable number of houses by the local authorities. The Ministry of Munitions recognized that where additional housing was provided for munition workers, it was fair that the Ministry should make some contribution to the extra cost over and above the cost before the war, and such an arrangement had been made with the local authorities.

In reply to questions Dr. Addison said that he would prefer not to give figures, but the contribution towards the extra cost would be satisfactory. A great deal of temporary accommodation would also be required, and the Ministry was directly responsible for its provision. In Sheffield, in addition to the permanent scheme there would be a very large scheme for the provision of temporary houses of a satisfactory and even a picturesque kind, which at the same time would, considering the difficulties of this situation, be fairly cheap. A costs and accounts department had been formed whose sole business it would be to check costs. At Coventry there was a scheme for the provision of 600 permanent houses, because Coventry was already congested. The Coventry Garden Suburb Society was also providing an additional 120 houses. In Glasgow one scheme adopted in connexion with one of the large firms would provide 6,700 additional houses, and there was another scheme for the provision of another 150 houses at Moss End. Mr. Thorne asked how it was proposed to stop the raising of rents, and Dr. Addison replied that if additional houses were provided for 45,000 workers, it would at all events greatly relieve the pressure; he hoped the houses would be ready before Christmas. He recalled Mr. Lloyd George's statement on the previous day, that the Government would not hesitate if necessary to ask Parliament for any powers to deal with the situation.

Gallipoli Casualties.—Mr. Tennant stated on October 14th that the casualties in the Mediterranean Expeditionary Force up to October 9th were:

	Officers.	Other Ranks.
Killed or died of wounds	1,185	17,772
Wounded	2,832	66,520
Missing	383	8,707
	4,200	92,699
Total	96,899	

Of these the casualties in the Australian and New Zealand forces were as follows:

	Officers.	Other Ranks.
Killed or died of wounds	335	5,664
Wounded	814	20,180
Missing	52	2,076
	1,201	27,920
Total	29,121	

Disease at the Dardanelles.—Mr. Tennant, replying on October 20th to Mr. Joynson-Hicks, who asked about the number of cases of sickness removed from the Dardanelles and the proportion of sick to wounded, said he would endeavour to get figures. Statistics as to the number now in hospitals in the Mediterranean area, of those who had died from sickness in that area, and of those who had been in hospitals in that area and had recovered and returned to duty were not available, and to obtain them it would be necessary to telegraph. He regretted that he could not immediately give any additional information except to reassure the House that in the case of dysentery, which had been the chief disease, the figures showed a remarkable and gratifying decline since the beginning of this month.

Territorial Medical Officers.—Mr. King asked the Under Secretary for War on October 14th what steps, if any, had been taken to ameliorate the conditions of pay and service of Territorial Force medical officers as compared with those of medical men serving in the Royal Army Medical Corps of the new armies. Mr. Forster said that by Special Army Order of August 5th, 1915, lieutenants of the Royal Army Medical Corps (Territorial Force) were made eligible for promotion to the rank of captain on the completion of six months' embodied service.

Mentally Injured Soldiers.—In reply to Mr. Rendall, who on October 14th asked a question with reference to the certification of mentally injured soldiers, Mr. Tennant said that the three classes of patients it was proposed to certify could not properly be described as mentally

injured soldiers, if it was to be understood by that term that the mental injury was originated by the hardships of active service. The whole procedure of certification was prescribed by Act of Parliament, and he was not aware of any instance in which, after the ordinary military procedure had been carried out, any soldier had expressed a grievance owing to the fact that the opportunity to appeal had been to a general officer commanding in chief and not to a civil magistrate. As to another point raised by Mr. Randall—namely, whether it would not be proper to provide that the certificate should not be given by an officer of the R.A.M.C. holding office in an asylum—Mr. Tennant said that he regarded it as an advantage to have the opinion of a medical officer with special training and knowledge in these very difficult cases. In reply to a further question by Mr. Randall, Mr. Tennant said that he had received the report of the Fellows of the Royal College of Physicians appointed to inquire into the methods adopted by the War Office to deal with mentally injured soldiers, and would place copies in the Library.

Australian General Hospitals.—On October 19th Mr. Cathcart Wason asked whether the 10th Australian General Hospital arrived here fully equipped with twenty medical officers and seventy-one sisters, and whether so far it had been found impossible to utilize their services; who was responsible for such a state of affairs; and if, out of respect for Australian sentiment, this specially equipped unit would not be split up, but be employed as a unit. Mr. Tennant said he had communicated with the High Commissioner for Australia, and was informed that the medical officers and nurses referred to did not constitute the complete staff of a general hospital; that they arrived without equipment; and that they were sent to this country in view of contemplated extensions of accommodation for Australians in the 3rd General Hospital, and to provide the staff for that purpose. Arrangements were in progress for such extensions, and it was proposed that the services of this staff should be used in this connexion.

Medical Inspection in Factories.—In replying to Mr. King, on October 12th, who asked whether there was not overlapping and consequent unnecessary strain on medical men's work in respect of the medical examination under the Education and Factory Acts, Mr. Brace said that the factory examination served a different purpose from that of the school examination, and to provide for it through the system of school medical inspection would involve a considerable development of the work of the school medical officers, which could not be undertaken at present. Even if this were done he doubted whether any considerable saving would result, and in any case the saving would not accrue to public funds, as the charge for the factory examination at present was borne by the employer and not by the State.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

THE WEEK'S SUBSCRIPTIONS.

The following additional subscriptions to the Belgian Doctors' and Pharmacists' Relief Fund have been received:

	£ s. d.		£ s. d.
Durban Medical Society (per Dr. E. J. Bray, Hon. Sec.)	25 0 0	"Surgeon-Major," Dublin	1 0 0
Lancaster and District Pharmacists' Association (per Mr. J. B. Shattock)	1 1 0	South Carmarvon and Merioneth Pharmacists' Association (per Mr. W. E. Morris)	0 17 6
Mr. F. A. Williamson	0 15 0	Mr. A. Chapman	0 11 3

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE APPEAL FOR SURGICAL INSTRUMENTS.

Surgical instruments should be sent to the Master of the Society of Apothecaries, Apothecaries' Hall, Blackfriars, E.C. The Master acknowledges gifts from:

The Lady Georgina Home Drummond, per Dr. R. Dods Brown (2nd London), Perth.
Mr. W. A. S. Loyds, Sidcup.

Dr. Watson Williams, Clifton, Bristol.
Dr. N. S. Parakh, Rangoon.
Anonymous, Weymouth.

THE WAR.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[From a Special Correspondent in Northern France.]

SEWAGE DISPOSAL.

THE principle underlying the septic tank method of dealing with sewage has been well recognized for many years. It is the liquefying action of anaerobes on solid organic matter, and enters more or less into all the biological methods which of late years have been so largely used at sewage farms and the like in place of chemical means of securing satisfactory effluents.

But application of the principle in the fashion originally suggested by Cameron is comparatively uncommon. Its efficacy is admitted, as also its convenience—more especially when the amount of sewage that has to be dealt with daily is relatively small—but engineering difficulties are sometimes encountered, and for these and other reasons the pure septic tank, as distinct from the septic sewer and the watertight cesspit, is not so very often seen.

It is interesting, therefore, to be able to note that the septic tank principle is being utilized to some extent by the British Expeditionary Force in France, and that tanks which meet Cameron's specifications almost completely have been erected at two Indian hospitals at Marseilles and at one of the hospital camps in the Boulogne area, where the tank is being worked in connexion with an equal novelty in field sanitation—namely, a complete water-carriage system.

The tank is sunk in the gravel clay and rock, some 50 ft. from the edge of a sea cliff; it is of such size as to be able to hold the whole of the camp output for not less than twenty-four hours, and the average storm water in addition. The pipes enter below the surface, and the gradient is low, so there is neither splashing nor agitation as the sewage flows in. The exit is also submerged, but only just below the mean average level of the surface. The effluent thus always represents sewage which has been submitted to anaerobic action for at least twenty-four hours.

Strictly speaking, according to the original plan, there should be added to the tank a definite means of securing further changes in the effluent by aërobes but, in this particular case, the whole remaining needs are adequately met by causing the effluent to project by gravitation through a long spout on to the tide-washed beach at the bottom of the adjoining cliff.

The outlay on this sewerage plant and the connected water-closets must, no doubt, have been considerable, but the results are very satisfactory and the added convenience, together with the immense saving in labour, are an ample offset against the primary cost of the undertaking. At Marseilles a tank has been added to the existing sanitary arrangements of a chateau used as a stationary hospital and the other is at a large tent hospital. The latrines at the latter are formed by cemented sloping troughs which are flushed by water at intervals.

At Boulogne it was, very possibly, the proximity of the cliff that suggested getting rid of the purified sewage effluent of this camp by turning it into the sea after preliminary treatment, but in any case the sanitary specialist in charge of the area would have had to exercise ingenuity in dealing with the problem.

The extent which the ordinary methods of standing camp sanitation can be expected to afford satisfactory results varies greatly with the precise character of the camp site in question. It may always be possible to arrange for the daily removal of latrine buckets by a contractor, or for the destruction of their contents at the camp itself by means of a Horsfall or other incinerator, as also for getting rid of rubbish in general—especially fly-attracting rubbish—in similar ways; but the problem of dealing with liquid refuse—urine, wash-house, kitchen, and other waste water—will still remain.

As a rule, but by no means always, it can easily be solved. If there is good natural drainage, so that the ground, though not especially absorbent, is never likely to become waterlogged, even in very wet weather, or if the subsoil itself is capable of dealing with almost unlimited

quantities of water, all the fluid waste of the camp can be run off into "soakage" pits—covered in pits of varying depth and size, filled in loosely with rubble—or the outlets of all waste water can be led into one or more of the anti-suffic wells known by the French as *puitsards*.

Such means are, for instance, adopted with great success at the many hospital camps of Rouen, which are close to each other when the site, though somewhat flat, is deep gravel; and also at Etaples, where the equally numerous hospital camps stand on a chalk formation overlain for the most part by a foot or two of sandy soil. But in the Boulogne area solid rock in many places outcrops close to the surface and at others the subsoil is heavy marl or clay. The redeeming feature is that the area, if not always hilly, everywhere presents plenty of slopes and contours. Advantage has been taken of this characteristic in dealing with the fluid waste of hospital and other camps. In some cases it has been possible to turn the waste, after filtration through brushwood or the like, into streams totally unconnected with any water supply; in others catch-pits have been connected with subsoil drainage pipes running just under the surface of a declivity. In one case where such plans were deemed unlikely to prove satisfactory, the needs have been met by linking up the camp waste water outlets with the surface drainage system of the town itself. This involved quite a considerable pipe-laying operation. In the case of the camp at which the septic tank mentioned has been installed a departure from more conventional methods was necessitated by the unabsorbent nature of the subsoil and the fact that the only slope suitable for soil filtration and drainage led in the direction of another hospital.

If the conservancy of hospital camps often presents considerable difficulties and invariably demands unrelaxing supervision the same is sometimes true of hospitals housed in hotels, schools, and other permanent buildings. Their sanitary arrangements may possibly be capable of passing muster when the buildings are in use for their original purpose, but the quantities of liquid refuse resulting from hospital work throw upon them a strain which they often fail to sustain.

Furthermore, there are occasions when the drainage preoccupations of a sanitary expert in France may have to extend over the houses of a large civilian population. One remembers in this connexion a town on a hill just behind the allied line. It had no water-carriage system, but practically all houses were provided with a cesspool, and these, owing to past neglect and the increase of the population through the influx of troops, soon began to show signs of being full to overflowing. It was, therefore, the task of the sanitary expert to secure the emptying of those on premises used as billets, or otherwise occupied by troops, and, in view of the lack of effective pump-carts, it was no light undertaking.

In the same town, too, at a later date, the sanitary expert had no little difficulty in dealing with surface drainage, which, together with waste water and much solid rubbish from the houses, was supposed to leave the town by some half-dozen natural drains or open ditches; a few weeks' dry weather reduced the flow in these to a minimum, and between the rapid growth of weeds and accumulations of solid rubbish, all became practically choked. With the amount of labour for the time being available all the sanitary officer could do was to remove from each drain the principal obstructions each day and defer real ditching work for a future occasion.

Primarily it was the duty of the civil authorities, not of the sanitary expert, to attend to these matters, but in all towns within the zone of the British army it is the sanitary expert who must step into the breach if the civilian sanitary department is either non-existent, or, for the moment, is inoperative. In most towns, indeed, not only conservancy but all sorts of public health work may have to be undertaken by him. He must, for instance, always keep the character of its water supply and its adequacy constantly in mind, secure the cleansing of billets as soon as vacated by any given body of men, and watch for outbreaks of infective diseases among the civil inmates of houses where individual soldiers lodge; he must also, if occasion demands, extend his intervention in the civil life of the town much further. As already seen, he may practically have to make himself responsible for its drainage, and he may also have to attend to general conservancy

work, such as the daily removal of all rubbish from back streets and the abolition or treatment of accumulations of stable manure in back yards. All this demands not only knowledge and resource but the exercise of much tact and patience; so, if any sanitary expert at all is to be envied, it is, on the whole, he whose area includes the smallest number of civilian inhabitants.

BIRMINGHAM MILITARY HOSPITALS.

THERE are now a large number of beds available in Birmingham for military patients. The military hospitals in Birmingham are the 1st Southern General Hospital, and the 1st and 2nd Birmingham War Hospitals. The 1st Southern General Hospital consists of the Edgbaston, Dudley Road, Stourbridge, Selly Park, and King's Heath Sections, and Auxiliary Hospitals.

The 1st Southern General Hospital originally commenced in the University Buildings at Edgbaston with 520 beds. This was gradually extended in the manner indicated, and was further increased by the addition of an open-air ward of 40 beds in the beginning of October, 1915. The Dudley Road Section was opened in May, and consists of the Infirmary, which has been adapted for military patients. The Stourbridge Section was opened at the beginning of September, and is also in the Infirmary there. The Selly Park Section and the King's Heath Section have been formed by the conversion of two elementary schools; they were opened in the beginning of this month. The Auxiliary Hospitals consist of beds in civil hospitals, private hospitals, and V.A.D. hospitals. The large civil hospitals have generously given up beds, and besides these the largest V.A.D. hospital is that at Highbury (100 beds), the house of the late Right Honourable Joseph Chamberlain. The administrator of the 1st Southern General Hospital is Lieutenant-Colonel F. Marsh; the assistant administrator at the Edgbaston Section is Major J. E. H. Sawyer; at the Dudley Road Section, Lieutenant-Colonel Ellis; and at the Stourbridge Section, Major Kirkpatrick. The other two smaller sections are attached to the Edgbaston Section, and have a medical officer in charge.

Two railway goods stations have been arranged for the detrainment of sick and wounded to the 1st Southern General Hospital, one at the Selly Oak goods station on the Midland Railway, and the other at the Soho and Winson Green goods station on the Great Western Railway.

The 1st Birmingham War Hospital was opened in July at Rubery, and has been formed by the conversion of the lunatic asylum there. It has made a splendid hospital, and is situated in beautiful grounds. The administrator is Lieutenant-Colonel Suffer. The 2nd Birmingham War Hospital has been formed by adapting the Holywood Asylum, which is about half a mile distant from Rubery Asylum. It also has auxiliary hospitals. The administrator is Lieutenant-Colonel Thompson, I.M.S. This hospital was also opened in July. The railway station at Rubery has been adapted so as to make it suitable for the detrainment of the sick and wounded arriving for the two war hospitals.

A great amount of transport is required, not only to take the patients from the ambulance trains, but also to remove them from the central hospitals to the auxiliary hospitals. In addition the patients require to be transported from the hospitals to the various railway stations when they are discharged from hospital, or when they are transferred to the convalescent hospitals in various parts of the country. Arrangements have been made by a transport committee, including representatives of the Midland Automobile Club, the Automobile Association, and Motor Union, and of which Mr. E. M. Tailby and the chief constable of Birmingham are members, and an adequate number of motor cars are at the disposal of all the hospitals. The owners of these cars have been most willing to lend their services at any time of the night or day. In addition there are fourteen trailer ambulances which can be drawn by cars which have a suitable cross-bar attached at the rear. These have been found extremely useful and very comfortable. They were designed by Mr. E. M. Tailby, who is an indefatigable worker for the hospital transport. Besides these ambulances, each large section of the 1st Southern General Hospital and the war hospitals has

ambulances of its own, so that there are plenty of ambulances to deal with all the stretcher cases which arrive in one conveyance.

An out-patient station has been formed in the Children's Hospital out-patient department in Steelhouse Lane in the centre of the city. This is found very useful for soldiers who fall ill while on leave or sick furlough, as none of the military hospitals are within two miles of the centre of the city. The out-patient station was opened in January last, and is attached to the 1st Southern General Hospital.

THE WORK OF THE 2ND EASTERN GENERAL HOSPITAL, BRIGHTON.

ALTHOUGH the chief work of the 2nd Eastern General Hospital, Brighton, like that of all other Territorial hospitals, has been the treatment of men sent back wounded or sick from the front, this by no means comprises all its activities. In addition to the convoys of wounded from the Expeditionary Force, numbers of men from the camps in the neighbourhood have been treated at the hospital for various illnesses, diseases, and accidents. The area from which the hospital receives its patients is considerable. It comprises the greater part of Sussex and Kent. There are, in addition to the 2nd Eastern General Hospital itself, twelve principal auxiliary hospitals (four in Brighton, four in Eastbourne, and four in Hastings), under the care of the administrator, Lieutenant-Colonel James Rookh, and many smaller voluntary aid hospitals and convalescent homes, distributed about the two counties.

Of the work carried out the following examples may be mentioned:

Infectious Diseases.

At first cases of measles and German measles admitted from the camps were treated in special wards at the hospital. All other cases of infectious diseases, except the few cases of typhoid fever which were met with, were sent to the borough sanatorium. These included scarlet fever and epidemic cerebro-spinal meningitis.

Mental Cases.

Many men suffering from excessive strain, either from training in camp or from the nerve-racking experiences of the front, have been admitted suffering from neurasthenia, psychasthenia, and, in some few instances, actual mental disease, with suicidal tendencies. These latter were, as soon as possible, transferred to Netley if from the Expeditionary Force, otherwise they were handed over to the guardians of their parishes.

Medical Cases.

Every variety of disease—typhoid, influenza, tonsillitis, gastric troubles, bronchitis, pneumonia, laryngitis, intestinal disorders, nephritis, rheumatic fever—has been treated just as in an ordinary general hospital. The number of deaths has been very small. The cases of gas poisoning admitted have mostly been of quite a mild type. An outbreak of food poisoning occurred in one of the camps, and some thirty men were admitted. All were mild cases, with diarrhoea and vomiting, slight pyrexia, and general malaise as the symptoms. Treatment consisted in a purge, milk diet, and rest in bed for a few days. Some of the men complained of considerable debility during convalescence. A few instances of quite unusual diseases have been admitted, such as one of mediastinal tumour, and one of suspected foot and mouth disease, but the great majority of the medical cases has consisted of the ordinary illnesses which one would expect to occur in an ordinary community.

Accidents.

Accidents of many varieties, fractures of limbs, simple and compound fractures of the skull, of the spine, of the collar-bone, burns, bruises, sprains, and concussion, have been admitted. In cases of compound fractures of the tibia and fibula, often due to the kick of a horse, the treatment adopted has been to disinfect the wound thoroughly with iodine or carbolic acid, etc., and fix the limb in splints. Generally this has been sufficient to prevent the wound becoming septic. A few cases have been **plated** or screwed or otherwise mechanically treated.

Operations of Expediency.

Operations have been done for hernia, varicocele, hæmorrhoids, varicose veins, and deformities of the feet, such as hammer-toe or hallux valgus. There have been in addition a good many cases of appendicitis and a few of other acute abdominal lesions, and of various minor diseases.

Hernia.—The herniæ were nearly all of the inguinal variety with just a few femoral. Most of the men came in for operation. Many of them merely complained of a swelling of the groin, which they had only recently noticed, after heavy work or marching. In a large proportion very little, if any, inconvenience was caused by the swelling, but they had been sent in by their medical officer for operation to render them fit to continue on active service, especially active service abroad. The majority of the surgeons performed either a Bassini operation (exposure of the sac, by splitting up the external oblique tendon, and excision of it after ligation of the neck as high as possible, with approximation of the conjoined tendon to Poupart's ligament) or some modification of this, such as replacing the cord superficial to the external oblique tendon. Several of the surgeons, believing that in young, vigorous, healthy adults with good muscles, it is better not to interfere more than possible with the structures forming the canal, simply slit the external oblique fibres, ligatured the sac at its neck high up, excised it, and then sewed the external oblique tendon up again, not touching the deeper parts of the canal. The results appear to be quite satisfactory.

Varicose Veins.—The operation for varicose veins mostly performed is excision, either of small portions through many small incisions, or of the whole affected vein in its continuity. This is combined in many cases with ligation of the internal saphena vein, either low down or as it enters the femoral. The accurate preliminary marking out of the veins was found to be of the utmost importance in facilitating the operation. It seems to be generally agreed that the most satisfactory method is to paint the distended vein carefully with carbol-fuchsin or red ink.

Hæmorrhoids.—The operations for hæmorrhoids carried out were many and included crushing, ligation, or excision. There seemed to be no special advantage in any one method.

Varicocele.—The operation performed by all the surgeons was exposure and excision of about two inches of the pampiniform plexus. Care was taken not to include more than about two-thirds of the veins, leaving the remaining third to carry on the blood supply. The upper and lower ligatures were then tied together to shorten the remaining structures. The necessity of absolutely checking all hæmorrhage—so readily does a large hæmatoma form in the scrotum—was found to be most important, as was also the strictest asepsis in a part so liable to infection.

Deformities of the Feet.—Men have been admitted with various deformities of the feet, such as hammer-toe, hallux valgus, bunions, corns, flat foot, ingrowing toenails, etc. Many of these were operated on. The usual procedure for hammer-toe was excision of the head of the first phalanx, and this on the whole proved satisfactory. In a few cases the toe was amputated. For ingrowing toenail the nail was removed, and proper boots ordered.

Appendicitis.—A good many men have been admitted for acute appendicitis. All the surgeons are in agreement as to the advisability of immediate operation—the sooner the better for the patient. The incision adopted has generally been the vertical one on the outer border of the rectus. Some surgeons have used a transverse incision, at the level of the umbilicus, with satisfaction. If the case was accompanied by suppuration the rule has been not to hunt for the appendix, only to remove it if it were easily found. There have been a few cases of acute suppurative peritonitis due to appendix trouble, and these have been treated by incision and drainage with large drainage tubes.

Special Departments.

There are several special departments in the hospital. In the ophthalmic clinic are treated the various diseases of the eye, and refraction cases. In the throat, nose, and ear department cases of large tonsils and adenoids, enlarged turbinate bones, deflected septum, mastoid disease, otitis media, etc., have been dealt with. In the dental department extractions and fillings only are carried out. If artificial teeth are required they must be obtained otherwise.

The neurological department deals with nerve cases, chiefly by various electrical therapeutic methods, such as ionization, high frequency currents, and sinusoidal currents. Dowsing radiant heat is also used.

The 2nd Eastern General Hospital has, since its mobilization a year ago, had many thousand patients pass through its gates, and a great number of operations of every description have been performed. The results of treatment, both among the men from the Expeditionary Force and from the camps, have been thoroughly satisfactory.

AUSTRIAN EXPERIENCES.

THE RAVAGES OF THE VOLUNTEER NURSE.

In *Der Militärarzt*, issued as a supplement to the *Wiener medizinische Wochenschrift* for July 3rd, Dr. Max Schaechter has made some caustic comments on the treatment of wounds by his countrymen. His most scathing criticism was directed against the amateur performances of patriotic but ignorant ladies, whose social position apparently qualified them to impose their services on the surgeon and professional nurse. However wonderful the achievements of Professor Döllinger may have been in stamping out of the earth thousands of volunteer nurses to attend the wounded, the results, according to Dr. Schaechter, were often anything but brilliant. Military discipline, he said, prevented outspoken criticism of his superior's orders; but having paid this perfunctory tribute to the spirit of discipline, Dr. Schaechter proceeded to give ludicrous accounts of the blunders committed by the "wohlthätigen, hochstehenden, vornehmen, freiwilligen, patriotischen Damen." It appears that some of these ladies expected, not only to nurse, but also to direct and superintend the treatment of the wounded. Having attended a three or four weeks' course of lectures, they donned the uniform of the Red Cross nurse, attended operations, and even removed bullets from wounds. Dr. Schaechter writes: "Should we medical men permit or encourage this?" He answers this question by giving concrete examples of mistakes perpetrated in one case by a volunteer nurse, and in another case by an orderly. In the first case the patient was wounded in the hand, the ring finger being dislocated by a bullet. The finger was set so that when the wound healed the finger-nail appeared on the palmar aspect of the hand. The treatment of this case had been exclusively in the hands of "wohlthätigen Damen," but Dr. Schaechter laid the blame for this fiasco on the medical authorities who permitted such dilettante work. In the second case one of the patient's ears was split by a sabre, which also inflicted a severe wound in the back of the neck. The wound was dressed by an orderly in such a way that the lower half of the ear became adherent to the wound in the back of the head, while the upper half of the ear stood up like a pathetic question mark, arousing the mirth of every onlooker. Fortunately, in this case, a secondary operation restored the lower flap of the ear to its original position. Dr. Schaechter also drew attention to the anomaly of a skilled surgeon operating with gloves on his hands, a mask on his face, and rubber shoes on his feet, and then leaving the further care of the wound to the tender mercies of an ignorant volunteer nurse. A third patient came from Prague, bristling with large drainage tubes which had been inserted by volunteer nurses into a small wound in the sole of the foot.

THE TREATMENT OF WOUNDS BY RULE OF THUMB.

Another abuse at which Dr. Schaechter had a vigorous tilt was the modern tendency to adopt one special system for the treatment of wounds to the exclusion of all others and of common sense. This tendency, he said, did much to play into the hands of the interfering amateur, who found it much easier to master a set of hard-and-fast rules of some special system than to familiarize himself with the elementary principles of physiology and surgery. Thus, with regard to treatment with tincture of iodine he had often seen the enthusiast apply it not only to the skin around the wound, but also to the wound itself, however clean it might be, in the belief that what was good for the surroundings of the wound could not be bad for the wound itself. Yet the clean wound did not require iodine, and the septic wound suffered less from many other available

remedies. Iodine used rationally was of the greatest value, but of late its use had been pushed to an extent reminiscent of "the most gloomy days of the early antiseptic era."

ASEPSIS VERSUS ANTISEPSIS.

Again, with regard to the conflicting claims of asepsis and antiseptics, Dr. Schaechter confessed that he had been an ardent advocate of the former in times of peace, but that the war had taught him no longer to despise antiseptics. It might, he said, be well enough for surgeons to adhere to their aseptic principles in the field by working with only a few instruments sterilized by steam, and with only one assistant; but the time was bound to come when they must miss the support of an antiseptic. Dr. Schaechter mentioned carbolic acid, only to compare it unfavourably with hydrogen peroxide, which he had found of great value in immediately arresting stinking necrosis of wounds. Potassium permanganate acted in the same manner, and was of great use, when given in baths, for suppurating wounds. Balsam of Peru was also applied with advantage to wounds covered with discharge. Iodoform gauze should not be used to plug wounds, but, when lightly inserted, it afforded a useful method of drainage. Iodoform was found to exert a satisfactory and prolonged antiseptic action in wounds of the mouth and nasal cavities, as well as in wounds of the intestines and anus. It was seldom necessary to apply silver nitrate ointment to granulations in young subjects with normal vitality, but this remedy was not to be despised. Dr. Schaechter had found no use for the modern antiseptic powders, such as xeroform, dermatol, noviform, etc.

THE DANGER OF PLUGGING WOUNDS.

Dr. Schaechter had learnt to avoid plugging wounds whenever possible; he plugged only to arrest haemorrhage, for early in his experience he had seen how mischievous the plugging of wounds might be. As a solemn warning he recorded the case of a soldier who was shot at close range, the bullet entering the thigh, plunging up the muscles of the leg, penetrating the astragalus, and finally passing out at the heel. When he was admitted to hospital four days later, the surgeon's first task was to pull out a large quantity of iodoform gauze which had been stuffed into the wound, and which was, in the opinion of Dr. Schaechter, responsible for the gangrenous condition of the limb, and the symptoms of general infection. The patient recovered slowly from the effects of this abuse of iodoform gauze. Whenever plugged wounds subsequently came under Dr. Schaechter's observation, he was sure to find the wound itself in a bad condition, and the patient suffering from general symptoms of early sepsis. Almost invariably the removal of the plugging substance was followed by improvement in the local and general condition.

THE USE OF DRAINAGE TUBES AND SUTURES.

Drainage tubes were seldom found to be necessary, for the wounds were either so small and dry that they quickly closed and healed of themselves, or they were so large and widely open that the discharge usually escaped of itself. Dr. Schaechter had often to remove rubber tubing thrust into wounds by his more zealous colleagues, and he often saw the removal of tubing followed almost instantaneously by cessation of suppuration and closure of the wound. Though not irreconcilably opposed to the use of drainage tubes, he had learnt to restrict their use considerably, and he severely censured their employment as a matter of routine. Again, he had seldom found the suture of wounds necessary. For bullet wounds it was superfluous, and for the much rarer incised wounds there were seldom either facilities or time for suturing. The few wounds which had been sutured before the patient was admitted to hospital were almost invariably septic, and the first step taken in hospital was to remove the sutures.

DRY VERSUS WET DRESSINGS.

Dr. Schaechter had little good to say of the wet dressing, which kept the wound warm and moist, and thus facilitated the growth of micro-organisms; whereas the dry dressing ensured the absorption of moisture and the maintenance of the wound in a condition unfavourable to suppuration. But he had not found this view generally shared by his colleagues, and he had even to submit to

being lectured on the merits of wet dressings by a titled lady of the "wet dressing school." In one hospital he had found the rule was to apply dry dressings to small wounds and wet dressings to large wounds, as if the size of a wound affected the fundamental processes of healing. Most irrational of all was, in his opinion, the treatment meted out to a patient whose wound was painted every other day with silver nitrate, and was then covered by a wet dressing.

THE SUPPLY OF DRESSINGS.

Early in the war it was noticed that young surgeons and hospital surgeons, accustomed to an unlimited supply of dressings, were using up material at an alarming rate. The use of charpie as a substitute for lint and other dressings was advocated by Professor Hocheneck, and surgeons were urged to practise the greatest economy in dressings. This campaign of economy led to the unexpected result that prices rose excessively, while the quality of the dressing supplied by the manufacturers was sometimes very bad, yet there was no real shortage of good material. At Dr. Schaechter's hospital a consignment of dressings was received, consisting chiefly of cotton waste and dust. Only the wrappings in which this rubbish was packed were made of proper material. When the scandal of the jobbing in dressings was exposed, an adequate supply of suitable material was at once forthcoming, and had since been maintained. When the paper factories were requested to make dressings from wood pulp, they seized this order as an excuse to put up the prices of all kinds of paper.

"LEUKOPLAST" AND "VULNOPLAST."

Admirable though leukoplast proved as a dressing, its value was diminished by its lack of permeability, which prevented the escape of discharge from the wound and helped to macerate the skin under the leukoplast in the neighbourhood of the wound. This fault was avoided in vulnoplast, which consisted of a plaster covered by some layers of gauze, constituting a simple but complete dressing. This contrivance did much to simplify the dressing of slight wounds; but, after it had been in use a fortnight in Dr. Schaechter's hospital, an order was issued that this dressing, unauthorized by the senior command, was to be applied only to officers' wounds. Being unable to stomach this invidious distinction, Dr. Schaechter fell back on other dressings for officers and men alike.

IMMOBILIZATION OF WOUNDED LIMBS.

Immobilization of wounded limbs by plaster-of-Paris splints, even when only the soft tissues were involved, greatly hastened recovery. In times of peace it seldom occurred to a surgeon to treat a slight wound of a limb by immobilizing it in plaster-of-Paris. But Dr. Schaechter said that his experience during the war had taught him to rely more and more on this procedure. Large and small wounds of the limbs showed striking improvement as soon as the limbs were immobilized. The discharge from freely suppurating wounds rapidly diminished, and as the processes of healing were thus shortened, there was scarcely time enough for the limb to become stiff.

CONSERVATIVE TREATMENT OF GAS PHELGOM.

In several cases amputation of a partially gangrenous limb was avoided by the use of potassium permanganate baths. A young soldier was admitted to hospital with his left forearm black and swollen. A bullet had ploughed up the soft tissues on its flexor aspect, and they were already gangrenous. The skin of the rest of the forearm and also of part of the upper arm was covered by purulent vesicles. The mucous membranes and the skin of the rest of the body were of an intense yellow colour. The cracking characteristic of gas phlegmon was demonstrable under the skin of the whole of the arm. There was no line of demarcation, and rapid extension of the gangrenous phlegmon seemed most probable. Though all his colleagues urged immediate amputation of the limb, Dr. Schaechter decided to try permanent baths, with which he had been very successful in similar desperate cases. He kept the arm for eight days and nights in a solution of potassium permanganate (strength not given), frequently changed. By the second day the fever had abated, the phlegmon had ceased to extend, and the gangrenous tissues had begun to slough off. On the eighth day the

wound was practically clean, and the bath was given for only a few hours at a time. The radius and ulna were completely exposed for a distance of 15 cm., and their total necrosis was prophesied by Dr. Schaechter's somewhat pessimistic colleagues, who again advised amputation. This he decided against; and his optimism was justified by the rapid growth of granulations over the bare areas of both bones. Ultimately the wound was covered by a fresh growth of skin, but as much muscle had been destroyed, the movements of the limb were considerably impaired. Still, the man's life was saved, and an operation was avoided which might well have been fatal. In another case gas phlegmon and gangrene of the thigh were so severe that, in spite of prolonged baths in a solution of potassium permanganate, given for two hours twice a day, necrotic masses of muscle, weighing as much as a kilo, sloughed off. Nevertheless the patient's life and limb were saved.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

LIEUTENANT THOMAS JONES LATHAM, R.A.M.C., was killed in France on October 3rd. He was the second surviving son of the late Dr. Charles W. Latham, of Hackney Road, London, and was educated at the London Hospital, where he gained an entrance scholarship, and matriculated at London University. After taking the M.R.C.S. and L.R.C.P.Lond. in 1906, he joined his brother, Dr. D. W. T. Latham, in practice at Barnsbury, Islington. He took a temporary commission as Lieutenant, R.A.M.C., from October 21st, 1914.

Captain George Leonard Grant, R.A.M.C., was killed in France, aged 25, on October 11th. He was the only son of Dr. Leonard Grant, of New Southgate, and was educated at Epsom College, at Queen's College, Cambridge, where he graduated B.A., and at the London Hospital. At Epsom he gained the Brand prize and the Stone scholarship, the former testifying to the esteem felt for his character and conduct. He took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1914, was a keen member of the Officers' Training Corps, and at the beginning of the war enlisted in the London Scottish. Soon after his arrival in France with his regiment he received his commission as temporary Lieutenant in the R.A.M.C. (September 30th, 1914), and was appointed to an ambulance train. Later on he was appointed to be medical officer to the London Scottish, with which regiment he was serving when killed by a shell in the trenches. He was promoted to Captain on completion of a year's service. His Commanding Officer writes that "he was a man whom we all admired and loved, always hard working and efficient, and particularly cool and courageous in action." During the fierce action of September 25th he devoted himself without regard to his own safety to the relief of the wounded on the field and was unscathed, but on October 11th, when he was in the act of doing his morning sick parade, a shell burst in the trench, hitting him and five others. He was wounded in the back of the head and died a quarter of an hour later without recovering consciousness.

The death of Captain Keith Maurice Levi, of the Australian Army Medical Corps, was reported in the BRITISH MEDICAL JOURNAL of August 28th. Further particulars about this officer are now available. He was 24 years old, and was the younger son of Mr. Joseph Levi, of St. Kilda, Victoria. He was educated at Melbourne University, where he graduated in 1914, subsequently filling the post of resident medical officer of the hospital at Perth, the capital of Western Australia. When the war began he received a commission as Captain in the Australian A.M.C., and accompanied the Australian Light Horse to Egypt. He then served successively in the 1st Australian General Hospital at Heliopolis, on a transport conveying wounded from the Dardanelles to Alexandria, and as medical officer of the 2nd Battalion Hampshire Regiment, with which he was serving when killed, in the attack on Suvla Bay, by a shell which fell on a dressing station.

Captain Eric Louis Giblin, R.A.M.C.(T.F.), is reported in the casualty list of October 19th as killed in France. He was educated at Sydney University, where he graduated M.B. and Ch.M. in 1913. He joined the 24th (Queen's)

Battalion of the London Regiment as Lieutenant and medical officer on August 6th, 1914, and was promoted to Captain on completion of a year's service.

Captain John Harry Meers, R.A.M.C., was killed in France on October 13th, aged 30. He was the elder son of Mr. J. B. Meers, of Lancaster Gate, London, and took the diplomas of M.R.C.S. and L.R.C.P. London, in 1910. After acting as assistant medical officer of the Islington Infirmary, he went into practice in Wandsworth Bridge Road, London. On war being declared, he took a temporary commission as Lieutenant in the R.A.M.C. from August 16th, 1914, and was promoted to Captain after a year's service. He was attached to the 1st Battalion Loyal North Lancashire Regiment, and, while bringing in wounded, was hit in the arm by a bullet, and soon after killed by shrapnel.

Died on Service.

Major William Aberdeine Malcolm, R.A.M.C. (T.F.), died recently at Malta of enteric fever contracted at the Dardanelles. He was the fourth son of the late George Malcolm, of Dundee, and was educated at Edinburgh, where he graduated M.B. and C.M. in 1893. After filling the appointments of house-surgeon and general superintendent of the Ayr County Hospital, he became surgeon to the North Islington and Holloway Dispensary, and successively anaesthetist, casualty officer, registrar, and clinical assistant in the skin department at the Great Northern Central Hospital. He was medical officer to the Post Office, and honorary medical officer to the Charity Organization Society; and was a Fellow of the London Medical Society, a member of the Harveian Society, and a past president of the North London Medico-Chirurgical Society. He joined the 11th (County of London) Battalion of the London Regiment (Finsbury Rifles), as Lieutenant and Medical Officer on October 21st, 1902, and attained the rank of Major on November 21st, 1914.

Wounded.

Lieutenant-Colonel J. F. Donegan, R.A.M.C., Persian Gulf.

Major R. M. West, R.A.M.C. (T.F.), France.

Surgeon-Captain P. J. Bodington, R.A.M.C., Royal Horse Guards, France.

Captain T. E. Roberts, R.A.M.C. (temporary), France.

Captain F. A. Bearn, R.A.M.C. (Special Reserve), France.

Captain J. Dinnie, R.A.M.C. (T.F.), France.

Lieutenant P. J. O'Reilly, R.A.M.C. (temporary), France.
Lieutenant W. B. U. Patterson, R.A.M.C. (temporary), France.

Wounded and Missing.

Lieutenant A. S. Cohen, R.A.M.C. (temporary), France.

Missing.

Captain D. A. Laird, R.A.M.C. (temporary), reported missing, has since been reported as a prisoner of war, un wounded, at the officers' camp at Gutersloh, Germany.

DEATHS AMONG SONS OF MEDICAL MEN.

Greener, Noel Hindmarsh, Lieutenant 6th Battalion King's Own Scottish Borderers, only son of the late Dr. Greener, of Cardiff, killed in France on September 25th, aged 23. He was educated at Fairfield, at Malvern, and at Repton. When the war began he was in Canada, returned, and got a commission on September 25th, 1914. He was promoted to Lieutenant on October 21st, went to France in May as machine gun officer of 11th Battalion, and was returned as missing after the advance on September 25th to 27th. On October 12th he was reported to have been killed on September 25th.

Kennedy, William, Second Lieutenant 2nd Battalion Argyll and Sutherland Highlanders, son of Dr. Kennedy, of Dunbeath, killed in France at the end of September, aged 19. He was educated at Wick and Tain Schools and at Aberdeen University, and enlisted in the Gordon Highlanders at the beginning of the war, had been recommended for the Distinguished Conduct Medal, and was recently promoted and transferred to the A. and S.H.

Linton, Henry McEwan, Lieutenant 12th Battalion Highland Light Infantry, only son of the late Surgeon-Lieutenant-Colonel H. J. Linton, I.M.S., died in France of wounds received on September 16th, 1914. His first commission was dated September 16th, 1914; he was promoted on February 1st, 1915.

Monk, Gerald Patrick du Bailion, Captain 1st Battalion Welsh Regiment, son of Lieutenant-Colonel C. Monk, I.M.S. (retired), of Burlton Lodge, Darnes, Surrey, killed in France on October 3rd. He was educated at Fton, joined the army as Second Lieutenant in September, 1911, became Lieutenant on October 1st, 1912, and was recently promoted to Captain. He was the great grandson of Colonel the Count du Bailion, the last French Governor of Strasburg.

Wainwright, Geoffrey Lennox, Second Lieutenant 3rd Battalion Royal Sussex Regiment, elder son of Dr. Wainwright of Folkestone, killed in France on September 25th, aged 21. He was educated at Tonbridge School, and at Christ's College, Cambridge, and got a commission on August 15th, 1914.

Willis, Geoffrey, Second Lieutenant Northumberland Fusiliers, son of the late Dr. Wilkins, of Turnham Green, died in France of wounds in France on October 2nd, 1914, and was buried at Westminster, joined the Artists Rifles at the beginning of the war, and got a commission in May.

Wood, Oswald Ireland, Captain 1st Battalion Suffolk Regiment, elder son of the late Colonel Oswald Gillespie Wood, R.A.M.C., killed in France, October 1st-3rd, aged 25. He was educated at Sherborne, Rugby, Ardvreck, and Wellington, and went to Sandhurst as a King's Cadet in September, 1911, and joined the army as Second Lieutenant in September, 1911, became Lieutenant on May 13th, 1914, and was recently promoted to Captain. When war was declared he was in Egypt with his regiment, came with it to France, was wounded in April, and returned to the front in July.

MEDICAL STUDENTS.

Macpherson, Ian C., Second Lieutenant 5th Battalion Gordon Highlanders, son of Mr. Macpherson, rector of Banff school, killed in the recent fighting in France. He was educated at Banff school and at Aberdeen University, where he had taken the M.A. and was studying medicine. He enlisted at the beginning of the war, and got his commission on January 5th. His father, Gordon Macpherson, youngest son of the late Mr. Milne, farmer, of Andrewsford, killed in the recent advance in France. He was a medical student at Aberdeen, and enlisted in the Gordons early in the war.

Oke, Robert William Leslie, Captain 2nd Battalion Royal Berkshire Regiment, killed lately in France. He was the only son of Mr. A. W. Oke, of Southampton and Hove, and was educated at Sherborne, Rugby, Cambridge, and the London Hospital, where he was a medical student. He was appointed to the 3rd (Reserve) Battalion of the Berkshires as Second Lieutenant on January 3rd, 1914, and became Lieutenant on December 9th.

Rolland, Frederick James Gordon, Lieutenant 6th Battalion King's Own Scottish Borderers, killed in France on September 25th, aged 22. He was the son of Bailie William Rolland of Paisley, was educated at Glasgow University, where he took the M.A. and was studying medicine, and got a commission on September 16th. He was at first reported missing.

Stenhouse, Andrew, Second Lieutenant 10th Battalion Scottish Rifles (Cameronians), died in France of wounds received on September 25-27th. He was the son of Mr. James Stenhouse of Riverslea, Dumbarton, and was a medical student at Glasgow University, where he was in the hospital. He got a commission on September 16th, 1914, became Lieutenant in June, and in July went to France, where he was serving as bomb officer of his battalion.

NURSES.

Died on Service.

Miss Mabel Elizabeth Chadwick, V.A.D. nurse, died in hospital at Alexandria on October 15th of enteric fever. She was the daughter of Mrs. E. M. Chadwick of Leicester.

SIR LAUDER BRUNTON has received a telegram in the following terms: "The King and Queen deeply regret the loss you and the army have sustained by the death of your son in the service of his country. Their Majesties truly sympathize with you in your sorrow." All the members of his profession will desire to express their sympathy to Sir Lauder Brunton in his bereavement. As was noted in the JOURNAL of October 16th, Mr. E. H. Pollock Brunton, who took the diplomas of M.R.C.S. and L.R.C.P. in 1913, joined the R.A.M.C. with a temporary commission on April 2nd, 1915, and had been attached to the 4th Battalion of the Grenadier Guards since July.

NOTES.

NEW MILITARY HOSPITAL, GLASGOW.

The Scottish Red Cross Hospital, erected in the Bellahouston Park, Glasgow, was opened on October 14th by the Duchess of Montrose. The cost has been provided by contributions not only from Glasgow, but from all over Scotland and distant parts of the empire. It is placed on a fine open site, surrounded with spacious grounds and woodland, and will serve not only as a hospital but as a convalescent home. Sir George Eatson, the president of the Scottish Branch of the Red Cross Society, who was in the chair, said that Glasgow had now provided 1,200 beds—500 at Springburn and Woodside and the remainder in the new hospital. Altogether Scotland had provided 4,985 beds, and the meeting was designed to celebrate the work done throughout the country. The Duchess of Montrose said that Ayrshire and Renfrewshire had each given one block, Dumfriesshire and Fifeshire one ward, and Stirling and Peeblesshire beds. Generous subscriptions from all parts of Scotland and from all classes of the community, and from such distant places as

Honolulu and South Africa, had rendered it possible to establish the hospital without encroaching upon the general funds of the society. When, after the war, the last convalescent had left, the buildings might be utilized as a sanatorium for consumption or some other excellent purpose. General Bouche accepted the gift, and expressed the thanks of the War Office and the Army Medical Service to the Scottish Branch of the Red Cross Society and the people of Scotland. A few hours before the opening ceremony a hospital train had arrived in Glasgow, and 80 wounded soldiers from France, including 40 stretcher cases, had been admitted to Bellahouston. On the previous day 100 wounded men from the Dardanelles had been admitted to the Stobhill Hospital.

THE LORD DERBY WAR HOSPITAL, WARRINGTON.

In the brief account of this hospital published last week we were able to give only the names of the administrator and deputy administrator. We are now able to add that Major Nash, R.A.M.C., is the chief resident physician, and Captains C. E. Murphy, F.R.C.S., and G. Sichel, F.R.C.S., R.A.M.C., are the chief operating surgeons.

COAL OWNERS' AND MINERS' AMBULANCES.

The coal owners and miners of Nottinghamshire and Derbyshire have provided at a cost of £70,000 one hundred fresh motor ambulances for the British Red Cross Society. The cost has been met jointly, the owners raising a levy on the basis of their coal output in 1914, and the miners making a voluntary weekly levy on their wages. The convoy was inspected by the King and Queen on October 14th, and the cars are now being dispatched to France. Altogether it is stated that the British Red Cross and Order of St. John have provided a thousand motor vehicles—ambulances, cars, lorries, cycles, repair wagons, and motor soup-kitchens, as well as six motor launches, a steam picket boat, and a lighter, sent to the Dardanelles and the Persian Gulf, in addition to the hospital trains running in France and Belgium, of which we recently gave an account.

MEDICAL OFFICERS WANTED.

1st Home Counties Casualty Clearing Station, R.A.M.C.(T.).

Medical officers (surgeons preferred) are required to fill vacancies in this unit. Must sign imperial service obligation and go on foreign service with the unit when ordered. Pay and allowances as in regular army, with promotion to rank of captain in six months. Applications to Lieutenant-Colonel J. S. Warrack, Officer Commanding 1st H.C. Casualty Clearing Station, R.A.M.C.(T.), West Camp, Halton Park, Tring, Herts.

Ireland.

RESIGNATION OF PROFESSOR WHITE.

THE announcement that, owing to reasons of health, Professor A. H. White has considered it necessary to resign the chair of pathology in the school of the Royal College of Surgeons in Ireland, which he has held for the last seventeen years, has been received with great regret. Every one has admired the courage with which he has continued his work in the school and for the profession at large, in spite of serious indisposition, for many years. He was a distinguished student of the school, and was at one time assistant in the pathological department of University College, London. In addition to his chair in the college he has been surgical pathologist to the Meath Hospital, Dublin, and bacteriologist to the Cork Street Fever Hospital, and his contributions to scientific literature have related chiefly to bacteriology. In the profession generally he was perhaps best known for the political work he has done for it. He was honorary secretary of the Irish Committee of the British Medical Association. He was also for some years a member of the Council of the Association. When the insurance controversy arose he became honorary secretary to the first Conjoint Committee to deal with the questions then raised. For two years he worked hard, and the substantial union in the profession in Ireland during 1911 and 1912 was in large measure due to his unstinting exertions and organizing power. All that he did was done not only thoroughly but so modestly that the value of his services

is perhaps hardly yet appreciated. We hope that after a period of rest Professor White will be able to resume his useful work for science and for the profession.

POOR LAW MEDICAL OFFICERS ON MILITARY SERVICE.

ON the whole, boards of guardians in Ireland have facilitated the desire of their medical officers to join the R.A.M.C. by appointing the substitutes nominated by them to discharge their official duties as Poor Law medical officers and to take charge of their private practice during their absence. In most cases, too, the guardians pay either a portion or the whole of the official salaries of their medical officers who join the R.A.M.C., as well as the salaries of their substitutes. The Local Government Board in Ireland approves of boards of guardians paying a portion of or the whole official salary—which is invariably small and, in many cases, insufficient to cover the working expenses of the district—and it also urges that the substitute nominated by the medical officer absent on military service to take charge of his district during his absence should be appointed by the guardians provided the convenience and interests of the sick poor are safeguarded. The Kenmare (Kerry) Board of Guardians refused, by a substantial majority, to pay any portion of the salary of their medical officer who had joined the R.A.M.C., and further refused to appoint the doctor he nominated to take charge of his district and to look after his private practice during his absence. The guardians instead appointed a doctor who holds the position of part-time medical certifier, under the Insurance Act, for such an extensive area in the county of Kerry that the Local Government Board refused to sanction his temporary appointment, stating that it would be impossible for one doctor to discharge efficiently the duties of a Poor Law medical officer of a large dispensary district while discharging, as medical certifier under the Insurance Act, duties which would necessitate his absence for long intervals from his district. The Kenmare guardians refuse to accept the ruling of the Local Government Board, and by way of a reply, at their last meeting adopted a very long resolution, urging that the Local Government Board exceeded its power, which, the guardians contend, should be confined to the question of remuneration. The Kenmare guardians' contention is obviously absurd, both from the legal and common-sense points of view; otherwise it would mean that if a board of guardians appointed a doctor to discharge the duties of an entire union instead of a dispensary district, the only question the Local Government Board could deal with would be the question of remuneration, while the more important matter of safeguarding the interests of the sick poor would be altogether outside its jurisdiction.

It is an ethical rule, approved of by the Local Government Board, in the Poor Law medical service in Ireland that a doctor shall not seek to be appointed as locum tenens without the invitation of the doctor seeking leave of absence, and it is owing to the general observance of this rule that proceedings such as have taken place in the Kenmare Union are of very rare occurrence.

ROYAL VICTORIA HOSPITAL, BELFAST.

THE opening address of this session was delivered by Sir John Byers, chairman of the medical staff. After welcoming old and new students, he drew attention to the awful paradox in the war, where the highest science was at one and the same time devoted to the destruction and to the saving of human lives. The credit balance was apparent in their splendid Royal Army Medical Corps, by which both soldier and sailor were cared for and preserved in a way never attained before. He illustrated the excellence of the transport and sanitation services, the scientific care displayed in ferreting out infection. They in that school had done their share. The board of management of the hospital had offered 100 beds to the War Office. In addition to the care of the wounded, they had rendered fit for service some 150 recruits; four of their active staff had left them for military or naval service; another of their colleagues was surgical specialist for the Belfast Military District; eleven of their staff were attached to the Ulster Volunteer Force Hospital, with 180 beds. Seventy former students held commissions in the R.A.M.C., besides many older members whose exact locale it was impossible to trace.

In the Royal Navy they had traced eleven old students holding medical commissions and two surgeon probationers. There were also four of their sisters and thirty-seven of their nurses in foreign and home army service. Among those old students who had already been mentioned in dispatches and decorated were Colonel J. Meek, R.A.M.C., who was attached to the Headquarters Staff, and who had received the C.B.; Captain F. S. Irvine, R.A.M.C., who had received the D.S.O.; while Captain W. Brook Purdon, Lieutenants W. Tyrrell, W. M. Chesney, and W. M. K. H. Cullagh (all of the R.A.M.C.) were awarded the Military Cross, and Lieutenant J. L. Jackson (R.A.M.C.) was mentioned in dispatches. They had most regretfully to record the death of Captain T. M. C. Phillips, Lieutenant F. J. Wisely, and Lieutenant Walter McCurry (mentioned in dispatches), all of the R.A.M.C. and all their old hospital students. These heroes died a noble death while actually in the thick of battle ministering to the wounded; and they now tendered to their sorrowing friends their most sincere sympathy for their irreparable loss. They were all medical men who, humanly speaking, had the prospect of a bright career. As regards the future, sufficient medical men had come forward to equip the previous armies, but new armies had to be equipped, and they would be in a deplorable state unless the younger members of the medical profession continued to come forward. Sir John Byers concluded by saying that the tradition of a school was an imperishable asset; all those he had mentioned had more than maintained, they had extended that tradition; devotion to duty, self-sacrifice, and patriotism still called; it was their duty and their glad effort that this tradition should not be tarnished, but still further brightened and widened.

A vote of thanks was heartily accorded to Sir John Byers for his address, on the proposition of Professor Sinclair, seconded by Professor Lindsay.

England and Wales.

HEALTH OF LONDON CHILDREN.

THE policy of the London County Council with regard to the general medical treatment of school children has been to contract with outside bodies and institutions which assume responsibility for the medical side of the work, subject to the supervision of the school medical officer. At the first weekly meeting after the recess it was agreed that any scheme for school accommodation for tuberculous children who required treatment in non-residential institutions should entrust the treatment to the authorities of such institutions—dispensaries or hospitals—as the Public Health Committee might determine.

The rules issued by the Council for the guidance of teachers in connexion with scarlet fever and diphtheria have been altered to allow of the period of exclusion from school, in the case of children suffering from sore throat, being reduced from four weeks to two weeks. An addition has been made to the rules in respect of measles, to the effect that when measles is known to have occurred in the neighbourhood, every effort should be made to obtain information with regard to all absentees at the earliest possible moment.

Canada.

EFFECTS OF THE WAR ON HOSPITALS.

THE war seems to have resulted in an increase in the number of patients in the large hospitals. This does not necessarily mean an increased amount of illness; the explanation probably lies in the fact that many people now apply for admission to the public wards of hospitals who in normal times would be prepared to pay for medical attendance. This applies also to the outdoor department. In spite of the fact that the building was recently enlarged, the Montreal General Hospital has been obliged to refuse admission to many applicants during the present year. A large number of the members of the staff of the institution are on active service, but their places have been taken by

younger men who have been associated with the hospital, and the work of the institution has been continued along established lines without interruption. A department for massage and remedial gymnastics has been established in the hospital in connexion with the School of Physical Education at McGill University.

THE MEDICAL COUNCIL OF CANADA.

In his address at the annual session of the Medical Council of Canada, the President, Dr. Thornton, of Deloraine, Manitoba, in discussing the question of reciprocity between Great Britain and Canada, said that he was informed that all of the nine provinces had signified their desire to enter into reciprocal relations with Great Britain, or had already entered into such agreement. A number of applications had been received by the Registrar, Dr. R. W. Powell, of Ottawa, from men on active service, asking to be given the L.M.C.C. without examination, in consideration of the fact that they were unable to come up for examination. The matter was carefully considered by the Council, and it was decided that it would be unwise to grant the request, as it might possibly compromise the Council in the eyes of the provincial medical councils. A report from the Special Committee on Standards of Education, on co-ordination of the curriculum in the different medical colleges in Canada, was presented, and the committee was made permanent. The Committee on Reciprocity with Great Britain presented its report through the late Dr. A. W. H. Lindsay, of Halifax. The next meeting of the Council will take place on the first Tuesday in June, 1916, under the presidency of Dr. R. J. Gibson.

The College of Physicians and Surgeons of the province of Saskatchewan has decided to discontinue the provincial medical examinations after next December in favour of those of the Dominion Medical Council. Saskatchewan is the first of the provinces to take this step. The other provinces recognize the examinations of the Medical Council of Canada, and a student who has passed the latter examinations can practise in any province in the Dominion, but the provincial examinations are still held for those who wish to practise only in one province.

The Ontario Medical Council has adopted regulations defining the conditions of reciprocity of registration between the United Kingdom and the Province of Ontario.

MEDICAL EDUCATION IN ONTARIO.

THE Provincial Government has now appointed the Hon. Frank Hodgins, Justice of the Ontario Supreme Court, to inquire and report upon the constitution, powers, duties, and regulations of any body, corporate or unincorporated, and of any faculty or department thereof having any relation to medicine; the exercise of the same and the revenue and expenditures thereof; the situation, legal or otherwise, of such bodies in regard to each other or to the province; the establishment, creation, control, and regulation of any new body intended to have relation to medicine; the existing or possible methods of examining, licensing, or otherwise authorizing the carrying on by individuals of the practice of any methods having any relation to medicine and the standards prescribed and followed or proper to be established and followed; the present position, status, and practice of osteopaths, dentists, nurses, opticians, optometrists, chiropractors, Christian Scientists, or others practising or professing medicine; and the existing laws of Ontario in relation to any of the foregoing and their practical operation.

CANADIAN PUBLIC HEALTH ASSOCIATION.

At the fourth annual conference of the Canadian Public Health Association, held at Toronto in September, five general sessions were held. The President, Dr. M. M. Seymour, Commissioner of Health for the province of Saskatchewan, delivered an address in which he spoke of the various phases of public health work and the progress made in the field of preventive medicine. The following papers were read: Modern methods of sewage disposal, by George W. Fuller, Consulting Sanitary Engineer, New York City; Control of municipal and industrial wastes, by Mr. I. S. Osborne; The work of the International Waterways Commission, by Professor George Phelps, formerly of Harvard University, now on the commission appointed to investigate the extent of pollution of the international waterways between Canada and the United States; Practical methods of obtaining pure milk,

by Dr. Charles E. North, consulting sanitary expert of New York City. A conference was held on the diagnosis and care of the feeble-minded, and among the papers read was one by Dr. J. D. Pagé of Quebec on the immigration of the feeble-minded. An interesting discussion was held on the housing problem, and houses built by the Toronto Housing Company were inspected. The conference closed with a discussion on medical social service, which included papers by Dr. Evans on control of venereal diseases in municipalities and military camps, and by Dr. J. A. Hutchinson of Montreal on notification of venereal diseases. Dr. Charles J. Hastings, Medical Officer of Health, Toronto, was elected president for the year 1915-16.

India.

PUNJAB LUNATIC ASYLUM.

THE report of the Punjab Lunatic Asylum for the triennium ending 1914 shows that the population of the asylum has increased annually, the daily average strength in the three years under report being 682.58, 709.22, and 735.92, whilst the total population of the last year under report amounted to 991. A noteworthy feature is the continued and steady increase in the number of females admitted, which has risen now to 216. The Lieutenant-Governor agrees that this progressive increase of population is a clear indication of the growing popularity of the institution, and a proof of the care and sympathy bestowed upon its inmates.

Many improvements have been made during the last three years. The buildings have been enlarged and the interiors have been suitably tiled and floored. The asylum has now a maximum capacity of 830 patients, allowing 50 cubic feet for each, but the introduction of the cubicle system has reduced the number that can be accommodated; this, however, is fully counterbalanced by the superior arrangements for the care and comfort of the patients which the system affords. The recent provision of a new quarantine ward has supplied a long-felt want. The institution is fortunate in possessing shady gardens and ample grounds for recreation and exercise. The provision of a staff of attendants who will carry out their duties with efficiency and sympathy for the unfortunate patients has been difficult, but the appointment of two non-commissioned officers of the Indian army as superior warders has done much to raise the standard of efficiency of the attendants generally. The pay of the lower grades of attendants has also been revised and materially improved. A European warder has also been appointed primarily to look after European patients and to assist in general supervision and maintenance of discipline among the staff. As to the types of cases admitted, there is an increasing prevalence of idiopathic mania and melancholia, a type of insanity occurring mostly among the educated classes. The percentage of cures to the daily average strength rose slightly during the triennium, being 22.71, 17.48, and 18.07 for the three years respectively, as compared with 15.17, 15.03, and 16.69 for the years 1909-11.

The health of the inmates has been satisfactory. The asylum was visited by cholera in 1912 and 1913, but all precautions were taken and its spread prevented. Four deaths were due to the disease on the first occasion and two on the second. Five escapes occurred during the three years, due in all cases to carelessness of attendants. Five deaths occurred as the result of assaults by fellow patients, but in no case was any of the attendants held to be blame. The total annual cost of the asylum averaged in round figures Rs. 164,000 yearly during the triennium, as against an average of Rs. 115,000 in the previous triennium. The main item of increase is under building charges. Lieut.-Colonel Evens, who had held charge of the asylum since its foundation some fifteen years ago, died on September 9th, 1914. The Lieutenant-Governor heartily endorses the remarks made in the report and by the Inspector-General of Civil Hospitals on his work as Superintendent. The institution owes its progress in efficiency and popularity almost entirely to his untiring effort and sympathetic care of the inmates.

Correspondence.

URIC ACID STONES UNDER THE X RAYS.

SIR,—In a paper by Dr. Newman on ureteral calculus, in the *JOURNAL* of October 16th, p. 557, there is the following statement: "It (radiography) is now so perfect that even a small uric acid stone in the lower segment of the ureter can easily be discovered." This statement, in my opinion, requires some proof.

My experience of the last ten years is that I have never yet been able to show with x rays the shadow of a pure uric acid calculus anywhere in the urinary tract. The description "uric acid calculus" from the x-ray point of view must necessarily mean "pure" uric acid, as the point is whether the uric acid, and not other constituents of the stone, casts the shadow.

Some years ago Mr. Thelwall Thomas had a number of stones examined both qualitatively and quantitatively; a number of these to the eye suggested uric acid stones. Not one of these was found to consist of uric acid, and many had no uric acid in them at all. On the other hand, in several cases of large bladder stones not shown on good x-ray negatives, the examination showed them to consist entirely of uric acid and moisture, without a trace of any other constituent.

It is impossible to conceive of large uric acid bladder stones not showing, and small lower ureter stones being "easily" discovered.

I have never yet seen a stone shown by radiography, removed by operation, and properly examined, which consisted of pure uric acid. I have not during the last ten years seen a stone removed from a kidney or ureter which had not thrown a distinct shadow on an x-ray plate.

The pure uric acid stone of what may be described as "of surgical size" must be of very rare occurrence in a kidney or ureter, and I feel sure that if all supposed uric acid stones were carefully and thoroughly examined before being described we should hear less of the demonstration by x rays of "uric acid calculi."—I am, etc.,

Liverpool, Oct. 18th.

C. THURSTAN HOLLAND.

BROMIDES IN EPILEPSY.

SIR,—In the *BRITISH MEDICAL JOURNAL* of October 9th a correspondent asks what is the best substitute for bromides in epilepsy, saying that he has seventeen epileptics who must have their full dose of bromide. But why must they? The routine administration of bromides in epilepsy is about as intelligent as the routine administration of "alteratives" in "rheumatism" or the routine administration of "antipyretics" in "fever," or the routine administration of any other drug in any other group of diseases. For the recurring convulsion that we call epilepsy is not a disease—it is a group of diseases; it is certainly more than one disease. There are certain cases of epilepsy—that is to say, there is one of these diseases—in which immense benefit follows the administration of bromides, and these are the cases which make the reputation of bromides in epilepsy and of certain quack remedies containing bromides that are advertised as a cure for epilepsy; but these cases form but a very small percentage of the whole. In most cases of epilepsy bromides are not of the slightest value, and in many are actively pernicious. There are at the present time hundreds of epileptic patients who are taking bromides and who would be very much better without them. Let your correspondent cease to give bromides to his seventeen epileptics, and he will find that most of them, if not all, will become more lively, more intelligent, and will get rid of their bromide rash. If one of them—it is very unlikely that there will be more than one out of seventeen—should show a decided increase in the number and severity of his fits, it will be easy to let that one resume his bromides, but the rest will be far better without them.—I am, etc.,

Parkstone, Dorset, Oct. 18th.

CHAS. A. MERCIER.

INFANT FEEDING.

SIR,—The evil of attempting argument by correspondence is the necessity for restatement. I wrote in my lecture that since the public was now interesting itself in

the subject of infant mortality and its control it would seem necessary to devise, and adhere to, a standard diet which it should be the part of these lay helpers to supervise. With the carbohydrate patent foods, I said, they must have nothing to do, because these diets were therapeutic diets, in many cases copied from successful prescriptions by well-known medical men for ailing infants in the past, and I quoted examples.

So far we are all in agreement, but I said in my paper that, to my way of thinking, it did not matter very much whether we chose whole-citrated milk as the standard diet, or diluted the milk a little and added a little sugar. Dr. Vining and Dr. Langmead would have us confine the standard diet to whole-citrated milk. That, I think, represents the difference between us—not a great one. None of us contend, as I have seen it contended, that whole-milk is a panacea for all the manifold types of infantile indigestion.

Dr. Langmead's well-known work has proved once and for all that citrated whole milk is well tolerated by the majority of healthy infants without alimentary disturbance. I would go further than this and say that it is doubly curative of the commonest of all forms of infantile dyspepsia—that due to overfeeding with starch and sugar, which is characterized by the familiar acid, green, watery stool, and that, because this condition is so common among the poor, the routine use of citrated whole milk is bound to achieve a large measure of success. The mothers of the poor look upon sugar not as a valuable food, but as a sweetening agent. With this object, as much as two ounces of cane sugar a day is quite commonly added to the milk of a tiny child. Sweetened condensed milk in great concentration and patent foods containing starch add their quota. In all cases of overfeeding with starch and sugar, the use of whole milk is promptly curative; but this prescription occasionally gives rise to troubles of its own. Whole cow's milk, in a minority of all cases, and in a considerable percentage of very young infants, tends to produce fat dyspepsia; and the symptoms of fat dyspepsia—constipation, or the passage of bulky, formed, pale alkaline stools, with a strong putrefactive odour which contrasts with the sour-smelling green evacuation of sugar dyspepsia—are, as might be expected, the very converse of those which a diet too rich in sugar or starch produces. They in turn are promptly relieved by adding sugar, preferably malt sugar, to the diet, and the frequency of their occurrence explains the occasional undoubted success of the proprietary malted foods. Such was the substance of my lectures.

Dr. Vining's experience does not include cases of fat dyspepsia such as I describe, or the malnutrition which results from their continued neglect. I have no way of proving their existence to him, but I cannot follow him in attributing symptoms such as these to an excess of sugar in the diet. It seems to me clear that sugar is too valuable a part of the diet, both for the maintenance of the body heat and for improving the tone and nutrition of the muscles, to be maintained always and in all cases at the low level found in cow's milk, on the ground that its use is often violently abused by ignorant mothers who are unable to measure and control the diet. For these reasons, in choosing a diet there is something to be said in favour of moving in a direction a little away from the safety from diarrhoeal disorders which whole citrated milk confers—of diluting the milk a little and adding a little sugar. In selecting a standard diet I would avoid all extremes. Let us choose something sensible, and, if necessary, modify it in individual cases in the light of the symptoms which result. Dilute milk with added malt sugar might be the routine for the first three months, whole milk thereafter. To add cream as a routine measure is to defeat the object of the dilution—the reduction of the high fat percentage in cow's milk.

In conclusion, may I say that all this discussion is foreign to the purpose of my paper? I urged in a single sentence that in infant mortality work a standard diet should be erected; I did not presume to choose one. I am driven to this reiteration by the very disquieting suggestion—first made by Dr. Vining and repeated by Dr. Langmead—that because I am willing to accept a standard diet for young infants composed of milk with a moderate addition of water and sugar, I am proposing a diet which

is itself the common cause of all the distress and mortality which I had imagined I was addressing myself to relieve.—I am, etc.,

London, W., Oct. 18th.

H. CHARLES CAMERON.

THE WAR EMERGENCY.

THE NEED FOR SELECTION.

SIR,—Before I reply to Dr. Court's letter I should like to clear up one personal matter. Some one writes suggesting that for the work I am doing for the War Office I am receiving remuneration from the State. He is mistaken. I do not even receive my out-of-pocket expenses.

Dr. Court states that I made some ungenerous remarks about the recruiting returns of the panel doctors. I made no remarks; I simply gave the figures—that amongst us officials 90 per cent. had gone, amongst panel doctors 12 per cent. I do not claim that we officials are any more patriotic than the doctors on the panel, but that the difference in the figures showed the necessity for proper organization under which men could go, feeling that their interests would not suffer.

Dr. Court is wrong in saying that our Tuberculosis Committee were willing to close the sanatorium for the duration of the war. Before opening the sanatorium the county council offered it to the War Office, together with the staff to administer a hospital of 300 beds. The War Office refused the offer. The sanatorium was then opened and the Insurance Committee handed over to the county council between six and seven thousand pounds a year for the administration of sanatorium benefit within the county. Having put our hands to the plough we cannot turn back. It would be unfair to the Insurance Committee and to the insured persons. From Dr. Court's letter I find that it is the Chesterfield Division which has taken this matter up, while the sanatorium is for the whole county, with a population of 580,000. The Chesterfield Division of the British Medical Association has been asked to find six men. It strikes me as lacking in sense of proportion for a local Division to ask the one man responsible for this important work to desert the post where his special knowledge is of the greatest use to the community, and I protest against this being done without any communication being sent either to the Local Government Board or the county council. The officer in question wishes to go, but has subordinated his own inclination to his obvious public duty.

Dr. Court's objection to my scheme for the State taking over the medical profession, as they have taken over munition works, is that it would put an end to "free choice of doctor." Surely the profession can let the public raise this point. We have no free choice of judges, clergy, or magistrates, nor of any civil servants. There is no free choice of doctor for the men who are fighting our battles abroad. If the Government require a large number of medical men, and the War Emergency Committee wish to hear how a State service for the period of the war can be organized, I shall be glad to go into details with that Committee.—I am, etc.,

County Offices, Derby, Oct. 19th.

SIDNEY BARWISE.

Public Health

AND

POOR LAW MEDICAL SERVICES.

DUTIES OF DISTRICT MEDICAL OFFICERS.

NESTOR.—There is nothing in the Poor Law Orders requiring a district medical officer to obtain the leave of his board of guardians before taking a holiday. It is customary to notify the clerk when about to take a holiday, and to send him the name of the deputy who is to carry out the duties in the absence of the medical officer. The only complete manual of the rules of the Local Government Board is *Glenn's Poor Law Orders*, published by Knight and Co. The *Poor Law Medical Officers' Association* published some years ago a small handbook (price 2s. 6d.) entitled *The Law Relating to the Poor Law Medical Officer and Vaccination*. This contains most of the information "Nestor" requires. The honorary secretary (Dr. Major Greenwood, 34, Cophall Avenue, London Wall, E.C.), still has a few copies of the last edition for disposal.

Universities and Colleges.

UNIVERSITY OF LONDON.

MATRICULATION.

At the September matriculation examination 270 candidates were successful, 65 being placed in the first, and 207 in the second, division. In September, 1914, the number of successful candidates was 162, and in September, 1913, it was 289.

UNIVERSITY OF EDINBURGH.

GRADUATION CEREMONY.

At the graduation ceremony on October 15th fifty-three degrees were conferred, the candidates absent being already on service, and of those who attended some were in uniform. The Principal, Sir William Turner, who presided, said that the graduation in October was always small compared with the summer. The new graduates who had already joined the military services were following the example of those who had graduated in the course of the summer, and that set by all the universities in the United Kingdom. The academic youth of Great Britain and Ireland had shown themselves worthy of the great universities; they had not forgotten that they had a voice in the affairs of their country and had shown themselves equal to looking on their lives and themselves as belonging to a great country with a great history which had brought it into the very highest place among the nations and which they in their turn must help to preserve.

The following medical degrees were conferred:

M.P., Ch.F.—M. H. Alkhan, T. C. Bowie, A. F. Campbell, E. J. Clark, P. B. Corbett, J. Dick (with second-class honours), R. B. Edie, P. W. Edwards, G. Elsworth, Heier M. Gall, W. Goldie, E. S. Hawken, A. N. Homewood, T. J. Lloyd, M. McGarrity, C. F. MacLachlan, A. J. R. Taylor, W. E. Thompson (in absentia), A. A. Watson.

UNIVERSITY OF ST. ANDREWS.

GRADUATION CEREMONIAL.

At a graduation ceremonial held in St. Mary's College Library Hall the following degrees were conferred by Principal Herkless:

M.B., Ch.B.—T. Easterman, T. L. Henderson, W. P. Starforth.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE HARVEIAN CELEBRATION.

THE HARVEIAN oration was delivered on St. Luke's Day, October 18th, by Dr. Sidney Coupland, but the usual dinner at which the College is in the habit of entertaining some distinguished guests was not held.

The following medals were awarded:

The Moxon gold medal, founded in memory of the late Dr. Walter Moxon, physician to Guy's Hospital, and awarded every third year, on the recommendation of the Council, to the person who should be deemed to have most distinguished himself by observation and research in clinical medicine, was awarded to Professor Jules Dejerine, Clinical Professor of Diseases of the Nervous System in Paris, and Physician to the Salpêtrière. Professor Dejerine being unable to be present to receive the medal, it was handed by the President to one of the secretaries of the French Embassy for transmission to the professor.

The Baly Gold Medal, instituted in 1866 by the late Dr. F. D. Dyster in *memoriam Gulielmi Baly*, and awarded every alternate year to the person who shall be deemed to have most distinguished himself in the science of physiology, especially during the two years immediately preceding the award, was presented to Frederick Gowland Hopkins, M.B. Lond., F.R.S.

The Weber Parkes medal of 150 guineas and a silver medal, founded in 1895 by Sir Hermann Weber in memory of the late Dr. E. A. Parkes and awarded every third year to the author of the best essay upon some subject connected with the etiology, prevention, pathology, or treatment of tuberculosis, especially in reference to pulmonary consumption in man, was awarded to Dr. Noel Dean Barlowell, Medical Superintendent to King Edward VII Sanatorium, Midhurst, Sussex.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council was held on October 15th, when Sir Frederic Eve, Vice-President, was in the chair.

War Service.

The Secretary reported that the President had left England for the Dardanelles as Surgeon-General in the Royal Navy. Mr. Waterhouse reported that he had undertaken to proceed to Russia in charge of the Anglo-Russian Hospital, and was given leave of absence during the period of his services abroad. Mr. R. H. Burne was given further leave of absence of three months that he might be able to continue his services in France under the French Red Cross.

Vacancy on the Conjoint Examining Board.

Dr. Cameron having accepted the Chair of Anatomy at the University of Halifax, Nova Scotia, the vacancy on the Conjoint Examining Board occasioned by his resignation will be filled up in June, 1916.

Annual Report.

The annual report to be presented to the Fellows and Members at the annual meeting on Thursday, November 18th, was adopted.

War Emergency Committee.

Sir Rickman Godlee was appointed to represent the College on a special War Emergency Committee meeting at the offices of the British Medical Association.

CONJOINT BOARD IN ENGLAND.

The following candidates have been approved at the examinations indicated:

FIRST EXAMINATION.—Part I, *Chemistry*: Part II, *Physics*: *F. Barker, Anna B. Broman, H. S. Chadwick, J. F. de Silva, H. L. Dibrstein, G. P. Evans, Kate Glyn-Jones, D. P. Gullfoyle, A. Hamid, E. Hardy, S. G. Harrison, J. A. Hawkrige, W. E. Howell, M. A. R. Khalifa, G. B. Kirkland, Emilia B. M. Krause, *P. Lindsey, *T. D. Llewellyn, D. Maxinos, J. L. O'Flynn, W. V. Parry, A. R. Paul, H. L. J. Reason, G. K. Reeves, H. H. Roe, I. A. G. Sykes, G. M. Trist, J. S. White, G. B. Withers. Part III, *Elementary Biology*: S. Ackroyd, A. B. Aldred, C. B. Dix, J. E. H. Duckworth, A. E. Ferguson, R. D. French, S. Godsell, Emilia B. M. Krause, R. O. Lahami, Kathleen M. B. McArthur, D. Mackay, V. A. Newton, H. C. Randall-Stevens, F. A. Smoritt.

* Passed in Part Only. † Passed in Part II Only.

The Services.

EXCHANGES DESIRED.

TERRITORIAL FORCE.

CAPTAIN A. R. PATERSON, R.A.M.C.(T.), attached 14th Dorset Regiment, Ambala, India, wishes to find substitute so as to enable him to transfer to a unit at home or in France. Communications should be addressed to Dr. Le Fleming, Wimborne, Dorset, who will give all details.

Captain serving with a home service field ambulance is anxious to exchange with an officer of similar rank now serving in a casualty clearing station or hospital. Imperial service will be undertaken. Exchange into a home unit stationed in South of England would be considered. Please reply to H., Box No. 5200, c/o BRITISH MEDICAL JOURNAL, 429, Strand, W.C.

Obituary.

CARLOS FINLAY, M.D.

CHIEF SANITARY OFFICER OF CUBA.

DR. CARLOS J. FINLAY of Havana, whose name is well known to all interested in tropical diseases in connexion with the discovery of the causation of yellow fever, died on August 20th. He was born at Camagüey, in Cuba, on December 3rd, 1853. His father was a native of Scotland and his mother, Isabel de Barrés, a Frenchwoman. In 1844 he was sent to a school in Havre, but had to return home in 1846 on account of ill health. In 1848 he attempted to go back to France to complete his education, but the revolution of that year compelled him to stay for a time in London. When the political atmosphere was clear he entered the Lycée at Rouen, where he remained till 1851, when his studies were again interrupted by an attack of typhoid fever. On his recovery he went home and sought for admission to the medical faculty of the University of Havana on the strength of his course of study in France. His application being rejected, he went to Philadelphia, where he graduated M.D. at the Jefferson Medical College in 1855. There he came under the influence of John Kearsly Mitchell, one of the earliest advocates of the microbial theory of disease. With the son of that professor, S. Weir Mitchell, young Finlay formed a friendship which continued till the end. He was the first pupil of Weir Mitchell, who continued to direct his studies during three years.

On his return to Cuba, Finlay settled as a general practitioner in Havana. In 1881 he represented the Cuban Government at the International Sanitary Conference held at Washington, and it was on that occasion that he first brought formally before the medical profession his theory that yellow fever was transmitted by the bite of a mosquito then known by the name of *Culex fasciata*, now called *Stegomyia calopus*. For a long time, owing to

the lack of experimental proof his voice was as that of one crying in the wilderness. He was looked upon as a visionary till the work of Reed and his colleagues of the American Commission in 1900 and 1901 supplied the basis of fact necessary to make his hypothesis a scientific truth. The general acceptance of his doctrine was celebrated by a banquet given him by the profession of Cuba, which was presided over by General Leonard Wood.

In 1902 Dr. Finlay was appointed chief sanitary officer of Cuba and president of the Superior Board of Health. He resigned these appointments in 1908. The value of Finlay's work was attested by the numerous honours of which he was the recipient. On the proposal of Dr. Weir Mitchell the Philadelphia College of Physicians elected him an honorary fellow. In 1907 the Liverpool School of Tropical Medicine awarded him the Mary Kingsley Medal. In 1908 the French Government sent him the decoration of Officer of the Legion of Honour. In 1911 the Paris Academy of Medicine elected him a corresponding member. On the proposal of the first Cuban Medical Congress, the Government gave him a pension and undertook the publication of a complete edition of his works. By decree of the President of the Republic of Cuba, he was given a State funeral at the public expense.

WE have to record with much regret the death of Mr. W. J. CANT of Lincoln, which occurred on October 7th at the age of 59. Mr. Cant received his medical education at Birmingham, and took the diplomas M.R.C.S. and L.S.A. in 1877 and that of L.R.C.P. in 1879. Soon after the foundation of the University of Birmingham he received (in 1902) as a distinguished alumnus of the Birmingham Medical School the degree of M.B., B.Ch. In 1877 he became assistant house-surgeon to the Nottingham General Infirmary and two years later house-surgeon to the Lincoln County Hospital. In 1882 he entered into partnership with Mr. Charles Brook and Mr. Wilkinson, and was later associated with Mr. Charles Brook and Dr. W. H. B. Brook, with whom he worked until 1910, when he suffered a breakdown in health. He recovered sufficiently to resume practice, specializing in ophthalmic surgery. He had been appointed surgeon to the Lincoln County Hospital in 1887 and to the Lincoln General Dispensary in 1892. In 1901 he became consulting surgeon to the Lincoln County Hospital, and had been medical referee under the Workmen's Compensation Act since 1898. In 1904 his health again failed and he retired from practice; since then he had been an invalid, and for a month had been perceptibly failing in health. His illness was attended with much suffering, and on October 5th there came a sudden collapse from which he never rallied. He will be remembered by many for the considerable work he did as joint secretary with Canon W. W. Fowler for the Lincolnshire Loan Exhibition in 1887, and for the ever-ready help and interest he took in elementary and continuation schools, in science classes, and in the Lincoln Free Library. He married in 1891 the daughter of Mr. John Turner of Pendlebury, and leaves one daughter. He contributed to this JOURNAL papers on the treatment of conical cornea and on cataract extraction without iridectomy, described a tarso-choleoplastic operation for trichiasis in the *Lancet*, and reported a case of right congenital ptosis treated by Mules's operation to the Ophthalmological Society (*Transactions*, 1897); he also wrote in the *Sheffield Medical Journal* (1893) on the after-treatment of abdominal section, and reported one of the few recorded cases of idiopathic hæmatoporphyria.

BRIGADE-SURGEON ANDREW BARRY, Bombay Medical Service (retired), died at St. Andrews on October 3rd, aged 72. He was educated at Glasgow University, where he graduated M.D. in 1864. He also took the diplomas of L.R.C.S.Ed. in 1864, and of F.R.C.S.Ed. in 1873. He entered the Army Medical Department as an assistant surgeon in February, 1865. In the spring of that year the Indian Medical Service, which had been closed for four and a half years, was again thrown open to competition, and several of the assistant surgeons on probation for the Army Medical Department went in for the examination for the Indian Medical Service, among them Surgeon-Generals James Cleghorn and Robert

Harvey and Barry. He was gazetted assistant surgeon, I.M.S., from April 1st, 1865, became surgeon on April 1st, 1873, surgeon-major on April 1st, 1897, and brigade-surgeon on February 26th, 1888, retiring on August 31st, 1895. He had seen a good deal of war service—the expedition against Wagher tribes in 1865-6, and the operations of the Kathiawar Field Force in the Burda Hills; Abyssinia, 1867-8, medal; and Afghanistan, 1879-80, in the force which relieved Kandahar, medal.

CAPTAIN ERNEST GEORGE FORD, R.A.M.C., retired, died at Wolston, near Coventry, at the age of 40, after a short illness, on October 7th. He was the son of Mr. George Ford, of Beverley, and was educated at Edinburgh, where he took the degrees of M.B. and Ch.B. in 1899. He entered the army as lieutenant on April 25th, 1900, became captain on April 25th, 1903, and retired on April 8th, 1911. He served in the South African war from September, 1900, to its close in May, 1902, taking part in operations in the Transvaal and Orange River Colony, and received the Queen's medal with three clasps, and the King's medal with two clasps.

Medical News.

DR. JAMES CROMBIE (Sideup) has been appointed to the Commission of the Peace for the county of Kent.

FIVE cases of plague and four deaths from the disease were reported in Mauritius in the two weeks ending October 14th.

DR. H. E. H. OAKELEY of Kimberley, S.A., was entertained at dinner by the local profession immediately before his departure for military service in Europe.

MESSRS. Taylor's Typewriter Co., Ltd., of 74, Chancery Lane, W.C., wish to notify their customers that their Chancery Lane branch business is being carried on as usual.

DR. J. JOHNSTON of Bolton, long lecturer to the St. John Ambulance Corps, has been appointed to the Queen Mary's Military Hospital established in the new asylum of the Lancashire Board at Whalley.

AT the first scientific meeting of the Zoological Society of London, at 5.30 p.m. on Tuesday next, Lieutenant-Colonel R. T. Leiper, D.Sc., F.Z.S., will give a demonstration on the migration of *Bitharsia cercarica* through the skin.

AT a meeting of the Aberdeen County Committee on Secondary Education on October 15th it was resolved to suspend the scheme of medical inspection of school children for the county owing to the scarcity of medical men for war service.

MR. JOHN D. ROCKEFELLER, JUN., Chairman of the New York Bureau of Social Hygiene, has given £5,600 to be used in the construction and furnishing of a hospital for victims of the drug habit. With this amount added to the sum of £2,000 contributed a short time ago for the same purpose by Mrs. W. K. Vanderbilt, it will be possible to begin the erection of the hospital as soon as the plans are completed. It is to be situated on Riker's Island, and will provide accommodation for 132 patients.

AN order was recently granted by the King's Bench Division, Dublin, to presume the death of Dr. Joseph Garry, assistant surgeon to the *Lustania*, who was drowned on May 7th, after that vessel had been torpedoed by a German submarine. According to the affidavit of the steward who acted as his servant, Dr. Garry, on being handed a lifebelt, immediately gave it to a lady, and he was last seen about the wreckage. Prior to becoming connected with the Cunard line, Dr. Garry had practised at Manchester, Bolton, and other places.

THE lectures before the Royal College of Physicians of London this autumn will be given as follows: The Bradshaw Lecture, by Dr. Michell Clarke, on November 2nd, the subject being nervous affections of the sixth and seventh decades of life; the FitzPatrick Lectures on November 4th and 9th, by Dr. W. H. R. Rivers, on medicine, magic, and religion; and the Goulstonian Lectures, by Dr. Gordon Holmes, on November 16th, 18th, and 23rd, on acute spinal lesions, with special reference to those of warfare. The lectures will be given at the College on each day at 5 p.m.

Letters, Notes, and Answers.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Antelope, Westminster, London*; telephone, 2531, GERRARD. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Antelope, Westminster, London*; telephone, 2530, GERRARD. (3) MEDICAL SECRETARY, *Medicines, Westminster, London*; telephone, 2530, GERRARD. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

X. Y. Z. asks whether malt is contraindicated in diabetes. Cod-liver oil by itself is not well tolerated, but maltine or any preparation of malt and cod-liver oil is. If malt is contraindicated, in what form can cod-liver oil be given?

INCOME TAX.

Assessment on Total Income £1,000 to £1,500.

NESTOR has been assessed at Is. 9d. in the £ for 1915-16, the surveyor informing him that "where the total income exceeds £1,000 the rate of tax is Is. 9d. plus 20 per cent. for the current year." He inquires whether this is correct.

Yes. If our correspondent's total income is between £1,000 and £1,500, the rate applying to his assessment is Is. 9d. (Finance Act, 1915, Sec. 10, and Finance Act, 1914, Sec. 3). The "Finance (No. 3) Bill" now before Parliament provides for the increase of the pre-existing rates by 40 per cent. "for the last six months of the current income tax year," being in effect an increase of 20 per cent. for the whole year. The additional tax—that is, in this case the extra 20 per cent.—will become payable next July.

Assessment of Medical Officers on Service.

CAPTAIN M. is on foreign service and in the meantime has placed a locumtenent in charge of his practice. It is now being carried on at a loss, the deficiency having to be made good from his military pay. Income tax to the amount of £35 17s. 6d. has been assessed. What course should he adopt?

Under Section 13 (1) of the Finance Act, 1914 (Session 2), our correspondent is entitled to have the assessment reduced to the actual profits of the year—that is, to nil. We suggest that he should write to the local surveyor of taxes intimating that he claims relief under this section, and forwarding, if he has not already done so, a statement of the receipts and expenses of the practice for the year in question. If the surveyor cannot deal with the matter without an interview with our correspondent, he will, no doubt, be able to arrange for the question to remain in abeyance. In the circumstances we do not think that there is any likelihood of payment of the tax being required until the appeal is settled, but if there should be any such insistence the Board of Inland Revenue might be approached direct with a request for postponement of further proceedings.

ANSWERS.

LOCAL ANAESTHESIA FOR REMOVAL OF PILES.

DR. C. E. WINCKWORTH (Shefford, Beds) writes to recommend as a local anaesthetic for the removal of piles a watery solution of morphine hydrochloride gr. ½, eucaine and cocaine aa gr. 1. The solution is to be injected into the skin at four equidistant parts around the anus. It has been used by a practitioner for himself.

THE CIGARETTE HABIT.

H. F. W. writes, in reply to "Monk" (September 18th, p. 459), that *Caladium sepium* (synonym *Arum sepium*) has a reputation with some medical men for destroying the craving for tobacco. It can be given in the form of the tincture, 2 or 3 minims twice or thrice daily. It is especially indicated when, in addition to the tobacco habit, there is loss of sexual vigour.

DR. ROWLAND THURHAM (Nordrach-upon-Mendip, Bristol) recommends the use of tobacco which has been treated by a process which removes most of the nicotine.

DR. C. F. BUEB (Upton-on-Severn) desires to know the strength of silver nitrate solution recommended as a mouth application.

LETTERS, NOTES, ETC.

WEIR'S VACCINATION INSTRUMENT.

MR. BARRY HOPKINS, who has been connected with the surgical instrument trade for over fifty years, informs us that Cooper Rose's vaccinator, when it first came out between 1860 and

1870, was a metal tube containing loose needles, something after the style of a miniature pepper box, having a cap with holes to keep the needles steady, the idea being that the old needles could be replaced as required. In the next pattern the needles were fixed firmly into the base, and the cap was joined to cover the needle was furnished with a bayonet joint. The outer end of the case was made so as to hold capillary tubes. In the final pattern, as used by Dr. Tebb, the centre needle was made a little longer than the four other points which surrounded it. It was pressed upon the arm and revolved between the fingers and thumb, forming a pivot while the outer needles made an abrasion. These needles were covered with a cap, as in the second pattern. A spatula was fitted to the other end of the instrument to rub in the lymph which was blown on to the abraded surface. This is the pattern of Cooper Rose's vaccinator now kept in stock by dealers. Weir's pattern, when it first came out about 1878, bore four or five needles at one end. At the other end was a flat knife, the point curved down and sharpened so as to lift up the cuticle, while its sides were flat, to serve as a spatula; the needles at the other; it was made wholly of metal. The third and modern pattern of Weir's instrument was also forged out of one piece of metal. The needles and the spatula were somewhat longer. The Government ordered some to be made with the edges of the spatula sharp. At first the needles were used so as to pass just under the cuticle, which could be then lifted up, but now they are made so as to scratch the skin, something like a gridiron. In 1902 Dr. L. C. S. Broughton brought out a vaccinator after Weir's pattern with a neck or shank at each end; a description and a drawing of the vaccinator will be found in the BRITISH MEDICAL JOURNAL, 1902, vol. ii, p. 711.

THE GRIEVANCES OF SHIPS' SURGEONS.

DR. RICHARD JAY writes: I venture to give an unqualified contradiction to the statements of "Nautical" in the BRITISH MEDICAL JOURNAL of October 16th. The surgeon's status is not that of the second steward or ship's barber, but that of one of the senior officers of the ship. Sailors are the best fellows in the world and the easiest to get on with, provided always that the surgeon does not put on side or magnify his office; after all, he is not so important a member of the ship's crew as the captain or chief engineer. He ranks with, but slightly below, the chief officer; in the absence of these, the chief executive officer for the time being is his superior. The surgeon's cabin is often unfavourably placed, especially when it is also the surgery. It would not do to have sick members of the crew crowding on to the promenade deck. I have served on seven ships in four steam-ship companies. Three times I had a cabin on deck, once I did not like the position of my cabin, and then I was allowed to use the passenger's cabin. Once my cabin was also the surgery; it was otherwise an excellent one. I advise surgeons to insist on their cabin being separate from the surgery, as it usually is; it is not pleasant to see larvae in one's bedroom. I have spent three years at sea during the last seventeen years, and have always been treated with courtesy and respect. Personally I should be sorry to hold my office aloof from my brother officers and messmates by not wearing their uniform. My refer jacket is still in use ashore, robbed of its brass buttons and braid. The frock coat is seldom required for an odd voyage; I have served in the Royal Mail without it. A mess jacket can now be worn in the waistcoat (brass buttons) of the trousers of an ordinary dress suit. By artificial light the difference in shade is not very obvious. I have dressed in that manner in the Royal Mail and two other first-class steamship companies.

ICED AIR.

DR. M. A. DUTCH, F.R.C.S., writes: The following "tip" may be useful. Take a coffee, tea, mustard, or in fact, any tin of suitable size with a lid. Punch in half a dozen holes at the top and bottom when the tin is held with its greatest measurement horizontal. One larger hole for the insertion of a penny tin funnel is to be punched in the lid (the funnel can be dispensed with if not at hand). A piece of thin jaconet waterproof and a piece of old flannel are now placed in the bottom of the tin; on the top of this is put, and the whole is complete. I have found this most useful in cases of obstinate hæmoptysis and in oedematous conditions of the throat, etc. The condensation of the atmosphere also relieves the dyspnoea.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 5 8
A whole column	3 0 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first-post on Wednesday morning, preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *posteo restante* letters addressed either in initials or numbers.

A Lecture

ON

WOUND INFECTIONS AND THEIR TREATMENT.

DELIVERED (WITH DEMONSTRATIONS) AT THE OPENING OF AN EXHIBITION OF SURGICAL APPLIANCES FOR THE TREATMENT OF THE WOUNDED HELD AT THE ROYAL SOCIETY OF MEDICINE FROM OCTOBER 8TH TO 14TH.

By COLONEL SIR ALMROTH E. WRIGHT, M.D., F.R.S., C.B.,

A CONSULTANT PHYSICIAN TO THE EXPEDITIONARY FORCE IN FRANCE. (From the Research Laboratory attached to No. 13 General Hospital, Boulogne-sur-Mer.)

PART I.

IN undertaking to deliver an introductory lecture on such an occasion as this I feel myself under a very heavy disability. While I am impressed—very profoundly impressed—with the ingenuity and value of the mechanical devices and appliances which have been brought together within these walls, I am, as you know, quite lacking in that expert knowledge required for the proper appraisal of such things. There is, however, one—and it is, I would urge, by far the most important—aspect of wounds which does fall within my particular department of study. It is this that emboldens me to address you on this occasion.

I would, at the very outset, put it to you that the distinction between the *sick* and *wounded* is, from the point of view of science, an entirely improper one. Those who are classed as wounded are as universally as, perhaps even more universally than, those classified as sick, suffering from bacterial infection.

Ever since the days when Lister demonstrated that sepsis in surgical wounds was avoidable, very little study has been devoted to the bacterial infections which here come into consideration. For the surgeon has set before himself as his goal, not the successful treatment of septic infections of wounds, but their avoidance. And who will say that he is wrong? Less excusable, as it seems to me, was it for him to think that he had in reserve—if occasion should ever require it—an effective ready-made method of treatment for septic infections of wounds. After a year of war there are on that point very few illusions left.

There has in the meanwhile, I hope, been growing up a conviction that we shall not arrive at an effective treatment of wounds without strenuous study of the infecting microbes, the conditions in the wound, and the therapeutic agents which we employ, and the defensive operations of the organism.

Let me, drawing upon the research work which my fellow workers and I have been doing in France, try to put before you, as briefly as may be, in connexion with these questions, such points as seem to me most deserving of attention.

The wounded man seen just after he has received his wound is a man seen in the *incubation period* of his infection just after the microbes have been implanted—these being, as you know, carried into the wound, upon particles of infected skin and clothing.

The problem presented by the patient when first seen accordingly shapes itself thus. What is here the chance that the defensive mechanism of the body will prove adequate for the destruction of the microbes; and may we reasonably look to see the infection aborted? And in the event of the infection not being extinguished, what kind of course will it shape?

The extinction or non-extinction of the infection will depend upon the amplitude of the microbial implantation, and the favourable or unfavourable physiological conditions in the wound.

Rifle Wounds Traversing only Soft Parts.

The first type of wound which we have to consider is the perforating rifle wound where the bullet traverses the soft parts without touching bone. Here, nearly always, the bullet will cut into the wall of blood vessels. As a result there will be haemorrhage from the wound, and when the blood coagulates the track will become plugged

with clot. Later, when the patient is moved and the wound thereby disturbed, oozing may take place from the track.

Here we have a very light microbial implantation—only small numbers of microbes having been left behind by the missile on its passage through the soft tissues. Further, the walls of the track will have been scoured by the out-flowing blood. And finally, such microbes as are here left are enveloped in clot—in other words, we have here brought to bear upon the residual microbes the full bactericidal power of the volume of blood which occupies the wound. We have, in fact, exactly the same conditions as we have in experiments conducted in capillary tubes with a very small number of microbes implanted into a unit volume of blood.

As a sequea, as indicated above, we may have oozing. It is not, as might be supposed, blood which then escapes from the mouth of the wound. It is a thinner incoagulable fluid, containing only a small proportion of red corpuscles. It is, to come to the point, serum expelled from the clot by the *vis a tergo* of blood pouring into the upper reaches of the wound. There attaches, as I think, to this oozing a therapeutic significance. It is, in point of fact, equivalent to a reinforcement of the clot in protective elements.

You have already seized the point that when oozing occurs the serum of the clot—and serum is a fluid which when implanted with microbes tends to lose its antibacterial power—is replaced by blood fluids fresh from the vessels. And you appreciate that the outflowing stream of serum will tend to wash microbes out from the clot and convey them out of the wound. But it might, perhaps, be overlooked that when oozing takes place the clot is reinforced by red, and, this is important, by white corpuscles.

What, I take it, is occurring in the oozing wound can be brought quite easily before the eye in the capillary tube. And let me describe the experiment in detail, for I want you here at the outset to have before you a perfectly clear idea of the method of working in capillary tubes with washes and mural implantations.

Description of a Reinforcing Experiment.

We take a capillary tube pipette fitted with a teat, place upon the stem a fiducial mark, fill in with a 15 per cent. solution of citrate of soda, blow this out—leaving thus what we may call a *wash*—on the walls of the pipette—fill up with a unit volume of blood, and then mix by moving the blood with its wash of citrate up and down in the stem of the tube.

We now, leaving in the distal end of the stem an air space somewhat greater than that occupied by our unit volume, draw up into our pipette a suspension of microbes and blow it out again, leaving a wash of microbes on the wall. We follow on now with a unit volume of blood and incorporate into this the microbes left on the wall (this is what I mean by a *mural implantation*). Finally, we carry our volume of incoagulable, and our volume of implanted coagulable, blood up some little distance away from the mouth of the pipette, and then seal up our tube. The implanted blood now clots, giving us an ordinary *reinforced* clot. Such a clot is shown diagrammatically and on an enlarged scale in Fig. 1, B.

It consists of a meshwork with spaces shown as half filled in with corpuscles and half with serum—we have in the blood, it will be remembered, almost equal volumes of corpuscles and serum.

To imitate the conditions in the oozing wound we have now to feed the incoagulable blood in the upper part of our tube

¹ A series of weighings made with the form of balance used by Bang in weighing drops of blood, on filter paper for sugar estimations have brought out the fact that a "wash" of watery fluid in a capillary tube corresponds to between a twentieth and a thirtieth of a unit volume.

FIG. 1.—A. In the neck of the capillary pipette we have the reinforcing incoagulated blood, and in the distal end of the stem the blood clot which has been implanted with microbes, and connexion has been made between the two by the introduction of a very fine glass stylet. B. We have here a more magnified image of the clot showing the creeping down of reinforcing blood along the stylet, and, below the clot, the expelled serum that previously filled in its meshes.

into the coagulum in the lower part of our tube. We do this by taking a fine filament of glass (made by drawing out a capillary tube in the by-pass flame of a Bunsen burner) and passing it down through the unclotted into the clotted blood (Fig. 1, A). Contact having in this manner been established, both the fluid and the formed elements of the uncoagulated blood creep slowly down along the capillary filament into the clot (Fig. 1, B). Arrived there, they expel the serum from the clot (Fig. 1, B)—driving it out of the tube if we have broken off the tip of the pipette—and occupy all the unfiled spaces.

In this way we not only carry out from the clot blood fluids which may be exhausted of their antibacterial elements, but we fill up the clot with red and white corpuscles, bringing to the leucocytes of the clot, which, of course, are the elements which count, a reinforcement of 100 per cent.

Going back now to our rifle-bullet wound, we have to consider what will happen if the implanted microbes are not killed off. In this case we shall presently find an infected purulent fluid coming down along the walls of the track; and very soon the blood clot will disintegrate and come away, and we shall have a surface infection all along the track. We now pass to consider other types of wounds.

Rifle Wounds where the Bullet has Comminuted Bone.

Where a projectile comes up against a bone it will shatter it and make a large exit wound by blowing out the fragments and splinters, at the same time scattering the charge of microbes, which would otherwise have been sown only on the walls of the track, far and wide through the tissues.

We have here obviously very unfavourable physiological conditions. For not only is the circulation in the wound completely disorganized, but the wound will contain bone and soft tissues cut off from their blood supply and bound to necrose and slough; and deep in the tissues we have an implantation of microbes which no outflowing blood will wash away. And even more important, the outflow of lymph from the wounded surface—an outflow which meant the continuous replacement of invalidated by potent lymph—is going to be arrested by desiccation of the external wound surfaces. The wound, in other words, will, if left to itself, become lymph-bound. And, finally, the wound is, by virtue of its large exposed surface, going to lie open to all manner of after-infection from without.

These same unfavourable physiological conditions are associated also with shrapnel, shell, and bomb wounds. We shall consider them further in connexion with these.

Severe Shrapnel, Shell, and Bomb Wounds.

The essential feature about this class of wound is that we have here blunt or flat missiles, and that by consequence, as compared with bullet wounds, we have less penetration and perforation, and proportionately more bruising; and at the same time larger portions of infected skin and clothing are carried in by the missile. In other words, we have in the wound much worse physiological conditions; and along with this a heavier microbial implantation.

It will be a convenient arrangement to consider, in connexion with the severer types of wound, the effects of the bruising and the cutting off of the blood supply and the implantation of microbes into devitalized tissues; and then, in connexion with the lighter types of wound, to deal with the effects of the bacterial implantation into tissues not devitalized.

The disorganization and the shutting off of blood supply which is the feature of all severe wounds is followed, of course, by mortification; and thereafter the necrotic tissues fall a prey to every type of microbe: serophytic and sero-saprophytic, aerobic and anaerobic, non-sporing and sporing. And all these influences, working in combination, will cause the tissues to turn black and putrefy and disintegrate; giving, where the wound is allowed to desiccate, a condition of *Ary gangrene*. Under the black gangrenous coating there will, if the infection fails to spread to the underlying tissues, and if things are not composed otherwise by the growing out of the tetanus bacillus in the necrotic tissues, gradually be formed a line of demarcation. And finally, the gangrenous layer will be exfoliated, leaving underneath a granulating membrane and a surface infection. Essentially the same sequence of events will supervene if the wound is kept moist. Only here we shall have *met gangrene*, and the necrotic tissues will be converted into sloughs, and there will be earlier and more profuse suppuration.

Slighter Punched-in Wounds Produced by Shrapnel and Shell.

We come now to the lighter wounds which are inflicted by blunt missiles, to the wounds which we may call *punched-in wounds*. They are comparatively superficial wounds with steep sides going down to a floor sunk below the level of the surrounding skin. Here the microbes have been carried in over an area corresponding to the superficies of the wound, and they are implanted into the walls and the floor. What is important in connexion with this implantation is, that it is made not into an open track from the walls of which the microbes might be washed off by outflowing blood, nor yet into effused blood, which is up to a point a very ungenial culture medium for microbes; but into lymph standing in lymph spaces. Now the lymph in such spaces is only under very low pressure—a pressure as low as, or lower than, that of the capillaries—and by consequence when lymph spaces are broken into we have nothing in any way analogous to the outflow of blood from a wounded vein or artery. There will at most be a little weeping of lymph, and the conditions will be comparable to those produced if, after dealing a heavy blow with a hammer upon the bark of a tree, there followed a little exudation which afterwards dried, forming an impermeable coating. It is clear that we should then have, instead of a washing away, an embedding of microbes in the outflowing fluid, and an incorporation of these into the subjacent tissue. The conditions in the punched-in wound are, as you will now see, very unfavourable. They will be unfavourable, first, because the antibacterial power of the lymph with which the microbes are brought in contact is bound to be quickly exhausted; and, further, because with the arrest of the lymph flow there will no longer be any renewal of the lymph. Again, the conditions are unfavourable also in the respect that the leucocytes coming, as they do in such a case, only tardily into a zone which is already poisoned by microbes, cannot press home their attack. The emigrating leucocytes will therefore do nothing but choke up the tissues for a considerable area round each focus of bacterial infection.

In this way we get in the course of a very few days all round our punched-in wound a hard infiltrated edge, margined towards the healthy skin by a zone of pale pink; and in the indurated walls of the wound we have an *imprisoned infection*. That infection will now extend, and, if it finds its way outwards to the surface too solidly obstructed, will spread inwards; giving rise, according to circumstances and the character of the microbe infection, to *cellulitis* or *gas gangrene*. In the ordinary course, however, the infection will manage to break through to the surface, and then again we have an ordinary suppurating surface with an *infection of flowing discharges*.

It is important to appreciate that the processes that have just been described take place not only in the punched-in wound, but everywhere where microbes are implanted into lymph spaces, and where we have afterwards an effusion of lymph which desiccates and seals up the wound.

And precisely the same sequence of events as follows upon the original implantation of microbes will, just so long as the microbes still maintain themselves in the walls of the tissues, recur if at any moment the wound is allowed to desiccate and become lymph-bound. A setback of this kind will, for instance, almost inevitably follow when, by the transporting of the patient from hospital to hospital, the washing out of the infected walls of the wound is interrupted.

Nature of the Microbe Infection met with in Wounds.

We now pass to consider very briefly the nature of the microbes which are carried into wounds from the soiled skin and clothing of the soldier. These microbes may, as I pointed out in a previous lecture, be classified—and the classification is important for treatment as well as for the understanding of the mode of infection and of the evolution of the wound—into two main classes, a class of *serophytes* which (presumably because they find ready-made pabulum in the blood fluids) can live and multiply in serum; and a class of *sero-saprophytes* which, so far as we know, can develop in the blood fluids only after these have lost their antityptic property—the property in question being that which inhibits those digestive processes which would be capable of converting the native

albumin of the serum into pabulum for microbes. Intermediate in character between the serophytes and serosaprophytes is a class of microbes which cannot grow in the serum when we make only a small implantation, but which, no doubt owing to the fact that they bring into operation powerful digestive ferments,² succeed in establishing themselves when we make a heavy implantation. We may call these *imperfect* or *secondary serophytes*.

To the category of *serophytes* belong the streptococcus and the staphylococcus—the latter being far inferior to the former with respect to its power of multiplying in unaltered serum. To the category of *imperfect serophytes* belong the *Bacillus arrogans capsulatus* of Welch (*Bacillus perforans*); the *Bacillus proteus*; its close congener, the *Bacillus pyocyaneus*; and the wisp-shaped diptheroid bacilli commonly found in foul suppurating wounds.

To the class of *sero-saprophytes* belong the larger number of microbes found in such wounds.

It will suffice here to bring out a few of the more important points in connexion with the serophytes and imperfect serophytes which are found in wounds.

The microbe most universally present is a streptococcus. It differs in very many respects from the classical *Streptococcus pyogenes*, which is met with, though much more rarely, in wounds. In film preparations of pus the streptococcus here in question shows up nearly always as a diplococcus. As obtained from agar and broth cultures, the elements of the diplococcus are lancet-shaped, and they are bent into an angle. To follow the French description, they resemble a circumflex accent or take the form of saddle bags (*formes en besace*). In broth cultures we have interspersed with these a few short chains. The colonies as they grow upon agar are more opaque, less sharply margined, and are somewhat larger than those of the *Streptococcus pyogenes*. Instead of being as colourless as glass and severely discrete, they show up as very faintly grey-green, and, when planted closely, tend to run together. As compared with the ordinary *Streptococcus pyogenes*, growth is also much more rapid—luxuriant cultures being obtained at 37° C. on broth and agar in four or five hours. Moreover, growth is obtained, not only at 37° C., but also at the temperature of the laboratory bench.

The most remarkable characteristic of this streptococcus is, however, the freedom with which it grows out in normal serum, and also upon agar when transplanted in blood. When we implant into blood in emigration tubes, putting the tubes directly into the centrifuge, and from this into the incubator, we obtain after three to five hours with a moderate implantation a growth in the form of diplococci and short chains permeating the whole white clot; or, with very light implantation, a growth in the form of colonies clearly visible to the naked eye and consisting of typical convoluted chains made up of indefinitely numerous elements. In the case where we implant into blood and then implant the blood culture on agar, we have very opaque white convex colonies which may be as much as half, or even one, centimetre in diameter; and which, except for the fact that they are rather moister, closely resemble staphylococcus colonies. These are made up of lancet-shaped diplococci, which might easily be taken for pneumococci. The surrounding blood is not haemolyzed.

There will be no doubt in the mind of any one who has studied descriptions and illustrations of the *enterococcus* and its mode of growth on ordinary media as given in French bacteriological textbooks that the streptococcus here in question is the *enterococcus* of the French authors. Moreover, it may be taken as assured—for we have compared our cultures of streptococci from wounds with a series of cultures of streptococci obtained by Professor Freyer and his colleagues from the stools of patients who were being searched in the ordinary way for typhoid and paratyphoid bacilli—that the streptococcus we are here considering is the ordinary streptococcus of the faeces. And assurance is made still more complete by the fact that when searching normal faeces by the *Jacco-sero-*

*culture method*³ my fellow worker, Lieutenant A. C. Inman invariably obtained from the faeces in his after-washes a pure culture of a streptococcus which was, in all the above-mentioned morphological and biological characters, indistinguishable from that which is practically invariably present in the wounds. We may therefore take it as unquestionable that the streptococcus which is commonest in wounds is of faecal derivation, and both our *Jacco-* and *pyo-sero-cultures* show that if the smallest possible implantation of this microbe is made, in no matter what bacterial admixture, into serum, it will immediately grow out there.

With regard to the presence of staphylococci in wounds, it may be pointed out that, by reason of its wide distribution in the skin and its serophytic properties, it is bound to be present in practically all wounds. We shall, however, presently, in discussing the results of our *pyo-sero-cultures*, appreciate that its growth in the wound is very quickly restricted by changes in the blood fluids (and with these there may possibly be associated also changes in the leucocytes) which are produced by the immunizing responses of the patient.

Like the staphylococcus and the *Streptococcus faecalis*, which we have just been discussing, the *Bacillus of Welch*—which is also, of course, a constant inhabitant of the faeces—is implanted, one may take it, into every wound. This microbe, be it noted, is only an imperfect serophyte. In point of fact, as my fellow worker, Captain d'Esto Emery, has succeeded in showing, the serum exerts upon the bacillus of Welch a very considerable bactericidal power; and it is therefore in serum cultures only the surviving microbes which grow and multiply, and in blood cultures only those which both resist the action of the serum and also elude destruction by phagocytes. All this means—and clinical experience amply bears this out—that if we can bring the blood fluids and leucocytes to bear on Welch's bacillus we have very little indeed to fear from it.

What little requires to be said about the *Bacillus pyocyaneus* and *proteus* and other members of the class of imperfect serophytes may for the moment be reserved.

Before passing on something may appropriately be said about methods of cultivation, and I may limit myself to the description of methods of obtaining cultures in serum. For it is only by implantation into serum that we learn what microbes threaten danger, and how far the body is protecting itself against these. And again it is only by the method of serum culture that we can, when dealing with a complicated mixture of microbes, choose out from among these those which we ought to employ as vaccines.

What we want for these purposes is a cultivation method which will enable us to make first a moderate implantation and then a series of smaller and smaller implantations.

The *wet wash method*, or as we may also call it when implanting microbes the *method of mural implantation*, gives us what we here want, and there are two different procedures by which we can obtain the progressively diminishing implantations we require. We may call these respectively the *wash and after-wash* and the *wet-wash* methods.

Wash and After-wash Method.—Here taking a capillary pipette fitted with a teat and furnished with a fiducial mark, we fill it up to that mark with such a mixed bacterial culture as is furnished by pus, sputum, or faeces, and then expel this volume, leaving behind a *unit wash* on the walls of our capillary stem. We then aspirate a unit volume of serum, then aspirate a unit volume of serum, then aspirate a unit volume of serum separated by air-bubbles. In this way we obtain in successive volumes of serum a series of smaller and smaller implantations. If we want, as we may often do, a series of implantations in which the number of microbes falls off more steeply,⁴ we can, after filling in the first unit volume of serum and expelling it some little distance up the stem, resect this part in the ordinary way the filling in of the pipette. Or we can, leaving the stem unresected, arrive at the same result by making each unit volume, as we fill it in, pass several times up and down over the implanted portion of the tube, thus washing off the microbes more effectively.

² This method is modelled in all respects upon the *pyo-sero-culture method* presently to be described.

³ It may be well to bring out at this point that, though one could hardly, when dealing with a solution of a chemical agent, ask for a series of smaller and smaller dilutions than that furnished by the wash and after-wash method—for we do so down here by sixes of 25, 625, 15,625, 400,000, and 10,000,000 quite a different standard comes into application when diluting a microbial culture. For in the first case we are dealing with dissolved chemical agents, and inponderable quantities do not come into the account; and in the second case we are dealing with particulate matter, and quite inponderable quantities come very strongly into reckoning. And, in point of fact, experiment shows that a series of smaller and smaller dilutions can be obtained in pipettes implanted with a unit wash of pus and then filled up by the wash and after-wash method with unit volumes of serum we implant in many cases—as far as the fifteenth and in some cases as far as the twentieth after-wash.

⁴ The suggestion here made wins support from the fact that the streptococcus, which we may take as the type of a true serophyte, does not, when growing in clear serum, exact any reduction in its anti-toxic power, whereas both the *Bacillus proteus* and the bacillus of Welch do this. And it will be remembered in this connexion that the streptococcus does not liquefy gas in, while the *Bacillus proteus* and the bacillus of Welch rapidly digest albuminous substances (even coagulated white of egg and gelatin, and, as the case may be, urea, and other substances).

Wash Method.—Here we place two fiducial marks on the stem of our pipette, and then, at the proximal mark for the serum and the distal for the air bubble, fill in with unit volumes of serum separated off from each other by measured instead of, as in the ordinary way, with unmeasured volumes of air. Then at the end of the series we fill in up to the proximal mark with the diluted bacterial suspension which is to serve as our implanting fluid. Retaining this accurately in place, we now offen further fiducial marks on our capillary stem, marking off in this way the distal end of the last and penultimate of our volumes of serum. We now, relaxing the pressure of our fingers upon the test, carry the whole system of volumes and intervening bubbles upwards in our capillary stem, arresting the movement as soon as the distal end of the pipette reaches the common level with the first, or, if we prefer it, the second of the fiducial marks we have just inscribed. We may call this implanting movement a *seara wash*, and may speak of a *one-unit* or *two-unit* wash according as the implanting fluid is carried up into the segment of tube belonging to the next or the next but one volume of serum. We make a series of these washes (generally a series of six or twelve), making with these not only an implantation of microbes from the implanting fluid into the neighbouring volume or volumes of serum, but also at the same time implantations from the implanted into the previously unimplanted volumes of serum.

Method of making Anaerobic Cultures in Capillary Tubes.—When we want to cultivate under anaerobic conditions we proceed as follows, omitting, according as we want to cultivate only one volume of serum, or a series of volumes of serum, the first or the second of the procedures now to be described.

Method of making a Single as distinguished from a Multiple Anaerobic Culture in a Capillary Tube.—Taking a capillary pipette fitted with a test we then, the stem deep down into a rubber tube delivering hydrogen or ordinary coal gas, and now alternately compressing and relaxing pressure upon the test we expel the air, and fill test and pipette with unoxidized gas. We now withdraw the end of the pipette from the delivery tube, keeping as we do so the orifice of the pipette directed downwards, and then, after expelling a little of the gas, draw up from a drop of implanted serum placed ready to hand a convenient quantity into the stem of the pipette. Keeping the serum close down to the orifice of the pipette so as to prevent any entrance of air, we now once more thrust the capillary stem deep into the gas delivery tube, and draw in sufficient gas to give us comfortable space at the end for sealing up the anaerobic barrel. We then, the stem deep down into our operations by boring through the tube capillary stem just below the barrel of the pipette.

Method of making Anaerobic Cultures of a Series of Volumes of Serum Implanted by the "Wash and After-wash" or the "Wash-wash" Methods.—We begin by fitting to our gas delivery tube the barrel of a capillary pipette which has been truncated by resecting the stem just below the neck. We sterilize this by flaming, and let our hydrogen or coal gas run through it sufficiently long to expel all admixture of air. Then, directing the orifice downwards, we turn off the gas and compress the rubber tube between the forefinger and thumb of the left hand so as to expel a little of the contained gas. Then we dip the orifice of the glass end-piece into a large drop of serum placed ready at hand and draw this up, and then, by regulating the pressure with our fingers, keep the serum closely applied to the open orifice (Fig. 2).

We now take into our right hand a capillary pipette furnished with a test and a fiducial mark, and implanted, if we are using the wash and after-wash method, with a wash or microbial suspension. The tip of the pipette is now introduced into the serum in the mouth of the glass end-piece, and we now draw up into it first, as in Fig. 2, A, a unit volume of serum, and then pushing, as in Fig. 2, B, the point out into the gas, a bubble of gas; and so on in series until we have filled up the stem of our capillary pipette.

Fig. 2.

which is trapped by the test, a bubble of gas; and so on in series until we have filled up the stem of our capillary pipette.

Response of the Wounded Man to his Wound Infection and Blood Changes Induced in him by Auto-inoculation.

In wound infections, as everywhere where bacterial toxins are elaborated and absorbed into the blood, the machinery of immunization is after a time called into operation, and as a result the blood is put into a better condition for defence. And then begins a serious conflict between the invaded organism and the invading microbes. It is in connexion with septicæmic invasions, such, for

instance, as typhoid fever, gradually becoming to be understood that it is by the event of this conflict that the issue is decided; and that the physician in attendance is not following, much less directing, events. But it is as yet a quite unfamiliar thesis that the wounded, like the typhoid patient is reacting to his infection with a systemic immunizing response; and that the changes so induced in the blood exert a quite decisive influence on the course of the infection, while the surgeon who is dressing the wound and making local applications, is only in a subordinate way helping or, as the case may be, hindering the curative procedures of Nature.

It will be well before considering the surgeon's task to take cognisance of what the immunizing responses of the patient are doing in the matter of fortifying his blood.

We have, of course, in connexion with this only very imperfect knowledge, and we shall therefore have to keep very close to our experimental data. It will be convenient to marshal our facts under headings supplied by our methods of blood testing.

Data Furnished by Measurements of the Antitryptic Power of the Patient's Serum.

Reference has already been made to the antitryptic power of the blood fluids. In point of fact, the antitryptic power of the serum acts as a check upon all microbial growth.⁵ In the case of *sero-saprophytic bacteria* it completely balks their efforts to establish themselves in the serum. In the case of *imperfect serophytes* it places a very formidable obstacle in the way of growth. And in the case of *serophytes proper* it also, as a comparison between serums of low and high antitryptic index, and between serums which have, and serums which have not, received an addition of trypsin shows, determines whether the culture in serum⁶ shall be scanty or luxuriant.

It will be obvious from the above that an increase of the antitryptic power of the blood fluids would operate in restraint of any blood invasion, and that it would also, so far as the blood fluids came into application unaltered, restrain the growth of all forms of microbes, both in tissues and in the wound. In other words, an increase of antitryptic power would operate as a non-specific factor in immunization. Now we have, as I already indicated in my last lecture,⁷ in every or practically every wounded man a notable increase in the antitryptic power of his serum. Already within thirty six hours or less after the infliction of the wound the antitryptic index has risen far above the level of the normal; and reckoning the antitryptic power of the normal serum as unity, antitryptic indices of four and five are very common in the patients under treatment at the base.

More than that, we have found a quite similar but smaller increase in the antitryptic power of the blood after inoculating ourselves—one of us with typhoid vaccine, another of us with streptococcus vaccine, and a third with staphylococcus vaccine.

And let me here recall to you that attention has, in connexion with inoculations against plague, typhoid fever, and pneumonia, been time and again called to the probability that these vaccines give some protection against diseases other than the particular disease which the inoculation is designed to ward off. Particularly convincing in this respect are the results in the form of *diminished incidence of "other diseases"* which were obtained in South Africa by the inoculation of pneumococcus vaccine upon the Premier Mine.⁸ And I think all those who have had much experience of vaccines will have seen cases where therapeutic effects lying quite outside the range of the particular vaccine employed, and therefore as we thought not quite creditable to science, have been obtained by vaccine therapy.

⁵ The antitryptic power of the blood fluids represents, be it noted, much more than merely a power of inhibiting microbial growth. With the loss of antitryptic power go lost also the complementing, opsonic, bactericidal and coagulating powers of the blood.

⁶ Where instead of implanting streptococci into serum free from leucocytes we implant into blood containing leucocytes these are broken down, with the result that the antitryptic power is diminished and we have then, as already described in connexion with emigration tube cultures, always after a sufficient interval, luxuriant growth.

⁷ Vide Section I, Subsection of Section 3, last paragraph.
⁸ Vide Appendix II in my *Treatise on Preventive Inoculation against Pneumonia in the African Native*. Constable, London, 1914.

Data Furnished by Pyo-sero-culture.

The method of pyo-sero-culture was described in my last lecture (Section 1, Subsection 1).⁹ We may, however, substitute for the lengthier procedure there set out the wash and after-wash method (*vide supra*).

Having by this method introduced into pipettes similarly implanted with the patient's pus—into the one a series of unit volumes of the patient's blood, and into the other a series of unit volumes of a normal serum—and having incubated these for from six to twelve hours, we now follow the procedure portrayed in Fig. 3, *A, infra*. Beginning with the volume nearest the distal end of the stem which has received the smallest implantation, we blow out our successive serum cultures in separate drops on to the surface of a sterile slide; and then, with a platinum needle or glass filament, stroke out these in succession upon an agar plate, making in this way a series of linear implantations. On incubating our plates we then obtain, with the serum of a wounded man who is unimpaired by his infection, exactly the same results as with the normal serum. In the case of

FIG. 3.—Method of Pyo-sero-culture.

A, Pipette which has been implanted by the wet-wall method and has then been filled in by the wash and after-wash procedure with unit volumes of serum. By the side of the pipette to the right are ranged a series of discs representing the series of unit volumes of serum blown out in order from the pipette, and, finally, to the right of the discs are a series of lines representing linear implantations made upon agar.

B, Results of the series of linear implantations made with the unit volumes of the patient's serum.
C, Results of the series of linear implantations made with the unit volumes of the normal serum which was used as a control.

a wounded man in the negative phase of his infection, we obtain cultures containing a variety of microbes (all of them members of the class of imperfect saprophytes) unrepresented in the cultures made with the normal serum; and, moreover, as compared with these, the cultures made with the patient's serum are more luxuriant and extend also into higher dilutions. In cultures made with the serum of a wounded man who is making satisfactory immunizing response—and the illustration reproduces the results actually obtained, by implanting the pus of such a patient into his own serum, and into that of a normal man—we have in both series of pyo-sero-cultures only saprophytes, staphylococci and streptococci, but while the cultures made with the patient's serum (Fig. 3, B) furnish only a few discrete colonies, and these only the first wash and two after-washes, we have with the normal

serum (Fig. 3, C) massed colonies in the first seven plantings, and the first eight plantings furnish cultures.

The significance of such data will, perhaps, best be appraised if we compare the method of sero-pyo-culture—considered as a procedure for the appraisement of the clinical condition and prospects of the wounded man—with the method of pyo-culture which Delbet has quite recently proposed to use for these same purposes.

The real value of the method of sero-pyo-culture lies in this, that it tells us up to what point the blood fluids of the patient would, without aid received from the leucocytes, be capable of protecting themselves against an implantation of microbes, and specifically against an implantation of microbes from the wound. Now merely to tell us this, is not to tell us how the microbes are going to fare in the wound. For we are not entitled to assume of the blood fluids that they will in the wound obtain unrestricted access to the microbes; nor of the leucocytes that they will not die in the wound, converting thereby the effused lymph into a favourable culture medium for microbes. Still, evidence of satisfactory immunizing response obtained by the method of pyo-sero-culture is, so far as it goes, evidence of favourable import, always with the proviso that the wound be treated in a rational manner.

The method of pyo-culture aims at arriving by an idyllically simple procedure going straight to its goal, at a trustworthy forecast of the future of the wound. It is suggested that by merely incubating the pus and then examining microscopically to see whether the number of microbes has increased or remained stationary we shall be able to foretell the future, and to decide, where the clinical appearances seem to prescribe amputation or other radical surgical procedure, whether operation can be avoided. In connexion with this proposed method of investigation, the first point to note is that the pictures which are furnished by it are generally the very reverse of clear, and that we are not in any way helped by controlling, as we are invited to do, our culture in pus by cultures made by implanting pus into bouillon. In point of fact, this particular method of controlling our results could only mislead, for the common pyogenic micro-organisms, and in particular the coliform organisms, would, no matter how sparingly they might be present in pus, always grow out luxuriantly in the bouillon culture. But let us suppose for a moment the case that we have been able to satisfy ourselves that the micro-organisms in our pyo-culture have increased, or to satisfy ourselves that they have not increased; and let us then ask ourselves what prognostic value would attach to the one or the other finding. There cannot be any doubt as to the answers to these questions. A multiplication of the microbes in the pyo-culture would, of course, indicate an unsatisfactory condition in the wound; but we should not know whether to interpret this as a consequence of a defective immunizing response on the part of the patient, or as a consequence of the surgeon having suffered the wound discharges to accumulate and become corrupt in the wound. On the other hand, if the microbes definitely failed to grow out in the patient's pus, this would clearly suggest that the patient was making good immunizing response; and that, in correspondence with this, the wound would, given requisite attention, be likely to progress favourably.

Data Furnished by Measurements of the Opsonic Power of the Patient's Serum.

The changes in the serum which gradually render it a more and more un congenial culture medium for microbial growth have their counterpart in changes in the serum which render the microbes an easier prey for phagocytes. These changes in the opsonic power of the serum are exactly similar to those which manifest themselves in all other forms of localized infection; and we find, when we look for them, in connexion with wounds, all the phenomena of autoinoculation with which we are familiar in other bacterial infections. And every day it becomes clearer that every displacement or movement of a fractured and infected limb—such displacements, for instance, as are associated with the transport of the wounded man, or the sagging of his limb when it is dressed, and also all those unguarded passive movements which the surgeon or orderly may inflict when the patient is under an anaesthetic—operate as autoinoculations, and are followed by that sequence of negative and positive phases which we are accustomed to witness after the stirring up of a focus

⁹ BRITISH MEDICAL JOURNAL, April 10th, 1915, p. 625.

of infection by active exercise, massage, or the application of Bier's bandages.¹⁰

Data Furnished by a Study of the Emigration Response of the Patient's Leucocytes.

As was already brought out in my last lecture, comparative experiments made with the method of testing emigration there described show that we have in patients who have made immunizing response to their wound infections or to the inoculation of streptococcus vaccines, an emigration response to streptococcus implantation which is strikingly greater than that of the normal man. I do not, until the method of estimation shall have been further improved, desire to be more detailed on this question. I prefer to pass on to consider the bactericidal power of the whole blood, for we have in this the resultant of all those factors in immunity which we have been separately considering.

Data Furnished by a Study of the Bactericidal Power of the Whole Blood.

The experiments on the bactericidal power of the whole blood which I undertook in connexion with work on pneumonia in South Africa¹¹ constituted a first attempt to make a complete evaluation of the bactericidal power of the blood fluids and leucocytes working in conjunction and reinforcing each other.

Let me lead up to what I have to say upon this matter by reminding you in connexion with these experiments with the pneumococcus that the blood fluids exert no bactericidal effect upon that microbe. And let me also very briefly go back over the procedure which I employed.

That procedure was to make by the wet-wall method implantations of the pneumococcus into blood drawn direct from the finger, or, as the case might be, into washed corpuscles suspended in serum, decalcified blood, blood kept liquid upon ice, and into what I will, to distinguish it from *exovascular* blood, venture barbarously to call *exocoagular* blood.

I mean by that—the red and white corpuscles and serum which come out from the blood clot when it contracts. The experiments conducted with all these different varieties of blood gave, as perhaps some of you will remember, very remarkable but undeniably paradoxical results. With blood drawn directly from the finger a very striking bactericidal effect—an effect which was upon occasion equivalent to a killing off of 600,000, to as much as 1,000,000 pneumococci per cubic centimetre of blood—was achieved. But it was not in every instance achieved.

With one of the other varieties of blood was any bactericidal effect achieved; or if there was any effect it was very insignificant and very inconstant. The reason for these diverging results did not at that time appear. I made some guesses which fell wide of the mark.

This was the position of the question when I again, in connexion with the streptococcus, addressed myself to the study of the bactericidal power of the whole blood. And the situation to be dealt with was here essentially the same as in

the case of the pneumococcus, saving only in the respect that the serum is a much better culture medium for the streptococcus than for the pneumococcus.

During many months of work only very disappointing results were obtained. The blood of normal men, the blood of wounded men who were progressing favourably, and my own blood and that of two of my colleagues after we had been inoculated with streptococcus vaccine, alike gave, when implanted in a graduated manner, as good as no evidence of any bactericidal power. Or at any rate only very inconstant results were obtained.

This was even a more violent paradox than that encountered with the pneumococcus, for the blood that failed to kill streptococcus was not blood which had in any way been tampered with, but blood drawn directly from the finger; and it is, in view of the favourable event of most streptococcus infections, and the striking therapeutic effects obtained by streptococcus vaccine, impossible to doubt that streptococci are killed in the blood.

At the end, a possible explanation of the contradiction between the results obtained *in vivo* and *in vitro* suggested itself. I suddenly woke up to the fact that there was a flaw in the technique I was employing.

The nature of this flaw will be understood on referring to the accompanying diagrams. In my experiments the implantation of microbes into the blood was made by what I have called the method of mural implantation. And the particular form of mural implantation employed was the *complete mural implantation* (Fig. 4, B).

Now what follows in the case where we implant into a blood which afterwards clots is brought before the eye in Fig. 5. When the clot contracts the space which was at the outset filled with unclotted blood and then with coagulum (Fig. 5, A) divides itself up into two regions (Fig. 5, B), a region occupied by clear serum and a region occupied in part by the clot and in part by the corpuscles which have fallen out from the clot and have ranged themselves round its base. The first of these regions is one in which streptococci—supposing they had once managed to find their way there—would be quite safe from phagocytic attack and would find conditions favourable to their growth. In the second region, inasmuch as the phagocytes would be crawling about and fossicking for microbes in the clot and escaped red corpuscles, there would at any rate be a chance of the leucocytes extinguishing the infection. *Mutatis mutandis*, this would apply also in experiments conducted with the different varieties of incoagulable blood. In each case the corpuscles would settle to the bottom, and there would be left above them a band of clear serum where microbes would be quite safe from phagocytic attack.

It will be obvious that these quite elementary considerations provide a very simple explanation of all the blank results obtained in our bactericidal experiments. They do more than that. They point the way to a better technique. For clearly, if instead of making a *complete mural implantation*, we now limit ourselves to what I may call a *wainscot implantation* (Fig. 4, A) we shall be planting all our microbes into a region of the blood where they will have to run the gauntlet of the white corpuscles; and there will no longer be for them, as there was with the complete mural implantation, any direct way of escape into a region of safety provided by the serum.

It will suffice to say in connexion with this improved technique that it has answered even beyond expectation, and that when we limit ourselves to a wainscot implantation, and make implantations with graduated dilutions of streptococcus, we obtain not only with exovascular blood but also with exocoagular and citrated blood conclusive evidence of bactericidal power.

Let me, however, make the following point plain. Even with this improved technique, the demon of chance has

FIG. 5.

Fig. 4.—The figure shows two forms of mural implantation into blood—in A a "wainscot," in B a "complete mural" implantation. In A the distal end of the capillary stem has, as a first operation, been fitted on as far as the upper fiducial mark with blood. An air bubble was then drawn in; after this the tip of the tube was dipped into a microbial suspension, and then was allowed to run in as far as the distal fiducial mark. After this the microbial suspension was expelled and the blood was then, to receive its "wainscot implantation," driven down to the orifice of the tube. In B, where the blood receives a "complete mural implantation," an essentially similar procedure was followed.

¹⁰ *Vide* in this connexion the autoinoculation curves set out in the author's *Studies on Immunization*. Constable, London.

¹¹ *Lancet*, January 3rd, 1914, p. 1.

not been exercised from our experiments. And since chance will always, in our experiments, play a part in the ordering and disposition of leucocytes, it will be impossible in the case where the bactericidal power of the blood is centred upon these, and so operates only where gravity permits, to get regular quantitatively accurate results, such as are attainable when the bactericidal power is centred in the serum, and so operates uniformly through the medium.

I would ask you to note this point. It is necessary to emphasize it here where we are considering the blood changes produced by immunizing response to autoinoculation, and it will be necessary to emphasize it again when I come to speak of vaccines and their employment in connexion with wound infections.

But we have not, in the matter of the leucocytes and the factors which determine the bactericidal effect they exert, got quite to the end of our story. You will find the following experiment very full of instruction, and it has, as we shall presently see, very important applications in connexion with the treatment of wounds.

We take a couple of looped pipettes, such as are shown in Fig. 7, and we proceed as follows. In a first operation

the pipettes in hand one after the other, make into each a minimal implantation of streptococcus. We do this by just dipping the tip of the tube into a streptococcus suspension and then very cautiously bringing the corpuscles, or, as the case may be, the plasma, into contact with the infected inner surface of the tip of the tube. We now incubate the pipettes for three or more hours—the one in the upright, the other in the inverted position. And, finally, using the procedure as described in my textbook of technique,¹² we carry up the implanted blood into the nutrient fluid provided in the incubation chamber.

We obtain in experiments of this sort always one invariable result. In the case of the pipette which is kept upright—that is, in the case where the implanted streptococci have to run the gauntlet of the white corpuscles—the microbes are all killed off, and in consequence our nutrient medium undergoes no change. In the case where the pipette is inverted and we implant directly into the plasma the streptococci survive, and our nutrient fluid changes from blue to red.

And we can vary our experiment in all sorts of ways, and still each time get the same result. For instance, we can, by very simple devices, cut the red corpuscles out of our experiment and work, as in the wound, only with leucocytes and plasma. Or we can at the outset invert our pipettes, and then, after implanting into the plasma, dispose them upright, thus raining down our leucocytes upon the microbes and aborting the infection.

All this shows, as I think, that we have arrived at a generalization which must be important for practice. Let me formulate it for you thus.

Where the leucocytes are in the front rank and the blood fluids behind, the elements of the blood are marshalled in that order which is most favourable for combating streptococcal infections. I will venture to call that arrangement the *agathotropic arrangement*; but I should have no quarrel with any lover of superlatives who might feel moved to call it the *aristotropic arrangement*; nor yet with any grammatical purist who might prefer to call it the *eutropic arrangement*; I would only insist that where we set out to extinguish a streptococcal infection we ought to place the leucocytes in the forefront of the battle.

When we have realized what is the favourable arrangement of the elements of the blood for the combating of streptococcus infections, there will have come home to us also that there is an unfavourable arrangement. And we have seen that the unfavourable arrangement is that in which the blood fluids are ranged up in front and the leucocytes are behind. I would ask you to let me call that the *kakotropic*, but there is no reason why you should not call it the *kakistropic* or the *dystropic arrangement*.

With this I bring to a conclusion the preliminary portion of our subject matter, and let me say that of the lessons that can be drawn from it many will only appear later.

(To be continued.)

¹² *Technique of the Test and Capillary Glass Tube*. Constable, London.

A COMMISSION has been appointed by the Governor of Indiana to investigate the causes and means of prevention of mental deficiency in that State. We learn from the *New York Medical Record* that a report recently published by the American Eugenic Society recommends the sterilization of an increasing number of defectives each year until the number reaches about half a million. It is estimated that if this recommendation were carried out the propagation of the mentally unfit in the United States would be practically at an end.

IN the September number of the *Cronica Medico-Quirurgica* of Havana some particulars are given of the Java School of Medicine, founded in the city of Batavia in 1865. It has 116 students, and degrees are conferred on some ten or twelve candidates every year. As the population of the Dutch Indies is 52 millions, these figures show that the medical profession is not overcrowded there. The course of study extends over nine years, of which three are spent in an arts school and six in the School of Medicine. The lectures are given in Dutch. Forty bodies are dissected each year, and the clinical and bacteriological teaching is said to be sound. Admission to the classes is free; the students are lodged and boarded without charge and receive an allowance of 5 to 10 dollars a month from the Government. A new school, with accommodation for 400 students, is now being built at the cost of the State.

Fig. 6.

Fig. 7.

Fig. 6.—The figure shows a magnified view of the distal ends of the capillary pipette represented in Fig. 7, filled in with citrated blood, which is disposed, with respect to microbes positioned at +, in A in the *agathotropic*, and in B in the *kakotropic* arrangement. In A the pipette has been placed upright, in B in the inverted position, and in each case the blood has settled down in three layers, the red corpuscles below, a layer of white corpuscles above them, and at the top clear plasma.

Fig. 7.—In A and B the elements of the blood had before implantation been allowed to settle down respectively into the "agathotropic" and "kakotropic" arrangements, and we have represented here the final result, the nutrient medium remaining in the former case sterile, while it shows in the latter a microbial growth.

we fill into the cultivation chamber in the barrel of the pipette a nutrient medium which will reveal by a colour change any growth of streptococcus (we have such a medium in cane-sugar litmus-broth). We then fill up to a fiducial mark on the stem with a 15 per cent. solution of citrate of soda, blow this out again, and then fill in with a unit volume of blood from the sterile finger. We now, after carrying the blood several times up and down the capillary stem so as to mix thoroughly with the citrate, seal up the end of the tube. This done we place our pipettes in a test-tube rack—the one in the upright position, the other with the tip turned upwards—and we let the blood sediment. The red corpuscles will now, in the upright pipette, be brought to the distal, and in the inverted pipette to the proximal, end of the volume of decalcified blood. (Fig. 6, A and B.) And in each case there will be on the top of the red a layer of white corpuscles, and above this a layer of clear plasma. We now, taking, of course,

NOTE ON

FUNCTIONAL MURMURS AND IRREGULARITIES
OF THE HEART.

BY SIR JAMES F. GOODHART, Bt., M.D.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL, ETC.

THAT the War Office should have issued a memorandum on "The significance of abnormal signs in the recruit's heart," from the pen of Sir James Mackenzie, is a very wise and useful move, that may be expected to be of great assistance to all those engaged in the examination of recruits, and not alone to them—it will be a help to many at work in general practice. It must often have been a matter of knowledge to many, quite unconnected with the present war, that many a young, healthy man, eager for service, and apparently well fitted for it, was too often refused for a quite unimportant murmur.

In the course of years I have several times had a quasi-impersonal tussle with a medical board for rejecting a candidate for an imperfect heart who had nothing of that sort the matter with him, and I doubt if the candidate has ever been successful. Once or twice I have even encouraged an appeal, only to hear that it has ended in costing the appellant a fee of several guineas for the special board, the original verdict being sustained. I do not altogether dissent from this attitude of army boards, for they need to look at an individual from many points of view, and on them is the responsibility if one, who ultimately proves unequal to the strain, be accepted. Nor is it, indeed, confined to examinations for the army: a very similar thing happens, and happens frequently, in the business of life insurance, and many a life has been loaded that had no cause for any such impost, and no doubt a great injustice is sometimes done thereby to young men just entering life.

The question to be decided is one needing experience and judgement, and though we may all give the best we have, we cannot dispense with what we have not got. I have often wished that it were possible in all cases of doubt to introduce the element of civil experience upon the boards; it would surely add to the weight of the opinion and tend to a real adjustment of any inequalities of judgement.

Nothing could be better than Sir James Mackenzie's memorandum, whether it deals with murmurs or irregularities or the effects of excitement, as temporarily disturbing the action of the heart. I would have some of his dicta scored in red and handed not only to a special section of us, but to every one. To remember that "physiological murmurs are always systolic in time and may be situated at apex or base or between," would alone save many a mistake when considered in conjunction with such other points as are here wisely brought to our notice. In the matter of irregularities of the heart, however, we except the quite young, there are indeed sometimes real difficulties that may well cause even the seasoned one to be at fault, and which there might just now, when men are so wanted, be a tendency even unduly to belittle.

This is where my own doubts have crept in, and perhaps it may help some one else if I say so: the heart is in this or that case, as I think, physiologically sound—that is its valves and muscle. Except in the case of the young recruit, to whom chiefly, and sufficiently, the memorandum refers, would it be safe to pass such irregularities of action even though such are admittedly often quite innocent?

Let me mention two cases in point:

A man over 50 had never been ill in his life till taken out at the front, with appendicitis, and after that with something else, two separate operations being necessitated. He recovered from these quite well, and remained so for two or three months, when his heart "began to jump," as he expresses it, and now it is sometimes very irregular, the systole frequently failing to give a radial pulse. The heart in its better moods is apparently quite sound, there being neither murmur nor dilatation nor short-windedness, and in civil life I should send him away and make little of it. There are many such cases where the heart's action is disturbed; it may be persistently rapid, apart from any tickatable malady; or slow, as after severe shock or other depressing influence; or there may be irregularity from digestive disturbances. In all these the heart may appear to be sound, and the fault some failure in the

cerebral nerve drive—not much, one might think, to keep a man back. Yet is such a one safe if allowed to return? I think one must say No. He is not as yet able to stand the impact of emergencies, and he is unfit, not by reason of actual disease of valves or muscle, but from a general want of stamina, from which the heart suffers in common with all our other members. A further possibility also would seem to attach to this form of irregularity, that as middle age approaches the heart's action may never again recover its proper stability, although capable of many years of useful if not of excessive work.

The second case is very similar, but in a younger man, only just over 40. He was evidently a very nervous man, so that I was rather prepossessed in favour of making little of his complaints; yet, on careful consideration, there seemed good ground for believing that the irregularity of the heart's action was due to faulty cerebral control, for he had been working twenty-four hours round, and needed rest for the taking in fresh supplies of energy.

There must be many who have come into touch with cases like this—cases where the outlook is encouraging, yet where it cannot be said to be devoid of possibilities, and where decision may be difficult.

THE RECRUIT'S HEART.

BY

ALEXANDER MORISON, M.D., F.R.C.P.,

SENIOR PHYSICIAN, GREAT NORTHERN CENTRAL HOSPITAL.

HAVING, during the progress of the present war, had to consider, both in hospital and private practice, the suitability of officers and men for military service, on account of some cardiac condition or anomaly, I have read with care Sir James Mackenzie's memorandum on the recruit's heart, which appeared in the BRITISH MEDICAL JOURNAL for October 15th. As it is issued at the desire of the Army Medical Service, evidently with a view of preventing the rejection of as many recruits as may be considered safely possible, whose cardiac state does not satisfy examiners, I should hesitate to comment upon it. But the matter is important, and the paragraphs of which the memorandum consists require, in my opinion, both amplification and qualification to be safely used as guides by examiners, who must of necessity vary considerably in their experience of the conditions dealt with in them.

The first suggestion of the memorandum is, that before examining the heart by the usual methods, its efficiency should be gauged by ascertaining the history of past exertion and the behaviour of the patient under strenuous effort. A judgement, favourable or unfavourable, might be based upon the data thus gathered, but a favourable judgement might have to be qualified by the discovery of local error in the mechanism of the heart, and an unfavourable judgement on this point should not necessarily lead to the rejection of a recruit who was found on examination to have a mechanically perfect heart which, in training, might, like his whole muscular system, somatic and visceral, gain power by exercise.

The next paragraph of the memorandum, however, which deals with murmurs, and which, like all of them, has the merit of a brevity which might with advantage and without prolixity have been expanded, offers a certain amount of argument in its closing lines. "It is manifest," it reads, "that, if the cause which produces the murmur hampers or embarrasses the heart in its work, the size of the embarrassed chamber will increase, and its functional efficiency be impaired."

The "size," however, of a heart with even an organic valvular lesion, as determinable by the methods employed at a recruiting office, may not be found to be increased, and the past history of behaviour on the part of an organically affected heart may be good. The prognosis of future behaviour under the conditions of military life would, however, not safely be thus calculable. The nature of the mechanical defect would therefore require careful diagnosis before the future stability of the heart could be estimated.

It may be stated in general terms that the heart which manifests an endocardial bruit after the exertion of coming to the recruiting office and after having been given exercise there to determine its persistence, is either

organically affected, or, if "functionally," shows such a degree of lack of tone in the cardiac muscle that the recruit should only be accepted on probation. I can scarcely expect the writer of the memorandum to agree with me on this point, for I think I do him no injustice when I state that, judging from his public utterances on the subject on various occasions, he would not hesitate to accept one who showed organic valvular lesion provided the muscular action of the heart satisfied him. I presume, however, that experience has satisfied the Army Medical Service that, notwithstanding exceptions to the rule (usually accidentally discovered), there is wisdom in absolutely rejecting the recruit with organic valvular disease of the heart.

The "cardio-pulmonary bruit" the writer of the annotation on the recruit's heart in the same number of the *JOURNAL* appears to regard as synonymous with the "functional murmur." It is, however, exocardial and negligible, except in so far as it may occasionally denote some enlargement of the organ by the pulmonary rub against the heart, chiefly towards the end of inspiration.

The negligible functional bruit at the apex of the heart should disappear on assuming the erect position and on exercise. Basic systolic bruits may persist and be less important under the same circumstances.

As regards the frequency of these functional bruits in adolescents, the younger the man the more likely is such a murmur to be met with, but even in youth they cannot be said to be common, as is often asserted. Among a hundred healthy boys at a public school how many manifest them? Very few; and what is true of schoolboys of the so-called better classes is also true of the poorer, as practice among them teaches. Their very transiency, moreover, denotes a temporary abnormality; their persistence renders them not negligible for prognostic purposes.

What is true of the heart affected with functional endocardial murmurs is true also of the extra-systolic heart. The extra-systole, which is not abolished by the augmented and accelerated heart of exercise, is one not often met with in the young. When it persists, as it often does in the older, it is usually associated with other signs denoting cardiac fault.

"Auricular fibrillation" at the recruiting age will usually be found associated with mitral valvular disease, of which the fibrillation is the more or less direct consequence, and a recruit presenting himself with it should be rejected on account of the mechanical defect.

The "heart-block" determinable by the methods usually pursued by the examiner of recruits and at the recruiting age is so rare that its occurrence would almost be a medical curiosity, and the country will lose the services of few on this account.

The rhythmical variation of pulsation associated with respiration, so long known and common in the young, in whom it is often coupled with an occasional reduplication of the second sound, being purely physiological, is, of course, no cause for rejection. At all ages it may be induced by forced respiration and its detection by an examiner ought to be regarded as evidence of his care and accuracy in investigation.

Finally, the accelerated and augmented action of the emotional heart ought also to lead to few rejections. Even the inexperienced, who themselves possess hearts and have known emotion, are unlikely to err on this point.

I trust that these remarks will not be regarded as unduly critical on my part. For my experience of cardiac failure among soldiers during the present war has been considerable and has convinced me that the estimation of the recruit's heart is so important a point in judging of his fitness for active service that I feel it a duty to raise a warning note against that minimization of mechanical error in cardiac action which in civil life may be merely unwise, but in military life, under the conditions of modern war, may prove disastrous, not only to the individual, but be a source of expense and invalidism inconvenient to the service.

THE late Dr. Bruce Goff, of Bothwell, Renfrewshire, left personal estate in the United Kingdom valued at £34,218.

THE Government of the Republic of Panama proposes to establish a university in Colon. The United States Government has under consideration a proposal to found one at San José de Puerto Rico.

THE EFFECT OF EXERTION ON THE CIRCULATION.*

By J. M. MACPHAIL, M.D., EDIN.,
EDINBURGH.

CONSIDERABLE attention has recently been directed to the effect of exertion on the circulation, and many attempts have been made to gauge the efficiency of the diseased heart by its reaction to exertion. The study of the subject has yielded conflicting results, but the weight of evidence points to a rise in systolic pulse pressure after moderate exertion, and a fall in blood pressure where the heart is failing or the exertion excessive.

Of the tests employed sphygmometric observations have held a prominent place, but doubt has been thrown on their value as an index to the work performed by the heart or a guide to its functional ability; and a method is surely defective which merely registers the maximal pressure but fails to indicate the pressure maintained between the arterial beats. Thus, with a high systolic pressure of sudden and fugitive nature we may have associated an extremely low diastolic pressure, a combination which probably represents greater cardiac inefficiency than a blood pressure of lower but better sustained character. The pulse of aortic incompetence, with its high systolic pulse pressure and sudden fall to a very low diastolic pressure, is an example of this type of inefficiency.

In recording my results, I have used the sphygmograph of the Mackenzie clinical polygraph, with its long tracing paper, and the method adopted was as follows.

A tracing of the pulse was taken in the sitting and in the erect posture, and, with the sphygmograph and paper still in position, the patient was asked to ascend twenty steps. Immediately on arrival the clockwork was again set in motion, and the result was a study of the pulse within the first second or so of the completion of the exertion. The pulse changes in character so rapidly from moment to moment that time is all-important in recording the delicate changes.

The sphygmograph has lost caste recently, and is considered quite unreliable as a guide to blood pressure; but it affords a means of estimating the power of the heart, as compared with the resistance it has to overcome (Lauder Brunton²), and gives some idea of the condition of the circulation during a complete cardiac cycle. The tracings exhibit a fall in pulse tension, as shown by a lowering of the aortic notch, a flattening of the diastolic portion of the tracing, and a falling away or absence of the predicrotic wave. There is also very frequently a great variation of systolic and diastolic pressure with each pulse wave, and a marked respiratory irregularity. Though I have no doubt the systolic pulse pressure is increased, the actual result is the production of a collapsing pulse with a great lowering of diastolic pressure. Schott,³ Mahomed,⁴ and Sansom,⁵ have called attention to this characteristic feature of the pulse after exertion. A reduction in arterial tension occurred in every instance; but this was more evident where the patients examined suffered from cardiac disease with failing compensation; and the more serious the cardiac disease, the more pronounced was this reduction in tension.

A glance at the tracings reveals the extreme changes induced by exertion, even to a close mimicry of the pulse found associated with such diseased conditions as aortic incompetence and the terminal stages of pneumonia.

In testing cardiac efficiency it has been claimed that the most reliable indications are the subjective symptoms of breathlessness and palpitation, but it is of interest to have a permanent record of the changes.

Subjoined are the tracings with their explanations.

CASE I.

A male patient, aged 63, suffering from cardiac dilatation, with oedema of the ankles, a mitral systolic murmur and breathlessness on exertion. The systolic pulse pressure was 140 mm. in the sitting posture. Exertion causes a very evident and distinct fall of arterial tension, the artery being apparently as empty at the end of cardiac systole as at the end of diastole.

* Extract from thesis for M.D., Edinburgh University, 1911.

The predicrotic wave is all but lost, whilst respiratory irregularity and hyperdicrotism appear. Such a fall of tension in a

Fig. 1.

old patient with moderately high arterial pressure indicates serious cardiac inadequacy.

CASE II.

A woman, aged 63, suffering from heart failure, with oedema of the ankles, a mitral systolic murmur and a grossly irregular pulse. On exertion the irregularity becomes extreme, but the pressure varies with each arterial beat; the pulse is markedly

Fig. 2.

affected by respiration, and is apparently very empty during diastole. There is a complete absence of the predicrotic wave, and some of the pulsations are almost monocrotic.

In these two cases the almost complete disappearance of the predicrotic wave is presumptive evidence of a diminished systolic pulse pressure.

CASE III.

The man of 72 years whose pulse tracing this represents was not a patient, but was so breathless on exertion that some degree of cardiac inefficiency seemed certain. The tracing shows the condition of the circulation where urgent dyspnoea is a prominent symptom. The systolic pulse pressure was

Fig. 3.

150 mm. in the sitting posture, but apart from some hypertrophy of the heart there were no other evident signs of cardiac disease. The respiratory irregularity, the sudden and abrupt nature of the systole, and the empty condition of the artery during diastole, deserve attention. Note the gradual return to a higher tension one minute afterwards.

CASE IV.

A male patient of 56 years, suffering from cardiac dilatation, with a mitral systolic murmur, oedema of the ankles, engorgement of the liver, and well-marked dyspnoea. On exertion feeble contractions, with a flat plateau at the summit, such as

Fig. 4.

we associate with heart failure, develop. There are also intervals during which the pulse fails to affect the tracing. The evidence here points to a much diminished systolic pulse pressure.

CASE V.

A female patient of 67 years, suffering from chronic bronchitis, with cardiac dilatation, and a mitral systolic murmur. While at rest, the pulse of this patient was irregular in rate and rhythm, with about five "intermissions" during the minute, not shown in the tracing; but after exertion there

Fig. 5.

is great irregularity of the pulse. At first one "extra-systole" occurs after each full contraction, but towards the end of the tracing these increase in number till they finally leave the descending line, and appear as small, rounded, independent contractions along the base line.

CASE VI.

This continuous tracing shows the effect the running of half a mile at a quick pace had on the pulse of a healthy

boy of 18 years. Before the start the sphygmograph was applied to the wrist, but some adjustment was called for at the end of the first quarter mile. The attention necessary at the end of the half-mile was very slight, and after inserting the smoked paper an additional 100 yards were run to keep up the action. The result was chronicled almost immediately. The prominent features are the very

Fig. 6.

low diastolic pressure, the marked respiratory irregularity, the hyperdicrotism, and the variations in force and fullness of the artery with each pulse wave. The effect is not unlike that produced by the inhalation of amyl nitrite, and certainly suggests a pulse of low tension, though the systolic pulse pressure is undoubtedly powerful. After a few seconds the arterial tension begins to improve.

Cleghorn⁶ took pulse tracings of runners two minutes after a Marathon race, and he and Williams⁷ found that there was a great reduction in blood pressure after such severe exertion.

CONCLUSIONS.

1. Exertion causes a rise in systolic pulse pressure, though a general vaso-dilatation may nullify this effect.

2. There is always a lowering of diastolic pressure.

3. In heart disease with failing compensation the fall in diastolic pressure is most pronounced; and there is often an almost complete absence of the predicrotic wave, pointing to a diminished systolic pulse pressure.

RAPIDITY OF THE PULSE DEPENDENT UPON PERSISTENT DISTURBANCE OF THE VASOMOTOR MECHANISM.

By KNOWLES BONEY, M.D. LOND.,
CAPTAIN R.A.M.C.

The following remarks are based upon observation of a series of twenty cases of rapid pulse in my charge. The subjects were all Indians drawn from units of the Indian Expeditionary Force in Flanders, who, after undergoing treatment at a casualty clearing station and base hospital for various injuries and ailments, had eventually been transferred to a convalescent camp. In this camp it was noticed that a certain number of the men did not improve as they should; they always appeared languid, tired, and generally unfit. On being questioned no particular complaint would be made, the man probably saying that he felt weak and unable to do anything; his general aspect coincided with this view of things.

The brief physical examination possible under the circumstances revealed nothing much except the rapidity of the pulse, and the patient was placed among the group requiring prolonged convalescence. Improvement was either very slow or did not take place at all, and it soon became apparent that there was a permanent residue of "unfits" in the camp—a residue which was slowly but surely increasing.

I was privileged to investigate and report upon a certain number of these "unfits," and the following remarks are based upon observation of a series of twenty during a period of six weeks.

The experience gained by medical officers during the South African war on the subject of cordite and its effect on the heart is probably well known, and in order, as far as possible, to eliminate errors of this nature, the patients were placed in a special ward, and were not allowed to leave it for any purpose, a guard being mounted to enforce this.

Every article of clothing and kit was taken away from them except water bottles. Food and water were brought

to them, and special latrine arrangements made. No smoking was allowed, and no drug of any kind administered. The patients were kept in bed until after I had made the morning visit; subsequently they were allowed to get up and walk about the ward.

Among the twenty cases there was no common factor which could be taken directly as having a causative influence. They were of all races and castes—Mohammedans who smoke and do not smoke; Hindus and Gurkhas who usually do both. Most of them had been in France nine or ten months, and for the greater part of that time had, according to their own statement, been occupied in digging trenches. Two had been gassed and four had been sent down with mumps. None had recently suffered from any acute debilitating disease, and none had undergone a period of prolonged rest in bed. Only three had been wounded; a good many of them had never taken part in an engagement.

When first seen by me they all presented the same general characters—a tired, listless expression, fatigue on walking a few yards or after a few simple exercises, and in one or two cases undue shortness of breath after any such slight exertion. In no case was any complaint made of pain, palpitation, or other subjective symptom.

Physical examination of the patients while lying in bed gave the following results:

One patient had marked dullness to the right of the sternum. An x-ray photograph showed a normal shadow, and at a subsequent examination two days later the dullness was no longer present. One other patient had dullness to the extent of a fingerbreadth to the right of the sternum, but there was no upward increase, and the position of the apex beat was normal. In this same patient was also observed slight pulsation in the jugular veins. The heart sounds were normal and there was no oedema.

With this possible exception there was no evidence of dilatation of the heart in any of them. None presented signs of hypertrophy. In every patient the position of the apex beat was within the nipple line. The cardiac impulse was not forcible or heaving, in fact, in some cases it was so weak as to be difficult of localization. The heart sounds were normal in character and correctly spaced. Accentuation of the pulmonary second sound was absent, and no reduplication was observed. No form of irregularity was present.

With regard to the character of the pulse, in every patient except one the rate was normal while lying down. The volume was good, and no irregularity in rate or force could be detected by the finger. The tone of the vessel wall appeared good, but as a certain number of them showed thickening of the vessel wall (in five of them it was marked, although no cardiac hypertrophy was present) it is difficult to generalize about this. Blood pressure in the radial measured by a Riva-Rocci manometer varied from 120 mm. to 140 mm. Hg. In no case was there any diastolic.

On slowly assuming the erect position, in six patients only did the pulse keep within what was considered normal limits. In the remaining fourteen the rate was enormously increased, in some cases going up to 130 or even 140—in one case to 155. In this latter case the increase amounted to nearly double the rate, and in nearly all it represented an increase of at least 30 beats a minute over the rate while recumbent. On walking the ward twice slowly, the rate might be further increased by six to eight beats a minute, but in some cases it hardly suffered any increase at all. Thus in every one of these 14 cases the great increase in rate took place merely as a result of standing up, done in every case slowly and without effort. The character of the pulse underwent a corresponding change. The volume became poor and the radial vessel appeared only half filled.

Blood pressure readings taken again showed in most cases a drop of 5 to 10 mm. Hg. In a few cases the drop was greater than this, reaching 15 to 20 mm. Hg. In one case the reading fell from 135 mm. to 110 mm. Hg. There were no missed beats and no diastolic could be observed.

After the patient had been standing a couple of minutes the rate would probably fall by 6 to 8 beats per minute, after which there would be no further alteration. On lying down again the pulse would continue to beat at its

altered rate for 4, 6, or 8 beats, and then drop suddenly to normal. In a few cases this reduction would take place gradually, and the normal rate would not be gained for 30 seconds.

I next tried the effect of raising the patient passively from the bed into a sitting posture. The increase in this case was usually not as marked as on standing up, but was nevertheless very striking. I append figures illustrative of this, as below:

Lying.	Raised to Sitting Position.	Standing.	After Standing Three Minutes.	Lying Down Again.
Pulse ... 80	112	120	120	Sudden drop to 96 after 6 beats.
B.P. ... 128		122		
Pulse ... 80	104	120		Sudden drop to 80 after 4 beats.
B.P. ... 150		126		
Pulse ... 84	116	120		Sudden drop to 94 after 7 beats.
B.P. ... 140		120		
Pulse ... 64	84	100	100	Gradual drop to 80 at end of 30 secs.
B.P. ... 134		116		

These figures will serve to show what took place in a typical case. The extreme cases I have purposely omitted.

Referring to the six cases to which exception was made in the first place, the fluctuations were not so marked. In these six, on standing up the rate was increased by 15 to 25 beats a minute, and after walking the ward twice slowly the rate did not exceed 100; but if an increase in rate of about 10 beats a minute on resuming the erect position be considered normal, even these six would show abnormality.

Assuming that these facts could best be explained on the hypothesis of some vasomotor disturbance, the urine of every patient was examined for intermittent albuminuria, controls being done at the same time on a dozen healthy Indian soldiers who had never been to the firing line.

Immediately on waking, samples of urine were taken, and after the patients had been walking about the ward samples were again taken four hours later. On one occasion six, and on another occasion seven, of the patients showed faint traces of albumin in the second specimen.

The first urine passed was free from albumin on both the above occasions, with one exception—a patient subsequently invalided with nephritis. Of the twelve controls made on healthy men, there was a trace of albumin in one specimen only.

Other evidence of vasomotor instability was to be found in various circulatory disturbances exhibited in some cases. Cold hands and feet, even when warmly wrapped up in bed, were commonly noted, and in two cases flushing of the face was so marked as to be spontaneously remarked upon by an independent observer. A "tache" could be obtained in two cases.

Such, then, briefly stated, were the facts brought to light during this period of observation, and it but remains to appraise them at their true value.

I think it will be admitted that everything points to a central lesion of the controlling nervous mechanism. The patients neither showed signs of hypertrophy nor of dilatation supervening on hypertrophy. There was nothing in the condition analogous to the staleness of the over-trained athlete, neither was there evidence of complete breakdown due to cardiac overstress from hard work. Blood examination made on two unselected cases showed red count and colour index within the normal limits.

Toxic action, whether that of a toxin of endogenous or of exogenous nature, must also be excluded as a possible cause, since any such toxin must be supposed to act independently of bodily position.

That somewhat vague expression, "irritable heart," has been applied, according to Albutt, to two states which are radically different—the one a functional condition, a "sort of restless distress on muscular exertion," occurring chiefly in growing boys, and eminently curable; the other comprising the group also known as "soldier's heart," a condition involving more or less permanent myocardial damage, and too often incurable. But in the cases of my series there is no evidence of any such damage, and in this Sir

John Rose Bradford, who also saw the cases, agreed; consequently they cannot fall into this category.

With regard to the former ailment—the irritable heart of adolescents—the case is different. Under this heading Da Costa and others described cases in which the heart action was feeble for long periods, and attempts to sit up were followed by fainting attacks and vanishing pulse (Albatt). A psychological element was often prominent, although not a necessary concomitant.

As to the mechanism of central nervous control, we know that reflex acceleration of the heart may be brought about by (1) accumulation of blood in the great venous reservoirs; (2) diminution of the total volume of the blood as after a haemorrhage, and (3) peripheral expansion; the principle involved being the same in each case—namely, stimulation of the cardiac centre brought about either by inferiority in the quality or in the quantity of the blood supplying it.

The third of these factors corresponds to a loss of vaso-motor control, and is represented by a general diminution of tone all over the body.

It is also known that loss of tone occurs as a result of

general exhaustion, although, judging by recorded cases, it would not appear to be of long duration. Instances are mentioned by Albatt of rapidity of the pulse supervening on muscular exertion in which the vasomotor system was obviously at fault, but they recovered in a week or so, or at any rate showed marked improvement, whereas, of the cases mentioned in this report, all of which were of at least two months' duration when first seen by me, the majority at the end of six weeks showed no improvement at all. Further, in my cases there is no history of great muscular effort. The history is rather one of laborious work of more or less vexatious nature, spread over a considerable time in a strange climate, and frequently under conditions of great personal danger—conditions which with more reason might have been expected to produce the signs of strain as exhibited in "soldier's heart."

The causation is probably to be found in a great complexity of factors, into which the psychology of the Indian, the exposure, shock, and fatigue of the campaign in a climate to which he is unaccustomed, all enter.

ESCAPE OF THE VENTRICLE, IN ASSOCIATION WITH CEREBRO-SPINAL FEVER.

BY J. DAVENPORT WINDLE, M.D.,

SOUTHALL.

By escape of the ventricle is understood interruption of the normal mechanism of the heart by the occasional manifestation of the idio-ventricular rhythm. It is an unusual mechanism, and I do not know whether it has been noted before in course of acute disease. In the present case illustrating this arrhythmia (Figs. 1 and 2), the diagnosis of

Fig. 1.

cerebro-spinal fever was established by bacteriological examination of the spinal puncture fluid.

The patient, a factory worker, aged 15 years, left work on April 16th, 1915, because of headache and biliousness. He came to my surgery on April 20th, looking pale and tired, and complaining of sickness. He said he had been subject to sick headache on and off for some months past. I could find nothing definitely wrong, and told him to let me know how he was getting on in a day or two. I did not see him again until the evening of April 30th; he said that since his last visit the headache had been very bad, he had been sick occasionally, and had had diarrhoea. However, he had kept about, and felt so much better on April 20th that he went to work for half the day. The temperature was 99° F., the pulse quite regular at 86 to 90 per minute. He looked very poorly, and I sent him home to bed. I visited him at his home next morning (May 1st). He complained of headache, was drowsy, and had been sick. The temperature was 100° F., pulse regular at about 80 per minute, no physical signs in chest or abdomen, the pupils were equal and reacted normally. Kernig's sign was present; his mental condition was clear.

On May 2nd the general condition was much the same, except that he was more drowsy and the pulse was irregular at about 60 per minute; tracings of the pulses and breathing showed sinus irregularity, the shortest diastoles falling with inspiration.

On the morning of May 3rd the general condition was much the same; on examining the heart, however, occasional beats were noted to be unusually forcible, and with these beats the sounds of the heart were modified, and there was a large single pulse in the veins of the neck. These events suggested that the auricles and ventricles

were contracting at the same time, as commonly happens in extra-systole of the ventricle and with some of the beats in heart-block.

Evidence of simultaneous chamber contraction is furnished by the records (Figs. 1 and 2) taken on this day; but analysis indicates that the mechanism by which it is brought about is due to "escape of the ventricle," the stimulus probably originating at the α - r node. In Fig. 1 the normal mechanism of the heart is disturbed in three places, by simultaneous contraction of auricles and ventricles, as evidenced by the large waves "a", corresponding to the radial pulses marked r . These beats are due to idio-ventricular contractions, the inherent rhythm of the ventricle becoming operative, because the auricular rate is slowed to, or a trifle below the idio-ventricular rate. The inter-auricular intervals next after the escaped beats are nearly but not quite so long, measuring $\frac{2}{3}$ against $\frac{2}{3}$ sec. This slight difference, however, allows time for the sinus impulse to reach and provoke the ventricle before the idio-ventricular stimulus can become operative.

Fig. 2 was recorded some hours later on the same day as Fig. 1; here ventricular escape is shown after inter-auricular intervals of $\frac{2}{3}$ sec., whereas the normal mechanism is maintained in Fig. 2 with an interval of $\frac{2}{3}$ sec. The relationship of the escape of the ventricle to the respiratory movements is notable; it occurs at the lowest part of the venous curve, that is to say, at the end of expiration. Expiratory inhibition of the auricle is a common phenomenon in meningitis, but it rarely shows the heart below a rate of 45 to 50. The extreme susceptibility of

Fig. 2.

the inhibitory mechanism to respiratory influence in the present case suggests that the vagus centres were involved in the lesion.

The patient died suddenly in the night (May 4th), about twelve hours after Fig. 2 was recorded. When I left him his general condition seemed satisfactory; there was no symptom other than the heart rhythm to arouse immediate anxiety; presumably death was occasioned by vagus inhibition.

At the annual meeting of the American Gynecological Society in Washington next May a discussion will take place on the relations of syphilis to obstetrics and gynecology. Dr. George Gellhorn, of 713, Metropolitan Buildings, St. Louis, Missouri, who has been delegated to arrange details, asks for the assistance of those who are doing scientific work on the subject.

SUCCESSFUL EARLY OPERATION IN WOUND OF SMALL INTESTINE.

By CAPTAIN JOHN H. STEPHEN, R.A.M.C.,
82TH FIELD AMBULANCE (1ST HIGHLAND).

On August 13th Private S. was admitted to our dressing station, situated in a gully, a small branch of the famous ravine running from the Gallipolan coast up to Achi Bahr. Half an hour before a shell had blown in the trench in which he was; it killed two men at his side, and he himself sustained a penetrating wound of the abdomen.

From the wound, which was only about an inch long and just above McBurney's point, was protruding a small lobule of bowel; this I intended to wash well with saline and replace in the abdomen, then inserting a small drain. Something prompted me to insert my finger in the wound after replacing the bowel, and I found a small particle of shell, about half an inch long, firmly embedded in the omentum. I hooked it out along with the omentum, which I then tied off preparatory to replacing it. Lieutenant Thompson was assisting me, he having previously put the man under chloroform, when suddenly, owing to the light anaesthesia, the patient attempted to vomit; the effort brought forth from the wound a coil of ileum, at least six inches of which was entirely riddled by shell and really hardly existed as bowel. Two things only could be done—either to put it back or resect. I resolved on the latter, and there and then, although with very limited means and much unsuitable material to work with, I did an end-to-end anastomosis with the quickest possible speed, replacing the bowel through the slightly enlarged wound after washing well with saline, putting in a gauze drain and closing the aperture as necessary.

The patient, who was suffering considerably from shock upon admission, was placed under a tarpaulin on a stretcher in Fowler's position, a large saline was administered by the rectum, and an immediate improvement became visible in spite of the flies and dust. Throughout the day he was given sips of water with occasionally a few drops of brandy; throughout the night when not sleeping he had a teaspoonful of milk and water every hour. A small hypodermic injection of morphine was given to relieve restlessness. Next morning the pulse had improved very much; it never rose above 80, but as it was still soft a continuous saline apparatus was erected, and during the day many pints were given and retained.

One small mouthful of green bilious fluid was brought up, but generally speaking the patient was improving and feeling well and wanting nourishment. At night beef-tea and milk and water, one dessertspoonful of each alternately, was ordered; all was retained. In addition one-third of a grain of calomel was given every two hours, the order being that it was to be continued until the bowel moved. On the afternoon of the third day flatus was passed, and the patient felt very much better. He looked almost normal; all signs of shock had disappeared, and he slept well all night. Next morning (August 16th) I removed the gauze drain, which was perfectly dry and sweet, and put in a smaller one.

At 11 a.m. we had orders to evacuate immediately, and I banded the patient over to another field ambulance in another gully 100 yards away. I heard no more of him until August 23rd, when at Suvla Bay I was attending to Lieutenant C. of a field ambulance, who had been shot in the knee at the battle of Chocolate Hill, and there he told me that the case had done splendidly, the bowels had moved well, and the man was feeling very fit and eating well. The patient had been evacuated by the ambulance to which we had sent him shortly after we had gone, and he had a long journey down the gully to a casualty clearing station; yet no harm had been done.

I consider this case worth noting, first, for the fact of the rough and ready material at our hands for an operation of this kind; secondly, for the fact that the case was tackled within an hour of the injury, instead of undergoing operation after a long and exhausting journey down country to the beach, with an added burden in the way of a long sea trip on a lighter or a trawler before reaching a hospital ship, with perhaps the delay of many hours in a casualty clearing station. It is a proof that many cases of abdominal injury might be saved if dealt with on the spot by the field ambulances,

provided always that the right case is chosen for operation. It is interesting to read in the JOURNAL of July 31st that the German military surgeons now incline to the idea of operating early and on nearly all abdominal cases coming into field hospitals, and that their statistics show that the mortality in these cases is in direct proportion to the length of time elapsing between the wounding and the operation and to the length of journey that the patient has to undergo before treatment.

SOME CASES OF HEAD WOUNDS.

By
CAPTAIN H. H. TAYLOR, R.A.M.C.(T.),
2ND EASTERN GENERAL HOSPITAL, BRIGHTON.

The following cases of head injury show some features of interest.

CASE I.

Private T. H., aged 26 years, was struck on May 11th by a shrapnel bullet on the head. He was unconscious for a few minutes, and then walked back to the dressing station. On admission to hospital there was a small septic wound just to the right of the middle line above the ear; the bone was exposed; there were no signs of intracranial mischief; x rays showed small pieces of metal in the outer table and depression of the inner table. The metal was removed, the wound in the outer table enlarged, and about one square inch of depressed and broken-up inner table removed. The dura mater was intact. He made an uninterrupted recovery.

CASE II.

Private A. L., aged 21 years, was hit on May 9th by a bullet. He was unconscious for a short time, and then walked back to the dressing station. He had no symptoms of intracranial mischief.

On admission on May 15th there was a healed wound of the scalp just to the right of the middle line, and in a line with the posterior edge of the ear; x rays showed depression of the inner table. On cutting down to the bone a round opening about 4 mm. in diameter was found. This was enlarged, and several small fragments of the inner table were removed. The dura mater was uninjured. He made a rapid recovery.

In both these cases the optic discs were very much injected, but there was no swelling.

CASE III.

Private T. S., aged 19 years, received a bullet wound when attacking on May 9th. He was knocked down, but not rendered unconscious, and walked back to the dressing station. He suffered from continuous headache and frequent vomiting.

When admitted, on May 17th, there was a transverse wound about three inches long just below the upper border of the occipital bone; it was septic, and exposed bone could be felt with the probe. After admission he complained of considerable headache, and at first he vomited on several days. He was in a very dull condition. The retinal veins were enlarged in both eyes, with very considerable swelling of the discs. The vomiting and headache soon ceased, and his mental condition improved. The x rays showed no injury to the skull. In spite of this, as the signs of pressure were so marked, it was decided to cut down on to the bone. After careful examination, as no fissure could be found, nothing further was done. He made a good recovery, and went to a convalescent home. The discs when he left the hospital, although improved, were still swollen.

The first two cases illustrate well what is now well recognized—that when the outer table is injured, however slightly, there is nearly sure to be some injury to the inner table, and hence thorough exploration is necessary.

The third case is difficult to understand. There was no apparent intracranial injury, and yet the symptoms and signs of such were well marked. It would be interesting to know whether similar cases have been met with.

CASE IV.

Private H. B., aged 27 years, when attacking on August 9th, 1915, was struck on the head by shrapnel bullet. He did not become unconscious and walked back to the dressing station. He forgets whether he had any headache, but he did not vomit. Just over the motor area on the left side was a ragged septic wound nearly healed. There was very marked hesitancy in speech, and slow cerebration, but no headache or sickness. The pupils were equal and active, and the discs were normal. There was no definite alteration in face muscles. The grasp was perhaps weaker on the right side; the knee jerks active and equal on both sides. X rays showed no injury to bone. He remained in this condition for two or three days and then gradually improved. In about a week his mental condition cleared up and his speech became normal. He was sent to a convalescent hospital apparently quite well.

As the x rays showed no signs of injury to the bone, and there were no definite signs of pressure, it was concluded

that the mental condition was due to shock; and this view appears to have been correct. I saw him three months after he left the hospital, and he appeared then quite well.

THE MANUFACTURE OF ASEPTIC HOSPITAL FURNITURE.

By J. LIONEL STRETTON,

SENIOR SURGEON TO THE MIDDLESEX INFIRMARY AND
CHILDREN'S HOSPITAL.

ALTHOUGH hospital furniture has been improved during the last twenty years, it is still far from perfect from an aseptic point of view. A considerable proportion of it has been made in Germany, and now that this source of supply

Fig. 1.—An operating-room table.

The angles A, A are all rounded and scalloped out. The socket carrying the castor is continuous with the table leg, so that no joint is visible, B. The rabbit holding the upper glass shelf C is scalloped out, though this is not seen in the photograph. The rounded and scalloped inside of the angles is seen at D.

is cut off, there is some difficulty in meeting the present increased demand.

At such a juncture I feel that it may be an advantage if I describe some of the articles which I have invented.

On examining some specimens of hospital furniture it will be seen that the manufacturers have left angles and depressions which act as receptacles for dirt and germs. It is difficult, and in some instances impossible, to clean them. I have endeavoured to guide some of the makers from their erroneous ways into the right direction. Hitherto my efforts have been without result; even when I have submitted models these have sometimes been incorrectly copied.

Fig. 2.—A ward wagon.

This is somewhat similar to the table, Fig. 1, but is of larger size and is provided with a metal rail, which has rounded angles at A, A. The feet are so constructed that they fit into the wagon, leaving a scooped-out edge, as shown in Fig. B.

Manufacturers appear to have adopted a stereotyped method of employing cornices, panels and ornamentation, and to be unable to avoid such adornment. Furthermore, they are not surgeons; they do not fully understand what we require, and they are consequently incapable of attending to the necessary details. It is equally true that surgeons are not furniture makers. If a perfect article is to be produced, combined effort is essential.

I have been fortunate in finding a local cabinet-maker able and willing to work with me and carry out my views. The drawings illustrate furniture he has recently con-

Fig. 3.—An instrument cabinet.

There is an entire absence of ornamentation. The angles are all rounded at A, A, A, and the same applies to all the inside angles. The bottom, C, is made to open flush, without any ledge to catch the dust and dirt, and the corners are all rounded as at D. The catch and striking plates are let in flush, and there is a spring stop in the striking plate to prevent a hole, which would contain dirt. The door is rounded at the corners to avoid angles, as at A, and it is bevelled down to the glass inside and outside. The edge is rounded, and fits into a scalloped rabbit. The glass shelves are supported by rounded metal pins, which can easily be removed and reinscribed.

structured under my supervision. These show my methods of construction, which it is difficult to explain clearly in an article.

Briefly, my object is to avoid any depression or angle—to make the furniture in such a way that the most

Fig. 4.—An operating-table.

The angles A, A, A are all rounded and scalloped. Where the cross pieces join, B, B, B, it is also scalloped. There are wheels on the feet of the table at the head, so that it is easy to move it about if the foot end is raised. The rack allows the head to be raised or lowered.

perfunctory dusting cannot fail to clean every portion of it.

To attain this end it is necessary to apply the above principles to the parts hidden at the back and underneath, as well as to those which are in full view. So far as I can judge, it is possible to obtain perfection in this respect—that is, to construct a piece of furniture without any receptacle for dirt.

All this furniture is constructed of wood and is enamelled white.

Some surgeons maintain that all hospital furniture must be constructed of iron. I understand that the argument in favour of this is that iron is non-absorbent. Do the advocates of metal realize that it is covered with a coat of enamel, and that it consequently becomes a question of this material? The enamel burnt on to metal is, perhaps, harder than the enamel on wood, but it possesses the great disadvantage of chipping. These chipped places provide spaces which form as commodious dwelling-places for germs as the caves in the rocks did for our ancestors. I have never seen a piece of enamelled metal furniture which has not chipped in a few weeks, and most of it is bespeckled before a year has passed. Enamel on wooden furniture never chips. There may be some separation of joints or a crack in the wood, but these can easily be filled with hard stopping. The furniture can be rubbed down and re-enamelled at intervals, after which treatment it comes out like new.

Wooden furniture is far lighter for moving about; it is strong enough for its purpose, and the cost is less than half that of the metal. I prefer wood. Those who retain an affection for metal could, no doubt, obtain furniture made after my designs.

The cabinet-maker who has assisted me is unable to manufacture any large quantity. Messrs. Salt, of Birmingham, assure me that they are in a position to do so.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

IONIZATION OF ADHESIONS AFTER WOUNDS.

DR. GIUSEPPI, in his interesting note in the *BRITISH MEDICAL JOURNAL* for October 16th, mentions the inconvenience and disability caused by the adhesion of scars to muscles and tendons. In such cases he would find that Leduc's method of ionization with chlorine ions gives good results, and obviates the necessity for operative treatment. In the case of stiff joints due to adhesions this method also answers well, and, I think, should always be given a fair trial before such a drastic proceeding as forcibly breaking down the adhesions is resorted to. If, as so often happens, there is a more or less constant aching pain in the wounded limb, ionization with a 1 per cent. or 2 per cent. solution of sodium salicylate is very effectual in relieving this symptom. After three or four applications the pain disappears and the patient is able to sleep better, and the adhesions can then be dealt with by ionization with sodium chloride solution. Should a bullet or any pieces of shell be left in the wound I think ionization is not desirable, as in one of my cases much pain and irritation was caused in the neighbourhood of a piece of shell embedded in the arm by an interrupted galvanic current with which I was treating some paralysed muscles. The sinusoidal current has no such disastrous effect.

LONDON.

MAY RATHBONE.

REDUCTION BY MANIPULATION OF OLD-STANDING BILATERAL DISLOCATION OF JAW.

THOMSON and MILES state that dislocation of the jaw of over three months' standing is rarely reducible by manipulation, but that it has been accomplished as long as ten months after the accident.

A. M. was sent to the Livingstonia Mission Hospital, Bandawe, by a Government medical officer, on January 23rd. He was found to be suffering from bilateral dislocation of the jaw, and stated that it had occurred the previous October in the course of conversation. The patient was thin, owing to inability to take food properly, and he had suffered from a large ulcer over the left anterior pillar of the fauces due to the pressure of the condyle, but this had healed. Native medicine had been applied externally without effect.

It was found that the condyles had slipped up beyond the zygomatic processes on both sides, and were lying in the temporal fossae; there they were firmly fixed, little movement being possible.

On January 25th and 27th unsuccessful attempts were made to reduce by manipulation, both with fingers in the mouth and with corks between the teeth, the most vigorous traction only resulting in slight loosening of the adhesions. Preparations were accordingly made for the open method, but when the patient was under chloroform a third attempt to reduce without cutting was made, and succeeded by the following manoeuvre: Instead of trying to reduce both condyles simultaneously, the right condyle was used as a fulcrum to lever the left condyle out of the temporal fossa; the patient lying on his back, traction was made by the fingers of the right hand on the left lower molars, while both thumbs pressed on the chin, and the jaw being thus grasped between both hands the left condyle was levered downwards around the right condyle as fulcrum in the temporal fossa, and so delivered below the left malar arch. The right condyle was then easily delivered from the right malar arch, and the dislocation reduced.

The condyles, however, did not slip into the glenoid cavities, as these were filled up with organized extravasation, and the process of grinding them into place was not thoroughly enough done, as the patient on recovering from the anaesthetic re-dislocated his jaw in spite of a tight bandage. A few days later chloroform was administered for a fourth time, the dislocation was easily reduced by the method above described, the condyles were ground thoroughly home, and a tight bandage applied. This time the result was permanent, as the patient went home quite pleased after a day or too, and has since been seen at his village.

1. In the only two skulls to which I have access the space between the condyles is wider than that between the malar arches, so it is obvious that the condyles could only slip up one at a time, and must also be reduced one at a time.

2. By reducing one side at a time much greater leverage can be obtained; the whole length of the jaw acts as lever instead of half. The physics of this might be difficult to demonstrate because of the shape of the bone, but in practice there is no doubt of the fact.

Nyasaland. WM. Y. TURNER, M.A., M.B., Ch.B., D.T.M.

Reports of Societies.

DISCUSSION ON GUNSHOT WOUNDS OF PERIPHERAL NERVES.

At a meeting of the Medical Society of London on October 25th, the President, Dr. W. PASTEUR, being in the chair, Dr. WILFRED HARRIS in opening, from the medical aspect, a discussion on gunshot wounds of the peripheral nerves, considered the subject under two main headings—the one, diagnosis and accurate localization; the other, the degree and kind of injury, its prognosis, and the decision as to whether operation were advisable. Hysterical phenomena of anaesthesia and motor paralysis were common complications of nerve injuries, and the true symptoms must be carefully sifted from the false. Again, multiple nerve injuries might occur, and the resulting paralysis must be correctly apportioned. Careful charts of the sensory loss were usually a better guide to an estimation of the severity of a nerve lesion than the degree of muscular paralysis, even with reaction of degeneration. Charts were shown illustrating commencing recovery of sensation in sutured nerves as early as seven and thirteen days after operation. Recovery in nerves compressed by scar tissue was even more rapid after successful operation. He illustrated by means of the epidiascope the defects in sensation which he had met with in various gunshot injuries of nerves, and the improvement which followed operative procedure.

Mr. WILFRED TROTTER (temporary Captain R.A.M.C.) opened the discussion from the surgical aspect. He said that the problem of the restoration to the normal of an injured nerve presented certain peculiarities which distinguished it from all other similar tasks of plastic surgery, for (1) the interruption of a nerve left a permanent defect in the physiological equipment of the body, which could not be overcome or compensated for by any other mechanism; (2) the restoration of a nerve to its normal anatomical continuity, although an essential preliminary

to recovery was by no means a guarantee of it: (3) incomplete lesion or incomplete recovery of a nerve might be more disabling than a total loss of function. These peculiarities rendered the task of the surgeon exceptionally difficult: they made it urgent, they made it precarious, and they exposed him to some risk of increasing rather than diminishing the disability of his patient. The following rough, tentative and purely clinical classification was suggested as a basis for discussion:

1. Intracardial nerve injuries, almost entirely lesions of the cauda equina.
2. Peripheral nerve injuries:
 - (a) Typical complete lesions of one or more nerve trunks.
 - (b) Mixed lesions with complete division of some and incomplete division of other closely adjacent trunks—chiefly seen in the brachial and sacral plexuses.
 - (c) Incomplete lesions without pain, usually due to combined bruising, laceration, scarring and pressure.
 - (d) Incomplete lesions with pain.
 - (e) Pure pressure lesions as from a prominence of bone or a foreign body. Painful complete lesions were curiously uncommon.

Typical Complete Lesions.—In their diagnosis there were three essential points—the situation of the injury was consistent with a lesion of the nerve; the symptoms involved the whole distribution of the nerve, and were absolutely stationary, in spite of adequate treatment, by which he meant massage, electricity, and muscular relaxation, the last being the most important.

Mixed lesions were chiefly seen in the brachial plexus. A common picture was that of a complete paralysis of the plexus following on the injury, then a gradual improvement which ultimately came to a standstill, leaving an irreducible residue of symptoms. It was of the utmost importance that proper relaxation treatment should be carried out before operation was decided upon, otherwise the operator might find his difficult task made much harder by perplexity in deciding what should be resected and what left.

Incomplete lesions without pain produced paralysis and defect of sensation which improved but left a persistent residue. The experience of a neurologist was often necessary to decide whether an operation should be advised or not.

Incomplete lesions with pain were most important and often distressing cases. The motor loss of function was often profound, but the sensory loss was incomplete and accompanied by intense hypersensitiveness in the affected area, often with slight trophic changes in the skin. The hypersensitiveness was not a true hyperaesthesia, and light touches were often less tolerable than firm pressure. In some cases symptoms often subsided within a few weeks by rest and protection of the limb, but if such treatment failed there should be no delay in advising operation. The pain was particularly intolerable and apt to undermine the mental stability in a remarkable way.

Pure pressure lesions were apt not to present themselves as true lesions at all. While the patient was in hospital the symptoms were often slight, and consisted of an occasional twinge during movement or under accidental pressure. It was to be feared that resumption of active life would lead to persistent irritative symptoms, and an operation for the removal of the cause should, if feasible, be undertaken.

After enunciating certain principles which underlie operative treatment, he dealt with practical considerations. In lesions of the cauda equina regeneration could not occur, but as it was impossible to determine how far the symptoms of such an injury were due to pressure and how far to actual nerve division, this was an argument for early operation in every case where there was the least suspicion of an element of pressure. The only reason for delay would be the fear of sepsis. In peripheral operations time would be saved by making an incision free enough to give access to the nerve above and below the injured part. When the nerve had been exposed and dissected out, the extent to which its continuity was interrupted would have to be determined. When it was not obviously completely divided, three points would have to be taken into consideration: (1) The presence or absence of a bulbous end above the scar; (2) the presence or absence of a distinct longitudinal fibrillation of the scar; (3) the effect of strong faradic stimulation above the scar. The bulbous end should be freely excised. For large defects in nerve trunks there were two alternatives—

implanting both ends of the nerve into an adjacent trunk or filling the gap with one or more lengths of some large cutaneous nerve like the internal saphenous. Such care should be given to securing the exactest possible coaptation of the sutured ends by means of the finest catgut. When the suture was complete, the junction should be wrapped in a layer of subcutaneous fat about $\frac{1}{2}$ in. extending for 2 in. on each side of the junction. The most rigid asepsis was essential. In incomplete lesions, if resection was unnecessary, the nerve should be freed from the scar and carefully wrapped in fat, and at the same time any bony prominence tending to press upon it removed, and any muscles, tendons, or other scarred structure resisting free movement divided, if such were permissible. The most important points in the technique of nerve resection were free excision, exact coaptation, careful insulation, and perfect asepsis. Muscular relaxation before and after the operation was, perhaps, equally important.

The discussion will be reopened by Sir Frederic Evo on November 1st, and will be continued by Dr. F. W. Mott, Dr. Farquhar Buzzard, Mr. Jocelyn Swan, Mr. Paul B. Roth, and Dr. S. A. K. Wilson.

ASSOCIATION OF REGISTERED MEDICAL WOMEN.

At the annual meeting on October 12th the newly-elected President, Dr. HELEN BOYLE, delivered an address on her recent visit to Serbia. She had gone out in April with two women orderlies, two motor cars, a large Thresh disinfectant and a destructor, to join Mr. and Mrs. James Berry's unit at Vrujatehka Banja. At Salonika a large number of parasites were met with, even in a good hotel. Serbia, owing to a wise move on the part of England in sending out a strong contingent of the Royal Army Medical Corps, had been greatly aided in cleaning and disinfecting, and even the railway traffic had been held up for a time to allow of disinfection of the rolling stock. The Berry unit had charge of six hospitals, two of which when Dr. Boyle left were almost full of wounded soldiers, many very severe cases, although not freshly wounded. One, the typhus barrack, erected in a fortnight, according to Mr. Berry's instructions, and very satisfactory, was used chiefly for the civil population, and two had convalescent soldiers. The civil population needed medical care badly, most of the civilian doctors having been either commandeered for military duty or having died of typhus. Fevers were common—typhoid, typhus, small pox, scarlet fever, measles, diptheria, malaria, and relapsing fever. There was also a good deal of gynaecological work to be done. The Serbian people were described as simple, grateful, and intelligent. There was a scarcity of sugar, milk, and, at times, potatoes, and there was no butter; the chief articles of diet for the people were fruit, vegetables, and Indian corn. Dr. ETTIE SAYER showed Bergonié's electro-vibreur localizer, as used in many French military hospitals. It consisted of an iron cone connected with an alternating electric current; the cone was held within a few inches of the body. When the hand was passed over the body vibrations could be felt immediately over any metal, however small.

THE French Minister of War has, by a recent decree, established a permanent mission of prophylaxis. It is to be under the direction of the Under Secretary of State for the army health service and to remain in being till the end of the war. The members are Medical Inspector-General Vaillard; Dr. E. Roux, director of the Pasteur Institute; Dr. A. Laveran, of the Institute of France; M. Brissac, head of the Public Health Department of the Ministry of the Interior; Professor Simonin, of the Val-de-Grâce; and Dr. Pottevin, Member of the Superior Council of Public Hygiene of France.

WE learn from the *Medical Record* of September 25th that the New York Commissioner of Licences recently forbade the Motherhood Education Society to give public moving picture exhibitions of the twilight sleep technique. The official prohibition was endorsed by the opinion of a number of medical practitioners that the exhibition had no educational value. At a meeting of the American Association of Obstetricians and Gynecologists recently held in Pittsburgh a number of the members declared themselves strongly opposed to the routine employment of this method in cases of childbirth.

Rebivus.

PRACTICAL PHYSIOLOGICAL CHEMISTRY.

The second edition of Mr. R. H. A. PLIMMER'S *Practical Physiological Chemistry* has involved the amplification and recasting of the entire work, which now appears as a manual of *Practical Organic and Bio-Chemistry*.¹ The basis of the book is organic chemistry, and many new sections on that subject and on the organic substances found in plants have been added. The term "bio-chemistry" is substituted for "physiological chemistry" in the title because the latter term is so often applied to animal chemistry alone, excluding vegetable chemistry. The book is intended mainly for medical students, but it contains the essentials for all students of biology. It begins with a general account of the various simpler groups of organic compounds, written from the point of view of their detection and quantitative estimation and their occurrence in animated nature. From the simpler organic compounds the pages pass on to the more complex, and serviceable accounts of such things as the alkaloids, enzyme action, colloids and colloidal solutions, and practical urinary analysis are given in the course of the text. The book is comprehensive, well arranged, and clearly written; the various analytical methods recommended are clearly described, and references to the original articles in which they are given in fuller detail have been included in footnotes for purposes of reference. The text is well up to date and contains but few misprints, although there are two such errors in the definition of the micromillimetre on p. 376. The book is meant mainly for use in the laboratory; it may be warmly recommended to pathologists, physiologists, and advanced medical students who wish for precise knowledge of the organic compounds with which the study of medicine—using the phrase in its widest sense—is concerned.

TEXTBOOKS OF OBSTETRICS.

A PERUSAL OF PROFESSOR DONALD'S *Introduction to Midwifery*² makes it easy to understand why it has passed through no fewer than six large editions in the course of little more than twenty years. No book of its particular kind that we know is more full of instruction, more lucidly written, or more practical in its design. The author's large experience, both as a practical obstetrician and as a teacher, is to be felt running through the whole text; nor can it have been an easy task to write a book which is designed both for medical students and midwives. The former are apt to despise what is written ostensibly for midwives, while the latter would find the ordinary students' textbook considerably over their heads. Professor Donald, however, has succeeded in meeting the requirements of both; and while his volume is a most admirable textbook for nurses, it is at the same time an ideal book for students who are taking out their practical midwifery either in a maternity hospital or in outdoor practice. That being so it seems a pity that the printing, and more particularly the old-fashioned illustrations, are so reminiscent of the books of twenty years ago. The publishers would, we think, be well advised to bring the appearance of the book up to date in these respects, and so make it worthy of the writing and teaching which it contains. Some of the illustrations are actually misleading—as, for example, No. 41, in which the accoucheur is shown making a vaginal examination without having troubled to roll up either his coat sleeve or a very septic-looking cuff; and No. 42, which represents the hand taking a side to side grasp of the uterus in expressing the placenta. There is little that is superfluous in the book, but it hardly seems necessary to take up any space with the description of the rarer forms of contracted pelvis, and to figure, for example, the spondylolisthetic pelvis. The space so occupied might with advantage have been devoted to the subject of the artificial feeding of infants, which is the one subject in the book that appears to be inadequately treated.

¹ *Practical Organic and Bio-Chemistry*. By R. H. A. Plimmer, Reader in Physiological Chemistry, University of London, University College, London. Longmans, Green, and Co. 1915. (Roy. 8vo, pp. 697; 86 figures, 1 plate. 12s. 6d. net.)

² *An Introduction to Midwifery: A Handbook for Medical Students and Midwives*. By A. Donald, M.A., M.D., C.M. Edin., M.R.C.P. Lond. Seventh edition, revised. London: G. Griffin. 1915. (Post 8vo, pp. 114; 71 figures, 5s.)

Professor POLAK³ has succeeded in producing something new in obstetrics by the format which he has selected for this student's manual. Though nearing five hundred pages, it is less than $\frac{3}{4}$ in. thick, and its dress of dark flexible leather, with red edges, is reminiscent of quite another style of textbook. This seductive exterior is, however, no needed compensation for lack of internal merit, for it is a good manual, with a text as clear as its type and its matter as modern as its form. From the small compass the style is necessarily succinct and dogmatic, but the positions are, on the whole, judicious, and space has been found for a relatively full description of human embryology, which ends with a useful table of the forms of developmental abnormalities.

DIET AND DISEASE IN INFANCY.

In his handbook for medical men, *Diet and Disease in Infancy*,⁴ Dr. CAMERON has dealt with the common nutritional disorders of infants during the first year of life from a clinical standpoint. He holds strongly that the diet of infants should be controlled wholly by medical men; the subject is so complex as to be beyond the scope of the best trained nurse. Two early chapters by Dr. Janet Laue-Clayton give an account of what may, for want of a better term, be called "high-grade" milk, and the care required for its commercial production. Such a milk contains 3.25 per cent. of fat, 8.5 per cent. of solids not fat, and not more than 10,000 microbes (of non-pathogenic varieties) per cubic centimetre. It is added that Berlin milk "of excellent quality" contains 30,000 to 40,000 bacteria per cubic centimetre. Dr. Cameron's twenty-six chapters discuss the diet of infants in health and sickness, breast feeding and its difficulties, dyspepsia and diarrhoea in infants, marasmus, constipation, rickets, spasmodic, the exudative diathesis, scurvy, convulsions, and other such important topics. He writes clearly and with precision; it is obvious, as indeed his preface suggests, that not a little of his inspiration comes from German and Austrian sources. This raises the interesting question how far one disease or diathesis is the same in different countries with their different peoples and habits; by the time it has been transferred to England, Czerny's "exudative diathesis" may be used to account for almost all the acute and chronic disorders of infancy and childhood, if Dr. Cameron's exposition (pp. 170-178) of its features may be believed. Wide views are excellent, but is it not possible to take too wide views? To many physicians the "exudative diathesis" will appear to be a purely speculative explanation on the lines of *ignotum per ignotum*; at any rate, it throws no light on pathology or treatment. Dr. Cameron's book appears at a timely moment, when much thought is being given to the care and future of infants. It is didactic, a little uneven, but full of useful information and valuable advice, and may be cordially recommended to senior medical students, house officers, and practitioners of medicine, who have to direct the feeding of infants in health or sickness.

NOTES ON BOOKS.

In his *Practical Manual of Tuberculosis for Nurses* Dr. BURRA⁵ gives a brief but clear account of the various forms of the disease that should be of practical value to nurses who have care of cases of tuberculosis, and might be read with advantage by a considerably wider circle of persons. It is divided into four sections. The first deals with general considerations about the disease; the second and longest is devoted to pulmonary tuberculosis in all its aspects; the third describes the most important forms of non-pulmonary tuberculosis; and the fourth gives an account of the use of the powerful drug tuberculin in the diagnosis and treatment of tuberculosis. The book may be warmly recommended to the attention of nurses, home visitors, lay workers, and the like, who have to deal with cases of tuberculosis in town and country.

³ *Manual of Obstetrics*. By J. O. Polak, M.Sc., M.D. New York and London: D. Appleton and Co. 1915. (Demy 8vo, pp. 487; 3 plates, 119 figures. 12s. 6d. net.)

⁴ *Diet and Disease in Infancy*. By H. C. Cameron, M.D., F.R.C.P. London: J. and A. Churchill. 1915. (Med. 8vo, pp. 216; 13 figures, 8s. 6d. net.)

⁵ *A Practical Manual of Tuberculosis for Nurses*. By L. T. Burra, M.D. Oxon. London: J. Bale, Sons, and Danielsson, Limited. 1915. (Cr. 8vo, pp. 145. 2s. net.)

MEDICINAL AND DIETETIC PREPARATIONS.

"Synthetic Milk."

A DEMONSTRATION of a process of synthetic milk making was given recently at the Meico Laboratories (56, Great Peter Street, Westminster). The casein and albumin of the new product are supplied by the ground-nut, called in America the pea-nut (*Arachis hypogaea*), which is extensively cultivated in many tropical and subtropical countries. This nut, which is admittedly rich in proteins and fat, and has been used as a diabetic food, is skinned and minced into a porridge-like meal, to which alkaline water is added, as well as the sugar principle in the form of malted dextrose, and the salts associated with cow's milk. The mash is stirred in double-jacketed pans at a temperature well below boiling point, and the product then passes through certain strainings, and is treated with fatty acids, the whole process lasting two hours. A culture is added in the form of a special growth of lactic bacteria which has been acclimated to the new milk. The cost price of the milk, including labour, is said to work out at 3d. a gallon, as against 8d. a gallon for cow's milk on the farm; the residual meal after the extraction of the milk-white fluid can also be used as a foodstuff. The fluid certainly has all the appearance of cow's milk, but the flavour of the nut, which to many tastes would not be agreeable, is somewhat pronounced. If the milk is allowed to stand for a short time, all the solids sink towards the bottom, but recombination is quickly obtained by a slight shake of the vessel. The total solid content of the milk is 13 per cent., as compared with the Government standard of 11.50 per cent. in the case of cow's milk. The process is ingenious and interesting.

INCOME TAX.

MEDICAL PRACTITIONERS ON ACTIVE SERVICE.

We have recently received a large number of communications from medical men serving with the forces with regard to the income tax assessments made in respect of their civil practices. The matter is rather complicated, and is the more difficult to deal with inasmuch as many of the practitioners concerned are abroad in France, the Dardanelles, or elsewhere, and of those who remain in this country many may not have found time to give the question very prolonged consideration. In the meantime the authorities appear to be assessing the practices and issuing notices of the amounts so assessed to the officers or their representatives. These amounts being presumably based on the average of the three previous years, exceed the maximum income which the practices can be expected to yield to the officer in existing circumstances. In view of the high rates of taxation now in operation such an excess involves payment of a substantial sum, and we propose to examine the subject in greater detail than has been possible in answering individual correspondents.

In the first place, let us dispose of the suggestion sometimes made that the system of basing assessments on an average of the three previous years will in the long run give to the person assessed every allowance to which he is fairly entitled. In ordinary circumstances this may be so, though even then the system would be open to the charge that it was unfair to demand a full tax in a year when profits were at their lowest, but it is clear that the proposition does not hold good to-day. According to the Finance (No. 3) Bill now before Parliament the minimum "earned" rate of tax will be 1s. 9d. for the current year, as compared with 9d. in pre-war days. Probably few taxpayers are optimistic enough to expect an early return to the 9d. rate, but it is perhaps not too much to hope that in four years' time we shall have lower rates of tax than those now in force. Consequently the medical practitioner serving with the forces would—unless given some statutory claim to relief—now be liable to pay income tax at a high rate on an income which in fact he is not receiving, and would not be adequately compensated by the probability that in two or three years' time he would be paying tax at a lower rate on an average less than his actual income. This view of the matter seems to have commended itself to the Exchequer and a provision now exists—Section 13 of the Finance Act, 1914 (Session 2)—

which if properly carried out should give adequate relief. Unfortunately the parliamentary draughtsman, with a natural preference for using language which has already been tested and construed in the courts, carried out the intention by the re-enactment of an old provision—Section 133 of the Income Tax Act of 1842—which had been repealed in 1907; we say unfortunately because, however clear its effect may be to the legal mind, Section 13 of the Act of 1914 is hardly intelligible to the majority of the taxpayers whom it is intended to relieve. Briefly stated, the effect of the provision is to enable any person serving in the army or navy, or working abroad under the British Red Cross or St. John Ambulance Associations, to claim an adjustment of the Schedule D assessment on his profession, etc., reducing it to the amount of his profits for the actual year.

It should be remembered that this provision grants relief; it does not invalidate the "average" assessment. The distinction is of importance in two ways: In the first place, the assessment holds good until it is discharged or amended on application, the initiation and proof of the claim resting with the person assessed; and, in the second place, the limitation to twenty-one days of the period during which the presentation of a "notice of appeal" against an assessment can be made does not apply. In point of fact, Section 133 of the Act of 1842, on which the provision under discussion is based, contemplates repayment of portion of the duty as being the usual mode of adjustment. This appears natural enough when it is remembered that in normal circumstances any person assessed would not know whether he had any right of claim until the year had expired, but the circumstances of a practice carried on for the benefit of an absentee must be so well understood that it is hardly likely that payment of the full duty charged will be called for where it is known that a claim under the operative section will be made. We therefore suggest that every officer concerned should, as soon as practicable, send an intimation of his intention to claim the benefit of Section 13 of the Finance Act, 1914 (Session 2) to the surveyor of taxes for the district in which the practice is situated. In some cases applicants appear to be asked to make some payment on account, leaving the balance over for future settlement, and there can be no objection to such payment so long as it is reasonable in amount; the mere fact of payment would not affect the right of claim.

Having indicated the legal position with regard to the application, there remains the practical question as to the preparation of the necessary account to show the reduced liability. As already mentioned, the onus of proof lies on the applicant, and it may safely be assumed that the evidence required to discharge that burden will be similar to that required for the "appeals," with which taxpayers as a whole are more familiar. That is to say, it will be an account showing on the one side the gross receipts of the practice for the year, and on the other side a classified and totalled list of the expenses incurred in earning those receipts.

The first point to be decided is as to the precise year to be taken; where such an account has been regularly prepared in previous years it will probably be found most convenient to select the corresponding date—for example, December 31st. At the same time, such an account may not give the full measure of relief. The financial year ends on April 5th, and the ideal account for the purpose would end approximately at that date. Let us, for example, take the case of a medical practitioner accepting a commission and holding a military appointment as from April, 1915. If he makes up an account to March 31st, 1916, it is wholly covered by his period of military service. On the other hand, if he files an account made up to December 31st, 1915, he is including therein three months during which the position of the practice was normal and excluding three months when it was abnormal. One case has come to our notice in which an assessment for the year 1914-15 has been adjusted on an account to December 31st, 1914, and the local surveyor of taxes has undertaken to make a further adjustment on the same assessment when the account for 1915 is available, tax being finally payable on an amount made up by taking three-quarters of the 1914 profit and one-quarter of the 1915 profit. Whilst theoretically open to criticism this method is certainly convenient, and the final result would

no doubt be sufficiently accurate for all practical purposes. We cannot say whether this method is being generally adopted, but there were apparently no special circumstances in the case referred to which call for exceptional treatment.

The determination of the amount of the "receipts" would seem simple enough, but is not without difficulty if full advantage is to be taken of the relief under consideration, the point being whether it will be correct or reasonable to take the usual cash basis—that is, to compute the receipts at the actual amount received in cash irrespective of when they were earned. This basis is fair only on the assumption that the real value of the fees earned in any particular year are approximately equivalent to the cash received. While this assumption generally holds good in any long-standing practice, it will not apply where the practitioner has been an absentee for the whole or part of the year, for the cash received, being in respect of periods during which he was able to give the practice his undivided attention, will in all probability be greater than the fees, etc., earned by his substitutes. This consideration accordingly suggests the advisability of preparing the account on the basis not of "cash receipts" but of the gross bookings less a reasonable amount for bad debts. If this course be impracticable, it will perhaps be worth while remembering that the "cash basis" will, in the peculiar circumstances of the case, probably place the revenue in a favourable position, and might justify rather generous treatment in any debatable questions arising in connexion with the expenses.

The above observations are of general application, but with regard to the allowable expenses which have to be set out in the adjustment statement we must refer specifically to the manner in which the practice is being carried on in the absence of the officer whose assessment requires adjusting.

The simplest case is that in which a locumtenent is appointed to take complete charge of a "sole" practice. In this case the expenses will be arrived at in the same way as in previous years, the principal difference being the addition of the fees paid to the locumtenent and the increase in the cost of drugs, etc. It may perhaps be pointed out that for such period as the house is not used by the officer or any member of his family the whole of the rent, rates, servants' wages, etc., would appear to be allowable deductions, and not only the two-thirds allowed when the practitioner is in residence.

In the case of a practice carried on by the absentee's partner the complete statement of claim will consist of the usual account exhibiting the firm's receipts and expenses for the year, and the absentee will be entitled to have his assessment reduced to his share of that year's profits. It should be borne in mind that the relief applies to the individual member of the firm serving with the forces, and that in consequence the same adjustment cannot be claimed by his partner. On the other hand, it may well be that the partnership agreement has been modified for the period of the war, and that the member of the firm who remains to carry on the practice may be liable to a greater amount of income tax than if no such modification had been made. An example of this may serve to explain the general position, as well as to make this particular point clearer. A. and B. are partners dividing the profits of the practice equally; the firm is assessed for the year 1915-16 on £1,600, being the average of the following amounts for the three years to December 31st, 1914—namely, to £1,400, £1,600, and £1,800. A. accepts a military commission, and the partners agree that B. shall carry on the practice and receive £400 of the profits before the division is made; the profits for 1915 are £1,400; A's military pay is, of course, taxed by the army agents, and is kept quite distinct from the firm's accounts. In this case, A. is entitled to have his liability reduced from half of £1,600 (£800) to half of (£1,400 - £400) = £500; but on the other hand B. is liable to payment of tax on £400 plus half of (£1,600 - £400) = £1,000. A., therefore, is relieved of tax on £300, but B. pays on £200 more than he would have done had no rearrangement of the terms of partnership been made.

We have now to consider cases arising under the special schemes which have been adopted in various parts of the country for safeguarding the practices of medical men serving with the forces. These schemes have a common origin in that put forward by the Scottish Medical Service

Emergency Committee and subsequently adopted by the Committee for England and Wales,¹ but are otherwise distinct. They have been drawn up to meet special local conditions and under the influence of different ideas, and the resulting divergencies—so far as the method of dealing with the collection of the receipts and the payment of the expenses of the absentee's practice—are so substantial as to prohibit any attempt to lay down useful generalizations as to the assessment of the absentee's profits. We therefore propose to examine one or two dissimilar schemes, hoping that comment on the schemes selected may be of use not only to the officers directly affected, but also to others whose practices are being carried on under other schemes.

The Brighton scheme supplies a good instance of an arrangement under which the absentee retains the maximum of control over the practice; he selects the substitutes as far as possible, he leaves a power of attorney with a local agent, the service is considered to be rendered on his behalf, he or his agent sends out the accounts, and he pays one-half of the out-of-pocket expenses of his substitutes. In these circumstances it seems clear that the practice is being carried on by the absentee through his local agent, and that the substitute fulfils the functions of a locumtenent. The appropriate account for a practice carried on under such a scheme would accordingly consist of (1) a statement of the gross receipts of the practice, and (2) a list of expenses, including under this head all payments to substitutes—that is, not only the proportion of the out-of-pocket expenses, but also those moiety of the fees and payments by the Insurance Committee which are handed over in accordance with the scheme.

An essentially different scheme is that adopted in the Kingston-on-Thames Division. It provides, where necessary, for the practices of absentees to be put into the hands of trustees, who are empowered to collect fees and defray expenses. In this case the absentee has practically divested himself of the control of his practice for the time being, and the "income" would appear to be simply the sum payable to him by the trustees, less any dispensary or other expenses which he may have to pay thereout.

Again, officers whose practices fall within the Oldham scheme will not be able to make a definite statement of their adjusted liability until they have returned to their practices, inasmuch as in the meantime the Central Committee cannot say what they will be called upon to contribute for the services rendered to their practices by the various local practitioners acting as substitutes. We have no doubt as to the suitability of the scheme or its convenience and general equity, but it would seem that the absentee practitioners will find considerable difficulty in dealing with the yearly statements necessary for a proper adjustment of their liabilities. Possibly the revenue authorities may agree to wait until such time as the contributions have been fixed, and then to regard the profits of the absentees as spread equally over the period of their absence.

We have already remarked that the existing rates of income tax are high; a further consideration arises from the fact that they vary, according to the amount of total income, within narrower limits than was the case until recently. This point is worth bearing in mind, because a reduction of liability reduces *pro tanto* the amount of total income by which the rate of tax is determined, and may ultimately give a larger measure of relief than might otherwise have been anticipated.

In conclusion we would call attention to the fact that an adjustment of liability under the provision discussed does not affect the assessment for the next year. Thus, if C., whose profits for the past three years have been £600, £700, and £800, accepts a commission, appoints a locumtenent, and finds his 1915 net profits reduced to £300, he is entitled to pay for 1915-16 on £300 instead of £700, and the £300 will still come into the average for future years; the 1916-17 assessment will therefore be £600, again reducible to the actual profits for 1916, and so on, as long as C. remains in the forces. In other words, Section 13 gives a clear right to set the average aside in favour of the amount of the year's profits, and does not prohibit the inclusion of that lower sum in the average for future assessments.

¹ SUPPLEMENT, JANUARY 16th, 1915, p. 17; AUGUST 21st, p. 98.

MEDICAL STUDENTS AND THE WAR.

The Central Medical War Committee has received, in reply to an inquiry, a letter from the Assistant Director-General Army Medical Service, stating that "the Director-General considers that all medical students in the fourth and fifth year of their curriculum should continue with their studies and obtain a registrable qualification as soon as possible. In the case of the junior students, however, their course of action during the present national emergency is entirely a matter for their own personal consideration."

This is in accordance with the letter addressed to Professor Halliburton by direction of Lord Kitchener on August 11th. This letter stated that

it is advisable for medical students in their fourth and fifth years to continue their studies, with a view to qualifying as soon as possible. The War Office would be unwilling to suggest that junior students should be discouraged from taking combatant commissions.

AN OPEN LETTER TO STUDENTS.

Dr. R. A. Duff, Director of Studies in Glasgow University, in an open letter to students who have asked for guidance as to their own decision as to their duty in the present crisis, notes, in the first place, that

The University has urged all its students to consider carefully the claims of the nation upon them for military service and (for those who cannot give this) for munition service. At the same time it is opening most of its classes as usual and leaving it to each individual to decide whether he should continue or interrupt his studies. In thus acting it is simply following the present policy of the national Government, that in this matter each man should act as his own conscience dictates.

Dr. Duff then continues as follows:

Whilst this is the official position, I feel that I should be false to my country and to myself if I did not voice my personal opinion frankly, and use any influence or power of persuasion I might have to help a great cause. . . .

Practically all our men students are of (or very nearly of) military age, and many who are not are capable of doing efficiently vital munition work. Some hundreds of them have already enlisted or obtained commissions, some hundreds more have been doing and intend to continue doing valuable munition work. What of the others? Is their duty less urgent, or are their circumstances harder? After hearing many hundreds of cases my opinion is that (with rare exceptions) there is no real difference, except in sensitiveness to public duty and in vividness of imagination, between those who are ready to make all sacrifices and those who are ready to make none. In many cases what checks the natural generosity of youth is a narrow or a frigid home atmosphere, in others it is loyalty to home obligations and blindness to other and greater ones, while in others it is, I fear, a selfish wish to make hay while the sun shines. The common plea that studies and careers long prepared for will be interrupted and endangered excuses all or excuses none. And with the exception of the fourth and fifth years medical students no adequate reason seems to me to exist for the rest of our students pursuing their normal life while their comrades who sit on the same benches with them are giving up not only their careers, but health and limb and life, to make this possible.

Are our students (as well as other classes) doing their best to help? Many of them are. But I am not a believer in the new popular creed that if a considerable proportion of students, or miners, or doctors, or shopmen, or clerks, are doing public service, therefore the whole class may take to itself the credit, and say "Haven't we done well?" It is the other way about. If so many in any calling have offered, are the others playing the game in not offering? The fact that in many callings large numbers must remain at home has no bearing on the matter. For those who have remained do so by their own choice. No reflected glory falls upon them from their comrades' toils in the field and in the factory, but only a deeper shadow, because they stand so near the light of their own mates and neutralize it as far as they can.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

At a meeting of the Committee in London on October 21st reports were received of the proceedings of the weekly meetings in Brussels from August 19th to September 16th inclusive, and it was resolved to send a further sum of money for the relief of the immediate needs of doctors and pharmacists in Belgium. The report of the Committee meeting in Brussels showed that it had established a separate fund to assist doctors and pharmacists to repair and refurbish houses which were capable of restoration at

small expense. The question whether the British Committee should make a contribution to this fund was considered, but no decision was reached.

Mr. Meredith Townsend reported that out of the instruments sent to the Master of the Apothecaries' Society, Blackfriars, London, E.C., he had sent through Mr. Hoover three further cases, and the Secretary said that the previous consignments of instruments had been gratefully acknowledged.

THE WEEK'S SUBSCRIPTIONS.

The following additional subscriptions have been received:

	£ s. d.		£ s. d.
Dr. Watson Williams	1 0 0	mond, Dr. Spiers,	
Dr. Dudley C. Trotter	5 0 0	Dr. John Galloway,	
North of England Branch		Dr. Thompson, Dr.	
of Fund (per Dr.		Durant, Dr. L. A. H.	
Don.) Gateshead		Bulkeley, Dr. Adam-	
Doctors' Recruiting		son, Dr. Leech, Dr.	
Dees (collected by		Scott	28 13 6
Dr. Durant)		Grimsby Pharmacists'	
Dr. Stanley Robson,		Association (per Mr. C.	
Dr. James Patton,		Dewling)	8 17 0
Dr. Charles Hou-			

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Voeux, at 14, Buckingham Gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee, held on October 12th, twenty-eight cases were considered, and £227 7s. was granted to twenty-seven of the applicants. The following is a summary of the cases relieved:

M.R.C.S.Eng., aged 59, who practised at Stone, Staffordshire. Had total paralysis in the right side three years ago, and unable to do anything. With his wife has been living on the proceeds of the sale of the practice, now practically exhausted. Help wanted towards the purchase of a self-propelling chair. With the help of the Fund's visitor at Bristol a secondhand chair was procured at the cost of £2 5s., and becomes the property of the Fund. The applicant has since died.

Widow, aged 61, of M.R.C.P. and S. Edin., who practised at Lincoln and died in 1892. Was left with two children now aged 18 and 19 years, and has supported herself by nursing since husband's death. Her son, aged 18, has just left Epsom College, and has joined the army. A little help required for purchase of army equipment. Voted £2 2s.

Widow, aged 72, of M.B., C.M. Edin., who practised at Wakefield and New Zealand, and died in 1886. Applicant was left entirely unprovided for and earned a living for a number of years by nursing; but ill health and old age—in fact she is now bedridden—prevents her from doing anything. Shares a home with a sister. Help wanted for invalid comforts. Voted £5, and referred to the Guild.

Widow, aged 57, of M.R.C.S.Eng., who practised at Swansea and died in 1896. Left the applicant totally unprovided for. Health too precarious to work, and only a little from friends. Voted £15.

Widow, aged 57, of M.D. Glasg., who practised at Downe, N.B., and died in 1907. Was left unprovided for at husband's death, with two sons both now married and unable to help. Tries to make a little by taking in boarders, but has none at present. Voted a temporary grant of £2, and referred to the Glasgow branch of the Guild.

Daughter, aged 46, of M.R.C.S.Eng., who practised at Stilton and died in 1881. Applicant has kept a boarding house at Cambridge for undergraduates and managed to pay her way until the war commenced, but cannot get any boarders now. Voted £10 in two instalments.

(To be continued.)

The claims of the fund are steadily increasing, largely in consequence of the war; and though the ordinary subscriptions remain at much the same level, there is a constantly increasing adverse balance. Thus in July the deficit was £535, increasing in August to £575, and in the present month it reached the total of £646. To meet this the Committee has had to draw heavily upon its limited reserves, and unless increased support be rapidly forthcoming the work of the Fund will have to be very seriously curtailed. Subscriptions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos Street, Cavendish Square, London, W.

The Royal Medical Benevolent Fund Guild appeals for gifts of secondhand clothing, boots, and shoes in good condition, also household linen. The gifts should be sent to the Secretary, Royal Medical Benevolent Fund Guild, 43, Bolsover Street, W.

British Medical Journal.

SATURDAY, OCTOBER 30th, 1915.

THE WAR AND THE FALLING BIRTH-RATE.

WE are all apt to be depressed by the quickly-following lists of casualties and by the hope deferred that soon these melancholy indications of the war will cease with the establishment of a hardly earned but honourable and lasting peace, and that instead of the fathers there will be the children. But will there be the children to fill the places of the fathers? The question cannot be answered with the confidence that one would like to feel.

During the past fifteen or twenty years, and indeed for much further back, there have been other casualty lists appearing and little regarded. The infantile mortality in every town and village in the United Kingdom has been a casualty list, and, until the present generation, little or no attention was paid to it; there were plenty of babies—too many, some were even heard to say—and a few dropped by the way mattered nothing, would perhaps relieve threatened over-stocking.

The falling birth-rate has been a casualty list; it has been passed by with indecisive comments, with unimpassioned questionings as to its possible causes, with colourless prognostications as to its conceivable effects some fifty or a hundred years hence, and generally with a striking absence of excitement. Yet the rate has kept on falling; one could not help noting that. The headlines in the daily papers have been taking on a stereotyped appearance, and might indeed have been set up once and for all with "decreasing birth-rate," "smallest birth-rate since registration," and the like as their burden.

Lately, however, there has been some awakening of interest. A commission has been appointed¹ to inquire into the decreasing birth-rate, has been sitting for some time, and will no doubt duly make some report; but it has been a private venture, not a Royal Commission. The Notification of Births Act has been made compulsory, and before long it will be possible to estimate with fair accuracy the casualty list of the premature infants as well as of the full-term babies; but still the country will be without a knowledge of the much more serious casualty list of the miscarriages, the antenatal lives lost before the twenty-eighth week. It has been estimated—and Dr. Arthur Newsholme, C.B., has accepted the estimate—that in the forty weeks of antenatal life 150 infants die out of every 1,000, and that in this way England and Wales during 1914 lost 138,249 lives; but this is an estimate not from exact knowledge, and as such, whilst it may, let us hope, be an overestimate, it may also, we fear, turn out to be under the correct figure. Something more is needed than notification of births to reveal the full tale of these antenatal deaths. Nevertheless the extended Act will do good in many directions and will introduce greater accuracy into the statistics which are obtainable. Then, again, a meeting was held in the Guildhall on Tuesday last (October 26th) to organize

"a national campaign to promote the welfare of motherhood and infancy," and from this beginning much benefit may accrue.

For one thing in particular all those interested in antenatal hygiene will be truly grateful to the Notification of Births (Extension) Act of 1915; it contains one clause which if properly worked cannot fail to do much good. It is this: "Any local authority within the meaning of the Principal Act (that is, the Notification of Births Act of 1907), whether a sanitary authority or not, may, for the purpose of the care of expectant mothers and nursing mothers, and young children, exercise any powers which a sanitary authority has under the Public Health Acts, 1875 to 1907, or the Public Health (London) Act, 1891, as the case requires." Without essential modification this clause has been made applicable to Scotland and Ireland as well. It would seem, therefore, that if money be forthcoming (a somewhat important proviso), a great deal may be done not only to reduce the infant mortality after birth, but also to diminish the many deaths which in the form of premature labours and miscarriages take place at or before it. The clause, however, must not be allowed to become a dead letter, and local authorities must be induced to establish antenatal clinics, prematernity homes, wards, and resting houses, prenatal nurses, and popular instruction (printed and oral) on all such matters throughout the length and breadth of the land. A Midwives Act for Scotland must also be secured, for that will do something to check the loss of infantile life at the time of birth in the northern part of Great Britain.

All these matters have become suddenly urgent on account of the war, and of the times which must follow it. It would have been well if these things had been regarded some twenty years ago; it would, to put it solely on a purely material basis, have given the country two or three more army corps, even without talk of compulsion. For the birth-rate of a nation, of any nation, is a vital question in every sense of the word.

In an address on the nature of pregnancy, which was printed in the JOURNAL on February 14th, 1914, nearly six months before the war, Dr. Ballantyne said: "Finally, the birth-rate of a country enters into the sphere of high politics. . . . Napoleon said that the great need of his exhausted country was more mothers, and the same may be said of France now; but it may be said in another sense and for another object. France now requires more mothers and more pregnancies and a higher birth-rate, not that she may have more soldiers to wage wars of conquest or aggrandisement, but that she may not fall in numerical strength below the level of her rivals. Unless the birth-rate of France rises or that of her neighbour falls more quickly than it is doing, the French people will feel the loss of national strength so acutely that fear will enter in, and where fear enters there too often and too soon follows war. The nation with a high birth and survival rate and a limited territory must find room by colonization; where two races are living side by side in a country, the one with the higher birth-rate (the survival rates being equal and migration inconsiderable) will inevitably rule, although the event may be delayed; the people who will not propagate must die. No wonder a far-seeing statesman said lately, in answer to his own question, What is the greatest thing in the world? 'A baby!' In the ultimate issue of things babies are of greater import than battalions, and they are the true dreadnoughts of a nation; if they are well nourished before they are

¹ BRITISH MEDICAL JOURNAL, November 1st, 1915, p. 1167.

born, if they are brought into the world with care, and if they are handled afterwards with tenderness, and educated with knowledge and foresight but without fads, they will not only stand to arms if need be for the defence of their land in their manhood, and be apt for the replenishing of her millions in their womanhood, but will also help to maintain her high rank among the nations in science, in literature, in commerce, and in all else that is worthy."

As read now after fourteen months of war, there is seen to have been something of the prophetic in the sentences which have been quoted, and especially do the mutterings from beyond the Rhine regarding a fall in the birth-rate in Germanic countries come to us as a significant commentary upon some of the principles laid down in these closing sentences of the address. But, apart from these considerations, the main lesson for the nation to learn is: "in the midst of war to prepare for peace," and how can that be done better than to take a long look forward, and try by every means in its power to see to it that the mothers of the unborn infants of the future are brought happily and healthily through their pregnancies, that the children themselves are carried safe and strong to the birth, and that they are kept sound in wind and limb thereafter to play their part worthily for their country, and for her high destiny in the years which are to follow?

THE NEW APPEALS.

THE members of the medical profession who in such large numbers have put aside every consideration of personal interest and domestic ties to enter the military service of the country have been actuated by a sense of duty and love of country and not by any desire to stand in the limelight. Still when praise comes it would be churlish not to acknowledge it, and affectation to pretend that it was not agreeable. We must therefore take note of the generous tribute paid in the *Times* Red Cross Supplement last week by Sir Frederick Treves, whose work for the British Red Cross Society has taken him into so many parts of the war area, and given him in other ways unusual opportunities for forming a just estimate of the services of the profession and the spirit in which they have been rendered.

"Very conspicuous," he says, "has been the sacrifice made by the members of the medical profession. The doctor is not a man of wealth, nor is his living made by other than hard and exacting toil, and yet he has volunteered for the war as if he were a man of leisure who had need to take no thought of the morrow. That every young medical man in the country should hurry to enlist for service at the call of arms can be no matter of surprise. They have, indeed, come forward in a body, utterly regardless of their future or of the position which they may have already made for themselves. . . . What is remarkable is that older men, with large and lucrative practices, with heavy responsibilities and with families dependent upon them, have simply left their work, have abandoned their appointments, and have gone to the wars." Such a man, Sir Frederick Treves continues, "is making a sacrifice that may impose upon him a burden very hard to bear, but without a murmur, without a sign of regret, and without a thought of the cost of the venture, he sweeps away the work of years and then comes to say that he is ready. This generous devotion is by no means limited to Great Britain. Doctors from Canada, from Australia, and from New Zealand have made the same sacrifice, and

have hurried to England to offer their services, without any regard to pay, appointments, or prospect of reward. In actual money the war will cost these good men heavily, but the memory of what they have done for England will be to them as the gold of Havilah, of which it is truly said, 'and the gold of that land is good.'"

The needs of the army are not yet satisfied, and the Medical Committees, both in England and Wales and in Scotland, are appealing for more medical men, physically fit and of military age, to join the army. Local committees have been set up in nearly all areas, and in order to co-ordinate and facilitate their work they have been informed of the number of men that, from a general consideration of the position, each should yield. The quota to be furnished by each district can finally be determined only when local conditions are fully understood and have been given their due weight. In some sparsely populated districts further depletion of the medical profession is probably impossible without running serious risk of depriving the civil population of medical assistance; and in other areas recent increases of population, due to the establishment or the enlargement of munition works, may well render it impossible for any more medical men to go. But looking to the country as a whole, there seems to be no escape from the conclusion that the demands must be met, and at present the medical profession has it in its own hands to meet the emergency by schemes which it shall itself establish and work. Already we hear of cases in which Lord Derby's local committees, with their lists of all kinds and conditions of men eligible for military service, have applied to medical men, but we would hope that when the action already taken by the medical profession itself is understood, such applications will not be repeated. But this can only be on condition that the effort made by the medical profession through its own organizations is successful.

The King in his appeal spoke of the pride he felt in the voluntary response from British subjects all over the world "who have sacrificed home, fortune, and life itself, in order that another may not inherit the free empire which their ancestors and mine have built. I ask you to make good these sacrifices. The end is not in sight. More men and yet more are wanted to keep my armies in the field, and through them to secure victory and enduring peace." Lord Derby, in launching the scheme of voluntary recruiting, for which as Director-General of Recruiting he is responsible, told every man that he must ask himself "whether, in a country fighting as ours is for its very existence, you are doing all you can for its safety, and whether the reason you have hitherto held valid as one for not enlisting holds good at the present crisis."

The medical service is an essential part of a successful army, and its value has been abundantly proved in this war by the high standard of health maintained among the troops, by the almost complete absence of epidemic disease, and by the efficient transport and treatment of the wounded. If, then, we believe that we shall win the war an adequate medical service must be supplied and its wastage made good; if we do not win the war in France and in the Mediterranean, we shall have to fight it in this country, and General Joffre, who seems to be a man given to weighing his words, said recently: "The policy of terrorism was as coldly and calmly determined upon as the decision to violate the neutrality and break the national word of honour in the invasion

¹In an interview published in *Collier's Weekly* and quoted in the *Times*.

of Belgium. It is the German military theory of invasion, decided upon by the German military leaders, that the way to break down the resistance of the country you are invading is to devastate it, burn its villages, shoot civilians on trumped-up pretexts, or drive them before your own troops to stop the fire of the enemy, as they did in numerous cases with us, in the belief that human beings can be terrorized to the extent that they will prefer to surrender rather than risk the horrible results of resisting the invader."

If we allow a stalemate with a consequent patched-up peace, we shall not only have to bear losses in men and money, which we must in any case bear, but we shall have to bear them knowing that they have been incurred in vain, for, again to quote General Joffre, "Peace to-day would be a crime toward posterity. It would only be an armistice in which every nation would continue feverishly to prepare for war. The French nation is too intelligent to deceive itself or to be deceived. We are not fighting a nation with the same ideas as our own, but a nation drunk with the idea of imperial domination, a nation which believes that in the progress of the world there is no place for little nations. The decision as to whether Europe will continue as free and individual will be made in this war alone. Either we win the right now to continue democratic and peaceful, or we surrender Europe to the imposition of an imperial idea. You will find, wherever you go, that the French people know this. You will find them absolutely of one opinion. They are prepared for anything, and they know what the issue is. We do not need to lie to our soldiers. No matter how long the war lasts, it will be fought out until we have conquered the right to leave a heritage of peace to our children."

LORD DERBY'S COMMITTEES AND THE MEDICAL PROFESSION.

We hear that in a certain district the local representatives of the Director-General of Recruiting have approached some of the medical men of military age whose names have not been "stared." This news should awaken the profession to the fate which is in store for it if the call to service made in England and Wales by the Central Medical War Committee is disregarded. It is hardly likely that Lord Derby's local committees contain the adequate medical representation upon which so much stress used to be laid in another connexion. In the case of the particular doctors to whom communications have so far been addressed, we believe that the difficulties to be surmounted in setting them free to take service are very great indeed, but those difficulties will not appeal to laymen with the same force as to members of the medical profession. As a forerunner of what will happen if conscription should come into being, the new recruiting methods seem worthy of notice, and we hope that our readers will ask themselves whether the scheme of enrolment for selection by such a committee as the Central Medical War Committee is not better suited to the conditions which must be fulfilled in order to satisfy the medical needs both of the army and of the civilian population. The question seems to invite the attention also of the Director-General of Recruiting and of the medical authorities at the War Office. To Lord Derby we would suggest that the special services required from the medical profession demand special treatment analogous to that recognized to be necessary in the case of munition workers, railwaymen, and others engaged in work necessary to the conduct of the war and the minimum requirements of the civil population. Medical men are urgently required in this country as well as with the armies at the front; and the adjustment of

service in the two capacities is a delicate matter requiring expert knowledge. The Army Medical Department, we are sure, will give every assistance to the attempt to supply its needs without resort to conscription, and will avail itself of the sympathetic and whole-hearted support offered by the Central Medical War Committee. Until this support seems likely to fail, we may hope that the department will not favour the newer methods.

MISS CAVELL'S FATE.

MISS EDITH CAVELL, whose execution, after a summary trial, and in such haste that the protests of the American and Spanish ambassadors were not heard, has excited the indignation of the civilized world, was matron of *l'École Belge des Infirmières diplômées* at Brussels. That institution at the outbreak of war had about eighty nurses and pupils engaged in working and training at public hospitals and a clinic, and as school nurses. She remained in Brussels after the German occupation, carried on her work, and nursed persons of all nationalities. The Germans seem already to have discovered that the abominable act perpetrated in the Belgian capital was a blunder, worse than a crime. How bad a blunder it was is shown by the futile excuses that have been made. The latest, put forward this time by the German Under Secretary of Foreign Affairs, is that Miss Cavell was one of the leading members of a conspiracy to assist British, Belgian, and French soldiers to escape from Belgium. Therefore, says Herr Zimmermann of his nation, "Headless of the world's verdict, we must travel the hard road of duty"; or, in other words, "we must continue our system of frightfulness." There are a great many judicial murders in history which have been justified by lawyers, and this is one of them. The prerogative of mercy resides in the Crown, and the German Emperor in this case did not exercise it, although, according to the telegraph agencies, he was at the time in Belgium, and could, in any case, have been reached in an hour or two, wherever he was. He is reported to have said recently, when reading a diplomatic document relating to Great Britain, "I will never forget." Nor will we, "but put in every honest hand a whip to lash the rascals naked through the world." A fund is being raised in memory of Miss Cavell, and it is proposed to devote it to the extension and improvement of the nurses' home at the London Hospital, where she was trained. Without wishing to discourage a laudable impulse, we are inclined to think that Lady Frances Balfour has said the truest word: "Let her name be graven on the fleshy tablets of the heart of her countrymen. Let the men remember Edith Cavell as they enlist in the armies of her King and country. Let gifts flow into those hospitals and nursing institutions which are being served by women as ready to do, to dare, and to die as was this type of England's race. There are other lessons to be learnt by Great Britain from the life and story of this citizen of our land. The times are not yet when her deeds can be enshrined in the immemorial walls of past history. Her blood calls from the earth for the greatest of all reprisals, that of showing that what she represented and stood for is the ideal goal of uncounted thousands of her country and her race."

LIFE INSURANCE IN INDIA.

In a paper read some little time ago before the members of the Life Assurance Medical Officers' Association,¹ Dr. Caddy reached a number of conclusions that should be of considerable interest to Europeans born or working in India. He holds that the European does not acclimatize in the tropics, but requires a change to a temperate climate at least every four or five years. Prolonged residence in the tropics debilitates him; and his children, if reared in India,

¹ *Transactions of the Life Assurance Medical Officers' Association, London.* Comprising the Report of the Proceedings for 1912 and 1913. London, 1914. (Denby 8vo, pp. xii + 266.)

have not, Dr. Caddy thinks, the same ability or capacity for work when they grow up as children sent home to England at the customary age of 4 or 5 years for education. Even after years of residence in hot climates the European acquires no power to withstand the tropical sun without any head covering, but rather the reverse. Dr. Caddy also finds that to have passed the first few years of life in India leads to physical debilitation, such children tending to be poorer specimens of humanity than their parents. So far as the natives of India are concerned, he remarks that the differences from the point of view of insurance between the various native races in India seem to be much more trivial than those met with in Europe; his own experience has been mainly with Bengalis. He concludes that the native of India is a shorter man than the European, but, height for height, of equal weight; he is very subject to glycosuria because of his carbohydrate diet, and to hydrocele for some reason that is not known. The opium habit, and the habit of smoking Indian hemp as "ganga" or "charas," or drinking it as "bhang," uncommon in Indians seeking to insure themselves, are probably more harmful to the individual than is commonly believed. As for Eurasians, or persons of mixed European and Asiatic descent, Dr. Caddy believes that the admixture of one-sixteenth of Asiatic blood is just noticeable; in accordance with a recent census return, all Eurasians are now called "Anglo-Indians," an unfortunate occurrence in view of the fact that "country bred" Europeans reared in India (as distinguished from those "home bred" by upbringing in Europe) still call themselves "Anglo-Indians." The imported European, we are told, earns in Calcutta a salary twice as great as the country-bred European, and four times as great as the Eurasian. The relative incapacity thus shown by the country-bred European, and still more by the Eurasian, is attributed by Dr. Caddy chiefly to the debilitating effects of the Indian climate. He concludes that Europeans born in India should leave the country as soon as may be, and should not return to work there. We give Dr. Caddy's views without in any way endorsing them. Many exceptions to his final generalization will occur to every one.

OPTOQUIN AND ANTIPNEUMOCOCCAL SERUM.

DR. H. F. MOORE has quite recently made a further addition to our knowledge of the treatment of pneumococcal infections by the quinine derivative, ethylhydrocupreine, otherwise known as optoquin, or, in German, as optochin. A reference to his previous work will be found in the BRITISH MEDICAL JOURNAL of October 9th last (p. 542). In his latest paper¹ Dr. Moore describes the excellent therapeutic results obtained by combining optoquin with antipneumococcal serum in the treatment of virulent pneumococcal peritonitis in mice. The bacterial culture and antiserum were injected together into the peritoneal cavity; the optoquin was administered in the form of a 2 per cent. solution in olive oil injected under the skin of the back. The pneumococcal strain employed was so virulent that one-millionth of a cubic centimetre of a twenty-four-hour broth culture was fatal to mice in forty-eight hours. Preliminary experiments showed that the antipneumococcal serum in a dose of 0.2 c.c.m. protected the mice against something between one-hundredth and one-thousandth of a cubic centimetre of the culture; while the injection of optoquin was inadequate to protect the mice against even so little as 0.0001 c.c.m. of the culture. Yet in combination, the antiserum and optoquin protected the mice against as much as 0.5 c.c.m. of the culture in seven cases out of eight, one mouse succumbing to pneumococcal septicaemia on the fourth day. Thus it appears that the single small dose of optoquin was capable of increasing the threshold value of the type homologous serum, to use Dr. Moore's words, at least fifty times; there is no simple summation here of the

protective effects of the serum and optoquin. No such effect was obtained when the antiserum used was one produced from a different strain of pneumococcus, and not from the strain employed for the infection of the experimental animals. The treatment of pneumonia in man by antipneumococcal serum has often been attempted, but has proved generally disappointing. It would be interesting to know if the combined treatment here by the specific antiserum and optoquin will be found efficacious. At first sight one would doubt whether in this instance mice and men are on an equal footing.

SERUM THERAPY IN POLIOMYELITIS.

SINCE the summer of 1909 sporadic cases and small epidemics of acute anterior poliomyelitis, or infantile paralysis, have not been uncommon in France. This fact has enabled Dr. Netter to develop¹ a method of treatment that promises to have a certain value in the acute stages of the disease, and has, indeed, already been employed in thirty-two cases during the last five years. The treatment consists in the intrathecal injection of the serum of a patient who has recovered from the disease. It is not lacking in an experimental basis. Thus Flexner and Lewis have shown that, in the case of apes, such serum possesses a distinct curative power if administered early in the course of the poliomyelitis, whether the serum is of human origin or simian. Attempts to obtain an active antipoliomyelitic serum from the horse have hitherto failed. Netter points out that poliomyelitis is generally a far more serious disease in apes than it is in man. In apes it incubates for about a week, and then causes a general muscular paralysis within a day or two, death habitually following from one to six days after the onset. The prodromal symptoms before paralysis appears last only half a day or a day in apes; whereas in man the prodromal period lasts from two to four days, a point of capital importance in view of the fact that Dr. Netter's treatment is designed to render the attack of poliomyelitis abortive, and should be applied if possible before or soon after the paralysis has declared itself. The mortality of poliomyelitis is less in human beings than it is in apes, having varied between 5 and 17 per cent. in the different European and American epidemics of the last decade. The type of disease was severe in Dr. Netter's 32 cases; 8 of them died, 7 with signs of bulbar paralysis. The treatment consists in the daily intrathecal injection, usually for eight consecutive days, of from 5 to 13 c.c.m. of the sterile ("tyndallized") human serum, derived from a patient who has had poliomyelitis. Dr. Netter remarks that the serum of a person who has had infantile paralysis appears to preserve its efficacy for as much as thirty years; he prefers, however, to employ the serum of people whose poliomyelitis dates back only five years or less. He has noticed that this human serum is less irritating to the patient's system than horse serum, but may give rise to a typical outburst of urticaria; it also occasions an inflammatory reaction in the spinal meninges, the "purulent aseptic effusion" described by Widal, highly albuminous and containing mainly polymorphonuclear leucocytes. This "serous meningitis" may cause alarming symptoms, but is not really to be feared. It appears that Dr. Netter would increase the amount of serum injected in his treatment if it were not so hard to come by. What are the results hitherto obtained? As has been mentioned already, most of the 32 cases were severe in type, and only came under treatment after the paralytic stage had lasted several days. Six of the patients made rapid and complete recoveries, 3 made nearly complete recoveries, 7 were greatly improved; in 5 cases the improvement was considerable, but could not be certainly attributed to the treatment, 3 patients were unimproved, and 8 died. Dr. Netter finds these figures full of encouragement, and urges the further employment of his

¹ *Journ. Exper. Med.*, New York, 1915, xxii, 383.

¹ *Bull. de l'Acad. de Méd.*, Paris, 1915, lxxiv, 405.

treatment. The earlier it is begun—say within from one to four days of the onset of the paralysis—the better the outlook.

WAR ORTHOPAEDICS.

WE ventured to say, in an article on war orthopaedics published a fortnight ago, that we had some reason to think that sufficient use was not being made of the military orthopaedic centre at Alder Hey, near Liverpool. This belief has been confirmed by information subsequently received, and it may therefore be useful again to mention the matter. Alder Hey was started as a centre where orthopaedic cases among wounded men might receive special attention. It was intended in particular that cases of stiff or deformed joints, contracted muscles, malunited or ununited fractures, and other cases of similar nature, should be sent there from the various military hospitals in the country. It is provided with special equipment for dealing with such cases, and has the advantage of the services of Major Robert Jones, Lecturer on Orthopaedic Surgery in the University of Liverpool. In the Eastern Command a hospital was opened at Croydon last July for the treatment of men suffering from the results of gunshot injuries of peripheral nerves, stiff joints, etc. The equipment was organized under the direction of Sir Frederic Eve, a consulting surgeon to the command, and Dr. R. S. Woods. There is an operating-room where operations on nerves are performed, suitable appliances for electrical and radiant heat treatment, and for passive and active movements by the latest type of mechanical apparatus. A portion of the hospital is set aside for the treatment by massage and passive movement of slighter disabilities arising from stiff joints, under Lieutenant-Colonel Romer, R.A.M.C. A staff of masseuses has been supplied by the Almeric Paget Massage Institution.

HYPOCHLOROUS ACID AS AN ANTISEPTIC.

SURGEON H. E. R. STEPHENS, R.N., contributes to the October issue of the *Journal of the Royal Naval Medical Service* a paper on the use of hypochlorous acid as an antiseptic. His observations were made with eupad and esul, the preparations devised by Professor Lorrain Smith and his colleagues in Edinburgh and described in the *BRITISH MEDICAL JOURNAL* of July 24th. Surgeon Stephens says that the solution has been used as a general antiseptic in H.M.S. *Lion* since June 11th, 1915. If fresh wounds were washed freely with esul, no pus was seen subsequently, and the experience, though limited, was that the progress of wounds of all kinds bore out fully the results of experimental investigation. Boils, after incision, were syringed out with the solution, and a wick of gauze impregnated with eupad inserted; they cleaned rapidly; whitlows were treated in a similar manner. Cases of follicular tonsillitis and sore throat were treated successfully with esul, and in pyorrhoea alveolaris fetor disappeared, the gums took on a healthier appearance, and the discharge of pus was considerably diminished. The chief disadvantages were that the solution readily attacked metallic instruments and fabrics of all kinds, and that both powder and solution must be kept in stoppered bottles in a cool place out of light. If used in close compartments ventilation should be attended to. Its advantages were that it was an extremely powerful antiseptic, that its effect was purely local, that it was extremely cheap (at least 150 times less expensive than iodine), and that it was simple to prepare and did not irritate the wound. If a slight tingling sensation was experienced it passed off as a rule in a few minutes. Some oedema of the skin surrounding the wound might be observed if a esul compress were applied for a long

period, but this could be prevented by a vaseline smear. He also considers that the antiseptic, being gaseous, penetrates deeper than solutions.

ENTRIES AT THE MEDICAL SCHOOLS.

THE number of medical students who have entered at Cambridge this year is 41. The number who entered at the corresponding period last year was 64; in 1913 there were 116. In London there seems to have been, as was stated last week, a general falling off of students entering for the full course. At St. Thomas's Hospital the entry is about 45 per cent. of the average, and it is believed that many of the students so entering will in present conditions enlist within the next few weeks. At St. Mary's Hospital the decline, as compared with the average for the three years prior to 1914, is about 23 per cent.; at King's College Hospital Medical School it is about 11 per cent.; at Guy's it is about 10 per cent.; at St. Bartholomew's only 2 per cent. At University College Hospital Medical School the entry is a little below the normal, while at the London Hospital Medical School the entry is only 5 per cent. below the normal, and is actually larger than in 1913. These statements are subject, more or less, to the same qualification as is noted in regard to St. Thomas's—namely, that many men who now enter may presently abandon medical studies in order to enter the army. At all the schools the entry for special post-graduate classes has declined materially, and probably the experience of other schools is similar to that of St. Mary's Hospital, where the returns for 1914 showed a fall of 48 per cent. and those for 1915 of 62 per cent., as compared with the average figures for the entries for post-graduate courses for the three years before the war. At the London School of Medicine for Women the number of students who have entered is 110, as compared with 69 last year, and an average of 44 for the three years preceding the war.

NOSTRUMS IN THE UNITED STATES.

THE American Public Health Association, at its recent meeting in Rochester, New York, adopted a resolution condemning the sale of "patent medicines" and nostrums whose constituents are unknown to the health authorities, and heartily endorsing the ordinance of the New York City Department of Health, which requires the manufacturers of proprietary remedies sold without a physician's prescription to file with the department a statement of their active constituents and the therapeutic claims made for them. The *Medical Record* states that the Health Department reports that the new registration ordinance is meeting with encouraging response; a considerable number of manufacturers have already applied for registration, and several of the larger retail druggists in New York have notified the manufacturers of patent medicines that after January 1st they will refuse to handle all patent medicines which fail to comply with the ordinance.

THE next session of the General Medical Council will begin on Tuesday, November 2nd, when the President, Sir Donald MacAlister, K.C.B., M.D., will take the chair at 2 p.m.

THE *Times* announces that, with the full concurrence of the Governor-General in Council, His Majesty's Government has decided to postpone indefinitely the publication of the report of the Royal Commission on the Indian Public Services, which was signed last August. The decision is in accordance with the desire expressed last January by the Viceroy, and loyally carried out by the non-official members of the Council, that controversial issues should be set aside during the continuance of the war.

Medical Notes in Parliament.

Naval and Military War Pensions Bill.—When the Lords' amendments were brought up on October 14th the Chancellor of the Exchequer obtained an adjournment of the discussion. On October 21st Mr. Hayes Fisher, Parliamentary Secretary to the Local Government Board, in moving that the Lords' amendments should be considered, said that the Government was convinced that the subject required much more drastic and thorough treatment than could be given to it at the present time owing to the pressure of other business. He hoped that a larger measure would eventually co-ordinate the work so as to bring all matters connected with pensions, grants, and allowances to sailors and soldiers under one pensions board and into one pensions buildings with which he hoped auxiliary voluntary bodies would be in close communication. While accepting some of the Lords' amendments, the Government desired to restore the provision with regard to the Royal Patriotic Fund Corporation, thus making the statutory committee more or less a voluntary body relying more or less upon voluntary funds. The Government desired that the bill should be taken much in the shape in which it left the House of Commons, as an experiment to be worked as well as possible for the next six months. During that time much would be learnt about the scope and permanence of the problem. The House agreed to the course proposed by the Government, the most important point in which it disagreed with the Lords being the proposal to set up a "War Allowance Board." The amendment providing for the appointment on the statutory committee of two representatives of the Soldiers' and Sailors' Families Association was agreed to.

Midwives Bill (Scotland).—Mr. Lloyd George informed Mr. Hogge, on October 26th, that he was not without hope that arrangements would be made for introducing a Midwives Bill for Scotland at an early date.

Bovine Tuberculosis Order (Ireland).—On October 20th Mr. Clancy asked a question as to a resolution passed by the County of Dublin Insurance Committee relative to what was described as the grave danger to the purity of the milk supply and the consequent results to the health of the community, especially of the young, caused by the withdrawal of the Iovine Tuberculosis Order. Mr. Birrell said that all provisions of the Order save one had been suspended in Ireland as in Great Britain, and for the same reason, namely, retrenchment of expenditure. The local authorities were not consulted before the suspension, but a circular fully explanatory of the position was sent to each local authority by the department.

Experiments on Living Animals.—On October 20th Mr. Greenwood asked why the names of those licensed experimenters on living animals who had committed a breach of the law in the course of such experiments were suppressed in the returns relating to such experiments. Sir John Simon said that if the offences were serious and a prosecution followed the name would, of course, become public; but it had never been the practice to publish the names of persons guilty of technical offences or the omission of formalities which could be adequately dealt with by reprimand. He did not think any useful purpose would be served by altering the rule. The Royal Commission discussed the point in their report, but made no recommendation in favour of publication. Sir John Simon, in replying to a further question by Mr. Greenwood on October 21st, said that it was decided this year on grounds of economy, in the return of experiments on living animals during 1914 and other Home Office returns, to exclude any matter not really essential. Information regarding the various certificates granted under which experiments were allowed could be obtained by reference to the return for any preceding year.

Drugs from Germany.—Mr. Rawlinson on October 21st asked whether facilities had been and were being given by

the Foreign Office for the free passage from Germany to neutral countries of drugs and other articles manufactured in Germany, and, if so, whether he could state the approximate value of such goods ordered and delivered since March 1st, 1915; and further, under what Order in Council or document such facilities had been granted. Sir E. Grey said that to describe the action of His Majesty's Government in these cases as a grant of facilities was to use a form of words which might give rise to misapprehension. There was no question of any action taken under an Order in Council or in virtue of any legislative enactment. What His Majesty's Government did was to give directions to His Majesty's ships that particular consignments were not to be captured and brought in for adjudication in a Prize Court. As regards goods ordered and delivered since March 1st, 1915, such action had only been taken—

(1) In the case of a few consignments of certain drugs unobtainable except from enemy territory or having no chemical equivalents procurable outside enemy territory, such as salvarsan and novocain; (2) in the case of certain natural products—for example, sugar beet seed—urgently required by important industries in other countries and unobtainable except from enemy territory; and (3) in the case of machine knitting needles, beet sugar slicing knives, scientific or technical publications required by universities or educational establishments in a neutral country, and a few articles, such as a stained glass window, required by religious establishments to complete orders placed a long time ago with an enemy firm.

It was difficult to form an estimate of the value of these articles, but he believed it would be certainly less than £300,000 altogether. It should be added that these consignments had been allowed to pass either in response to urgent representations by certain neutral Governments, based sometimes on undeniable humanitarian grounds, or to meet certain home demands.

Gallipoli Casualties.—Dr. Macnamara stated, in reply to Mr. King on October 21st, that exclusive of the Royal Naval Division, the casualties for which were included in the figures given by the Under Secretary of State for War on October 14th, the figures up to October 20th were as follows:

	Officers.	Men.
Killed	54	859
Wounded	56	524
Missing	9	80

Gifts from India.—In the course of a reply to Sir John Jardine on October 20th, with reference to the contributions received from the ruling chiefs and others in India in connexion with the war, Mr. Chamberlain, Secretary of State for India, stated that three hospital ships had left India—the *Loyalty*, given jointly by the ruling chiefs; the *Madras*, given by the Madras War Fund; and the *Bengali*, given by the people of Bengal. The last had unfortunately been wrecked on its way to the Persian Gulf; the first two had been continuously employed this year in carrying sick and wounded between India and the theatres of war. Among the gifts of the Maharaja Sindhia of Gwalior was a motor ambulance fleet, while the Maharajas of Kashmir and Patiala and the Jam of Nawanganar, besides other services, were jointly maintaining a hospital for officers in a house at Staines which His Highness the Jam had given for the purpose.

Mentally Injured Soldiers.—In reply to Mr. Touche, Mr. Tennant stated, on October 26th, that the administration of asylums or parts of asylums in which soldiers were treated was under the full control of the War Office. The arrangements now in force adequately safeguarded the interests of uncertifiable soldiers. The cases of mentally injured soldiers admitted to such institutions were treated as nerve shock cases in which recovery was possible or probable. The number of certifiable cases relatively to the size of the army was very small.

Doctors' Chauffeurs and Badges.—In reply to Mr. Tyson Wilson, who on October 26th asked whether chauffeurs of medical men who were attending military hospitals two or three days a week would be allowed to wear war badges, Mr. Lloyd George said that it was not considered that in these cases the conditions governing the use of war service badges had been satisfied.

THE WAR.

DUCHESS OF CONNAUGHT CANADIAN RED CROSS HOSPITAL.

THE Duchess of Connaught Red Cross Hospital at Cliveden, Taplow, has been considerably enlarged. The original hospital was created by Major Waldorf Astor, M.P., out of covered tennis, fives, and racquets courts, and consisted of four wards of 130 beds, with an operating and x-ray room. A dining-room, kitchen, and annexes were built on. The equipment was done by Colonel Hodgkiss, Commissioner of the Canadian Red Cross, and the hospital was placed under Lieutenant-Colonel Ford, and subsequently, when he went to France, under Lieutenant-Colonel C. W. F. Gorrill, who is now in command. The Registrar is Captain Neff of Edmonton, and the pathologist and bacteriologist Captain Morell, city pathologist, Regina. All the other members of the medical and surgical staff belong to the Canadian Army Medical Corps, but as the personnel varies from time to time we are not in a position to give a list of the staff. All the nurses and orderlies are furnished by the Canadian Army Medical Corps. The medical officer and nurses are commissioned, the latter with the relative rank of lieutenant in the Canadian Army Medical Corps. The hospital is one of the central hospitals of the Southern Command, and accepts direct from overseas all patients sent by the D.D.M.S., Southampton. That is to say, its patients are not confined to the men of the Canadian contingent, and recently the majority of inmates were not Canadian.

In response to the request for further accommodation, a large hut hospital has been erected by the Canadian Red Cross Society, by contributions from Canada, on a site facing south and east, adjoining the original structure.

The new buildings, which were taken into use on July 12th, consist of five pairs of wards facing southward at a very open angle (butterfly pattern), strung together by two central corridors. Each of the principal wards has a verandah where patients can sit out, and where many of them sleep. The southern windows are not glazed, but fitted with fine woven wire netting. Between the two central corridors are the lavatories for each pair of wards, and on either side of the approach to each ward proper a ward scullery, a room for washing pans, two single bed wards, and a small kitchen for making tea and so on, are provided. The southern end is a building differently arranged, providing three wards, and towards the north is another separate building for "walking cases." Isolation beds are provided in a separate building. The medical and nursing staff are accommodated in a house and half a dozen cottages which have been provided and fitted up for them by Major Astor on the estate.

The wards are one-story buildings; the framework is constructed of wood, with double asbestos walls. The new operating theatre has just been completed. It consists of a large and well lighted theatre, with anaesthetic, sterilizing, x-ray, and dark rooms, and lavatories for the surgeons. In another block are rooms for the special departments, eye and ear, dental, and pathology. The original dining room and kitchen are being enlarged. The food is taken from the latter in heated food-carrier trolleys to a central serving-room provided with hot plates. The portions are here served and taken in smaller heated food trolleys, each of which has space to serve one ward. The hospital is lighted throughout by electricity made on the spot, and has its own water supply also provided from Cliveden. Sewage is disposed of on the septic tank principle, and garbage and dressings are incinerated.

The feature of the hospital which seemed to us on a recent visit particularly worthy of commendation is the reception block. It is a long building containing five apartments. The motor ambulances which bring the men from Taplow station, about two miles away, draw up at the southern end of this building. The wounded man is immediately brought into the reception office, where his name and other particulars are entered and compared with the nominal roll from the ambulance train. He then passes into a waiting-room provided with chairs, where he stays until he can be admitted into the dressing-room. There he leaves all his clothes except his cap and boots,

and passes into the bathroom, where there are ten fitted baths provided with hot water. From there he goes into the next room, is given clean clothes, and directed by the orderly officer to the appropriate ward. The time occupied from the moment the man leaves the station in the motor ambulance to the moment when he is in bed in his ward is under an hour, and it has been found possible to pass as many as sixty men an hour through the reception block.

Canadian convalescents are drafted from the Cliveden Hospital to the Canadian Convalescent Hospital at Hillingdon House, Uxbridge, and men must often leave with regret, for Cliveden is beautifully situated, and the grounds are a fine example of landscape gardening on the large scale.

MEDICAL ARRANGEMENTS OF THE BRITISH EXPEDITIONARY FORCE.

[From a Special Correspondent in Northern France.]

THE WORK OF FIELD AMBULANCES.

IN a note published in the BRITISH MEDICAL JOURNAL last winter it was indicated that while no adequate reason had yet presented itself for departing from accepted methods of conducting the training of field ambulance units, it was clear that the work of those then in process of formation or awaiting orders for the front might not be quite what they expected.

At the time this statement was made there were already circumstances which justified it, and the accuracy of the forecast has been borne in all particulars by the events of the past six months. That period has seen the arrival in France of troops who were then only in training, and it was contact with certain field ambulances connected with these reinforcements that reminded the writer of what he had read in the JOURNAL as to the diversity of offices that field ambulances as a whole might find themselves expected to fulfil.

The first of these units, which may be entitled A, was engaged in work in no wise resembling that which the term "field ambulance" suggests. Instead of being more or less constantly on the move, and occupied in the collection of the wounded from the regimental aid posts, in doing emergency operations, and in passing on its cases to a casualty clearing station, it was an entirely stationary unit, fulfilling a triple function of a much less exciting kind. Its vehicles had been parked for the time being, and its staff and personnel were divided up to run a clearing station for infectious cases, a bathing establishment, and an institution somewhat misleadingly termed a "convalescent hospital."

Its occupation, it is to be noted, was not in the least due to the fact that it was a newly arrived unit. The primary cause was that a need for the work in question had been created by the circumstances of the war, and that the need was not directly anticipated by the *ante bellum* textbooks or assisted by army regulations to any unit created for the purpose. The secondary cause was that A was free to undertake it. It was free to undertake it because, thanks to the siege-like character of the military operations then and now in progress, to the abundance of motor ambulance convoys, and to the proximity of the casualty clearing stations, two of the three field ambulances belonging to the division served by unit A fully sufficed for all the field work required.

The occupation of other field ambulances—which may be called B, C and D—also illustrated the same point, though not perhaps quite so completely.

B, like A, was a territorial unit, but serving a different division, and also like A had at least three jobs in hand. It was running simultaneously a rest station, a laundry, an advanced dressing station, and a respirator factory. At the latter native labour was employed, but the whole work was in charge of an officer of unit B, with a file or two to assist him in its supervision.

The head quarters of units A and B were in a town of some size but unit C was more or less under canvas. It was running a rest camp and small bathing station, and was bivouacked around the farm buildings taken over for the purpose. C was a unit of long standing; it had, in fact, arrived in France with the first detachment of the Expeditionary Force, but, just as in the case of units A and B, its services in its usual capacity were not

required for the moment by the division to which it belonged.

As for D, this letter relates not to a single unit but to all three field ambulances of one particular division. On paper they preserved their independence, but otherwise they had practically combined. Their general head quarters were in a village of some size, and between them they were running a large rest camp, which included a bathing station, a "convalescent hospital"—established in a permanent building of some size—and two dressing stations, one in an advanced, the other in an intermediate position.

Their various officers were taking turns of duty at regular intervals in connexion with all the different enterprises conjointly carried on, and in this way all shared fairly whatever was to be had in the way of dull work or exciting work, risky posts or safe posts, soft jobs or hard jobs.

The same idea of sharing all forms of work also underlay, I understood, the arrangements of the divisions to which units A, B, and C belonged; at intervals the different field ambulances of each of the divisions concerned were to exchange position and occupation. Whether the plan was ever put into effect I do not know, for the next time I was in the same area I found that units A, B, and C, together with the divisions to which they belonged, had all moved to a distant part of the line, and the work they had been doing was now in other hands.

The occupations described do not as a whole sound particularly interesting or likely to appeal to men so mentally and physically constituted as to be led—as far as concerns the officers of units A and B—when joining the Territorial Force, to select a field ambulance unit.

Nevertheless, there did not seem to be any disposition to grumble at their existing employment. They did not expect to be thus engaged for any very long period, and meantime they were anything but mere machines. The work demanded not only industry and energy, but also plenty of organizing power. In addition, its utility was obvious.

It will have been observed that in the case of only one of the units did the duties described include no field work whatever. They were, in short, not exceptionally situated units, but engaged in a fashion which made them as a whole a very fair sample of their class. The needs of all divisions are much the same in the matter of baths, cleansing operations, rest camps, and their like, and unless they are met by some arrangement available to a large number of divisions it is to its A.D.M.S. and the field ambulance under his command that a division looks for assistance in the matter. Obviously rest camp and convalescent work is medical, and baths and clean underclothes are such powerful adjuncts to directly medical measures for keeping the men in good health that all A.D.M.S., I believe, regard it as part of their ordinary duty to see that they are made available. But, of course, they always bear in mind the possibility of a general advance or a heavy local offensive or defensive operation suddenly and greatly increasing the need for field work, and take care that it should be possible instantly to release the personnel of the field ambulance units for this purpose. Given the occasion, rest camps and convalescent hospitals must be temporarily evacuated, baths and washhouses closed, unless the D.D.M.S. of the army corps involved prefers to fill the vacated posts by drawing M.O.'s temporarily from some other division or by asking the D.M.S. of the army to which his corps belongs to get up additional medical officers from the base. But in this matter there can rarely be any great difficulty. Divisions which are heavily engaged have no time for baths, and heavy fighting seems in itself to be a sovereign remedy for most of the ills that help to fill the rest camps and convalescent hospitals. A glance at the sickness and casualty chart of almost any division will show this.

The infectious case clearing station mentioned at the beginning of this note was not specially intended for the benefit of the division to which the field ambulance in charge of it belonged. Like an ordinary casualty clearing station it was an army head quarters unit and part of the general machinery—some prearranged, some improvised, to meet new needs—for keeping down the wastage due to zymotic disorders. All cases of illness diagnosed at a regimental aid post or an advanced dressing station or elsewhere in the area as probably of an infectious order were sent there

for final diagnosis and disposal, instead of to the nearest casualty clearing station. The necessary accommodation was provided by some modern farm buildings and a number of marquees, and it allowed of six different classes of cases being separately isolated. The patients remained, as a rule, only a very few days. The diagnosis assured—with the help of a mobile laboratory, if need be—the patient was sent on to a base, either in the isolation coach of a hospital train or by a special ambulance, usually the latter.

The scope and status of the other enterprises varied a little. The rest camps and convalescent hospitals confined their work to men of their own respective divisions, but one of the bathing establishments seemed to have been prepared for work on a still larger scale.

The means at the disposal of these bathing establishments were in some cases primitive, but their scheme of work was identical and they all attained their primary aim. This was to provide each man admitted with a bath of hot water and plenty of soap, and to substitute for the underclothing that he was then wearing a set which was both clean and in good repair. At the larger establishment that has been mentioned they went a good deal farther than this—they turned a man out not only completely re-equipped in the matter of under garments, but attended to his external clothing as well.

As it had been dealing on these lines with an average of just under 1,000 men a day for many successive weeks, it is natural to surmise that its arrangements were elaborate and its premises especially suited to the end in view, and this was the case. The work was done in a very large building which, being in peace times a linen weaving and dyeing factory, possessed fittings readily adaptable to the requirements of a combined bathing, clothes washing, and repairing establishment on a very extensive scale—boilers, hot-water pipes, drying racks, and huge vats in each of which half a dozen men could bathe simultaneously.

The men as they arrived—commonly in companies—made their outer clothes, all except their boots, into bundles, which were then taken to a sterilizer, and the men moved in sections into the vat room. There they stripped to the buff, throwing each separate garment into a separate receptacle—one for vests, one for pants, one for socks; they then took their baths and dried themselves, the whole process being timed and lasting a given number of minutes. The redressing arrangements, which included the issue of fresh underclothing in good condition, were conducted in a separate hall. Meantime and all day long laundry and repairing work went on in different halls, all the various appliances required in the way of washing, wringing, and sewing machines being provided, and about 100 women being employed to work them.

The term "convalescent hospital," which has been used in speaking of the work of two of the units mentioned in the previous note, is not strictly official. The institutions to which it is applied were two large, well-fitted buildings, which might be regarded as the tent sections of the ambulances concerned. Their accommodation was more elaborate, but their work was identical with that of the rest stations or camps. The patients were for the most part men suffering from slight ailments or injuries—tired men, footsore men, men with slight bronchial attacks, stomach troubles, passing skin complaints, men undergoing antipyretic inoculation, and men suffering from pyrexia not deemed to be premonitory of serious disorder. If any patient failed to fulfil expectations by not getting quite well within a few days, or if he developed symptoms suggesting the probability of prolonged illness, he could always be sent to a base via a casualty clearing station, and meantime he was receiving all the attention he required. These rest stations, in short, fulfilled a double purpose. They supplied a means (1) of bringing a possibly serious case under treatment when in an incipient stage, (2) of conforming to an accepted axiom, namely, that cases likely to be fit to return to duty within a limited time should not be removed for treatment to a greater distance from their units than was unavoidable.

Finally, it should be mentioned that it is not always under the title of rest station or convalescent that work of this kind is carried on. A good deal depends on local circumstances, including the proximity of the field ambulances to one another and to a casualty clearing station; the character of the accommodation that a field ambulance

can secure; and the nature of the ground just behind the actual fighting line; and the distance between the opposing trenches.

In some cases ambulances may be so situated that they can carry on both rest stations and ordinary tent section work, simultaneously and in the same building. In other words, they can provide both for the seriously wounded and sick men who, after receiving a certain amount of attention, will be sent on to a casualty clearing station, and for the light cases whose treatment would begin and end at the ambulance itself.

As for the field work of ambulances its description or discussion was not one of the objects of this note. Since, however, so much stress has been laid herein on what may be described as the civil side of field ambulance life, it may be well to accentuate the fact that it is for youngish or at all events hardy men that ambulance duty is best fitted. Taken as a whole it involves a roughish life and a considerable spice of danger.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Died on Service.

Honorary Lieutenant and Quartermaster J. T. Fry, R.A.M.C., was reported in the casualty list published on October 25th as having died on service in France. He was promoted to a commission so recently as last July.

Wounded.

Captain R. O'Kelly, R.A.M.C., France.
 Captain E. Scott, R.A.M.C. (temporary), France.
 Lieutenant A. K. Roche, R.A.M.C. (temporary), France.
 Lieutenant J. P. Shaw, R.A.M.C. (temporary), France.
 Lieutenant J. Macgregor, R.A.M.C. (temporary), France.
 Lieutenant C. K. Dudgeon, R.A.M.C. (temporary), France.
 Lieutenant W. T. C. Frew, R.A.M.C. (temporary), France.
 Dr. K. K. Grieve, West African Medical Staff, Cameroons.
 Captain H. C. Mulholland, R.A.M.C. (temporary), France.
 Captain W. K. Campbell, R.A.M.C. (Special Reserve), France.
 Lieutenant L. L. Fyfe, R.A.M.C. (temporary), France.
 Lieutenant C. M. Dickinson, R.A.M.C. (temporary), France.

Wounded and Suffering from Gas Poisoning.

Lieutenant J. R. Turner, R.A.M.C. (temporary), France.

Suffering from Gas Poisoning.

Lieutenant N. S. Whitton, R.A.M.C. (temporary), France.

Missing.

Captain J. Morham, of the 4th Queen's Edinburgh Battalion of the Royal Scots, reported as missing in the Dardanelles, though serving as a combatant officer, was a medical man. He was the son of the late Robert Morham, City Architect, Edinburgh, and was educated at the Edinburgh Institution, where he was for some years in the Rugby fifteen. He took the L.D.S. of the Edinburgh Royal College of Surgeons in 1906, and the Scottish triple qualification in 1908, and was in practice as a dentist in Edinburgh. He joined the 4th Queen's Edinburgh in 1900, became Second Lieutenant in 1910, Lieutenant on July 10th, 1912, and was recently promoted to Captain.

DEATHS AMONG SONS OF MEDICAL MEN.

Bunce, Ronald Macdonald, Second Lieutenant 3rd Lowland Brigade Royal Field Artillery (T.F.), only son of Dr. Alexander Bunce, of Pontefract, died at Craigleith Military Hospital, Edinburgh, on October 16th, from the effect of a fall from his horse. He was a medical student at Edinburgh University, where he was in the Officers' Training Corps, and had got his commission less than a month before, on September 22nd.

Fox, Andrew Stewart, Second Lieutenant 6th Battalion North Staffordshire Regiment, elder surviving son of Dr. Portescue Fox, of 36, Devonshire Place, London, W., killed in France, October 11th-13th, aged 21. His commission was dated March 20th, 1915.

Handford, Everard Francis Sale, Second Lieutenant 8th Battalion Sherwood Foresters, younger son of Henry Handford, M.D., F.R.C.P., of Elmfield, Southwell, Notts, killed in France, October 14th, aged 20. He was educated at Rugby, where he was in the fifteen, and had entered at Trinity College, Cambridge, but never joined, taking a commission from October 3rd, 1914.

Handford, Henry Basil Strutt, Captain 8th Battalion Sherwood Foresters, elder son of Henry Handford, M.D., F.R.C.P., killed in France on the same day as his brother, October 14th, aged 21. He also was educated at Rugby, where he was in the Officers' Training Corps; entered Trinity College, Cambridge, in 1912, and had taken a second class in the first part of the Law Tripos. He joined his battalion as Second Lieutenant in 1912, became Lieutenant on September 2nd, 1914, and had recently been promoted to Captain.

Nicholson, H. W., Captain 5th Battalion Lincolnshire Regiment, only son of Dr. J. W. Nicholson, late of Red Hall, Gainsborough, killed in France, October 11th-14th, aged 25. He was educated at Cheltenham and at Uppingham, and was by profession a civil engineer in the firm of Marshall, Sons and Co., Gainsborough. He joined the 5th Lincolns in 1908, and became Captain on September 7th, 1914.

Paton, James Ley, Second Lieutenant 1st Battalion Black Watch, eldest son of Major E. L. Paton, R.A.M.C.(T.F.), of Perth, killed in France on October 13th, aged 22. He was a final-year medical student of St. Andrews University, where he was captain of the university eleven and a member of the Rugby fifteen and of the golf team, enlisted at the beginning of the war, got a commission in the 8th Battalion of the Black Watch from November 4th, 1914, was transferred to the 1st Battalion, and went to the front during the summer.

Williams, Hubert C., Lieutenant 2nd Battalion Queen's Regiment, was killed in France on October 18th, while in command of a company of the 1st Battalion. He was 25 years of age, and the only son of the late Dr. Arthur Williams of St. Leonards, and Mrs. Arthur Williams, recently of Felixstowe. He was educated at Rugby, entered Sandhurst in February, 1911, and received his commission in the Queen's (Royal West Surrey) Regiment in February, 1912. He was wounded in Flanders during the operations after the fall of Antwerp, and for his gallant conduct at that time received the Military Cross. After recovering from the wound he was appointed signalling officer at Harwich, and had only returned to France at the beginning of October. He was a nephew of the Editor of this JOURNAL.

NOTES.

HONOURS.

The *London Gazette* of October 15th published a list of officers of the British and Dominion forces awarded decorations "for distinguished conduct in the field" in connexion with the operations in the Dardanelles. Among these officers is Colonel Michael Thomas Yarr, F.R.C.S.I., who receives the honour of C.B.

SANATORIUM FOR TUBERCULOUS SOLDIERS.

A sanatorium for tuberculous soldiers, sailors, and munition workers has been opened at Beechwood House, Newport, Monmouthshire. The building has been lent by the corporation to the Welsh Memorial Association, and will be available for men from Welsh and Monmouthshire units. Sir Garrud Thomas, M.D., who presided at the opening meeting, said that the corporation had very readily responded to the request of the deputation, of which he had been a member, and read a letter from Colonel David Davies, M.P., the president of the association, thanking the corporation for the use of the house and grounds.

MILITARY HOSPITAL AT BRADFORD.

The work of converting St. Luke's Hospital, lent by the Bradford Poor Law Union, into a military hospital is nearly completed. The St. John Ambulance Brigade or the V.A.D. will supply men for removing the wounded. It is estimated that fifteen ambulances will be required and from fifteen to twenty cars for the conveyance of wounded and other purposes of the hospital. It is understood that the hospital will be able to utilize Field House and Woodlands Convalescent Home for convalescents.

MEDICAL OFFICERS WANTED.

3/2nd South Midland Mounted Brigade Field Ambulance T.F.

Medical officers are required for the above unit, at present stationed at Great Missenden, Bucks, and shortly proceeding to Oxford for winter quarters. When trained and efficient, they must be prepared to be posted to the 2nd and 1st lines to replace casualties. Apply to Officer Commanding, 3/2nd South Midland Mounted Brigade Field Ambulance, T.F., Great Missenden, Bucks.

2/2nd Highland Field Ambulance.

Two medical officers are required for this ambulance. Applications to Major Cameron, officer commanding R.A.M.C. Headquarters, Comrie, Perthshire.

England and Wales.

CIVIL SANITATION AND THE WAR.

At the first meeting of the seventy-seventh session of the Liverpool Medical Institution, which took place on October 21st, 1915, the President, Dr. E. W. Hope, M.O.H. Liverpool, delivered an address on civil sanitation and the war. On the outbreak of war, he said, the civil and military authorities combined and rapidly organized camps, billets, took steps to prevent infection, to supervise contacts, to cleanse clothing and bedding, to provide baths, and to supervise food supplies and food contracts. Fazakerley Fever Hospital was handed over to the military. At first some difficulties arose owing to the dislocation of the sick and injured from hospital treatment which was the normal state in a large city. Fortunately no epidemic occurred, and the health of the city population had been remarkably good during the past twelve months. The city authorities had, however, made ample provision for any cases of imported infectious disease to which a seaport like Liverpool was especially liable. The number of medical practitioners had been considerably depleted, and extra work had devolved upon those who had been unable to respond to the call of their country. Nineteen out of the medical staff of twenty-five belonging to the health department had joined the colours. Dr. Stewart, who was an Associate of the institution, fell at the Dardanelles. His was the first death among the local medical men who so promptly responded at the outbreak of the war. One practical step was taken to ensure prompt medical aid for midwives in emergency cases. If the husband was at the front arrangements were made whereby the police could transmit urgent messages to medical practitioners from the various police stations. The scavenging department suffered from the depletion of its ranks. No fewer than 1,100 out of 3,500 promptly enlisted at the first call to arms, and their places had to be filled by persons less physically able and less skilled. In August the copious rainfall proved a blessing in disguise, for at this period, which was critical from a public health point of view, the city was cleaned far more effectively than usual. One remarkable effect of the war has been the great diminution of poverty owing to the unprecedented increased use of the Port of Liverpool. Thanks to the liberal separation allowances, a large proportion of families were in receipt of better and more regular incomes than before the war. The limitation of the hours during which public houses were permitted to be open and the abolition of treating had been wholly beneficial, and added considerably to the well-being and welfare of the working classes. During the first six months of the war, owing to the great congestion of shipping diverted to Liverpool and the inability of the dock labourers to cope with it, a considerable quantity of foodstuffs was unavoidably damaged, and some 3,500 tons were condemned as unfit for food. During the first six months of this year only 2,000 tons were destroyed. Food inspection had been systematically carried out, and the refrigerated meat destined for France or Italy had been transhipped to these countries or placed in cold storage until required. Many horses and mules reached Liverpool from ports scheduled under the orders of the Board of Agriculture, and dead animals and the destruction of fodder and litter had to be attended to lest any contagious disease should obtain a hold among the cattle of this country.

Dr. Hope's address was much appreciated, and every member felt that the organization of the work devolving on the civic authorities and the military authorities was being carried out effectively, and that the Port of Liverpool has well earned the prosperity it is now enjoying. Dr. T. R. Glynn, Professor of Medicine at the University, proposed in felicitous terms a hearty vote of thanks to the President, whose address was full of illuminating facts. Mr. Rushton Parker, Professor of Surgery, seconded, and the proposition was carried with acclamation. Afterwards a *conversazione* took place, and by the hospitality of the President refreshments were provided.

THE SALFORD ROYAL HOSPITAL.

In spite of the great demands made by the military authorities on the Salford Royal Hospital, the ordinary work of the hospital has been carried on without any serious break. Up to the present the medical board has

been able to retain the services of most of the resident staff, who were, in fact, practically indispensable if the ordinary patients were not to be neglected. At the annual meeting of the board last week it was stated that during the past year over 25,000 patients had been treated, of whom about 3,000 were in-patients and about 13,000 accident cases. The effect of the war on the ordinary funds of the hospital has not, perhaps, been as serious as might have been expected, for though the expenditure of the year was £15,844 and the income only £15,024, the deficiency is no greater than has occurred on several previous occasions before the war. Special arrangements have been made for the reception and treatment of wounded soldiers, and down to the end of June 755 soldiers had been treated. A number of the sisters and nurses have been accepted for military service, and to take their places certified members of the British Red Cross Society have been accepted for training in the hospital. In view of the great demand now being made for medical men below the age of 40 for service with the forces, the board expressed some concern lest it might lose the services of some of its resident staff, and might find difficulty in supplying their places for the necessary work of the hospital.

THE 2ND WESTERN GENERAL HOSPITAL.

At a recent visit of inspection of the 2nd Western Military Hospital at Whitworth Street, Manchester, Surgeon-General Sir Alfred Keogh and General Sir W. H. Mackinnon expressed their complete satisfaction with all the arrangements made for the reception and treatment of wounded soldiers. It is understood that the Manchester Base Hospital is the largest of its kind in the country, and has received more casualties than any one of the other base hospitals. During one period of ten days since the last British advance a large number of casualties were received for treatment, and through the excellent system of transport organized by the Red Cross Society the cases were distributed among the various attached hospitals with the least possible delay.

WELFARE OF MOTHERHOOD AND INFANCY.

The public meeting promoted by the Central Committee for National Patriotic Organizations and the National Association for the Prevention of Infant Mortality, to consider means for the promotion of the welfare of motherhood and infancy, was held at the Guildhall, London, on October 26th, under the presidency of Sir T. Vezey Strong, who took the place of the Lord Mayor, who was indisposed. The President of the Local Government Board said that the depletion in the numbers of the fathers of the future rendered it more urgent to care for the lives of the women, and to see that the children were protected in their youngest days. Statistics, he said, were against the assumption that poverty was the main cause of infantile mortality: ignorance, dirt, and neglect were far more important. He appealed to all those interested in the subject, and especially to women, to agree to work in one group. The Duchess of Marlborough said that the establishment of infant welfare centres had been followed by good results in reducing infant mortality. There was need for the appointment of a greater number of women as sanitary inspectors and health visitors, and no effort should be spared, especially by the women of the country, to initiate and administer the scheme which the action of the Local Government Board had made possible in every district. The Postmaster-General, who followed, said that it had to be realized that the security of our civilization depended not only on the quality and efficiency of our people, but also on their numbers, and it was a fact which gave food for thought that while the population of the United Kingdom increased in ten years by $\frac{3}{4}$ millions, that of Germany had increased by 8½ millions. Much of the mortality among infants was not inevitable, and, in addition, antenatal mortality must be considered. The saving of these lives was one of the few matters in which the Government and the legislature were ahead of the nation. The majority of local authorities showed little activity, and public opinion should awaken them from their lethargy. Sir James Crichton-Browne said that much of the mortality among infants could be prevented; doctors' babies died at the rate of only 40 per 1,000 in the first year because doctors knew how to

look after them, whereas those of miners who did not know how to look after them died at the rate of 160. Further investigation into antenatal pathology should be made, and for this purpose stillbirths should be registered and centres of scientific research established. It had been hoped that a grant of £25,000 would be made by Parliament for this purpose, and he understood that in certain circumstances the money might yet be asked for in a supplementary estimate. It was announced at the meeting that messages of sympathy had been received from the Queen, Queen Alexandra, the Prime Minister, the First Lord of the Admiralty, the Archbishops of Canterbury and York, the Chief Rabbi, and Dr. Leslie Mackenzie, medical member of the Local Government Board for Scotland.

A telegram from New York to the *Times*, under date October 24th, states that a newly-formed Gesellschaft für Bevölkerungspolitik recently held a meeting in Berlin, which was attended by men of science and sociologists and representatives of the Imperial Government. Among measures recommended for the renewal of Germany's male population were abolition of the legal age for marriage, the removal of all bureaucratic obstacles to marriage, assistance for those who feel they are unable to marry, and State premiums for large families on the one hand; and, on the other, heavy taxation of bachelors, old maid, childless couples, and those who adhere to the one or two children scale. A propaganda of an educational character was decided upon with the object of impressing upon men and women in Germany that it is their patriotic duty to increase and multiply. In this work the churches and schools are to be enlisted.

Major Leonard Darwin, president of the Eugenics Education Society, asks us to state that he desires to repudiate on behalf of the society all connexion with those who hold many of the views contained in a pamphlet called "Eugenic Peace," which has been distributed among the members of the society. "We know," he says, "that terrible damage must result from the wholesale slaughter of our fittest men, we foresee that many practical steps ought to be taken both now and at the conclusion of the war in order to rebuild the nation, but we hold that nothing must stand in the way of every man and woman devoting their whole available energies to the task of bringing this war to a successful conclusion."

Scotland.

LEITH HOSPITAL IN WAR TIME.

LEITH HOSPITAL has always had to deal with many wounded, for Leith is a seaport with large docks and many works, and accidents have hardly ever been wanting; but since November last (1914), when the first wounded soldiers from the front were received, its beneficent activities in this direction have been greatly increased. In something like four ways the hospital has been playing its part in the war.

In the first place, the institution has given freely of its consulting and acting staff. One of its consulting surgeons, Mr. Miles, has been rendering valuable service in the R.A.M.C.; both the physicians (Drs. Edwin Matthew and Murray Wood) are also in the R.A.M.C. Mr. Scot-Skirving, one of the surgeons, has been doing duty at Craigleigh, his work in the hospital having been carried on by Mr. W. W. Carlow (who has continued to act as registrar). Mr. J. W. Strothers has now returned to his post from France, where for some months he was doing war work; during his absence his duties were performed for a time by Mr. James M. Graham, and for another period by Mr. W. Q. Wood. The pathologist, Dr. A. Pirie Watson, is at the Dardanelles, and his place has been filled by Dr. Ninian Bruce. Of the assistant physicians Dr. H. L. Watson-Wemyss has been doing medical work at Dalmeny; whilst both the assistant surgeons (Mr. Henry Wade and Mr. D. P. D. Wilkie) have been engaged elsewhere, Mr. Wade having been with the Scottish Horse Field Ambulance and Mr. Wilkie at Portsmouth. Finally, the anaesthetist, Dr. H. Torrance Thomson, is in France. The nursing staff has been supplemented by Voluntary Aid Detachments from the Red Cross. As with so many other hospitals in these days, Leith has readily lent or given freely of its medical and surgical officers in the nation's need.

In the second place provision has been made for the reception, treatment, and nursing of wounded soldiers.

The first party arrived in November, 1914, and since then further numbers have come from time to time. Beds were provided for them in the medical and surgical wards of the hospital, and by utilizing other rooms in the building space has been found for all the requirements. A large proportion of the men have had surgical injuries, but there have been medical cases also, several "trench feet," and a few "gassed" patients.

The hospital has also been helping the navy, and a considerable number of sailors have been taken in since the beginning of the war, most of whom have come from nine sweepers and the like, and have been suffering principally from rheumatism, pneumonia, and from fractures. Further, an arrangement has been made to earmark a number of beds for use at any time to meet increased naval requirements. In the fourth place the wards of the hospital have been open for the reception of sick soldiers from among the various units undergoing training in the neighbourhood, and a number of these, mostly medical cases, have been dealt with.

Under peace conditions the hospital provided 114 beds—60 surgical (three wards), 46 medical (4 wards), and 8 gynaecological—but since the war began extra beds have been added.

Ireland.

ROYAL COLLEGE OF SURGEONS AND THE WAR.

AT the annual distribution of prizes the President, Mr. Conway Dwyer, in the course of his address, said that the great number of troops now in the fighting line and the consequent large percentage of casualties had thrown a great strain upon the Army Medical Corps. Thanks to the efficient organization of the corps effected long before the war broke out, largely due to the efforts of Sir Alfred Keogh, the needs of the situation were sufficiently met. The machinery for the immediate treatment and transport of the wounded to a base hospital notably diminished suffering and helped convalescence. The usual scourges of armies in the field, such as typhoid, dysentery, etc., had claimed in this campaign very few victims, thanks to the methods of sanitation and isolation systematically employed. It was a source of justifiable pride to the college to know that it had not been behind in aiding in this beneficent work. In proportion to its numbers, it had sent in one capacity or the other a very large number of men, many of whom had signally distinguished themselves. A roll of honour had been established in the college as a permanent record of the services rendered by students in the war, and that roll was ever lengthening. The students had collected a sum of money for the equipment of a ward in the Castle hospital. The President concluded by reading extracts from dispatches in which two of the licentiates of the college found most honourable mention, namely, Captain Ernest Cotter Deane and Surgeon-General O'Donnell. In the case of Surgeon-General O'Donnell, Sir John French said, in the course of his dispatch: "These results are due to the skill and energy which characterized in a marked degree the work of the Royal Army Medical Corps throughout the campaign, under the able supervision of Surgeon-General O'Donnell, D.S.O., Deputy Director-General Medical Services."

DR. WALTHER STRAUB, Professor of Pharmacology in the University of Freiburg in Breslau, has addressed a letter to the *Journal of the American Medical Association* stating that certain figures with regard to the consumption of alcohol in different armies published in the BRITISH MEDICAL JOURNAL are incorrect. He supports this assertion by a calculation of the number of railway cars which would be required to carry beer daily for 3,000,000 soldiers, and arrives at the conclusion that 887 such cars would be necessary, which he implies is a *reductio ad absurdum*. The purpose of the articles in this JOURNAL was to compare the war rations of the various armies and Zuntz's figures for the German army were taken. The real interest in Professor Straub's letter is the statement that there is no regular alcohol allowance to German soldiers in the field. This is not in accordance with the information published in the *Frankfurter Zeitung*, but we are not in a position to state which of these German authorities is correct.

Correspondence.

WAR ORTHOPAEDICS.

SIR,—My attention has been arrested by the paragraph quoted in the leading article on war orthopaedics in the *JOURNAL* of October 16th, p. 575, from Mr. Robert Jones's book on *Injuries of Joints*, and as the best expression of my sympathy with the purport of that article and of the quotation in particular, let me give two examples of a revolution in my practice due to the observation of Mr. Robert Jones's methods, for I believe, after a wide and long experience, that nearly every doctor to-day is as ignorant as I was on the subject of stumps and paralysed limbs. How many of those looking after our gallant and maimed soldiers in the hundreds of our hospitals in this country know the potentials of a good stump and the best way to obtain such a one? How many of the hundreds of the medical practitioners now at work have been in the habit of studying, in relation to the art of fashioning a useful artificial limb, the value of each joint and of muscles passing from the trunk to the scar at the end or side of the stump? From my own experience I can only answer that they are few—very few.

The first example I wish to relate occurred some fourteen years ago when on a visit to hospitals in Paris, where a case of ischaemic paralysis was shown, and the opinion of British surgeons present was asked. I knew the orthodox method and remarked upon its relative uselessness. Mr. Robert Jones, while agreeing generally, stated that he had had some success by doing very much less than was usually done, and indicated the lines of treatment. The surgeon under whose care the patient was tried it, with the result to the patient of a very useful instead of a withered hand; in these cases I find that wrong splinting, massage, forcible movements, electricity, and so on, still constitute the ordinary treatment.

The second example with unsatisfactory results has to do with a conical stump. In this case the bone was covered chiefly by skin for about 2 in., and consequently it appeared to be too long. It was, however, pointed out to me that some muscles had been allowed to retract after amputation, and that they might be liberated from their anchorings, mobilized, and fixed to or over the end of the bone so as to cover it. The application of this principle—new to me at the time—was of great value to the patient in controlling his artificial limb.

The point I wish to make is, that as knowledge of the recent advance in surgery of the stump and of the semi-paralysed or parietic limb is not yet widely disseminated, it is necessary that special means should be devised to put every one of our maimed patriots on the road to the best treatment that our country can give them. I do not think that even to circularize the officers commanding hospitals and to make the facts known in the medical press would meet the situation. I believe that the object would be attained if the War Office would appoint a surgeon of experience in this matter to visit the various military hospitals in this country to inspect stumps and paralysed limbs, with instructions to arrange that all suitable patients should be sent to special orthopaedic hospitals, such as the orthopaedic centre established at Alder Hey, near Liverpool.—I am, etc.,

October 18th.

F.R.C.S.

INFANT FEEDING.

SIR,—I wish to add my testimony in favour of the feeding of infants with undiluted milk.

The history of the artificial feeding of infants is not one which reflects great credit upon our profession. In no other department, probably, has theory governed practice so much. Each ingredient of cow's milk has in its turn been blamed for the frequent gastro-intestinal disturbances that so often haunt artificially-fed children, with the result that milk minus the fat (butter-milk), milk minus most of its caseinogen, milk minus most of its sugar, and milk minus, or at least lessened, in all its ingredients (dilutions with water) have all had their advocates. Percentage milk mixtures were introduced some years ago by Dr. Rotch, chiefly with the object of avoiding the then believed indigestible casein, and have had many supporters, especially on the other side of the Atlantic. The

chief difficulty was in getting the mixtures accurately made, and hence the introduction of milk laboratories, where they were dispensed from prescriptions of the practitioners. Dr. Rotch was most particular in all his writings that whatever mixture was used the child must always get sufficient nourishment, that is, sufficient calories for one of its age and weight. This seemed a most evident point, and yet some of the followers of this percentage plan of feeding have missed it, and who has not seen a poor, limp, anaemic, sweating child sucking wearily at a large bottle containing chiefly water, and then turning away from it, tired with the exertion but still hungry, and yet distended with water and little else? In such cases there is (from some oedema)—they are starved and waterlogged. This has been a fault in no way attributable to Dr. Rotch, who specially warned against it. Next, by a swing of the pendulum, and probably merely as a reversion to an older practice, advocates arose for the giving of the milk undiluted. Such a one, and a very urgent one, was the late Professor Budin of Paris. His method was to prepare the milk by heating it in a double boiler for forty minutes, the milk thus being kept to the boiling point of water for that period, and being thoroughly sterilized and otherwise changed, but not having been actually boiled. (The boiling point of milk is, of course, higher than that of water.) Some years ago I cautiously commenced to try this apparently drastic method of feeding in the out-patient department of our children's hospital in Toronto. This hospital is fitted with an excellent milk laboratory, and for years has been a centre of percentage milk mixture feeding. To my surprise and pleasure the results were infinitely superior to anything that we had seen with any form of artificial feeding. Children who were dragging along and looking thin and miserable on diluted mixtures, often with potbellies and more or less diarrhoea, with mucus in the stools, quickly changed and rapidly put on weight. They usually greedily took the undiluted milk, and it seldom disturbed the stomach.

We always use 2 grains of the sodium citrate to the ounce of milk, a precaution which Dr. Budin did not employ. The method of heating the milk is one which the most ignorant mother seems to carry out easily, the milk for the twenty-four hours being all heated at one time.

Roughly speaking, the child should get 1 oz. of the milk at each feeding for each month of its age. Occasionally a little sugar may be added to increase the caloric value of the food, but this does not seem, as a rule, to be necessary.

I was interested some years ago to learn that this method of feeding had been tried in the out-patient department of the Children's Hospital in Edinburgh, and that it was found to give better results than any other artificial way of feeding infants. I cannot give this exact reference at present, being "somewhere in France," and far from libraries.

Now, it is not for a moment advocated here that this modified Budin method of feeding infants is a panacea, or that it should be used in the case of really sick infants. These require special feeding, and often it may be necessary to cut off all milk, and even to stop all food for a time; but, as a routine system for the feeding of infants who unfortunately cannot be nourished at the breast, it is, in my opinion, the best that has yet been advocated, and it is to be hoped that more practitioners may be persuaded to try it.—I am, etc.,

R. D. RUDOLF, M.D. Edin., F.R.C.P. Lond.,
Lieutenant-Colonel C.A.M.C.

British Expeditionary Force, France, Oct. 20th.

SIR,—My first letter was written in criticism of Dr. Cameron's statement that the results of feeding with whole and diluted milk are very much the same. I entirely agreed with Dr. Cameron's address, and from what he has written since I gather that, in his opinion, cow's milk should be diluted to overcome the high fat percentage, and that a carbohydrate should be added, preferably in the form of malt sugar. This he would be glad to call a standard substitute diet. He is, apparently, not opposed to whole citrated milk, for he is willing to allow it at the third month. We are, therefore, not very far apart in our ideas as to what constitutes a suitable

diet. Dr. Cameron speaks of "diluting milk a little," and does not say whether he uses citrate with milk so diluted. It is difficult to understand how an infant can take milk diluted a little unless it is citrated. I am entirely in agreement with Dr. Cameron in thinking that the caseinogen difficulty has been greatly overstated. There is evidence that the excess of protein is in itself harmless, the difficulty rather being a mechanical one, the infant finding the tough firm clot of cow's milk the stumbling-block to easy digestion. With the advent of sodium citrate and the prevention of the clot the necessity for dilution passed away. Although the fat percentage of human is the same as that of cow's milk, Dr. Cameron would still have us go on diluting in order to reduce the fat which, in "the minority of all cases and a considerable percentage of very young infants," gives rise to a condition of affairs termed by Dr. Cameron "fat dyspepsia." In my experience, fat dyspepsia amongst the babies of the poor, who make a universal practice of milk dilution, is practically unknown, and in the babies I have watched being fed on whole milk I have been particularly struck by the absence of those signs and symptoms which Dr. Cameron has described. Constipation, I agree, is common, but it is not more severe or frequent than constipation in breast-fed babies, and one would be sorry to label them cases of fat dyspepsia. Dr. Langmuir's pioneer work with whole citrated milk has in the past done, and will in the future do, more to place the artificial feeding of infants on a practical and sensible basis than all the hundred and one theories and milk modifications that have from time to time been put forward, and my opposition is entirely directed against the principle of milk dilution, which, in the great majority of cases, I believe to be unwise and unnecessary.—I am, etc.,

Leeds, Oct. 25th.

C. W. VINING.

THE WAR EMERGENCY.

THE NEED OF SELECTION.

SIR.—May I ask Dr. Barwise where he gets his figures when he states that only 12 per cent. of panel practitioners are on active service? Sixty-six per cent. have gone from this town and 43 per cent. from the district. Those left at home are having a busy time, but they are doing the work of absentees free of charge. If these conditions are exceptions they may be dependent on each other; certainly they should be satisfactory to the State. Dr. Barwise compares choice of doctor with choice of judge and clergy. Choice of doctor is for the common good; choice of judge would be a power for evil. We have the choice of clergy and church. At home, as well as on the battlefield, in cases of serious injury the nearest medical man is called and the nearest hospital made use of. The system of each Division of the British Medical Association providing its fair share is undoubtedly the best, since it is economical and is most satisfactory to patient and doctor. Perhaps if the men remaining at home were more generous in their offers to prospective volunteers there would be a greater number of the latter. It is their duty to do the best they can for them.—I am, etc.,

Birstall, Oct. 25th.

W. AIRLIE OGILVY.

Obituary.

JAMES B. COLEMAN, C.M.G., M.D., F.R.C.P.L.,

PHYSICIAN TO THE RICHMOND HOSPITAL, DUBLIN.

By the death of Dr. Coleman, which took place on October 21st, Dublin has lost a very prominent figure, and one who ever upheld the best traditions of Irish medicine. James Byrne Coleman was born in 1865; he was educated at Clongowes Wood College, where he was a brilliant student. His medical career began with his entrance into the Catholic University, from which he passed to the Royal College of Surgeons. He obtained the degree of M.D. in 1888 from the Royal University of Ireland, and was awarded a gold medal. In the course of a few years he was appointed physician to Jervis Street Hospital, and in 1896 he was elected physician to the Richmond Hospital, where his clinical acumen, his scientific method, and his innate teaching ability brought him to the front rank of Dublin physicians. Students flocked to his class, for he had the

happy knack of establishing a clear connexion between pathological processes and their clinical manifestations, and of presenting the phenomena of disease in a lucid manner. From its establishment in 1896 down to 1913 he was one of the two visiting physicians of the National Hospital for Consumption at Newcastle (Wicklow), where he performed a vast amount of work on tuberculin and on "opsonins." Dr. Coleman must be regarded as a pioneer in vaccine therapy; his methods were never empirical, but always based on sound clinical and bacteriological evidence. He was a man with a strong sense of duty, which he ever put before pecuniary gain.

In 1900 he relinquished his practice, which was then increasing to a remarkable extent, in order to act as principal physician to Lord Iveagh's Irish Field Hospital. In this capacity he did extremely useful work in medicine generally and in the treatment of typhoid fever in particular. For his services there he was mentioned in despatches, was made a C.M.G., and received a medal with three clasps. Some months ago he accepted an invitation to take charge of the medical side of a base hospital at the front, although he felt that the work would be a considerable tax on his strength. The same devotion to duty resulted in his contracting small pox during an epidemic of that disease in Dublin many years ago.

Dr. Coleman took a prominent part in the medical life of the city, being a Fellow of the Royal Academy of Medicine in Ireland and a member of several medical clubs of a social character. As a Fellow of the Royal College of Physicians he devoted himself to the welfare of that body, and identified himself with everything that could further its interests. As a physician he was eminently sound in theory and practice, and always kept himself versed in new methods not only in medicine but in the kindred sciences. Personally Dr. Coleman, though of a retiring and quiet disposition, was a man who knew his own mind and who was never afraid of adopting his own line in medicine or in life.

WILLIAM GILBERT GRACE, L.R.C.P. EDIN.,
M.R.C.S. ENG.

W. G. GRACE, admittedly the greatest cricketer who ever played our national game, died suddenly on October 23rd at his residence, Mottingham, Eitham, Kent. The fourth son of Mr. Henry Mills Grace, of Downend, Gloucestershire, William Gilbert Grace was born there on July 18th, 1848. He was educated by tutors at home, and did not enter the Bristol School of Medicine until long after he had, at the age of 17, begun his career as a cricketer; later, he studied at St. Bartholomew's and the Westminster Medical Schools. For a time his tall form and his face, already well bearded even in early youth, were familiar to all who frequented the square of St. Bartholomew's Hospital. He showed little hurry about qualification, yet he intended to give up public cricket and start in practice in Bristol when in 1878 the Australian cricketers visited this country for the first time. The skillful Antipodeans scored wonderfully, and W. G. Grace, with commendable patriotism, remained in the field as Britain's recognized champion. He did not, however, abandon his determination to practise. He qualified in London and Edinburgh in 1879, and set up in practice in Stapleton Road, Bristol, at the end of the same year. There he remained until his retirement from practice in 1899, though latterly he had also a house at Ashley Down. During this period he held a number of appointments. He was medical officer to the Barton Regis Union, public vaccinator to a district in the same union, and surgeon to the Pennywell Collieries. His brother, Dr. Edward Mills Grace, was coroner for a district in the West of England, and played first-class cricket, as did a third brother, Mr. G. H. Grace. In 1899, W. G. Grace, on his retirement, took a house in Sydenham, where he resided for ten years; lastly he moved to Mottingham in 1909.

"W. G." was a man tall in stature and of splendid physique, possessing at the same time great manual skill. He was not only a great bat, his bowling was a superb sight—all the more so, perhaps, because it was by no means graceful, but the power which he exerted and the skill with which he overcame the batsman were alike sufficient to win the admiration of the expert and of the ignorant spectator. "W. G." was not given to severe training; on the other hand, it is interesting to hear in

mind that he never smoked. It appears that early in life he suffered from pulmonary disease, although he grew to be so robust. W. G. Grace, when he gave up the practice of our profession, did not abandon cricket, for he played only nine years ago for Gentlemen against Players at Kennington Oval, and took part in club cricket until 1913. He wrote three books on cricket, of which the most important was *Cricketing Reminiscences and Personal Recollections*, by "W. G." He loved sport and followed the beagles. Latterly he took much interest in the boy scout movement.

W. G. Grace was married and left two sons—Captain H. E. Grace, R.N., and Captain C. B. Grace, Kent Fortress Royal Engineers. His funeral took place on October 26th, at Elmers End Cemetery, Deckenham.

Dr. JOHN HOLMS, the oldest practitioner in Paisley, whose death is announced, began life as a clerk. By industry and perseverance, he obtained the degrees of M.B., C.M.Glasg. in 1871, and graduated M.D. in 1873. After acting as an assistant in the North of England he settled in Paisley over forty years ago, and acquired an important practice. He made a fine collection of pictures, many of which he lent to various loan collections. He died on October 18th from pneumonia, leaving a widow, two sons, and two daughters.

LAST summer a medical mission was sent by the St. Louis University to British Honduras for purposes of research. Dr. Edward Nelson Tobey, lecturer on tropical diseases in the University, was a member of the party. He was a passenger on board the fruit steamer *Marovijane* which was wrecked in a hurricane in the Caribbean Sea on August 13th, and is believed to have gone down with the ship. He was 44 years of age.

The Services.

EMOLUMENTS OF TERRITORIAL MEDICAL OFFICERS.

WE have received a number of inquiries with regard to the emoluments to which medical officers of the Territorial Force are entitled, and some of our correspondents have compared them unfavourably with the receipts of medical officers holding temporary commissions. The matter appears to be governed by the following paragraphs of the Royal Pay Warrant:

496. (a) Retired officers compulsorily recalled to service under Article 518, and (b) other officers specially taken into employment by reason of a national emergency, shall receive, while so employed, the same rates of pay and allowances as officers of corresponding army rank in the same arm or branch of the service; or, if holding a command or employed on the staff, the rates of consolidated pay laid down for their appointments. In the case of retired officers these rates shall be additional to any retired pay of which they may be in receipt, or, irrespective of any gratuity they may have received on retirement. Under (b) the following may be included: Re-employed retired officers other than those coming under (a); officers of the Special Reserve of Officers or Militia when embodied; officers of the Special Reserve of Officers and Territorial Force, employed with our regular army; ex-officers or civilians appointed to military positions in Imperial Forces, or officers of Colonial Forces to whom this article may be held by our Army Council to apply.

497. Officers employed under the conditions of Article 496 shall, provided that they served for the full period of their engagement, or of the emergency in respect of which they were employed (unless a shorter period is specially approved by our Army Council), be entitled, on the cessation of such employment, to a gratuity at the following rates:

(a) In the case of an officer who retired with retired pay or gratuity, thirty-one days' pay for every year of service or any part of a year.

(b) In the case of any other officer, one hundred and twenty-four days' pay for the first year of service, or any part of a year, and sixty-two days' pay for each subsequent year of service or part of a year.

For the purpose of such gratuity pay shall mean regimental, departmental, or staff, pay only, and shall not include additional pay of any kind, or (except in the case of officers drawing consolidated rates) allowances.

The following table affords, we believe, a correct comparison of the emoluments of officers of the R.A.M.C.(T.F.) and temporary lieutenants R.A.M.C.:

A. Pay and Allowances (Daily Rates).			
	R.A.M.C.(T.F.)		Temporary Lieutenant, R.A.M.C.
	At Home.	With E.F.	At Home or with E.F.
Lieutenant.			
Pay	s. d. 14 0	s. d. 14 0	
Field allowance	5 0	5 0	
Lodging allowance	—	5 0	
Fuel and light allowance (average)	—	0 9	
Total	17 0	20 0	
Captain.			
Pay	15 6	15 6	
Field allowance	3 6	3 6	
Lodging allowance	—	3 0	
Fuel and light allowance (average)	—	1 0	
Total	19 0	23 0	Consolidated rate. 24 0

In addition each receives free rations or the allowance in lieu.

B. Gratuity on Demobilisation.

Captain R.A.M.C.(T.F.)	Temporary Lieutenant R.A.M.C.
------------------------	-------------------------------

For the first year, £96 2s. (about 5s. 3d. a day).
 For the second year, £48 1s. (about £60 (about 5s. 3d. a day).
 2s. 7½d. a day)

It appears, therefore, that for the first year a captain R.A.M.C.(T.F.) with the Expeditionary Force receives, when the gratuity is taken into account, about 28s. 3d. a day, and a temporary lieutenant R.A.M.C. about 27s. 3d.; for the second year a captain R.A.M.C.(T.F.) with the Expeditionary Force receives about 25s. 7½d. a day, and a temporary lieutenant about 27s. 3d., as before. The advantage which the captain R.A.M.C.(T.F.) appears to have during the first year is about 1s. a day, but during the second year he is at a disadvantage, compared with the temporary lieutenant R.A.M.C. of 1s. 7½d. a day. If employed at home a captain R.A.M.C.(T.F.) is not entitled to lodging and fuel and light allowance, so that his emoluments in the first year (including gratuity) amount to 24s. 3d. a day, or 3s. less than the temporary lieutenant R.A.M.C. In the second year the discrepancy would be greater (about 5s. 7½d.). One other point occurs to us which may be to the advantage of the captain R.A.M.C.(T.F.), although, knowing the slipperiness of the ground covered by income tax legislation, we mention it with all reservations. It is that he will pay income tax on his pay (15s. 6d. a day), whereas the temporary lieutenant will pay on his consolidated pay (24s. a day).

ROYAL NAVY.

THE NAVAL MEDICAL COMPASSIONATE FUND.

THE Order in Council sanctioning the revision rules for the Naval Medical Compassionate Fund has been approved. The interest on the sum of £10,600 at present standing to the credit of the fund, together with the amount accruing from subscriptions, will be available for distribution among the widows and orphans of subscribers. The yearly subscription in future will be 21s., and an editorial note in the *Journal of the Royal Naval Medical Service* says, "Seldom does such an opportunity occur of making at a small cost some provision for wife and family in case of need." Subscribers will be admitted under the new conditions as from January 1st, 1916, and officers are now invited to notify the Honorary Secretary, Naval Medical Compassionate Fund, Medical Department, Admiralty, of their intention to join.

INDIAN MEDICAL SERVICE.

IT was recently announced in the press that after the open competitive examination held last July for admission to the Indian Medical Service no similar examination would be held during the continuance of the war, but that such appointments as might be required to meet the absolutely indispensable needs of the service would be made by nomination by the Secretary of State. To assist him in making these appointments, which, as already announced, will be limited in number to the absolutely indispensable needs of the service, Mr. Chamberlain has appointed a Selection Committee who will summon and interview such applicants as may appear to be *prima facie* suitable, and make recommendations for appointment.

Applications for appointment should be addressed to the Secretary of the Military Department, India Office, Whitehall, S.W., and should contain concise particulars of the applicant's medical degrees and career. Applicants must be over 21 and

under 32 years of age at the time of application. Particulars regarding pay, promotion, etc., in the service can be obtained from the Secretary, Military Department.

EXCHANGES DESIRED.

TERRITORIAL FORCE.

CAPTAIN A. R. PATERSON, R.A.M.C.(T), attached 14th Dorset Regiment, Amhala, India, wishes to find substitute so as to enable him to transfer to a unit at home or in France. Communications should be addressed to Dr. Le Fleming, Wimborne, Dorset, who will refer all details.

Captain C. E. Silvester, R.A.M.C.T., 21st South Eastern Mounted Brigade Field Ambulance, now stationed at Cricket Ground, Canterbury, wishes to exchange with another M.O., preferably Field Ambulance or Casualty Clearing Station, abroad or about to proceed abroad.

Universities and Colleges.

UNIVERSITY OF EDINBURGH.

UNIVERSITY COURT.

At a meeting of the Court on October 18th leave of absence was granted to Professor Alexis Thomson and Professor Gulland, who have been appointed to important posts in the Army Medical Service, and to Mr. A. D. Darbishire, lecturer on genetics, and to other teachers who have also joined His Majesty's forces. Professor Dayley Balfour reported that the Australian Hebraicum bequeathed to the university by the late Dr. Alexander Morrison proved on examination to be the finest that had reached Europe from Australia since the early days of last century, when the Banksian plants collected by Robert Brown were placed in the British Museum.

UNIVERSITY OF GLASGOW.

THE session was opened on October 18th. The enrolment period extends until November 2nd, but it is stated that already the indications are that the number of first-year medical students will be over the average, and since those at an advanced stage have been advised to complete their course, the classes in medicine will probably be less affected by the war than those in other departments. The diminution is expected to be large in the arts classes, where between 300 and 400 of the students are engaged in munitions work; in the science faculty, in which the majority of the students study engineering, a number are engaged on war work of different kinds.

Principal Sir Donald MacAlister has written an introduction to the new issue of the *Students' Handbook*, in which he addresses in particular first-year students. He states that by the end of the first twelve months of the war 2,210 students of the university had enrolled themselves in the forces of the Crown, and of these 1,750 had received commissions as officers in the navy or army. During the summer the Officers' Training Corps passed through its special course about one hundred commissioned officers a month. Some fifty members of the teaching staff were employed in military or civil service connected with the war, and of the women students a large proportion are giving service to hospitals, ambulances, and relief organizations.

The Business Committee has reported to the General Council that it has a new issue of the roll of service in preparation. It would contain the names of 84 killed and 101 wounded. With a view to immediate future needs the scheme of part-time training for military hospital service arranged in April with the Western Infirmary, and subsequently with the Royal Infirmary, which last year six women graduates and sixty-eight students had taken advantage, will be continued throughout the winter at the former institution. The head quarters of the Officers' Training Corps in University Avenue were now recognized by the War Office as a regular school of military instruction for young officers. The staff, with the exception of one regular officer, was composed of graduates. Work has been continued during the vacation.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

Fellowship.

The following gentlemen have been admitted Fellows: H. Chaffer, J. A. Cowie, A. M. Stuart, P. C. Woollatt.

CONJOINT BOARD IN IRELAND.

The following candidates have been approved at the examinations indicated:

PRELIMINARY EXAMINATION.—I. W. Arnovitch, Lucretia H. H. Byrne, R. B. Clery, W. E. Colahan, R. M. Corbett, J. J. Clune, T. E. Dobovana, A. B. Doyle, T. C. Doyle, A. C. Emond, M. W. Frazer, Robert E. Fisher, H. E. Graham, S. A. Gilmore, T. M. G. Golden, T. Hoffmann, J. Hewitt, Margaret Holliday, P. Killean, J. J. A. Lord-Flood, T. J. McCormack, A. McLean, E. T. Macaulay, A. Martinson, P. Moylan, R. J. O'Connell, P. J. A. O'Connor, T. L. Quinn, J. Reibenstein, G. E. Strahan, J. Sneed, B. T. Taylor, Mary E. Toppet, J. W. Tisdie, H. E. W. Waters.

SEPTENNIAL FINAL EXAMINATION.—J. Cohen, J. Dwyer, T. Farrell, O. J. M. Kerrigan, J. F. S. Magner, T. R. Ryan, J. J. Walsh, P. W. Walsh.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the annual meeting of the Royal College of Physicians of Ireland, held on St. Luke's Day (October 18th), the following officers were elected for the ensuing year: *President*, Dr. MacDowel Cosgrave; *Vice-President*, Dr. Joseph O'Carroll; *Censors*: Drs. Joseph O'Carroll, H. C. Drury, S. T. Gordon, and Gibbon FitzGibbon.

CONJOINT BOARD IN SCOTLAND.

The following candidates have been approved at the examinations indicated:

FIRST EXAMINATION.—E. J. Pearson (with distinction), T. F. Thomson, F. Minford, M. J. Woodberg, T. R. O'Keefe, W. Buchanan, and G. S. Woodhead.

SECOND EXAMINATION.—S. S. Barton, L. P. Samarasthina, D. A. Walpole, G. C. Gosser, P. L. Edwards, A. P. McLeod, D. C. Howard, J. T. W. Gale, and D. L. Henderson.

THIRD EXAMINATION.—Mary G. Jones, D. A. Jaysingha, G. L. Stauley, D. S. Taylor, J. Byrne, S. W. Joyland, Janie J. McBride, J. L. Wolf, M. Campbell, H. G. Fitzmaurice, A. Black, G. L. Fillans, J. S. Dunward, R. J. T. Malcolm-Gasper, H. C. A. Haynes, E. Butler, and E. M. L. Morsan.

FINAL EXAMINATION.—J. J. Armistead, E. A. Blok, A. Mathewson, W. H. A. D. Sutton, O. W. Bateman, J. P. Farley, E. A. Nishon, M. Seery, J. W. Robertson, J. E. Lezama, W. P. Walker, J. S. Dickson, D. C. M. Page, W. Turac, A. Evans, J. S. David, O. H. Jones, A. G. McKee, G. E. Mendis, and T. W. Drummond.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved in the subjects indicated:

SECRETARY.—H. H. Fairfax, *J. B. Fairclough, I. C. P. C. Sargent, *T. J. Thomas, *A. G. E. Wilcock, *F. H. Young.

MEDICINE.—G. T. Baker, H. H. Fairfax, *J. L. Hamilton, *I. H. Lloyd, I. C. P. C. Sargent, *T. J. Thomas.

FORENSIC MEDICINE.—J. B. Fairclough, P. Hughes, C. C. Russell.

MIDWIFERY.—E. V. Beaumont, J. E. Cheesman, J. Fox-Russell, P. Hughes, G. S. Mitchell, C. A. Mordock Brown, T. C. Russell, J. G. T. Thomas, A. J. A. Wilson, *F. H. Young.

Section I.

The diploma of the Society has been granted to Messrs. J. E. Cheesman, J. B. Fairclough, H. H. Fairfax, J. L. Hamilton, C. P. C. Sargent, and T. J. Thomas.

Medical News.

DISCUSSIONS on the treatment of the soldier's heart and on the treatment of war nephritis are being arranged by the Section of Therapeutics of the Royal Society of Medicine.

THE ladies of the St. John Ambulance classes in Exeter have presented Dr. J. A. W. Pereira with a handsome clock as a token of their esteem and gratitude.

THE Russian Red Cross has published a list which shows that up to the beginning of September forty-six Sisters of Charity were killed by shells thrown on the Red Cross Hospital by the Austro-German armies.

THE Child Study Society will hold its first meeting of the session on Thursday next, at 6 p.m., at 90, Buckingham Palace Road, under the chairmanship of Dr. James Kerr, when Miss C. E. Grant will read a paper on "The American child at school."

THE Romanes Lecture before the University of Oxford will be delivered this year by Professor E. B. Poulton, Hope Professor of Zoology in the University, on December 7th, at 3.30 p.m. The subject will be "Science and the Great War."

THE general meeting of the Röntgen Society will be held on Tuesday next, at 8.15 p.m., at the Institution of Electrical Engineers, when the President, Mr. J. H. Gardiner, will deliver an address and new apparatus will be exhibited.

THE Ingleby Lectures before the University of Birmingham will be given by Professor Douglas Stauley, M.D., M.R.C.P., physician to the Queen's and Children's Hospitals, on Wednesdays, November 3rd and 10th, at 5 p.m. The subject of the lectures is "Pneumonia and its sequelae in children."

STARTING with the frank acknowledgement that "the welfare of infants depends in very large measure on that of their mothers," Dr. Arthur Newsholme, C.B., presents a Report on Maternal Mortality in Connection with Child-bearing and its Relation to Infant Mortality (Cd. 8085, price 7½d.), which is interesting and suggestive from beginning to end. The national aspect of the subject is first discussed, and then the remarkable local differences of mortality in childbearing are displayed. In a third part of the report some of the evils associated with this excessive mortality are set out, and the presumption is shown to be justified that better arrangements for antenatal care and for midwifery attendance would go far to reduce the mortality from childbearing. The fourth part

of the report gives in detail some of the work which has already been undertaken to make these arrangements and the results obtained. We hope ere long to discuss some of the aspects of the subjects brought so prominently forward; meantime, it is an earnest of better things still in store that, in the midst of a great war, the Government should be so alive to the value of maternal and infantile life and health.

ACCORDING to the *New York Medical Journal*, the supply of certain drugs of botanic origin is falling short in the United States as in this country. Many of them were formerly collected by European peasants as a by-trade. The cultivation in America would be costly, and it is feared that return to normal prices after peace would ruin the cultivator unless the Government instituted a system of protection.

MRS. F. E. SMEDLEY, M.B., B.S., Lond., has been appointed, with the approval of the Local Government Board, acting county medical officer of health and school medical officer for West Sussex, in the place of her husband, Dr. Ralph Smedley, who has been commissioned as a temporary Lieutenant R.A.M.C., and has been on military duty since the end of August. Mrs. Smedley has also been appointed medical adviser to the West Sussex Insurance Committee during the temporary absence of the tuberculosis officer (Dr. M. J. Johnston), who is also engaged on military duty, and is at present in France.

THE King Edward Nurses is the name of an institution founded as a South African memorial to commemorate the life and aims of King Edward VII. The report for 1914-15, the second year of its existence, has been issued by the Superintendent General, Miss J. E. Pritchard. The organization is intended to comprise two divisions: (a) European, (b) coloured and native. The funds and organization of the two divisions are to be kept apart. At the request of the committee in South Africa the Colonial Nursing Association in England undertook to select nurses to fill up vacancies, and at the beginning of 1915 there was a full staff, which has been continually at work. The money subscribed by natives towards the King Edward VII Memorial was set aside to be devoted entirely to work among the natives, and in this connexion a start has been made at De Aar, where a native nurse has been placed to work as district nurse.

IN his report to the Bureau of Health for the Philippine Islands for the fourth quarter of 1914, V. Heiser, Assistant Director of Health, states that no cases of plague was reported in the city of Manila, and only four rats were found in which there was a suspicion of infection, although this was not clearly demonstrated bacteriologically. A total of 21,772 rats were caught by traps and poison in the city of Manila. In the city of Manila 35 deaths from typhoid fever were reported and 276 from the provinces. Cholera, which began on July 4th, 1914, still continued, though with greatly decreased virulence. During a leper-collecting trip made between December 5th and 20th by a medical inspector of the Bureau, with other physicians and a bacteriologist, 265 persons were examined in the twelve provinces visited. The total number of lepers sent to Cullion on clinical or microscopic evidence was 235. Four of these had escaped from the colony, and were re-admitted. Thirty suspects who did not show sufficient clinical symptoms of the disease, and were found microscopically negative, were sent back to their homes.

DR. RICHARD P. STRONG, Chief of the American Sanitary Commission to Serbia, and most of the members of his staff have returned to the United States. Dr. Strong, in a summary of the work of the Commission, stated that the methods so successful in the Philippines, Panama, and elsewhere had been enforced. One of the most efficacious measures was the disinfection of the population by means of a special train carrying baths, an immense disinfecter for clothing, and cars fitted up as dressing-rooms and for shaving and hair-cutting. By this train system the clothing disinfected and washed of hundreds of persons could be done in a few minutes; the houses in each place visited were disinfected at the same time. All persons found affected with typhus were taken to hospitals. The entire Serbian army and numbers of the people were vaccinated against cholera and typhus, the vaccines being manufactured for the most part in the American Red Cross laboratory. The spread of typhus in Montenegro also had been prevented by adopting energetic sanitary measures. Shortly before he left Serbia Dr. Strong was decorated with the Order of San Sava, and forty-three American doctors and sanitary engineers, representatives of the Rockefeller Foundation and the American Red Cross, also received decorations in recognition of their services.

Letters, Notes, and Answers.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Atkinson, Westward, London*; telephone, 2531, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (advertisements, etc.), *Atkinson, Westward, London*; telephone, 2531, Gerrard. (3) MEDICAL SECRETARY, *Medisecra, Westward, London*; telephone, 2534, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

TREY JHAJ inquires as to results in cases of recurrent winter catarrh of treatment by compound catarrhal vaccine, the frequency of the dose, and amount of constitutional disturbance after each dose.

INCOME TAX.

DEVONIENSIS has, owing to the illness of the incumbent, been appointed deputy medical officer of health for six months, and took up the work on July 1st. He has been assessed as deputy medical officer as from October 1st, and asks whether this is correct.

The appointment is one which comes under Schedule E, to which the average does not apply, and the procedure adopted seems correct in law. Presumably the medical officer of health for whom "Devoniensis" is acting as deputy did not arrange for his "Schedule E" liability to be dealt with in one sum with his general practice receipts. If our correspondent pays the tax he is entitled to exclude the amount received from his Schedule D return next year. On the other hand, if he assures the local surveyor of taxes that the receipts will be returned under Schedule D, the latter may discharge the assessment. The ultimate result will in either case be much the same.

ANSWERS.

SUGGESTED ISOLATION OF CANCER PATIENTS.

STEP.—There is no evidence from experience of human or animal cancer of transmission of the disease from the affected to healthy individuals by contact. There is, therefore, no justification for the strict isolation of cancer patients. Where ulceration and foul discharges are present it may be necessary in the interests of other patients, but in most cases careful nursing and antiseptic dressings should minimize this objection to cancer patients being housed alongside other patients. From the standpoint of humanity it seems inadvisable to segregate persons suffering from a disease of long duration. They have then no intercourse except with sufferers like themselves, which can only aggravate their condition—particularly in workhouses where the nursing staff is so fully occupied. This consideration should be held to justify intercourse with other patients in the interests of the sufferers from cancer themselves.

LETTERS, NOTES, ETC.

UTERUS DIDELPHYS.

IN the EPITOME for September 26th, 1915, paragraph 92 bore a heading, "Parasitic Entozoa in Utero Dydelpho," "Dydelpho" is of course wrong, for which we must plead guilty to the extent of having carelessly followed the German author. "Didelphus" is a word unknown to Hippocrates, Aristotle, or Galen. It was given by Linnaeus to the American opossum, and made use of as an adjective by teratologists to signify a completely double uterus. Linnaeus, in his *Systema Naturae* (edition of 1767), spells the word "Didelphis," and the modern Greek dictionary of Kyriakides recognizes only the adjective Didelphos as a modern word used solely in science. Hence, on the whole, it would seem better to decline "Didelphus," and to write "of a uterus didelphyia," and "in a uterus didelphyia."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	—	—	—
Each additional line	—	—	0 5 0
A whole column	—	—	3 10 0
A page	—	—	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive postal remittance letters addressed either in initials or numbers.

The Bradshahu Lecture

ON

NERVOUS AFFECTIONS OF THE SIXTH AND SEVENTH DECADES OF LIFE.*

By J. MICHELL CLARKE, M.A., M.D. CANTAB.,
LL.D. BRISTOL, F.R.C.P.

PROFESSOR OF MEDICINE, UNIVERSITY OF BRISTOL; LIEUTENANT-COLONEL R.A.M.C. (R).

The sixth and seventh decades of life constitute a period which has certain marked characteristics. The age of 45, which Dante fixed as the end of the period of youth, might have been taken as the lower limit, but that would involve in most women the inclusion of the climacteric, which I thought it better to avoid.

Many nervous diseases run a very long course, and we should therefore expect to find that the nervous affections of this period will be made up of some which began at an earlier age, and of others, fewer in number, whose incidence is entirely contained within it. I do not propose to include mental affections.

SPINAL CORD.

The diseases of the spinal cord between 50 and 70 years of age are both numerous and important. Tumours of the cord present no especial features at this age; secondary metastases in the cord itself to cancer elsewhere are very rare. I have seen two examples of secondary growths in the cauda equina; the primary growths were in the breast and prostate respectively.

Myelitis is not a common disease after 50. In 156 cases reported as myelitis, acute or subacute, excluding pressure myelitis, 18 per cent. occurred after this age. The age given in hospital reports probably represents very nearly that of onset, as chronic cases with secondary degenerations would come under other designations, for example, spastic paraplegia. This relative infrequency after 50 might be expected, as the common causes of myelitis are chiefly some acute infection or intoxication, in which the myelitis may be either primary or secondary, and syphilis. Taylor and Buzzard¹ state that syphilis is responsible for the great majority of cases, probably 80 per cent. of cases of myelitis. The term "myelomalacia" is more accurate than "myelitis" for many cases. One night, perhaps, have anticipated an influx of cases of myelitis, or rather myelomalacia, in later life, due to vascular occlusion from arterial degeneration, but large patches of softening in the cord seem rarely to result from this cause: the contrast with the frequency of areas of softening in the brain is remarkable. Arterio-sclerosis in the cord seems to affect the smaller vessels and to produce small sclerotic foci or diffuse areas of degeneration.

The diseases of the spinal cord which are especially characteristic of this age are diffuse lesions of the posterior or lateral columns, mostly degenerative—cases formerly grouped together as the "combined scleroses." In some, symptoms due to disease of the lateral columns predominate, and the clinical picture is that of spastic paraplegia, a very definite clinical syndrome, but due to various pathological states. In other cases the posterior columns are chiefly affected, and many are of pathological rather than of clinical interest, as the changes in the cord either give rise to no symptoms, or else these are overshadowed by more urgent ones due to the general disease in the course of which they occur. Such are the degenerations of the posterior columns found in cachectic states, in carcinoma, in glycosuria or diabetes, the slighter forms of the cord degenerations of pernicious anaemia, and also those found in some cases of chronic cystitis and enlarged prostate. In all the lower part of the cord is solely or chiefly affected, and the predominant symptom is paraplegia, or paraplegic weakness with ataxy, with or without some, generally not profound, sensory affection.

Cases of paraplegia of this kind are found recorded under the names of spastic, ataxic, or senile paraplegia, combined sclerosis, or subacute combined degeneration.

* In preparing this lecture for publication here it has been necessary, owing to considerations of space, to omit some passages.

Unfortunately these terms are not always used in the same sense; whilst cases of one group shade by degrees into those of another, and, except in the case of subacute combined degeneration, convey no very clear idea of the pathological changes. For instance, under such a name as "ataxic paraplegia" will be found included quite distinct diseases, whilst "spastic paraplegia" merely indicates the predominant clinical feature irrespective of its pathological cause. An important step forward in differentiation was the separation of subacute combined degeneration, both clinically and pathologically, from among these various conditions by the work of Russell, Batten, and Collier.²

With the proviso that the above designations as given in reports of cases are not mutually exclusive, and only afford a rough idea of the age incidence, I find that of 114 cases of spastic and ataxic paraplegia, combined sclerosis and subacute combined degeneration, 38 per cent. occurred between 50 and 70 years of age. If spastic paraplegia is excluded for the reason that it will comprise many old-standing cases of lateral sclerosis secondary to myelitis and other causes, the proportion between these ages is higher—49 per cent.—and reaches its highest point in subacute combined degeneration.

Dr. Collier,³ in his excellent account of this disease, states as to the age of onset that the extremes are between 30 and 65 years, and that the highest incidence is reached between 55 and 60. Of 11 cases under my observation, in most of which the diagnosis was confirmed *post mortem*, the age in 9 was between 53 and 64. There was no definite cause for the disease in any; in 2 cases it appeared after severe diarrhoea and vomiting, and 1 patient had had syphilis; 3 of the patients suffered from pernicious anaemia, 3 from anaemia distinctly of the secondary type, and 4 were not anaemic.

None of these varieties of combined sclerosis of the cord can be regarded as true system degenerations, which appear earlier in life and are often hereditary or familial.

Haematomyelia of spontaneous and non traumatic origin is rare at any age. Of v. Pfungen's⁴ 10 cases 4 were between 50 and 65.

Weakness in the legs or paraparesis is occasionally a symptom of chronic uraemia in elderly persons. This may be the first sign of kidney disease for which the patient seeks relief. In three cases under my care the symptoms, of gradual onset, consisted of weakness in the legs, with a feeble, tottering, or uncertain gait. There was no affection of sensation; the deep reflexes were exaggerated, the superficial normal; there was constipation and difficulty of micturition. The affection lasted from three to six months before severe general symptoms of uraemia appeared.

Senile paraplegia is a name used for paraplegic weakness due to diverse pathological changes. For the most part the sufferers are beyond the age we are considering. A variety has, however, been described by Oppenheim⁵ which he attributes to arterio-sclerosis of the cord, and to perivascular sclerotic changes, especially in the white matter. According to Purves Stewart⁶ the cases so affected can hardly be called senile. The ages of Hirschel's cases varied from 44 to 65. The symptoms are those of a slowly progressing spastic paraparesis, ultimately leading to contraction of the limbs, with increase of deep reflexes. Sir William Gowers also described under the name of "simple senile paraplegia" a condition occurring especially in persons over 50 characterized by simple weakness of the legs with slowness of movements, but without wasting, sensory disorder, or alteration of reflexes, and resembling paralysis agitans without tremor.

Spastic paraparesis or even paraplegia may in later life be due to cerebral affections, for instance, small patches of softening on each side of the pons, or bilateral lesions of the cortical leg centres, causing degeneration of the pyramidal tracts.

Pressure Paraplegia.

Caries of the spine, hypertrophic cervical pachymeningitis and internal pachymeningitis involving a great extent of the cord, and probably of syphilitic origin,⁷ are very seldom met with after 50. The most important cause of compression paraplegia in later life is cancer of the vertebrae: the cases are almost all over 50, and the growth is nearly always secondary. The primary tumour is most frequently in the breast, but may be in the prostate, stomach, uterus, or other organ.

On account of the agonizing pain which often attends it this is one of the most terrible of diseases. The typical feature of the pain is that it is brought out or increased by movement, is in abeyance during rest, and is localized. Sometimes early, but more often later, in the course of the disease, pains from pressure on posterior nerve roots may occur, these are not so much affected by movement, are lancinating, and pass down the course of the nerves.

The diagnosis in the early stages is often difficult. The symptoms may be vague, but x-ray examination may clear up the diagnosis in a doubtful case. Late in the disease, when the patient is cachectic, wasted, has deformity of the spine, or the characteristic shortening of the trunk due to involvement of several vertebrae, and pressure paraplegia, the diagnosis is obvious. The onset of paraplegia may be almost sudden from the development of a patch of softening in the cord at the site of compression. In one case of a small scirrhous tumour of the breast the primary tumour was not noticed before paraplegia occurred. A history of a long interval between the discovery and the removal of the growth is important. Many years may pass between operation for the primary growth and the development of metastases in bone.

There may be no wasting, and patients may even become fat from enforced inactivity; tenderness or pain to percussion over the spines may be absent, even when the patient complains of intense pain on movement; and deformity of the spinal column may not occur until late in the illness. The early pains may be set down to rheumatism or hysteria. In some cases both the pains and the difficulty of carrying out certain movements may entirely disappear for a time.

A rare cause of pressure paraplegia in later life is limited osteo-arthritis of the vertebrae. I refer only to those cases in which paraplegia, generally painful, is caused by an osteo-arthritic lesion limited to a few vertebrae. Such a case is described by Bailey and Casamajor, in which the existence of an extra-mucillary tumour seemed probable as the cause of the paraplegia, but at the operation the laminae and spinous processes of the twelfth dorsal were found thickened, abnormally soft, and greyish in colour, and were removed. Pathological investigation showed chronic osteo-chondritis with new bone formation. The patient completely recovered. In a man of 65 whom I saw there was paraplegia of subacute onset, apparently due to a transverse myelitis at the level of the eleventh dorsal roots. At operation it was seen that the eighth, ninth, and tenth dorsal laminae had undergone some form of sclerosing osteitis, with great thickening, that of the ninth being fully one inch thick.

Tubes Dorsalis.

Tubes dorsalis fairly maintains its frequency in the sixth decade of life. Of 700 cases, the proportion living over 50 was 24 per cent. In Byrom Bramwell's⁹ statistics of 263 cases the onset occurred in 9.6 per cent. over 50, and 1.9 per cent. over 60 years.

Cases in which the onset occurs after 45 as a rule run a more favourable course. The longer the interval after infection before symptoms of tubes appear the less acute the course of the disease. In some cases the symptoms are slight, and do not advance; in another group the disease is more pronounced, but the average duration before the patient is incapacitated is fifteen years.

Tubes shows a decided falling off after 50 as compared with the period 30-50, and a very marked fall after 60. Arthropathies seem to be present in a larger proportion of cases than in younger patients; in several cases the character of the work as involving the special use of certain joints seemed to determine the site of the arthropathy. Aortic disease is more frequent in elderly tabetics, and other complications are hemiplegia or recurrent paralysis, either monoplegic or hemiplegic, due to syphilitic disease of the cerebral arteries. In some of these patients the signs of tubes may be first discovered when the patient seeks advice for one of these complications.

Cases following an acute course with severe ataxy are rarely met with after 50. The prognosis as to life is not bad, except when there is aortic or vascular disease, or cystitis following old-standing difficulties of micturition.

The Muscular Atrophies.

The myopathic forms of muscular atrophy do not arise in the period of life under consideration, but the myelo-

pathic forms—progressive muscular atrophy, bulbar paralysis, and amyotrophic lateral sclerosis—are relatively frequent after 50. There is good evidence that syphilis may be the cause of myelopathic muscular atrophy in some cases. In several cases of progressive muscular atrophy in elderly patients I noticed that the atrophy started in muscles or groups of muscles which were chiefly used in the occupation, and may presumably have become exhausted. The rate of progress of the atrophy was rapid in these cases; the disease steadily spread beyond the muscles first affected, so that there was no question of a mistake in diagnosis for a limited atrophy of muscles due to occupation. Is it possible that a muscular atrophy from occupation starting from over-fatigue of special muscles tends in an elderly person to spread widely, whilst in those younger it remains limited to the muscles involved in the particular action concerned? The occurrence of these forms of atrophy after 50 is not obviously connected with arterial disease, which was not more evident than in normal persons of the same age.

Some rare cases of progressive muscular atrophy run a subacute course, and are especially met with in the elderly. Oppenheim¹⁰ classes them apart as subacute and chronic anterior poliomyelitis, and suggests a toxic cause. Other writers assign the cause to traumatism. Of two well-marked cases of this affection, both in men in good circumstances and of previous good health, one was aged 67. Three weeks after a heavy fall weakness of the left hand and arm began and steadily increased; two months later he had very little use of the upper extremity, and its muscles generally showed atrophy with fibrillary tremor. Five months after the accident the muscular atrophy had greatly increased, both upper extremities and the neck being now involved. The disease shortly afterwards spread to the bulb, and he died quite suddenly. The other patient was aged 66. He had been overworked for some time before the onset of the disease. The distribution of the atrophy, as in the other case, was practically confined to the upper extremities. The course of the illness was four months, and he also died suddenly.

Disseminated Sclerosis.

Disseminated sclerosis generally begins much earlier than the period of life under consideration, but as it may run a long course there are a certain number of survivors after 50. Moreover, it is well known that remissions, sometimes of very many years' duration, may occur, and the final outbreak may exceptionally be deferred to quite late in life. The remissions may be of such duration as almost to amount to recovery from the disease; possibly such remissions may very occasionally be permanent.¹¹ Allowing for a source of error from the fact that in common diseases only exceptional cases are recorded, instances of the onset of the disease in patients over 50 are very uncommon. In 536 cases from various sources irrespective of age of onset, the number over 50 years of age was from 4 to 5 per cent.

The few cases in which the onset occurs late seem often to present exceptional features, and are therefore of importance from the point of view of diagnosis. The rare form in which disseminated sclerosis runs its course with muscular atrophy, and may resemble amyotrophic lateral sclerosis, is considered by Schmitzler¹² to affect older patients and to run a more rapid course. There are also cases such as those reported by Bornstein,¹³ in two women aged 60 and 62 respectively. The clinical signs were those of subacute transverse myelitis, and pathological examination showed areas of multiple sclerosis, together with marked changes in the vessels.

Syringomyelia.

The large majority of cases of syringomyelia occur between 20 and 45 years of age. The disease, however, is met with at all ages, and considering that it is one of the rarer nervous diseases, fairly often over 50. Out of 135 cases 23 per cent. were between 50 and 70. Hospital statistics give a rather lower percentage (about 17 per cent.) than reports of special cases. On the view now generally held that syringomyelia is due to a gliosis of the cord, it is interesting to compare the age incidence with that of glioma elsewhere. Dr. Tooth,¹⁴ in 127 cases of glioma of the brain, gives 11 per cent. with onset between 50 and 70. Syringomyelia may run a very long course,

and such cases form a certain proportion of those over 50; on the other hand the onset may be after that age; this happened in 13 out of 79 cases. Sometimes the disease suddenly takes on an acute phase, or progresses afresh in later life after quiescence for long periods. Although there is still a difference of opinion on the point, the evidence that the cause of this activity is often an injury is strong.¹

Pathologically syringomyelia in later life is characterized (1) by the replacing of gliosis tissue by connective tissue, which originates from the adventitia of diseased vessels, and (2) by the formation of cavities in the lateral columns of the cord not connected with the central canal and due to patches of softening.² The first appearance of syringomyelia in later life, or the sudden aggravation of symptoms, may be due, at any rate in part, to secondary vascular changes in the cord and to haemorrhages.³ Haemorrhage from diseased vessels may easily occur into the cavities, and has been actually found as the cause of a sudden aggravation of the disease in elderly people.

In other cases the symptoms are clinically those of syringomyelia, but are due to the formation of cavities in the cord, as a direct result of haemorrhage from vessels with degenerated walls. When syringomyelia originates or starts into fresh activity late in life it is generally progressive.

Destructive disease of the joints in atypical syringomyelia is probably more frequent than is generally recognized. A remarkable case came under my notice. A woman, aged 62, had her left leg amputated above the knee five and a half years previously because it was so extremely contracted as to cause great pain, and the heel was forcibly pressed against the anus and hindered defaecation. Subsequently the right leg became contracted and flexed across the abdomen. When I saw her this leg had been straightened by osteotomy. At the operation the femur and tibia were found to be remarkably brittle and atrophic.

Neuritis.

In 250 cases of multiple neuritis from various sources only 10 per cent. occurred over the age of 50, and 75 per cent. of the cases were between the ages of 30 to 50.

In 45 cases under my care 24, of whom 18 were women, were between the ages of 40 and 53 years. There seems to be a special incidence of alcoholic neuritis during the climacteric. The mental depression and the feelings of nervous exhaustion or lassitude which are such common features of the climacteric tend to induce the less strong-minded to seek relief in alcohol. The nervous changes of the climacteric may possibly impair the nutrition of the lower neurones, and render them more susceptible to the poisonous action of alcohol. As to symptoms, I think that the characteristic mental symptoms of Korsakov's syndrome are more frequent and pronounced in this group than in cases occurring at an earlier age, and also that there is, very constantly, affection of the heart muscle.

Of the less common forms of multiple neuritis, the glycosuric is perhaps relatively the most frequent after 50. The etiology is often mixed—gout, glycosuria, and alcohol. A rare but grave form is acute or subacute toxic polyneuritis. Instances of this disease may occur at any age, though the majority fall between 20 and 45. Of 13 cases under my care, 4 occurred at the ages of 72, 68, 50, and 49 respectively.⁴ A widespread paralysis of acute or subacute onset due to toxic polyneuritis may follow an ascending course and constitutes one group of the cases classed as Landry's paralysis. In the majority the presence of decided sensory changes, "glove" and "stocking" anaesthesia, pains, and muscular tenderness are distinctive of polyneuritis, but there is one form which affects the lower motor neurones almost exclusively; early diagnosis from the spinal form of ascending paralysis may then be difficult.

It remains to mention the caeclastic forms of neuritis, and especially that which develops in connexion with carcinoma, for the majority of such cases fall between the ages of 50 and 70. The symptoms as a rule are of slight intensity. Towards the end of this period the senile form of multiple neuritis, which in some instances is referable to arterio-sclerosis or atheroma, appears. Brachial neuritis is in my experience relatively not infrequent between 50 and 60, and this also applies to anterior cranial neuritis, which often seems to be started by slight traumas or by muscular effort.

Of 50 cases of sciatic neuritis, many very severe and of long standing, and all of them sufficiently bad to compel the patients to seek treatment in hospital or to confine them to bed, 27 occurred between 30 and 50, and 23 cases between 50 and 70 years of age, 16 of the latter falling between 50 and 60. Rheumatism and gout, with exposure to cold and wet, and excessive muscular exertion are the chief causes. In my experience the prognosis is not distinctly worse, nor treatment less successful, in patients over 50. The treatment adopted in nearly all the cases was immobilization by means of the long splint.

BRAIN.

I do not propose to deal with meningitis except briefly with the tuberculous variety, and that on account of the peculiarity of its symptoms in adults. Meningitis due to pus-producing organisms becomes uncommon after 50; when it occurs as a primary infection the diagnosis is now greatly facilitated by lumbar puncture. Perhaps the most frequent form is the pneumococcal, which may either be primary, or a complication of pneumonia, or one feature of a general pneumococcal infection.

Tuberculous meningitis in persons over 50 is very exceptional. Of 560 cases of tuberculous meningitis, 4 had passed this age. There were also 8 cases between 40 and 50. In adults it occurs chiefly as the termination of chronic pulmonary tuberculosis. The early symptoms may be deceptive and mistaken for early mental disease, hysteria, or delirium tremens.

Cerebral Haemorrhage and Thrombosis.

The most common of all nervous affections between 50 and 70 years of age are those due to disease of the cerebral vessels, and the causes and methods of prevention therefore belong to diseases of the vascular rather than of the nervous system. The subject is too extensive to be considered here. Of 500 cases of cerebral haemorrhage, the onset was between the ages of 50 and 70 in 321, or 64 per cent., and, of 110 cases of cerebral thrombosis, in 67, or 60.9 per cent.

Cerebral Tumours.

With regard to the age incidence of intracranial tumours there are available the valuable statistics compiled by Dr. H. H. Tooth.⁵ The first symptoms in his 500 cases occurred between the ages of 50 and 70 in 7.2 per cent. In 238 of these the nature of the growth was verified by operation or *post mortem*: of these the age at onset was between 50 and 70 in 9.6 per cent. Gliomata constituted 49.2 per cent. of the total, and of these 10.2 per cent. occurred at from 50 to 60, and 0.7 per cent. at 60 to 70 years of age. Carcinomata were few in number, but the percentage between 50 and 70 was nearly 40. In a further number of 485 cases which I have collected from various sources, similarly verified or not, the proportion between 50 and 70 is rather higher—13 per cent. In 18 cases of intracranial tumour observed by myself in persons over 50, in 12 of which the diagnosis was verified *post mortem* or at operation, in 1 the tumour was cerebellar, in 2 the tumour was in the cerebello-pontine angle, and in the remainder in various parts of the cerebrum. Three patients were over 60 years of age. In several of the cases the sudden onset of symptoms suggested some intracranial circulatory disturbance. Optic neuritis was well marked in these cases, attacks of vertigo especially frequent, and, apart from the situation of the growth, mental changes were prominent. In 2 the intracranial growth was secondary to cancer of the breast. Affection of the nervous system by cancer is generally through secondary metastatic growths. The order of frequency of metastases is (1) vertebrae, (2) bones of skull, (3) brain, and (4)—very rarely—spinal cord. The secondary growths may occur in any part of the brain, and are often multiple, and may be diffuse or localized. The symptoms they cause may be pronounced or, on the other hand, absent or overshadowed by those due to growths in other organs, and the intracranial metastases only discovered *post mortem*.

The diagnosis of a cerebral tumour in a person over 50 is often difficult. In the case of a primary tumour the symptoms may be attributed to other diseases of the brain more frequent at this period of life. Thus for the mental disturbance produced by a growth other causes may easily

be assigned; headache and vertigo are common complaints in persons over 50, and of various origin; and hemiplegia or monoplegia would rather suggest vascular disease, though the gradual onset of hemiplegia is always suggestive of a tumour.

To sum up, an intracranial tumour is rarely met with in persons over 50, and still more rarely in those over 60; when it occurs diagnosis may be more difficult than in younger persons.

Cerebro-spinal Syphilis.

Of 261 cases of cerebral syphilis, 9 per cent. were over 50 and only 3 cases over 60 years of age; these include 60 personal cases, of which the number over 50 was 8. The interval between infection and onset of nervous symptoms is in the majority within ten years, often, of course, much earlier. The statement that has been made, that the older the patient the shorter the interval between infection and appearance of cerebral symptoms, seems not to be correct.²⁰ In cases over 50 a certain number are due to late syphilitic infection; in 3 of my cases the age of infection was 35, 44, and 46 respectively, and signs of cerebral syphilis appeared from twelve to fifteen years later. In the remainder the late onset of cerebral disease is due to a long interval after infection.

The symptoms do not seem to differ greatly from those in younger patients. In two of my cases in which the interval between onset and infection was very long, affection of the cranial nerves was the chief feature; many cranial nerves and also some spinal roots may be affected. Vertigo is often a prominent symptom. The question as to the part played by previous syphilitic infection in the production of disease of the cerebral vessels, that is, as to the proportion of cases of apoplexy or hemiplegia occurring after 50 which are due to vascular disease as the direct result of a previous syphilitic infection, is very important, but I am not able to give exact figures.

It is now generally recognized that fits indistinguishable from those of idiopathic epilepsy may occur as a result of cerebral syphilis. So far as I have been able to ascertain the age of onset as a rule is before 50. I have seen two cases over 50; in one man aged 60, who had syphilis at 46, the attacks resembled *petit mal*, and the other was first affected by repeated severe epileptic seizures at 54.

Syphilitic affections of the spinal cord are relatively still more uncommon after 50 than those of the brain. Though Head²¹ states that "there is no period after infection when the patient may not be attacked by a paraplegia," yet in most the symptoms of spinal syphilis follow somewhat early after infection. This is especially the case in syphilitic meningo-myelitis, which may occur within six months of infection.

In 3 out of 35 cases of various forms of spinal syphilis the patients were over 50. The first was a man of 53 who contracted syphilis at 22, with onset of spinal symptoms at 40. Affection of spinal roots gave rise to the chief symptoms. The disease was probably a chronic meningitis, and was remarkable for its long duration. The second case was clinically a transverse myelitis in the lower dorsal region of the cord, and syphilitic infection occurred at 37. The onset was subacute at the age of 56. The third was one of spastic paraplegia in a woman of 62, whose husband had tabs.

To sum up, the onset of cerebral syphilis after 50 is not common, of spinal syphilis rare, and after 60 still more rare in both.

THE NEUROSES.

The commonly received opinion is that sufferers from migraine either lose their attacks in later life or that they become mitigated, and that in women this relief is to be expected after the climacteric. Speaking generally, this opinion seems to be correct, and migraine is uncommon, at any rate in a severe form, after 50. A confident prognosis can, however, only be given on general grounds; it is impossible to say in an individual case that lapse of years will give relief. Some patients suffer from more frequent attacks during the climacteric, and in a certain number an increase in the frequency and severity of the attacks dates from this epoch. I have seen two cases in which premonitory hemipia has been a constant feature of the paroxysm, and permanent hemipia resulted—one instance

in a woman aged 35, and another in a man aged 54; but he had also arterio-sclerosis, high blood pressure, and glycosuria. There are also instances on record of permanent paralysis following migraine, but these are mostly in persons under 50. Most of the patients showed disease of the vessels, but others were young with presumably healthy arteries. Such consequences of migraine seem to be so rare as to be of little practical importance, and do not especially occur after 50.

Headache in connexion with contracted granular kidney may closely simulate migraine. Thus a patient with well-marked signs of contracted kidney of some years' duration first began to suffer at the age of 55 from attacks of headache exactly resembling migraine, with ocular prodromata in the left eye, in which there was commencing albuminuric retinitis. As migraine never begins late in life, no mistake in diagnosis should be possible, for though in some patients there may be an intermission lasting years, careful inquiry will elicit a history of former attacks. On the other hand, I have come across several instances in which lifelong sufferers from migraine developed granular kidney after 50, the headaches becoming more severe but retaining their original form.

An important question is whether migraine leads to epilepsy in later life. It is a matter of common observation that migraine and epilepsy not unfrequently occur in different members of the same family, either in collaterals or in previous generations. The similarity of some features of the two diseases is also remarkable. The further assumption of anything like identity between them is, however, not justified. Occasionally a patient is subject to both affections.²

Epilepsy.

It is well known that the frequency of epilepsy diminishes as life goes on, but it is also true that epilepsy may begin at any age. I cannot give extensive statistics, but of 100 consecutive out-patient cases 6 per cent. had their first fit after 50, and in 100 consecutive private patients 9 per cent. Especial care is necessary in the diagnosis of idiopathic epilepsy in later life to be sure that the case is not one of an epileptiform attack, symptomatic of some underlying disease. This especially applies to Jacksonian epilepsy, for, after 50, localized epileptiform attacks from the partial closure of a diseased cerebral artery are not uncommon. As to direct heredity in epilepsy of late onset, Gowers gives it as 26 per cent. in those which begin after 40, and Turner 10 per cent. in cases arising between 41 and 70. Finch, however, puts the proportion as high as 66 per cent. In 8 personal cases in which the onset was between 52 and 64 years there was an hereditary history in 2 only. In late epilepsy men are more frequently affected than women. Idiopathic epilepsy between the ages of 50 and 70 comprises: (1) Cases in which the disease persists throughout life; (2) cases in which the patient suffered from fits in childhood or early life, and then was free for a number of years, with a subsequent reappearance late in life; and (3) those in which the onset is after 50.

The occurrence of epileptiform fits after 50 years of age may be connected with the presence of arterio-sclerosis and high blood pressure. These cases cannot be brought into the category of idiopathic epilepsy. Whether the fits are due directly to the high blood pressure or to the toxæmia which produces it is a moot point, but as cases of hypertension are common after 50, and epileptic attacks rare, there is probably some other factor in the causation. The attacks may be severe general epileptiform ones or those of minor epilepsy (*petit mal*). Some of these cases are undoubtedly due to contracted granular kidney, but in others the kidney is not involved, and they cannot therefore be regarded as uræmic.

In late epilepsy, supervening at an age when the wear and tear of life has often produced changes in the blood vessels, it would be anticipated that the strain on the cerebral circulation produced by a fit should sometimes lead to hæmorrhage. Of this I have seen two instances; one was in a lifelong epileptic who at the age of 70 died of hæmorrhage from a cerebral artery which ruptured in the course of a fit. In the other case the first fit took place at 60, others occurred between that age and 70, when he was left aphasic and hemiplegic after a fit.

Vertigo.

Vertigo is occasionally the chief symptom in an attack of late epilepsy, when the differential diagnosis from other possible causes is sometimes difficult and especially so when epileptic attacks and aural vertigo co-exist in the same patient. Thus a man of 47 had a sudden attack of severe vertigo which left him deaf in the left ear, and liable to attacks of vertigo with tinnitus; at 53 he began to suffer from fits in which he felt an indescribable feeling rising from the stomach, lost consciousness, and fell, hurting himself in falling. There was no memory of the attacks. Gowers gives several instances of this coincidence of aural vertigo and epilepsy.²⁷ It may be difficult to determine the nature of a single attack.

Vertigo is one of the common, and certainly one of the most distressing, nervous affections of later life. By far the most frequent form is aural vertigo. Next in frequency come the cases due to increased intracranial pressure. It is also met with over 50 as a symptom of atheroma of the cerebral vessels, in stenosis of the aortic valves, in granular kidney, in cerebral tumours, and in neurasthenia. In a few instances an association with migraine, probably accidental, was present. The patients were between 50 and 60, they had suffered from typical attacks of migraine with ocular symptoms which ceased at or before the age of 50, and then at about 55 began to be affected with severe aural vertigo. Vertigo is a rare premonitory symptom of migraine.

The form of vertigo associated with hypertension, sometimes an early symptom of contracted granular kidney, is worse on movement, and especially apt to occur on getting up in the morning; the attacks are often attended by severe vomiting, which may persist for some time after the vertigo has gone. Consciousness is not affected. In one case with frequent attacks of vertigo and vomiting during two years, often lasting for two days at a time, haemorrhage into the pons Varolii with paralysis of the third, fifth, sixth, and seventh nerves subsequently occurred.

Hysteria.

The more severe hysterical affections are undoubtedly uncommon after 50. They may occasionally appear in persons who have not suffered from hysteria previously. Because severe hysteria is uncommon in later life, errors of diagnosis may be made, and if the patient is a male the true nature of his complaint is the more likely to be mistaken. Hysterical mental disorders and fits are most uncommon after 55, and in the presence of a presumed case it is necessary to bear in mind Dr. Ormerod's warning to exclude alcoholism. I have once seen a severe hysterical fit in a woman over 55, which was followed by hysterical hemiplegia, and due to the shock of her mother's sudden death.

Hysterical paralysis and contractures occur rather more frequently. I can recall two cases of typical hysterical paraplegia in men, both aged 64. Under appropriate treatment they recovered completely. Two instances of hysterical contracture of the leg in women, aged 53 and 51 respectively, are of interest, because in each case there was a possible source of autostimulation; for one patient was a nurse, who had chiefly to do with paralytic cases, and the other lived with a sister whose knee was permanently contracted after an accident. Both recovered after removal to hospital.

Neurasthenia.

The large majority of cases of neurasthenia occur between the ages of 25 and 50. Many neurasthenics, as they reach later life, though perhaps never becoming robust, yet arrive at a measure of health and freedom from morbid anxieties. At the same time neurasthenia, though not frequent, may occur after 50 up to old age. The symptoms present no special feature, except perhaps that vertigo is relatively more frequent and troublesome, that loss of memory may be a pronounced symptom, and morbid fears, if present, often take the form either of fear of paralysis or of sudden death. The diagnosis of neurasthenia, always one of exclusion, requires especial care in later life, because in cases over 50 with symptoms resembling those of ordinary neurasthenia, it is often found that the patient has arterio-sclerosis with abnormally high blood pressure, or early signs of a granular kidney, or that the symptoms are due to changes in the nutrition of the brain from disease of its vessels.

The traumatic neuroses are apt to affect persons after 50 very severely as the result of an accident, and to take the form of neurasthenia rather than of some more strictly hysterical manifestation. Here again the matter is confused by the frequent pre-existence of chronic disease of the vessels, heart, or kidney, so that it may be difficult after an accident to apportion correctly the share of the illness due to nervous shock and that due to antecedent disease. The difficulty is increased by the common experience that the patient, from the gradual onset of these infirmities of advancing age, was unconscious of them before the accident. In medico-legal cases of elderly workmen claiming compensation after an accident—and it is only human nature for them to attribute all their trouble to it—a just decision is often extremely hard. Working men over 60, after a life of toil, generally show signs of vascular or cardio-vascular degenerative changes; they may go on working so long as no accident or acute illness occurs, but they are in an unstable equilibrium, and if unfortunate enough to meet with a bad accident, they are likely to be permanently incapacitated. The prognosis as to return to work in traumatic neurasthenia in persons over 55 is in my experience not good.

Neuralgia.

Between 50 and 70 true neuralgia is not an infrequent affliction. Gout, arterio-sclerosis, various cachexias, and presenile disturbances of nutrition are the chief causes. The senile and arterio-sclerotic forms chiefly affect the fifth nerve. Neuralgia may be a complication of a granular kidney, and in my experience this often affects the occipital nerve. Occipital pain, not definite neuralgia, is sometimes a symptom of uraemia. Lapinsky has traced the neuralgia of nephritis to disease of the vessels of the nerves.

A most severe form of neuralgia in the elderly is that which follows herpes zoster. A sufferer from herpes in later life rarely escapes without subsequent neuralgia, often lasting for months. Erans²⁸ thinks that a large majority of cases of herpes zoster are microbial in origin, and regards this as the essential form of the disease, to which he attributes most cases occurring in children, whilst those which occur after 40 are due to causes yet undetermined. He states that half his cases were under 14 years of age, and one-sixth over the age of 40. Head says that of 378 cases, 29 were over 40 years of age.

Paralysis Agitans.

Though not a very common disease, paralysis agitans is pre-eminently one of the period of life between 50 and 70 years. Its main incidence is narrower and lies between 50 and 65. Sir W. Gowers²⁹ states that in 51 out of 236 cases the onset was between 40 and 49, in 100 from 50 to 59, and in 60 from 60 to 69—altogether 211 cases. After 70 there were 10 cases. Stuart Hart³⁰ in 219 cases found the age of onset to be between 40 and 50 in 54, between 50 and 60 in 88, between 60 and 70 in 42, and none after that age. Onset over 65 is thus uncommon. The disease is therefore one of the presenile period. Its cause remains mysterious and it is not especially associated with vascular degeneration or other bodily changes incidental to this age.

CONCLUSION.

If from the foregoing considerations we try to get a general view of the nervous affections of the sixth and seventh decades, it is clear that many nervous diseases do not occur at all, others are modified in their symptoms and course, and a few especially affect this time of life. Except for one important group of diseases, it comes out more favourably in comparison with other ages than one would perhaps have expected.

It is hardly necessary to say that the lesions of the brain due to vascular disease form the exception, and although, strictly speaking, these are not primarily nervous diseases, yet from the practical point of view they are by far the most important of the nervous affections of this period, because of the great frequency of cerebral haemorrhage and thrombosis after 50, and of their disastrous effects both as to life itself and, if that is preserved, as to future usefulness. The frequency alone of such serious diseases marks them as first in importance. Cerebral haemorrhage, thrombosis, and hemiplegia afford a very large proportion of the sufferers between 50 and 70 from all the diseases considered in this

lecture. Further, it has been shown that disease of the arteries materially affects the course of most nervous affections at this period. Since nervous tissue, once destroyed, cannot be restored, the prevention of vascular disease becomes of paramount importance. How this is to be accomplished I cannot consider at length. Often the tendency to vascular disease is hereditary, and beyond our powers to remedy, but apart from such cases it is certain that the chief measures to prevent degenerative changes in the circulatory system are abstemiousness in eating and drinking, care to keep efficient the organs of digestion and excretion, and regular physical exercise. The simple life may prevent, and certainly mitigate, the progress of vascular decay.

Again, granular kidney, a disease for which unfortunately our treatment is merely palliative and not preventive, is the cause of a large proportion of cases of cerebral hæmorrhage. Whilst on the one hand over-feeding has to be avoided, on the other excessive work with insufficient nutrition is also a danger. Exhaustion, over-fatigue, or overstrain are doubtless causes of such diseases as the muscular atrophies in later life. The need for moderation of former activities, both mental and physical, is a lesson that many learn too late. Defect of nutrition, again, may be local in the nervous system from defective supply of blood, due to localized arterial disease.

Turning from the vascular degenerations to those affections more purely of nervous origin, the period from 50 to 70 compares favourably with that of either childhood and adolescence or the age from 25 to 50. In both the latter periods falls the incidence of the nervous diseases due to infections and intoxications, from which the age after 50 is mostly exempt. The main period of onset of the hereditary and familial diseases, those included under Gowers's designation of "abiotrophy," occurs in childhood or adolescence; whilst from 25 to 50, together with some abiotrophic diseases whose onset is late, the numerous nervous affections due to syphilis and alcohol are rife.

We have seen that, with regard to syphilis after 50, the chances of the occurrence of cerebro-spinal syphilis are comparatively slight.

Lastly, the purely nervous diseases which are especially characteristic of this period of life are paralysis agitans, some of the combined scleroses of the spinal cord, and certain muscular atrophies of central origin. It is possible that some of these affections owe their origin to that process of premature senescence or defective vital endurance of certain neuronic systems known as abiotrophy, and that this pathological process may occur at any age. Paralysis agitans especially, in its narrow age incidence, uniformity of symptoms, steadily progressive character, and occasional familial tendency, suggests this mode of origin.

The *Weekly Bulletin* of the U.S. Health Department quotes from the summary of the investigation concerning the physiological aspects of the liquor problem, by Dr. John S. Billings, junr., which was prepared for a special committee, showing that the common idea that a large part of the injury to health from the use of alcoholic drinks is caused by injurious substances in the liquor, such as fusel oil and furfural which have not been properly removed, is erroneous, as is also the notion that cheap liquors contain larger quantities of such ingredients than others. The injurious effects of the fusel oil are trifling in comparison with those of ethyl alcohol. The general conclusion is that fine old brandies and whiskies are nearly as likely to produce ill effects as the cheaper varieties if taken in the same quantities, and the injurious effect is in proportion to the ethyl alcohol contained.

A Lecture

ON WOUND INFECTIONS AND THEIR TREATMENT.

DELIVERED WITH DEMONSTRATIONS AT THE OPENING OF AN EXHIBITION OF SURGICAL APPLIANCES FOR THE TREATMENT OF THE WOUNDED HELD AT THE ROYAL SOCIETY OF MEDICINE FROM OCTOBER 8TH TO 14TH.

By COLONEL SIR ALTHROE E. WRIGHT, M.D., F.R.S., C.B.,

A CONSULTANT PHYSICIAN TO THE EXPEDITIONARY FORCE IN FRANCE.
(From the Research Laboratory attached to No. 15 General Hospital, Boulogne-sur-Mer.)

PART II.

FROM the introductory studies which have up to this occupied our attention I pass to the subject-matter proper of this lecture,

THE TREATMENT OF MICROBIAL INFECTIONS OF WOUNDS.

I would propose, despite the fact that this will sometimes carry me over ground traversed in my last lecture, to discuss with you, one by one, the various therapeutic procedures which have been employed or suggested for use. And then at the end it will perhaps be possible to draw up something in the nature of a general programme for the treatment of infected wounds in their different stages.

Let me tell you—for you will then see our road ahead—what are the therapeutic procedures we shall be dealing with. These are—and I enumerate them in the order which I shall follow—*treatment by antiseptics; treatment by surgical procedures; treatment by "physiological," or, as I would now for the sake of clearer definition wish to call them, "phylacogenic" methods; and, lastly, treatment by vaccines.*

TREATMENT BY ANTISEPTICS.

That one thing, where the organism is unable to deal effectually with an infection, to resort to the use of antiseptics seems to many minds to be perfectly clear *a priori*. Now when a proposition of this sort is said to be evident *a priori*, what this really means is, not that the proposition has been established by clinical experience, but that it has been demonstrated by laboratory experiments; and that we may confidently take those laboratory experiments as our guide.

But, of course, everything will here hinge upon the question whether the laboratory experiments which we trust accurately reproduce the conditions in the wound. Now the earlier experiments on antiseptics—and it is almost upon antiquated experiments that the current doctrine of the day rests—did not even aim at reproducing the conditions in the wound. The antiseptics came into application, not as in the wound upon microbes enveloped in albuminous fluids, but upon microbes simply suspended in water. And again it passed as an axiom that if *in vitro* all the microbes were destroyed, then also all the microbes *in vivo* would be destroyed; and there was no thought that the microbes in the cavity and the recesses of the wound, and, above all, the microbes in the infiltrated or granulating wall, might escape destruction.

We have now in the matter of theoretical requirements made satisfactory advance. We now ask of laboratory experiments with antiseptics that they shall conform more closely to the conditions in the wound; and we ask in particular that it shall be kept in view that we have to deal in the wound with microbes enveloped in albuminous fluids; and that antiseptic solutions cannot come into direct contact with all the microbes which we wish to destroy. In other words, we now ask in connexion with every antiseptic for a testimonial of *bactericidal efficiency in albuminous fluids*, and for a testimonial of *penetrating power*. And in accordance with this we find in the prospectus of every new-hatched antiseptic this double certificate of character. It would plainly be beyond the scope of this lecture to look into all these certificates; but I think it will, perhaps, be useful to explain in a general way what sort of an attitude one ought to take up when traffic is made with such credentials.

On Certificates of Character which Testify to the Bactericidal Efficacy of Antiseptics in Albuminous Fluids.

It is familiar matter that the ordinary antiseptics (I shall return later to the case of some very special antiseptics) form chemical combinations indifferently with all native albumins, and not specifically with those which compose bacterial protoplasm. It is a corollary to this that whenever we have in an experiment an antiseptic, and albuminous substances, and microbes, it will, if we propose to sterilize our albuminous fluid, be necessary to cut down very severely its content in albuminous substances. And, again, it will follow from this that every promoter of antiseptics will, if he is conducting his experiments with any of the albuminous fluids of the body, find it to his advantage to employ serum rather than whole blood, and whole blood rather than pus. And, again, when he is operating with serum he will find it to his advantage either to operate with very little serum, or—and this amounts to the same—to use a large number of volumes of antiseptic to every volume of serum. This particular device is, one may see, legitimate or illegitimate according as the experiment is designed to elicit what strength of antiseptic is required for flushing out and irrigating a wound; or to create the impression that the circle has been squared, and that an albuminotropic antiseptic can do its office efficiently in the presence of albuminous substances. Let us reflect that if our ordinary antiseptics, instead of combining as they do with the albuminous substances of the blood, combined only with microbial protoplasm, it would be a perfectly proper policy to administer them intravenously in septicæmia.

Let us, however—for the above may be thought to savour of theoretical discussion—come down to the hard fact. It is, we have found, practically impossible, when employing as material pus from foul, suppurating wounds, to sterilize it by addition of any ordinary antiseptic.

Let me, with the aid of these rough coloured diagrams

FIG. 8.

(reproduced with shading instead of colour in Fig. 8), indicate what he stands in our way. In Fig. 8, B, I have a representation of a test-tube full of thick pus, and I have represented the thick albuminous pus by a uniform wash of deep yellow, and the contained microbes by a stippling of orange. In Fig. 8, A, I have represented in a very rough way, by quite irregular hatchings of blue chalk, the effect that would be obtained by an addition of antiseptic. You will appreciate that no matter how long I go on imposing blue strokes upon my yellow ground, there will, because my blue strokes will never fuse and run into each other, still remain over small islands of yellow stippled with specks of orange. Now we have here a rough representation of what occurs when we add an antiseptic to pus and shake it up. What that gives us is a system made up of islands of pus intersected by channels of antiseptic—the sphere of action of the antiseptic being in each case limited

by confining banks of coagulated albumin. When we dilute pus with very many volumes of an antiseptic solution, as we do in washing out a wound, we, of course, effectively sterilize.

On Certificates of Character attributing to the Antiseptic Penetrating Powers such as would render it Efficacious in the Sterilization of the Wound.

It will be well in embarking upon the discussion of this question to place it clearly before ourselves that when we speak of an antiseptic having *penetrating power*, we mean that the active agent will diffuse out into, and come into operation in, any contiguous fluid.

In other words—if I may illustrate exactly what I mean by the aid of this diagram (Fig. 9)—we say that a chemical agent has penetrating power when, applied in a fluid a, it

passes out into, and produces its effects in, a contiguous fluid b—and let me, for the sake of facilitating exposition, call a the *disbursing fluid*, and b the *recipient fluid*.

Having recognized that penetration is only diffusion under another name, it will be plain that we shall be able to consider the question of penetration without travelling outside familiar ground. We know in connexion with chemical agents generally that their rate of diffusion, that is, the rate at which they will pass out from a disbursing into a recipient fluid, will—exclusive of the influences exerted by temperature, extent of surface of contact, and such like—be determined by the concentration of the chemical agent in the disbursing fluid, and the receptivity of the recipient fluid—in other words, it will depend upon the respective *plentitude* and the *avidity* of the contiguous fluids.

Now, in the case of the ordinary antiseptics which are employed in wounds we have chemical agents, which, owing to their toxicity and escharotic properties, are of necessity brought into application only in dilute solutions;

and, moreover, many of these chemical agents are not very soluble in water. By consequence we are, when dealing with ordinary antiseptics, confronted with conditions which are anything but favourable to diffusion. They will resemble those roughly indicated in the diagram on the blackboard (reproduced with stippling for colour in Fig. 9, A), where we have a dark blue disbursing fluid superposed upon a colourless recipient fluid, and have below the line of contact of the fluids a comparatively narrow zone of paler blue representing a slight carrying over of colour by diffusion.

But in reality the conditions in the wound, where our recipient fluid is, instead of water, a concentrated albuminous fluid, much more nearly resemble those depicted at c (Fig. 9, c). Here we have, as before, our blue disbursing fluid, but there has been substituted for the colourless watery recipient a deep yellow fluid stippled with orange, representing pus with scattered microbes. And you see what we get. Instead of the narrow blue zone which diffusion gave us in Fig. 9, a, we have now a much narrower zone which is—for yellow quenches blue—nearly colourless. I think you will recognize that under conditions such as are here postulated, the prospect of getting any penetration which would be worth while may be abandoned as hopeless.

But perhaps you will suggest that one ought not to place too much confidence in demonstrations conducted on blackboards with coloured chalks; and you would wish the experiment coloured from the blackboard into the real world in order to see whether it would also apply there. Let me suggest such an experiment.

I will suppose that we have as our disbursing fluid a dilute solution of nitrate of silver standing over a recipient fluid consisting, in the one case, of water derived from a fresh-water pond; and, in the other case, of sea-water—both peopled with living organisms. You will discern what would then happen. In the case of the pond water, the nitrate of silver will slowly diffuse into it: killing, as it is carried in, all the living organisms it encounters. In the case of the sea-water, the effect would be quite other. Where the two fluids meet, the nitrate of silver would be thrown down and rendered inert. And below, the marine life would go on absolutely unaffected.

FIG. 9. In A is represented a test-tube containing: above a test-tube containing: above a watery solution of methylene blue, and below clear water. In B is represented a test-tube with a watery solution of methylene blue above and strong salt solution below. In C we have represented above a deep blue, and below a deep yellow fluid.

But you will wish for actual experiments conducted with an antiseptic, and blood fluids, and leucocytes, and microbes such as we have in the wound. Let me therefore show you here in the form of a rough diagram the results of typical experiments—experiments carried out with blood implanted with streptococci, and then centrifugized and allowed to clot in emigration tubes, and then covered in

FIG. 13.

with carbolic acid in strengths of from 1 in 50 to 1 in 20 (Fig. 10). You will see that we have here in our white clot, and—I want you to note—quite close up under the covering layer of antiseptic, colonies of streptococci derived from those we have implanted. And below—as you discerned would happen in our sea-water—you have the living elements going about their avocations quite unaffected. The leucocytes have, as you see, emigrated into the white clot, and they have, in point of fact, been hunting down and ingesting the microbes. And I see no reason to doubt that the results would have come out just the same if we had in our experiments used instead of carbolic acid any other of the antiseptics which are employed in wounds.

With this, I think, we have, in connexion with the sterilizing and penetrating power of ordinary antiseptics, got before us all the really vital points in the evidence furnished by laboratory experiments. And let me now—for you will bear in mind that the advocates of antiseptics rest their case almost exclusively on the data of laboratory experiments—try to summarize for you what these

experiments really teach.

And there are here, as I see the matter, two distinct issues. The first has reference to the effect exerted upon the microbes of pus which are removed by washing; the second to the effect exerted on the microbes which are left behind in the wound.

In connexion with the first of these issues, it has been shown that while it is all but impossible to sterilize undiluted pus by any addition of antiseptics, it is quite practicable, by diluting and mixing the pus thoroughly with many times its volume of an antiseptic fluid, to kill all the microbes.

But, note, to kill these microbes is simply a work of supererogation; for they are in any case destined to go down the drain. And, moreover, pus is not in the same case with typhoid stools, which we might hesitate to put down the drain unsterilized.

Coming, then, to the microbes we have really to combat—that is, that washing does not remove from the wound—it will be clear that these will be killed off only so far as the antiseptic may possess penetrating power. And we have seen how the case stands with regard to this. We have appreciated that our antiseptics are incapable of penetrating through anything more than the very thinnest film of pus. They will therefore fail to kill the microbes which washing does not dislodge from the blind passages and cul-de-sacs and pockets of the wound. And *a fortiori* the antiseptic will not come into operation upon the microbes in the solid barriers of albuminous substance provided, in the early stages of the wound, by exposed muscle and connective tissue, and, in the later stages, by infiltrated walls or granulating membrane.

And what holds true of the suppurating wound would clearly hold true also of that filled with blood clot. The antiseptic will, if it exerts any influence at all, exert it here only at the particular spot to which it is applied.

I am not at all sure that the kind of evidence I have just tried to summarize—or, indeed, any array of laboratory experiments—could convert from his beliefs the man who knows with *a priori* knowledge that antiseptics must be useful in wounds. And with regard to that type of man I feel that, despite the fact that his faith in antiseptics is really based upon laboratory experiments, he will, now that the old laboratory experiments have been invalidated by the new, desire to appeal from these to the tribunal of clinical experience. And he will, I take it, desire to discover by cross-examination whether clinical or bac-

teriological investigation has not furnished data which might tend to show that the course of wound infections has sometimes been favourably modified by treatment with antiseptics.

On the important principle of logic which is here raised—that is, on the issue as to how far therapeutic measures ought to be adjudicated upon by laboratory methods, and how far by an appeal to clinical observation—I would here only say this. What we are, in difficult issues such as that in which we are here involved, concerned to arrive at is a verdict based on unambiguous evidence; and I feel confident that clinical observation cannot safely adjudicate upon a therapeutic measure unless it happen to give either outstandingly good or outstandingly bad results. Where the results are neither brilliantly successful nor the reverse—and antiseptic treatment of wound infections is precisely an instance in point—I submit that we shall be well advised if we guide ourselves, when this is unambiguous, by the verdict of laboratory experiments.

With thus much by way of protest and explanation, I will try to put before you the clinical evidence as I see it; and to resume for you the data of our bacteriological examinations of wounds treated with antiseptics.

I can put what I have to say in a very few words. I have not myself come across—and I have the permission of all my fellow-workers to say that they also have not come across—any satisfactory clinical or bacteriological evidence of the utility of antiseptics as employed in infected wounds. In connexion with this, let me say that working as we have been for the last year in the largest base hospital in Boulogne, we must, I think, have watched and examined bacteriologically very many thousands of wounds—to say nothing of our having conducted the bacteriological examinations in no less than four long series of clinical experiments undertaken to put to the test the confident prognostications of reputable promoters of this or that antiseptic. And let me also say here that the opinion I have just expressed—that is, the opinion that, judged by its clinical results, the antiseptic treatment of infected wounds is of quite doubtful utility—is that which is, I believe, held by the very large majority of those who have had prolonged practical experience in this war.

I am well aware that also contrary opinions have been expressed. I would, however, submit that these should be very largely discounted. For the more part they are opinions expressed by persons possessing a very limited experience and unfamiliar with the course the wound follows when left to itself. Moreover, the observers here in question were, as I think, deceived by the fallaciously favourable appearance of the wound in the stage that precedes the advent of suppuration. Coming to those favourable opinions which have, as I hear, been expressed by a few experienced and very competent observers, I would submit that it is possible that credit may have been given to the antiseptic, where it ought really to have been given either to the menstruum in which it was applied, or to incidental circumstances attendant upon the treatment. Thus, for instance, continuous irrigation practised with antiseptic solutions would effectively wash out the wound and keep it constantly moist; a hypertonic menstruum used as an excipient for the antiseptic would act as a lymphagogue; peroxide of hydrogen would effectively assist in the evacuation of the pus; carbolic acid or other antiseptic used in the form of hot fomentations would bring heat and moisture to bear; and no doubt many different varieties of antiseptic would induce temporary hyperaemia. I think it will be seen that favourable results occasionally manifesting themselves after antiseptic treatment, might quite well be interpreted in the sense here suggested.

So far we have considered in connexion with the clinical data only the question whether the antiseptic has had any beneficial effect in the wound. Let us now turn the leaf, and see whether there are entries also on the debit side; and let us here consider the effects produced in the wound itself, dealing afterwards with those produced on the healthy skin in its neighbourhood. In connexion with this let me first emphasize the fact that disastrous results—I am thinking more particularly of the development of gaseous gangrene—supervene when antiseptics made up in viscid or semi-solid excipients are introduced into the wound. For

this result the excipient which confines the discharges and imprisons the infection would seem to be primarily responsible.

It is, however, not only antiseptics in unsuitable menstrua which arrest the outflow of lymph and imprison the infection. With perhaps the exception of carbolic acid employed in concentrated form, all antiseptics in their degree, and strong antiseptics in particular, would seem, by coagulating the albuminous substances on the surface of the wound, to exert this prejudicial effect.

Coming now to the application of antiseptics to the skin surface in the neighbourhood of the wound, we have, of course, here a procedure which has exactly the same aims as the preparation of the skin for operation, except only that it is here foreseen that the wound will remain open.

The usual procedure for the sterilization of the skin in field ambulances is to paint strong iodine all round the wound, and then—plant for sterilizing dressings not being available so far to the front—to cover in the wound with cyanide gauze. This in many cases is followed by results like those which used to be obtained when carbolic fomentations were used as a prelude to surgical operations. There is produced—and this applies quite generally in connexion with every application which "irritates the skin"—first, reddening of the epidermis; then effusion and blistering; and then there develops in the blisters a luxuriant growth of serophytic microbes. In other words, by our misdirected energy we cultivate at the very doors of our wound, upon the very area of skin which we intended to keep free from microbes, a copious harvest of streptococci and staphylococci.

This, however, has been of the nature of a digression, and I must now, before saying something about a fundamentally different variety of antiseptics, come back and try to make clear what is the general conclusion which emerges from the clinical study of the effects of antiseptic treatment. It can be put into a sentence. The data of clinical observation, such as they are, not only confirm the verdict of the laboratory as to the inefficacy of antiseptic treatment; but they suggest that such treatment may sometimes be not only useless but prejudicial.

Antiseptics which are, instead of Indiscriminately Albuminotropic, Specifically Bacteriotoxic.

I have now to say just one word about a kind of antiseptic which concentrates its chemical energy upon the microbe; instead of like the ordinary antiseptic, expending it wastefully upon the albuminous substances in which the microbe may be embedded. Those of you who have followed the development of "chemiotherapy" will immediately perceive that I refer to *sarvarsan* and ethylhydrocuprein hydrochlorate* (now known as *optoquin*), and will appreciate that, if these chemical agents can be shown to exert a powerful bactericidal effect upon pyogenic organisms, and in particular upon serophytes, they might perhaps usefully be applied both directly in the wound and also by the channel of the blood: reaching in these ways all the microbes in the body with the exception only of those embedded in dead spaces and infiltrated tissues.

We have made in connexion with this subject-matter as yet only preliminary researches; and I do not here propose to say anything more than that my fellow-workers, Captain S. R. Douglas and Lieutenant A. C. Luman, working the one with *sarvarsan* and neo-sarvarsan, and the other with *optoquin*, have found that these kill off the streptococcus in serum, and that *optoquin* in particular kills the streptococcus in serum in very high dilutions.

TREATMENT BY SURGICAL PROCEDURES.

A long series of surgical procedures all having reference to the treatment of wound infections might quite properly come up for consideration here if this were a treatise instead of an introductory lecture. Let me, however, just run over the list, indicating in connexion with each the place that it would take in the treatment of the wound infections. We have, first, the opening up of the wound, and the incision of the tissues undertaken to get drainage for imprisoned infections; secondly, the washing out of the wound and the irrigation of the walls with therapeutic

fluids; thirdly, the immobilization of the limb for the avoidance of autoinoculations; fourthly, the ablation of the heavily infected and infiltrated walls and floor of the wound; and, fifthly, the secondary suturing of the wound for restricting the area of exposed and infected surface, and closing the wound when the infection has been overcome.

The first of these procedures I have already treated of. Its rationale and the methods of making it really effective were considered in a Memorandum on Wounds which was officially circulated to the Medical Service of the Army and which was published in the BRITISH MEDICAL JOURNAL of April 24th, 1915, p. 735.

The second and third procedures—those for the irrigation of wounds and the splinting of fractured limbs—form the subject matter of the demonstrations which are to be given in this exhibition.

The principles involved in the so-called "excision" and "secondary suture" of wounds I propose here very briefly to consider.

Ablation of the Heavily Infected and Infiltrated Lining of the Wound.

The customary procedure in connexion with wounds is to remove only those portions which are sloughing; and to amputate, where a limb is involved, only that portion which is deprived of its blood supply, or quite hopelessly infected. To Colonel H. M. W. Gray is due the credit of pointing out and enforcing by a long series of cases successfully treated under his supervision in the military hospitals at Rouen, that it is possible in suitable cases to abort wound infections by the excision of the infiltrated wall and floor, the operation being completed by sewing up the wound immediately, or after treatment with hypertonic salt solution. I may explain that the kind of cases which Colonel Gray selects for treatment by excision are scalp wounds and what we may call "gouged out" and "punched in" wounds of soft tissues.

The theoretical considerations which commend the procedure of Colonel Gray are that it removes heavily infected portions of tissue which, though they could be brought back to a healthy condition, are for the moment incapable of contending successfully with infection. And, above all, the method holds out a prospect of immediate victory over the infection; and, of course, practically immediate convalescence.

There, however, suggests itself in connexion with the procedure the plenary question as to what amount and kind of microbial infection we can allow ourselves to shut up inside a wound. This is the issue which confronts us everywhere in connexion with secondary suture.

Secondary Suture of Wounds.

That a deep wound when once infected must be allowed to granulate up from the bottom, and that a surface wound must be allowed to close by the growing in of skin from the sides, are maxims which would be in their proper place in a system of surgery which aimed at doing all it could to delay healing and keep the patient in hospital for the longest possible time.

On the other hand it might quite well be imprudent to embark deliberately upon a policy of sewing up microbes in wounds to accelerate healing.

This is the kind of dilemma which sooner or later confronts us in connexion with every wound. To resolve it we must sit down, and take thought, and ask ourselves what precisely are the risks we have to take; and whether there are not precautions to be adopted; and whether we really are, in the matter of the closure of the wound, irrevocably condemned to a policy of inertia and inaction.

Let us place before ourselves first these facts. An infection of subcutaneous tissues is always of more serious import than a mere surface infection. There will always be something unfavourable either in the general condition or in the histological conditions when microbes succeed in maintaining themselves in the tissues. Here at least the leucocytes and the blood fluids ought to be able to hold their own. Exactly the contrary holds true of surface infection. On denuded surfaces, no matter how healthy the condition,

* In connexion with this drug, vide the author's *Treatise on Pharmacotherapy and Preventive Inoculation Applied to Pneumonia in the African Native*, Part I. and Appendix I.

† See the Memorandum by the author on the Employment of Bandages for the Irrigation of Wound-Surfaces with Therapeutic Solutions, and the Drainage of Wounds, BRITISH MEDICAL JOURNAL, October 16th, p. 561.

the microbes, though they may sometimes have to struggle, will always find means to maintain themselves. We may, I think, attribute this to the circumstance that on an exposed surface the leucocytes are subjected to every kind of uncongenial condition—to aerobic surroundings, to desiccation, to a tryptic or diminished antitryptic environment, and—who can tell?—perhaps also to conditions of famine.

We now see that where we have an infection of tissues—that is, a form of infection which would, if conditions had been favourable, have been driven out, and been converted into a mere surface infection—we shall be taking a serious risk if we sew up the wound. For that would be to follow leisurely and with deliberation the disastrous practice of those who in the earlier period of the war in the hospitals at the front precipitately sutured infected wounds, or securely sealed up imprisoned infections by resorting to escharotic or glucy antiseptic applications.

On the other hand, we see that, if we are dealing with a purely surface infection, it will be possible, by bringing the opposing surfaces of the wound into intimate contact, to procure for the leucocytes and blood fluids those more favourable conditions which prevail in the interior of tissues; and, by procuring these, to contribute to the destruction of the microbes.

But clearly our decision as to whether we may, or may not, bring the edges of the wound together ought not to be determined solely by whether we are dealing with an imprisoned, or a surface infection. There will in connexion with surface infections be other factors to be taken into account.

There is, for instance, a great deal of sound common sense hidden away in the maxim, that an infected wound which goes down into the depths must be allowed to granulate up from the bottom. The lessons which that precept enforces are, first, that if we allow dead spaces to develop in closed wounds we must expect to find the infection go ahead therein; and, secondly, that, since pus will gravitate downwards, dead spaces will tend to develop at the bottom of the wound, while the upper part unites and converts the dead space into the abscess sac. Of all the mechanical conditions which have to be secured in secondary suturing of wounds, the most important will clearly be the avoidance of such dead spaces.

There is another important consideration to be kept in view—and this time it is not a mechanical consideration. We must expect success or failure in secondary suturing to depend in large measure on the condition of the surfaces, and the number of microbes on those surfaces. Where we have very few microbes and a profusion of active leucocytes we may confidently look forward to success. Where we have a large population of microbes and disintegrated leucocytes it will be only reasonable to expect to fail.

This much by way of general principles. And let us now turn and inquire how these can be applied in practice, and by what methods we ought to proceed in deciding whether a wound is in fit condition to be closed down. We shall have first to certify ourselves that we are dealing only with a surface infection; and then we shall require a method of examination to tell us what is the condition of the leucocytes, and the number of microbes on the surface of the wound.

The first of these points is resolved by a mere clinical examination. As long as the floor and walls of the wound are still indurated we can be sure that we are still dealing with an imprisoned infection. On the other hand, when we have lying naked before us in the wound a system of lymph spaces communicating freely with one another, filled in with clear fluid, and fed from full capillaries, we then know that we have got rid of the imprisoned infection; and that if any infection still lingers it is a purely surface infection.

There remains the question as to what number of microbes have to be dealt with on the surface of the wound, and what force of active leucocytes we have there at disposal. It will probably in the case where the walls and the floor of a wound have been freshly resected—provided always that this has been done in a workman-like way—be unnecessary to insist upon such inquisition. But where we are dealing with a granulating wound whose edges have not been refreshed it will assuredly be required.

The method of obtaining the information is quite simple. We first prepare a number of cover-glasses by coating them on one side with a layer of agar or serum (serum is preferable) and then letting them dry. We then bring the coated side down upon the surface of the wound. And we make in this way (using, of course, a number of cover-glasses) a series of impression preparations. We now fix and stain either by the method of Gram or with carbol thionin. Micro-copic examination then tells us whether we have few or many leucocytes; and whether the leucocytes are degenerated or well preserved.

And a concluding word may now be said on the technique of closing in the wound and on the procedure to be followed.

Except possibly in cases where we pass directly from the excision of the wound to secondary suture it will be well always to preface the operation by phylacogogic treatment conducted upon the lines laid down in the next section of my lecture, and controlled, of course, by the making of impression preparations.

Where we are dealing with a deep and extensive wound it will be well to undertake the work in stages and to content oneself at first with bridging and subdividing the wound by bringing the walls into application by sutures passed in from the skin from each side deep into the tissues. And I may add in connexion with such sutures that they ought, in order to prevent extension of the microbes along their track, to be withdrawn at the earliest possible moment. Where bridging operations have been undertaken, the interspaces between the connecting bridges ought still to be irrigated and drained. Where it is a question of the closure of large gaping "gouged-out" wounds, it will be well to choose for the patient such a position as will minimize the gaping of the wound and the strain upon the sutures. Where large surfaces of skin have been carried away grafting ought to be resorted to; or the skin ought to be unperfected, and the liberated flaps drawn over the wound by strips of adhesive plaster. Where a limb has been amputated by the flapless operation, the sleeve of skin ought to be slowly drawn down over the stump by an extension apparatus.

TREATMENT BY PHYLACOGOGIC METHODS.

When I was discussing with you the clinical results obtained by the antiseptic treatment of wounds, I drew your attention to the fact that with this a variety of physiological stimuli were brought into application, and that the good results which were upon occasion witnessed might quite well be credited to these.

Now, of course, physiological stimuli are in connexion with wounds applied, not only incidentally to antiseptic treatment, but also of set purpose as therapeutic agents. Dry or moist heat is brought into application; ether is introduced into the cavity of the wound; stimulating ointments and lotions are applied; or, as the case may be, the wounds are uncovered to air; they are exposed to sunlight, or electricity and radium are exploited: each of these measures being resorted to with a more or less vague idea that the particular form of stimulus in question will directly or indirectly assist in combating the wound infection.

So far as I can discern, all these are forms of treatment—and the same holds true also of the surgical procedures we have considered above, of the methods of Bier, and, of course, of saline solutions and vaccines—which are capable of bringing the protective elements of the body—that is, the blood fluids and leucocytes—into application in the wound. And I would submit that they can be useful only so far as they serve as—let me suggest the word—*phylacogogic* agents.

We ought therefore to give up employing these agents as fetichs, and ought to preclude their use by a careful study of their physiological action.

This field of study being so endlessly wide I propose here to confine myself to the study of strong and weak salt solutions. We shall see that we have in these *phylacogogic* agents—in hypertonic saline solution a *lymphocogic*; and in physiological saline solution a *leucocytogogic* agent.

Physical and Physiological Action of Hypertonic Salt Solutions.

Hypertonic salt solutions exert three kinds of effects: a physical effect; a physiological effect; and an effect on

the condition of the wound and the bacterial infection. Let me deal first with the physical action, for it was this which I had chiefly in view when I suggested the employment of hypertonic solutions in the treatment of infiltrated tissues which were the seat of bacterial invasions.

Physical Action of Strong Saline Solutions.—I can perhaps most conveniently introduce what I have to say with reference to the physical action of strong salt solutions if I take up again the discussion of the phenomena of diffusion at the point where I left off when I was discussing with you the penetrative powers of antiseptics.

What we were there considering was the conveyance of the chemical agent outwards by diffusion from the discharging to the recipient fluid; and we did not then need to concern ourselves with the return movement from the recipient into the discharging fluid. But in connexion with every diffusion there is always a process of barter and exchange: so that when we have, as in Fig. 9, a, as our discharging fluid water containing a colouring material, and as our recipient fluid clear water, there is, in point of fact, not only a passing out of colour into the recipient fluid, but also a return flow of water; and, as a result, a certain dilution of the discharging fluid.

It will subserve the purposes of exposition, and perhaps help to call up in the mind clearer pictures, if, speaking as we do of the conveyance of the chemical agent into the recipient fluid as *diffusion*, we may call the conveyance of the water (or other excipient) into the discharging fluid, *infusion*.

Let us now look—for this will carry us a step further—from Fig. 9 a to Fig. 9 b. Here, while the coloured fluid in the upper part of the test-tube remains as before, strong salt solution has at the bottom of the tube been substituted for clear water; and we have now a double process of diffusion—a diffusion of colouring matter downwards into the coloured water; and along with this we have also infusion into each fluid. This will give, on either side of the surface of contact, a broader zone of mixture; and you have in Fig. 9, b, below the junction of the coloured and colourless fluids a broader band of stippling representing colour.

We can by the aid of a very simple experiment satisfy ourselves that there is a much greater indrawing with a strong salt solution than with a weak solution or simply water. We take a capillary pipette, seal it at the end, fit on a rubber teat, and then squeezing this with the fingers so as to get up a positive pressure in the interior, introduce a small portion of the wall, about half way down the stem, into the flame of a by-pass. The glass will, as soon as it softens, blow out here and give us a lateral opening. We now resect our capillary stem at some little distance above, and again some little distance below, this opening. Having provided ourselves with such tubes we fill in one with strong salt solution and another with water, and then pour a little water solution of methylene blue into a Petri dish or other shallow, flat-bottomed vessel. This done, we take up first one, and then the other, of our capillary tubes. We seize it in the middle with a pair of forceps; hold the central orifice uppermost and the two limbs horizontally; and in this position immerse for a matter of a second or two into the coloured fluid. We then wash the outsides and compare the two tubes.

In the tube of water there will be three narrow, and in the tube of salt, for there is here more indrawing, there will be three very broad bands of blue: one occupying the middle and the others the ends of the tubes.

And let me show you also another experiment which brings clearly before the eye the drawing power of salt. I have here two test-tubes filled in each case to a depth of 3 or 4 centimetres with a watery solution of methylene blue; and standing in these test-tubes I have two pieces of glass tubing, open at both ends and packed with moist cotton-wool; and, lastly, in the one tube I have at the top of the cotton-wool a layer of salt. These pieces of tubing have been standing, as they are standing now, since last night. I now lift them out, and you see that here again the methylene blue has been drawn far up into the tube where we have the salt; while it has in the companion tube been carried in only a very short way.

With this we have come some little distance on the way

The actual procedure employed was to fill in the cotton-wool, to immerse in water, and then to remove the superfluous fluid by centrifugalization.

to an understanding of the physical action of hypertonic salt solutions applied in wounds. This further series of test-tube experiments (reproduced in Fig. 11) will, I think, show you exactly what happens.

I have here a tube of water agar (Fig. 11, a). That is to say, I have dissolved in the distilled water, which is here going to serve as a recipient fluid, a sufficiency of agar to set it into a firm jelly. And I have added also a little trace of nitrate of silver. Into the next tube (Fig. 11, b)—a precisely similar tube—I introduced some twelve hours ago a cube of sodium chloride, imposing it upon the surface of the just moist jelly. And you here see the result. The sodium chloride has diffused into the water agar to a considerable depth, discolouring the silver salt. But the important thing to note is the counter movement. Water has been drawn out from the jelly, and we have now, round what remains of the pellet of salt, as you see, a layer of fluid a centimetre or a centimetre and a half in depth.

This is the particular effect which I set out to get when I suggested the employment of hypertonic solutions as a dressing for infected surfaces. I expected to get that combination of diffusion and infusion which we have under our eyes here—in other words, a process of barter in which salt and water should be exchanged, not in volumetric equivalents, but, as you see here, in the ratio of very many volumes of fluid for one of the solid.

Let me try to make plain another point. The whole question of diffusion and infusion is to the ordinary medical man and biological student complicated by ideas connected with osmosis: his mind being taken up in particular with the idea that crystalloid substances can, and albuminous substances cannot, traverse a so-called vegetable or animal membrane. In fact, some have come to believe that it is the interposition of a membrane between the recipient and discharging fluid which calls into existence the attractive forces of salt for water and all the phenomena of infusion; or, to put it in other words, that it is the interposition of the sieve which confers upon the salt the power of drawing water to itself. It is this confusion of thought which has inspired the criticism: that while hypertonic solutions may be competent to draw fluid out from the walls of a wound, the fluid thus extracted will by theoretical necessity be a fluid deprived of all its albuminous substances, and with these of all its antibacterial powers.

The test-tube I now show you demonstrates to the eye that the theoretical deduction here in question is quite unfounded. You see here (Fig. 11, c) a tube of water agar into which I have incorporated a considerable amount of blood. I have dealt with it in precisely the same way as with the tube of silver nitrate agar; that is to say, I imposed upon it yesterday a cube of sodium chloride. You will see for yourselves that the salt has here drawn out from the agar a very considerable amount of a turbid blood-stained fluid; and when I take a sample of this and boil, you will see that we obtain a very heavy precipitate of albuminous substances (Fig. 11, d).

Fig. 11.—A, A test-tube filled with water agar serving as a control to B and C. B, A test-tube filled with silver nitrate water agar upon which has been imposed a cubical block of sodium chloride, showing the precipitation of the silver salt in the interior of the agar, and on the surface of the agar the fluid which has been drawn out. C, A test-tube containing water agar in which blood has been incorporated on the surface of the agar; a cube of salt and the turbid blood-stained albuminous fluid which has been extracted by the action of the salt is seen. D, A small test-tube showing the albuminous precipitate thrown down on boiling a sample of the fluid obtained from C.

I think we may feel reasonably confident that this is exactly what occurs in the wound. And at any rate we may be sure that neither in the earliest stage of the wound, where the tissues lie exposed; nor yet in the later stage, when the walls are infiltrated; have we in the wound, any more than we have here in this test-tube, anything in the nature of a membrane which could filter out albuminous substances.

Arising directly out of the physical properties of concentrated salt solutions is another point which has a very important bearing on the therapeutical action of these agents. We have seen in connexion with antiseptics that inasmuch as they have as good as no penetrative power, they will exert their effect only at the immediate point where they are applied; and, in the case where the antiseptic marches with an albuminous fluid, only on the face where the two fluids come in contact. In other words, the antiseptic will not diffuse into, and come into application in pus held up in the upper reaches or recesses of the wound, nor even in islands of pus encompassed by antiseptic fluid.

Now the exact contrary of this holds true of strong saline solutions introduced into the wound. No sooner are they introduced than the sodium chloride—for it is, of course, highly diffusible and is not quenched by antiseptics—will radiate out by diffusion through all the fluids of the wound. (In an experiment in which a tube full of water agar was inverted in a shallow receptacle of 4 per cent. salt solution we found that diffusion carried the salt up $4\frac{1}{2}$ centimetres in a night.) We may therefore picture in our mind's eye, in connexion with strong saline solution applied to the mouth of a wound, that the salt will very soon, in the lower reaches of the wound, attain a high concentration and act as a lymphagogue; and that afterwards it will come into operation in the upper reaches in a dilute, but perhaps still therapeutically valuable, form.

But let us note that this will apply only if the concentration of the saline solution is maintained throughout. Where the salt solution is applied in the form of a damp pad, and is then very rapidly diluted by the exudation, we shall get, but only very temporarily, a hypertonic solution in the lower reaches of the wound, and after that we should obtain only the same effects as with an isotonic salt solution.

Finally—and this is a point which may upon occasion have a practical interest—let us remember that 4 per cent. salt solutions have a specific gravity equivalent to that of the serum; and more concentrated solutions of course a higher specific gravity. It will therefore be theoretically possible, by availing ourselves of gravity, to get strong saline solutions directly to the bottom, not perhaps of a wound filled with pus, but certainly of a wound in which we have only blood-clot and serum.

(To be continued.)

THE OPERATIVE TREATMENT OF GUNSHOT INJURIES OF NERVES.

BY

SIR FREDERIC EVE, F.R.C.S.,

TEMPORARY LIEUTENANT-COLONEL R.A.M.C.,
CONSULTING SURGEON, EASTERN COMMAND; VICE-PRESIDENT, ROYAL COLLEGE OF SURGEONS; CONSULTING SURGEON AND FELLOW OF THE
LIEUTENANT OF SURGERY, LONDON HOSPITAL;

AND

R. S. WOODS, M.D.LOND.,

PRESIDENT TO THE ELECTRO-THERAPEUTIC DEPARTMENT, LONDON HOSPITAL.

The majority of the patients were in the section of the War Hospital at Croydon which the Surgeon-General of the Eastern Command has set aside for the treatment of injuries of the peripheral nerves and for stiff joints arising from wounds, and which he requested Dr. Woods and myself to organize. Other patients were in military or V.A.D. hospitals in other portions of the Eastern Command, and three in H.R.H. Princess Henry of Battenberg's Hospital for Officers.

The cases operated on by one of us (F. E.) numbered

28, of which 21 were due to bullets, and 6 to shrapnel or shell wounds. As regards the distribution of the lesions: 5 were injuries of the brachial plexus, 8 of the musculospiral nerve, 1 of the posterior interosseous nerve, 5 of the ulnar, 2 of the median and ulnar nerves together, and 7 of the sciatic or external and internal popliteal nerves. In 6 cases the injured nerve or nerves were completely divided. The sciatic nerve, as might be anticipated on account of its size, was divided three times; the other nerves divided were the median and ulnar together in one case, musculospiral and posterior interosseous once each. In one instance the sciatic nerve was perforated with incomplete division of the external popliteal portion. Many of the cases having been in V.A.D. hospitals before being transferred to Croydon, the period elapsing between the receipt of the wound and the operation was often considerable. This period in all but 4 cases was three months or over; in the remainder the shortest period was seven weeks. In the absence of evidence of improvement, and if the electrical reactions indicate a severe injury of the nerve, we are of opinion that an operation should be performed as soon as the condition of the wound permits of its being carried out aseptically. Excluding the 5 injuries of the brachial plexus, it was thought necessary in 8 cases out of the remaining 23 to resect the damaged portion of the nerve, or to refresh the ends if they were separated. In other cases the nerve was separated from adhesions and surrounded with Cargile's membrane. The various reasons determining the procedure adopted are given below in considering the electrical reactions. The smallest nerve operated on was the posterior interosseous. This was found to have been completely severed (the ends being separated) by a bullet which had comminuted the head of the radius. The nerve was exposed by an incision on the outer side of the forearm, just below the external condyle and on a plane corresponding with the palmar surface of the head of the radius. After dividing the muscles attached to the external condyle, the proximal end of the nerve was at once found. The ends were refreshed and the junction surrounded by a portion of the basilic vein. As regards the 8 cases of injuries of the musculospiral nerve, half of them were associated with fracture of the humerus.

In those cases in which resection was performed the fibrotic tissue, or bulbous end, was removed on the proximal side until the section showed well-defined nerve bundles; and the distal end was refreshed. The ends were pierced with a round shafted needle, and united with one or, in the case of large trunks, two sutures of twenty day chronic catgut (0 or 1 size). It was always found possible to get the ends together by freeing the nerve above and below, and flexing the nearest joint or adducting the upper arm. Where a portion of the nerve was thickened and appeared to be "hided-out," chiefly from thickening of the perineurium, an incision was made into the thickened tissue.

The five cases of injuries to the brachial plexus furnished many points of interest. One was due to a bullet smashing the centre of the clavicle. The clavicle was divided, and fragments of bone were found pressing upon the anterior divisions of the fifth, sixth, and seventh nerves, which were enveloped by dense scar tissue. This was removed, the nerves were surrounded with Cargile's membrane, and the clavicle wired. In another case the injury was by a bullet at the root of the neck. At an operation, two months after the injury, the trunks of the fifth, sixth, and seventh cervical nerves were found thickened and more or less adherent. The condenser reaction of the paralysed muscles read from 1 to 4 microfarads charged at 70 volts. The thickened nerves were separated from adhesions and surrounded with Cargile's membrane. Five months after the operation there was a good return of movement in the paralysed muscles. In the other cases the injuries were below the clavicle, and in two instances were of a most extensive character. The difficulty in dealing with these cases is increased by the fact that the axillary artery and vein are usually involved in the scar tissue and require careful separation. In one case it was found necessary to ligature the artery and vein above and below the lesion. No trouble occurred as regards the circulation of the limb, probably because the anastomotic circulation had been enlarged owing to partial occlusion of the axillary artery. A dense mass of

* A paper read before the Medical Society of London on November 1st, 1915.

ciatricial tissue had matted together all the cords of the brachial plexus and was adherent to the anterior aspect of the subscapularis muscle.

When confronted for the first time with this condition of things surgical interference appears hopeless, but it was found that by cutting combined with teasing by blunt dissection the various strands of the cords could finally be separated out and the ciatricial tissue removed. In the case above referred to, a rounded mass of fibro-neuromatous tissue the size of a thrush's egg was removed from the posterior cord; and a portion of the inner cord, three-eighths of an inch in length, was resected and the nerve united. In another case the cords were matted together by a dense scar behind the pectoralis minor, just above the point where the internal circumflex is given off. The bullet had entered on the posterior surface of the root of the neck through the outer part of the trapezius, had passed under the clavicle, and made its exit behind the anterior axillary fold. The site of the lesion of the plexus was fixed as just below the point where the musculocutaneous is given off, by the fact that the muscles on the front of the arm were the only ones giving normal reactions. It was found possible to separate the median nerve from the ciatrix, but half an inch of the posterior cord and three-eighths of an inch of the internal cord were excised, and end-to-end union effected. Dr. Pantou kindly examined the portion excised from the posterior cord: it consisted solely of dense fibrous tissue, and contained no nerve fibres.

In a third case the median and ulnar trunks were matted together below the lower edge of the pectoralis minor, but were separated and surrounded with Cargile's membrane.

Boldness is justifiable in operating on these severe lesions, as one knows that the limb must remain useless unless restoration of conduction in the nerves can be effected by surgical measures. There is the less hesitation in operating freely since it has been established by the experiments of Professor Robert Kennedy¹ that the junction of the peripheral end of a divided nerve to the corresponding proximal portion of the same nerve is not necessary for the re-establishment of function. He writes: "In Macacus the paralysis resulting from section of the fifth and sixth nerves may be largely restored by anastomosis of the peripheral segments of the two roots to the seventh cervical nerve, or to the spinal accessory." Two cases of partial paralysis of the brachial plexus as a result of arterio-venous aneurysm in the axilla have been met with. At the operation in one case pressure was found on the median, ulnar, and musculo-spiral nerves in the lower part of the axilla. The other case is an example of an arterio-venous aneurysm involving the lower part of the axillary artery with paralysis of the musculo-spiral nerve. After keeping the patient under observation, it has been found that the aneurysm is increasing and the condenser shows that the paralysis is not improving, in spite of the treatment. An operation will therefore be performed.

All the cases except one have been tested electrically by Dr. Woods. In practically all instances the paralysed muscles did not react to faradization. We found the Lewis Jones condenser of great assistance, as it furnished a numerical equivalent indicating the degree of interruption to conduction through the nerve and the condition of the muscle; for example, in 6 cases in which there was evidence of complete division of a nerve, in one instance there was no response with the condenser, while in 4 the numbers ranged from 2 to 4 m.f. charged at 70 to 100 volts.* In these cases operation was performed three to five months after the infliction of the wound. The period elapsing after the infliction of the wound must be taken into consideration, for in the remaining case, in which operation was performed for complete division of the internal popliteal nerve seven weeks after the wound, the muscles responded to a 1 m.f. capacity at 70 volts. There could be no doubt as to the nature of the lesion, since the ends of the nerve were widely separated. This patient had received massage and electrical treatment from an early date, and the consequent state of nutrition of his

muscles probably had an effect as regards the electrical reactions.

As showing the effect of time on the reactions obtained by the condenser, it may be noted that in the case of division of the posterior interosseous nerve operated on five months after the injury, the muscles at the back of the forearm, except the extensor carpi radialis longior, gave no response to testing with the condenser.

The chief point in the operative treatment of these nerve lesions is to determine whether simply to separate the injured nerve from the surrounding tissues or to resect it; and this is of greater importance owing to the fact that anatomical division is comparatively rare. A definite indication is usually afforded by inspection. There may be evidence of complete division with union by a band of fibrous tissue, and in this case an enlargement of the proximal end will be present; or the site of division, which may be partial or complete, is indicated only by a well-defined bulbous enlargement. In less severe injuries there is often a fusiform thickening of some extent involving the nerve trunk. In other cases, especially in injuries to the musculo-spiral nerve associated with fractures of the humerus, the nerve may be embedded in callus. In one case it was stretched round a spicule of bone. The musculo-spiral nerve may be generally thickened and enlarged for some length; it was in a case of fracture of the humerus as thick as the end of a little finger. The condenser required for the extensors of the wrist and digits was of 2 m.f. capacity at 70 volts; nevertheless, after freeing the nerve voluntary movement returned rapidly, and in two and a half months there was almost complete restoration of function.

Not infrequently the affected nerve is evidently constricted by ciatricial tissue surrounding it, or by the pressure of a dense ciatrix of the integuments. Where doubt exists as to the advisability of resection, an indication of the amount of damage is sometimes furnished by blunt dissection of the nerve bundles from above into the ciatrix to ascertain if they are continuous across it.

The condenser also furnishes important indications of the site and severity of the lesion. In a case of wound of the thigh at its middle third by a portion of shell the sciatic nerve had been perforated. The condenser required was of 4 m.f. at 120 volts for the muscles on the front of the leg, 1 m.f. at 70 volts for the peronei and 0.25 for the calf, showing that the damage was to a portion of the external popliteal nerve. At the operation the internal popliteal nerve was separated from the external nerve by blunt section, and a dense nodule or neuroma was found involving the inner half of the external popliteal. This was excised without interfering with the outer strands of the external popliteal, and the gap was united with catgut.

Further, the condenser gives reliable and easily recognized indications as to when cases of nerve injury are improving under treatment. The two following cases may be quoted:

CASE I.

An officer received a bullet wound at close range which carried away the internal condyle and paralysed his ulnar nerve; very definite improvement occurred. Three weeks after the injury the muscles supplied by the ulnar nerve required a condenser of 2 m.f. capacity, the charging voltage being 75. Nine months later the reactions were precisely the same and the improvement as regards sensation and voluntary power had remained stationary for some time. Operation was therefore decided on. The nerve was constricted, and just above the injured part was a small, bulbous enlargement. Seeing that there had been considerable restoration of function the nerve was freed and surrounded with Cargile's membrane. Treatment by massage and electricity was continued. At the end of two months the condenser test was exactly the same as before the operation. The patient was therefore advised to submit to resection of the injured portion of the nerve.

CASE II.

A patient was admitted to Crofton War Hospital with a shrapnel wound behind and above the head of the fibula and paralysis of the muscles of the front and back of the leg. On August 25th the condenser required for the peronei muscles was of 0.25 m.f. capacity at 70 volts. After continuous treatment the condenser capacity for the peronei, seven weeks later, was 4 m.f. at 80 volts. Operation showed that the external popliteal nerve was definitely thinned at a point corresponding to pressure by a very indurated ciatrix of the integument.

The disappointing feature of the treatment of nerve injuries is the long period required for the completion of

* Normal muscles give, with a condenser, a reading of 0.025 to 0.075 micro-farads capacity charged at 70 volts. In a moderately severe lesion of a nerve the muscle gives 0.75 to 1 micro-farads charged at 70 volts, and a severe lesion 1 to 4 micro-farads charged at 70 to 100 volts.

the reparative processes, and so far we can give very little information as regards the ultimate results of our work in respect of restoration of function, most of the cases having been operated on after the beginning of August.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

MAGNETIC PROPERTY OF GERMAN BULLETS.
It does not appear to be generally known that German rifle bullets are strongly attracted by an ordinary magnet, whereas the English bullet is quite devoid of this quality. The difference is due to the composition of the casings. The English bullet has a casing of 80 per cent. copper and 20 per cent. nickel, and although nickel and many of its alloys possess magnetic qualities, the alloy of nickel and copper in the above proportions is non-magnetic.

At my request, Mr. Leslie Aitchison, M.Met., of the Sheffield University, very kindly made an analysis of a German bullet, with the following result:

The casing is a steel containing 3.36 per cent. nickel and low in carbon. The body of the bullet contains 96.92 per cent. lead and 2.95 per cent. antimony.

With the highly successful methods now available for localizing war missiles in the body by x rays, magnetic tests are no longer of any value for this purpose, but the magnetic attraction possessed by the German bullet may, under certain circumstances, be utilized to assist in its removal from the body. The following notes of a case will indicate what I have in mind:

I. W., aged 38 years, a sergeant in the 6th Sherwood Foresters, was standing up in a trench with his hands in his greatcoat pockets when he was struck by a bullet in the right arm, just below the insertion of the deltoid muscle. The bullet passed upwards and inwards until it encountered the first rib, which it fractured. The resistance so offered was sufficient to arrest its momentum, and it fell into the pleural space and gravitated to the base of the right lung.

Examinations with the x-ray screen demonstrated that it was freely movable in the pleura in response to alterations in the patient's posture, and, as it was causing discomfort, it was decided to attempt its removal by a giant magnet which my ophthalmic colleague, Major Pooley, kindly placed at my disposal.

The idea was to employ intratracheal ether anaesthesia, and under the positive intrapulmonary pressure thus secured to make an opening into the pleura and extract the bullet by means of a soft iron probe connected at one end to the magnet. Tests showed that the attractive force so available would be amply sufficient for the purpose. But "the best laid schemes o' mice and men gaug aft a-gley." On the eve of the day selected for the attempt the intratracheal apparatus was unfortunately broken, and the delay caused thereby led to the bullet being extracted in the ordinary way. The case had an ironic aspect. The bullet turned out to be an English one, and was, of course, unresponsive to a magnet.

My excuse for sending this note for publication is that I have not come across any reference to the matter in the literature within my reach.

SINCLAIR WHITE, Lieutenant-Colonel,
Officer Commanding Surgical Section 3rd Northern General
Hospital T.F.

COMPOUND DISLOCATION OF THE KNEE: RECOVERY WITH A USEFUL LIMB.

A STATEMENT in Major Robert Jones's recent work on *Injuries of Joints* leads me to record a case which I treated at Nablous some few years ago.

An Arab aged about 60 was brought to the C.M.S. Hospital at Nablous, Palestine, in 1903 or 1904 one morning, on the back of a fellow-workman, a distance of fully half a mile. He had bled considerably on the way, and the femur was not only dislocated but had ruptured the skin posteriorly and was protruding therefrom.

The history of the case was interesting because, from the account of the English nurses at the above hospital, he

had been treated twice before at intervals of two years, once for fracture of the same thigh, and also, I was told, for dislocation. In spite of the weakness of the joint he was still following his avocation of a porter, and whilst so engaged and carrying a heavy load the knee gave way under him, with the result stated.

It was found absolutely impossible to reduce the dislocation without further enlarging the rent in the skin, which tightly grasped the femur above the condyles. This was possibly a blessing in disguise.

After reduction the limb was put up on a side splint and a large-sized drainage tube inserted; after a daily or almost daily syringing with mercury perchloride 1 in 2,000 for about a month, the wound closed without infection of the joint or rise of temperature; there was very free discharge of synovia.

The patient left the hospital with a weak but not a useless limb. I am sorry not to have further details, since I was only in temporary charge of the hospital.

Chepstow.

JOHN CROPPER, M.D., B.C.Cantab.

Reports of Societies.

DISCUSSION ON GUNSHOT WOUNDS OF PERIPHERAL NERVES.

THE discussion on this subject was resumed at a meeting of the Medical Society of London on November 1st, when Sir FREDERIC EVE made the communication which is published in full at page 676.

Dr. E. F. BUZZARD said that information was required concerning three points especially: (1) Which cases should be operated upon; (2) what should be done at the operation; (3) how could pain be relieved? With regard to the first point, it was difficult to lay down any rule, but he thought it wise to explore in cases of doubt. Whether operation should be performed or not depended upon whether the local conditions were favourable to return of function. He was sceptical as to the value of the electrical reaction of degeneration, as it was influenced by the treatment applied. It was difficult to decide what should be done at the operation when a fusiform swelling was found consisting largely of scar tissue, but carrying many nerve fibres. In peripheral nerve lesions he advised that the nerve should be examined carefully both with the eye and with the finger. In the case of partially divided nerves, whether the nerve were excised or merely stunted, incomplete recovery would follow. Pain and hyperaesthesia of a most severe type might continue for months. In such cases operative treatment was required, and excision might be necessary, although the injury was only partial. Injection of alcohol into the proximal end of the nerve was of great value as a means of abolishing pain.

Mr. JOCELYN SWAN gave his experiences of 63 cases of nerve injury: 38 had been operated upon, 41 nerves being explored, and 25 were not operated upon. Of these, 6 had refused operation; in 3 it had been deemed inadvisable; 4 had been deferred, and in the remaining 12 improvement and recovery of function had occurred in from two to four weeks after the injury. Those cases which thus recovered had been ascribed to "nerve concussion," and in such it was difficult to say whether any actual damage had been done to the nerve or not. In them a strong faradic current produced a reaction, and this provided a valuable prognostic guide. He thought that no operation should be undertaken until the surface wounds had firmly healed, and there was no evidence of an underlying focus of infection. If there were paralysis of muscles, a corresponding area of anaesthesia, and an absence of faradic reaction, he advised exploration. In some cases with partial injury to a nerve some muscles escaped and anaesthesia was imperfect. Of the 41 nerves explored complete division was found in 13, and in the remaining 28 scar tissue had to be dealt with to free the nerve. In 2 cases metallic fragments were buried in the nerve, and in another a fragment of bone. There was no means of distinguishing between complete division of the nerve and its binding by scar tissue. When the latter had been encountered the result had been more satisfactory when both nerve and scar had been excised. Voluntary movements often returned long before even a feeble reaction was obtained to a strong faradic current. He had

found the skin damp and sweating in the area of distribution of nerves which had been injured.

Mr. BERNARD ROTH was of opinion that all cases in which definite recovery was not taking place after a few weeks should be operated upon. In a large majority of the cases the symptoms were due to compression merely. If the nerve were partially severed he favoured leaving the undamaged fibres and approximating those which were divided. When a so-called neuroma was found this should be left if it affected only a part of the nerve. It could be removed afterwards if necessary. With regard to post-operative treatment, he said that if the leg were affected a suitable walking instrument should be provided to prevent dropping of the foot. It was the efficiency of after-treatment which often decided the degree of recovery.

Dr. E. G. FEARNSIDES agreed with Dr. Harris that accurate chartings of the interferences with sensibility were of greater value in estimating the completeness or incompleteness of the injury than the presence of complete muscular paralysis with the reaction of degeneration. The alteration should be charted at varying intervals, special attention being paid to the delineation of the borders at which the patient appreciated any change in the sensation evoked by the stimulus. At first motor losses and areas of sensory interference often did not match the anatomical distribution of nerves. It was important to attempt to separate disabilities owing to gross mechanical causes from those of directly nervous origin. He still thought that the nerve fibres underlying deep sensibility run a course to the spinal cord different from that of the fibres which underlie cutaneous sensibility. It was not right to speak of "ulnar" or "median" anaesthesia, for in each case it varied with the situation of the injury as well as with its extent. In cases of injury of the brachial plexus the association of pain due to an involvement of a peripheral nerve, with referred neuralgia due to visceral disease, was not infrequent.

Dr. F. HERNIMAN-JOHNSON demonstrated the Lewis Jones condenser, and made a plea for the standardization of the method by which it was used.

Dr. WILFRED HARRIS and Mr. WILFRED TROTTER briefly replied.

At the first meeting for the session of the Section of Dermatology of the Royal Society of Medicine, on October 21st, the chair was taken by Dr. J. H. STOWERS, who has succeeded Dr. J. J. Pringle in the presidency. A number of cases were exhibited, among others one by Dr. H. SPENCE (introduced by Mr. McDONAGH) showing the results of *Eczeliative dermatitis* following novarsenobenzol (French). The patient, who had received one intravenous injection, had cicatricial alopecia and marked arsenical pigmentation. The rash appeared a few days after the injection, and the patient was unable to leave the hospital for six months. Mr. McDONAGH related nine similar mishaps, two of which ended fatally.

Revisus.

VENEREAL DISEASES.

Mr. McDONAGH's recent work on *The Biology and Treatment of Venereal Diseases*¹ is one of the most original books on this subject which has appeared. The statement that "the *Spirochaeta pallida* is not the cause of syphilis, and its destruction does not result in the cure of the disease," is, at first sight, rather startling. The explanation given by Mr. McDONAGH is that the spore of the parasite of syphilis is the true cause of the symptoms, and the *S. pallida* only the male gamete of the life-cycle of an organism which he has named the *Leucozytozoon syphilitidis*, of which he gives a minute description, illustrated with microphotographs and coloured plates. It must be borne in mind that other observers have described developmental changes in *S. pallida*—Lauriaux and Geets and MacLennan in 1906, and more recently H. Ross in 1912. Mr. McDONAGH does not refer to the two former observations, and states that the life-cycle described by Ross was not observed in the living state, and, further, that the

bodies described by him have been found in non-syphilitic material. It appears to us that none of the descriptions of these life-cycles are convincing, and that the subject might well be reinvestigated by an independent protozoologist. The assumption made by McDONAGH that the spore is the real cause of the symptoms naturally influences his views as to treatment and prognosis.

Thus, concerning the curability of syphilis, he holds that a cure cannot be guaranteed after generalization of the parasite has occurred, but he is optimistic as to the results of treatment commenced in the primary stage. The method he now adopts consists in intravenous injections of neo-salvarsan, combined with intramuscular injections of grey oil. Neo-salvarsan is preferred to salvarsan because it can be given to out-patients and at shorter intervals than salvarsan—every four days—with as good results. As regards intrathecal injections of salvarsanized serum, Mr. McDONAGH rightly remarks that this method is based on theoretical grounds, and its value in the future can only be decided by experience. He recommends it in meningeal syphilis, and also in generalized syphilis, when the cerebro-spinal fluid is altered. In degenerative encephalitis no antisyphilitic drugs are advised, but sodium nucleinate is said to be useful. With regard to other arsenical preparations, he thinks galy and lilyl inferior to neo-salvarsan. In addition to neo-salvarsan, McDONAGH makes free use of mercury and iodides. In congenital syphilis he prefers these to salvarsan, but his reason for this is not obvious.

Discussing the chemotherapy of salvarsan, McDONAGH expresses the opinion that Ehrlich's work is unsound, because it was directed against the destruction of the *S. pallida* and not against the spore, which is resistant to direct attack. McDONAGH places less reliance on the Wassermann reaction than he formerly did, and states that antibodies may continue to be found long after the syphilitic organisms are destroyed; hence, a positive Wassermann reaction is not necessarily a sign of active syphilis. With regard to the question of syphilis and marriage, his views are that if the patient is under treatment before generalization occurs he may marry, after four or five injections of neo-salvarsan and a year's course of mercury; but that if treatment is not commenced till generalization has occurred, there is a risk of recurrence, although this risk is small after nine injections of neo-salvarsan and a two years' course of mercury. On this view, the value of salvarsan and neo-salvarsan appears doubtful, for it is quite common for a man to marry and not infect his wife after a course of two years' mercury alone, although marriage is not to be recommended in so short a time. A better rule is to wait till two years after the last symptoms.

The chapters dealing with gonorrhoea are excellent; in McDONAGH's opinion "too much and too drastic treatment are the curse of the present-day treatment of gonorrhoea," and the urethroscopie is of little use for diagnosis and no guide to treatment. The urethroscopie, he holds, is not wanted in anterior urethritis, and is often dangerous in posterior urethritis. The difficulty of urethroscopie treatment is due to the presence of gonococci in the sub-epithelial tissues, which cannot be reached by local applications. He gives an account of investigations conducted by Klein and himself with regard to vaccines in gonorrhoea, and concludes that vaccine treatment is useful provided it is only supplementary to local and general treatment. As a rule he prefers sensitized vaccines, and considers that those sensitized with human antigenococcal serum are superior to those sensitized with immune horse serum. The complement fixation test in gonorrhoea he thinks valuable in diagnosis and useful for regulating vaccine treatment. He attributes the destruction of gonococci to the action of antibodies, chemical substances produced by the epithelial cells, and the growth of secondary organisms, rather than to phagocytosis, which is the idea generally accepted.

In an interesting chapter on venereal disease and public health the evidence obtained by the Royal Commission on Venereal Disease is adversely criticized. In later chapters of the book dealing with the biology of inflammation and its relation to malignant disease, the author puts forward some ingenious and interesting views.

To sum up: whether we agree or not with McDONAGH's views on the life-history of the parasite of syphilis and other

¹ *The Biology and Treatment of Venereal Diseases*. By J. E. R. McDONAGH, F.R.C.S. London: Harrison and Sons, 1915. (Cr. 4to, pp. 665; 54 plates. 25s. net.)

questions of a theoretical nature, we must admit that he has produced a monograph of much practical value and an important addition to the literature of syphilology. The book is well illustrated with coloured plates and microphotographs.

MATERNITY FROM THE WOMAN'S SIDE.

Maternity is a remarkable book, and one which the profession in general and the obstetricians in particular will do well to read and ponder over. It consists of letters from working women collected by the large and active body known as the Women's Co-operative Guild, and, as Mr. HERBERT SAMUEL says in the preface, "these letters give an intimate picture of the difficulties, the troubles, often the miseries, sometimes the agonies, that afflict many millions of our people, as a consequence of normal functions of their lives." "An unwise reticence," continues Mr. Samuel, "has prevented the public mind from realizing that maternity among the poorer classes presents a whole series of urgent social problems. These letters give the facts." They do, indeed—a series of 160 human documents which, in all truth, throws a pathetic sidelight upon the circumstances, antecedent and sequent, under which childbirth in many homes (save the mark) takes place. One may fastidiously object to the direct and homely phraseology in which the women recount their obstetric experiences, and one may see here and there, perhaps, the inevitable tendency to distribute the blame capriciously, but none of these considerations should for a moment be allowed to divert attention from the stories of strain and misery themselves. The writer of the introduction, who remains anonymous, is scarcely seeing the facts in proper focus when reproaching the medical profession with encouraging the attitude of carelessness towards the pains of motherhood and in summing it up in the saying, "You'll be worse before you're better." Such a reflection can hardly be brought against the profession which in the person of Sir James Simpson gave first ether and then chloroform to the suffering world or women in childbirth and pressed the use of anaesthesia even in normal labour. It may be admitted, however, that possibly medical men have been a little slow to recognize all the unrelieved and often unrecorded pain and trouble of pregnancy, although it must be said on the other side that some obstetricians have pressed this aspect of the subject upon the profession, and that this JOURNAL for the past fifteen years has constantly advocated primumaternity provision for suffering expectant mothers. It may confidently be said that no one who ill read the touching letters published in this book will any longer be blind to the pressing necessity there exists for helping women about to become mothers, and indeed the nation as a whole must set its house in order that there may be in the future strong and healthy men and women to carry on its imperial tasks.

NOTES ON BOOKS.

The new edition of the *Pharmacopœia* of University College Hospital, edited by Mr. HAMPSHIRE, contains a full list of the stock prescriptions in use at the hospital, and in addition a large amount of information of service to senior students and house officers. The editor seems to have done his work excellently. Quantities in both metric and the imperial measures are given side by side where dosage is mentioned. We doubt if many students can be familiar with the subdivision of the inch into "lines" that Peacock used (p. 68). The book is interleaved, and is well printed.

The *Transactions and Annual Report of the London Dermatological Society* has been published in a small volume which contains the reports and meetings held from October 20th, 1914, to June 15th, 1915, with notes on exhibits and the discussions held.

ROYAL MEDICAL BENEVOLENT FUND.

(Continued from p. 645.)

At the last meeting of the Committee, held on October 12th, twenty-eight cases were considered, and £227 7s. was granted to twenty-seven of the applicants. The following is a summary of the cases relieved:

Wife, aged 35, of M.B. Dubl. who practised in Ireland but took to drink and drugs and then deserted his wife who had a baby a few months old. Applicant, a trained nurse and able to take a light case, but must be somewhere near her baby. Wants a little help towards the support of the child. Voted £9 in twelve instalments and referred to the Guild.

M.D. Glasg. and M.D. 76, married, and who practised in Harrow Road, has recently had a paralytic seizure and now unable to do any work. Has no means, and his wife only a small income of her own. Has three children, two sons abroad, and a daughter married, none able to help. Voted £18 in twelve instalments and referred to the Guild.

Widow, aged 61, of L.R.C.P. and N. Ircl. who practised in the City of London and died in 1893. Applicant a trained midwife, and managed to make a living until severe illness, followed by an operation, prevented her from working. Hopes to be able to work again when she is a little stronger. Friends lent a room. Voted £12 in twelve instalments and referred to the Guild.

Daughter, aged 56, of M.R.C.S. Eng. who practised at Newport, Mon. Since death of her father in 1892 has managed to make a living by keeping a small school, but owing to the war has lost most of her pupils. Her health is also bad. Has spinal curvature and a varicose vein. Voted £12 in twelve instalments and referred to the Guild.

Widow, aged 81, of M.R.C.S. Eng. who receives some help from the Fund and Guild. Joint income not sufficient to keep them and provide the invalid comforts necessary. £12 voted to the Guild to distribute as they consider best.

Widow, aged 49, of M.R.C.S. Eng., L.R.C.P. Lond. who was a naval surgeon, and died in 1904. Help required to assist son, who was educated at Epsom College, and has now obtained a scholarship at one of the London hospitals. Voted £5 and referred to the Guild.

Widow, aged 65, of M.R.C.S. Eng. who practised in London. Left quite unprovided for at husband's death in 1889. Suffers from chronic neuritis. Three sons, married, with families, only able to help very slightly. Previous relief ten times. £12b. Voted £12 in twelve instalments and referred to the Guild.

Widow, aged 56, of M.R.C.S. Eng. who practised at North Kensington. Until the war managed to make a living by taking in boarders. One son abroad, unable to help. Previous relief twice, £20. Voted £10 in two instalments and referred to the Guild.

Daughter, aged 59, of M.R.C.S. Eng. who practised at Dorking and died in 1913. Applicant a trained nurse, but, owing to ill health, unable to work. Only income a grant of 5s. per week from another charity. Voted £10 in two instalments and referred to the Liverpool branch of the Guild.

Widow, aged 68, of M.B., B.S. Lond. who practised at Islington. Was left with a very small income on the death of her husband in 1912. Has three sons married and only able to help slightly. Relieved once, £12. Voted £5.

Daughter, aged 49, of M.D. Glasg. who practised at Glasgow. Applicant tries to make a living by taking in boarders, but owing to the war has not been able to get sufficient to pay her way. Relieved once, £10. Voted £10.

Daughter, aged 57, of M.R.C.S. Eng. who did not practise on account of ill health. Applicant, who lives in North London, is suffering from cancer, and is quite unable to work. Only income £40 per annum. Relieved once, £12. Voted £12 in twelve instalments and referred to the Guild.

Widow, aged 62, of M.D. Dublin who practised at Acton, and died in 1912. Endeavours to make a little by taking boarders but has not been very successful lately. Son in South Africa unable to help a little before the war, and daughter, an actress, has had very little work of late. Relieved three times, £15. Voted £10 in two instalments.

Daughter, aged 53, of M.R.C.S. Eng. who practised at Birmingham. Applicant lives in a cottage at a seaside resort in Wales, and tries to make a living by taking in lodgers, but for the last few years has been very unsuccessful. Eyesight very bad. Relieved four times, £44. Voted £12 in twelve instalments and referred to the Guild.

Daughter, aged 37, of M.R.C.S. Eng. who practised at Strat-ham and died in 1914. Applicant's only certain income £17 per annum. Health very bad and unable to work. Has earned a little by painting but no sale for her work at present. Relieved once, £5. Voted £5.

Daughter, aged 62, of M.D. Lond. who practised at Notting Hill and died in 1885. Applicant is blind. Only income a pension from a blind society. Relieved three times, £36. Voted £12 in twelve instalments.

Subscriptions may be sent to the honorary treasurer, Dr. Samuel West, 11, Claudos Street, Cavendish Square, London, W.

The Royal Medical Benevolent Fund Guild appeals for gifts of secondhand clothing, boots, and shoes in good condition, also household linen. The gifts should be sent to the Secretary, Royal Medical Benevolent Fund Guild, 43, Bolsover Street, W.

British Medical Journal.

SATURDAY, NOVEMBER 6TH, 1915.

THE PREVENTION OF CEREBRO-SPINAL FEVER.

TEMPORARY SURGEON-GENERAL H. D. ROLLESTON, at the end of an able report¹ on the occurrence of cerebro-spinal fever in the navy from August, 1914, to August, 1915, gives a number of suggestions for the limitation of the occurrence and spread of the disease. There have been 170 cases in the navy during this period, with a mortality of 53 per cent.; 146 of the cases occurred in the first four months of the present year. Some evidence of infection was traced in only 59 of the 170 cases; but there can be little doubt that the disease is spread by patients or carriers, to judge from the way in which outbreaks appear to be stopped by the isolation of contacts and mild disinfection of the throat. Overcrowding does not seem, by itself, to exercise any great influence on the spread of the disease; catarrhal affections of the nose and throat, thus vaguely diagnosed, do appear to be related to cerebro-spinal fever, as the two vary together. Youth and recent enlistment both predispose to the disease; on the other hand, bad weather, including north and east winds, a low atmospheric temperature, and sudden falls in the temperature, appear to exert no influence on the outbreak of cerebro-spinal fever. The statistical results of various forms of treatment in the 163 patients the notes of whom were abstracted can only be described as disappointing; they will be found in the BRITISH MEDICAL JOURNAL of October 23rd last (p. 604).

Dr. Rolleston does not discuss the ordinary symptoms of the disease further than to say that rashes, rare in sporadic cases, occurred in this epidemic in 102 out of 163 cases (62.6 per cent.); of the cases with rash 52 died and 50 recovered. In a few of the cases the rash was papular; in the rest it was petechial or purpuric. The rashes with large hæmorrhages were specially fatal. The rash came out early in the septicaemic stage, being comparable in this respect with the rose spots of enteric fever, and was commonly present when the patient was first seen; in some instances a hæmorrhagic rash occurred before death. Herpes was noted in 35 cases; in 18 of these there was also a rash; in 5 the rash and the herpes occurred together; in 13 the herpes followed the rash, usually after an interval of four days. In a few instances the herpes extended to the ears, or was very extensive. Serum rashes were mentioned in the notes of 19 cases, but it is thought likely that they were commoner than this would seem to show, and in a few instances they were accompanied by pains in the joints. Synovitis, Dr. Rolleston states, occurred in 8 cases, 6 of which recovered; in 2 of these cases the meningeal symptoms were absent or very slight; it has been stated that the prognosis is good in cases with articular manifestations, because the joints receive the meningococci and so divert them from the meninges. The

synovitis was usually multiple and transient, and never suppurated.

The recommendations as to the prevention of the disease and of its spread are comparatively simple. The ideal is to avoid the introduction of carriers of the bacillus into barracks, establishments, and ships. Practically speaking, however, this is impossible from the bacteriological point of view on any but a small scale. All suspects should be examined before an outbreak of the fever is expected; this might well be done in December. In order to avoid the risks entailed by the presence of intermittent carriers, it would be advisable to invalid out of the service all those who have recovered from an attack of cerebro-spinal fever. Overcrowding should be avoided, and special attention should be paid to the ventilation of sleeping rooms. Recent recruits should be treated tenderly, so far as may be, to avoid the increased susceptibility associated with over-fatigue from unaccustomed exercises. The patients should be isolated as far as possible. Every effort should be made to limit the spread of catarrhal affections such as influenza, coryza, tonsillitis, sore throat; the use of handkerchiefs and towels in common should be stopped. When the disease has made its appearance, its spread should be controlled by the well-known routine methods of disinfection and isolation, with bacteriological examination of the suspect and contact cases. Carriers spring up freely around a case of cerebro-spinal fever, but speaking generally it suffices that the two who sleep and the two who mess on either side of the patient, and his two most intimate friends, should be examined as possible carriers; further inquiry should show whether special circumstances make the examination of further suspects desirable. The naso-pharyngeal secretion and urine of the contacts and suspects should be specially destroyed; their noses and throats should be douched two or three times a day with some warm mildly antiseptic solution. Their isolation need not be carried out in hospital; they may be placed in a camp or buildings preferably in the neighbourhood of a medical establishment.

THE WORKING EXPENSES OF LONDON HOSPITALS.

THE statistical reports issued every year by the managers of King Edward's Hospital Fund for London have hitherto provided a vast amount of useful information as to the manner in which the various hospitals in the metropolis are spending the funds allotted to them. With each succeeding year some improvements have been added to render such information more easily assimilable, but there still remain many striking discrepancies as between one institution and another doing similar work but at dissimilar cost. The attention of all hospital administrators might well be drawn to some of these, and the report for the year 1914¹ supplies much food for careful consideration on their part.

The disturbing influence of the war, entailing upon many of the hospitals a large increase of expenditure, only partially met by Government grants, has rendered it impossible to carry on the statistical report in quite the same form as heretofore. Hence the opportunity has been taken to introduce certain alterations and improvements which may with advantage be

¹ Statistical Report on the Ordinary Expenditure of One Hundred and Eight London Hospitals for the Year 1914. For King Edward's Hospital Fund for London. Spottiswoode and Co., Ltd. August, 1915. 1s. net; post free 1s. 2d.

adopted in future. Of these new features, the most marked is the separation of the details of management of the large general hospitals with medical schools, from the larger general hospitals without schools, and these again from the group of smaller general hospitals.

The report is admirably arranged for easy comparison. In each group the tables are presented in exactly the same form, so that any general or special increase or decrease of relative expenditure can promptly be traced to the department which may be chiefly responsible for it.

The main interest centres round the expenditure upon those items which are controllable from year to year. The charges for repairs and establishment, official salaries and pensions, finance, rates and taxes are excluded, and hence cannot be held to explain the variations which in some instances are very marked. It is a very striking fact that the large general hospitals with medical schools attached to them are spending on the average nearly £16 more for each occupied bed than the larger general hospitals without schools. This difference may be traced through all the departments of administration except that of management (apart from official salaries, etc.): the lower rate here may be due to the fact that a considerable amount of unpaid work is done by students or by the school as apart from the hospital.

In the group of the smaller general hospitals there is less difference, but their expenditure would appear to be at a slightly higher rate than that of the larger hospitals without schools.

In the group of three consumption hospitals a very marked difference is to be noted between the expenses of one of them as compared with the other two. There would seem to be no reason why a difference of £13 for each occupied bed should subsist between kindred institutions doing exactly the same class of work. Such discrepancies should be brought to the notice of the respective committees, but it is to be feared that the reports in which these facts have been appearing year by year seldom penetrate beyond official circles. It would be well if greater publicity were afforded by a somewhat more liberal distribution of them to all members of hospital committees at any rate, if not to a wider circle.

Turning to other groups of special hospitals, it will be noted that the range of expenditure in most of them is by no means insignificant. The general average of cost in children's hospitals is, perhaps, the most uniform, while that of the hospitals for paralysis and epilepsy presents some remarkable differences.

It will be seen that a careful perusal of the figures given in such simply classified form should enable any one to discover the lines upon which expenditure may be running too freely in any given institution with a view to ascertaining the reason thereof. In many instances, no doubt, there would be found to be some adequate cause in operation, but it is not easy to explain some of the large discrepancies referred to, except as being due to preventable causes.

The statistics of 108 London hospitals are recorded in the report for 1914, which concludes with some useful details as to the cost of washing and of some of the most important drugs.

A large number of beds in civil hospitals were occupied during a part of the year by naval and military patients, and in most cases the expenditure upon them and the corresponding figures of cost per bed have been included in the general account. It is obvious that this must have introduced a disturbing element into the whole statistical report.

WAR PENSIONS AND ALLOWANCES.

The differences between the Houses of Lords and Commons as to the Naval and Military Pensions Bill were settled on November 2nd, when the House of Lords accepted the amendments carried at the instance of the Government in the House of Commons. The bill provides for the creation of a statutory authority closely associated with the Royal Patriotic Fund Corporation, and containing representatives from Government departments, including each of the three Local Government Boards of the kingdom, and the Joint Committee of Insurance Commissioners. This central body is to supervise the setting up of Local Committees—for example, for the counties and county boroughs—which in their turn are to create subcommittees for smaller areas, and delegate powers and duties to them; the functions of such local and subcommittees are to consist mainly of reporting on individual cases to the central authority and granting supplementary assistance. The Lords proposed to abolish the representation of the four departments referred to, and to reduce the number of representatives of the Royal Patriotic Fund Corporation, making up the full number of the central body by increasing the number of representatives appointed by the Crown and also those appointed by the Soldiers' and Sailors' Families Association. The central authority would then have consisted of a "Board" with a constitution approximating to that of a Government Department, but in dealing with the constitution of the local committees greater attention would have been given to existing voluntary associations—particularly to the Soldiers' and Sailors' Families Association—than in the original bill: for instance, there would have been some members of such associations on the local committee, and the delegation of the duties might have proceeded not only down to a subcommittee, but further to a local committee of those associations, so long as they performed the required functions to the satisfaction of the local committee.

It will be seen that the points in dispute involved principles of some importance, and not mere matters of detail. The broad distinction is between, on the one hand, a central voluntary body based on the Royal Patriotic Fund Corporation and delegating powers down to local committees appointed *ad hoc*, and on the other hand, a central Government authority delegating down to existing voluntary organizations, which in practice, and in the contemplation of the Lords, would have meant down to local committees of the Soldiers' and Sailors' Families Association. Which of these two schemes would be found to be most satisfactory in working was fair matter for argument; what was not open to question was that the matter should be settled one way or the other at once, so that the committees to be set up may commence their operations.

The Government issued, on October 25th, a white paper¹ setting out the general effect of the Admiralty Orders and the Army Orders and Regulations made or to be made for the payment of allowances from navy or army funds to the dependants (other than widows and children) of sailors and soldiers whose deaths are due to the present war. It does not appear to be intended to apply to officers. For parents wholly dependent on the deceased the allowance is not to exceed the amount of the ascertained dependence prior to mobilization or subsequent enlistment, or the amount of the widow's pension appropriate to the deceased's rank, whichever

be the less. In the case of other dependants or parents partially dependent, the maximum allowance is to be 5s., whatever may have been the ascertained dependence. Disablement (but not sickness) benefit under the Insurance Act and old age pension will be reckoned in diminution of these benefits. Women who have been entirely dependent and would otherwise be destitute will have a gratuity or weekly payment not exceeding in all the amount of a year's separation allowance and allotment; further allowances may be paid where the woman is wholly or partially incapable of self-support or where there are children. Disablement (but not sickness) benefit under the Insurance Act and old age pension will be reckoned in diminution of the above benefits to the woman (not to the children).

It is clear that there is an urgent need for the setting up of local machinery for testing, recommending, and paying claims. The Naval and Military Pensions Bill is entitled "A bill to make better provision as to the pensions, grants, and allowances made in respect of the present war to officers and men in the Naval and Military Service of His Majesty and their dependants, and the care of officers and men disabled in consequence of the present war, and for purposes connected therewith," and should be considered in connexion with the third special report of the Select Committee on Naval and Military Services (Pensions and Grants), which was analysed in the *JOURNAL* of September 18th, p. 437. That report made a number of recommendations with regard to combatant officers disabled through war services, and to widows and orphans and dependants of combatant officers, and stated that the cases of other officers should be reviewed departmentally where necessary on similar lines.

CENTRAL MEDICAL WAR COMMITTEE.

THE Central Medical War Committee has issued to the authorities of voluntary hospitals a letter directing their attention to methods for staffing these hospitals during the war. While recognizing that there are grounds for fearing lest a further withdrawal of men from these hospitals should endanger their efficiency, to the disadvantage of the civil population and of the sick and wounded soldiers admitted to them, it is pointed out that the hospital committees must realize that the withdrawal of men of military age from their institutions is inevitable, for war is essentially work for young men. Hospital residents, from the nature of their present work and their experience of responsibility, are particularly suitable as army medical officers; and, since the successful termination of the war is the first consideration for the whole nation, the army must have the first claim on their services. Suggestions founded on actual experience are made. In the first place, it is pointed out that the honorary staff of a hospital is technically responsible for the whole of its medical work, and it is suggested that during the war its members should be actually responsible, supplementing the work of such residents as remain by undertaking some of that usually left to junior officers. Where the number of residents is insufficient for emergency work, it might be undertaken by members of the honorary staff doing service in rotation as "orderly" officers, and residing in the hospital for arranged periods. This plan is already in force, we understand, in some hospitals in London. The memorandum goes on to suggest that all teaching hospitals should take advantage of the scheme approved by the War Office under which recently qualified men are given honorary commissions and seconded to voluntary hospitals as residents for three months, subject to the liability of being called up in emergency at forty-eight hours' notice. At present this

regulation applies only to teaching hospitals, but it may be possible for certain other hospitals to arrange for the employment of senior students supplied from the teaching hospitals to act as dressers, their time being counted for graduation purposes. In the one case application should be made to the War Office, and in the other to the Dean of a medical school. It is suggested further that general practitioners living near hospitals should be appointed as casualty medical and surgical officers to give service at certain hours, or to attend in case of emergency. To obtain such services it is suggested that the hospital committee should make application to the local Medical War Committee, and it appears from a return presented to the meeting of the Executive Committee of the Central Medical War Committee held on Monday that 162 such committees have been appointed and that they cover all but nineteen of the Divisions of the British Medical Association in England and Wales. The desire of the Central Medical War Committee is to co-operate with the governing bodies of voluntary hospitals in England and Wales in regulating the flow of medical men for the services, and in order that the matter may be put on a business footing it is hoped that members of hospital staffs who are of military age will fill up the enrolment form, copies of which can be obtained from the secretaries of the Central Medical War Committee, 429, Strand, London, W.C. The main functions of the local Medical War Committees are concerned with protecting the interests of men on service, and advising the Central Committee on matters of importance or urgency relating to their districts. A list is kept at the central office in which each local committee is credited definitely with the men posted by the War Office as having applied for commissions but have not yet received them. From these lists it would appear that there may be some considerable interval between the date on which a practitioner applies for a commission and that on which it is officially granted. The Committee is considering the possibility of the withdrawal of more men from the service of local authorities, and particularly from the tuberculosis service. Acting on the principle enunciated in the memorandum to the governing bodies of hospitals, that the successful termination of the war is the first consideration for the whole nation, and that therefore the army must have the first claim on the services of all efficient men, it has been argued that in the matter of tuberculosis the unfit must give way to the needs of the fit, and, regrettable as it may be to diminish in any way the efficiency of the tuberculosis service, it appears that further curtailment is necessary. It may, however, be found possible, as we think it should, to provide that tuberculous patients should be looked after by men above military age, and possibly in the case of sanatoriums which cannot be converted into military hospitals, to utilize for supervision the services of general practitioners resident in the neighbourhood.

A NAVAL SURGEON OF THE FIRST FRENCH REPUBLIC.

IN a note published in the *BRITISH MEDICAL JOURNAL* of October 2nd (p. 513) it was stated that, after the suppression of the faculties of medicine of old France, the armed forces of the Republic one and indivisible came near to extinction in its early years for lack of doctors. It was at war with the civilized world, and hospitals, churches, convents, and private houses were overcrowded with sick and wounded soldiers, who, starving and uncared-for, died like flies. The crews of the fleet were in like case, and all contemporary records speak of the foul and unhealthy state of the ships. In this extremity the Government issued a requisition, dated August 23rd, 1793, by which all medical practitioners of France from 18 to 40 years of age were placed at the disposal of the Ministers of War and Marine. As the need for surgeons became more pressing, further requisitions were made, and

medical students were taken from the dissecting-room and the hospital and compelled to serve in the army or navy. Among these was Joseph Claude Anthelme Récamier, who afterwards rose to the highest position in his profession, and who has a permanent place in the history of medicine as a leading pioneer of French gynaecology. He was a godson of Brillat-Savarin, the author of *Physiologie du Goût*, and a relation of the famous beauty, Madame Récamier. He was born in 1774 at Rochefort-en-Bugy, a small village in the Ain department. His family was one of the oldest and most respected in the province, and many of his ancestors had been doctors. He was working under his cousin, Anthelme Récamier, at the Belley Hospital when, in 1793, he was summoned to serve forthwith and sent to sea as *aide-major* in a corvette. He had to go on board without linen, clothes, or books, which, left behind in the hurry of departure, never reached him. He had no money and was half starved. Privation and overwork brought on an illness, for which he was admitted to the naval hospital at Toulon. The conditions there were so bad that he was glad to leave it after a sojourn of a month almost as ill as when he entered. He was appointed to the line of battleship *Çaïra* (80 guns) which carried five surgeons and an apothecary. Récamier's letters to his father give a vivid glimpse of the life he led. He received no pay except in worthless paper and continually begs for help to enable him to get food. Apparently the stern parent, who was burdened with a large family and ground down by the exactions of the Government, had hinted that his son was living too luxuriously, for the young man indignantly says: "You speak to me of making good cheer, whereas I am speaking of bread, of bread and hunger." In March, 1795, he sailed from Toulon with a fleet sent to open up the Mediterranean to French transports, to assist the operations of the army of Italy and to attempt a landing in Corsica. On March 13th this fleet found itself face to face with a British fleet of thirteen ships under Hotham opposite Cape Noli. The *Çaïra* got separated from its division and had to engage the whole British vanguard commanded by Nelson. The slaughter was terrible. At the beginning of the action the surgeon-major was cut in two by a cannon ball while dressing a man whose arm had been carried away, and Récamier was knocked down and fell covered with blood and splinters. He was thought to be dead, but had not received a scratch. Soon the wounded were brought down twenty and thirty at a time. There were no slight wounds—nothing but arms and legs shot away. The third medical officer was killed while Récamier, who had taken the place of his chief, was dressing him. When three-fourths of the crew were killed or wounded the *Çaïra* struck her flag. Years afterwards the survivors spoke with admiration of the courage and devotion shown by Récamier. He was interned at Saint Florent in Corsica, where he fell ill of typhoid fever. When scarcely convalescent he was placed in medical charge of the hospital in which he had been a patient. After a captivity of some months he was exchanged for the surgeon of a British ship and sent back to Toulon, where he arrived in a destitute condition, having been robbed of everything he possessed, not, as his biographer, Triaire, is careful to inform us, by his captors, but by French soldiers.¹ He was attached to the naval hospital, and in spite of many difficulties found means to pursue his medical studies there. He worked at anatomy and operative surgery under Larrey, who thought very highly of the abilities of his pupil. When Larrey left Toulon, Récamier got himself discharged from military service and obtained an appointment in the Hôtel-Dieu at Lyons. There he remained till September, 1797, when he went to Paris to finish his studies. We need not follow him through the rest of his brilliant career. Our purpose

has been to show the stuff of which so many of the men of his day were made. Struggling against the disadvantages of poverty and imperfect training, Récamier never lost heart, and declared that if he did not die very young his teachers would have no cause to be ashamed of him. His life is a fine record of success, achieved not only by power of intellect but by strength of character developed by early contact with the practical problems of life.

THE VACCINE TREATMENT OF TYPHOID FEVER.

In a memorandum by the Board of Health of Hungary to the Minister of the Interior an opinion has been given on the value of inoculation after the outbreak of typhoid fever. "Sufficiently satisfactory results have," it is stated,¹ "been obtained." It was ascertained by Hungarian medical men that in cases of typhoid fever, the diagnosis of which was confirmed by a bacteriological examination, rapid recovery or definite improvement was traced to the inoculation in 40 to 50 per cent. of all the patients thus treated. These favourable results were practically confined to cases in which inoculation was undertaken within ten to fifteen days of the outbreak of the disease. But the Board of Health did not consider that this treatment had emerged from the experimental stage, for the number of cases thus treated and closely observed scarcely amounted to 200, and there were also many factors still requiring elucidation. Thus, little was yet known as to the effect of therapeutic inoculation on patients who had previously undergone prophylactic inoculation. The choice of case, the time at which to inoculate, the dosage, and the comparative value of intravenous and subcutaneous injections, were all matters about which exact data were still wanting. There were also as many as four different vaccines in use for therapeutic purposes—namely: (1) Ichikawa's sensitized vaccine, made from bacteria acted on by the serum of convalescents; (2) Besredka's vaccine; (3) a vaccine made from bacteria killed by heat; and (4) a vaccine made from bacteria killed by chemicals, such as carbolic acid and ether. It was not possible to estimate the relative values of these preparations, but, with regard to the method of administration, it had become evident that intravenous injections should be given only where every facility for preventing sepsis existed. Unfortunately there had been many obscure cases of sudden death following intravenous injections. In the case of Ichikawa's vaccine, an intravenous injection should not be given unless there were guarantees that the serum used for sensitizing the bacteria was not obtained from a convalescent who had suffered from, or was suffering from, some other infectious disease. As a rule, the subcutaneous injection, though less rapidly effective, was preferable, for it was not dangerous, provided due cleanliness was exercised. Though the comparative merits of the various vaccines had not yet been fully tested, the Board of Health recommended Besredka's vaccine, as experience in its use was larger than in the case of the others.

TRANSPLANTATION OF NERVES.

A good deal of work has been done during the last twenty years on the transplantation of nerves. In view of the large number of cases of injury to the nerves now being met with by military surgeons, Dr. R. Ingebrigtsen's recent experimental work on the subject² is of particular interest. His experiments were made on rabbits and guinea-pigs, and transplantations with the excised sciatic nerve of the rabbit. He divides the latter into three classes: (1) Autoplastic transplantations, made into the sciatic nerve of the same rabbit; (2) homoplastic transplantations, made into another rabbit; and (3) heteroplastic transplantations, made into the guinea-pig. His conclusions are as follows: In heteroplastic transplanted

¹ *Récamier et ses Contemporains*, 1774-1852. Par Paul Triaire, Paris, 1895.

² *Deut. med. Woch.*, August 5th.

³ *Journ. Experim. Medicine*, New York, 1915, xxxi, 418.

nerves myelin ovoids, or oval aggregations of myelin, are formed early, but there is no proliferation of the cells of the sheath of Schwann, and no Wallerian degeneration is seen. The graft becomes necrotic in about two weeks, and Dr. Ingbriquets concludes that heteroplastic grafts are unsuitable as bridges in cases of nerve defects in human beings. In homoplastic nerve grafts a process resembling Wallerian degeneration takes place, and the cells of Schwann multiply and survive for a time. In a fortnight, however, there is an immigration of leucocytes, and at the end of the third week the cells of Schwann develop a necrobiotic appearance. The author remarks that the occurrence of a Wallerian degeneration in these grafts during the first two or three weeks after the transplantation should make homoplastic nerve bridging a promising operation, and indicates the possibility of a regeneration of the nerve fibres. In autoplasmic transplanted nerves a degeneration resembling the Wallerian occurs; it may be added that, from the practical point of view, autoplasmic nerve grafts can but rarely be available for use in the human subject.

THE ACCIDENT TO THE KING.

THE results of the accident to the King have been more lasting and incapacitating than the first reports which reached this country led the public to anticipate. The horse when it slipped on the muddy ground in rearing fell backwards, the rider receiving part of its weight on the right side of the trunk and the right thigh. We have the best authority for stating that, though there was considerable shock, careful examination showed that no serious visceral injury had occurred. There was most extensive bruising, and much muscular stiffness has developed, so that His Majesty has been obliged to remain, up till now, in a completely recumbent position. The rumour that any kind of operation has been performed, and on the other hand the report that the King was able to walk to his car, are alike unfounded. The nurse who attended His Majesty when lying ill with typhoid fever is now in attendance on him, in company with other nurses. We need hardly say that it is not the lady who tended the angust patient's father during his attack of typhoid fever in 1872. That lady, previously one of the well-known sisters at St. Bartholomew's Hospital, was certainly not a young woman when she distinguished herself forty-three years ago by taking so large a part in saving the life of the future King Edward VII.

MEDICAL INSURANCE AGENCY.

At a meeting of the Medical Insurance Agency on October 28th the chairman, Dr. G. E. Haslip, reported that the business transacted during the September quarter had been well maintained; that done for the first nine months of 1915 showed a substantial increase on the previous year. Though a fair number of life risks had been adjusted business in life insurance was slack, as those contemplating such insurance were indisposed to entertain the contracts which, owing to military risks, were obtainable under existing conditions. Although the amount of commission earnable in respect of aerial risks was not proportionate to the time and trouble involved, it had been thought advisable to negotiate such risks when requested. On the other hand, motor business had been wonderfully steady and formed an important part of the work done by the agency. The amount of the commissions actually earned by the agency during the nine months ending September 30th had been £900, while the working expenses had been £232. The grants made to medical benevolent institutions of various kinds during the first six months of the year totalled £400. On the present occasion the Committee had a surplus of £270. The Chairman proposed that £230 should be distributed, which would raise the total amount distributed by the

agency for medical benevolence to £1,700. It had been possible to make this important contribution for the benefit of the profession, while at the same time the agency had been able to save to those insured through it something like £5,000. The chairman's report was adopted, and it was resolved to divide a further sum of £230 as follows: The Royal Medical Benevolent Fund, £80, making £230 given to this Fund during the year; the Royal Medical Benevolent Fund Guild, £60, making a total of £160 for the year; Epsom College Benevolent Fund, £45, making a total of £145 for the year; the Royal Medical Benevolent Society of Ireland, £30; and the Royal St. Anne's School, £15. In addition, a sum of £50 has been granted to the Royal Army Medical Corps Benevolent Fund. In view of existing conditions, and in particular of the increasing cost of locomotives, the agency has thought it well to make arrangements for issuing sickness and accident policies. In the case of the policies issued by many insurance companies the contract is annual—that is to say, the company retains the power to refuse renewal of the policy at the end of any year, and cases are known in which a doctor who has claimed for two or three attacks of influenza has been refused when he applied for renewal unless he would consent to exclude influenza from benefit under the policy for the future. The Medical Insurance Agency has arranged with an office of good standing to issue a policy which cannot be discontinued by the company so long as the premiums are punctually paid, until the assured attains a selected age, which must not exceed 65. This policy covers disablement by sickness or accident of any kind; if desired, a provision can be made for the guaranteed return, on the assured attaining the selected age or at his earlier death, of all premiums paid without deduction for any claims that have been paid. As an alternative to the return of premiums, the insured may have a capital sum, with a share in profits, payable at a selected age or previous death. The sickness and accident benefits under the policy are not limited, as is usually the case, to 26 or 52 weeks; they are payable continuously so long as the disablement lasts up to age 65, and therefore afford provision against a permanent breakdown in health. The larger portion of the premium payable for this policy may be deducted from the insured's return for income-tax assessment. It is worth while emphasizing the fact that the agency has been able since its establishment to give £1,700 to medical benevolent institutions. This was one of the motives with which the agency was established, and is the reason why the Committee, consisting of members of the medical profession, under which the agency is conducted by Mr. Guy Elliston, Financial Secretary to the British Medical Association, give their services freely. Nothing is taken out of the pockets of the profession; on the contrary, those who insure through the agency pay a substantially smaller premium than they would pay were their policies effected through any other agency. Full particulars can be obtained on application to the Medical Insurance Agency, c/o. British Medical Association, 429, Strand, W.C.

"RESPECTABLE."

A NORTH country correspondent takes exception to the use of the term "any respectable medical man" in defining a person competent to fill up an interrogatory for the admission of a boy to a certified industrial school near Manchester. It is possible that the word "respectable" in this connexion may be a survival from the days antecedent to the Medical Acts. Such an archaism, with its implied slur on the respectability of the profession as a whole, might, however, gracefully be abandoned and the expression "registered medical practitioner" substituted, which, moreover, would include the duly qualified woman practitioner of to-day. "Respectable" has in modern

lines acquired somewhat of an ambiguous flavour; and Carlyle in his *French Revolution* speaks of "secret scoundrels, in their fair-sounding formulas, speciosities, respectabilities, hollow within; the race of quacks was grown many as the sands of the sea." The authorities of the institution referred to will do well to adopt a less questionable term in dealing with an honourable profession.

Medical Notes in Parliament.

Medical Students and Recruiting.

SIR PHILIP MAGNUS asked the Under Secretary of State for War, on November 3rd, whether he was aware that second and third year medical students had received copies of the letter addressed by Lord Derby to unstarred men eligible for military service, and that they were being actively canvassed at their homes to join the army; and whether, having regard to the difficult position in which first, second, and third year students found themselves as to their duty in the matter of joining the forces of the Crown owing to the absence of any definite expression of opinion on the part of the War Office, he would say at what stage in their course of studies the Secretary of State and he concurred in desiring that medical students should answer to the call to join the army, and also at what stage they should remain at college to continue and complete their studies with a view to qualifying as medical practitioners, of whom it was feared there would be a considerable shortage at the close of the war. Mr. Snowden asked if the policy of the War Office, as explained recently, had been changed in regard to the enlistment of first and second year medical students—namely, that it was neither in the interests of the nation nor the army that they should enlist: if a notification had just been made to such students by the university authorities which said that the Medical Council, in consultation with the War Office, had decided that first, second, and third year students might enlist: and if this decision was made with the knowledge of the seriousness of such a step in relation to the future scarcity and efficiency of doctors. Mr. Tennant, in reply, stated that he presumed Mr. Snowden referred to the answer given to Sir Philip Magnus on June 21st. Mr. Tennant then stated: "It is clear that, if students in their first or second years join the combatant ranks in very large numbers, there will probably be for some years after the war a serious scarcity of doctors. Any expression, therefore, of official opinion which might seem to place on them the obligation of taking up immediate military duty would hardly be in the interests either of the army or of the community as a whole." In reply to Sir Philip Magnus, Mr. Tennant said: "I would now, in the light of the experience of the last few months, make this modification of that statement. I think we must remember that we have first to win the war, and afterwards to encounter problems arising out of it, if they do arise. I would therefore answer these questions by saying that the view of the War Office at the present time is that fourth and fifth year students should continue their studies, but that students in the first and second and third years must consider for themselves what answer they should make to the recruiting appeal addressed to them, and not regard themselves, so far as the War Office is concerned, as under the duty of continuing their medical studies."

The Secretary of the Faculty of Medicine of the University of London informs us that the Dean of the Faculty, Sir Alfred Pearce Gould, who was accompanied by the Presidents of the Royal College of Physicians of London and the Royal College of Surgeons of England, and Dr. Shore, Dean of St. Bartholomew's Hospital Medical School, had an interview with Lord Derby, Director General of Recruiting, on November 2nd. After considering all that the deputation could urge as to the importance of maintaining a contiguous supply of qualified medical men for the needs of the country, Lord Derby stated that in his opinion "it is the duty of medical students, other than those in their fourth and fifth years of study, to join His Majesty's forces."

Casualty Statistics.—In a written reply to Mr. Molton, issued on October 29th, the Prime Minister stated that the casualties up to October 9th in the western and other areas of operations totalled 493,294, made up as follows:

	Western Area.		Other Areas.	
	Officers.	Other Ranks.	Officers.	Other Ranks.
Killed	4,401	63,059	2,259	31,933
Wounded	9,169	225,716	3,464	79,116
Missing	1,567	61,134	433	11,043
	365,046		128,248	

Australian General Hospitals.—With reference to the answer to Mr. Cathcart Watson by Mr. Tennant on October 19th (JOURNAL, October 23rd, p. 616), Mr. Tennant stated on November 2nd, in reply to a further question by Mr. Watson, that a general hospital consisted of 34 officers, 72 nurses, and 201 non-commissioned officers and men, with about 1,000 tons of ordnance and medical stores. The personnel of the 10th Australian General Hospital was at the disposal of the Australian military authorities, and he understood that most of its members were employed on special work in connexion with a large number of Australian sick and wounded at present in the United Kingdom. There was a possibility of this personnel being utilized in one or more special units, but he was not in a position to make any definite statement.

Inoculation.—Mr. Partington asked the Under Secretary for War on October 28th whether there had been reported to the War Office any, and, if so, how many, cases in which pneumonia had supervened upon inoculation for typhoid, and where, in some cases, inoculation had brought on madness and in others led to invalidity, so that men had become totally unfitted for their duties and had been cast diseased upon the world incapable of gaining their livelihood. Mr. Tennant said that such reports as those mentioned in the question had been made to the War Office by Mr. H. G. Chancellor, but not, so far as he was aware, by other persons. Investigation had been made, and it had been proved that the individuals spoken of as having died as a result of inoculation against enteric fever had, in fact, died of some quite ordinary disease. In particular his attention had been called to a speech delivered on October 16th by Mr. H. G. Chancellor, and he would like to say with reference to the statements then made, some of which were reproduced in the question, that they were not only without foundation, but were grotesque misrepresentations of the results of a treatment from which the army had derived incalculable benefits.

Vivisection.—In reply to Mr. George Greenwood, on October 28th, the Home Secretary said that paragraph 122 of the report of the Royal Commission on Vivisection related to the selection and appointment of an advisory committee, and his predecessor, who consulted the Chairman of the Royal Commission as to the precise scope of the recommendation, was informed by him that it was not the intention of the Commission that the names of the persons who were recommended for licences and were granted certificates should be published; the object they had in view was to secure the publication of the names of the persons selected by the Secretary of State to form an advisory committee, and effect had been given to their personal proposal in the annual returns.

THE annual meeting of Fellows and Members of the Royal College of Surgeons of England will be held at the College, Lincoln's Inn Fields, W.C., on November 18th at 3 p.m. A resolution will be moved on behalf of the Society of Members affirming the desirability of admitting members to direct representation on the Council, and another requesting the President to explain the view of the Council with regard to this matter.

THE WAR.

THE CARRIER PROBLEM IN WAR.

The Parliamentary Secretary to the War Office stated in the House of Commons on Tuesday (November 2nd) that the total number of officers and men, including native Indian troops, leaving the Gallipoli peninsula on account of sickness from April 25th to October 20th was in approximate figures 3,200 officers and 75,000 other ranks. Of these two aggregates, 1,500 and 27,000 respectively had been removed to England. During the month of August approximately 160 officers and 3,800 other ranks, and during September 600 officers and 11,500 other ranks were removed to England on account of sickness, but he was unable to give the number of those removed from the peninsula in the two months mentioned.

A large proportion of the sick have, we believe, suffered from bowel complaints, typhoid fever, paratyphoid fever A and B, and dysentery, as well as certain other disorders of the intestines, the exact nature of which has not yet, we gather, been fully worked out either clinically or bacteriologically. The dysentery has, we understand, been both of the amoebic and bacillary type, but opinions differ as to whether the one or the other has preponderated.

The "carrier" problem is one of the most serious with which the military and civil medical administration is confronted at the present time. It arises in particular with regard to enteric cases, whether of the typhoid or paratyphoid type, and applies also to dysentery. We announced some time ago that with the approval of the Director-General A.M.S. and of the British Red Cross the house and grounds of Addington Park, near Croydon, had been placed at the disposal of a committee, of which Bishop Boyd Carpenter is chairman and Lord George Hamilton treasurer, to provide treatment in this country for cases of infectious fevers of all kinds, especially typhoid fever and dysentery. The hospital has been at work for about eleven months, and has, of course, had to give close attention to the carrier problem; the staff includes a pathologist and two assistant pathologists. The general principle proposed to be followed at the Addington Hospital was, we understand, somewhat as follows: In the case of a man convalescent from typhoid or paratyphoid fever, the faeces and urine were to be examined four times at intervals of a week; at the end of a period of four weeks, if the results were negative, the man would go to a convalescent home for three weeks, during which period three examinations would be made, and he would then return to Addington, when he would again be kept under observation while further bacterioscopic examinations were made.

The "carrier" of typhoid or paratyphoid may seem to be, and so far as he himself is concerned may really be, in excellent health, yet his urine and faeces may constantly or intermittently contain the microbe in a virulent state, and may easily, especially under conditions of camp life, be transferred from him to the host. The length of time for which a carrier may carry the infective microbe is indeterminate, and cases have been recorded in which the condition has persisted for years, but the general experience seems to be that by the tenth week of convalescence the typhoid or paratyphoid bacillus has disappeared in all but a very small percentage of cases, possibly under 1 per cent.

Treatment by drugs, which was very systematically tried in the navy and army before the war, has not given constant or encouraging results. The agglutination test, even if it did not involve tedious and difficult manipulation, is found not to give constant results, either negative or positive. We are therefore driven back upon bacterioscopic methods, and it has to be recognized that the absence of the microbe at a single examination during convalescence is not conclusive; the technique is not easy, and apart from errors due to this source the presence of the microbe in the excretions may, as has been said, be intermittent. Repeated bacterioscopic examinations are therefore necessary before a man can be given a clean bill, and this fact has introduced a most serious complication into military medical administration. The War Office, we understand, has recently issued an order that the stools and urine of every typhoid convalescent shall be examined

four times at intervals of a week. This order must involve a serious tax on the time of the pathologists of military hospitals and may interfere with other pathological investigations, as for instance, with regard to dysentery, which must be regarded as only of lesser importance. It would appear, therefore, that the time has come when the pathological departments of military hospitals in this country must be considerably increased. The difficulty of finding competent men will, we fear, be considerable, but it may be found that sufficient use has not yet been made in some centres of the pathological laboratories of universities and teaching institutions.

From the administrative point of view, the problem, as has been said, is extremely difficult. To return carriers of typhoid fever or dysentery to an army in the field is not to be thought of. Looking at the matter solely from a military point of view, it will at once be admitted that the enteric carrier, owing to the efficiency of the precautions taken with regard to the water supply, is now properly to be regarded as the chief source of typhoid fever and paratyphoid fever in an army in the field. On the other hand, to discharge carriers of typhoid or paratyphoid fever from the army to mingle with the general population, or even to give them six weeks' furlough to go to their homes or friends, is a serious matter from the point of view of civil and public health administration. To dysentery similar observations apply, but with this addition—that a man carrying the infection, although apparently well, may at any time suffer a relapse or develop a liver abscess. At the same time it seems undesirable to keep typhoid convalescents in hospital during the time that they are necessarily under suspicion of being carriers, and it may be that a solution of the difficulty will best be found through an extension of convalescent camps, where the men can be exercised in military work, while adequately staffed bacteriological laboratories would be able to carry out the periodic examination of excretions.

WITH AN AUSTRIAN HOSPITAL TRAIN.

An account is given by Dr. Alfred Neumann¹ of his experiences in a hospital train, to which he was attached as senior medical officer from the beginning of the war. Owing to the rapidly changing conditions arising out of the Austrian army's advances and retreats, his experiences were both varied and instructive. At one time his train was only three to four kilometres behind the fighting line, and the wounded were conveyed direct from the field into the train. At another time most of the casualties had occurred several days before the wounded were drafted from the dressing stations into the train, and though most of these patients were in a fit condition for travelling, it was sometimes impossible to refuse recent cases of lung and abdominal wounds, although they were not really fit to be moved. At another time, again, the hospital train was employed in the interior, the wounded at this stage having already passed through the base hospitals, where their wounds had healed sufficiently to enable further transport by train to be effected without risk.

Operations in a Moving Train.

Although there were excellent facilities for operating in the train, Dr. Neumann came to the conclusion, shared by his German colleagues, that, whenever it was possible, it was wiser to slant the carriage occupied by the patient than to undertake the operation while the train was moving. Urgent operations, such as tracheotomy and ligation of vessels, had, however, sometimes to be carried out in the moving train. While operations were thus reduced to a minimum, there was no limit to the conservative treatment of wounds. Thanks to the excellent construction of the Austrian ambulance trains, the dressings of the wounded in their beds were, with a little practice, quickly changed, provided the train did not jolt much. To prevent excessive jolting the train was slowed down for curves, but in the straight it was easy to change dressings when the train was travelling at forty-five kilometres an hour. In the interior of the country, and far from the fighting line, it was often convenient to travel at a rate of sixty kilometres when the wounds had

¹ *Der Militärarzt*, July 24th, 1915.

already been well attended to, and the wounded thought more of getting quickly to their destination than of escaping jolting.

Fast or Slow Trains for the Wounded.

Dr. Neumann came to the conclusion that increased speed had only a trifling effect on the pain of the wounds, for the jolting caused at certain points on the rails was inevitable, whether the train was travelling fast or slowly, and the more rapid succession of these jolts due to the greater speed of the train was to a certain extent compensated for by the jolts themselves being reduced by the greater speed. On one occasion, when the train was empty, a member of Dr. Neumann's staff developed acute appendicitis as the train was travelling at 60 kilometres. The pain was severe, and Dr. Neumann thought he would mitigate it by reducing the speed of the train to 45 kilometres. But this change did not affect the pain, and the patient himself begged that the original speed should be resumed so that he might reach his destination sooner.

Nature of the Casualties Treated in the Train.

Most of the wounds of the head and neck treated were inflicted by rifle bullets; but some of the wounds, notably those of the face, were caused by shrapnel. Even recent wounds of the brain were not invariably a contraindication to a long journey by train, and in some cases, during a journey of two or three days, patients suffering from severe wounds of the skull improved greatly, consciousness returning in the train, the pulse improving and the temperature remaining normal. Owing to the great danger of infection, it was made a rule not to change the dressings of these wounds, and when alarming symptoms occurred, the carriage in which the patient lay was slung at the first opportunity. With regard to other wounds of the head and neck, excellent results were observed in the case of wounds of the cheek and mouth, and patients admitted to the train with severe haemorrhage, suppuration and oedema of the tongue and pharynx improved rapidly on the journey, during which fragments of bone were removed, and the wounds were kept clean by frequent and careful irrigation with hydrogen peroxide. Thus, at the end of the journey, these patients could often eat, drink, speak, and breathe freely, and showed no signs of fever. Even cases of recent wound of the abdomen and lungs stood the journey surprisingly well. Careful dieting and nursing were insisted on in these cases, which were slung as soon as alarming symptoms developed. To show how successful the early transport by train of the severely wounded can be, Dr. Neumann recorded the case of a lieutenant, aged 29, who was wounded on September 13th, 1914. Next day he was admitted to the hospital train, where a bullet wound of the left lower abdomen was found. The bullet had passed out through the left lumbar region. The temperature was 38.9 C., the pulse was 110, and there was a faecal fistula. It was impossible to slung the carriage in which the patient lay, and the patient's urgent request to be conveyed to Vienna was therefore granted. An icebag was applied, 0.005 gram of morphine was given every day, a fluid diet and complete rest were prescribed, and a drain was inserted into the abdominal cavity. The fever abated, the pulse improved, and no sign of general peritonitis supervened. After a journey of three days the patient reached Vienna safely. Another patient was an ensign, aged 21, who was wounded on March 21st, 1915. A rifle bullet had entered the chest close to the apex of the heart, and had passed out again between the fifth and sixth ribs in the posterior axillary line. He was kept in a field hospital for a day and was transferred on March 23rd to the hospital train, in which he had not been long before he suddenly collapsed. The temperature was 39.2, and the pulse 140, very small and irregular. There was a haematoma as large as a plate over the apex of the heart, the nostrils were distended, and the patient was dyspnoeic. Injections of amorphous and morphine were given, combined with digalen. An icebag was applied to the heart, and absolute rest was maintained. In the evening of the same day, when the train was about to start, the patient was not slung, as he had improved considerably, and as it was advisable to transport even the severely wounded, for they were very near the firing line. During the two days' journey the patient improved greatly.

In the case of wounds of the lungs the regular administration of morphine was considered necessary on account of the danger of haemorrhage. In the case of wounds of the spine, particularly in the lumbar region, with paralysis of both legs, the bladder and large intestine required catheterization twice daily, and, when cystitis developed, irrigation of the bladder was also undertaken in the train. The numerous bullet wounds of the limbs which were uncomplicated by fractures were dressed without difficulty during the journey, and when these wounds were complicated by fractures, Cramer's splints proved of great value. It was necessary to slung the patients suffering from wounds of the limbs only when an immediate operation was indicated. The injection of saline solution was found to be most efficient in combating the effects of severe haemorrhage. Many medical cases, including inflammation of the lungs, pleurae, kidneys, and joints, also came under Dr. Neumann's observation. They were treated on ordinary principles and stood the journey well.

The Use of Narcotics during the Transport of the Wounded.

The common view that narcotics should be given as a rule to the wounded during transport, to relieve the severe pain caused by jolting, is not, in Dr. Neumann's experience, sound. He, as well as other medical men attached to hospital trains, came to the conclusion that this procedure was often superfluous. After their exhausting experiences, the wounded found the change to a clean bed, the absence of excitement, and the opportunities for sleep so conducive to peace of body and mind that they often hardly noticed the discomforts of the journey. Though they must often have suffered severe pain, they fell asleep during the journey, and though they frequently asked for a sedative as soon as they entered the train, they fell asleep before it could be given them. So small a dose as 10 drops of tincture of opium was often sufficient to relieve their pain. Dr. Neumann considered that the routine use of morphine for the wounded during transport is not only often superfluous, but is in some cases likely to be the beginning of the morphine habit.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Died of Wounds.

CAPTAIN ALEXANDER GRAHAM, R.A.M.C.(T.F.), is reported as having recently died of wounds in the Dardanelles. He was educated at Glasgow University, where he took the degree of B.Sc. in Agriculture in 1902, and those of B.Sc. in Pure Science, M.B., and Ch.B. in 1905. Afterwards he was successively resident medical officer at the Victoria Hospital, Burnley, clinical assistant at the Woodlee Asylum, Lenzie, Glasgow, assistant medical officer at the Brook Fever Hospital of the Metropolitan Asylums Board, and medical inspector of schools to the county borough of West Ham. He then settled in practice at Stratford, London, where he was clinical assistant to the Victoria Park Chest Hospital. He was medical officer of the 7th battalion of the Essex Regiment, in which he attained the rank of Captain last year.

Died on Service.

Lieutenant Bertram Chiene Letts, R.A.M.C., died on October 21st at Alexandria, of dysentery contracted at the Dardanelles. He was the only son of Professor Letts, of Belfast, and was educated at the university of that city, where he took the M.B., B.Ch., and B.A.O. in 1913. He had only recently taken a temporary commission in the R.A.M.C.

Major J. O'Leary, I.M.S., whose death in Egypt was noted in the BRITISH MEDICAL JOURNAL of September 25th, was accidentally drowned at Ismailia on September 9th.

Wounded.

Captain W. Brown, R.A.M.C.(T.F.), Dardanelles.
Captain A. B. Foot, R.A.M.C. (temporary), France.
Captain Y. C. Martin, R.A.M.C. (temporary), France.
Lieutenant N. Booth, R.A.M.C. (temporary), France.
Lieutenant A. C. Giles, R.A.M.C. (temporary), France.
Second Lieutenant R. D. M. Macpherson, M.B.Ed., 7th Seaforth's, France.

DEATHS AMONG SONS OF MEDICAL MEN.

Anderson, Laurence, Second Lieutenant 14th Battalion Lincolnshire Regiment, son of the late Mr. William Anderson, Surgeon of St. Thomas's Hospital, was killed in France, October 11th-15th. His commission was dated September 19th, 1914.

Cook, Gerald Haslam, Lieutenant 101st Grenadiers, Indian Army, son of the late Surgeon-General H. Cook, I.M.S., died as a prisoner of war in German East Africa, on July 25th, of wounds received in action on November 4th, 1914. He was born on July 14th, 1876, joined the army as Second Lieutenant on August 29th, 1906, joined the Indian Army on October 17th, 1907, and became Lieutenant on November 25th, 1908.

Davies, Geoffrey Boisselier, Captain 11th Battalion Essex Regiment, only son of Dr. Hughes Davies, of Woodford, Essex, killed near Hullein, France, on September 26th, aged 22. He was educated at Rossall, where he gained a classical scholarship, was captain of the school eleven, captain of his house, rackets and lives champion, joint editor of the school gazette, and vice-president in the O.T.C. From Rossall he went on to Selwyn College, Cambridge, with a classical exhibition. At the University he got his cricket blue in his first summer term, played for Cambridge for three years, for two years he headed the Cambridge bowling averages, and for three weeks in 1914 that for all England. He also played frequently for Essex. He joined the Essex Regiment as Second Lieutenant on September 14th, 1914, became Lieutenant on January 29th, 1915, and was recently promoted to Captain.

Falmey, Eric P., Sergeant 8th Battalion Seaforth Highlanders, son of Dr. A. Falmey, of Amoy, China, was killed in France on September 25th, aged 24. He was born in Egypt, and educated at Edinburgh University, where he was a well-known Rugby football player, being captain of the Lismore football club.

Gay, J., Second Lieutenant Royal Flying Corps, second son of Dr. J. Gay, of Putney, was killed in France on October 16th, aged 22nd, as the result of a fight in the air while taking photographs over the German lines. He was educated at Felsted school and at St. Bartholomew's Hospital. He was a member of the City of London Yeomanry, and got a commission on March 30th, 1915.

Hartley, Horace Neville, Second Lieutenant 16th Battalion North Staffordshire Regiment, eldest son of the late Dr. Horace Hartley, of Stone, Staffordshire, was killed in France, October 11th-15th, aged 26.

Hunt, A. L., Captain Royal Field Artillery (T.F.), fourth son of the late A. Hunt, M.D., of Dungarvan, County Waterford, and of Pau, France, was killed during an attack by an Austrian submarine while engaged on transport work for Gallipoli at the mouth of the Bay, aged 46. He joined the 1st Battery, 1st City of London Brigade, R.F.A. (T.F.), as Lieutenant on October 26th, 1914.

James, Baron Trevenen, Captain R.E., attached Royal Flying Corps, eldest son of Dr. C. A. James, of the Pollard Elms, Upper Clapton, killed near Avret, close to Hooge, on July 15th, aged 26; was at first reported missing in July. He joined the Royal Engineers as Second Lieutenant in 1909, became Lieutenant on January 23rd, 1912, and joined the Royal Flying Corps in the same year, becoming Flight Commander and temporary Captain on November 24th, 1914. He went to the front in August, 1914, was mentioned in despatches in February, and awarded the Military Cross in June. He was well known for his experimental work in wireless telegraphy from aeroplanes, and wireless ranging with artillery.

Leahy, George Geoffrey Whitely, Lieutenant 10th Battalion, Gloucestershire Regiment, only son of Dr. E. G. Leahy, of Alfreton, Derbyshire, was killed in Flanders on September 25th, aged 23. His commission was dated October 29th, 1914.

Macnaught, Frederick Clement, Lieutenant R.E., elder son of the late Dr. F. J. Macnaught, of Walsbam le Willows, Suffolk, was killed in France on September 25th, aged 29. He was educated at Brighton School, and took the B.Sc. at the University of London. For seven years he served in the Westminster Dragoons 2nd County of London Yeomanry, and held the rank of Squadron Sergeant-Major when promoted to Second Lieutenant in the Royal Engineers on October 24th, 1914. He went to France with the 91st Field Company, R.E., in July, and was promoted to Lieutenant on July 18th.

MEDICAL STUDENTS.

Badecek, Arthur Laurence, Second Lieutenant King's Own Yorkshire Light Infantry, youngest son of the late Rev. Thomas Badecek, Rector of Walgrave, Northampton, was killed in the recent advance in France, aged 21. He was educated at Radley, where he was in the O.T.C., and at St. John's College, Cambridge, where he was a medical student. He got a commission in the 5th Battalion Northamptonshire Regiment as second Lieutenant on September 29th, 1914, and was subsequently transferred to the K.O.Y.L.I.

Farragher-Thomson, D., Second Lieutenant 10th Battalion Gordon Highlanders, attached 1st Cameron Highlanders, killed in the recent fighting in France, aged 26. He was a medical student at the University of Edinburgh, where he was in the O.T.C. His commission was dated October 14th, 1914.

Wilson, Robert A., Captain Royal Field Artillery, only son of the late John R. Wilson, killed in the late battle in France, aged 32. He was a medical student at the University of Edinburgh, joined the R.F.A. as Second Lieutenant on October 6th, 1914, became Lieutenant on March 7th, 1915, and was recently promoted to Captain.

NOTES.

HONOURS.

Legion of Honour.

Among the officers decorated by President Poincaré on the occasion of the visit of the King to the Forces in France, was Surgeon-General Sir A. T. Sloggett, K.C.B., K.C.M.G., Director-General of the Medical Department of the British Army, who received the decoration of Commander of the Legion of Honour.

British Honours.

In the *London Gazette* of October 29th was published a list of honours conferred for services in Mesopotamia, Egypt, and other minor seats of war in the East. Among them were included the following medical officers. Colonel Hehir is Principal Medical Officer of the Indian troops in Mesopotamia, and Colonel Robinson of those in Egypt. Lieutenant-Colonel Hennessy, Major Bransbury, Captains Allnut and Wright, and Lieutenant Bal were all recently mentioned in despatches for services with the Persian Gulf expedition.

To be C.B.

Colonel P. Hehir, I.M.S.
Lieutenant-Colonel (temporary Colonel) W. H. B. Robinson, I.M.S.
Lieutenant-Colonel J. Hennessy, R.A.M.C.

To be C.M.G.

Lieutenant-Colonel W. G. Fridmore, I.M.S.

Awarded D.S.O.

Major H. A. Bransbury, R.A.M.C.
Major R. W. Knox, I.M.S.

Awarded Military Cross.

Captain E. B. Allnut, R.A.M.C.
Lieutenant N. K. Bal, I.M.S.

Promoted to Brevet Major.

Captain R. E. Wright, I.M.S.

In the same *Gazette* the D.S.O. was conferred upon fourteen officers, and the Military Cross upon thirty-four, for services in Flanders and Gallipoli. Among them one medical officer, Captain B. S. Finn, of the New Zealand Medical Corps, received the D.S.O., and two, temporary Lieutenants A. N. Minns and H. B. Walker, R.A.M.C., the Military Cross, for the following services:

Captain Bertram Sibbald Finn, New Zealand Medical Corps. For conspicuous devotion to duty in the Gallipoli peninsula during operations from August 6th to 9th, 1915, when he worked day and night with unceasing zeal and without rest evacuating the wounded. His work was carried out under continuous fire, on one occasion the dressing station being heavily shelled for an hour, and many assistants and wounded being hit. Owing to Captain Finn's efforts the wounded lying in the more exposed positions were got into a place of greater safety.

Temporary Lieutenant Allan Noel Minns, 39th Field Ambulance, R.A.M.C. For conspicuous gallantry and devotion to duty at Suvla Bay, Gallipoli peninsula, on August 30th, 1915, when attending to the wounded under heavy shrapnel fire. Another officer who was assisting him was killed. Lieutenant Minns later returned to the dressing station, took out twelve stretcher squads, and brought in twenty-four wounded men.

Temporary Lieutenant Harry Bertram Walker, M.B., R.A.M.C., attached 9th Battalion York and Lancaster Regiment. For conspicuous gallantry and devotion to duty near Amiens on September 25th, 1915. A battery was being heavily shelled, but he proceeded at once to attend to the wounded at one of the guns. While doing this the next gun was put out of action, all the detachment being killed, but he continued to attend to the wounded till the arrival of the field ambulance. Mr. Walker received his medical education at the London Hospital, took the diplomas of M.R.C.S., L.R.C.P. in 1911, and the degree of M.B., B.S. in 1915. He had filled the appointment of senior dresser to surgical out-patients, pathological assistant, and house-physician to the hospital, and had also held appointments at the Poplar Hospital.

ANGLO-RUSSIAN HOSPITAL.

As was mentioned some time ago, a committee, with Lord Chylesmore as chairman and Sir Starr Jameson as vice-chairman of its executive committee, was formed in London about three months ago to organize and equip a complete hospital unit for service in Russia as practical evidence of the sympathy of the British with the Russian people. It has now been arranged that the hospital shall be established in the Dumri Palace in Petrograd, which is being adapted for the purpose. An advance party went out some time ago, and a further part of the medical staff, together with nurses and orderlies, left London on November 2nd.

MEDICAL OFFICERS WANTED.

2nd South Wales Mounted Field Ambulance.

There is a vacancy for a lieutenant in this unit, which is now stationed on the East Coast. There is also a vacancy for a regimental medical officer in one of the yeomanry regiments of the brigade. All particulars concerning these vacancies can be obtained from Lieutenant-Colonel Herbert Jones, Lyons Farm, Blythburgh, Halesworth.

2nd London Field Ambulance.

There are at present a few vacancies for medical officers in this unit, which is expected shortly to go overseas. Candidates will be expected to sign the imperial service obligation. Promotion to captain after six months' satisfactory service assured. The conditions of this service have just been considerably improved, and now compare very favourably with terms offered to civil surgeons. Full particulars can be obtained by communicating with Officer Commanding, 2nd London Field Ambulance, R.A.M.C.T., Bishop's Stortford.

Canada.

MEDICAL COUNCIL EXAMINATIONS.

THE autumn examinations of the Medical Council of Canada were conducted during October in Montreal. There were fifty candidates from all parts of Canada, and those who are successful will receive the L.M.C.C., which under the provisions of the Canada Medical Act—commonly known as the "Roddick Act," since Sir Thomas Roddick of Montreal was its father—entitles the holder to practise in any province of Canada. Every facility was offered by the medical faculty of McGill University for the conduct of the examinations, and the four chief general hospitals in Montreal granted the use of their public wards for the clinical examinations. But for the war the proportion of candidates would probably have been much larger. At the spring examination in Winnipeg last June forty candidates presented themselves. The next examinations will be held simultaneously at Toronto and Winnipeg in June, 1916.

THE PROFESSION AND THE WAR.

In his address on October 3rd, 1915, before the Academy of Medicine, Toronto, Dr. W. H. B. Aikens reminded his audience that 61 Fellows of the Academy were on active service. The medical students of Toronto University had also responded to the call, and had supplied 6 officers and 88 men. There were also 252 medical graduates serving. Soon after the outbreak of the war the Fellows of the Academy of Medicine pledged themselves to undertake, without charge, the professional care of the needy dependants of the men on active service. Dr. Aikens further recalled the fact that medical reciprocity had been established between Ontario and Great Britain in consequence of the war. The Fellows had found that many patients could no longer afford to pay the ordinary fees; but while consultants and specialists were suffering considerable pecuniary loss this was less felt by the general practitioners, who in a few cases had benefited financially by the absence of their colleagues on military service. The United States had done much to help in the treatment of wounded Canadians, and had made generous contributions towards the equipment of hospitals.

UNIVERSITY NEWS.

AS was to be expected, the number of students who have registered in the medical faculties of the universities is somewhat smaller than usual. The eighty-fourth session of the faculty of medicine of McGill University opened on October 4th, with a total registration of 297 students and, in addition, 35 students in the dental department. It was hoped that fifth year students who accompanied the McGill Military Hospital would return to complete their studies, but owing to some misunderstanding it has not been possible to arrange for their release from duty with the hospital. The work of the faculty is being carried on by a staff much reduced in number, as many of its members are on active service, but all the regular courses are being conducted in a satisfactory manner. Dr. A. D. Blackader is acting as Dean of the Faculty during the absence of Colonel Birkett, who is in command of the McGill Military Hospital, No. 3 Canadian General.

At the University of Toronto 507 students have registered in the medical faculty for the present session, as compared with 568 last session and 533 during the year

1913-14. A large number of members of the staff of this university also are on active service, many of them with the No. 4 Canadian General Hospital at the Dardanelles. About 100 undergraduates of the faculty of medicine are at the front. The fourth and fifth year students have returned from the front to complete their studies. This is also the case with the students of the Manitoba Medical College, where the total number of students enrolled this year is 108, as compared with 180 last session. The decrease here is due partly to the fact that a number of students have gone to Europe and partly to the new arrangement whereby one year's work in science is now required before a student can enter the faculty of medicine; the result has been a decrease in the number of freshmen from 40 to 11. Fifteen members of the staff are at present overseas and others are preparing to go very shortly.

The new session opened at Western University, London, Ontario, on October 1st, with a total registration of sixty-six students, which is rather less than usual. New equipment has been procured during the summer, and a physical laboratory has been established. A course for the diploma of public health graduates in medicine was opened on October 1st at the Institute of Public Health, of which Dr. Hill, M.O.H. for the City of London, is director. The Institute was established and is maintained by the Ontario Government as the Public Health Department of the Western University. It conducts courses in public health for the faculty of arts as well as medicine, and undertakes for the Provincial Board of Health official diagnostic examinations in diphtheria, typhoid fever, tuberculosis, water and sewage analysis, etc., for the western portion of the province. Clinical laboratory work of all descriptions is also done at the Institute.

At Dalhousie University, Halifax, Nova Scotia, the medical session commenced on September 15th, the number of freshmen enrolled being 22. The fifth year men intend to volunteer for active service as soon as they have received their degrees. The faculties of arts and science have been removed to the new building, thus leaving the old university building for the medical faculty and the faculties of law, dentistry, and pharmacy. Dr. John Cameron, of the Middlesex Hospital, London, has been appointed to the Campbell Chair of Anatomy as successor to the late Dr. A. W. H. Lindsay.

The University of Alberta, at Edmonton South, is offering the first three years in the study of medicine; last year the faculty was only able to give instruction in the first two years. The university authorities have made arrangements with the Universities of McGill and Toronto whereby its students will be accepted without further examination for the fourth and fifth years in medicine. The university hopes at some time in the near future to be in a position to give instruction in the final years. The number of students enrolled this year is about the same for the three years as it was last session for the two years offered.

At Queen's University, Kingston, Ontario, the staff has been much depleted, as many of its members are on active service. A number of changes have been made, and it has been found particularly difficult to fill the place of Dr. Connell, professor of bacteriology, who is at Cairo. In the meantime Dr. William Gibson of Kingston is conducting the course in bacteriology.

South Australia.

FROM OUR SPECIAL CORRESPONDENT.

THE WAR.

THERE are yet more demands being made upon the ranks of our profession for service in England, in Egypt, and on transport steamers. Dr. J. A. G. Hamilton, the lecturer on gynecology at the university; Dr. Smeaton, a clinical lecturer at the Adelaide Hospital; Dr. Gilbert, a surgeon of the Children's Hospital—all have gone, and still more recently Dr. W. T. Hayward, who is to be attached to a military hospital in England. Meanwhile many of the juniors have silently disappeared; we see them in brand new uniforms one day, and hear of them at Lemnos shortly afterwards. We others, whom on account of age

or infirmity the fates have left behind, naturally admire the pluck and self-denial of those who have gone at such sacrifice to their own interests, and notice with pride that Drs. H. A. Powell and John Corbin have been mentioned in despatches. As the result of an inquiry into the management of the No. 1 Australian General Hospital at Helopolis, Lieutenant-Colonel Ramsay Smith has relinquished its command. The Director of Medical Services in Australia (Colonel Fetherston) has left for Egypt to straighten out matters, and Colonel Shepherd of Adelaide is now filling his post.

DEATH OF DOCTORS.

The departure of so many senior men and the filling up of their places on hospital and university staffs, and still more the drain on the recently qualified members of our profession, have produced such an effect that it is well nigh impossible to obtain qualified house-surgeons. The Adelaide Hospital is partly manned by fifth year students, whilst the Children's Hospital has to be content with third year men as resident clinical assistants; vacations have been dispensed with, and examinations have been held earlier so that students may become qualified in four and a half years instead of five, the understanding being that those who are eligible immediately enter on active military service. Meanwhile, too, the authorities are refusing to enrol medical students in any capacity, it being considered more important for them to complete their course and take a degree.

BELGIAN DOCTORS' RELIEF FUND.

The committee decided to close this fund, and a final draft was sent last week, making £527 in all forwarded from South Australia and Broken Hill.

HEALTH OF CAMPS.

This is a matter which is causing both the profession and the laity great anxiety. Measles has been prevalent and men have died of pneumonia, but a more formidable enemy in the shape of cerebro-spinal meningitis has appeared, and in Adelaide many deaths have been caused by it.

Ireland.

IRISH FOOD AND FOOD SUPPLIES.

PROFESSOR W. H. THOMPSON has written a valuable report,¹ clear and concise in expression, on food values, adding a note on Irish food supplies, and in another pamphlet, written for the Women's National Health Association of Ireland, he deals in particular with the food of the Dublin labourer. He first presents to the reader the content of water and nourishing material and energy of the chief foods, expressing the protein and energy obtained for 40. in a diagram. Taking 3,500 calories as the energy requirement of a day of moderate work, he shows the cost of each food to supply this. The composition and energy value of the chief classes of foods are set forth very clearly in a series of tables and diagrams. The cheapness of Indian corn is noteworthy; 2½d. worth against bread 6½d. (1915 prices), gives 3,500 calories. Whole meal 3½d., oatmeal 4½d., potatoes 7d., peas 7½d. are other relative prices. In an appendix several recipes for cooking Indian corn are given and an effort is made to popularize this valuable foodstuff. The need for attractive and varied diet, together with the supply of vitamins, and the importance of kitchen and house-craft, are insisted on. Professor Thompson says - we Irish are far too indifferent to the selection and preparation of our food. There seems to be almost an innate feeling, widely prevalent particularly amongst the less well-to-do classes, that it is mean or wrong to think much about what one should eat, and yet it is not overstating the case to say that national prosperity depends much more closely upon the kitchen than is at all appreciated. . . . The proverbial efficiency of Irishmen abroad is at bottom a question of feeding. . . . Cooking amongst the working classes of the city is almost a lost art; the reason often is to be found in the absence of proper or convenient cooking arrangements in the tenement dwellings." The world has seen how, regardless

of expense, the physical health of vast armies has been organized since the war began. In times of peace, on the other hand, how great has been the neglect, not only in Ireland, seen in the uncontrolled exploitation of land leading to slum cities and townships, tenement dwellings unfitted for the purpose they are put to, the shutting out of wind, sunlight, contact with the beauties of nature, and opportunities for healthy recreation in physical exercise in the open air. Now the nation faces the retribution—a diminished working power and social unrest in the time of stress. It is interesting to note that 94 per cent. of the wheat consumed in Ireland is imported, while the yield of potatoes is 3,200,000 tons, of which only 800,000 tons are consumed as human food. "If only half of that used by livestock were released, it would double the supply of potatoes ordinarily needed in this country for the human population." As to oatmeal, Professor Thompson rightly says, "the change of diet which its neglect indicates is one of, if not the most deplorable fact in the history of the country for centuries." The mill hands of Ulster demand the whitest of breads and tea in place of the old-time oatmeal and milk. As to barley, 74 per cent. raised in Ireland goes to the brewery. "It takes 6 lb. of barley to produce 1 gallon of beer. There is ten times as much nourishment in the barley used as in the beer." In regard to the raising of cattle, the author estimates that an acre of good land yields an output of eatable potatoes giving seventeen times as much protein and thirty times as much food energy as if it were used for grazing and the production of animal food; of oats eighteen times as much protein; of wheat nineteen times as much protein, and fifteen times as much energy. The yield of an acre of such land in potatoes furnishes as bacon nearly five times as much protein and more than seven times as much energy as if the land were used for grazing sheep or cattle. These figures illustrate the advantage of pig keeping. There is plenty of room for food conserving, and no harm will be done to the health of the well-to-do in replacing much of the animal food eaten by cereals, potatoes, and pulses.

INFANTILE MORTALITY AND MILK SUPPLY IN DUBLIN.

The infantile mortality is far higher in Dublin than in any other city of the United Kingdom; the death-rate of children under 1 year per 1,000 of the estimated population of England and Wales during 1914 was 105; for London alone, 101; and for ninety-seven of the principal English towns, 111. For Dublin it was 141 per 1,000. According to the latest report of Sir Charles Cameron, about one-fifth of the total deaths in Dublin are those of infants. Much of this abnormal death-rate is directly attributable to the milk supply. In 1914, of the deaths recorded, 2,772, or 30 per cent., were children under the age of 5 years. Of these deaths, 346 were from diarrhoeal diseases, and only two of the victims were over 2 years of age. The greater number of deaths took place during the summer months, and the increase during the last three months of the present year was, it is believed, greater than it has been for any similar period during the past ten years. It is understood that the infantile death-rate in Dublin during the months of July, August, and September has been really alarming. The medical officer of health officially attributes this to the higher temperature of these months, but the relation between the rise of temperature and infantile mortality is not stated. The explanation is that in impure milk the bacteria which cause gastro-intestinal trouble and diarrhoea multiply rapidly during the summer months. The city milk is, as a rule, only examined bacteriologically when there has been an outbreak of one of the zymotic diseases. There are in the city of Dublin 5,604 heads of families who earn not more than 15s. a week, 9,000 who earn 15s. to 20s., and 2,585 who earn 20s. to 25s. Many of the milk shops in the poorer districts are so situated and managed that the milk is almost certain to be contaminated. The Public Health Committee has prosecuted a number of persons for having dirty dairy shops and cowsheds, but the fines imposed, varying from 5s. to 10s., are small in view of the serious nature of the offence. It is, however, encouraging to find that the police magistrates have now announced that in future the fines in all cases will be commensurate with the offence. During the coming winter the cost of milk is likely to increase. Last

¹ Dublin: Ponsoby. Published for the benefit of the Dublin University Voluntary Aid Detachment Hospital. Price 3s.

winter the price in Dublin was raised to 4d. a quart, and during the summer the usual reduction in price did not occur, the excuse given being that owing to the war the cost of everything was increased. The dairymen have now announced their intention of raising the price to 5d. a quart. As milk can be purchased within fifty miles or so of Dublin for 7d. and 8d. a gallon, and transport by train is only 1d. per gallon up to 100 miles, it would seem that there was no necessity for this further rise in price. There have been public meetings and a great deal of press comment on this threatened rise in price, but so far without any obvious practical result.

The Registrar-General, in his quarterly return, states that in the Dublin registration area, which consists of the City of Dublin and the urban districts of Rathmines and Rathgar, Pembroke, Blackrock and Kingstown, the total area of which is 13,745 acres, and the population estimated at the middle of 1915 to be 409,000, there were registered during the thirteen weeks ending October 2nd, 2,652 births (1,347 boys and 1,305 girls) being equal to an annual rate of 25.9 in every 1,000 of the population. The number of births registered in the city was 2,307, equivalent to an annual rate of 29.5 in every 1,000 of the population. The total number of deaths registered in the Dublin registration area during the quarter was 1,797 (922 males and 875 females) affording an annual rate of 17.6 in every 1,000 of the estimated population. The annual mean mortality represented by the deaths registered during the third quarter of the ten years 1905-1914 in the Dublin registration area was 19.8 per 1,000 of the estimated mean population of those years. Of the 1,797 persons whose deaths were registered 557 were under 5 years of age, and included 397 infants under 1 year of age, the latter representing a rate of 149.7 per 1,000 of the births registered.

Correspondence.

URIC ACID STONES UNDER THE X RAYS.

SIR,—In your issue of October 23rd Mr. C. Thurstan Holland calls in question a statement made by me in an article on ureteral calculus in the JOURNAL of October 16th, and quotes: "It (radiography) is now so perfect that even a small uric acid stone in the lower segment of the ureter can easily be discovered."

To call a concretion a "uric acid stone" does not imply that it is composed entirely of uric acid, but that it is a smooth, brownish-yellow rounded stone, not very heavy in weight for its size, and is composed to a large extent of uric acid. This is the clinical definition; it would not do to limit the term to only concretions of pure uric acid, which give no x-ray shadow. They are very rare.

A number of years ago I was interested in the subject of the composition of calculi, and made sections of the renal and vesical stones in the museums of the Royal and the Western Infirmaries, and had them examined chemically. The composition of 208 stones was as follows: 71 were formed of one substance only, while 137 were made up of two or more. Of the simple calculi, 32 were of phosphates, 26 of uric acid, 12 of oxalate of lime, and 1 of cystine. Of the compound calculi, 118 had, as one of their constituents, uric acid, so that collectively out of the 208 calculi 144 contained uric acid, but of these not one was chemically pure; all contained some earthy matter, as shown by ash on fusion. Examination of my own collection gives very much the same results. Later the question of resistance of calculi to x rays excited interest. On making artificially a pure uric acid stone, I found it practically gave no shadow, but when even a small proportion of earthy salts was added, a shadow was got. Therefore, I may safely say that Mr. Holland and I do not differ in our views as to the want of resistance to the x rays shown by uric acid in its pure state. If the term "uric acid calculus" is to be limited to those stones containing no other ingredient beyond uric acid, I admit that x rays will not detect them.

However, as far as my experience goes, pure uric acid stones are not met with in the kidney and the ureter, while what are commonly classified as uric acid calculi, as distinguished from those composed of oxalate of lime, phosphate of lime, or of mixed phosphates, are by no means uncommon. It is to those I referred in

my article. Not long ago the art of skiagraphy failed to detect them, but now, with more perfect methods, stones containing a very moderate amount of earthy salts "can easily be discovered." So, while I willingly admit that Mr. Holland is correct in stating that pure uric acid calculus gives no shadow, he will no doubt own that the uric acid stone met with in the kidney and ureter, being in the vast majority of cases impure, should show itself by a shadow on a well-taken plate. This has been my experience, certainly for the last six years.—I am, etc.,

Glasgow, Oct. 23rd.

DAVID NEWMAN.

WAR EMERGENCY COMMITTEE.

SIR,—Is it not time for plain speaking to the War Office? While strong and urgent appeals are being issued to members of the profession to give up their practices and take up military duties abroad the authorities at home are still appointing young men to positions on the base hospitals.

Within the last two or three weeks three unmarried men of military age have been appointed on the staff of the 3rd Western General Hospital at Cardiff in addition to those on the staff already, while at least two first class surgeons are passed by men capable of performing any operations—as well as others capable of rendering efficient service who are scarcely young enough to go abroad.

To my own knowledge this is having a prejudicial effect on the effort to obtain men locally for the war, and if it is being repeated throughout the country much harm is being done. Men are saying, and not without justification, Why should I leave my practice and my wife and children to go on war service while the Government is appointing young single men to the comfortable posts at home? I am, etc.,

Cardiff, Nov. 1st.

W. B. CRAWFORD TREASURE.

BROMIDES IN EPILEPSY.

SIR,—Years ago I was resident medical officer in Hoxton House when the late Dr. Hunt was medical superintendent. We often discussed the use of bromides in epilepsy. He deprecated their use in the majority of cases. He was of opinion that even in cases where they diminished the frequency of the fits a more violent attack might be induced which would immediately prove fatal. We used tincture of hyoscyamus as an alternative, which in some cases, at least, was beneficial.

Dr. Mercier's views appear to be similar to Dr. Hunt's regarding bromides. He states, however, a somewhat new idea, that epilepsy is not a disease but a group of diseases, and then qualifies this remark by saying it is certainly more than one.

In one of these diseases of which epilepsy is the outward manifestation he admits immense benefit follows the use of bromides. He does not, however, indicate what that disease is.

That the bromides, whether of potassium, sodium, or ammonium, are useful in many cases is unquestionable. Their continued use without intervals of rest is, however, a mistake. Otherwise they produce both mental and bodily enfeeblement. In such cases they should be stopped, and tonic treatment often proves useful in diminishing the frequency of the attacks. There is one remedy which for some years I have found useful to diminish both the frequency and intensity of the fits, namely, calcium bromide. It is effective in half the doses of the potassium salt. Mental activity increases and general health improves. These results are striking if the patient has previously been taking potassium bromide.—I am, etc.,

Bournemouth, Oct. 27th.

A. HEMPREEY DAVY, M.D.

A STANDARD DIET FOR INFANT FEEDING.

SIR,—The suggestion that there should be a standard diet for infants is a good one because at present a great deal of contradictory, and sometimes quite erroneous, advice is being circulated in leaflets issued by medical officers of health, baby centres, and societies of different kinds. I think it would be a good thing if those of us who are working at infant feeding could agree upon a standard diet for standard babies, and prescribe it for a year or two in all cases unless there should be a definite reason for (probably temporarily) prescribing something else. The method should be as simple, and the directions for carrying it out as definite and practical as possible. It

would then be an easy thing to instruct the health visitors, and through the health visitors the mothers, much more systematically than is done at present. It would be a very valuable experiment if a standard diet could be tried on a large scale, and the results carefully observed, or if two standards were adopted and tried in different towns, for example, the two standards suggested by Dr. Cameron—whole citrated milk, and milk diluted "a little," plus "a little" sugar. But Dr. Cameron will have to tell us what he means by "a little" water, "a little" sugar, "a very young infant," and a "tiny child."—I am, etc.,

Leithburgh, October 27th.

W. B. DRUMMOND.

MEDICAL AUTOGRAPHS.

Sir,—A year ago you inserted an appeal on behalf of the Reading Pathological Society for medical autographs, which that society has for some years been collecting. In response, a large number of specimens have been kindly contributed by the editors of the BRITISH MEDICAL JOURNAL and the *Lancet*, by Sir Lauder Brunton, Mr. D'Arcy Power, Sir R. J. Goode, Sir Dyer Duckworth, and others.

Our album now contains lithographs or autographs, often accompanied by portraits, of Lister, Charcot, Brodie, Paget, Billings, Weir Mitchell, Virchow, Michael Foster, Oliver Wendell Holmes, Jenner, Huxley, Farr, Lawrence, Liston, *inter multos alios*. Our attitude, however, is that of Oliver Twist when he craved for more, and we shall gratefully welcome further additions. "*In tali nunquam lassat renatio splem.*"

There is a fascination in preserving the portraits, the handwriting, and the signatures of those masters of medicine, who in most cases have ceased from their labours on earth, but whose names must live for ever as benefactors of mankind. Such mementos of the love we bear them and their writings help to keep their memory green, and inspire us to follow in their steps.

May I add that we possess some duplicates which are at the disposal of other medical societies that contemplate forming a similar collection?—I am, etc.,

JAMES B. HURRY.

Westfield, Reading, Oct. 22nd.

CHILBLAINS.

DR. RICHARD W. LLOYD (London, W.) writes with reference to the note on chilblains in the JOURNAL of October 23rd, p. 614: I remember the late Sir William Savory said in the course of one of his lectures, "Opium is a sovereign remedy for chilblains." Recollection and appreciation of that remark has on occasion enabled me to cause all unbroken chilblains, even when numerous, to disappear in the course of two or three days, and those that are broken, suppurating or ulcerating to commence forthwith to clean and rapidly to heal, under, in addition, unguentum resinæ and general treatment. Only in severe cases of the kind have I resorted to that drug, for I have always had in mind what is well expressed in Sir William Collins's remark, which appears in the previous article on the same page of the JOURNAL under the heading "Drug and Alcohol Addiction," that "it would be salutary if medical men would think, not once or twice, but many times before prescribing potent drugs of addiction for internal exhibition, if, as often happened, simpler and non-alcoholic remedies would meet the case." Indeed, it has been my custom to arrange that the chemist supplying it should withhold the prescription. Attention to diet, hygienic measures and medication indicated to improve the general health and nutrition should always be prescribed, and generally I have been content with them. But in bad cases of chilblains, which sometimes occur in otherwise fairly healthy persons, I have found that 1 to 1 gr. of opium taken on going to bed, or liq. opii sed. mij —two or three times in the twenty-four hours acts like a charm. The explanation is, I believe, in the effect of opium upon the capillary circulation. It is interesting to recall, in considering the constipating effect of opium, that Sir Lauder Brunton (with whom we all deeply sympathize on the loss of his son in his country's service), speaking of opium, has said that, while moderate doses are constipating, minute doses (mij or mss of the tincture when the constipation does not depend upon insensibility of the intestinal nerves) and large doses are

purgative in their effect. Any constipating effect of the moderate doses mentioned may be suitably provided against.

Dr. C. SMYTH recommends the administration of cod-liver oil, beginning in September before the weather breaks up. When chilblains have developed he advises tincture of opium, mij , three times a day. For broken chilblains he recommends resin ointment.

C. H., who states that he was a martyr to chilblains, found some ten years ago that the complete omission of meat from his diet was followed by their disappearance, and they have not reappeared.

L. B. writes: It might be worth while for your correspondent (whose case is described in the BRITISH MEDICAL JOURNAL, October 23rd, p. 614) to try thyroid gland, beginning with 1 grain every night, and gradually increasing the dose either by taking more at bedtime or by taking the medicine three times a day.

Another correspondent says that he tried last year the suggestion of a correspondent to toast the affected parts in front of a good fire almost up to scorching point, and found the method very effective.

Dr. F. HEKXAMAN-JOHNSON states that chilblains are comparatively easy to prevent, provided prophylactic treatment is commenced at least a month before the expected onset of cold and damp weather. A sinusoidal current generator is desirable, but an ordinary faradic battery is a fair substitute. Two basins are filled with water as hot as can be comfortably borne, and a hand placed in each. The current is then turned on for ten to fifteen minutes, at a strength which just fails to cause cramping, but which can be distinctly felt. This procedure is repeated daily for four to five weeks. The feet may, if necessary, be treated in a similar manner. The treatment is not suitable for chilblains actually established. For mild cases, the high frequency vacuum electrode may be employed, the glass being moved to and fro, lightly touching the skin. In the more severe forms, no instruments must be brought into contact with the inflamed and possibly ulcerated surfaces. The sedative "breeze" is useful, and very small doses of x rays often promote healing.

Universities and Colleges.

UNIVERSITY OF EDINBURGH.

(GENERAL COUNCIL.)

THE half-yearly meeting of the General Council of the University of Edinburgh was held on October 29th in the Old University. Principal Sir William Turner presided, but vacated the chair during the election of two assessors in the University Court. The retiring assessors, Dr. R. McKenzie Johnston and Dr. G. Andrew Berry, were re-elected, the former on the motion of Dr. Norman Walker, seconded by Mr. J. Robertson Christie, and the latter on the motion of Dr. A. H. F. Barbour, seconded by Dr. J. W. Ballantyne.

The Convener of the Business Committee (Mr. J. B. Clark), in submitting the report, stated that whilst in May last the university roll of honour contained over 2,000 names, by July 8th it had risen to 3,550, made up as follows: Chancellor, rector, and members of the University Court, 3; teaching staff, 43; clerical staff, 5; technical staff, 21; graduates, 2,233; alumni, 378; undergraduates, 865; and University Military Committee, 5. Since July this number had been largely augmented, but the exact figures could not yet be given. Many honours had also come to the university men on service, including 8 appointments to the Distinguished Service Order, 12 Military Crosses, 1 Distinguished Service Cross, and 1 D.C.M., whilst upwards of 70 had been mentioned in dispatches. The women also had done well in various branches of war service, and special reference might be made to the Scottish Women's Hospitals in France and Serbia, which had been largely organized and staffed by Scottish women medical graduates and students. There were now four hospitals in Serbia and one in France, whilst a second French hospital had, at the request of the French Government, gone with the new Expeditionary Force to Salonika. In connexion with this work the names of Drs. Elsie Inglis, Alice Hutchison, Beatrice Macgregor, and Helen Porter would be specially associated. There was also cause for sorrow, for no fewer than 102 sons of the Alma Mater had fallen in the light, including 54 fellow members of the General Council.

UNIVERSITY OF GLASGOW.

(GENERAL COUNCIL.)

PRINCIPAL SIR DONALD MACALISTER presided at the statutory half-yearly meeting of the General Council of the University

of Glasgow on October 27th, when Sir David C. McVail and Dr. David Murray, the retiring assessors of the Council, were re-elected.

The Council approved of a minute placing on record their appreciation of Professor John Ferguson, who has resigned the Chair of Chemistry "at the close of an academic career so long and so distinguished."

A proposal to ask the General Medical Council that in the preliminary examination for registration there be only one language other than English required, and that that language need not be Latin, was not approved, the previous question being carried by 18 votes to 7.

UNIVERSITY OF ABERDEEN.

Owing mainly to the number of young men who have joined His Majesty's forces the number of students enrolled in the present winter session shows a decrease of 158 as compared with a year ago. The total number last year was 800, this year it is 642. The number of male students last year was 472, and of female students 328; this year the number of male students is 358, and of female students 284. The number of male medical students is the same this year as last year—186, the number of female medical students has risen from 37 to 53.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on Thursday, October 28th, Dr. Frederick Taylor, the President, being in the chair.

Admission of Fellow and Members.

Dr. Thomas Reuter Elliot, who was elected as a Fellow in April last, was admitted to the Fellowship of the College.

The following, who had passed the necessary examination, were admitted Members of the College: Charles Nelson Atter, Miss Hazel Haward Cuthbert, M.D., London, and Edmund Walter Neill Holthouse, M.B., Oxfr.

Licences Granted.

Licences to practise physic were granted to 105 gentlemen who had passed the required examinations.

Johns Scholar.

It was announced that Mr. Ralph Stanley Swindell had been appointed the twenty-third Johns scholar.

lection of Senior Censor.

On the nomination of the Council, Dr. Percy Kidd was elected senior censor in the place of the late Dr. David Bridge Lees. The President paid a tribute of respect to the memory of Dr. Lees, referring to the services he had rendered to the College.

The Library of Louvain.

In response to an invitation from the President of the British Academy, the President and the Harveian Librarian (Dr. Norman Moore) were appointed delegates to a committee whose object is to reconstitute in the future the library of Louvain.

Medico-Legal.

CHARGE AGAINST AN EDINBURGH HERBALIST.

ON October 18th, before the Lord Justice Clerk in the High Court of Justiciary, Edinburgh, Charles Alder, *alias* Charles Smith, was charged with having performed an illegal operation upon Margaret Elaine Anderson, as the result of which she died. According to the report in the *Scotsman*, the Sheriff Substitute said that on July 21st the deceased emitted a dying deposition which stated that "Dr. Temple" by arrangement came to her house on July 1st and used an instrument, as reported in the deposition, on July 5th. Sheriff Substitute Macleod said that on July 24th the deceased emitted a deposition as follows: "I am shown the accused. I recognize him. I know him as 'Dr. Temple.' He is the man who came to see me on the two occasions mentioned in my former deposition, and he used the instrument upon me as mentioned in said deposition, which has now been read over to me." John Baird, clerk, said that he had meetings with the deceased, who in the middle of June told him that she was pregnant. He subsequently called on "Dr. Temple" at West Register Street, and saw the accused, who said that he could not give medicine but had a treatment which would cost £5. He told the deceased about "Dr. Temple," and she consented to see him. He again saw "Dr. Temple," and told him that they were to be no operation. He afterwards endeavoured to stop the matter, but paid the accused £5 on July 2nd. Dr. D. M. Barker stated that he had been called to see Miss Anderson, and finding her seriously ill arranged for her admission to the Infirmary. Dr. A. H. T. Barbour said that the deceased was admitted to the Infirmary on July 20th, and he got from her a statement as to the history. She was suffering from acute inflammation and died on July 26th. The following day a *post-mortem* examination was made by him and Professor Harvey Littlejohn, and they certified that death was due to blood poisoning the result of abortion. In cross-examination, Dr. Barbour said that taking the *post-mortem* examination alone there was nothing which would justify him in saying that this was a criminal abortion as distinguished from one from natural or accidental causes. It was the third month in the case which was most dangerous so far as abortion was concerned. Professor Harvey Littlejohn gave corroborative evidence. Dr. G. B.

Marshall (Glasgow) said that there was nothing in the medical report to indicate that the septic condition was the result of the introduction of a poisonous instrument.

The accused, giving evidence on his own behalf, said that his name was Charles Anthony Alder, and was born in Stanterland; he practised as a herbalist in massage and in connexion with certain diseases. He had bought a business from Mr. Smith and used the name of Charles Smith. At the end of May, in response to an advertisement by "Dr. Temple" for an assistant, he was engaged at £2 10s. a week. The business in Edinburgh was carried on under the name of "Dr. Temple and Co." He denied that he had performed the operation stated in the charge. The Lord Justice Clerk, in summing up, directed the jury as a matter of law that there was not sufficient evidence to justify them in bringing a verdict of murder, but they had to decide the serious question whether there was sufficient evidence to justify them in bringing in a verdict of culpable homicide. The jury returned the unanimous verdict of not proven.

References to the business conducted under the name of "Dr. Temple" or "Dr. Temple and Co.," in Edinburgh will be found in the *JOURNAL* of January 23rd, 1915, p. 186, and February 27th, 1915, p. 402. The person concerned in the cases then reported was not the same as the person concerned in the trial on October 18th.

CHARGES OF ALLEGED IMPERSONATION.

HENRY JOHN HERRING, described as a chemist, was, according to a report in the *Morning Advertiser*, charged at the North London Police Court on October 30th with feloniously giving false certificates of death. Mr. Bodkin, who appeared for the Director of Public Prosecutions, said that the accused had impersonated a gentleman who practised at West Matland, New South Wales, whose name was Edward Ken Herring, and whose qualifications were M.B.C.S. Eng. and L.R.C.P. Lond. Evidence was given by Dr. Hugh Woods, Secretary of the London and Counties Medical Protection Society, who said that he had communicated with Dr. Herring at the address mentioned in Australia, and had received a reply. The accused was asked to be dealt with at once, but the magistrate committed him to the Central Criminal Court for trial.

At the recent Worestershire Assizes, George Bowie Farnham, aged 31, a dispenser, was charged with making false death certificates at Wollaston, Dudley. Counsel for the defence took a legal objection, but in the event prosecutor pleaded guilty. His counsel said that no harm was done because the certificates were perfectly in order, though he agreed that it might have been a serious matter. Prosecuting counsel said that the case was persisted in because of the danger to the public of an unqualified medical practitioner giving certificates of death. The judge, Mr. Justice Bailliac, said that he agreed with that view, and it ought not to be overlooked when it came to the attention of the authorities. He thought that a sentence of two or three months' imprisonment would have met the case, and as prisoner had been in custody since July 20th he ordered his release.

Obituary.

THE RIGHT HON. SIR CHARLES TUPPER, Bt., M.D. EDINB.

ONE TIME HIGH COMMISSIONER OF CANADA IN LONDON.

ONE of the Fathers of Canadian Federation, a distinguished politician, and probably the oldest medical graduate of the University of Edinburgh, Sir Charles Tupper has passed to his rest, full of years and honours, at the patriarchal age of 94. Few men have lived more vigorously, first in the rough and tumble of a large general practice in Nova Scotia, and then in the more turbulent area of politics; yet he retained good health of mind and body nearly to the end. Like so many distinguished Nova Scotians, he was of New England stock, and descended from Thomas Tupper, who emigrated from England in 1635.

Charles Tupper was born in 1821, the son of a Baptist clergyman; he had his early education at Horton Academy, U.S., and in 1839 went to Edinburgh University, graduating in 1843 with a thesis "On the Mechanism and Management of Parturition, illustrated by a report of 116 cases." He was never tired of talking of the happy life spent there as a medical student. Simpson, then newly appointed to the chair of midwifery, was his favourite teacher, and he kept up warm friendships with many of his old professors. Only a few months ago he promised the writer to jot down the reminiscences of his Edinburgh life. Returning to his native town, Amherst, he very quickly had a large and widespread practice. He was fond of surgery, and there were few men among us who could talk of personal experiences in pre-anæsthetic days. He told the writer of an amputation at the hip-joint for sarcoma performed on a farmer's wife, on the kitchen table, with a sailor as

assistant. The patient lived eighteen miles away, so he was never able to make a second visit. Three months later the farmer drove to Amherst with his wife strong and well.

In 1855 Sir Charles entered public life as member of the Nova Scotia Assembly, and immediately pushed to the front rank in local politics, becoming successively Provincial Secretary, and in 1864 Premier of the Province. In the preliminaries to confederation, 1867, he took a prominent part, and was a member of the Westminster Conference. In 1870 he became President of the Council in the Dominion Government, and Minister of Customs in 1872. Following the fall of the McDonald Government he was the life of the Conservative party, and to him more than to any other was due their return to power in 1878. In 1884 he retired from the ministry, and took the position as High Commissioner in London for the Dominion. For a short period he was again in the Ottawa Cabinet as Minister of Finance, but returned as Commissioner to London, where he remained until 1896. In this year he became Prime Minister of Canada. After the defeat of his party he was the leader of the Opposition, but in 1900, after the general election, he retired from public life. In 1898 he was created a Baronet of the United Kingdom.

At intervals in this busy life he practised his profession at Halifax, Ottawa, and for a year or more at Toronto. He took an active part in the formation of the Canadian Medical Association, and to the end retained keen interest in the progress of medicine.

Canada owes a deep debt to Sir Charles Tupper, and his political opponent, Sir Wilfrid Laurier, very truly said that next to Sir John A. McDonald, the man who did most to bring about the federation of the Canadian provinces was Sir Charles Tupper. With a strong and daring personality, he had all the qualities for success in public life—calmness and clear judgment in victory, resolution and hopefulness in defeat. Nothing in his history was more remarkable than to have "stumped the country" successfully for his party when in his 80th year. A strong Imperialist, Sir Charles once remarked that "the two aims he has always kept in view . . . have been the strengthening of the golden link which connects England with the first and greatest of her colonies, and the holding aloft of the standard of right of the nation so that she may prove herself worthy of the proud position she has made her own." His life is an illustration of the brilliant success of the doctor in politics. We have to go to France or to the South American Republic to parallel his career. But he never really served two masters; from 1855 he was a politician first, and a practitioner only when stranded by the exigencies of party.

A few months ago, in reply to a question as to what he attributed his kindly old age, said, "A good constitution, a good digestion, and a capacity to sleep." It was in truth his good arteries, which were scarcely palpable when the blood stream was pressed out. Yet here was a man who in 1880-1 was ready to throw up the sponge, as he was believed to have Bright's disease! Some years ago, in a paper "On the advantages of a trace of albumin and a few tubercasts in the urine of men above 50 years of age," the writer mentioned his case. In 1881 he saw Andrew Clark, who gave most sensible advice, but was inclined to take a grave view of the renal condition. The advantage of the discovery was never better illustrated, as he ever after lived a careful life. Of Sir Charles's sons, the elder, Stewart, died a few months ago, and the baronetcy falls to his son a barrister in Winnipeg.

W. O.

J. W. N. MACKAY, M.D.,

ELGIN, SCOTLAND.

DR. J. W. NORRIS MACKAY, of Elgin, died recently at the age of 83. His father was the Rev. George Mackay, D.D., of Raaford, one of the number of Scottish clergymen who followed the dictates of their convictions, and "came out" at the stormy time in Scotland's ecclesiastical history, in 1843. The historical events of those famous times made a lasting impression on the mind of the subject of this notice.

Norris Mackay was educated at Elgin Academy and King's College, Aberdeen, where he took the degree of M.A. He then proceeded to Edinburgh, where he took the diploma of L.R.C.S. in 1852, and the degree of M.D. in the following year. While at Edinburgh he was a

member of the Royal Medical Society. He studied afterwards at the universities of Paris and Vienna.

When he returned to his native country he became resident surgeon to Gray's Hospital, Elgin, and when he relinquished that post he started general practice in the same town. Through his scholarly attainments and his genial disposition, he quickly built up a very large practice in Elgin and the district round about. There was a thoroughness and directness in his methods which brooked no opposition when he set out to probe a case, but at the same time it was accompanied by a sympathetic kindness which won him the ready appreciation of all with whom he came in contact. In every sense of the word Dr. Mackay was a physician of the old school, of a type which is too quickly passing away. In his professional work he never spared himself, and his figure was a familiar one at all hours of the day and night in the district, either on horseback or in his high dogcart.

Dr. Mackay was a member of the British Medical Association for a long period of time, and was secretary for the local Branch for close on thirty years. To commemorate this long service, and to mark their appreciation of his work and worth, his fellow-members in 1895 presented him with his portrait in oils, by Sir George Reid. During his long professional career Dr. Mackay held many appointments connected with the various institutions and public bodies in the town and neighbourhood. He took a keen interest in educational and religious matters, being chairman of the local School Board for many years, and a leading elder of the South United Free Church for over thirty-five years. Dr. Mackay was joined in partnership by his son, Dr. George Mackay, whose early death was deeply and widely mourned. Later he took into partnership Dr. D. G. Campbell. Failing eyesight compelled Dr. Mackay to relinquish his work about ten years ago, but it did not diminish his vigour, for his active figure was, up till a short time before his death, still to be seen about the town where he had laboured so lovingly for nigh sixty years. The death of his wife some years ago told heavily upon him, but his closing years were watched over by two of his daughters.

The large and sympathetic attendance of mourners at the funeral testified to the honour and esteem in which Dr. Mackay had been held by all who knew him.

PROFESSOR CHARLES BOUCHARD,

PARIS.

PROFESSOR BOUCHARD, who died recently after a long illness in a nursing home at Lyons, was for many years one of the chief figures in academic medicine in Paris. He was born at Montier-en-Der, in the Haute Marne department, in 1837, and graduated in 1866, and was appointed professor of general pathology and physician to the Lariboisière Hospital in 1870. He was elected a member of the Académie de Médecine in 1880, and of the Académie des Sciences in 1887, and had been president of both these learned bodies. He wrote a book on pathology, which was the popular students' textbook of its day, and he was one of the first to recognize the importance of antioxydation. It was, however, as an administrator that he did his most important work, and when dean of the Faculty of Medicine he encouraged many reforms. He was a Grand Cross of the Legion of Honour, and but for the war would have received the Nobel prize in 1914.

At this moment we may recall the part he took in the very earliest movement towards the establishment of the Entente Cordiale. It was in 1904 that some friends of Great Britain in France, and of France in Great Britain, all of them members of the medical profession, got into communication: the result was the visit of a large party of French doctors to London in October of that year, when they were shown some of our medical institutions, and were entertained at a dinner at which very cordial fraternal sentiments were expressed. There followed the visit of a large number of British doctors to Paris in May, 1905, when the modest hospitality which London had been able to show the French party was altogether eclipsed. The Committee in Paris which made arrangements for this visit had Professor Bouchard as its chairman, the late M. Lucas-Championnière as its vice-chairman, and Drs. Triboulet (Paris) and Sillonville (Aix-les-Bains) as its secretaries.

The Services.

EXCHANGE DESIRED.

An officer in a field ambulance wishes an exchange with one on an ambulance train, boat, or base hospital in France. Address No. 5390, BRITISH MEDICAL JOURNAL OFFICE, 423, Strand, W.C.

INDIAN MEDICAL SERVICE.

The India Office notify that the following gentlemen have been appointed to the Indian Medical Service: I. D. Grant, M.B., Ch.B., Glasgow, A. Hunter Brown, M.B., Ch.B., Aberdeen.

Medical News.

The Nobel prize for medicine for 1914, of the value of about £8,000, has been awarded to Dr. Robert Barany, privat-docent in otology in the University of Vienna, for his work on the physiology and pathology of the vestibule of the ear. The prize for medicine for 1915 is reserved until next year.

At the annual meeting of the Royal Society of Edinburgh on October 25th, Dr. John Horne, F.R.S., formerly assistant director of the Geological Survey of Scotland, was elected president, and among the vice-presidents elected were Sir Thomas R. Fraser, M.D., F.R.S., and Sir Edward Schäfer, F.R.S. The secretaries of ordinary meetings elected were Dr. Robert Kidston and Professor Arthur Robinson, M.D.

A DISCUSSION on paratyphoid fever will be held by the Section of Medicine of the Royal Society of Medicine on Tuesday, November 9th, at 5 p.m. The discussion will be opened by Sir Bertrand Dawson, who will be followed by Dr. Dreyer and Sir William Osler. The Section of Psychiatry will hold a discussion, jointly with the Section of Neurology, on the functional neuroses caused by shell shock without visible sign of injury, on January 25th, at 8.30 p.m.

A DISCUSSION on gunshot wounds of the head will be opened by Lieutenant-Colonel Percy Sargent, R.A.M.C., F.R.C.S., and Lieutenant-Colonel Gordon Holmes, R.A.M.C., M.D., at the meeting of the Medical Society of London on Monday, November 15th, at 8.30 p.m. Mr. L. B. Rawling and Dr. Wilfred Harris will speak, and Fellows and others desirous of taking part in the discussion are requested to communicate with the honorary secretaries or the registrar.

The regulations made by the French War Office with regard to the sale of alcoholic beverages will not seem to readers in this country very stringent. They apply to soldiers, persons liable to be mobilized, and to munition workers. The sale of wine, beer, cider, perry, and hydromel is permitted, as is also that of aromatized wines not exceeding 18, and of liquors prepared from fresh fruits and not exceeding 25 in strength.

An exhibition organized by the *Daily Express* under the title of "Women and their Work" will be opened at the Princess Skating Club, Knightsbridge, by Queen Amélie of Portugal, on November 8th, and will remain open until November 27th. Among the patrons are Queen Alexandra, Princess Arthur of Connaught, the Duchess of Teck, the Duchess of Wellington, the Duchess of Sutherland, the Marchioness of Londonderry, and many other well-known ladies interested in women's work. The exhibition is intended to show the new openings to women workers which have been created by the war. A particularly interesting feature will be a section of village industries, which it is one of the objects of the exhibition to re-establish. They include South Indian lacework, Devon embroidery and knitting, toy making, Scottish linen weaving, Essex handicraft work, straw plaiting, leather work, and sea moss work from East Coast villages. Other sections are intended to illustrate social and philanthropic work, food reform, economy in the home, hygiene, cooking, and so forth. Everything that can be made for the men in the trenches, from socks to sandbags, will be manufactured by women at the exhibition. Among the exhibitors are Queen Alexandra's Schools of Woodworking and Needlework, Sandringham; the Salvation Army, the Professional Classes War Relief Council, the British Women's Emigration Society, the Women's Emergency Corps, National Food Economy League, the Central Depôt, Surgical Branch Queen Mary's Needlework Guild, and the Home-work Society. The Organizing Secretary is Mr. Ernest C. Digby, 23, St. Bride's Street, London, E.C.

Letters, Notes, and Answers.

THE telegraphic address of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: 41, FLEET STREET, THE BRITISH MEDICAL JOURNAL, Attily, Westrand, London; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Attily, Westrand, London; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, Attily, Westrand, London; telephone, 2634, Gerrard. The address of the Irish office of the British Medical Association is 16, South Frederick Street, Dublin.

Queries, answers, and communications relating to subjects of which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

INCOME TAX.

H. F. inquires whether a four and a half months' illness and a prospective reduction of work entitle him to calculate his liability on the year's profits instead of on the previous three years' average, and (2) whether benefits derived from sickness societies should be included in one's income.

(1) No, unless in "H. F." is serving in the forces of the Crown or in the foreign work of the British Red Cross Society or St. John Ambulance Association, or (b) he is giving up his practice and taking another, in which case the reduction might be claimed for the period subsequent to the change. If the prospective decrease in work consists in the giving up of a public appointment he is entitled to have the assessment reduced by the net proceeds of the appointment accruing during the subsequent portion of the financial year. (2) No. Such payments do not appear to be liable to tax, unless they constitute annual payments.

LETTERS, NOTES, ETC.

THE IONIZATION OF ADHESIONS.

DR. ETTIE SAYER (London, W.) writes: As one who has continually had varied traumatisms under electric treatment during the past fourteen years, I should like to confirm Dr. Weyl's remarks (October 30th, p. 645) on the value of chlorine ions in the treatment of adhesions. But why allow adhesions to form at all? If any adhesion can be dissolved by chlorine ions, then its formation should have been prevented by the addition of electro-therapeutics and the ordinary surgical routine at an early stage of treatment.

STARVING AND PURGING FADDISTS.

DR. JOHN HADGON (Hawick) writes: In the JOURNAL of August 28th Dr. Cotton, in his letter, mentions my name along with those of other so-called faddists, whose treatment he describes as "starvation and purging." I hope you will allow me to correct that statement, so far as it concerns me. The treatment set forth in my book I believe to be safer than even fasting from all food; and, as to purging, I look upon it as an unnatural and, in some cases, a most dangerous practice.

WEIR'S VACCINATION INSTRUMENT.

MR. BARRY HOPKINS described in the JOURNAL of October 23rd, p. 628, the evolution of this well-known contrivance. There remains, however, some doubt about the inventor, who is generally believed to be Dr. Alexander McCook Weir. We are informed that Professor John Chiene, C.B., is able to testify that the Edinburgh students used the instrument in question in the Sixties and called it the "Weir vaccinator," and it was always believed that Dr. Graham Weir, with whom Professor Chiene was well acquainted, invented it. The sample in the Lister collection in the museum of the College of Surgeons was most probably given to SYME by Graham Weir. The former bequeathed all his instruments to his son-in-law, Lord Lister.

CHANGE OF NAME.

DR. O. LEYTON writes: I wish to let you know that I have changed my name from Grünbaum to Leyton. The reason for my doing this is a desire to dissociate myself as far as possible from a nation the deeds of which make it lose any right to be included amongst the civilized races. I should like to add that I have not been conscious that my German name has led to my being submitted to any discourtesy.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 8
A whole column	3 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

Preliminary Note

ON THE

CLINICAL ASPECTS AND DIAGNOSIS OF PARATYPHOID FEVER,

BY

J. A. TORRENS, M.B., B.S., M.R.C.P. LOND.,
CAPTAIN R.A.M.C., T.C.

AND

T. H. WHITTINGTON, M.D. LOND.,
LIEUTENANT R.A.M.C., T.C.

In attempting to describe the diseases known as paratyphoid fever, it must be remembered that it is only within quite recent years that any considerable amount of work has been done on the subject; that very little has been published in this connexion, and that any statements now made are largely the result of impressions received while observing some three or four hundred cases of paratyphoid fever in hospital, and may require modification when the material is more fully investigated and scientifically collated at the end of the war.

Paratyphoid fever is a disease caused by one of two bacilli, and is therefore known as "para A" or "para B," according to the particular organism present in any case. Both these bacilli resemble very closely the *Bacillus typhosus* in their morphology and general cultural characteristics, but in their behaviour with specific immune serums and in their reactions on certain nutrient media they differ so markedly from the *B. typhosus* and also from each other that there can be no doubt that they are specific micro-organisms and not varieties of the *B. typhosus* which have become modified by environment.

In 1898 N. B. Gwynne cultivated a "paracolon bacillus" from the blood of a patient "presenting all the clinical features of typhoid fever," and this seems to be the first instance of the definite diagnosis of a case of paratyphoid fever. This case showed throughout negative agglutination reactions with the *B. typhosus*, but the various specimens of serum were kept and were found to give definite agglutination with the organism isolated from the blood.

Many cases of "paracolon" and paratyphoid infections have been described since then, and also cases of infections by other bacilli supposed to be closely allied to these.

Some German writers have contended that food poisoning and paratyphoid B infections are identical, and others have certainly confused the two diseases in their descriptions.

Bainbridge and O'Brien, in 1911, showed that two distinct organisms had been described under the title of *Bacillus paratyphosus* B. Bainbridge, in his Milroy lectures of 1912, clearly showed that meat and food poisoning are due to *B. stipitifer* or *B. enteritidis*, which are conveyed to man in and can be recovered from infected foodstuffs, whereas paratyphoid fever is due, and due only, to one of the paratyphoid organisms—that is to say, para A or para B. The same writer also showed that these last organisms are in practically every case disseminated by the human carrier, and that the other cases of so-called "allied infections" were almost without exception due to one of these four organisms and belonged to one or other of the two distinct diseases—paratyphoid fever on the one hand, and food poisoning on the other.

The incidence of paratyphoid fever is greater, owing to cases being missed or owing to incomplete laboratory examinations, than is generally supposed.

Paratyphoid A is well known in India; and the disease has been described and the methods of isolating the organism well worked out by officers of the R.A.M.C. (Grattan and Wood, Harvey, Firth, and others), whose work ought to be more widely known. In passing it may be noted that all these observers insist on the importance of the "carrier," and therefore on the importance of the clinical recognition of the disease.

Up to 1912 Bainbridge could find no record of para A in England. In America, Proschner and Reddy (quoted by Bainbridge) found that in 262 patients with "enteric fever" whom they examined 8 per cent. had paratyphoid A.

Paratyphoid B is better known in England. Boyce,

some years ago suggested that 3 per cent. of the cases notified in Great Britain were really para B.

In Western Europe paratyphoid fever seems much more often due to the bacillus para B, and this is certainly borne out in so far as the statistics of the hospital from which this is written are concerned. In an extensive series of blood cultures made at Pretoria Slatham found that 25 per cent. of the cases of continued fever investigated were "paratyphoid fever," both varieties of organism being isolated.

Thanks to protective inoculation and careful sanitary precautions the danger of typhoid fever proving any very serious menace to our troops in this campaign is, we believe, not great; but in so far as protective inoculation against paratyphoid is in its infancy and as yet not widely practised, though eminently desirable, the risk of our having to deal with large numbers of cases of paratyphoid fever is by no means negligible.

The possible modes of infection in paratyphoid fever are many, and, just as in typhoid fever, water, food and milk may all play an important part; but however the disease is ultimately conveyed, the primary and inevitable source of infection is some one who himself has or has had paratyphoid fever. Hence it is of paramount necessity not to overlook any cases of paratyphoid fever, both from the point of view of the immediate risks from improper bestowal of infective dejecta, and equally in order to avoid the possibility of letting loose a number of paratyphoid carriers, any or all of whom may initiate an epidemic of the disease.

It is especially in connexion with this question of carriers that it is hoped our remarks on paratyphoid may be of use. For the important thing is, not to differentiate paratyphoid fever from typhoid fever, but to recognize it or at least to suspect its presence in what appear to be much milder conditions.

These milder diseases are sure to be diagnosed again and again instead of paratyphoid if this latter name suggests to our minds only the classical symptoms of "typhoid," and this is rather the impression one might gather from reading the somewhat cursory remarks on the subject in many textbooks.

The matter, therefore, is not one which only concerns the bacteriologists, since they will not be given the opportunity of examining material unless it is sent to them, and the "material" ought to be sent unless the patients' medical officer suspects the presence of paratyphoid.

To give an instance of the truth that paratyphoid cannot be eliminated if the "carrier" is not eliminated, it is only necessary to refer again to the incidence of paratyphoid A fever.

A number of our troops at the front came from India. Since the arrival of these troops paratyphoid A has occurred amongst other soldiers in France. The great majority of the patients with this fever in our series have either come from India themselves or have been in close association with the troops of the Indian divisions. Some of the cases have been Territorials or men of new battalions who in France have been attached to units from India. It seems fairly certain, therefore, that paratyphoid A has been planted amongst our troops out here by "carriers" from abroad.

How, then, is it possible to reduce to a minimum the risks of labelling paratyphoid fever, P.U.O., influenza, etc.?

It should be stated at once that in some few cases it is impossible even to suspect paratyphoid fever unless a thorough bacteriological examination is made; but in the great majority of cases, if one is alive to the possibility of these infections, one is enabled to exclude the negative cases, but only—and we cannot too much emphasize this point—by the aid of a thoroughly competent bacteriologist.

To put this in another way, it may be said that paratyphoid fever may be so mild and so atypical that only complete bacteriological investigation will reveal its presence: at the same time, even in these atypical cases there will often be some small point which is sufficient to justify one in treating them as suspects until the negative is proved, and happily it is possible to prove the negative in 99 per cent. of all cases, provided that the investigations are begun at a sufficiently early date. On the other hand, paratyphoid fever, whether A or B (but especially B), may in some cases be so severe as to simulate exactly the gravest and most toxic case of typhoid fever. Such cases are described in all textbooks and are familiar to every one.

It is the more typical and very mild cases that principally concern us in this paper, for they are the cases that are most likely to be confounded with influenza, simple chill, "trunch" fever, rheumatism, and other diseases with similar titles which are really little more than confessions of ignorance.

In the first place it is more than unprofitable to attempt to discriminate clinically between para A and para B. A lucky guess may be made, but that is all. Suffice it to say that typically para B is a ten to eighteen day fever, while the average para A, as seen in this hospital, lasts three or four days longer. The temperature in both forms shows a characteristic disinclination finally to settle down, but the symptoms in para A tend to be even milder than in para B. If all the very mild cases were diagnosed, the average duration of fever would be found to be less than that above stated. This, we think, is especially true of paratyphoid A.

CLINICAL DIAGNOSIS.

The clinical phenomena which may lead to the classing of a case as "suspected paratyphoid" will now be considered in more detail.

To clear the ground it may be suggested that one fertile source of error seems to be the assumption that a case cannot be one of the enteric group which does not present a more or less "typhoid" appearance, or at any rate some abdominal disturbance in the direction of pain or diarrhoea.

The Onset.

This is usually by no means the gradual affair which one is accustomed to associate with the classical descriptions of typhoid fever. It is true that the majority of the cases when pressed will admit to feeling out of sorts for two, three, or more days, but for all practical purposes many of them are not ill until the day on which they are compelled to report sick.

Two main groups may be recognized. The first (60 per cent. of the cases) comprises those who feel increasingly ill for a variable number of days (the average being four) before they report sick. The second group (40 per cent. of the cases) comprises those who are bowled over in a few hours or collapse in the course of their ordinary duties.

A man develops a headache, has slight abdominal pain, with a couple of days' diarrhoea, but does not report sick, for, as he says, he "thought he would get over it." The diarrhoea does pass off, but backache with generalized aching pains and headache (especially the last) persist, and even get worse, till by the fourth day he is so weak and ill at ease that he reports sick. Such a case is typical of the first group.

In the second group a man may go to sleep feeling well, but he wakes up with abdominal pain, diarrhoea, and severe headache, feels feverish, and has a shivering attack, and in a few hours becomes so extremely weak that he is quite obviously too ill to carry on.

The similarity of this type of onset to that seen in many cases of influenza is worthy of note. If this sudden onset occurs while the man is on duty in the trenches or on the march, we get the history of sudden collapse, "legs giving way," fainting, etc.

As the result of an analysis by one of us of 100 cases of para B and 50 cases of para A taken without prejudice from our series it is found that there are eight symptoms which occur in at least 20 per cent. of the cases at the onset. In order of frequency these are:

1. Headache (85 per cent.).
2. Diarrhoea (55 per cent.).
3. Abdominal pain (35 per cent.).
4. Aching pains in the limbs (30 per cent.).
5. Shivering (25 per cent.).
6. Extreme general weakness (25 per cent.).
7. Backache (25 per cent.).
8. Epistaxis (20 per cent.).

Headache is usually vertical in distribution, though a migrainous type, especially severe behind the eyes, has been present in several cases of para A. Of course, headache may be a leading feature in practically every acute infection, but the predominant nature of the headache over the other symptoms is certainly worthy of notice. Eighty per cent. of all cases will voluntarily mention severe headache as a symptom of the onset.

Abdominal pain is rarely severe or colicky and is usually generalized, and does not often last more than two or three days. Sometimes in cases with very rapid onset it may be severe and associated with nausea and vomiting. Typically, it is not more than a general feeling of uneasiness in the abdomen.

The initial diarrhoea is in marked contrast to the constipation which is so common after the end of the first week. It is rarely severe, being usually limited to three or four loose stools per diem. If one is lucky enough to get the case in this initial stage, the motions will be found to be fairly typical of the "typhoid" variety of stool. Otherwise observation of the stools gives little help in diagnosis.

Pain other than abdominal pain or headache is usually referred to the back or limbs. "Pains all over" is a description often given. Joint pains reminiscent of acute rheumatism have been a feature of some cases, but no swelling of the joints has been detected.

Extreme general weakness is often very sudden in its onset, and sometimes this and headache are the only symptoms. It accounts for many of the cases of sudden collapse, though of course there is a suspicion in such cases that the case may have been ambulatory without previous symptoms.

Epistaxis is rarely volunteered by the patient as one of his symptoms. This is because it is usually so small in amount. Its value as a positive sign is very great and it occurs as frequently in paratyphoid as it does in typhoid fever. It may occur during sleep, and sometimes it may be found to have occurred in the earliest days of the onset or even before, when the patient was feeling quite well.

Shivering.—While it is liable to occur in the course of any infection with the liberation of toxins or bacteria into the blood stream, yet the occurrence of repeated shivering attacks seems of special significance at the onset of paratyphoid fever. This is especially true of paratyphoid A, in which shivering is met with in nearly 30 per cent. of cases at the onset, and in which it is liable to occur with rigors throughout the disease (Case vi). Two patients from whom the bacillus of paratyphoid A was isolated stated that they "thought they had ague."

Other symptoms which may not rarely be complained of or elicited are, in order of frequency, cough, nausea and vomiting, loss of appetite, dizziness, deafness, constipation.

Cough is complained of in nearly 20 per cent. of cases, and seems more common in para B, but is rarely troublesome. It is certainly much less frequent than is the case in "typhoid fever," and in view of the almost universal habit of smoking to excess in the British army it is probable that in a number of the cases the cough is not a manifestation of the paratyphoid fever.

Vomiting is far more common in paratyphoid fever than in typhoid fever. This is especially so in para B cases, in which vomiting occurred in 17 per cent. In association with severe abdominal pain and severe diarrhoea, it occurs in that type of para B which simulates food poisoning in its onset—that is, about 3 per cent. of all cases of this variety.

Dizziness and deafness occurred in 7 per cent. of all cases. Deafness would possibly have been found more commonly had it always been asked for, as it is usually transient.

Sore throat or hoarse voice as evidence of laryngitis or pharyngitis occurred only in 5 per cent. of the cases, all those being cases of para B. It was present only in those severe cases which tend to simulate the toxic type of true typhoid fever.

Temperature during the Onset.—As regards this we are not able to speak with great certainty as cases do not usually reach this hospital until the seventh day or later. Patients in whom the onset was rapid have said that their temperatures were 102° to 103° when first taken. Cases which have started in a hospital where the patient was being treated for some wound, and where the temperature was being taken as a routine measure show a rapid rise, the maximum usually being reached in forty-eight hours. Such a case is shown in Chart 7. It seems fairly certain that the "step-ladder" rise so frequently seen in typhoid fever is far from common in paratyphoid.

GENERAL COURSE.

Although a careful history is of the utmost importance, when all is said and done in this direction, the main data

for diagnosis are often only to be obtained by a thorough examination of the patient. The objective features which may be observed in an average case of paratyphoid fever in the second and third weeks will therefore be considered.

Aspect.

The aspect of the patient, if seen in the early days, will tell much. There is then a peculiar heaviness about any except the mildest cases. This is of considerable significance but is rather difficult to describe. One finds the terms "lethargic," "heavy," "drowsy," "inert," applied to the condition. This appearance, we imagine, can usually be distinguished from the bright-eyed, flushed appearance associated with most of the febrile states. The condition is, however, rarely so well marked as in typhoid fever.

The patient can, except in the quite severe cases, be roused up to give a clear history. In 40 per cent. of the cases the patient is flushed, but the eyes are dull, with the pupils often rather dilated. The chief complaint will be headache, or possibly backache. While about 60 per cent. are of this type, there are two extremes: on the one hand, there is the fairly large group of mild cases (25 to 30 per cent.), which often look and feel fairly well by the second week, and are certainly not at all suggestive of enteric fever. There is the other smaller group (10 to 15 per cent.) which are obviously ill—toxic-looking and mentally blurred. These are the cases that will probably be diagnosed as enteric fever in any case.

The Temperature.

During the second week, in the average case, the temperature ranges between 99.2 and 102.4. This produces a "spiky" temperature chart which is very characteristic (see charts, especially Chart 2).

Sixty per cent. of the cases analysed showed this remittent type of fever, while about 20 per cent. were intermittent (see Chart 12). A "spiky" temperature chart with variations of at least 2 and more is therefore seen in 80 per cent. of all cases.

A really steady temperature in the second week was only seen in 5 per cent. of cases; 70 per cent. of all cases of para B and 40 per cent. of para A are of twenty days' duration or less. In about 30 per cent. of all cases of each form the pyrexia lasts fifteen days or less (see Charts 1 and 7). In the average case the temperature in the second week and at the beginning of the third week does not reach as high as 103 (see Charts 4 and 10). Only about 35 per cent. of all cases of paratyphoid fever ever reach 103, and only about 12 per cent. reach as high as 104.

Pulse.

The pulse is one of the most important aids to diagnosis. The rate is uniformly slow as compared with the temperature. While a relatively slow pulse in typhoid fever is common enough, this feature is still more marked in paratyphoid fever. A temperature of 102.5 with a pulse of 70 is characteristic and is more than significant of a group infection. The pulse, while almost always comparatively slow, varies in its slowness. Without any apparent change in the general condition, the rate may be at one time 65 and at another 85 or 90, and, curiously, a high temperature may coincide with a low pulse rate, and vice versa.

The quality of the pulse is characteristic and very important. There is a most marked softness or compressibility present. This is noted in quite 80 per cent. of the cases. About 15 per cent. only of the cases show diastolic, but when present it is almost pathognomonic of an enteric group infection. A slow diastolic pulse in a man without the typical general appearance of enteric fever strongly suggests paratyphoid fever.

The blood pressure in a small series of cases examined by one of us with the sphygmomanometer was found, as might be expected, to vary from 80 to 100 mm. Hg. Some of the lowest blood pressures were found when the temperature was just reaching normal. This phenomenon may therefore be of use in cases which are not met with till late in their course.

Spots.

Spots are present in as many as 75 per cent. of all cases at some time during the disease. They appear in crops, and last three to four days, as in typhoid fever. Owing to

the circumstances in which we get the cases it is difficult to find the average day of the disease on which they first appear. It is probably about the seventh to the tenth day, and they may continue to appear as late as the thirty-fifth day. In 20 per cent. of the cases spots are present after the temperature has reached normal. This is of importance in those rapid mild cases which are not seen until the stage of defervescence is reached, since the presence of spots does not seem to bear any close relation to the severity of the disease.

The spots are larger and much more irregular in outline and of a deeper red colour than those of true typhoid. If scanty they are seen only over the lower ribs in front and on the flanks and on the back of the shoulders. Fortunately paratyphoid spots are usually fairly definite things, and because a doubtful case does not suggest "enteric" it is most unwise to neglect examining for them. The spots may be very profuse, sometimes they may be minutely vesicular and occasionally anemiciform. The rash of para A especially tends to be very profuse and may be rather morbilliform. Cases have been sent to the hospital with profuse paratyphoid rashes which have led to the diagnosis of measles, german measles, chicken-pox, and in one case even small-pox was suggested, without, however, much reason.

Gastro-intestinal Symptoms.

The tongue often gives valuable assistance. In nearly all cases it is dry during the acute stage, and in the severe cases it is exactly like the tongue of a severe case of typhoid fever—dry, brown, and cracked. Even in the milder cases the tongue is fairly characteristic. It is dry and furred, and the fur is distributed in two dorsal slabs, leaving a red tip and red edges, and often a red band up the centre. The red tip is often smooth and glazed, in marked contrast to the rough fur. The fur is not so persistently brown as in typhoid fever. It is frequently thick and dirty-white in colour. On the whole, the presence of a "typhoid" tongue without the other general appearances of typhoid fever is fairly frequent, and in these circumstances is very suggestive of paratyphoid fever.

The abdomen is not nearly so informative as in true typhoid. Frequently it is absolutely normal in appearance and feel. In over 60 per cent. of the cases there is no distension whatever. However, in a fair proportion of cases (about 35 per cent.) the belly can be described as "full," "tummy," or "slightly distended," and in these cases there is a suggestive soft elastic feel about it. Tenderness on palpation is rare and pain is rarely complained of by the time the patient reaches a base hospital. Gurgling on pressure in the caecal region is rare. Pain when feeling for the spleen or in the left lumbar region is suggestive and is present in about 10 per cent. of all cases. Marked distension is very rare and is only seen in the few very severe cases.

Enlargement of the liver and tenderness over the gall bladder, unless cholecystitis is present as a complication, are conspicuous by their absence.

The spleen is either palpable or enlarged to percussion in nearly 60 per cent. of cases; it can be felt in about 35 per cent. of all cases some time during the course of the disease. When felt the paratyphoid spleen seems to be firmer in consistence and remains palpable for a longer period (possibly by reason of this greater hardness) than it does in typhoid fever. On the whole, too, it seems less tender. The value of a palpable spleen is tremendous, and it is just as often present in the quite mild cases as in the more obvious ones, and therefore, like the spots, should be sought for always. Owing to the frequency with which it occurs in a quite undistended abdomen, the paratyphoid enlargement is comparatively easy to make out. It is easy to exclude malaria and the blood dyscrasias in the average patient, and other causes of enlarged spleen are very rare.

Examination of the heart is negative.

Examination of the lungs will show bronchitis in less than 30 per cent. of the cases. Severe bronchitis only occurs in about 5 per cent. of cases, and then only in that type of case resembling true typhoid which is not likely to be missed.

The central nervous system shows no constant abnormality. A very few cases have simulated meningitis, and from every point of view it is desirable to perform lumbar puncture to settle the question without delay.

Only once has a paratyphoid meningismus closely simulated cerebro-spinal fever, and in this case the spinal fluid was quite clear, sterile and free from pus cells.

Defervescence.

In the third week the temperature of the average paratyphoid case reaches normal, while even if fever continues beyond the end of the third week there is nearly always a decided improvement in symptoms. It is quite common to see a case of paratyphoid fever with a temperature ranging up to 102° or even 103° lying on his side reading the newspaper, quite clear mentally and ready for a joke (see Case 11). This, of course, is in marked contrast with true typhoid fever. It has been remarked that para B is a fever of about sixteen to nineteen days, while para A as seen in this hospital is longer. This is due to a characteristic tendency for the temperature in para A to take a long time to settle down, and a tendency to be remittent and to recrudescence just when settling down, although the patient's general condition is obviously improving. This is well seen in Charts 2 and 5. Most of the cases which are apparently rather severe and which simulate typhoid, characteristically take a sudden turn for the better and markedly improve after being in hospital from three to five days, and this quite apart from any measures other than dieting and nursing (see Chart 9). It is important to recognize this feature, otherwise it may be attributed to certain treatments adopted. The termination of the fever is often characteristic. The temperature tends to settle by modified crisis or by short lysis lasting little more than two days (see Charts 4, 7, 10, and 12). It is certainly rare to see the steady long-drawn-out defervescence so common in typhoid fever. The pulse is the chief and almost only reliable guide to the actual condition of the patient. As long as the pulse is regular, below 90, and not too soft in quality it matters not how high the temperature is. A pulse persistently over 100 nearly always means a serious infection. Distension and severe bronchitis are also apt to mean a serious case.

SUMMARY OF SYMPTOMS.

An endeavour has been made in the preceding remarks to describe the signs and symptoms which may be met with in paratyphoid fever.

To recapitulate, in a doubtful case the most important individual features are probably:

1. An onset of about four days with malaise, pains in head, back, and limbs, a tendency to shiver, and abdominal discomfort with a short period of looseness of the bowels.
